Pharmacotherapy Principles & Practice

NOTICE

Medicine is an ever-changing science. As new research and clinical experience broaden our knowledge, changes in treatment and drug therapy are required. The authors and the publisher of this work have checked with sources believed to be reliable in their efforts to provide information that is complete and generally in accord with the standards accepted at the time of publication. However, in view of the possibility of human error or changes in medical sciences, neither the authors nor the publisher nor any other party who has been involved in the preparation or publication of this work warrants that the information contained herein is in every respect accurate or complete, and they disclaim all responsibility for any errors or omissions or for the results obtained from use of the information contained in this work. Readers are encouraged to confirm the information contained herein with other sources. For example and in particular, readers are advised to check the product information sheet included in the package of each drug they plan to administer to be certain that the information contained in this work is accurate and that changes have not been made in the recommended dose or in the contraindications for administration. This recommendation is of particular importance in connection with new or infrequently used drugs.

Pharmacotherapy Principles & Practice

FIFTH EDITION

Editors

Marie A. Chisholm-Burns, PharmD, MPH, MBA, FCCP, FASHP, FAST

Dean and Professor
College of Pharmacy
University of Tennessee Health Science Center
Memphis, Knoxville, and Nashville, Tennessee

Terry L. Schwinghammer, PharmD, FCCP, FASHP, FAPhA, BCPS

Professor Emeritus
Department of Clinical Pharmacy
School of Pharmacy
West Virginia University
Morgantown, West Virginia

Patrick M. Malone, PharmD, FASHP

Professor and Associate Dean, Internal Affairs
College of Pharmacy
The University of Findlay
Findlay, Ohio

Jill M. Kolesar, PharmD, MS, FCCP, BCPS

Professor, Colleges of Pharmacy and Medicine
University of Kentucky
Director, Precision Medicine Initiatives
Markey Cancer Center
Lexington, Kentucky

P. Brandon Bookstaver, PharmD, FCCP, FIDSA, BCPS

Associate Professor and Director of Residency and Fellowship Training
Department of Clinical Pharmacy and Outcomes Sciences
University of South Carolina College of Pharmacy
Columbia, South Carolina

Kelly C. Lee, PharmD, MAS, FCCP, BCPP

Professor and Associate Dean, Assessment and Accreditation
Skaggs School of Pharmacy and Pharmaceutical Sciences
University of California San Diego
La Jolla, California

ABOUT THE EDITORS

Marie A. Chisholm-Burns, PharmD, MPH, MBA, FCCP, FASHP, FAST, is Dean and Professor at the University of Tennessee Health Science Center College of Pharmacy. She received her BS and PharmD degrees from the University of Georgia, and completed a residency at Mercer University Southern School of Pharmacy and at Piedmont Hospital in Atlanta, Georgia. Dr. Chisholm-Burns is Founder and Director of the Medication Access Program which increases medication access to transplant recipients. She has also served in elected positions in numerous professional organizations. Dr. Chisholm-Burns has more than 320 publications and approximately $11 million in external funding. In 2008 and 2011, textbooks co-edited by Dr. Chisholm-Burns, *Pharmacotherapy Principles & Practice* and *Pharmacy Management, Leadership, Marketing, and Finance,* respectively, received the Medical Book Award from the American Medical Writers Association. She has also received numerous awards and honors including the Robert K. Chalmers Distinguished Pharmacy Educator Award from the American Association of Colleges of Pharmacy, Clinical Pharmacy Education Award from the American College of Clinical Pharmacy, Daniel B. Smith Practice Excellence Award from the American Pharmacists Association (APhA), Nicholas Andrew Cummings Award from the National Academies of Practice, Award of Excellence from the American Society of Health-System Pharmacists (ASHP), Pharmacy Practice Research Award (2011 and 2014) and Award for Sustained Contributions to the Literature from the ASHP Foundation, Research Achievement Award from APhA, and Rufus A. Lyman Award for most outstanding publication in the *American Journal of Pharmaceutical Education* (in 1996 and 2007). Dr. Chisholm-Burns is a Fulbright Scholar and a member of the board of directors for the Accreditation Council for Pharmacy Education (ACPE). She lives in Memphis, is married, and has one child, John Fitzgerald Burns Jr. She enjoys writing, cycling, and playing chess.

Terry L. Schwinghammer, PharmD, FCCP, FASHP, FAPhA, BCPS, is Professor Emeritus at the West Virginia University (WVU) School of Pharmacy. From 2005 to 2018, he was Professor and Chair of the Department of Clinical Pharmacy, and from 2015 to 2018 he held the Arthur I. Jacknowitz Distinguished Chair in Clinical Pharmacy at WVU. He was previously Professor of Pharmaceutical Sciences at the University of Pittsburgh School of Pharmacy. Dr. Schwinghammer received his BS and PharmD degrees from Purdue University and completed a pharmacy residency at Indiana University Hospitals. He is a Board Certified Pharmacotherapy Specialist and has practiced in adult inpatient and ambulatory care. Dr. Schwinghammer is a recipient of the American Pharmacists Association-APPM Distinguished Achievement Award in Clinical/Pharmacotherapeutic Practice and is a Distinguished Practitioner in the National Academies of Practice. He is a member of the Academy of Excellence in Teaching and Learning of the WVU Health Sciences Center. In addition to authoring over 100 research and other publications, he is founding editor of *The Pharmacotherapy Casebook* and co-editor of *The Pharmacotherapy Handbook* and the textbook *Pharmacotherapy Principles & Practice*. Dr. Schwinghammer has served the American Association of Colleges of Pharmacy (AACP) as Chair of the Pharmacy Practice Section, Chair of the Council of Faculties, and member of the Board of Directors. He is a past president of the Pennsylvania Society of Health-System Pharmacists and received the Pharmacist of the Year, Community Service, and Sister M. Gonzales Duffy Awards from the organization. He has served as Chair of the Board of Pharmacy Specialties and elected member of the Board of Regents of the American College of Clinical Pharmacy (ACCP). He is a Fellow of ACCP, the American Society of Health-System Pharmacists, and the American Pharmacists Association and has been elected to membership in the Rho Chi Pharmacy Honor Society and the Phi Lambda Sigma Pharmacy Leadership Society. He was named a Distinguished Alumnus of Purdue University in 2004. In 2016, he was named the recipient of the AACP Robert K. Chalmers Distinguished Pharmacy Educator Award.

Patrick M. Malone, PharmD, FASHP, is Professor and Associate Dean of Internal Affairs at The University of Findlay College of Pharmacy. Dr. Malone received his BS in Pharmacy from Albany College of Pharmacy and PharmD from the University of Michigan. He completed a clinical pharmacy residency at the Buffalo General Hospital, Drug Information Fellowship at the University of Nebraska Medical Center, and US West Fellowship in Academic Development and Technology at Creighton University. His practice and teaching have centered on drug information, and he is the first author for all six editions of *Drug Information—A Guide for Pharmacists* and has overseen the Innovations in Drug Information Practice and Research sessions at the ASHP Midyear Clinical Meetings for approximately 20 years. Dr. Malone was also the drug information pharmacist at the XIII Winter Olympics. He has approximately 120 publications and numerous presentations, and has held various offices in national organizations. He was the Director of the Web-Based Pharmacy Pathway at Creighton University Medical Center, from its initial establishment until after graduation of the first class. His hobby is building and flying radio-controlled aircraft.

Jill M. Kolesar, PharmD, MS, FCCP, BCPS, is Professor of Pharmacy at the University of Kentucky and holds administrative positions at the Markey Cancer Center as the Director of the Precision Medicine Initiatives, Co-Chair of the Molecular Tumor Board, and the Co-Leader of the Developmental Therapeutics Program. She is a member of the Graduate Faculty in the College of Pharmacy, a member of the Markey Cancer Center and holds a joint appointment in Internal Medicine in the College of Medicine. Dr. Kolesar received her Doctor of Pharmacy degree at the University of Texas Health Science Center in San Antonio, where she also completed a specialty practice residency in oncology/hematology and a fellowship in molecular oncology pharmacotherapy. She received an MS in Epidemiology with an emphasis in Genetic Epidemiology from the University of Wisconsin-Madison, College of Medicine and Public Health in 2016. Dr. Kolesar contributes professional service to both the National Cancer Institute (NCI) and several pharmacy organizations. Serving on both the Early Phase and Cancer Prevention Central IRBs (CIRBs), multiple NCI study sections, and the Cancer Therapy and Evaluation Program (CTEP) Pharmacology task force. She is a board certified Pharmacotherapy Specialist and an elected fellow of ACCP (American College of Clinical Pharmacy). She has served ACCP as the Chair of the Hematology Oncology PRN, and as a member of the Board of Regents and the Research Institute Board of Trustees. Dr. Kolesar is currently the President of ACCP. Dr. Kolesar's research focuses on the drug development of anticancer agents with an emphasis on targeted therapies and biomarkers. She has authored more than 200 abstracts, research articles, and book chapters, and as a principal investigator she has received more than $2.0 million in research funding from the NCI, American Cancer Society and other sources. She has received teaching and research awards from local, national, and international organizations including the Innovations in Teaching Award from the American Association of Colleges of Pharmacy. Other books she co-edits are the *Top 300 Pharmacy Drug Cards* and the *Top 100 Nonprescription Drug Cards*. Dr. Kolesar loves to read, run, ski, scuba dive, and travel with her husband and five children. She has completed 2 marathons and 16 half-marathons.

P. Brandon Bookstaver, PharmD, FCCP, FIDSA, BCPS, is Associate Professor and Director of Residency and Fellowship Training in the Department of Clinical Pharmacy and Outcomes Sciences at the University of South Carolina College of Pharmacy in Columbia, South Carolina. He also serves as Infectious Diseases Pharmacist at Palmetto Health Richland. Following graduation from the University of South Carolina College of Pharmacy in 2004, he completed a Pharmacy Practice residency and Infectious Diseases specialty residency at Wake Forest University Baptist Medical Center. Brandon thoroughly enjoys coordinating student research and is heavily involved in pharmacy residency training, including his role as the Infectious Diseases PGY2 Residency Director and Clinical Fellowship Director at USC/Palmetto Health. He has over 75 peer-reviewed publications in the areas of infectious diseases and teaching and learning. Outside of work, he enjoys spending time with his wife Nicole, son Aaron, and daughter Maddie Paige; traveling; and Gamecock athletics.

Kelly C. Lee, PharmD, MAS, FCCP, BCPP, is Professor of Clinical Pharmacy and Associate Dean for Assessment and Accreditation at the University of California, San Diego (UCSD) Skaggs School of Pharmacy and Pharmaceutical Sciences. She is also the Director of the PGY2 Psychiatric Pharmacy Residency at UCSD. Dr. Lee received her B.S. in Biology from UCLA, her PharmD from UCSF, and Master of Advanced Studies in Clinical Research at UCSD. She completed a PGY1 Residency in Pharmacy Practice and a 2-year fellowship in Behavioral Health Sciences at UCSF. She has published numerous peer-reviewed journal articles and consults for large health systems to optimize psychotropic drug utilization and establish innovative psychiatric pharmacy care models. She has also received the Dorfman Journal Paper Award from the Academy of Psychosomatic Medicine. Dr. Lee loves to play tennis, travel, and spend time with her husband Douglas and son, Travis.

CONTRIBUTORS

Val Adams, PharmD, BCOP
Associate Professor, Pharmacy Practice and Science, College of Pharmacy, University of Kentucky, Lexington, Kentucky
Chapter 90

Ronda L. Akins, PharmD
Infectious Diseases Clinical Pharmacy Specialist, Methodist Charlton Medical Center, Dallas, Texas; Adjunct Associate Professor, Department of Biological Sciences, University of Texas at Dallas, Richardson, Texas
Chapter 74

Lisa Anselmo, PharmD, BCOP
Director of Clinical Pharmacy, PGY1 Residency Director, University of New Mexico Hospital, Albuquerque, New Mexico
Chapter 95

Christina A. Bachmeier, PharmD, BCOP
Clinical Pharmacist, Cellular Immunotherapy, H. Lee Moffitt Cancer Center, Tampa, Florida
Chapter 98

Opal M. Bacon, PharmD
Clinical Assistant Professor, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University, Detroit, Michigan
Chapter 39

Justin M. Balko, PharmD, PhD
Assistant Professor, Department of Medicine, Ingram Cancer Center, Vanderbilt University, Nashville, Tennessee
Chapter 90

Mary F. Banoub, PharmD
Infectious Diseases Clinical Pharmacy Specialist, University of Maryland Medical Center; Clinical Assistant Professor, School of Pharmacy, University of Maryland, Baltimore, Maryland
Chapter 87

Kylie N. Barnes, PharmD, BCPS
Clinical Assistant Professor, Division of Pharmacy Practice and Administration, School of Pharmacy, University of Missouri-Kansas City, Kansas City, Missouri
Chapter 49

Allison Baxley, PharmD, BCOP
Clinical Pharmacist, Stephenson Cancer Center, University of Oklahoma, Oklahoma City, Oklahoma
Chapter 91

Régine Béliard, PharmD
Assistant Professor, Department of Clinical and Administrative Sciences, School of Pharmacy, Notre Dame of Maryland University, Baltimore, Maryland
Chapter 50

Lauren R. Biehle, PharmD, BCPS
Clinical Associate Professor of Pharmacy Practice, School of Pharmacy, University of Wyoming, Laramie, Wyoming
Chapters 62 and 73

Marianne Billeter, PharmD, BCPS
Pharmacy Manager, Patient Care Services, New Hanover Regional Medical Center, Wilmington, North Carolina
Chapter 86

Christopher M. Bland, PharmD, FCCP, FIDSA, BCPS
Clinical Associate Professor, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Savannah, Georgia
Chapter 82

P. Brandon Bookstaver, PharmD, FCCP, FIDSA, BCPS
Associate Professor and Director of Residency and Fellowship Training, Department of Clinical Pharmacy and Outcomes Sciences, University of South Carolina College of Pharmacy, Columbia, South Carolina
Chapter 70

Jill S. Borchert, PharmD, BCACP, BCPS
Vice-Chair and Professor of Pharmacy Practice, Chicago College of Pharmacy, Midwestern University, Chicago, Illinois
Chapter 60

Emily B. Borders, PharmD, BCOP
Clinical Pharmacist, Stephenson Cancer Center, University of Oklahoma, Oklahoma City, Oklahoma
Chapter 91

Mary Borovicka, PharmD, BCPP
Assistant Professor of Clinical Pharmacy, Department of Pharmacy Practice, College of Pharmacy and Pharmaceutical Sciences, University of Toledo, Toledo, Ohio
Chapter 37

Sheila R. Botts, PharmD, BCPP
Regional Administrator, Clinical Pharmacy Services; Chief, Clinical Pharmacy Research and Academic Affairs, Kaiser Permanente Colorado, Denver, Colorado
Chapter 40

Bradley A. Boucher, PharmD, BCPS
Professor, Department of Clinical Pharmacy and Translational Science, Associate Dean of Strategic Initiatives and Operations, College of Pharmacy, University of Tennessee Health Science Center, Memphis, Tennessee
Chapter 13

Julia Boyle, PharmD, BCPP
Assistant Professor, Department of Pharmacy Practice and Administrative Sciences, College of Pharmacy, Idaho State University, Pocatello, Idaho
Chapter 42

Trisha N. Branan, PharmD, BCCCP
Clinical Associate Professor, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, Georgia
Chapter 82

Evans Branch III, PharmD
Professor, College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Miami, Florida
Chapter 80

Gretchen M. Brophy, PharmD, BCPS
Professor of Pharmacotherapy and Outcomes Science and Neurosurgery, Virginia Commonwealth University, Medical College of Virginia, Richmond, Virginia
Chapter 32

Susan P. Bruce, PharmD, BCPS
Associate Dean for Pharmacy Education and Interprofessional Studies, Chair and Professor of Pharmacy Practice, College of Pharmacy, Northeast Ohio Medical University, Rootstown, Ohio
Chapter 57

Jessica E. Burchette, PharmD, BCPS
Professor, Bill Gatton College of Pharmacy, East Tennessee State University, Johnson City, Tennessee
Chapter 81

Diane M. Cappelletty, PharmD
Professor of Clinical Pharmacy, Chair, Department of Pharmacy Practice, Co-Director, The Infectious Disease Research Laboratory, College of Pharmacy and Pharmaceutical Sciences, University of Toledo, Toledo, Ohio
Chapter 71

Nicholas W. Carris, PharmD, BCPS
Assistant Professor, Department of Pharmacotherapeutics and Clinical Research, College of Pharmacy; Department of Family Medicine, Morsani College of Medicine, University of South Florida, Tampa, Florida
Chapter 58

Marshall E. Cates, PharmD, BCPP
Professor and Chair, Department of Pharmacy Practice, McWhorter School of Pharmacy, Samford University, Birmingham, Alabama
Chapter 38

Brandon Cave, PharmD, ASH-CHC
Clinical Assistant Professor, Department of Pharmacy Practice, South College School of Pharmacy, Knoxville, Tennessee
Chapter 5

Alice C. Ceacareanu, PhD, PharmD
President, ROAKETIN Inc, Amherst, New York
Chapter 93

Kevin W. Chamberlin, PharmD
Associate Clinical Professor, Assistant Head, Department of Pharmacy Practice, School of Pharmacy, University of Connecticut, Farmington, Connecticut
Chapter 29

Juliana Chan, PharmD, BCACP
Clinical Associate Professor, Gastroenterology and Hepatology; Clinical Pharmacist, Ambulatory Pharmacy Services, Clinical Associate Professor, Pharmacy Practice, Colleges of Pharmacy and Medicine, University of Illinois, Chicago, Illinois
Chapter 24

Sallie H. Charles, PMHNP-BC, MS, MBA
Advanced Practice Nurse, Psychiatry, Hidden Lake Medical Offices, Kaiser Permanente Colorado, Westminster, Colorado
Chapter 40

Judy T. Chen, PharmD, BCPS, BCACP, CDE
Clinical Associate Professor of Pharmacy Practice, Purdue University College of Pharmacy, West Lafayette, Indiana
Chapters 45 and 46

Kevin W. Cleveland, PharmD
Associate Professor and Assistant Dean for Experiential Education, Department of Pharmacy Practice and Administrative Sciences, College of Pharmacy, Idaho State University, Pocatello, Idaho
Chapter 42

David B. Cluck, PharmD, BCPS, AAHIVP
Associate Professor, Bill Gatton College of Pharmacy, East Tennessee State University, Johnson City, Tennessee
Chapter 81

Amanda H. Corbett, PharmD, BCPS, AAHIVE
Clinical Associate Professor, Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Chapter 87

Brian L. Crabtree, PharmD, BCPP
Professor and Dean, College of Pharmacy, Mercer University, Atlanta, Georgia
Chapter 39

Daniel J. Crona, PharmD, PhD, CPP
Assistant Professor, Division of Pharmacotherapy and Experimental Therapeutics, Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Chapter 92

Nicole S. Culhane, PharmD, BCPS
Assistant Dean, Experiential Education, and Professor, Clinical and Administrative Sciences, School of Pharmacy, Notre Dame of Maryland University, Baltimore, Maryland

Associate Professor, Lansing School of Nursing and Clinical Sciences, Bellarmine University, Louisville, Kentucky
Appendix D

Kathleen B. Haynes, PharmD, BCPS, CDE
Clinical Coordinator, Bridges to Health, Community Health Network, Indianapolis, Indiana
Chapter 48

Keith A. Hecht, PharmD, BCOP
Associate Professor, Department of Pharmacy Practice, School of Pharmacy, Southern Illinois University, Edwardsville, Illinois
Chapter 97

Nancy Heideman, PharmD, BCPS, BCOP
Oncology Clinical Pharmacy Lead, University of New Mexico Comprehensive Cancer Center
Chapter 95

Emily L. Heil, PharmD, BCPS AQ-ID, AAHIVP
Assistant Professor, School of Pharmacy, University of Maryland, Baltimore, Maryland
Chapter 87

Brian A. Hemstreet, PharmD, BCPS
Assistant Dean for Student Affairs and Professor of Pharmacy Practice, Regis University School of Pharmacy, Rueckert-Hartman College for Health Professions, Denver, Colorado
Chapter 19

Gerald Higa, PharmD
Professor, Schools of Pharmacy and Medicine, West Virginia University, Morgantown, West Virginia
Chapter 89

Michelle L. Hilaire, PharmD, CDE, BCPS, BCACP
Clinical Professor of Pharmacy Practice, Associate Dean of Students, University of Wyoming School of Pharmacy, Laramie, Wyoming
Chapter 62

Lisa M. Holle, PharmD, BCOP
Associate Clinical Professor, Department of Pharmacy Practice, University of Connecticut School of Pharmacy, Storrs, Connecticut
Chapter 88

Marlon S. Honeywell, PharmD
Executive Associate Dean and Professor, College of Pharmacy and Pharmaceutical Sciences, Florida A&M University, Tallahassee, Florida
Chapter 80

Jaime R. Hornecker, PharmD, BCPS, CDE, DPLA
Clinical Professor of Pharmacy Practice, School of Pharmacy, University of Wyoming, Laramie, Wyoming
Chapter 73

Augustus Hough, PharmD, BCPS AQ Cardiology
Clinical Pharmacy Specialist in Cardiology, PGY2 Cardiology Pharmacy Residency Program Director, West Palm Beach Veterans Affairs Medical Center, West Palm Beach, Florida
Chapter 5

Jill L. Isaacs, DNP, ANP, NP-C
Adult Nurse Practitioner, Gastroenterology, Digestive Disease Consultants, Mesa, Arizona
Appendix D

Cherry W. Jackson, PharmD, BCPP
Professor, Department of Pharmacy Practice, Auburn University; Clinical Professor, Department of Psychiatric and Behavioral Neurobiology, School of Medicine, University of Alabama, Birmingham, Alabama
Chapter 38

Mikael D. Jones, PharmD, BCPS
Associate Professor, Pharmacy Practice and Science, College of Pharmacy, University of Kentucky, Lexington, Kentucky
Chapter 61

Desha Jordan, MD
Fellow, Division of Allergy-Immunology, Department of Pediatrics, Medical College of Georgia, Augusta University, Augusta, Georgia
Chapter 54

Michael D. Katz, PharmD
Professor and Director, International Education, Department of Pharmacy Practice and Science, College of Pharmacy, University of Arizona, Tucson, Arizona
Chapter 44

Deanna L. Kelly, PharmD, BCPP
Professor of Psychiatry, Director and Chief, Treatment Research Program, Maryland Psychiatric Research Center, University of Maryland School of Medicine, Baltimore, Maryland
Chapter 37

Amy Kennedy, PharmD
Assistant Professor, Pharmacy Practice and Science, College of Pharmacy, University of Arizona, Tucson, Arizona
Chapter 64

Madeline A. King, PharmD
Assistant Professor of Clinical Pharmacy, Department of Pharmacy Practice and Pharmacy Administration, Philadelphia College of Pharmacy, University of the Sciences, Philadelphia, Pennsylvania
Chapter 78

Emily Knezevich, PharmD, BCPS, CDE
Associate Professor of Pharmacy Practice, School of Pharmacy and Health Professions, Creighton University, Omaha, Nebraska
Appendix D

Jon Knezevich, PharmD, BCPS
Pharmacy Coordinator, Diabetes; Nebraska Medicine, Omaha, Nebraska
Appendix D

Julia M. Koehler, PharmD
Professor and Associate Dean for Clinical Education and External Affiliations, College of Pharmacy and Health Sciences, Butler University; Ambulatory Care Clinical Pharmacist, Methodist Hospital of Indiana University Health, Indianapolis, Indiana
Chapter 48

Michael D. Kraft, PharmD, BCNSP
Clinical Professor, Department of Clinical Pharmacy, College of Pharmacy, University of Michigan, Ann Arbor, Michigan; Assistant Director-Education and Research, Department of Pharmacy Services, Michigan Medicine, Ann Arbor, Michigan
Chapter 100

Kelly R. Kroustos, PharmD, BCGP
Associate Professor of Pharmacy Practice, Raabe College of Pharmacy, Ohio Northern University, Ada, Ohio
Chapter 4

Sum Lam, PharmD, BCGP, BCPS
Associate Clinical Professor, Department of Clinical Health Professions, College of Pharmacy and Health Sciences, St. John's University, Queens, New York; Clinical Specialist in Geriatric Pharmacy, Divisions of Geriatric Medicine and Pharmacy, NYU Winthrop Hospital, Mineola, New York
Chapter 53

Dejan Landup, PharmD, BCPS
Heart Failure Clinical Pharmacist, Advocate Medical Group, Chicago, Illinois
Chapter 7

Amber P. Lawson, PharmD, BCOP
Assistant Professor, Pharmacy Practice and Science, College of Pharmacy, University of Kentucky, Lexington, Kentucky
Chapter 98

James C. Lee, PharmD, BCACP
Clinical Assistant Professor, Department of Pharmacy Practice, Clinical Pharmacist, Ambulatory Pharmacy Services, College of Pharmacy, University of Illinois at Chicago, Chicago, Illinois
Chapter 10

Jeannie K. Lee, PharmD, BCPS, BCGP
Assistant Dean for Student Services and Associate Professor College of Pharmacy; Clinical Associate Professor, College of Medicine, The University of Arizona, Tucson, Arizona
Chapter 2

Mary Lee, PharmD, BCPS, FCCP
Professor of Pharmacy Practice, Chicago College of Pharmacy, Vice President and Chief Academic Officer, Midwestern University, Chicago, Illinois
Chapter 52

Russell E. Lewis, PharmD, BCPS
Associate Professor, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy
Chapter 84

Teresa V. Lewis, PharmD, BCPS
Assistant Professor, Department of Clinical and Administrative Sciences, College of Pharmacy, University of Oklahoma College of Pharmacy, Oklahoma City, Oklahoma
Chapter 68

Cara Liday, PharmD, BCPS, CDE
Associate Professor, Department of Pharmacy Practice, College of Pharmacy, Idaho State University; Clinical Pharmacist, InterMountain Medical Clinic, Pocatello, Idaho
Chapter 51

Susanne E. Liewer, PharmD, BCOP
Pharmacy Coordinator, Blood and Marrow Transplant; Clinical Associate Professor, College of Pharmacy, University of Nebraska Medical Center, Omaha, Nebraska
Chapter 97

Melissa Lipari, PharmD, BCACP
Clinical Assistant Professor, Wayne State University Eugene Applebaum College of Pharmacy and Health Sciences; Clinical Pharmacy Specialist, Ambulatory Care, St. John Hospital and Medical Center, Detroit, Michigan
Chapter 20

Mark A. Malesker, PharmD, FCCP, FCCP, FCCM, FASHP, BCPS
Professor of Pharmacy Practice and Medicine, Creighton University, Omaha, Nebraska
Chapters 27 and 28

Joel C. Marrs, PharmD, BCPS AQ Cardiology, BCACP
Associate Professor, Department of Clinical Pharmacy, Skaggs School of Pharmacy and Pharmaceutical Sciences, University of Colorado, Aurora, Colorado
Chapter 12

Spencer T. Martin, PharmD, BCPS
Clinical Pharmacy Manager, Department of Pharmacy Services, Hartford Hospital, Hartford, Connecticut
Chapter 55

J. Russell May, PharmD
Clinical Professor and Associate Head, Department of Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Augusta, Georgia
Chapter 54

Kathleen May, MD
Division Chief and Associate Professor of Pediatrics, Division of Allergy, Immunology and Pediatric Rheumatology, Medical College of Georgia, Augusta University, Augusta, Georgia
Chapter 54

Joseph E. Mazur, PharmD, BCPS, BCNSP
Critical Care Clinical Specialist, Medical Intensive Care Unit; Adjunct Clinical Associate Professor, Medical University of South Carolina College of Pharmacy, Charleston, South Carolina
Chapter 77

J. Michael McGuire, PharmD
Associate Professor of Pharmacy Practice, Psychiatry, College of Pharmacy, Belmont University, Nashville, Tennessee
Chapter 38

Damian M. Mendoza, PharmD, CGP
Clinical Pharmacy Specialist, Geriatrics, Southern Arizona VA Health Care System, Tuscon, Arizona
Chapter 2

Sarah J. Miller, PharmD, BCNSP
Professor, Department of Pharmacy Practice, University of Montana Skaggs School of Pharmacy; Pharmacy Clinical Coordinator, Province Saint Patrick Hospital, Missoula, Montana
Chapter 101

Beverly C. Mims, PharmD
Associate Professor of Pharmacy Practice, College of Pharmacy, Howard University; Clinical Pharmacist, Howard University Hospital, Washington, DC
Chapter 21

M. Jane Mohler, NP-C, MSN, MPH, PhD
Co-Director, Arizona Geriatric Education Center, Associate Director, Reynolds Program in Applied Geriatrics, College of Medicine, University of Arizona, Tucson, Arizona
Chapter 2

Caroline Morin, BPharm, MSc
Pharmacist in Obstetrics and Gynecology, Associated Clinician, CHU Ste-Justine, Université de Montreal Pharmacist, Montreal, Quebec, Canada
Chapter 47

Lee E. Morrow, MD, MSc
Professor, Division of Pulmonary, Critical Care, and Sleep Medicine, Creighton University School of Medicine, Omaha, Nebraska
Chapters 27 and 28

Milap C. Nahata, PharmD, MS
Professor Emeritus of Pharmacy, Pediatrics and Internal Medicine; Director of the Institute of Therapeutic Innovations and Outcomes, College of Pharmacy, Ohio State University; Columbus, Ohio
Chapter 3

Rocsanna Namdar, PharmD, FCCP, BCPS
Inpatient Pharmacy Supervisor, New Mexico Veterans Affairs Healthcare System, Albuquerque, New Mexico
Chapter 75

Douglas A. Newton, MD, MPH
Child and Adolescent Psychiatrist, Colorado Permanente Medical Group, Denver, Colorado
Chapter 40

Tien M.H. Ng, PharmD, BCPS AQ Cardiology
Associate Professor, Clinical Pharmacy, School of Pharmacy, University of Southern California, Los Angeles, California
Chapter 6

Kimberly J. Novak, PharmD, BCPS, BCPPS
Clinical Pharmacy Specialist, Pediatric Pulmonary Medicine, Nationwide Children's Hospital, Columbus, Ohio
Chapter 16

Edith A. Nutescu, PharmD, MS, FCCP
Associate Professor, Department of Pharmacy Systems, Outcomes and Policy, and Director, Center for Pharmacoepidemiology and Pharmacoeconomic Research, College of Pharmacy, University of Illinois, Chicago, Illinois
Chapter 10

Catherine M. Oliphant, PharmD
Professor and Interim Chair, Department of Pharmacy Practice and Administrative Sciences, College of Pharmacy, Idaho State University, Meridian, Idaho
Chapter 69

Ali J. Olyaei, PharmD
Professor, Department of Medicine and Pharmacy Practice, Oregon State University and Oregon Health and Sciences University, Portland, Oregon
Chapter 55

Christine Karabin O'Neil, BS, PharmD, BCPS, CGP
Professor of Pharmacy Practice, Division of Clinical, Social, and Administrative Sciences, School of Pharmacy, Duquesne University, Pittsburgh, Pennsylvania
Chapter 34

Vinita B. Pai, PharmD, MS
Associate Professor of Clinical Pharmacy, Ohio State University, College of Pharmacy; Clinical Pharmacy Specialist, Pediatric Blood and Marrow Transplant Program, Nationwide Children's Hospital, Columbus, Ohio
Chapter 3

Lisa M. Palmisano, PharmD, BCACP
Assistant Professor, Department of Pharmacy Practice, Clinical Pharmacist, Chicago College of Pharmacy, Midwestern University, Chicago, Illinois
Chapter 60

David Parra, PharmD, FCCP, BCPS
Clinical Pharmacy Program Manager in Cardiology & Anticoagulation, Veterans Integrated Service Network 8, Pharmacy Benefits Management, Bay Pines, Florida; Clinical Associate Professor, Department of Experimental and Clinical Pharmacology, College of Pharmacy, University of Minnesota, Minneapolis, Minnesota
Chapter 5

Chris Paxos, PharmD, BCPP, BCPS, BCGP
Associate Professor of Pharmacy Practice, Associate Professor of Psychiatry, College of Pharmacy, Northeast Ohio Medical University, Rootstown, Ohio
Chapter 36

Charles Peloquin, PharmD, FCCP
Professor, Department of Pharmacotherapy and Translational Research, College of Pharmacy, University of Florida, Gainesville, Florida
Chapter 75

Maribel A. Pereiras, PharmD, BCPS, BCOP
Clinical Oncology Pharmacist, Hematopoietic Stem Cell Transplant and Cellular Therapy, John Theurer Cancer Center at Hackensack University Medical Center, Hackensack, New Jersey
Chapter 66

Laura A. Perry, PharmD, BCPS
Associate Professor, Department of Pharmacy Practice, University of Findlay College of Pharmacy, Findlay, Ohio
Chapter 65

Sarah Scarpace Peters, PharmD, MPH, BCOP
Associate Professor, Pharmacy Practice, Albany College of Pharmacy and Health Sciences in Albany, NY
Chapter 99

Hanna Phan, PharmD, FCCP, FPPAG
Associate Professor, Department of Pharmacy Practice and Science, Associate Professor, Department of Pediatrics, Colleges of Pharmacy and Medicine; Associate Research Scientist, Asthma and Airway Disease Research Center, The University of Arizona, Tucson, Arizona
Chapters 3 and 63

Beth Bryles Phillips, PharmD, FASHP, FCCP, BCPS, BCACP
Rite Aid Professor, College of Pharmacy, University of Georgia; Director VAMC/UGA PGY2 Ambulatory Care Residency Program, Athens, Georgia
Chapter 56

Bradley G. Phillips, PharmD, BCPS
Millikan-Revee Professor and Head, Department of Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, Georgia
Chapter 41

Amy M. Pick, PharmD, BCOP
Professor of Pharmacy Practice, Creighton University School of Pharmacy and Health Professions, Omaha, Nebraska
Chapter 96

Melissa R. Pleva, PharmD, BCNSP, BCCCP, BCPS
Manager-Surgery and Cardiovascular Services, Department of Pharmacy Services, Michigan Medicine, Ann Arbor, Michigan; Adjunct Clinical Assistant Professor, Department of Clinical Pharmacy, College of Pharmacy, University of Michigan, Ann Arbor, Michigan
Chapter 100

Christina M. Polomoff, PharmD, BCACP, BCGP
Assistant Clinical Professor, University of Connecticut School of Pharmacy; Population Health Clinical Pharmacist, Hartford HealthCare Integrated Care Partners, Storrs, Connecticut
Chapter 45

Elizabeth A. Price, PharmD, MSCR, BCPS
PGY2 Ambulatory Care Pharmacy Resident, University of Georgia College of Pharmacy, Athens, Georgia
Chapter 56

Amber E. Proctor, PharmD
Clinical Assistant Professor, Division of Pharmacotherapy and Experimental Therapy, Eshelman School of Pharmacy, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina
Chapter 92

Jeremy J. Prunty, PharmD, BCPS
Clinical Pharmacy Specialist—Oncology Internal Medicine, University Hospitals Cleveland Medical Center, Cleveland, Ohio
Chapter 17

Leesa M. Prunty, PharmD, BCPS, BCPPS
Clinical Pharmacy Specialist—Cystic Fibrosis, University Hospitals Home Care Services & Rainbow Babies and Children's Hospital, Cleveland, Ohio
Chapter 17

April Miller Quidley, PharmD, BCPS, BCCCP
Critical Care Pharmacist and Critical Care Residency Program Director, Vidant Medical Center, Greenville, North Carolina
Chapter 70

Catherine Bourg Rebitch, PharmD, BCPS, BCACP
Clinical Associate Professor, Clinical and Administrative Pharmacy; Director, PGY1 Community Residency Program, College of Pharmacy, University of Georgia, Athens, Georgia
Chapter 18

Treavor T. Riley, PharmD, BCPS, BCCCP
Associate Professor, School of Pharmacy, Wingate University, Hendersonville, North Carolina
Chapter 93

Anastasia Rivkin, PharmD, BCPS
Assistant Dean for Faculty and Professor of Pharmacy Practice, School of Pharmacy, Fairleigh Dickinson University, Florham Park, New Jersey
Chapter 67

Kelly C. Rogers, PharmD, FCCP, FACC
Professor, Department of Clinical Pharmacy and Translational Science, College of Pharmacy, University of Tennessee Health Science Center, Memphis, Tennessee
Chapter 8

P. David Rogers, PharmD, PhD
First Tennessee Endowed Chair of Excellence in Clinical Pharmacy, Vice Chair for Research, Director, Clinical and Experimental Therapeutics, and Professor of Clinical Pharmacy and Pediatrics, College of Pharmacy, University of Tennessee Health Science Center, Memphis, Tennessee
Chapter 84

Brendan S. Ross, MD
Staff Physician, G.V. (Sonny) Montgomery Veterans Affairs Medical Center; Clinical Associate Professor, Department of Pharmacy Practice, University of Mississippi School of Pharmacy, Jackson, Mississippi
Chapter 35

Leigh Ann Ross, PharmD, BCPS
Associate Dean for Clinical Affairs, Professor and Chair, Department of Pharmacy Practice, University of Mississippi School of Pharmacy, Jackson, Mississippi
Chapter 35

John C. Rotschafer, PharmD
Professor, College of Pharmacy, University of Minnesota, Minneapolis, Minnesota
Chapter 85

Laurajo Ryan, PharmD, MSc, BCPS, CDE
Clinical Associate Professor, University of Texas at Austin College of Pharmacy; University of Texas Health Science Center, Department of Medicine, Pharmacotherapy Education Research Center, Austin, Texas
Chapter 22

Melody Ryan, PharmD, MPH
Professor, Department of Pharmacy Practice and Science, College of Pharmacy, University of Kentucky, Lexington, Kentucky
Chapter 30

Lauren S. Schlesselman, MEd, PharmD
Director, Learning Initiatives & Educational Technology, Adjunct Assistant Clinical Professor, University of Connecticut, Storrs, Connecticut
Chapter 83

Kristine S. Schonder, PharmD
Assistant Professor, University of Pittsburgh School of Pharmacy; Clinical Specialist, Transplant, University of Pittsburgh Medical Center Health System, Pittsburgh, Pennsylvania
Chapter 26

Julie Sease, PharmD, FCCP, BCPS, CDE, BCACP
Professor of Pharmacy Practice and Associate Dean for Academic Affairs, School of Pharmacy, Presbyterian College, Clinton, South Carolina
Chapter 43

Corinne M. Self, MD
Assistant Professor of Geriatrics, Division of Internal Medicine, Geriatrics and Palliative Care, University of Arizona, College of Medicine, Tucson, Arizona
Chapter 2

Roohollah Sharifi, MD, FACS
Professor, Department of Urology and Surgery, College of Medicine, University of Illinois at Chicago, Chicago, Illinois and Section Chief of Urology, Jesse Browns Veterans Administration Medical Center, Chicago, Illinois
Chapter 52

Bradley W. Shinn, PharmD
Professor of Pharmacy Practice, University of Findlay College of Pharmacy, Findlay, Ohio
Chapter 76

April Smith, PharmD, BCPS
Associate Professor, School of Pharmacy and Health Professions, Creighton University, Omaha, Nebraska
Chapter 102

Judith A. Smith, PharmD, BCOP, CPHQ
Associate Professor, Department of Obstetrics, Gynecology and Reproductive Sciences, University of Texas Medical School at Houston, Houston, Texas
Chapter 94

Melanie N. Smith, PharmD, BCPS, BCCCP
Critical Care Specialist, Surgery-Trauma ICU, Affiliate Assistant Professor, Medical University of South Carolina College of Pharmacy, Charleston, South Carolina
Chapter 77

Steven M. Smith, PharmD, MPH, BCPS
Assistant Professor, Departments of Pharmacotherapy and Translational Research and Community Health & Family Medicine, Colleges of Pharmacy and Medicine, University of Florida, Gainesville, Florida
Chapter 58

Susan E. Smith, PharmD, BCPS, BCCCP
Clinical Assistant Professor, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, Georgia
Chapter 82

Thomas R. Smith, PharmD
Assistant Professor of Pharmacy Practice, College of Pharmacy, Natural, and Health Sciences, Manchester University, Fort Wayne, Indiana
Chapter 33

Sarah A. Spinler, PharmD, FCCP, FAHA, FASHP, AACC, BCPS AQ Cardiology
Professor and Chair, Department of Pharmacy Practice, School of Pharmacy and Pharmaceutical Sciences, Binghamton University, Binghamton, New York
Chapter 8

Mary K. Stamatakis, PharmD
Senior Associate Dean for Academic Affairs and Educational Innovation and Professor, West Virginia University School of Pharmacy, Morgantown, West Virginia
Chapter 25

Robert J. Straka, PharmD
Professor and Head, Experimental and Clinical Pharmacology Department, University of Minnesota College of Pharmacy, Minneapolis, Minnesota
Chapter 5

S. Scott Sutton, PharmD, BCPS AQ-ID
Professor and Chair, Department of Clinical Pharmacy and Outcomes Sciences, College of Pharmacy, University of South Carolina, Columbia, South Carolina
Chapter 82

Marc A. Sweeney, PharmD, MDiv
Professor and Dean, School of Pharmacy, Cedarville University, Cedarville, Ohio
Chapter 4

Marie-Lou Tardif, MD, FRCPC
Staff Physician, Université de Montréal
Montreal, Quebec
Chapter 47

Sharon Ternullo, PharmD, DABAT
Assistant Professor of Pharmacy Practice, University of Findlay College of Pharmacy, Findlay, Ohio
Chapter 76

Eljim P. Tesoro, PharmD, BCPS
Clinical Associate Professor, College of Pharmacy, Clinical Pharmacist, Neurosciences, Director, PGY2 Critical Care Residency, University of Illinois Hospital and Health Sciences System, Chicago, Illinois
Chapter 32

Christian J. Teter, PharmD, BCPP
Manager, Medical Affairs, Alkermes, Waltham, Massachusetts
Chapter 36

Heather M. Teufel, PharmD, BCPS, BCCCP
Clinical Pharmacist, Emergency Medicine, University of Pennsylvania Health System, Chester County Hospital, West Chester, Pennsylvania
Chapter 23

Janine E. Then, PharmD, BCPS
Lead Pharmacist–Clinical Services, University of Pittsburgh Medical Center, Presbyterian-Shadyside Hospital, Pittsburgh, Pennsylvania
Chapter 23

Michael L. Thiman, PharmD
Clinical Assistant Professor, Clinical and Administrative Pharmacy, College of Pharmacy, University of Georgia, Athens, Georgia
Chapter 18

Maria Miller Thurston, PharmD, BCPS
Clinical Associate Professor, Department of Pharmacy Practice, College of Pharmacy, Mercer University, Atlanta, Georgia
Chapter 59

James E. Tisdale, PharmD, BCPS, FCCP, FAPhA, FNAP, FAHA, FACC
Professor, College of Pharmacy, Purdue University; Adjunct Professor, School of Medicine, Indiana University, Indianapolis, Indiana
Chapter 9

Mary A. Ullman, PharmD
Pharmacist, Regions Hospital, St. Paul, Minnesota
Chapter 85

Sandeep Vansal, PharmD
Associate Professor and Director, Pharmaceutical Sciences, School of Pharmacy, Fairleigh Dickinson University, Florham Park, New Jersey
Chapter 67

Orly Vardeny, PharmD, MS, BCACP
Associate Professor, School of Medicine, University of Minnesota, Minneapolis, Minnesota
Chapter 6

Mary L. Wagner, PharmD, MS
Associate Professor, Department of Pharmacy Practice and Administration, Ernest Mario School of Pharmacy, Rutgers University, Piscataway, New Jersey
Chapter 33

Heidi J. Wehring, PharmD, BCPP
Assistant Professor, Department of Psychiatry, Maryland Psychiatric Research Center, University of Maryland School of Medicine, Washington, DC
Chapter 37

Lydia E. Weisser, DO, MBA
Medical Director, Bryan Psychiatric Hospital, Columbia, South Carolina
Chapter 39

Timothy E. Welty, PharmD, MA, BCPS
Professor and Chair, Department of Clinical Sciences, College of Pharmacy and Health Sciences, Drake University, Des Moines, Iowa
Chapter 31

Ya-Feng Wen, PharmD
PhD Student, Department of Experimental and Clinical Pharmacology, College of Pharmacy, University of Minnesota, Minneapolis, Minnesota
Chapter 5

Tara R. Whetsel, PharmD, BCACP, BC-ADM
Clinical Associate Professor, West Virginia University School of Pharmacy, Morgantown, West Virginia
Chapter 15

Jon P. Wietholter, PharmD, BCPS
Clinical Associate Professor, West Virginia University School of Pharmacy; Internal Medicine Clinical Pharmacist, WVU Medicine Ruby Memorial Hospital, Morgantown, West Virginia
Chapter 15

Sheila Wilhelm, PharmD, BCPS
Clinical Associate Professor, Department of Pharmacy Practice, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University; Clinical Pharmacy Specialist, Internal Medicine, Harper University Hospital, Detroit, Michigan
Chapter 20

Lori Wilken, PharmD
Clinical Pharmacist, University of Illinois Hospital and Health Sciences System; Clinical Assistant Professor, Pharmacy Practice, University of Illinois at Chicago College of Pharmacy, Chicago, Illinois
Chapter 14

Susan R. Winkler, PharmD, BCPS
Professor and Chair, Department of Pharmacy Practice, College of Pharmacy, Midwestern University Chicago, Downers Grove, Illinois
Chapter 11

G. Christopher Wood, PharmD, BCPS AQ-ID, BCCCP
Associate Professor, Department of Clinical Pharmacy, College of Pharmacy, University of Tennessee, Memphis, Tennessee
Chapter 13

Pharmacist, Mercy Hospital, St. Louis College of Pharmacy, St. Louis, Missouri

David Zimmerman, PharmD, BCPS, BCCCP
Assistant Professor, Division of Pharmacy Practice, School of Pharmacy, Duquesne University, Pittsburgh, Pennsylvania

PREFACE

Effective use of pharmacotherapy is vital for preventing and treating acute and chronic medical conditions. Although biomedical research continues to develop and provide medications with enormous potential to improve health, these same medications are often overused, underused, or misused, leading to suboptimal or unsafe results. It is our responsibility as health care practitioners to optimize positive health outcomes and limit adverse pharmacotherapeutic effects.

Provision of high quality, cost-effective pharmacotherapy requires an integration of scientific knowledge and clinical practice skills combined with a fiduciary responsibility to put the patient's needs first. The development of mature pharmacotherapists occurs through structured learning processes that include formal coursework, independent study, mentorship, interprofessional experiences, and direct involvement in the care of actual patients.

The fifth edition of *Pharmacotherapy Principles & Practice* is designed to provide student learners and health care practitioners with essential knowledge of the pathophysiology and pharmacotherapeutics of disease states likely to be encountered in routine practice. Chapters are written by content experts and peer reviewed by pharmacists, nurse practitioners, physician assistants, and physicians who are authorities in their professional disciplines.

Pharmacotherapy Principles & Practice, fifth edition, opens with an introductory chapter followed by chapters on pediatrics, geriatrics, and palliative care. Most of the remainder of the book consists of disease-based chapters that review disease epidemiology, etiology, pathophysiology, clinical presentation and diagnosis, and nonpharmacologic therapy, followed by an emphasis on clear therapeutic recommendations for medication selection, desired outcomes expected, dosing, and patient monitoring. The following features were designed in collaboration with educational design specialists to enhance learning and retention:

- *Structured learning objectives* at the beginning of each chapter, *w*ith information in the text that corresponds to each learning objective identified by a vertical rule in the margin, allowing the reader to quickly find content related to each objective.
- *Key concepts related to the disease, patient assessment, and treatment* highlighted with an easily identifiable icon throughout the chapter.
- *Patient encounters* that facilitate development of critical thinking skills and lend clinical relevance to the scientific foundation provided.
- A newly designed *patient care process* section modeling the Joint Commission of Pharmacy Practitioners (JCPP) Pharmacists' Patient Care Process that provides specific recommendations about the process of care for an individual patient involving five steps: collecting information, assessing information, developing a care plan, implementing the care plan, and following-up: monitor and evaluate.
- *Up-to-date literature citations* for each chapter to support treatment recommendations.
- *Tables, figures, and algorithms* that enhance understanding of pathophysiology, clinical presentation, medication selection, pharmacokinetics, and patient monitoring.
- *Medical abbreviations and their meanings* at the end of each chapter to facilitate learning the accepted shorthand used in real-world health care settings.
- *Self-assessment questions and answers for each chapter* in the Online Learning Center to facilitate self-evaluation of learning.
- *Laboratory values* expressed as both conventional units and Système International (SI) units.
- *Appendices* that contain: (1) conversion factors and anthropometrics; (2) common medical abbreviations; (3) glossary of medical terms (the first use of each term in a chapter appears in bold, colored font); and (4) prescription writing principles.
- *A table of common laboratory tests and reference ranges* appears on the inside covers of the book.

A companion textbook, *Pharmacotherapy Principles and Practice Study Guide: A Case-Based Care Plan Approach*, is available to further enhance learning by guiding students through the process of applying knowledge of pharmacotherapy to specific patient cases. This study guide contains approximately 100 patient cases that correspond to chapters published in the textbook.

The Online Learning Center at www.ChisholmPharmacotherapy.com provides self-assessment questions, grading and immediate feedback on the questions, and reporting capabilities. The complete textbook and study guide are available to subscribers of the publisher's AccessPharmacy site (www.accesspharmacy.com), an online educational resource for faculty and students of the health professions.

We are extremely grateful for the commitment and dedication of more than 190 contributing authors and more than 100 peer reviewers of the chapters in this new edition. We also thank the many educators, schools/colleges, and health care institutions that have adopted this textbook in courses or use it as a reference in practice settings. In closing, we extend our sincere thanks to the McGraw-Hill Education editorial team for their hard work and commitment to bringing this new edition to our readership.

- Joseph T. DiPiro, PharmD, FCCP

Original Artwork

Title: The Art of Pharmacotherapy

Cover illustration and design copyright © 2018 by Obi-Tabot Tabe, PharmD. The image is taken from an 18′ × 24′ oil painting by Obi-Tabot Tabe, PharmD, a painter, graphic designer, scientific illustrator, and pharmacist. The painting is housed at the University of Pittsburgh School of Pharmacy.

Dr. Tabe, originally from Cameroon, is a graduate of the University of Pittsburgh School of Pharmacy. The pharmacist scope of practice is expanding, and pharmacists are taking on a greater patient care role in collaborative drug therapy with physicians and other healthcare professionals. The painting depicts the collaborative relationship between the disciplines of pharmacy and medicine in the art of pharmacotherapy. Basic dispensing functions, drug information services, solutions to patient- and medication-related problems, and decisions regarding drug prescribing, monitoring and drug regimen adjustments are all collaborative efforts in pharmacotherapy. The intersecting circles represent collaboration between pharmacists, physicians, and other healthcare professionals in the art of pharmacotherapy. The subtle greens and blues in the painting, including carbon rings and molecular structures, represent natural and synthetic medicines. The pills (tablets and capsules) in one of the circles represent the knowledge and expertise of the pharmacist in drug information services and drug therapy; the stethoscope represents the clinical environment; and the pharmacokinetic curves represent the vitality to drug monitoring and adjustments.

Special Acknowledgment

On the occasion of her retirement, we especially acknowledge the many years of dedicated service provided by Ms. Laura Libretti, Administrative Assistant at McGraw-Hill Education.

Part I

Basic Concepts of Pharmacotherapy Principles and Practices

1 Introduction

Jack E. Fincham

INTRODUCTION

Health professionals are given significant responsibilities in our health care system. These roles may be taken for granted by patients until a pharmacist, nurse practitioner, physician assistant, physician, or others perform assigned tasks that make positive impacts upon patients and patients' families lives in countless ways. The exemplary manner in which health professionals provide necessary care to patients is a hallmark of health professional practice and delivery of US health care. Patients are thus well served, and fellow health professionals share knowledge and expertise specific to their profession. However, there are significant problems remaining in the US health care system from a structural standpoint. In 2016, the United States spent 17.2% of the gross domestic product (GDP) on health care,[1] yet the United States ranks 37th in the world when considering outcomes of care. Comparing the United States to similar industrialized countries, we rank 11th out of 11 comparator countries, and have poorer health outcomes.[2] The reasons for why the United States compares poorly with other countries will be discussed in the following paragraphs.

Tremendous uncertainty surrounds the current health care system in the United States. Efforts to repeal and replace the Patient Protection and Affordable Care Act (ACA) have failed at the US Congressional level. Bipartisan calls for improving the current ACA have met with both encouragement and disdain, depending upon the point of view of those speaking. Regardless of the form of health care delivery and insurance for such, the very bright note to point out is the realization of the excellence of the delivery and outcomes of care provided by US health care professionals. Health professionals improve the health of Americans daily through many efforts and accomplishments.

A significant issue in the United States is that countless other Americans in our midst are underinsured. They may have partial coverage after a fashion, but, for these Americans, the high price of deductibles, co-pays, and monthly payments for insurance create an economic dilemma each time they seek care or pay premiums. In a comprehensive report from Kalorama Information,[3] it was noted that consumer out-of-pocket health care costs have risen from $250 per year in 1980 to over $1400 in 2016. It was also noted in this report that those in less comprehensive health care coverage insurance plans have delays in treatment, which lead to increasing costs in the long term. Recently, Howard Bauchner, MD, the editor-in-chief of JAMA and The JAMA Network, has called for health professionals and professional organizations to speak with one voice and support health care coverage as a right for all.[4]

Recent US Center for Medicare and Medicaid (CMS) expenditure data projections posit that, in 2025 in the United States, a total of $4.72 trillion will be spent on health care.[5] The projection for spending on prescription drugs in 2025 is estimated to total $1.7 billion.[6]

There are tremendous opportunities for health professionals due to the implementation of outcome measures (clinical, economic, humanistic) via the ACA. For the first time in the structure of the US health care system there is now a tangible, significant effort to enhance the quality and outcomes of health care delivered.

The use of medications in the health care system provides enormous help to many; lives are saved or enhanced, and lifespans are lengthened. Many other uses of medications lead to significant side effects, worsening states of health, and premature deaths. So, how to separate these disparate pictures of drug use outcomes? You, within your practices and within your networks in the health care workplace, can help to promote the former and diminish the latter. The authors of the chapters in this book have written informative, current, and superb chapters that can empower you to positively influence medication use.

DRUG USE IN THE HEALTH CARE SYSTEM

Prescription medications are used daily; 48.5% of the population uses one prescription drug daily, 21.7% use three or more drugs daily, and 10.6% use five or more prescription drugs daily.[7] Problems occurring with the use of drugs can include:

- Medication errors
- Suboptimal drug, dose, regimen, dosage form, and duration of use
- Unnecessary drug therapy
- Therapeutic duplication
- Drug–drug, drug–disease, drug–food, or drug–nutrient interactions
- Drug allergies
- Adverse drug effects, some of which are preventable.

Clinicians are often called upon to resolve problems that occur due to undertreatment, overtreatment, or inappropriate treatment. Individuals can purchase medications through numerous outlets. Over-the-counter (OTC) medications can be purchased virtually anywhere. OTCs are widely used by all age groups. Prescription medications can be purchased through traditional channels (community chain and independent pharmacies), from mail-order pharmacies, through the Internet, from physicians, from health care institutions, and elsewhere. Herbal remedies are marketed and sold in numerous outlets. The monitoring of the positive and negative outcomes of the use of these drugs, both prescription and OTC, can be disjointed and incomplete. Clinicians and health professionals need to take ownership of these problems and improve patient outcomes resulting from drug use.

Although clinicians are the gatekeepers for patients to obtain prescription drugs, patients obtain prescription medications from numerous sources. Patients may also borrow from friends,

relatives, or even casual acquaintances. In addition, patients obtain OTC medications from physicians through prescriptions, on advice from pharmacists and other health professionals, through self-selection, or through the recommendations of friends or acquaintances. Through all of this, it must be recognized that there are both formal (structural) and informal (word-of-mouth) components at play. Health professionals may or may not be consulted regarding the use of medications, and, in some cases, are unaware of the drugs patients are taking.

External variables may greatly influence patients and their drug-taking behaviors. Coverage for prescribed drugs allows those with coverage to obtain medications with varying cost sharing requirements. However, many do not have insurance coverage for drugs or other health-related needs.

Self-Medication

Self-medication can be broadly defined as a decision made by a patient to consume a drug with or without the approval or direction of a health professional. The self-medication activities of patients have increased dramatically in the late 20th and early 21st centuries. Many factors affecting patients have continued to fuel this increase in self-medication. There have been many prescription items switched to OTC classification in the last 50 years, which is dramatically and significantly fueling the rapid expansion of OTC drug usage. In addition, patients are increasingly comfortable with self-diagnosing and self-selection of OTC remedies.

Through the rational use of drugs, patients may avoid more costly therapies or expenditures for other professional services. Self-limiting conditions, and even some chronic health conditions (eg, allergies and dermatologic conditions), if appropriately treated through patient self-medication, allow the patient to have a degree of autonomy in health care decisions.

Compliance Issues

Noncompliance with prescription regimens is one of the most understated problems in the health care system. Approximately 10% of initial prescriptions written by physicians are never filled.[8] Reasons can include trying too soon to obtain a new prescription, prior approval requirements, the prescribed drug may not be covered under the patient's insurance, and so on. The effects of noncompliance have enormous ramifications for patients, caregivers, and health professionals. Noncompliance is a multifaceted problem with a need for interprofessional, multidisciplinary solutions. Interventions that are organizational (how clinics are structured), educational (patient counseling, supportive approach), and behavioral (impacting health beliefs and expectations) are necessary. Compliant behavior can be enhanced through your actions with the patients for whom you provide care. Sometimes what is necessary is referral to specific clinicians for individualized treatment and monitoring to enhance compliance. The case histories provided in this textbook will allow you to follow what others have done in similar situations to optimally help patients succeed in improving compliance rates and subsequent positive health outcomes.

Drug Use by the Elderly

The major source of payment for prescription drugs for those aged 65 years and older in the United States is the Medicare Part D Drug Benefit. Seniors have benefitted tremendously from this component. Estimates place the expenditure for Medicare Part D to be $94 billion in 2017; this is 15.6% of Medicare expenditures.[9] Since the inception of Medicare Part D, recipients have had to pay costs after initial minimum threshold amounts are reached, then enter the so-called "donut hole" requiring payment out of pocket until a certain amount would be paid, and then coverage for payment would ensue. This so-called donut hole closes in 2020, which will provide more benefits for more enrollees. Enhanced use of pharmacoeconomic tenets to select appropriate therapy, while considering cost and therapeutic benefits for seniors and others, will become even more crucial for clinicians in the future.

Unnecessary drug therapy and over medication are problems with drug use in the elderly. Cost estimates are projected to be $1.3 billion per year for elderly patient polypharmacy alone.[10] A joint effort by health professionals working together is the best approach to aiding seniors in achieving optimal drug therapy. Evaluation of all medications taken by seniors at each patient visit can help prevent polypharmacy from occurring.

IMPACTING THE PROBLEMS OF DRUG USE

Medication Errors

There is a tremendous opportunity in medication use and monitoring for working to reduce medication errors. Untold morbidity and mortality occur due to the many errors in medication use. Studies have shown that reconciling the medications that patients take, with coordination by various caregivers providing care, can help reduce medication errors in patient populations.[8]

The incorporation of three key interventions—computerized physician order entry (CPOE), additional staffing, and bar coding—has been shown in an institutional setting to help reduce medication errors.[11]

Avoiding Prescribing Cascades

Prescribing cascades occur in health care when the side effect from a medication is interpreted as a new condition, and a second drug is prescribed to "treat" the side effect. Prescribing cascades are important because they can be prevented.[12]

Impacting the Opioid Crisis

The use and misuse of prescription opioid analgesic medications are at an all-time high and are increasing, and the negative consequences of this epidemic are many.[13] According to the Centers for Disease Control and Prevention (CDC), 91 Americans die daily from an opioid overdose, including prescription opioids and heroin.[14] The opioid crisis is not limited to the United States; it is a North American crisis as well, with the Canadian government providing funding to address the problem.[14,15] The CDC has published and promoted prescribing guidelines to help stem inappropriate prescribing of opioids for chronic pain.[16] Health professionals will play a vital role in reversing this epidemic and enhancing the health of many and society as well.

SUMMARY

Health professionals are at a crucial juncture facing an uncertain, yet promising future. The skills and knowledge that enable effective practice have never been more daunting among the numerous health professions. Technology can further empower health professionals to play an effective role in helping patients and fellow health professionals to practice safe and effective medicine. Health care reform has the potential to dramatically impact your practices in the health care system for the length of your careers.

The use of this text, which incorporates materials written by the finest minds in pharmacy practice and education, can enable the reader to play a crucial role in improving the drug use process for patients, providers, payers, and society. The thorough analysis of common disease states, discussion of therapies to treat these conditions, and specific advice for patients will help you in your practices. The purpose of this book is to help you make a real improvement in the therapies you provide to your patients. Current and future clinicians can rely on the information laid out here to enhance your knowledge and allow you to assist your patients with the sound advice that they expect you to provide. Use the text, case histories, and numerous examples here to expand your therapeutic skills and to help positively impact your patients in the years to come.

You can help reverse medication-related problems, improve outcomes of care both clinically and economically, and enable drug use to meet stated goals and objectives. This text provides a thorough analysis and summary of treatment options for commonly occurring diseases and the medications or alternative therapies used to successfully treat these conditions.

2 Geriatrics

Jeannie K. Lee, Damian M. Mendoza, M. Jane Mohler, and Corinne M. Self

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO
1. Explain changing aging population demographics.
2. Discuss age-related pharmacokinetic and pharmacodynamic changes.
3. Identify drug-related problems and associated morbidities commonly experienced by older adults.
4. Describe major components of geriatric assessment.
5. Recognize interprofessional patient care functions in various geriatric practice settings.

INTRODUCTION

The growth of the aging population and increasing lifespan require that health care professionals gain knowledge necessary to meeting the needs of this patient group. Despite the availability and benefit of numerous pharmacotherapies to treat their diseases, older patients commonly experience drug-related problems, resulting in additional morbidities. Therefore, it is essential for clinicians serving older adults across all health care settings to understand the epidemiology of aging, age-related physiological changes, drug-related problems prevalent in the elderly, comprehensive geriatric assessment, and interprofessional approaches to geriatric care.

EPIDEMIOLOGY AND ETIOLOGY

As humans age, they are at increasing risk of disease, disability, and death for three reasons: (a) genetic predisposition; (b) reduced immunological surveillance; and (c) the accumulated effects of physical, social, environmental, and behavioral exposures over the life course. Elders experience variably increasing vulnerability (homeostenosis) as they age, resulting in heterogeneity in health states and care requirements. While resilient elders can maintain high levels of physical and cognitive functioning, others suffer functional decline, frailty, disability, or premature death. There is an urgent need for all clinicians to better understand the epidemiology of aging in order to comprehensively provide high value services to optimize the function and health-related quality of life of older adults.[1]

Sociodemographics

▶ *Population*

KEY CONCEPT Our population is rapidly growing older. In 2015, 47.8 million US residents were 65 years and older (nearly 15% of the total population), with projections to more than double to 98 million by 2060.[2] Almost 6.3 million people were 85 years or older (the "oldest-old"), and nearly 77 thousand persons were aged 100 or older.[3] Those 85+ years individuals are projected to triple from 6.3 million in 2015 to over 14.6 million in 2040.[3] In 2015, older women aged 65 years and above (26.7 million) outnumbered older men (21.1 million), with a ratio of 100 women to 79 men; this ratio widens as elders age. In addition, minority elders are projected to increase to 21.1 million in 2020.[3] With changing aging population demographics, surviving baby boomers will be disproportionally female, more ethnically/racially diverse, better educated, live alone, and have more financial resources than were elders in previous generations.

LO 1

▶ *Economics*

More elders are enjoying higher economic prosperity than ever before, with only 10% living below the poverty line.[4] However, major inequalities persist, with older blacks and those without high school diplomas reporting fewer financial resources.[4] Considerable disparities exist, and may prevent less advantaged elders from being able to purchase all prescribed medications.

▶ *Education and Health Literacy*

By 2007, more than 75% of US elders had graduated from high school, and nearly 20% had a bachelor's degree or higher. Still, substantial educational differences exist among racial and ethnic minorities. While more than 80% of non-Hispanic white elders had high school degrees in 2007, 72% of Asians, 58% of blacks, and 42% of Hispanic elders were graduates.[5] Nearly 40% of people 75 years or older have low health literacy, more than any other age group.[4] Despite these limitations, the Pew Trust reports that today, 67% of adults aged 65 years and older say they use the Internet,[6] and large health care systems are increasingly offering online health information to older health consumers. These advances are important because communication between health care providers and elders is vital in providing quality care, supporting self-care, and in negotiating transitions of care.

Health Status

▶ *Life Expectancy*

Although Americans are living longer than ever before, an estimated average of 78.74 years overall in 2015, US life expectancy lags behind that of many other industrialized nations.[5] Life expectancy has increased; elders who survive to age 65 can expect to live an average of 19.3 more years.[4] Disparities in mortality persist, in 2014 life expectancy at birth for the white population

was 3.4 years longer than for the black population, a decrease of 1.8 years since 2004.[4] Nearly 35% of US deaths in 2000 were attributed to three risk behaviors: smoking, poor diet, and physical inactivity. Currently, only 9% of Americans older than 65 years smoke; however, nearly 54% of men and 21% of women are former smokers.[4,7] Overweight elders 65 to 74 years of age increased from 57% to 73% in 2004 largely due to inactivity and a diet high in refined foods, saturated fats, and sugared beverages.[4] Despite the proven health benefits of regular physical activity, more than half of the older population is sedentary; 47% of those 65 to 74 years and 61% older than 75 years report no physical activity and only 12% of people aged 65 years and older report participating in leisure-time aerobic and muscle-strengthening activities that meet US physical activity guidelines.[4,8]

The 2016 National Health Interview Survey indicated that in 2012–2014, older non-Hispanic White people were more likely to report good to excellent health than were non-Hispanic Black and Hispanic peers (80% vs 65% and 66%, respectively).[9] Approximately 80% of older adults have at least one chronic condition, and 50% have at least two. The prevalence of certain chronic conditions differs by sex, with women reporting higher levels of arthritis (54% vs 43%), and men reporting higher levels of heart disease (37% vs 26%) and cancer (24% vs 19%).[6] In 2014, the leading causes of death were heart disease, cancer, chronic lower respiratory diseases, stroke, Alzheimer disease, diabetes, unintentional injuries (mostly falls), and influenza and pneumonia regardless of sex, race, or ethnicity.[4] Figure 2–1 specifies the most common chronic conditions of older adults by sex. Frailty is a common biological syndrome in the elderly. Once frail, elders may rapidly progress toward failure to thrive and death. Only 3% to 7% of elders between the ages of 65 and 75 years are frail, increasing to more than 32% in those older than 90 years.[10]

Health Care Utilization and Cost

KEY CONCEPT Older Americans use more health care services than younger Americans do. Although older adults with one or more hospital stays decreased from 2000 to 2014 (18% vs 15.2%), they accounted for more than half of hospitalizations overall, with longer lengths of stay corresponding to increasing age.[11] In 2010 there were 1.3 million (3.6%) US nursing home residents aged 65 and older, and as the aged live longer, more will require assistance, which will be increasingly performed in the home. Health care costs among older Americans are greater than the cost for someone younger than 65 years. In 2015, older Americans spent 12.9% of their total expenditures on health

Patient Encounter Part 1

UA is a 78-year-old woman who moved to the United States after she retired to help care for her three grandchildren. Though UA finished high school in Brazil, she speaks very little English and has limited health literacy, even with the interpretation service. UA comes to the Interprofessional Geriatrics Clinic to receive comprehensive care of her multimorbidity and polypharmacy. Her past medical history includes hypertension, diabetes, dyslipidemia, stroke, hypothyroidism, arthritis, depression, insomnia, and peripheral neuropathy. UA uses 16 medications for her multiple chronic conditions and herbal supplements for "brain health." She is overweight, though reports trying to eat "healthy." She walks the family dog for about 30 minutes once a week and daily when her daughter's family is out of town.

What information is consistent with epidemiology of aging?

Which of UA's medical conditions are commonly found in older adults?

What additional information do you need before conducting a comprehensive medication review?

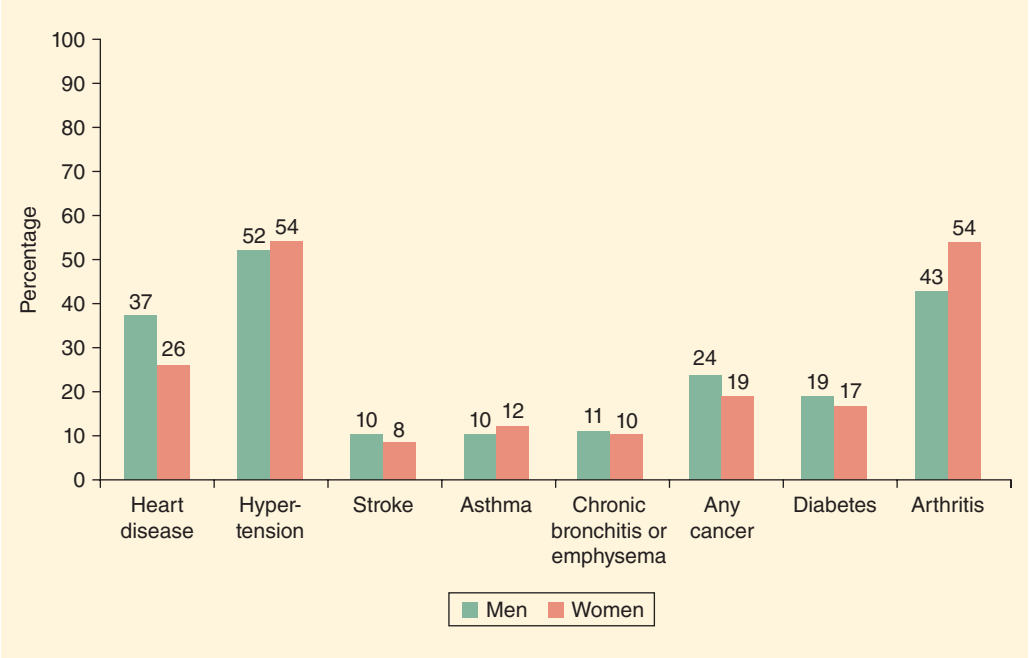

FIGURE 2–1. Percentage of people 65 years and older who reported having selected chronic conditions, by sex, 2005 to 2006. Note: Data are based on a 2-year average from 2005 to 2006. Reference population: These data refer to the noninstitutionalized population. (From Centers for Disease Control and Prevention, National Center for Health Statistics, National Health Interview Survey.)

compared with 7.8% among all consumers.[3] Medicare plays a major role in health care costs, accounting for 20% of total US health spending in 2012, 27% of spending on hospital care, and 23% of spending on physician services.[12]

By applying the epidemiology of aging, clinicians can better intervene with pharmacotherapy to postpone disease, disability, and mortality, and promote health, functioning, and health-related quality of life.

AGE-RELATED CHANGES

In basic terms, pharmacokinetics is what the body does to the drug, and pharmacodynamics is what the drug does to the body. KEY CONCEPT All four components of pharmacokinetics—absorption, distribution, metabolism, and excretion—are affected by aging; the most clinically important and consistent is the reduction of renal elimination of drugs.[13] As people age, they can become more frail and are more likely to experience altered and variable drug pharmacokinetics and pharmacodynamics. Even though this alteration is influenced more by a patient's clinical state than their chronological age, the older patient is more likely to be malnourished and suffering from diseases that affect pharmacokinetics and pharmacodynamics.[14] Older adults can develop significant drug-related problems when alterations in pharmacokinetics and pharmacodynamics are not appropriately accounted for in prescribing and monitoring of medications.[13] Clinicians have the responsibility to use pharmacokinetic and pharmacodynamic principles to improve the care of older patients and avoid adverse effects of pharmacotherapy. Due to the multitude of changes described below, many medications used to treat chronic conditions in older adults should be started at 50% of the recommended initial adult dose, and doses titrated slowly. This is a general recommendation to consider when initiating medications such as antihypertensives and antidepressants, but does not apply to the treatment of acute illness (eg, antibiotics for pneumonia).

LO 2

Pharmacokinetic Changes

▶ *Absorption*

Multiple changes occur throughout the GI tract with aging, but little evidence indicates that drug absorption is significantly altered. The changes include decreases in overall surface of the intestinal epithelium, gastric acid secretion, and splanchnic blood flow.[13] Peristalsis is weaker and gastric emptying delayed. These changes slow absorption in the stomach, especially for enteric-coated and delayed-release preparations. Delays in absorption may lead to a longer time required to achieve peak drug effects, but it does not significantly alter the amount of drug absorbed, and drug movement from the GI tract into circulation is not meaningfully changed.[13,14] However, relative **achlorhydria** can decrease the absorption of nutrients such as vitamin B_{12}, calcium, and iron.[14]

Aging facilitates atrophy of the epidermis and dermis along with a reduction in barrier function of the skin. Tissue blood perfusion is reduced, leading to decreased or variable rates of transdermal, subcutaneous, and intramuscular drug absorption. Therefore, intramuscular injections should generally be avoided in older adults due to unpredictable drug absorption.[13] Additionally, because saliva production decreases with age, medications that need to be absorbed rapidly by the buccal mucosa are absorbed at a slower rate. Yet, for most drugs, absorption is not significantly affected in older patients and the changes described are clinically inconsequential.[14,15]

▶ *Distribution*

The main physiological changes that affect distribution of drugs in older adults are changes in body fat and water, and changes in protein binding. Lean body mass can decrease by 12% to 19% through loss of skeletal muscle in older adults. Thus, blood levels of drugs primarily distributed in muscle increase (eg, digoxin), presenting a risk for overdose.[14] While lean muscle mass decreases, adipose tissue can increase with aging by 18% to 36% in men and 33% to 45% in women. Therefore, fat-soluble drugs (eg, diazepam, amitriptyline, amiodarone, valproic acid, and verapamil) have increased volume of distribution (V_d), leading to higher tissue concentrations and prolonged duration of action. Greater V_d leads to increased half-life and time required to reach steady-state serum concentration.[13,14]

Total body water decreases by 10% to 15% by age 80. This lowers V_d of hydrophilic drugs (eg, aspirin, digoxin, morphine, lithium, and ethanol) leading to higher plasma drug concentrations than in younger adults when equal doses are used.[13,14] Thus lower doses are needed to prevent toxicity. Toxic drug effects may be enhanced when dehydration occurs and when the extracellular space is reduced by diuretic use.

Likewise, plasma albumin concentration decreases by 10% to 20%, although disease and malnutrition contribute more to this decrease than age alone.[13] In patients with an acute illness, rapid decreases in serum albumin can increase drug effects. Examples of highly protein-bound drugs include warfarin, phenytoin, and diazepam.[14] For most chronic medications, these changes are not clinically important because although the changes affect peak level of a single dose, mean serum concentrations at steady state are not altered unless clearance is affected.[14] For highly protein-bound drugs with narrow therapeutic indices (eg, phenytoin), however, it is important to appropriately interpret serum drug levels in light of the older patient's albumin status. In a malnourished patient with hypoalbuminemia, a higher percentage of the total drug level consists of free drug than in a patient with normal serum albumin. Thus, if a hypoalbuminemic patient has a low total phenytoin level and phenytoin dose is increased, the free phenytoin concentration may rise to a toxic level.

▶ *Metabolism*

Drug metabolism is affected by age, acute and chronic diseases, and drug–drug interactions. The liver is the primary site of drug metabolism, which undergoes changes with age; though the decline is not consistent, older patients have decreased metabolism of many drugs.[13,16] Liver mass is reduced by 20% to 30% with advancing age, and hepatic blood flow is decreased by as much as 50%.[15] These changes can drastically reduce the amount of drug delivered to the liver per unit of time, reduce its metabolism, and increase the half-life.[14] Metabolic clearance of some drugs is decreased by 20% to 40% (eg, amiodarone, amitriptyline, warfarin, and verapamil), but it is unchanged for drugs with a low hepatic extraction.[14] Drugs that have high **extraction ratios** have significant first-pass metabolism, resulting in higher bioavailability for older adults. For example, the effect of morphine is increased due to a decrease in clearance by around 33%. Similar increases in bioavailability can be seen with propranolol, levodopa, calcium channel blockers, tricyclic antidepressants, and statins. Thus, older patients may experience a similar clinical response to that of younger patients using lower doses of these medications.[14-16]

The effect of aging on liver enzymes (cytochrome P450 system [CYP450]) may lead to a decreased elimination rate of drugs that undergo oxidative phase I metabolism, but this is controversial.[13] Originally, it was thought that the CYP450 system was impaired

in older adults, leading to decreased drug clearance and increased serum half-life, but studies have not consistently confirmed this. Thus variations in the CYP450 activity may not be due to aging but to lifestyle (eg, smoking), illness, or drug interactions.[14-16] A patient's nutritional status plays a role in drug metabolism as well. Frail elderly have a more diminished drug metabolism than those with healthy body weight.[13,16] Aging does not affect drugs that undergo phase II hepatic metabolism, known as conjugation or glucuronidation, but conjugation is reduced with frailty. Temazepam and lorazepam are examples of drugs that undergo phase II metabolism.[14]

▶ *Elimination*

Clinically, the most important pharmacokinetic change in older adults is the decrease in renal drug elimination.[13] As people age, renal blood flow, renal mass, glomerular filtration rate, filtration fraction, and tubular secretion decrease. After age 40, there is a decrease in the number of functional glomeruli, and renal blood flow declines by approximately 1% yearly. From age 25 to 85 years, average renal clearance declines by as much as 50% and is independent of the effects of disease.[13,14] Still, the impact of age on renal function is variable and not always linear. Longitudinal studies have suggested that a percentage (up to 33%) of older adults do not experience this age-related decline in renal function.[15] Clinically significant effects of decreased renal clearance include prolonged drug half-life, increased serum drug level, and increased potential for **adverse drug reactions (ADRs)**.[13] Special attention should be given to renally eliminated drugs with a narrow therapeutic index (eg, digoxin, aminoglycosides). Monitoring serum concentration and making appropriate dose adjustment for these agents can prevent serious ADR resulting from drug accumulation.[14] It is important to note that despite a dramatic decrease in renal function (creatinine clearance) with aging, serum creatinine may remain fairly unchanged and remain within normal limits. This is because older patients, especially the frail elderly, have decreased muscle mass resulting in less creatinine production for input into circulation.[13,14] Because chronic kidney disease can be overlooked if a clinician focuses only on the serum creatinine value, overdose and ADR can occur.

Thus, creatinine clearance should be calculated when starting or adjusting pharmacotherapy in older adults. Clearance measure using 24-hour urine collection is impractical, costly, and often done inaccurately. The Cockcroft-Gault equation is the most widely used formula for estimating creatinine clearance (mL/min) for adjusting drug doses. See Chapter 25 (Table 25–2) for more details.

$$\text{Creatinine clearance} = \frac{(140 - \text{Age}) \times \text{Weight (kg)}}{\text{Serum creatinine} \times 72} \times (0.85 \text{ if female})$$

This equation is also used by most drug manufacturers to determine renal dosing guidelines. The Cockcroft-Gault equation provides the best balance between predictive ability and bias in a study that compared it with the Modification of Diet in Renal Disease (MDRD) and Jelliffe "bedside" clearance equations.[14] The Cockcroft-Gault equation can overestimate renal function in obese individuals. In these cases an adjusted body weight should be used in the calculation [AjBW = IBW + 0.4(ABW – IBW)]. Understand that the predictive formulas can also significantly overestimate actual renal function in chronically ill, debilitated older patients.

Pharmacodynamic Changes

Pharmacodynamics refers to the actions of a drug at its target site and the body's response to that drug. Compared to pharmacokinetics, there is much less data on age-related pharmacodynamic changes. KEY CONCEPT In general, the pharmacodynamic changes that occur in older adults tend to increase their sensitivity to drug effects. Most pharmacodynamic changes in the elderly are associated with a progressive reduction in homeostatic mechanisms and changes in receptor properties. Although the end result of these changes is an increased sensitivity to the effects of many drugs, a decrease in response can also occur. The changes in the receptor site include alterations in binding affinity of the drug, number or density of active receptors at the target organ, structural features, and postreceptor effects (biochemical processes/signal transmission). These include receptors in the adrenergic, cholinergic, and dopaminergic systems, as well as γ-*aminobutyric acid* (GABA) and opioid receptors.[13-15]

▶ *Cardiovascular System*

Decreased homeostatic mechanisms in older adults increase their susceptibility to orthostatic hypotension when taking drugs that affect the cardiovascular system and lower the arterial blood pressure. This is explained by a decrease in arterial compliance and baroreceptor reflex response, which limits their ability to compensate quickly for postural changes in blood pressure. It has been estimated that 5% to 33% of older adults experience drug-induced orthostasis. Examples, other than typical antihypertensives, that have a higher likelihood of causing orthostatic hypotension in geriatric patients are tricyclic antidepressants, antipsychotics, loop diuretics, direct vasodilators, and opioids.[13-15] Older patients have a decreased β-adrenergic receptor function, and they are less sensitive to β-agonist and β-adrenergic antagonist effects in the cardiovascular system and possibly in the lungs, but their response to α-agonists and antagonists is unchanged.[14,15] Increased hypotensive and heart rate response (to a lesser degree) to calcium channel blockers (eg, verapamil) are reported. Increased risk of developing drug-induced QT prolongation and **torsade de pointes** is also present.[15] Therefore, clinicians must start medications at low doses and titrate slowly, closely monitoring the patient for any adverse effects.

▶ *Central Nervous System*

Overall, geriatric patients exhibit a greater sensitivity to the effects of drugs that gain access to the CNS, especially anticholinergic medications. In most cases, lower doses result in adequate response, and higher incidence of adverse effects may be seen with standard and high doses. For example, lower doses of opioids provide sufficient pain relief for older patients, whereas conventional doses can cause oversedation and respiratory depression.[13,14] The blood–brain barrier becomes more permeable as people age; thus more medications can cross the barrier and cause CNS adverse effects. Examples of problematic medications include benzodiazepines, antidepressants, antipsychotics, neuroleptics, and antihistamines. There is a decrease in the number of cholinergic neurons as well as nicotinic and muscarinic receptors, decreased choline uptake from the periphery, and increased acetylcholinesterase.[14,15] Older adults have a decreased ability to compensate for these imbalances of the neurotransmitters, which can lead to movement and memory disorders. Older adults have an increased number of dopamine type 2 receptors, making them more susceptible to delirium from anticholinergic

and dopaminergic medications. At the same time, they have a reduced number of dopamine and dopaminergic neurons in the substantia nigra of the brain resulting in higher incidence of extrapyramidal symptoms from antidopaminergic medications (eg, antipsychotics).[13,15]

▶ *Fluids and Electrolytes*

Fluid and electrolyte homeostatic mechanism is decreased in the older adult population. Older adults experience more severe dehydration with equal amounts of fluid loss compared with younger adults. The multitude of factors involved include decreased thirst and cardiovascular reflexes, decreased fluid intake, decreased ability of the kidneys to concentrate urine, increased atrial natriuretic peptide, decreased aldosterone response to hyperkalemia, and decreased response to antidiuretic hormone. The result is an increased incidence of hyponatremia, hyperkalemia, and prerenal azotemia, especially when the older patient is taking a diuretic (eg, hydrochlorothiazide, furosemide). Angiotensin-converting enzyme inhibitors have an increased potential to cause hyperkalemia and acute renal failure in older adults. Thus these agents need to be started with low doses, titrated slowly, and renal function should be monitored frequently.[13]

▶ *Glucose Metabolism*

An inverse relationship between glucose tolerance and age has been reported. This is likely due to reduced insulin secretion and sensitivity (greater insulin resistance). Consequently, the incidences of hypoglycemia are increased when using sulfonylureas (eg, glyburide, glipizide) from age-related impairment to counter-regulate the hypoglycemic response.[13] Due to an impaired autonomic nervous system, older patients may not distinguish symptoms of hypoglycemia such as sweating, palpitations, or tremors. They do experience neurological symptoms of syncope, ataxia, confusion, or seizures.

Patient Encounter Part 2

UA was recently hospitalized for urinary tract infection. Her daughter (interpreter) states that one of the hospital staff thought UA may need to double up her gabapentin dose due to complaints about pain and stop lisinopril because she was coughing. UA brought in medications used at home since the hospital discharge: (1) lisinopril 20 mg by mouth in the morning, (2) amlodipine 5 mg by mouth in the morning and evening, (3) hydrochlorothiazide 25 mg by mouth in the morning, (4) sertraline 100 mg by mouth in the evening, (5) glyburide 10 mg by mouth in the morning and evening, (6) gabapentin 600 mg by mouth twice a day, (7) atorvastatin 10 mg in the evening, (8) levothyroxine 50 mcg by mouth in the morning, (9) zolpidem 10 mg by mouth at bedtime, (10) calcium-vitamin D 600 mg-500 units by mouth in the morning and evening, (11) acetaminophen 500 mg 2 tablets by mouth every 4 hours as needed for pain, (12) pantoprazole 20 mg by mouth in the morning, (13) vitamin C 5000 mg by mouth in the morning, (14) ibuprofen 200 mg 2 tablets three times a day, (15) gingko biloba 240 mg by mouth in the morning, (16) diphenhydramine 25 mg by mouth at bedtime.

She is allergic to penicillin (hives) and intolerant to lisinopril (cough).

UA does not smoke; has one or two drinks a night.

VS: BP 110/56, P: 70 bpm, RR: 14, T: 38.4°C (101.1°F)

Ht: 5′2″ (157 cm), Wt: 66 kg, Pain 2/10

Labs: Na 141 mEq/L (mmol/L), K 4.2 mEq/L (mmol/L), Cl 98 mEq/L (mmol/L), CO_2 25 mEq/L (mmol/L), BUN 20 mg/dL (7.1 mmol/L), creatinine 1.5 mg/dL (133 µmol/L), glucose 98 mg/dL (5.4 mmol/L), $HgbA_{1c}$ 6.5% (0.065; 48 mmol/mol Hgb)

What is UA's estimated creatinine clearance?

What steps should be taken prior to increasing UA's gabapentin dose?

What drug-related problems are included in UA's medication list?

DRUG-RELATED PROBLEMS

KEY CONCEPT Comorbidities and polypharmacy complicate health status of older adults, particularly inappropriate medications that lead to drug-related problems. It is reported that 28% of hospitalizations in older adults are due to medication-related problems including nonadherence and ADRs. Studies indicated that over 58% of community-dwelling and hospital older adults were prescribed at least one potentially inappropriate medication.[17] Drug-related problems result in poor health outcomes for older adults such as adverse drug withdrawal effects, therapeutic failure, and adverse drug events.[18] Collaboration among interprofessional providers and older patients can ensure appropriate therapy, minimize adverse drug events, and maximize medication adherence and health outcomes.

LO 3

Polypharmacy

Polypharmacy is defined as taking multiple medications concurrently (four to ten medications or more have been used as criteria in studies). Polypharmacy is prevalent among older adults with 39% reporting the use of 5 or more medications in 2012 compared with polypharmacy use by 24% in 1999, signifying a dramatic increase.[19] In 2010, 38% of people aged 62–85 years used at least one over-the-counter (OTC) medication and 64% used at least one supplement.[20] The common use of dietary supplements and herbal products in this population adds to polypharmacy. In nursing home settings, 50.7% of patients with severe cognitive impairment received polypharmacy (5–9 medications) and 16.9% received excessive polypharmacy (≥ 10 medications) in the Services and Health for Elderly in Long Term Care (SHELTER) study.[21] As expected, polypharmacy contributes to increased outpatient visits and hospitalizations with an approximately 30% higher medical costs.[17] Among various reasons for polypharmacy, an apparent one is an older patient receiving multiple medications from different providers who treat the patient's comorbidities without coordinated care. Thus medication reconciliation becomes increasingly important as the aging population continues to grow.

A complete evaluation of all medications should be conducted by health care providers at each older patient visit to prevent inappropriate polypharmacy. Efforts should be made to reduce polypharmacy by discontinuing any medication without indication. However, clinicians should also understand that appropriate polypharmacy is indicated for older adults who have multiple diseases, and support should be provided for optimal adherence. Drug-related problems associated with polypharmacy can be identified by performing a comprehensive medication review (see Patient Care Process).

Inappropriate Prescribing

Inappropriate prescribing is defined as prescribing medications that cause a significant risk of an adverse event when there is an effective and safer alternative. A systematic review in 2012 reported that the median rate of inappropriate medication prescribing among elderly patients in the primary care setting was 19.6%.[22] The potentially inappropriate medications in older adults have been associated with negative outcomes such as confusion, falls, and mortality.[23] At times, medications are continued long after the initial indication has resolved. The clinician prescribing for older adults must understand the rate of adverse reactions and drug–drug interactions, the evidence available for using a specific medication, and patient use of OTC medications and herbal supplements.[17]

Screening tools have been developed to help the clinician identify potentially inappropriate medications in older adults. The most utilized in the United States is the Beers criteria.[23] The 2015 Beers Criteria includes medications or medication classes that are potentially inappropriate in older patients, listed in five categories: (a) medications to avoid in most older adults, (b) medications to avoid in older adults with certain diseases/syndromes, (c) medications to use with caution, (d) non-anti-infective medications with important drug interactions, and (e) non-anti-infective medications to avoid or renal-dose based on kidney function.[23]

Common medications included in the Beers criteria are:[23]

- Benzodiazepines such as lorazepam and diazepam (risk of cognitive impairment, delirium, falls, fractures, and motor vehicle accidents)
- First generation antihistamines, such as diphenhydramine and hydroxyzine (risk of confusion, dry mouth, constipation, and other anticholinergic symptoms)
- Tertiary tricyclic antidepressants (TCAs), such as amitriptyline and nortriptyline (risk of sedation, orthostatic hypotension, and anticholinergic symptoms)
- Nonsteroidal anti-inflammatory drugs (NSAIDs) such as ibuprofen and naproxen (risk of GI bleeding and ulcers)

Practical strategies for appropriate medication prescribing include establishing a partnership with patients and their care partners to enable them to understand and monitor medication effects. Clinicians should perform drug–drug and drug–disease interaction screening, use time-limited trials to evaluate the benefits and risks of new medications, and trial off medications to assess need.[22]

Undertreatment

Much has been written about the consequences of overmedication and polypharmacy in older adults. However, underutilization of medications is just as harmful, resulting in reduced functioning, and increased morbidity and mortality. There are instances when a drug is truly contraindicated, when a lower dose is indicated, or when prognoses dictate withholding therapy. Outside of these scenarios, many elders do not receive therapeutic interventions that would provide benefit.[18,24] Undertreatment is prevalent across diverse settings in the community, hospitals, and long-term care facilities.[25] This occurs for many reasons including: multimorbidity, polypharmacy, cost, concerns of nonadherence, fear of adverse effects and associated liability, limited evidence in the age group, starting low and failing to increase to an appropriate dose, skepticism regarding secondary prevention benefits, or ageism.[25] Common categories of geriatric undertreatment are listed in Table 2–1.

Table 2–1

Common Categories of Geriatric Undertreatment

Therapy	Concern
Anticoagulation in patients with atrial fibrillation	Overly concerned with risk of bleeding or the risk of falls if anticoagulated
Malignant and nonmalignant pain	Hesitant to prescribe opioids due to possible cognitive and bowel side effects, concerns about addiction; patients may often be hesitant to use opioids
Antihypertensive therapy	Underestimate the benefit on stroke and cardiovascular event prevention, and/or fail to add the second or third medication needed to attain control
β-Blocker treatment in heart failure	Concerned about complications in high-risk patients despite the substantial evidence of mortality benefit
Statin treatment for ASCVD	Underestimate benefit or have concerns about adverse events

ASCVD, atherosclerotic cardiovascular disease.

A clinical assessment to weigh the potential benefit versus harm of the older patient's complete medication regimen is required. Once obvious contraindications have been dismissed, the patient's (a) goals and preferences, (b) prognosis, and (c) time to therapeutic benefit should be taken into consideration to determine whether the pharmacotherapy meets treatment goals. Underprescribing can best be avoided by using clinical assessment strategies, improving adherence support, and liberalizing financial coverage of drugs.

Adverse Drug Reaction

ADR is defined by the World Health Organization as a reaction that is noxious and unintended, which occurs at dosages normally used in humans for prophylaxis, diagnosis, or therapy. (See the glossary for the American Society of Health-System Pharmacists' definition of an ADR.[26]) ADRs increase with polypharmacy use, and are the most frequently occurring drug-related problem among older nursing home residents. A brown bag medication review study found that 25% of community-dwelling older adults using at least five medications experienced ADRs.[27] Similarly, another study evaluating ADRs in patients after hospital discharge showed that 18.7% of them experienced an adverse drug event within 45 days.[28]

Seven predictors of ADRs in older adults have been identified[29]: (a) taking more than four medications; (b) more than 14-day hospital stay; (c) having more than four active medical problems; (d) general medical unit admission versus geriatric ward; (e) alcohol use history; (f) lower Mini-Mental State Examination score (confusion, dementia); and (g) two to four new medications added during a hospitalization. Similarly, there are four predictors for severe ADRs experienced by older adults[30]: (a) use of certain medications including diuretics, NSAIDs, antiplatelet medications, and digoxin; (b) number of drugs taken; (c) age; and (d) comorbidities. Suggested strategies to preventing ADRs in older adults are described in Table 2–2.[30] Particular caution must

Table 2–2[30]

Strategies to Prevent Adverse Drug Reactions in Older Adults

- Evaluating comorbidities, frailty, and cognitive function
- Identifying caregivers to take responsibility for medication management
- Evaluating renal function and adjusting doses appropriately
- Monitoring drug effects
- Recognizing that clinical signs or symptoms can be an ADR
- Minimizing number of medications prescribed
- Adapting treatment to patient's life expectancy
- Realizing that self-medication and nonadherence are common and can induce ADRs

ADR, adverse drug reaction.

Adapted, with permission, from Merle L, Laroche ML, Dantoine T, Charmes JP. Predicting and preventing adverse drug reactions in the very old. Drugs Aging. 2005;22(5):375–392.

be taken when prescribing drugs that alter cognition in older adults, including antidepressants, antihistamines, antipsychotics, benzodiazepines, opioids, and muscle relaxants.[30]

One of the most damaging ADRs that frequently occur in older adults is medication-related falls. Falls are associated with a poor prognosis ranging from premature institutionalization to early death, and polypharmacy is a risk factor. Multiple medications included in the Beers Criteria are related to falls.[23] For example, multiple studies of benzodiazepines found significant association with falls including an increased risk after a new prescription for benzodiazepines and twofold risk with combined use of two or more benzodiazepines.[31] Other agents having strong association with increased fall risk include sedative hypnotics, neuroleptics, antidepressants, and antipsychotics.[31] A comprehensive fall prevention intervention should include deprescribing by slow medication taper with close monitoring to prevent or resolve ADRs.

Nonadherence

America's other drug problem is the term given to medication nonadherence by the National Council on Patient Information and Education. Nonadherence to chronic medications is prevalent and escalates health care costs associated with worsening disease and increased hospitalization. *Medication adherence* describes a patient's medication-taking behavior, generally defined as the extent to which one adheres to an agreed regimen derived from collaboration with their health care provider.[32]

Table 2–3

Factors Influencing Medication Nonadherence

Three or more chronic medical conditions	Significant cognitive or physical impairments
Five or more chronic medications	Recent hospital discharge
Three times or more per day dosing or 12 or more medication doses per day	Caregiver reliance
Four or more medication changes in past 12 months	Low health literacy
Three or more prescribers	Medication cost
	History of medication nonadherence
	Living alone in the community

KEY CONCEPT Older adults are at greater risk for medication nonadherence due to the high prevalence of multimorbidities, cognitive deficit, polypharmacy, and financial barriers. Numerous barriers to optimal medication adherence exist and include patient's lack of understanding, provider's failure to educate, polypharmacy leading to **complex regimen** and inconvenience, treatment of asymptomatic conditions (such as hypertension and dyslipidemia), and cost of medications.[32] Factors influencing medication nonadherence are listed in Table 2–3.

Following is a list of six "how" questions to ask when assessing medication adherence:[33]

1. How do you take your medicines?
2. How do you organize your medicines to help you remember to take them?
3. How do you schedule your meal and medicine times?
4. How do you pay for your medicines?
5. How do you think the medicines are working for your conditions?
6. How many times in the last week/month have you missed your medicines?

Although no single intervention has found to improve adherence consistently, older person-centered multicomponent interventions, such as combining education, convenience, and regular follow-up, have resulted in a positive impact on medication adherence and associated health outcomes.[34] Future research needs to include adherence studies evaluating belief-related variables, such as personal and cultural beliefs, in larger and more ethnically diverse samples of older populations.

Patient Encounter Part 3

UA is now 88 years old and has been living at a long-term care facility for a year. Even though she was overweight most of her life, she has lost 7 kg in the past 6 months and developed a new coccyx ulcer. She is currently on multiple medications including: (1) aspirin 81 mg by mouth daily, (2) hydrochlorothiazide 25 mg by mouth daily, (3) metformin 500 mg by mouth twice daily, (4) levothyroxine 25 mcg by mouth daily, (5) ibuprofen 600 mg by mouth daily, (6) docusate sodium 100 mg by mouth twice daily, (7) lorazepam 1 mg by mouth twice daily, (8) atorvastatin 40 mg by mouth daily, (9) amitriptyline 10 mg by mouth at bedtime.

Today her pain score is 7/10.

What recommendations can be made about UA's medication regimen at this time?

Which quality indicators should be of concern in UA?

GERIATRIC ASSESSMENT

LO 4

The term *geriatric assessment* is used to describe the comprehensive interprofessional team evaluation of the frail or complex older adult's health including multimorbidity with functional and cognitive status. Such a team may include, but is not limited to, a geriatrician, nurse, pharmacist, case manager/social worker, physical therapist, occupational therapist, speech therapist, psychologist, dietician, dentist, optometrist, and audiologist. Assessment may be performed in a number of care settings and by a series of evaluations after which the team will conduct an interprofessional case conference to discuss the patient's care plan.

Table 2–4

Activities of Daily Living and Instrumental Activities of Daily Living

ADLs			
Transfers	Dressing	Mobility	Eating
Bathing	Toileting	Grooming	
IADLs			
Using transportation		If still driving, assess driving ability (including cognitive function, medications that can impair driving ability, vision, neuromuscular conditions that may interfere with reaction time, ability to turn head) at the time of license renewal	
Using the telephone		Check for emergency phone numbers located near the telephone	
Management of finances		Assess the ability to balance checkbook and pay bills on time	
Cooking		Check for safe operation of appliances and cooking tools as well as ability to prepare balanced meals	
Housekeeping		Check for decline in cleanliness or neatness	
Medication administration		Assess organization skills and adherence	

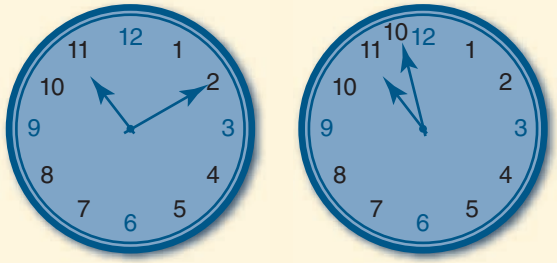
ADL, activity of daily living; IADL, instrumental activity of daily living.

Three item recall

1. Ask the patient if you may test his or her memory.
2. Give the patient 3 words (eg, apple, table, penny) to repeat and remember.
3. Have the patient repeat the 3 words from memory later (eg, after the clock drawing test).

Clock drawing test

1. Have the patient draw the face of a clock, including numbers.
2. Instruct the patient to place the hands at a specific time, such as 11:10.



Correct | Incorrect hands and inserted number

A positive dementia screen

1. Failure to remember all 3 words.
2. Failure to remember 1–2 words plus an abnormal clock drawing.

FIGURE 2–2. The mini-cog mental status examination. (Adapted from Borson S, Scanlan J, Brush M, Vitaliano P, Dokmak A. The mini-cog: a cognitive "vital signs" measure for dementia screening in multi-lingual elderly. Int J Geriatr Psychiatry. 2000;15(11):1021–1027.)

Patient Interview

KEY CONCEPT The clinical approach to assessing older adults frequently goes beyond a traditional "history and physical" used in general internal medicine practice.[35] Functional status must be determined, which includes the activities of daily living (ADL) and instrumental activities of daily living (IADL) (see Table 2–4). Cognitive assessment, which may require collateral history from family, friends, or other caregivers, is important in determining the patient's capacity to manage their medications and consent to medical treatment.[36] The mini-cog mental status examination[37] shown in Figure 2–2 is a quick tool to assess patient's cognitive abilities. Patients commonly have decreased visual acuity, hearing loss, dysphagia, and impaired dexterity. Decreased skin integrity, another common problem, greatly increases risk for pressure ulcers. Sexual function is a sensitive but important topic and should be specifically inquired about. Cardiac, renal, hepatic, and digestive insufficiencies can have significant implications for pharmacotherapy. Inadequate nutrition may lead to weight loss and impaired functioning at the cellular or organ level. See Table 2–5 for common problems experienced by older adults.

It is important to recognize "geriatric syndromes" such as cognitive impairment, functional impairment, polypharmacy, delirium, frailty, falls, osteoporosis, insomnia, and incontinence. In the older adult, common diseases may present with atypical symptoms, such as thyroid dysfunction or infection presenting as delirium. It is also important to assess for caregiver stress and be aware of older patients' support systems, which may include family, friends, social or religious networks, home health agencies, and hired caregivers. Such networks may facilitate older adults to continue to live independently. Safety should be assessed and includes a home safety assessment by an occupational therapist and a driving assessment for patients with cognitive or functional limitations. In addition, look for signs and symptoms of elder abuse, neglect, or exploitation. Health professionals are required to report suspicion of elder mistreatment to Adult Protective Services.[38]

Drug Therapy Monitoring

Geriatric patients often have multiple medications, medical comorbidities, and prescribers. It is essential that there be a

Table 2–5

The *Is* of Geriatrics: Common Problems in Older Adults

Impaired senses	

Hajjar ER, Gray SL, Slattum PW, Hersh LR, Naples JG, Hanlon JT. Geriatrics. In: DiPiro JT, Talbert RL, Yee GC, Matzke GR, Wells BG, Posey LM, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017. https://accesspharmacy.mhmedical.com/book.aspx?bookid=1861 Accessed August 2, 2017.

single provider who oversees the patient's pharmacotherapy. Particularly challenging in the geriatric population is identifying the cause(s) of medication nonadherence. Providers assessing older patients' medication regimens should keep the following questions in mind:

- Are medications skipped or reduced due to cost?
- Can the patient benefit from sample drugs? Starting a patient on a free drug sample may increase patient costs in the long term because samples typically are newer, expensive drugs.[39]
- Is there an educational barrier such as low health literacy?
- Does the patient speak English but only read in another language?
- Can the patient see labels and written instructions?
- Does the patient have hearing problems? Patients might not admit they cannot hear instructions.
- Can the patient manipulate pill bottles, syringes, inhalers, eye/ear drops?
- Has the patient's cognitive functioning worsened over time such that they can no longer follow the medication regimen?

Older patients require more frequent monitoring for adverse effects: symptoms, abnormal laboratory results, drug interactions, and drug levels.

On the subject of cost, the providers need to be aware of the patient's Medicare Part C or D plan, and what type of coverage these plans afford. What is the copayment for generic, formulary, and nonformulary drugs? Is the patient responsible for all drug costs during the Medicare "donut hole" period? (In basic part D plans, patients pay increasing percentages of drug costs up to $7,425 per year.[40]) Many Medicare patients, especially the socioeconomically challenged, have limited understanding of the complex Medicare drug benefit. This problem is compounded when the prescriber also does not understand the patient's insurance program.[39] Providers can assist patients by prescribing generic medications that are offered through retail pharmacy discount plans ($4 retail pharmacy programs do not bill insurance, thus are not counted toward their Medicare part D deductible) and help patients apply for the medication assistance programs offered by drug manufacturers.

Documentation

A clear, current, and accurate medication list must be available to the patient and all individuals involved in their care. It is particularly important for geriatric patients to bring medication containers for reconciliation by a provider. Medication adherence may require verification with the pharmacist, caregivers, or family. Transitions in patient care, such as hospital to sub-acute nursing facility or home, lead to medication errors because medications may have been deleted or added.[41] It is standard of care to conduct medication reconciliation upon hospital admission and discharge to ensure that the medication list is up to date.

Patient Education

Geriatric patients often have difficulty understanding and retaining provider instructions. "Ask me 3" cues the patient to ask three important questions of their providers to improve health literacy[42]:

1. What is my main problem?
2. What do I need to do?
3. Why is it important for me to do this?

The provider can assess patient grasp of medication instructions by asking the patient to repeat instructions initially and again in 3 minutes (teach-back method).

KEY CONCEPT Addressing deficits in vision, hearing, swallowing, cognition, motor impairment, and health literacy can lead to enhanced medication adherence. Specific drug formulations, such as metered-dose inhalers, ophthalmic/otic drops, nasal sprays, and subcutaneous injections, will require detailed education and practice. Patients who cannot swallow tablets or capsules need instructions on which tablets are safe to crush and which capsules are safe to open and sprinkle on food. Patients and/or caregivers need to be advised of potential ADRs and when to notify the provider.

GERIATRIC PRACTICE SITES

LO 5

Some say geriatrics has become a nonspecialty due to the aging population. Clinicians with geriatric certification or training practice in nearly all settings of health care, primary care to various spectrums of specialty care and long-term care. A couple of interprofessional practice sites are highlighted here.

Ambulatory Clinic and Home-Based Primary Care

Ambulatory geriatric clinics are established to provide a multitude of primary care needs specifically tailored to older adults. Home-based primary care is delivered in the home or independent living facility of homebound patients to facilitate independent living as long as possible. Patients are usually referred by their primary care physicians due to the desire for increased access to services, complex care needs due to multimorbidity and polypharmacy, and need for a comprehensive geriatric assessment. It is common for the onset of cognitive impairment to be the catalyst for a referral to such services. Interprofessional team care is the norm in these settings, which benefits patients with varied needs. The interprofessional teams hold regular meetings to discuss care plans of the patients. The geriatrician, who has specialized training in treating older adults, assesses physical, medical, emotional, and social needs. The clinical pharmacist focuses on optimizing the medication regimen by conducting comprehensive medication reviews; making evidence-based disease state management recommendations; screening and resolving drug-related problems; and educating patients, caregivers, and members of the health care team about pharmacotherapy and monitoring parameters. Nurses provide medical triage and day-to-day patient care activities such as obtaining vitals, providing wound care, educating patients, and ensuring adherence. Social workers are involved in various aspects from assessing mood and cognitive status, facilitating completion of advanced directives, and obtaining placement in higher levels of care. Physical/occupational therapists are often involved in improving the patient's functional status, providing fall prevention interventions, and maintaining a safe home environment. They provide adaptive equipment such as grab bars, raised toilet seat and shower bench for the bathroom, and cane or walker for ambulation. Dieticians evaluate the patient's nutritional status and educate on proper diet and weight management. Using these team collaborations, specialty geriatric clinical settings have developed including a multidisciplinary geriatric oncology clinic[43] and PACE centers (Programs of All-inclusive Care for the Elderly) which incorporate the interdisciplinary team as well as adult day health care in one center.[44]

Long-Term Care

Long-term care provides support for people who are dependent to varying degrees on ADLs and IADLs, numbering about

Collect Information:

- Perform a comprehensive medication review.
- Have the patient bring all medication bottles, including: prescriptions, OTC agents, vitamins, supplements, and herbal products.
- Review medical history and physical assessment.
- Ask about allergies/intolerance.
- Inquire about ADRs (Table 2–2).
- Collect adherence information using combination of methods (eg, self-report, refill history, dosage form count, demonstration of nonoral agent use).
- Ask about prevention including vaccinations.
- Collect vital signs and laboratory results.
- Inquire about functional status (Table 2–4).
- Measure cognitive status (Figure 2–2).

Assess the Information:

- Identify indication(s) for all medications.
- Assess medication doses to determine underdose/overdose.
- Screen for drug–drug/disease/supplement/herbal/food interactions.
- Check against allergies/intolerance.
- Identify ADRs.
- Assess medication adherence (Table 2–3).
- Identify untreated indication/undertreatment (Table 2–1).
- Evaluate vital signs, including pain and laboratory.
- Assess medication needs based on cognitive and functional status.
- Recognize common problems in older adults (Table 2–5).

Develop a Care Plan:

- Tailor regimen: discontinue unnecessary medications, simplify dosing times, and tailor regimen to individuals' daily routine to improve adherence.
- Develop educational materials, keeping in mind health literacy and cognitive status.
- Create solutions to any functional barriers (eg, non-child-resistant caps, tablet cutters).
- Draft referral plan to target nonpharmacological strategies (eg, diet, physical therapy, behavioral health, integrative health approaches).

Implement the Care Plan:

- Educate about medications and disease states in a health literacy-sensitive manner.
- Highlight any medication changes and tailored regimen.
- Educate on the use of nonoral agents (eg, inhalers, insulin, ophthalmic/otic drops).
- Provide a medication chart/list to include generic/brand names, indication, dose, directions for use, timing of dose, etc.
- Teach about medication storage, expiration date, and refill status.
- Emphasize adherence and what to do when a dose is missed/forgotten.
- Use medication organizers (eg, pillbox, blister pack) or other adherence aids (eg, alarm, phone reminder) when indicated.
- Implement solutions to any physical/functional barriers.
- Refer for nonpharmacological interventions.

Follow-up: Monitor and Evaluate:

- Provide a list of future appointments and follow-up.
- Promote self-monitoring (eg, recognize and report ADRs, use blood pressure monitors and glucometers).
- Encourage therapeutic lifestyle modifications including diet, exercise, and smoking cessation.
- Endorse prevention including immunizations, wellness visits, eye examinations, and dental care.
- Formulate a patient-centered and interprofessional team-based follow-up plan to track patient response, adverse events, adherence, and health outcomes.

9 million people older than 65 years in 2008.[45] Care is provided in the patient's home, in community settings such as adult care homes or assisted living facilities, and in nursing homes. Long-term care is expensive, typically several thousand dollars per month. Most care is provided at home by unpaid family members or friends. Medicare covers all or part of the cost of skilled nursing care for a limited period post hospitalization.[45] Medicare does not cover long-term care. Financing of long-term care comes from patients' and family savings and/or private long-term care insurance. When a patient's assets have been depleted, Medicaid provides basic nursing home care under long-term care insurance coverage.[45] However, this care is heavily discounted, often resulting in economizing such as lower caregiver-to-patient ratios and higher number of patients per room. Nursing homes are highly regulated by state and federal government through the Center for Medicare and Medicaid Services.[46] Initial and continuing certification of the facility depends on periodic state and federal review of the facility. Auditors' ratings are available to consumers in an online Nursing Home Report Card.[46] **Quality indicators** are used by facility administrators and government overseers to identify problem areas including[47]:

- Use of nine or more medications in single patient
- Prevalence of indwelling catheters
- Prevalence of antipsychotic, anxiolytic, and hypnotic use
- Use of physical restraints
- Prevalence of depression in patients without antidepressant therapy
- Clinical quality measures such as pressure ulcers
- Moderate daily pain or excruciating pain in residents

Long-term care geriatric practices emphasize the interprofessional team approach. The medical director leads regular meetings with disciplines delivering care. The pharmacist conducts a monthly drug review of each patient's medication list.[41] The physician is alerted to medication concerns and approves the patient's orders every 60 days. Such a team approach is vital to coordinate care for the typical frail, complex long-term care patient.

Abbreviations Introduced in This Chapter

ADL	Activities of daily living
ADR	Adverse drug reaction
GABA	γ-Aminobutyric acid
$HgbA_{1c}$	Hemoglobin A_{1c}
IADL	Instrumental activities of daily living
MDRD	Modification of diet in renal disease
NSAID	Nonsteroidal anti-inflammatory drug
OTC	Over-the-counter
V_d	Volume of distribution

3 Pediatrics

Hanna Phan, Vinita B. Pai, and Milap C. Nahata

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Define different age groups within the pediatric population.
2. Identify factors that affect selection of safe and effective drug therapy in pediatric patients.
3. Explain general pharmacokinetic and pharmacodynamic differences in pediatric versus adult patients.
4. Develop strategies for appropriate and effective medication administration to infants and young children.
5. Determine approaches to effectively communicate with patients and caregivers about appropriate medication use including expected outcomes, possible adverse effects, and appropriate administration.

INTRODUCTION

Pediatric clinical practice involves care of infants, children, and adolescents with the goal of optimizing health, growth, and development toward adulthood. Clinicians serve as advocates for this unique and vulnerable patient population to optimize their well-being. Care for pediatric patients is relevant in both inpatient and outpatient settings and requires additional considerations with regard to selection and monitoring of drug therapy.

KEY CONCEPT Despite the common misconception of pediatric patients as "smaller adults" where doses are scaled only for their smaller size, there are multiple factors to consider when selecting and providing drug therapy for patients in this specific population. Pediatric patients significantly differ within their age groups and from adults regarding drug administration, psychosocial development, and organ function development, which affect the efficacy and safety of pharmacotherapy.

FUNDAMENTALS OF PEDIATRIC PATIENTS

Classification of Pediatric Patients

LO 1

Pediatric patients are those younger than 18 years, although some pediatric clinicians may care for patients up to age 21. Unlike an adult patient, whose age is commonly measured in years, a pediatric patient's age can be expressed in days, weeks, months, and years. Patients are classified based on age and may be further described based on other factors, including birth weight and prematurity status (Table 3–1).[1-3]

Growth and Development

Children are monitored for physical, motor, cognitive, and psychosocial development through clinical recognition of timely milestones during routine well-child visits. As a newborn continues to progress to infant, child, and adolescent stages, different variables are monitored to assess growth compared with the general population of similar age and size. Growth charts are used to plot head circumference, weight, length or stature, weight-for-length, and body mass index (BMI) for a graphical representation of a child's growth compared with the general pediatric population. These markers of growth and development are both age- and gender-dependent; thus, the use of the correct tool for measurement is important. For children younger than 2 years, one should use the World Health Organization (WHO) growth standards (Figure 3–1).[4] For children 2 years and older, the Centers for Disease Control and Prevention (CDC) Growth Charts (Figure 3–2) are used.[5] These tools assess whether a child is meeting the appropriate physical growth milestones, thereby allowing identification of nutritional issues such as poor weight and height gain (eg, failure to thrive). Failure to thrive is defined as inadequate physical growth with weight that falls below the 5th percentile or decreases over time, crossing two or more major percentile lines. Body habitus is often evaluated at routine checkups or well-check visits, with definitions of underweight as BMI less than the 5th percentile for age, overweight as BMI between 85th to 94th percentile for age, and obese as BMI greater than 95th percentile.[6] Since these charts were developed based on a general, healthy population, growth charts may not be accurate evaluation of physical development in children with congenital diseases.

Differences in Vital Signs

Normal values for heart rate and respiratory rate vary based on age. Normal values for blood pressure vary based on gender and age for all pediatric patients, and also height percentile for patients older than 1 year. Respiratory rates are also higher in neonates and infants (30–60 breaths/min), decreasing with age to adult rates around 15 years of age (12–20 breaths/min) (Table 3–2).

Normal values for blood pressure in pediatric patients can be found in various national guidelines and other pediatric diagnostic references. In general, blood pressure increases with age, with average blood pressures of approximately 70/50 in neonates, increasing throughout childhood to approximately 110/65 in adolescents.[7] Heart rates are highest in neonates and infants, ranging from 90 to 205 beats per minute (bpm) and decrease with age, reaching adult rates (60–100 bpm) around 10 years of age.[7-9]

Table 3–1

Pediatric Age Groups, Age Terminology, and Weight Classification[1–3]

Age Group	Age
Neonate	≤ 28 days (4 weeks) of life
Infant	29 days to < 12 months
Child	1–12 years
Adolescent	13–17 years (most common definition)
Age Terminology	**Definition**
Gestational age (GA)	Age from date of mother's first day of last menstrual period to date of birth
Full term	Describes infants born at 37-weeks gestation or greater
Premature	Describes infants born before 37-weeks gestation
Small for GA	Neonates with birth weight below the 10th percentile among neonates of the same GA
Large for GA	Neonates with birth weight above the 90th percentile among neonates of the same GA
Chronological or postnatal age	Age from birth to present, measured in days, weeks, months, or years
Corrected or adjusted age	May be used to describe the age of a premature child up to 3 years of age: Corrected age = Chronological age in months – [(40 – GA at birth in weeks) × 1 month ÷ 4 weeks]. For example, if a former 29-week GA child is now 10 months old chronologically, his corrected age is approximately 7 months: 10 months – [(40 – 29 weeks) × 1 month ÷ 4 weeks] = 7.25 months
Weight Classification	**Definition**
LBW infant	Premature infant with birth weight between 1500 and 2500 g
VLBW infant	Premature infant with birth weight 1000 g to < 1500 g
ELBW infant	Premature infant with birth weight < 1000 g

ELBW, extremely low birth weight; GA, gestational age; LBW, low birth weight; VLBW, very low birth weight.

Another vital sign commonly monitored in children by their caregivers is body temperature, especially when they seem "warm to the touch." The American Academy of Pediatrics (AAP) supports the use of rectal measurement of body temperature as it is most accurate when appropriate technique is used; however, for other routes, the AAP offers an age-specific guideline on routes of measurement.[10,11] For patients aged less than 3 months, rectal measurement using a digital thermometer is recommended. For those 3 months and older, use of temporal artery measurement is an available option. The use of tympanic measurement is appropriate for those age 6 months and older. Axillary measurement is not considered first-line in this all age groups, as proper technique is important for accurate measurement and other accurate options are available. For patients age 4 or 5 years and older, oral measurement is reliable. Generally, fever is defined as temperature 100.4°F (38°C) and greater measured via rectal, otic, or temporal artery technique. For oral and axillary measurement, fever is defined as temperature 100°F (37.8°C) and 99°F (37.2°C) and greater, respectively.[11] Low-grade fevers range from 100° to 102°F (37.8°–38.9°C), with antipyretic treatment (eg, acetaminophen) considered by most pediatricians in cases of temperature greater than 38.3°C (101°F, any measurement route) accompanied by patient discomfort. Formal definition of fever, like other vital signs, is also age dependent, with a lower temperature threshold for neonates (38°C or 100.4°F) and infants (38.2°C or 100.7°F).[10,11]

Pain assessment is more challenging to assess in neonate, infants, and young children due to their inability to communicate symptoms. Indicators of possible pain include physiological changes, such as increased heart rate, respiratory rate, and blood pressure, decreased oxygen saturation, as well as behavior changes such as prolonged, high pitch crying, and facial expressions.[12] Such indicators are used in validated assessment scales, such as the FACES scale and FLACC behavioral tools.[13,14] The FACES scale is a visual analog scale, where patients aged 3 years and older can select a face that best associates with their current pain level.[13] The FLACC scale, intended for patients age 2 months to 7 years or those patients unable to communicate pain, is a scale in which a clinician scores a patient based on a series of criteria (facial expression, leg movement, activity, crying, and consolability).[14]

Fluid Requirements

Fluid requirement and balance are important to monitor in pediatric patients, especially in premature neonates and infants. Maintenance fluid requirement can be calculated based on body surface area for patients greater than 10 kg, with a range of 1500 to 2000 mL/m^2 per day. However, a weight-based method of determining normal maintenance fluid requirement for children is often used (Table 3–3).[15]

EFFECTS OF PHARMACOKINETIC AND PHARMACODYNAMIC DIFFERENCES ON DRUG THERAPY

Drug selection strategy may be similar or different depending on age and disease state, as a result of differences in pathophysiology of certain diseases and pharmacokinetic and pharmacodynamic parameters among pediatric and adult patients. It is noteworthy that pediatric patients may require the use of different medications from those used in adults affected by certain diseases. For

Patient Encounter Part 1

AB is a 30-week GA premature baby girl weighing 1.25 kg, length 38 cm, born to a 21-year-old woman today. AB is currently admitted to the neonatal intensive care unit.

What is AB's weight classification as a neonate?

Calculate AB's corrected age for TS 6 months from today.

How much maintenance fluid per day (mL) and overall rate (mL/hour) is appropriate at this time for AB?

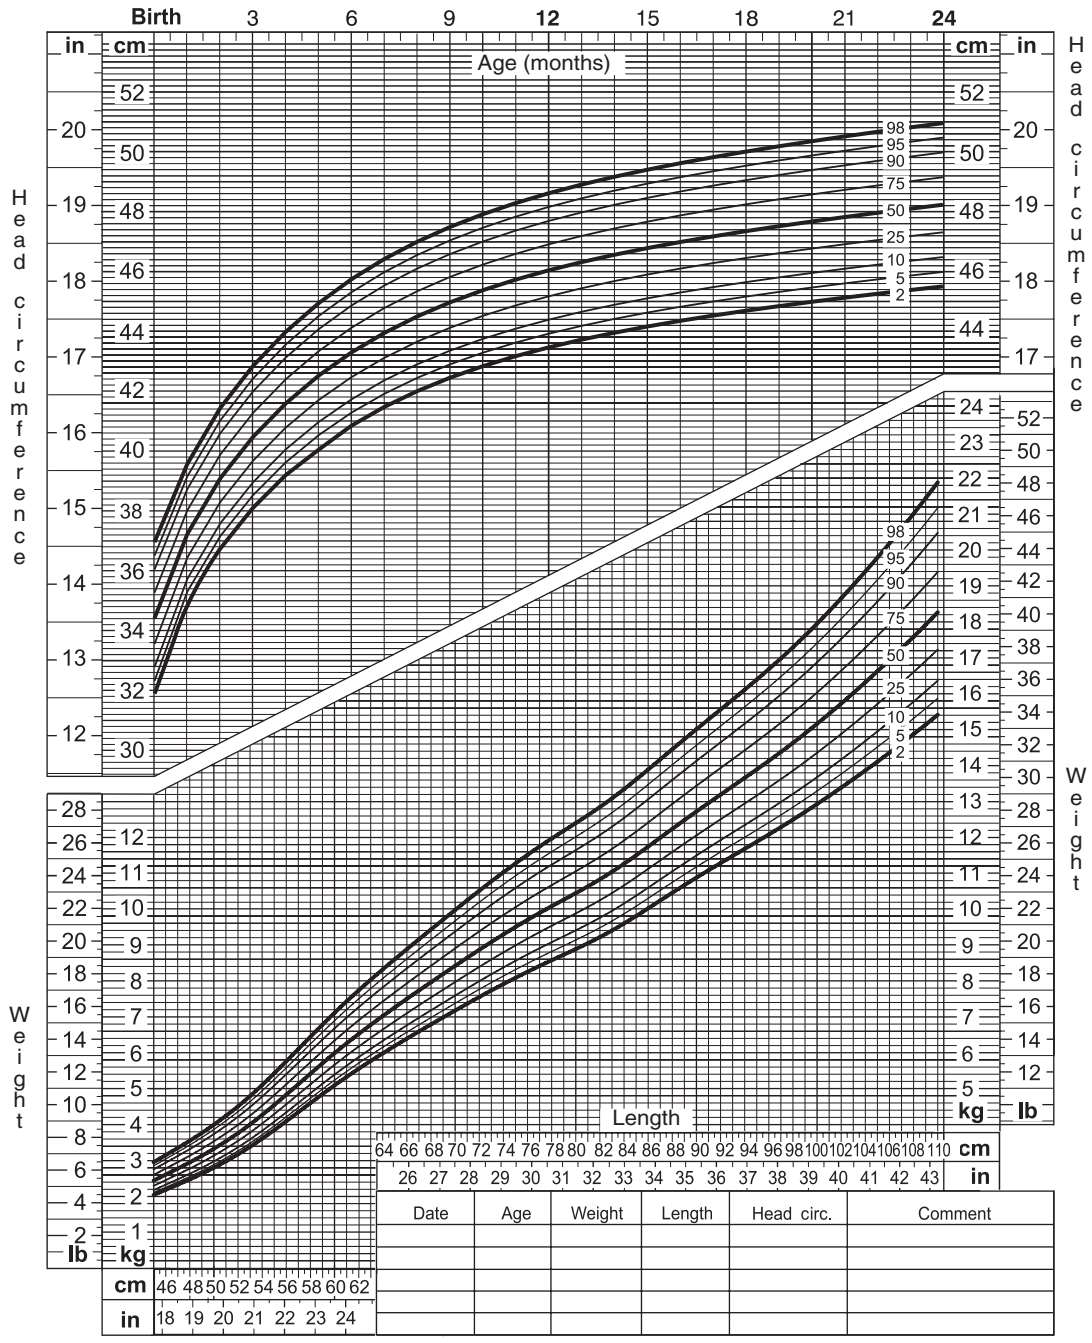

FIGURE 3–1. Example of WHO growth chart of girls, birth to 24 months: Head circumference-for-age and weight-for-length percentile, 2000. (From Centers for Disease Control and Prevention from the WHO Growth Standards. World Health Organization [WHO] Growth Standards, 2009 [updated September 9, 2010], http://www.cdc.gov/growthcharts/who_charts.htm.)

example, phenobarbital is commonly used for treatment of neonatal seizures, but seldom used for seizure treatment in adults, due to differences in seizure etiology and availability of extensive data regarding its use in neonates compared with newer antiepileptic medications. There also exist commonalties between pediatric and adult patients, such as therapeutic serum drug concentrations required to treat certain diseases. For example, gentamicin peak and trough serum concentrations needed for bacteremia treatment are the same in children and adults. Appropriate selection and dosing of drug therapy for a pediatric patient depends on a number of specific factors, such as age, weight, height, disease, comorbidities, developmental pharmacokinetics, and available drug dosage forms. Pediatric drug doses are often calculated based on body weight (eg, mg/kg/dose) compared with uniform dosing (eg, mg/day or mg/dose) for adult patients. Thus, accurate weight should be available while prescribing or dispensing medications for this patient population. Pediatric doses may exceed adult doses by body weight for certain medications due to differences in pharmacokinetics and pharmacodynamics; hence, the use of pediatric drug dosing guides is recommended.

LO 2

KEY CONCEPT Due to multiple differences, including age-dependent development of organ function in pediatric patients, the pharmacokinetics, efficacy, and safety of drugs often differ

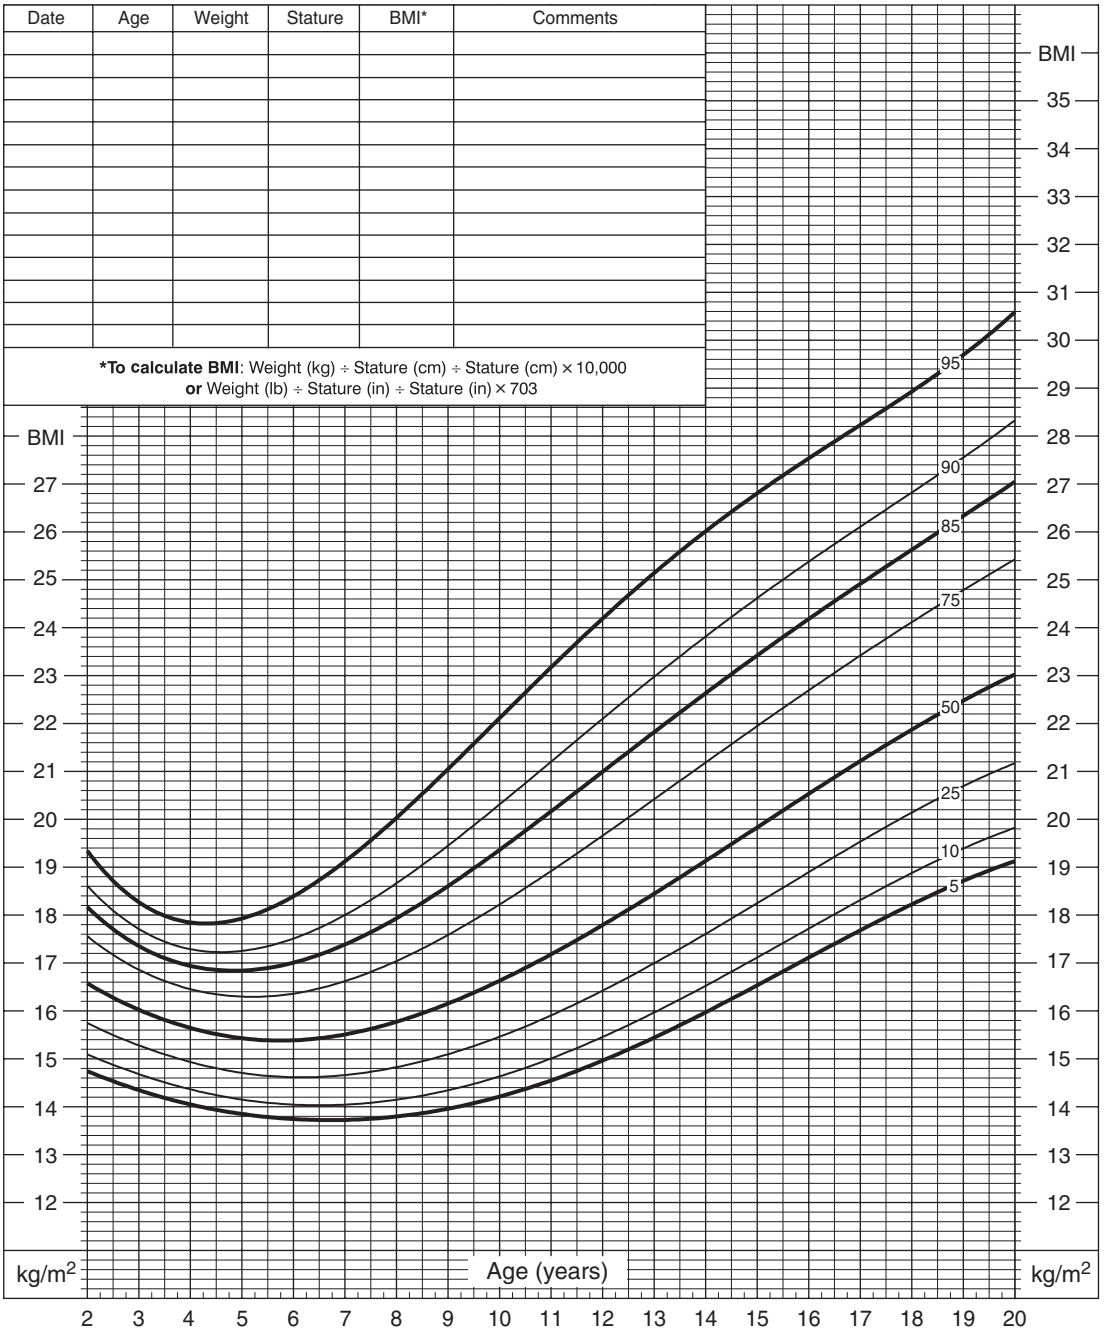

FIGURE 3–2. Example of CDC growth chart of boys, 2 to 20 years: Body mass index for age percentile, 2000. (From National Center for Health Statistics and National Center for Chronic Disease Prevention and Health Promotion. Center for Disease Control Growth Charts, 2000 [updated September 9, 2010], http://www.cdc.gov/growthcharts.)

between pediatric and adult patients; thus, pediatric dosing should not be calculated based on a single factor of difference. Equations proposed to estimate pediatric doses based on adjusted age or weight, such as the Clark's, Fried's, or Young's rule, should not be routinely used to calculate pediatric doses because they account for only one factor of difference (eg, age or weight), and lack integration of the effect of growth and development on drug pharmacokinetics and pharmacodynamics in this population. For off-label medication dosing, when no alternative treatment is available and limited dosage guidelines have been published, clinicians may estimate a pediatric dose based on body surface area ratio.

$$\text{Approximate pediatric dose} = \text{Adult dose} \times [\text{BSA (in m}^2) \div 1.73\ \text{m}^2]$$

Limitations for this dose-estimating approach include the need for the patient to be of normal height and weight for age, and lack of incorporation of exact pharmacokinetic differences regarding each medication.[16]

Absorption

LO 3

Oral absorption may be different in premature infants and neonates due to differences in gastric acid secretion and pancreatic and biliary function. Neonates and infants have increased gastric pH (eg, pH 6–8)

Table 3–2

Normal Ranges of Vital Signs (Heart Rate, Respiratory Rate, Blood Pressure) by Age Group[7–9]

Age Group	Heart Rate (Sleep)[a]	Heart Rate (Awake)[a]	Respiratory Rate[b]	Systolic Blood Pressure[c,d]	Diastolic Blood Pressure[c,d]
Neonate (< 28 days)	90–160	100–205	30–60	67–84	31–45
Infant (1–12 months)	90–160	100–190	30–53	72–104	37–56
Toddler (1–2 years)	80–120	98–140	22–37	86–106	42–63
Preschool (3–5 years)	65–100	80–120	20–28	89–112	46–72
School–age (6–11 years)	58–90	75–118	18–25	97–115	57–76
Adolescent (12–15 years)	50–90	60–100	12–20	102–131	61–83

Note: Prematurity can affect values. Values listed are average ranges.

[a]Beats per minute

[b]Breaths per minute

[c]mm Hg

[d]Exact normal values will vary based on age, height, and sex.

due to lower gastric acid output by body weight, reaching adult values by approximately 2 years of age.[17] Low gastric acid secretion can result in increased serum concentrations of weak bases and acid-labile medications, such as penicillin, and decreased serum concentrations of weak acid medications, such as phenobarbital, due to increased ionization. Additionally, gastric emptying time and intestinal transit time are delayed in premature infants, increasing drug contact time with the GI mucosa and drug absorption.[17,18] Diseases such as gastroesophageal reflux, respiratory distress syndrome, and congenital heart disease may further delay gastric emptying time. Pancreatic exocrine and biliary function are also reduced in newborns, with about 50% less secretion of amylase and lipase than adults, reaching adult values as early as the end of the first year and as late as 5 years of age. Deficiency in pancreatic secretions and bile salts in newborns can decrease bioavailability of prodrug esters, such as erythromycin, which requires solubilization or intraluminal hydrolysis.[18] Due to limited data on oral bioavailability of medications in infants and children for newer agents, some drug dosing recommendations may be extrapolated from adult safety and efficacy studies and case reports.

LO 3 Topical or percutaneous absorption in neonates and infants is increased due to a thinner stratum corneum, increased cutaneous perfusion, and greater body surface-to-weight ratio. Hence, application of topical medications, such as corticosteroids, should be limited to the smallest amount possible. Limiting exposure can help minimize serum concentrations of active drug as well as inactive, yet potentially harmful additives such as propylene glycol.

LO 3 Intramuscular absorption in premature and full-term infants can be erratic due to variable perfusion, poor muscle contraction, and decreased muscle mass compared with older patients.[17] Intramuscular administration may be appropriate for some medications; however, use of this route of administration can be painful and is usually reserved when other routes are not accessible, eg, initial IV doses of ampicillin and gentamicin for neonatal sepsis.

Table 3–3

Maintenance Fluid Calculations by Body Weight[15]

Patient Body Weight	Maintenance Fluid Requirement
< 10 kg	100 mL/kg/day
11–20 kg	1000 mL + 50 mL/kg over 10 kg
> 20 kg	1500 mL + 20 mL/kg over 20 kg

LO 3 Intrapulmonary absorption and distribution is largely due to anatomical size of the lungs and drug delivery. The smaller airways of neonates and lower inspiratory volume can result in greater drug concentrations in the upper and central airways. Particle size, breathing pattern, and route (eg, oral vs nasal) can impact the amount of drug absorbed and should be considered when utilizing pulmonary drug delivery devices such as nebulizers or inhalers.[19]

LO 3 Rectal absorption can also be erratic due to increased peristalsis causing early expulsion of the dosage form in younger patients (ie, infants and young children).[20] Thus it is not commonly recommended if other routes are available. This route is useful in cases of severe nausea and vomiting or seizure activity. For medications that undergo extensive first-pass metabolism, bioavailability increases as the blood supply bypasses the liver from the lower rectum directly to the inferior vena cava. Availability of rectal dosage forms varies and use of oral medications or other dosage forms rectally is based on limited studies and case reports. High osmolality and large volume form may present as limitations to using an oral liquid formulation for rectal use.

Volume of Distribution

LO 3 In pediatric patients, apparent volume of distribution (V_d) is normalized based on body weight and expressed as L/kg. Extracellular fluid and total body water per kilogram of body weight are increased in neonates and infants, resulting in higher V_d for water-soluble drugs, such as aminoglycosides, and decreases with age. Therefore, neonates and infants often require higher doses by weight (mg/kg) than older children and adolescents to achieve the same therapeutic serum concentrations.[17,20] Fluid overload and diuresis can affect V_d and should be assessed for when evaluating drug dosing and pharmacokinetics. The use of extracorporeal membrane oxygenation (ECMO) can further effect V_d of medications in patients due to the added volume from the circuit and potential fluid changes (eg, edema) while on the circuit. Thus, the use of additional clinical and, when available, therapeutic drug monitoring is recommended for those patients requiring ECMO.[21] Neonates and infants have a lower normal range for serum albumin (2–4 g/dL, 20–40 g/L), reaching adult levels after 1 year of age. Highly protein–bound drugs, such as sulfamethoxazole-trimethoprim and ceftriaxone, are not typically used in neonates due to theoretical concern for bilirubin displacement. This displacement may result in a complication known as kernicterus, from bilirubin encephalopathy.[22]

Although neonates have lower body adipose composition compared with older children and adults, their overall V_d for many lipid-soluble drugs (eg, lorazepam) is similar to that of infants and adults. Some medications (eg, vancomycin, phenobarbital) may also reach higher concentrations in the CNS of neonates due to an immature blood–brain barrier.[20]

Metabolism

LO 3

Hepatic drug metabolism is slower at birth in full-term infants compared with adolescents and adults, with further delay in premature neonates. Phase 1 reactions and enzymes, such as oxidation and alcohol dehydrogenase, are impaired in premature neonates and infants and do not fully develop until later childhood or adolescence. Accordingly, the use of products containing ethanol or propylene glycol can result in increased toxicities, including respiratory depression, hypoglycemia, hyperosmolarity, metabolic acidosis, and seizures, and thus should be avoided in neonates and infants. Age at which cytochrome P450 isoenzymes (eg, CYP3A4, CYP2C19) activity reaches adult values varies, depending on the isoenzyme, with delayed development in premature infants. Increased dose requirements by body weight (eg, mg/kg) for some hepatically metabolized medications (eg, phenytoin, valproic acid) in young children (ie, ages 2–4 years of age) are theorized due to an increased liver mass to body mass ratio.[23] This increase in metabolism slows to adult levels as the child goes through puberty into adulthood.[17,23]

Among phase 2 reactions, sulfate conjugation by sulfotransferases is well developed at birth in term infants. Glucuronidation by the uridine diphosphate glucuronosyltransferases, in contrast, is immature in neonates and infants, reaching adult values at 2 to 4 years of age.[18,24] In neonates, this deficiency results in adverse effects including cyanosis, ash gray color of the skin, limp body tone, and hypotension, also known as "gray baby syndrome" with use of chloramphenicol.[24] Products containing benzyl alcohol or benzoic acid should be avoided in neonates due to immature glycine conjugation, resulting in accumulation of benzoic acid. This accumulation can lead to "gasping syndrome," which includes respiratory depression, metabolic acidosis, hypotension, seizures or convulsions, and gasping respirations.[25] Acetylation via *N*-acetyltransferase reaches adult maturation at around 1 year of life; however, overall activity is dependent on genotypic variability.[17]

Elimination

LO 3

Nephrogenesis completes at approximately 36 weeks gestation; thus, premature neonates and infants have compromised glomerular and tubular function that may correlate with a glomerular filtration rate (GFR). This reduction in GFR affects renal drug clearance, thereby necessitating longer dosing intervals for renally cleared medications, such as vancomycin, to prevent accumulation. GFR increases with age and exceeds adult values in early childhood, after which there is a gradual decline to approximate adult value during adolescence. For example, vancomycin is often given every 18 to 24 hours in a low birth weight (LBW) premature neonate, every 6 hours in children with normal renal function, and every 8 to 12 hours in adult patients with normal renal function. Children with cystic fibrosis also present with greater renal clearance of drugs such as aminoglycosides, compared with children without the disease, requiring higher doses by weight and more frequent dosing intervals.[26]

Creatinine clearance (CrCl) is used as a surrogate marker for GFR; however, there are equations available to estimate GFR in the pediatric population. Pediatric GFR is often calculated to mL/min/1.73 m^2. The Cockroft-Gault, Jelliffe, or Modification of Diet in Renal Disease (MDRD) equations for estimating CrCl or GFR in adults should not be used for evaluating patients younger than 18 years, due to lack of validation of these equations in pediatric age ranges, even adolescents.[27,28] Past attempts for proposed application of equations, such as Cockroft-Gault, demonstrated that lack of agreement with measured GFR (via renal scan) in adolescents as young as 13 years of age.[29] Schwartz equation was the previously used method of estimating pediatric GFR from infancy up to 21 years of age (Figure 3–3). This equation uses patient length (cm), serum creatinine (mg/dL) (or μmol/L × 0.0113), and a constant, *k*, which depends on age (including LBW status for infants) for all patients and also gender for those older than 12 years.[30] This "original" Schwartz equation is no longer used by many clinicians due to the change in measurement of serum creatinine methods with calibration traceable to isotope dilution mass spectrometry (IDMS), which invalidates the equation's clinical application.[29,31] Currently the best method, according to the National Kidney Foundation, is the "bedside" Schwartz equation (Figure 3-4).[31]

$$\text{GFR} = \frac{k\text{L}}{\text{SCr}}$$

Age	*k*
Low birth weight < 1 year	0.33
Full term < 1 year	0.45
1–12 years	0.55
13–21 years (female)	0.55
13–21 years (male)	0.70

k = Proportionality constant

L = Length in cm

SCr = Serum creatinine in mg/dL

GFR = estimated glomerular filtration rate (ie, creatinine clearance) in mL/min/1.73 m^2

FIGURE 3–3. "Original" Schwartz equation for estimation of glomerular filtration rate (GFR) in pediatric patients up to 21 years of age. (From Schwartz GJ, Brion LP, Spitzer A. The use of plasma creatinine concentration for estimating glomerular filtration rate in infants, children, and adolescents. Pediatr Clin North Am. 1987;34(3):571–590.)

$$\textbf{Estimated GFR} = [0.413 \times \text{h}] \div \text{SCr}$$

h = height (in cm)

SCr = serum creatinine (in mg/dL)

Glomerular filtration rate (GFR) in mL/min/1.73 m^2

FIGURE 3–4. Bedside Schwartz equation for estimation of glomerular filtration rate (GFR) in pediatric patients ages 1–18 years old. (Data from Staples A, LeBlong R, Watkins CW, Brandt J. Validation of the revised Schwartz estimating equation in a predominantly non-CKD population. Pediatr Nephrol. 2010;25:2321–2326.)

Patient Encounter Part 2

JJ is a 3-week-old (weight 4 kg, length 55 cm, no known drug or food allergies), full-term male who presents to the emergency department with lethargy, poor oral intake, and fever. JJ is admitted to the general pediatric ward for further assessment including a neonatal sepsis and meningitis rule-out. Blood samples, cerebral spinal fluid, and urine were collected for Gram stain and culture, still pending results. Given his poor oral intake on admission, the team requests the consultation regarding antibiotic selection.

JJ's Laboratory Values	Normal Ranges
WBC 19 × 10^3/mm^3 (19 × 10^9/L)	6–17.5 × 10^3/mm^3 (6–17.5 × 10^9/L)
Bands 8% (0.08)	4–12% (0.04–0.12)
Segs 38% (0.38)	13–33% (0.13–0.33)
Lymphs 60% (0.6)	41–71% (0.41–0.71)
Monocytes 5% (0.05)	4–7% (0.04–0.07)
SCr 0.3 mg/dL (27 µmol/L)	≤ 0.6 mg/dL (53 µmol/L)

The medical resident asks you whether ceftriaxone (highly protein binding) or cefotaxime (low protein binding) should be used as part of the antibiotic regimen to treat JJ. Which is the most appropriate and why?

Because serum creatinine is a crude marker of GFR, the Schwartz equation, as with other estimation calculations, carries limitations including the potential for overestimating GFR in patients with moderate to severe renal insufficiency. As a result, for example, the original Schwartz using the *k* factor of 0.55 can overestimate GFR by up to 40%.[32,33] Urine output is also a parameter used to help assess renal function in pediatric patients, with a urine output more than 1 to 2 mL/kg/h considered normal.

SPECIFIC CONSIDERATIONS IN DRUG THERAPY

LO 2 In addition to differences in pharmacokinetics and pharmacodynamic parameters, other factors, including dosage formulations, medication administration techniques, and parent/caregiver education, should be considered when selecting drug therapy.

Off-Label Medication Use

Currently, there is a lack of pediatric dosing, safety, and efficacy information for more than 75% of drugs approved in adults.[34] Off-label use of medications occurs in both outpatient and inpatient settings. Off-label use of medication is the use of a drug outside of its approved labeled indication. This includes the use of a medication in the treatment of illnesses not listed on the manufacturer's package insert, use outside the licensed age range, dosing outside those recommended, or use of a different route of administration.[35,36] KEY CONCEPT It is appropriate to use a drug off-label when no alternatives are available; however, clinicians should refer to published studies and case reports for available safety, efficacy, and dosing information. FDA regulatory changes provide incentives for a pharmaceutical manufacturer to study and market new drugs for pediatric patients. However, such incentives are not available for generic drugs.

Routes of Administration and Drug Formulations

LO 4 Depending on age, disease, and disease severity, different routes of administration may be considered. The rectal route of administration is reserved for cases where oral administration is not possible and IV route is not necessary. Topical administration is often used for treatment of dermatologic ailments. Transdermal routes are not often used due to limited product availability. The injectable route of administration is used in patients with severe illnesses or when other routes of administration are not possible. As done with adult patients, IV compatibility and access should be evaluated when giving parenteral medications. Dilution of parenteral medications may be necessary to measure smaller doses for neonates. However, a higher concentration of parenteral medications may be necessary for patients with fluid restrictions, such as premature infants and patients with cardiac anomalies and/or renal disease. Appropriate stability and diluent selection data should be obtained from the literature.

When oral drug therapy is needed, one must also consider the dosage form availability and child's ability to swallow a solid dosage form. Children younger than 6 years are often not able to swallow oral tablets or capsules and may require oral liquid formulations. Not all oral medications, especially those unapproved for use in infants and children, have a commercially available liquid dosage form. Use of a liquid formulation compounded from a solid oral dosage form is an option when compounding and stability data are available. Factors such as drug stability, suspendability, dose uniformity, and palatability should be considered when compounding a liquid formulation.[37] Commonly used **suspending agents** include methylcellulose and carboxymethylcellulose (eg, Ora-Plus). Palatability of a liquid formulation can be enhanced by using simple syrup or OraSweet. If no dietary contraindications or interactions exist, doses can be mixed with food items such as pudding, fruit-flavored gelatin, chocolate syrup, applesauce, or other fruit puree immediately before administration of individual doses. Honey, although capable of masking unpleasant taste of medication, may contain spores of *Clostridium botulinum* and should not be given to infants younger than 1 year due to increased risk for developing botulism. Most hospitals caring for pediatric patients compound formulations in their inpatient pharmacy. Limited accessibility to compounded oral liquids in community pharmacies poses a greater challenge. A list of community pharmacies with compounding capabilities should be maintained and provided to the parents and caregivers before discharge from the hospital.

Common Errors in Pediatric Drug Therapy

Prevention of errors in pediatric drug therapy begins with identification of possible sources. The error rate for medications is as high as 1 in 6.4 orders among hospitalized pediatric patients.[38] Off-label use of medications increases risk of medication error and has been attributed to difference in frequency of errors compared with adults. One of the most common reasons for medication errors in this specialized population is incorrect dosing such as calculation error.[39,40] KEY CONCEPT Medication errors among pediatric patients are possible due to differences in dose calculation and preparation; it is important to identify potential errors through careful review of orders, calculations, dispensing, and administration of drug therapy to infants and children. It is crucial to verify accurate weight, height, and age for dosing calculations and dispensing of prescriptions because pediatric patients are a vulnerable population for medication error. Consistent units of measurements in reporting patient variables, such as weight (kg) and height (cm), should be used. Dosing units such as mg/kg, mcg/kg, mEq/kg, mmol/kg, or units/kg should also be used accurately. Given the age-related differences in metabolism of additives, such as propylene glycol

LO 2

and benzyl alcohol, careful consideration should be given to the active and inactive ingredients when selecting a formulation.

Decimal errors, including trailing zeroes (eg, 1.0 mg misread as 10 mg) and missing leading zeroes (eg, .5 mg misread as 5 mg), in drug dosing or body weight documentation are possible, resulting in several-fold overdosing. Strength or concentration of drug should also be clearly communicated by the clinician in prescription orders. Similarly, labels that look alike may lead to drug therapy errors (eg, mistaking a vial of heparin for insulin). Dosing errors of combination drug products can be prevented by using the right component for dose calculation (eg, dose of sulfamethoxazole/trimethoprim is calculated based on the trimethoprim component).

Use of standardized concentrations and programmable infusion pumps, such as smart pumps with built-in libraries, is encouraged to minimize errors with parenteral medications, especially those for continuous infusions such as inotropes. Electronic health records (EMR) with clinical decision support systems and barcoding technology, with ability for dose range checks by weight for pediatric medication orders and accurate matching of correct ordered medication to patient, respectively, have decreased medication errors.[40]

Prevention of medication errors is a joint effort between health care professionals, patients, and parents/caregivers. Obtaining a complete medication history, including over-the-counter (OTC) and complementary and alternative medicines (CAMs), simplification of medication regimen, clinician awareness for potential errors, and appropriate patient/parent/caregiver education on measurement and administration of medications are essential in preventing medication errors.

Complementary/Alternative and Over-the-Counter Medication Use

Between 30% and 70% of children with a chronic illness (eg, asthma, attention deficit hyperactivity disorder, autism, cancer) or disability use CAMs.[41] CAMs can include mind-body therapy (eg, imagery, hypnosis), energy field therapies (eg, acupuncture, acupressure), massage, antioxidants (eg, vitamins C and E), herbs (eg, St. John's wort, kava, ginger, valerian), prayer, immune modulators (eg, echinacea), or other folk/home remedies. It is important to encourage communication about CAM use, including interdisciplinary discussion between CAM providers and pediatric health care providers.[41] It is critical to appreciate that there are limited data establishing efficacy of various CAM therapies in children. For example, colic is a condition of unclear etiology in which an infant cries inconsolably for over a few hours in a 24-hour period, usually during the same time of day. Symptoms of excessive crying usually improve by the third month of life and often resolve by 9 months of age. No medication has been approved by the FDA for this condition. Some parents are advised by family and friends to use alternative treatments, such as gripe water, to treat colic. Gripe water is an oral solution containing a combination of ingredients, such as chamomile and sodium bicarbonate, not regulated by the FDA. In addition, some gripe water products may contain alcohol, which is not recommended for infants due to their limited metabolism ability (ie, alcohol dehydrogenase). Further, some CAM products (eg, St. John's wort) can interact with prescription drugs and produce undesired outcomes. It is important to assess OTC product use in pediatric patients. For example, treatment of the common cold in children is similar to adults, including symptom control with adequate fluid intake, rest, use of saline nasal spray, and acetaminophen (10–15 mg/kg/dose every 6–8 hours) or ibuprofen (4–10 mg/kg/dose every 8 hours) for relief of discomfort and fever. Other products, such as a topical vapor rub or oral honey, have demonstrated some potential for alleviation of symptoms, such as cough, based on survey studies of parents for children of 2 years and older.[42,43] Unlike adults, symptomatic relief through the use of pharmacologic agents, such as OTC combination cold remedies, is not recommended for pediatric patients younger than 4 years. Currently, the FDA does not recommend the use of OTC cough and cold medications (eg, diphenhydramine and dextromethorphan) in children younger than 2 years; however, the Consumer Healthcare Products Association, with the support of the FDA, has voluntarily changed product labeling of OTC cough and cold medications to state "do not use in children under 4 years of age." This is due to increased risk for adverse effects (eg, excessive sedation, respiratory depression) and no documented benefit in relieving symptoms. It has also been noted that these medications may be less effective in children younger than 6 years compared with older children and adults.[44,45] Also noteworthy is the potential for medication error with use of OTC products in older children, such as cold medications containing diphenhydramine and acetaminophen. A parent/caregiver may inadvertently overdose a child on one active ingredient, such as acetaminophen, by administering acetaminophen suspension for fever and an acetaminophen-containing combination product for cold symptoms. The use of aspirin as an antipyretic or analgesic (eg, for a "cold") in patients younger than 18 years with viral infections is not recommended due to the risk of Reye syndrome. Signs or symptoms of Reye syndrome, usually appearing several days after start of a viral infection, are relatively nonspecific, including diarrhea, persistent vomiting, increased respiratory rate, increasing lethargy, and seizure. While making an appropriate recommendation for an OTC product for a pediatric patient, the parent/caregiver should always be referred to their pediatrician for further advice and evaluation when severity of illness is a concern.

Clinicians should respect parents'/caregivers' beliefs in the use of CAM and OTC products and encourage open discussion with the intention of providing information regarding their risks and benefits to achieve desired health outcomes as well as optimize medication safety.

Medication Administration to Pediatric Patients and Caregiver Education

Considering the challenges in cooperation from infants and younger children, medication administration can become a difficult task for any parent or caregiver. One should also consider factors that may affect adherence to prescribed therapy including caregiver and/or patient's personal beliefs, socioeconomic limitation(s), and fear of adverse drug effects. One common factor to consider is ease of measurement and administration when selecting and dosing pediatric drug therapy. LO 2 Clinicians should check concentrations of available products and round doses to a measurable amount. For example, if a patient were to receive an oral formulation, such as amoxicillin 400 mg/5 mL suspension, and the dose was calculated to be 4.9 mL, the dose should be rounded to 5 mL for ease of administration. Rounding the dose by 10% to the closest easily measurable amount is commonly practiced for most medications (eg, antibiotics); however, drugs with narrow therapeutic indices (eg, anticoagulants) are exceptions to this guideline.

LO 2 The means or devices for measuring and administering medications should also be closely considered. Special measuring devices as well as clear and complete education about their use are essential. Oral syringes are accurate and offered at most community pharmacies for the measurement of oral liquid medications. Studies have demonstrated less error in dose measurement using an oral syringe compared to other devices

Table 3–4

Helpful Tips for Medication Administration for Selected Dosage Forms[48]

Dosage Form	Recommendations
Ophthalmic drops or ointment	• Wash hands thoroughly prior to administration • Position child laying down in supine position • Avoid contact of applicator tip to surfaces, including the eye • Drops should be placed in the pocket of the lower eyelid • Ointment strip should be placed along the pocket of the lower eyelid

Otic drops	• Wash hands thoroughly prior to administration
	• Position child laying down in prone position
	• Tilt head to expose treated ear, gently pull outer ear outward, then due to age-dependent change in angle of Eustachian tube:
	  • If child < 3 years of age, gently pull downward and back; apply drops
	  • If child > 3 years of age, gently pull upward and back; apply drops

Nasal drops	• Wash hands thoroughly prior to administration • Position child laying down in supine position • Slightly tilt head back; place drops in nostril(s) • Remain in position for appropriate distribution of medication
Rectal suppository	• Similar to adult administration; challenging route for administration • For younger patients (ie, < 3 years), a smaller finger (eg, pinky finger) should be used to insert suppository
Metered-dose inhalers	• Use a spacer • For younger children, use one with a mask, be sure the mask is secured/placed closely up against the child's face, avoiding gaps between face and mask and creating a seal to ensure medication delivery • Child should take slow breaths in with each dose • Wait at least 1 minute between doses

(eg, dosing cup, dropper, dosing spoon) and that in addition to appropriate device caregiver health literacy contributes to potential for medication dose measurement error.[46] Due to inconsistencies and risk for possible inaccuracy of measuring smaller doses, dosing or measuring spoons, oral droppers, and medicine cups are not recommended for measuring doses for infants and young children. Household dining or measuring spoons are not accurate or consistent and should not be used for the administration of oral liquids. Additionally, consistency in dosing units used for liquid formulation (eg, milliliters instead of teaspoons or ounces) is necessary to minimize further medication dosing errors.[47]

KEY CONCEPT Comprehensive and clear parent/caregiver education improves medication adherence, safety, and therapeutic outcomes and is essential in care of infants and young children. Information about the drug, including appropriate and safe storage away from children, possible drug interactions, duration of therapy, importance of adherence, possible adverse effects, and expected therapeutic outcomes should be provided. Parent/caregiver education is important in both inpatient and outpatient care settings and should be reviewed at each point of care.

LO 5

LO 5

Because parents/caregivers are often sole providers of home care for ill children, it is important to demonstrate appropriate dose preparation and administration techniques to the caregivers before medication dispensing. First, a child should be calm for successful dose administration. Yet, calming a child is often a challenge during many methods of administration (eg, otic, ophthalmic, rectal). Parents/caregivers should explain the process in a simple and understandable form to the child because this may decrease the child's potential anxiety. In addition, it is also recommended to distract younger children using a favorite item such as toy or to reward cooperative or "good" behavior during medication administration. Helpful tips regarding administration of selected dosage forms in pediatric patients are listed in Table 3–4.[48]

Patient Encounter Part 3

MM is an 18-month-old female who is brought to the clinic with a 5-day history of bilateral ear pain, excessive crying, decreased appetite, and difficulty sleeping. The child's temperature last night was 39°C (102.2°F) by electronic axial thermometer. MM also presents with some nasal congestion and occasional cough. Mom reports to have given the child several doses of ibuprofen, but the pain or temperature did not improve and none was given this morning. No other significant past medical history. The pediatrician diagnoses MM with acute otitis media requiring antibiotic treatment and asks you to develop a treatment care plan for MM including use of amoxicillin at 90 mg/kg/day divided twice a day.

What additional information would you need to develop an appropriate treatment care plan for MM?

Mom asks you if ibuprofen was the right choice for MM's fever and pain and if other options such as acetaminophen or aspirin could be used instead. What would you recommend for pain and fever for MM? Why?

The nurse provides you MM's weight as 25 pounds (11.4 kg). What is MM's calculated dose of amoxicillin based on the dosage form you need to use?

Mom asks you if there are any complementary/alternative OTC cough/cold medications that she can give MM for her nasal congestion and cough. What recommendations would you make to mom?

What items should mom be educated on with regard to the new prescription of amoxicillin?

Patient Care Process

Collect Information:

- For patients up to 2 years of age, review birth history, including gestational age (GA), birth weight, medical complications, postnatal age, and corrected age.
- Review patient's past medical history, comorbidities.
- Review patient's available laboratory data (eg, serum creatinine, liver function tests).
- Review all current medication therapy, including CAM and OTC.
- Review patient's medication allergies and/or intolerances.

Assess the Information:

- Assess appropriateness of therapy. Is patient on appropriate drug therapy for current diagnoses? Are current medication doses appropriate (ie, for age, weight, etc.)? Any medications without indication?
- Evaluate patient's organ function (renal and hepatic), including use of appropriate equations (eg, bedside Schwartz).
- Assess current therapy for safety and efficacy. Is the medication effective for this patient? Is the patient experiencing any adverse effects?
- Consider available data regarding safe and effective dosing of selected drug.
- Assess patient's (or patient's caregiver) history of medication adherence and health care beliefs.

Develop a Care Plan:

- Consider available routes of administration. What is the most appropriate route? If IV medication is needed, what types of IV accesses are available? For example, does the patient have a central or peripheral line? Determine if IV medication needs to be further diluted or concentrated based on patient's comorbidities and fluid status.
- Consider ease of administration for the patient and/or caregiver. Is the dose easily measurable? Is the dosing frequency reasonable for their family schedule?
- Verify accuracy of dose calculations. Verify current weight and dosing units (eg, mg/kg/day, mg/kg/dose). Is the dosing interval appropriate?
- Determine what drug–drug/drug–food interactions are possible with this new therapy. How can they be managed?

Implement the Care Plan:

- Communicate plan for care with patient care team.
- Educate parent/caregiver/patient regarding selected drug therapy including purpose, dose, administration, duration therapy, possible side effects, etc.

Follow-up: Monitor and Evaluate:

- Monitor signs and symptoms of clinical outcomes (improvement and decline). Measure drug serum concentrations when appropriate. Monitor for possible adverse drug events.
- Reinforce patient/caregiver education.

Accidental Ingestion in Pediatric Patients

Pediatric accidental ingestions most often occur in the home.[49] Various factors account for incidence of accidental ingestions in young children, including hand-to-mouth behaviors as well as new and increased mobility resulting in easier access areas where harmful substances are stored (eg, medication cabinets). Indeed, caregivers are encouraged to use "child-safe" devices to lock closets and cabinets to reduce risk of accidental ingestions; however, this is not a substitute for appropriate caregiver supervision.

Ingested substances can vary, from household cleaning solutions to prescription and nonprescription medications. The most common exposures in children age less than 5 years were cosmetics/personal care products, analgesics, household cleaning substances, foreign bodies (eg, small toys), and topical preparations.[49] Management of accidental ingestions varies depending on the ingested substance, the amount, and the age and size of the child. The American Academy of Clinical Toxicology and the AAP do not recommend the use of ipecac syrup for treatment of accidental ingestion; thus, inducing emesis is not a recommended approach for any type of ingestion.[50] Clinicians receiving calls regarding management of accidental ingestions, depending on severity of case, should direct them to the emergency department for evaluation and/or the local or regional poison control center for specific recommendations, which can be reached via a universal contact number (1-800-222-1222), with additional information located through the American Association of Poison Control Centers (www.aapcc.org).[51]

Abbreviations Introduced in This Chapter

AAP	American Academy of Pediatrics
ACIP	Advisory Committee on Immunization Practices
bpm	Beats per minute
CAM	Complementary and alternative medicine
CDC	Centers for Disease Control and Prevention
CPOE	Computer physician order entry
CrCl	Creatinine clearance
ELBW	Extremely low birth weight
GA	Gestational age
GFR	Glomerular filtration rate
LBW	Low birth weight
MDI	Metered-dose inhaler
OTC	Over-the-counter
V_d	Volume of distribution (apparent)
VLBW	Very low birth weight

4 Palliative Care

Kelly R. Kroustos and Marc A. Sweeney

LEARNING OBJECTIVES

LO **Upon completion of the chapter, the reader will be able to:**

1. Describe the philosophy of palliative care including hospice care and its impact on medication therapy management.
2. Discuss the therapeutic management of palliative care patients and how it differs from and is similar to traditional patient care at the end of life.
3. List the most common symptoms experienced by the terminally ill patient.
4. Explain the pathophysiology of the common symptoms experienced in the terminally ill patient.
5. Describe the pharmacologic rationale of medication therapy used for symptom management in the terminally ill patient.
6. Recommend nonpharmacologic and pharmacologic management of symptoms in a terminally ill patient.
7. Develop a patient-specific palliative care management plan.
8. Educate patients and caregivers regarding palliative care management plan, including rationale of treatment, importance of medication adherence, and assessment and monitoring of desired outcomes.

INTRODUCTION

LO1 KEY CONCEPT According to the World Health Organization (WHO), "Palliative care is an approach that improves the quality of life of patients and their families facing the problem associated with life-threatening illness, through the prevention and relief of suffering by means of early identification and impeccable assessment and treatment of pain and other problems, physical, psychosocial and spiritual." The goal of palliative care is to achieve the best quality of life for patients and their families.[1] "Palliate" literally means "to cloak." The WHO goal of achieving high quality of life depends on a team approach to manage disease-related symptoms while honoring the patient's goals for care.[2] Palliative care focuses on patients and their families and the challenges associated with life-threatening illness.[3] The goal is to prevent and relieve suffering by means of early identification, assessment, and treatment of pain and other physical symptoms, including associated psychosocial, emotional, and spiritual concerns.[1] Palliative medicine is rapidly becoming a well-recognized medical specialty[4] and is much needed due to the increased number of patients with chronic, slowly debilitating diseases.[2]

LO1

The term *palliative care* is frequently used synonymously with hospice, and although hospice programs provide palliative care, palliative care has a much broader application. In the United States, hospice is defined by Medicare and other third-party payers as a benefit available to individuals who have less than or equal to 6 months life expectancy if the disease runs its typical course.[2] Hospice care guidelines and regulations are primarily defined by federal regulations. Palliative care outside of the umbrella of hospice care, in contrast, is not currently regulated nor has the same reimbursement structure. Palliative care services may be provided at any point during the disease process and are not limited to the last 6 months of life; therefore, patients and families may receive palliative care services beginning at the time of diagnosis of life-limiting illness. Palliative care may be delivered in all care settings.[5] The foundation for providing quality palliative care centers around active participation of an interdisciplinary team working closely to meet patient and family goals.[6] Palliative care team members include representatives from medicine, nursing, social work, pastoral or related counseling, pharmacy, nutrition, rehabilitation, and other professional disciplines providing a holistic approach to the patient's care.

LO2

LO2

KEY CONCEPT The goals of palliative care include enhancing quality of life while maintaining or improving functionality.[6,7] Palliative care should most logically be delivered to patients from the onset of any chronic, life-altering disease. Before many of our modern medical and therapeutic advancements were developed, curative treatments were not normally available.[8] Provision of comfort was considered the mainstay for patient care. Advances in medical care, nutrition, public health, and trauma care resulted in fewer patient deaths and medical management shifted focus from comfort to a death-denying approach, with prolonging life as the primary goal. With this shift, palliative care became less emphasized until 1967 when the first modern hospice was established in London, England. Today the palliative care philosophy attempts to combine enhanced quality of life, compassionate care, and patient and family support with modern medical advances.

LO1

LO1

EPIDEMIOLOGY AND ETIOLOGY

The first hospice in the United States was founded in 1974. Since then, hospice acceptance and utilization has increased; currently, approximately 6100 hospice agencies care for patients across the United States.[9] In 2013, approximately 59% of hospice patients were cared for in the home, and 84% of hospice patients were older than 65 years.[9]

In a 2007 study, hospice patients lived 29 days longer than nonhospice patients, with the largest difference noted in chronic heart failure (CHF) patients.[10] Lung cancer patients receiving early palliative care survived 23% longer than those with delayed palliative care, according to a 2010 study.[11] Early referrals to hospice appear to improve overall care of the patient and offer prolonged survival in some patients. The integration of palliative care prior to the patient's eligibility for hospice care may prove to even further improve survival and quality of life and care of patients.

Because health care providers have an increasing recognition of the benefit of palliative care for patients with all life-limiting illness, increased integration of this model of care has extended to other disease states beyond cancer.

PATHOPHYSIOLOGY

LO 2 Understanding the pathophysiology of multiple end-stage disease states is daunting, yet in palliative care, the emphasis is not so much on the disease state management as it is on the assessment and appropriate treatment of associated physical, psychological, social, and spiritual symptoms. Palliative care focuses on symptom management for patients with progressive life-limiting illnesses from diagnosis through death where the pathophysiological impact of disease on a patient's symptoms may vary greatly depending on the stage of a patient's illness. KEY CONCEPT Palliative care is appropriate for all life-limiting diseases including cancer, chronic obstructive pulmonary disease (COPD), dementia (including Alzheimer disease), Parkinson disease, chronic cardiac disease, stroke, renal failure, hepatic failure, multiorgan failure, diabetes mellitus, and so on.

LO 2 For the purpose of this chapter, pathophysiology is not a primary focus. Rather, the philosophy of managing physical, psychological, social, and spiritual symptoms to maintain quality of life and prevent suffering is discussed within the context of progressively incurable illnesses. Although palliative may coexist with aggressive disease state management to extend life, as the patient approaches the end of life, philosophy and management generally move away from those principles related to the disease state management of patients where prolonging life is the goal.

CLINICAL PRESENTATION AND DIAGNOSIS

Cancer

LO 3 LO 4 Palliative care is most commonly associated with cancer patients. Regardless of whether or not the cancer is curable, most patients have various degrees of physical, psychological, social, and spiritual symptoms that arise once a diagnosis is confirmed. Once a cancer patient has failed curative and life-prolonging therapy, prognosis and disease trajectory is easier to determine than in patients with other life-limiting diseases. The change in focus from cure to symptom control becomes apparent and therefore more acceptable. Symptoms associated with cancer depend on both the primary tumor site and the location of metastatic spread. Symptoms may also result from the effects of cancer treatments such as chemotherapy and radiation. (See Chapters 88 to 99 for specific cancers and their treatments.)

End-Stage Heart Failure

LO 4 LO 3 Many forms of heart disease result in sudden death; however, the disease progression of heart failure is protracted yet unpredictable. Advanced heart failure (class III to IV or stage C or D) is characterized by persistent symptoms that limit activities of daily living despite optimal drug therapy. Common symptoms include fatigue, breathlessness, anxiety, fluid retention, and pain. In heart failure, standard medication management is intended to reduce progression of cardiac remodeling and is considered disease modifying. However, as patients approach the final months of life, with the exception of cholesterol-lowering agents, these same cardiac medications are also palliative and should not be discontinued prematurely without cause (Figure 4–1). Exacerbations of heart failure

	Mortality Benefit	Functional Benefit	Renal Dosing Adjustments	Risk vs Benefit Considerations
Diuretics *(eg, furosemide, torsemide, bumetanide)*	–	✓	✓	Continue for symptom management (edema, dyspnea) **Caution:** Dehydration, hypokalemia
ACEI *(eg, lisinopril, enalapril)*	✓	✓	✓	**Caution:** Dehydration, sepsis, concurrent NSAID use and renal artery stenosis can increase renal toxicity
Aldosterone antagonists *(eg, spironolactone)*	✓	–/✓	✓	Primary benefit for reducing mortality **Caution:** Hyperkalemia risk with renal insufficiency
β-Blockers *(eg, carvedilol, metoprolol)*	✓	✓	–	Taper doses prior to discontinuation **Caution:** May cause hypotension and bradycardia
Inotrope PO *(eg, digoxin)*	–	✓	✓	**Caution:** Digoxin toxicity (N/V, anorexia, confusion, arrhythmia)

FIGURE 4–1. Drugs, their use in Class III–IV heart failure, and their effects on mortality, hospital admissions, and functional status. Checkmark, indicating a positive impact on specified parameter, and—indicating no significant impact on specified parameter.[7,31]

symptoms should be aggressively treated as long as the patient is responsive to therapy and wishes to receive treatment. In hospice, this can often be accomplished through medication manipulation in the patient's home without the need for hospitalization (see Chapter 6).

Chronic Obstructive Pulmonary Disease

COPD has a prolonged and variable course. Patients with COPD have a high number of physician visits and hospital admissions. Palliative care treatment is directed at reducing symptoms, reducing the rate of decline in lung function, preventing and treating exacerbations, and maintaining quality of life. In end-stage COPD, bronchodilators and anti-inflammatory agents become less effective. As patients decline, their ability to use inhalers appropriately becomes more difficult. Utilizing a nebulizer to administer bronchodilators allows for more reliable drug delivery to the site of action. Symptoms of late-stage disease include wheezing, chronic sputum production, cough, frequent respiratory infections, **dyspnea** with exertion progressing to dyspnea at rest, fatigue, pain, hypoxia, and weight loss. Pulmonary hypertension may also occur and can lead to cor pulmonale or right-sided heart failure (see Chapter 15).

End-Stage Kidney Disease

Chronic kidney disease is progressive and leads to renal failure. In end-stage kidney disease, the only life-sustaining treatments are dialysis or renal transplant. Without treatment, kidney failure causes uremia, oliguria, hyperkalemia and other electrolyte disorders, fluid overload and hypertension unresponsive to treatment, anemia, hepatorenal syndrome, and uremic pericarditis. Symptoms associated with chronic kidney disease (stage 5) include fatigue, pruritus, nausea, vomiting, constipation, dysgeusia, muscle pain, agitation, and bleeding abnormalities. Palliative care in these patients includes the minimization of these symptoms; however, because many options for drug therapy will be cleared through the kidneys, agents should be chosen cautiously to avoid other complications (see Chapter 26).

End-Stage Liver Disease

Like kidney disease, the only treatment to prolong life in advanced liver disease is transplant. Patients with end-stage liver disease typically present with ascites, jaundice, pruritus, or encephalopathy, and frequently all four symptoms. Additionally, bleeding disorders are common, and associated esophageal or gastric varices bleeds are the cause of death in about one-third of those who die from liver disease. Palliative care in these patients focuses on the symptom management of end-stage liver disease complications.

Human Immunodeficiency Virus/Acquired Immune Deficiency Syndrome (HIV/AIDS)

Pharmacologic advances have changed prognosis and progression of HIV/AIDS. Palliative care is predominantly directed toward patients without access to drug therapy in the early stages of disease. Patients with progressed HIV/AIDS are susceptible to acquire opportunistic infections and cancer that may hasten their death. Common symptoms observed in individuals with HIV/AIDS at the end of their life include fatigue, profound weight loss, breathlessness, nausea, GI disturbances, and pain. The goal of palliative care in these patients is to minimize common AIDS-related symptoms (see Chapter 87).

Stroke/Cerebral Vascular Accident

Stroke results from hemorrhage or ischemia. The prognosis of cerebral vascular accident (CVA) patients is unpredictable and may be extended, resulting in caregiver fatigue. Approximately one-third of patients who have a stroke will die within 2 years. Patients with stroke deal with loss of physical and cognitive function, poststroke pain, and frequent depression. Incontinence, aphasia, **dysphagia**, and seizures are also common. Patients who have dysphagia have a high incidence of aspiration pneumonia, which often is the cause of death (see Chapter 11).

Parkinson Disease

Parkinson disease is a degenerative neurologic disease with a long chronic, progressive course evidenced by akinesia, rigidity, and tremor. The goal of therapy is to reduce symptoms and maintain or improve quality of life. Palliative care provides support to both the patient and caregiving system as patients become more disabled and as neuropsychiatric problems arise. Frequent symptoms are skin infections and breakdown, constipation, pain, depression, hallucinations, and confusion. Individuals with Parkinson disease often die from bronchial pneumonia due to dysphagia or complication from falls (see Chapter 33).

Amyotrophic Lateral Sclerosis (Lou Gehrig Disease)

Amyotrophic lateral sclerosis (ALS) is a chronic neurodegenerative disorder characterized by progressive loss of motor neurons. The median survival is approximately 3 years from the symptom onset with less than 15% of patients surviving 10 years. Initially, symptoms of ALS present as limb weakness, with other symptoms developing in no particular order including cramps, spasticity, pain, dysarthria, sialorrhea, fatigue, insomnia, depression, fear and anxiety, involuntary emotional expression disorder, constipation, aspiration, and laryngospasm. Many patients do not have cognitive impairment; however, one-fourth to one-half of patients with ALS may have associated frontal lobe dementia. Disease progression eventually involves all systems except sphincter control and eye movement. Unless the individual has long-term mechanical ventilation, the cause of death is typically respiratory failure.

Alzheimer Disease and Other Dementia

Dementia is a progressive, nonreversible deterioration in cognitive function with associated behavioral dysfunction. Alzheimer disease accounts for most dementia cases; vascular, Parkinson disease, dementia with Lewy body, and frontotemporal dementias are less prevalent. Drug therapy targets slowing progression of cognitive symptoms and preserving patient function. As patients progress toward end-stage dementia, in addition to memory loss and personality and behavioral changes, they require assistance in basic activities of daily living such as feeding, dressing, and toileting. At this point they may not respond to their surroundings, may not communicate, or have impaired movements and dysphagia. Depression, agitation, delusions, compulsions, confusion, hallucinations, incontinence, and disruption of sleep/wake cycles are all common symptoms in end-stage dementias. Symptom assessment is challenging due to the cognitive impairment and frequent aphasia. Palliative care is not only directed toward the patient, but also emotional support for those close to them (see Chapter 29).

TREATMENT

LO 7 KEY CONCEPT Following a complete assessment of the patient, developing a comprehensive therapeutic plan that utilizes the fewest number of medications to achieve the highest quality of life is essential. Many times, one drug may relieve multiple symptoms, resulting in better patient care, lower costs, and decreased medications. Cost-effective drug recommendations are essential to control costs. Avoiding polypharmacy will reduce adverse drug events related to drug interactions, excessive side effects, and therapy duplication. The following list of symptoms includes common symptoms observed in palliative and end-of-life care; however, it is not comprehensive. LO 3 KEY CONCEPT Palliative care is more than just pain management. It includes the treatment of symptoms resulting in the discomfort for the patient, which may include nausea and vomiting, agitation, anxiety, depression, delirium, dyspnea, anorexia and cachexia, constipation, diarrhea, pressure ulcers, and edema.

Note that many drugs used to treat symptoms in palliative and end-of-life care are often prescribed for unapproved uses, administered by unapproved routes or in dosages higher than that recommended by the package insert. This "off-label" use of medication is not unique to palliative care. Conducting large-scale, rigorous drug studies that supply necessary information for an approved drug indication possesses ethical difficulty due to the delicate nature of patient's receiving palliative and/or hospice care.

Anxiety

A comprehensive review of anxiety disorders may be found in Chapter 40.

▶ *Palliative Care Considerations*

- Anxiety is "characterized by apprehensive anticipation of future danger or misfortune accompanied by psychological symptoms such as worrying, vigilance, and rumination as well as by physical feelings such as tension, jitters, dyspnea, chest discomfort, or abdominal stress."[7]
- Anxiety is closely related to fear, but fear has an identified cause or source of worry (eg, fear of death). Fear may be more responsive to counseling than anxiety that the patient cannot attribute to a particular fearful stimulus. Anxiety disorders are the most prevalent class of mental disorders, so it is not surprising that anxiety is a common cause of distress at life's end.

LO 3 In addition to anxiety disorders, a variety of conditions can cause, mimic, or exacerbate anxiety.[12,13] Delirium, particularly in its early stages, can easily be confused with anxiety. Physical complications of illness, especially dyspnea and undertreated pain, are common precipitants. Significant anxiety is present in most patients with advanced lung disease and is closely related to periods of oxygen desaturation. Medication side effects, especially akathisia from older antipsychotics and antiemetics (including metoclopramide), can present as anxiety. Interpersonal, spiritual, or existential concerns can mimic and exacerbate anxiety. Patients with an anxious or dependent coping style are at high risk of anxiety as a complication of advanced illness. Short of making a diagnosis of a formal anxiety disorder, differentiating normal worry and apprehension from pathologic anxiety requires clinical judgment.

LO 3 Behaviors indicative of pathological anxiety include intense worry or dread, physical distress (eg, tension, jitteriness, or restlessness), maladaptive behaviors and diminished coping, and inability to relax.[12]

Pathological anxiety may be complicated by insomnia, depression, fatigue, GI upset, dyspnea, or dysphagia.[14] Anxiety can also worsen these conditions, if they are already present. Untreated anxiety may lead to numerous complications, including withdrawal from social support, poor coping, limited participation in palliative care treatment goals, and family distress. Reassess the patient for anxiety with any change in behavior or any change in the underlying medical condition. Assessment for formal anxiety disorders or other contributing factors is key to management. A comprehensive review of insomnia may be found in Chapter 41.

▶ *Nonpharmacologic Treatment*

LO 7 LO 8 Regardless of treatment approach chosen, the following principles apply. Ask questions and listen to patients' concerns and fears. Offer emotional support and reassurance when appropriate. Err on the side of treatment—be willing to palliate anxiety. Assess treatment response and side effects frequently. Aim to provide maximum resolution of anxiety and educate patients and families about anxiety and its treatments.

LO 6 Psychotherapies can help manage anxiety, although availability of trained therapists willing to make home visits, and limited stamina and attention span of seriously ill patients, typically make such therapies impractical in the hospice setting. Cognitive and behavioral therapies can be beneficial, including simple relaxation exercises or distraction strategies (ie, focusing on something pleasurable or at least emotionally neutral). Encourage pastoral care visits, especially if spiritual and existential concerns predominate.

LO 8 When an underlying cause of anxiety can be identified, treatment is initially aimed at the precipitating problem, with monitoring to see if anxiety improves or resolves as the underlying cause is addressed.[14]

▶ *Pharmacotherapy*

LO 5 In most cases, management of pathological anxiety in the hospice setting involves pharmacologic therapies. Benzodiazepines are standard treatment; however, selective serotonin reuptake inhibitors (SSRIs), typical and atypical antipsychotics, may be appropriate based on the patient's life expectancy.[14] The primary LO 6 goal of therapy for anxiety in hospice is patient comfort. Aim to prevent anxiety, not just treat it with as needed medications. Think of pain management as an analogy. As with all medications LO 5 that act in the CNS, anxiolytics, such as benzodiazepines, should be dosed at the lower end of the dose range to prevent unnecessary sedation, particularly in the frail and elderly. However, recognize that standard or higher doses may be required. Avoid use of bupropion and psychostimulants for anxiety. Although effective for depression, they are ineffective for anxiety and may make anxiety worse. Many patients have difficulty swallowing as they approach the end of life. Lorazepam, alprazolam, and diazepam tablets are commonly crushed and placed under the tongue with a few drops of water if the liquid formulations are not readily available. Low-dose haloperidol is also used to treat anxiety in palliative care, particularly if delirium is present.[15] Chapter 40 provides more detailed information on appropriate use of anxiolytic agents.

Delirium

▶ *Palliative Care Considerations*

Delirium is very common in hospice, occurring in more than 80% of terminally ill patients, most often in the last few days of life.[11] Potential causes of delirium in the hospice setting include, but are not limited to, medical illness, dehydration, hypoxia, sleep deprivation, metabolic disturbances, sepsis, side effects of drugs

(particularly anticholinergic agents, benzodiazepines, opioids, corticosteroids, tricyclic antidepressants), urinary retention, urinary tract infection, constipation or impaction, uncontrolled pain, or alcohol or drug withdrawal.[7,15]

LO 3 A classic symptom of delirium is clouding of consciousness. This can be manifested by an inability to either maintain or shift attention. Patients also have impaired cognitive functioning, which may or may not include memory disturbances. "Sundowning" is a very common phenomenon at the end of life, especially in the presence of delirium. It presents as daytime sleepiness and nighttime agitation and restlessness. Another common characteristic is fluctuation in severity of delirium symptoms during the course of the day. This can even occur within the course of a single hour or also from day to day. Patients exhibiting agitation from their delirium are easy to identify, but those who present as withdrawn and with diminished responsiveness ("quiet" delirium) are more difficult to diagnose. It is not uncommon for patients to exhibit both quiet and agitated delirium. Treatment is the same for both types of delirium. Delirium is difficult to distinguish from dementia. Delirium more commonly presents as a sudden onset (eg, hours to days), with an altered level of consciousness and a clouded sensorium. However, dementia more commonly presents gradually and with an unimpaired level of consciousness.[15]

LO 4

► *Nonpharmacologic Treatment*

LO 6 Establishing a safe, soothing environment including familiar objects such as photographs and familiar music can be helpful to calm the patient. Minimizing risk of injury is important when the patient is agitated. Providing education to families and caregivers about the causes of delirium, signs and symptoms, and how to best manage it will help reduce their anxiety and distress when it occurs.

► *Pharmacotherapy*

LO 5 The most important initial step is to determine the goal of care. If possible, reverse the underlying cause of delirium to restore the patient to a meaningful cognitive status.[7,11] If the precipitating factors cannot be reversed, initiate to treat the symptoms. If the patient is irreversibly delirious and agitated, drug therapy is generally indicated.

Antipsychotic (neuroleptic) drugs (conventional or atypical antipsychotics) are the drugs most commonly used to treat confusion and agitation associated with delirium. However, treatment of delirium with these drugs is an "off-label" indication. Atypical antipsychotics including risperidone, olanzapine, quetiapine, ziprasidone, paliperidone, and aripiprazole are also an option for management of delirium.[16]

Haloperidol, when given in doses less than 2 mg/day, is well tolerated and nonsedating. Doses greater than 4.5 mg/day are associated with increased incidence of extrapyramidal symptoms.[17] Cumulative doses of 35 mg or single IV doses greater than 20 mg have been associated with QTc prolongation.[18] When sedation is beneficial for terminal aggressive, agitated delirium, chlorpromazine provides more sedation as compared with low-dose haloperidol. When patients are bedbound and in the final stages of life, orthostatic hypotension common with chlorpromazine is not a concern. Haloperidol and chlorpromazine are commonly given sublingually or rectally if swallowing becomes difficult, although these are not approved routes of administration. Haloperidol, but not chlorpromazine, can be given subcutaneously.[19]

LO 5 Administering benzodiazepines alone in a patient with delirium can actually make the delirium and confusion worse. While addition of benzodiazepines with antipsychotics is not routinely used, delirium induced by withdrawal or untreated anxiety may benefit from addition of a benzodiazepine.[13]

Patient Encounter 1

LM is a 67-year-old man diagnosed with prostate cancer with metastases to the left anterior iliac crest and left femoral neck and greater trochanter. He is being seen by the inpatient palliative care team. Past medical history: coronary artery disease, hypertension, benign prostatic hyperplasia, hyperlipidemia, hypothyroidism, depression. No known allergies. LM reports left hip pain rating 7/10 (visual analog pain scale, 0–10). Pain is: deep, constant, aching pain causing limitation in mobility. Pain also radiates down the back of his left leg. Radiating pain is a 6/10 (visual analog pain scale, 0–10), episodic, exacerbated by movement and is a "lightning bolt" down his leg. LM reports worsening of urinary symptoms, constipation, and dizziness upon standing. LM reports bruising to his right elbow and knee after a recent fall.

VS: BP 101/60 mm Hg, RR 20 breaths/min, P 60, wt 60 kg (132 lbs), ht 5'7" (170 cm)

Medications: amlodipine 10 mg by mouth daily, fluoxetine 20 mg by mouth daily, simvastatin 40 mg by mouth daily, tamsulosin 0.4 mg by mouth daily, finasteride 5 mg by mouth daily, levothyroxine 200 mcg by mouth once daily, multivitamin by mouth once daily, hydrocodone/acetaminophen 5-325 1 tablet by mouth every 4 hours as needed, docusate 100 mg by mouth twice daily as needed.

What two types of pain is LM experiencing?

What may be contributing to the worsening of LM's urinary symptoms?

What other urinary symptoms and/or urinary related complications should be monitored for if LM's cancer progresses?

What potential drug–drug interactions may exist, and how would you monitor the patient for these drug interactions?

What medications should be added, changed, or discontinued?

List nonpharmacologic interventions that the practitioner could make to improve the care of LM.

Dyspnea

► *Palliative Care Considerations*

LO 3 Dyspnea is described as an uncomfortable awareness of breathing. It is a subjective sensation, and patient self-report is the only reliable indicator. Respiratory rate or Po_1 may not correlate with the feeling of breathlessness.[20] Respiratory effort and dyspnea are not the same. While opioids do not address bronchoconstriction or bronchospasm, patients may report substantial relief of dyspnea from opioids with no change in respiratory rate. The prevalence of dyspnea varies from 12% to 74%, worsening during the last week of life in terminally ill cancer patients to between 50% and 70%. History and physical examination should be taken and reversible causes of dyspnea should be identified and treated, if present.[21]

► *Nonpharmacologic Treatment*

LO 6 Provide information, anticipate and proactively prepare the patient and family for worsening symptoms. Identify and attempt to minimize triggers that cause episodes of dyspnea. Educate the patient and family regarding treatment of dyspnea, including the use of opioids and benzodiazepines for dyspnea-associated anxiety. Prevent isolation and address spiritual issues that can worsen symptoms. Encourage relaxation and minimize the need for exertion.

Reposition to comfort, usually to a more upright position or with the compromised lung down. Avoid strong odors, perfumes, and smoking in the patient's presence or in close proximity. Improve air circulation/quality: provide a draft, use fans, or open windows and adjust temperature/humidity with air conditioner or humidifier.

► *Pharmacotherapy*

LO 5 If no treatable causes can be identified or when treatments do not completely alleviate distressing symptoms, opioids are first-line agents for treating dyspnea.[21] Opioids suppress respiratory awareness, decrease response to hypoxia and hypercapnia, vasodilate, and have sedative properties. Low-dose opioids (eg, starting oral dose of morphine ~5 mg) have been shown to be safe and effective in the treatment of dyspnea. Opioid doses should be titrated judiciously. Once an effective dose of an opioid has been established, converting to an extended-release preparation may simplify dosing. When using opioids, anticipate side effects and prevent constipation by initiating a stimulant laxative/stool softener combination.

Nebulized opioids for treatment of dyspnea are controversial. Study results have been inconsistent.[22,23] Nonrandomized studies, case reports, and chart reviews describe anecdotal improvement in dyspnea using nebulized opioids; however, several controlled studies using nebulized opioids have provided inconclusive or negative results. Nebulized opioids may be an alternative in patients who are not able or willing to take an oral agent or cannot tolerate adverse effects of systemic administration.

LO 5 Nebulized furosemide appears effective for dyspnea refractive to other conventional therapies.[24] The hypothesized mechanism of action of nebulized furosemide is its ability to enhance pulmonary stretch receptor activity, inhibition of chloride movement through the membrane of the epithelial cell, and its ability to increase the synthesis of bronchodilating prostaglandins.[24]

LO 5 Because anxiety can exacerbate dyspnea, benzodiazepines and antidepressants that have anxiolytic properties are frequently beneficial. Not all dyspnea is caused by low oxygen saturation. However, oxygen therapy is useful and beneficial for dyspnea if hypoxia is present.

For known etiologies of dyspnea, consider the following:

Bronchospasm or COPD exacerbation: Albuterol, ipratropium, and/or oral steroids are effective for symptoms management. Nebulized bronchodilators are more effective than handheld inhalers in patients who are weak and have difficulty controlling breathing.

LO 5 **Thick secretions:** If cough reflex is strong, loosen secretions by increasing fluid intake. Guaifenesin may thin secretions; however, its efficacy in the absence of hydration is controversial. Nebulized saline may also help loosen secretions. If the patient is unable to cough, hyoscyamine, glycopyrrolate, or scopolamine patch can effectively dry secretions.[21] Oral glycopyrrolate is preferred since it has less propensity to cause the anticholinergic side effect of confusion.

Anxiety associated with dyspnea: Consider benzodiazepines (eg, lorazepam, diazepam).

Effusions: Thoracentesis may be necessary.

Low hemoglobin: Red blood cell transfusion (controversial) or erythropoietin (rarely used in hospice but might have larger role in palliative care).

LO 5 **Infections:** Antibiotic therapy as appropriate.

LO 5 **Pulmonary emboli:** Anticoagulants for prevention and treatment or vena cava filter placement (rarely used in hospice but might have a larger role in palliative care).

Patient Encounter 2

KP is a 74-year-old man admitted to hospice with a diagnosis of chronic obstructive pulmonary disease (COPD). Comorbidities include type 2 diabetes mellitus, hyperlipidemia, and hypothyroidism. KP continues to smoke cigarettes (1 ppd) and admits to consuming 2 to 4 beers per day. No known drug allergies. Pulmonary symptoms include moderate to severe dyspnea upon exertion with moderate dyspnea at rest, excessive secretions, chronic productive cough; he is oxygen dependent and has recurrent pneumonias requiring hospitalizations. KP reports poor appetite, uncontrolled anxiety, and insomnia.

VS: BP 145/50 mm Hg, RR 45 breaths/min, P 88, Wt 54.5 kg (120 lb), Ht 5'8" (173 cm)

Medications: Metformin 1000 mg by mouth twice daily, glipizide 5 mg by mouth once daily, atorvastatin 10 mg by mouth daily, levothyroxine 250 mcg daily, tiotropium handihaler inhale the contents of one capsule once daily, fluticasone/salmeterol dry powder inhaler, one inhalation by mouth twice daily, albuterol inhaler two puffs every 6 hours as needed for shortness of breath.

What parameters should be assessed prior to making changes to or adding additional interventions for KP's current situation?

What medications could be added, changed, or discontinued?

What are some nonpharmacologic interventions for treating KP's shortness of breath?

LO 5 **Rales due to volume overload:** Reduction of fluid intake or diuretic therapy as appropriate.

Nausea and Vomiting

A comprehensive review of nausea and vomiting may be found in Chapter 20.

► *Palliative Care Considerations*

Up to 71% of palliative care patients will develop nausea and vomiting with ~40% experiencing these symptoms in the last 6 weeks of life. Chronic nausea can be defined as lasting longer than a week and without a well-identified or self-limiting cause, such as chemotherapy, radiation, or infection.[3] Four major mechanisms are correlated with the stimulation of the vomiting center (Figure 4–2). Potentially reversible causes of nausea and vomiting should not be overlooked. Causes of chronic nausea in end-of-life patients may include autonomic dysfunction, constipation, antibiotics, nonsteroidal anti-inflammatory drugs (NSAIDs), other drugs, infection, bowel obstruction, metabolic abnormalities (eg, renal or hepatic failure, hypercalcemia), increased intracranial pressure, anxiety, radiation therapy, chemotherapy, or untreated pain.[23,25,26]

LO 3 LO 4

LO 4

► *Nonpharmacologic Treatment*

LO 6 Relaxation techniques may prove beneficial. Strong foods or odors should be avoided and eliminate offending medications.

► *Pharmacotherapy*

LO 5 Clinical features of nausea and vomiting should guide the choice of antiemetics used (for a more comprehensive review, see Chapter 20).

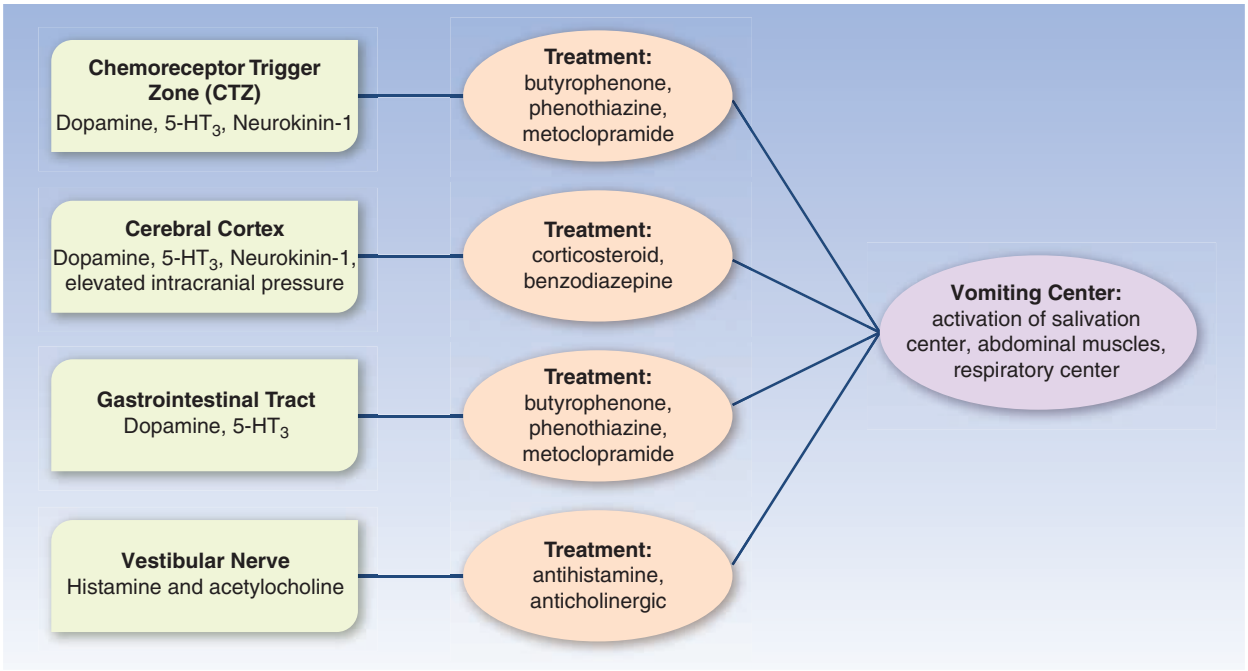

FIGURE 4–2. Mechanisms and associated neurotransmitters involved in nausea and vomiting.[7,28,25]

LO 5 Chemoreceptor trigger zone (CTZ)-induced nausea and vomiting are caused by chemotherapeutic agents, bacterial toxins, metabolic products (eg, uremia), and opioids. Dopamine (D_2), serotonin (5-Hydroxytryptamine [5-HT]), and neurokinin-1 are the primary neurotransmitters involved in this process. Therapy is based on blocking D_2 with D_2-antagonists including butyrophenones (eg, haloperidol), phenothiazines, and metoclopramide.

Due to receptor specificity, serotonin$_3$ (5-HT$_3$) antagonists such as ondansetron, granisetron, dolasetron, and palonosetron have limited usefulness in nausea and vomiting at the end of life.[7,25] They are typically indicated with emetogenic chemotherapy and up to 10 to 14 days posttreatment. Aprepitant is a neurokinin-1 antagonist indicated for the treatment of nausea due to highly emetogenic chemotherapy in combination with a 5-HT$_3$ antagonist and corticosteroid. Aprepitant should not be used as monotherapy.[23]

LO 4 LO 5 **Cerebral cortex**–induced nausea and vomiting can be caused by anxiety, taste, and smell, and also secondary to increased intracranial pressure. Corticosteroids decrease intracranial pressure due to tumor involvement. Corticosteroids have been found to be effective in nonspecific nausea and vomiting. The mechanism of this action is unknown. Anxiolytics such as benzodiazepines are used to treat anxiety and "anticipatory" gustatory and olfactory stimulation.[23]

Vestibular nausea and vomiting is triggered by motion. Opioids can sensitize the vestibular center resulting in movement-induced nausea. Since histamine and acetylcholine are the predominant neurotransmitters, antihistamines and anticholinergics are the drugs of choice in movement-induced nausea and vomiting.

LO 4 **GI tract** stimulation occurs through vagal and sympathetic pathways. These pathways are triggered by stimulation of mechanoreceptors or chemoreceptors located in the gut. Gastric stasis, GI obstruction, drugs, metastatic disease, bacterial toxins, chemotherapeutic agents, and irradiation may cause nausea and vomiting. Glossopharyngeal or vagus nerve stimulation in the pharynx by sputum, mucosal lesions, or infection (eg, *Candida*) can also evoke nausea. The major neurotransmitters in the upper GI tract are D_2, acetylcholine, and 5-HT. Metoclopramide is a 5-HT$_4$ agonist and increases gastric motility above the jejunum, whereas anticholinergics decrease GI spasticity and motility in nausea induced by gut hyperactivity. In high doses, metoclopramide also acts as a 5-HT$_3$ antagonist.[7,23]

Autonomic failure causes gastroparesis resulting in anorexia, nausea, early satiety, and constipation. Delayed gastric emptying occurs in patients with diabetes mellitus, chronic renal failure, and neurological disorders. Malnutrition, cachexia, lung and pancreatic cancers, HIV, radiotherapy, and drugs such as opioids, anticholinergics, antidepressants, and vasodilators have been associated with autonomic failure and resulting chronic nausea, poor performance, tachycardia, and malnutrition. Evaluate underlying causes, including multiple drugs that may cause gastroparesis. If drug therapy is indicated, metoclopramide is effective in improving gastric emptying.[7]

LO 4 LO 5 **GI irritation** can cause nausea and vomiting due to generalized gastritis, gastroesophageal reflux disease (GERD), or peptic ulcer disease. Histamine$_2$ (H_2) antagonists or proton pump inhibitors (PPIs) are considered the drugs of choice for ongoing gastritis.

Refractory cases of nausea and vomiting often require judiciously selected combinations of medications from different classes (eg, various combinations of haloperidol, metoclopramide, lorazepam, and dexamethasone).

Pain

A comprehensive review of pain management may be found in Chapter 34.

▶ *Palliative Care Considerations*

LO 7 According to the SUPPORT study, 74% to 95% of very ill or dying patients still experience uncontrolled pain.[26] Conducting a comprehensive pain assessment is key to choosing appropriate therapeutic interventions. Palliative care patients must be evaluated for anxiety, depression, delirium, and other neurological influences that may heighten a patient's awareness or response to pain.

▶ *Nonpharmacologic Treatment*

LO6 Nonpharmacologic treatment is essential. Physical, complementary, and cognitive behavioral interventions reduce the perception of pain and decrease the dose requirements of medications. Examples of such strategies may include providing education, massage, ice, heat, physical therapy, music therapy, imagery, pet therapy, and psychotherapy.

▶ *Pharmacotherapy*

LO7 LO5 Pain should be assessed thoroughly and frequently, especially at the onset of treatment. The WHO approach to pain management addresses nociceptive pain (see Chapter 34). Although opioid analgesics are not always necessary or appropriate for all types of pain, most patients with cancer-related pain require opioids. For chronic, constant pain, around-the-clock dosing of analgesics (preferably long-acting agents) is usually necessary and preferred.[27] When titrating opioid doses, increase daily maintenance doses by 25% to 50% if patients are routinely requiring three or more breakthrough doses per 24 hours as a result of around-the-clock maintenance dose failure. The around-the-clock maintenance doses should not be increased if breakthrough doses are used only for incident pain such as increased activity or dressing changes.

Fentanyl transdermal patches may be appropriate in some patients; however, many patients at the end of life experience fat and muscle wasting and dehydration, resulting in reduced and variable absorption. Fentanyl transdermal patches have a slow onset of action, contributing to difficulty in dose titration.[7]

LO5 Only short-acting opioids should be used for breakthrough pain (eg, immediate-release morphine, oxycodone, and hydromorphone are common examples). The dose of short-acting opioids for the treatment of breakthrough pain should be equal to 5% to 20% of the total daily maintenance dose. Frequencies for breakthrough dosing should not exceed the following:

- **Oral:** Every 1 to 2 hours
- **Subcutaneous:** Every 20 to 30 minutes
- **IV:** Every 8 to 20 minutes

LO8 Monitor for and appropriately treat common side effects of opioids. Common side effects of opioids include constipation, nausea and vomiting, itching, and transient sedation. Because constipation occurs with all chronic opioid therapy, prevention is imperative. Stimulant laxatives (senna or bisacodyl) with or without a stool softener (docusate) are the drugs of choice for opioid-induced constipation.[7] Myoclonus, delirium, hallucinations, and hyperalgesia are possible signs of opioid-induced neurotoxicity and require rotation to another opioid or dose reduction. Respiratory depression is uncommon with the appropriate opioid dose titration. However, if dangerous opioid-induced respiratory depression does occur, small doses (0.1 mg) of the μ receptor antagonist naloxone are appropriate and can be repeated as necessary. The goal is to increase respirations to a safe level while preventing the patient from experiencing a loss of pain control.

LO5 Different types of pain may require specific types of analgesics or adjuvant medications. Identification and treatment of these separate pain types will help avoid unnecessary opioid dose escalations and opioid side effects. Examples of pain types commonly seen in patients with advanced illness are as follows. See Figure 4–3 for medication options.

LO4 **Visceral pain** (nociceptive pain induced by stretching or spasms of visceral organs including the GI tract, liver, and pancreas) should be treated with an adjuvant such as an anticholinergic agents or, if inflammation is associated with the pain, corticosteroids.

Bone pain (metastatic site of cancer) is best treated with NSAIDs or corticosteroids in addition to standard opioid therapy.

Neuropathic pain (pain caused by damage to the afferent nociceptive fibers) can be managed with tricyclic antidepressants, antiepileptic drugs, tramadol, tapentadol or *N*-methyl-D-aspartate antagonists, such as ketamine. Methadone is an opioid μ-agonist that has a role in neuropathic pain given its added *N*-methyl-D-aspartate antagonist activity. Methadone has a very long half-life as compared to most other opioids, except buprenorphine. It should be used with caution and under the close supervision of clinicians experienced in the use of this drug for pain management.

Terminal Secretions

▶ *Palliative Care Considerations*

Terminal secretions, or death rattle, is the noise produced by the oscillatory movements of secretions in the upper airways in association with the inspiratory and expiratory phases of respiration.[28,29] LO4 As patients lose their ability to swallow and clear oral secretions, accumulation of mucus results in a rattling or gurgling sound produced by air passing through mucus in the lungs and air passages. The sound does not represent any discomfort for the patient. However, the sound is sometimes so distressing to the family that it should be treated. LO4 Terminal secretions are typically seen only in patients who are obtunded or are too weak to expectorate. LO5 Drugs that decrease secretions are best initiated at the first sign of death rattle because they do not affect existing respiratory secretions. These agents have limited or no impact when the secretions are secondary to pneumonia, pulmonary congestion, or edema.[30]

▶ *Nonpharmacologic Treatment*

LO6 Position the patient on their side or in a semiprone position to facilitate drainage of secretions. If necessary, place the patient in the Trendelenburg position (lowering the head of the bed); this allows fluids to move into the oropharynx, facilitating an easy removal. Do not maintain this position for long due to the risk of aspiration. Oropharyngeal suctioning is another option but may be disturbing to the patient and visitors. LO6 Fluid intake can also be decreased, as appropriate.[30]

▶ *Pharmacotherapy*

LO5 LO6 Anticholinergic drugs remain the standard of therapy for prevention and treatment of terminal secretions due to their ability to effectively reduce the future production of secretions.[28-30] Drugs used for this indication are similar pharmacologically, and one can be selected by anticholinergic potency, onset of action, route of administration, alertness of patient, and cost. LO6 The most commonly used anticholinergic agents are atropine, hyoscyamine, scopolamine, and glycopyrrolate.

Anticholinergic side effects include blurred vision, constipation, urinary retention, confusion, delirium, restlessness, hallucinations, dry mouth, and heart palpitations. Unlike the other anticholinergics, glycopyrrolate does not cross the blood–brain barrier and is associated with fewer CNS side effects, and is often preferred, if the use of anticholinergic intervention is prolonged for more than 7 to 10 days. Glycopyrrolate is a potent drying agent when compared with other agents and has the potential to cause excessive dryness.[30]

Pharmacologic Adjuvants: Nociceptive Pain	
Bone Pain *(inflammatory)*	
Nonsteroidal anti-inflammatory drug (NSAID)	
Ibuprofen (Motrin)[a] Naproxen (Naprosyn)[a] Celecoxib (Celebrex)[b] Meloxicam (Mobic)[b]	• Often first-line for untreated diffuse bone pain • Similar efficacy among NSAIDs; however, the risks of GI bleeding, GI ulcers, renal toxicity, and cardiovascular concerns are higher among the nonselective NSAIDs • Selective NSAIDs have less GI effects, but retain risk of renal toxicity
Bisphosphonates	
Zolendronic acid (Zometa) Pamidronate (Aredia) Ibandronate (Boniva)	• Role in treating diffuse bone pain • Intravenous administration with renal monitoring • Monitor: osteonecrosis of the jaw, follow-up with dental evaluation
Steroids	
Dexamethasone (Decadron) Methylprednisolone (Medrol) Prednisone (Deltasone)	• May be preferred over NSAIDs for diffuse bone pain in patients experiencing anorexia and fatigue • Burst and taper recommended for rapid pain control • Monitor: edema, glucose, insomnia, GI upset • Less edema with mineralcorticosteroid • Administer doses earlier in the day with food to avoid insomnia and GI upset
Visceral Pain	
Anticholinergic/Antispasmodics	
Dicyclomine (Bentyl) Glycopyrolate (Robinul IV) Hyoscyamine (Levsin) Scopolamine (Transderm Scop)	• Monitor: *(especially in elderly)* constipation, dry mouth, confusion, dizziness, urinary retention • Steroids may also be used concurrently for visceral pain with associated inflammatory processes (ie, pleuritic pain, capsular organ pain, diffuse intestinal cancer) • Often used short term for treatment of terminal secretions "death rattle"
[a]Nonselective NSAID [b]COX-II selective NSAID	

FIGURE 4–3. Pharmacologic adjuvants for the treatment of bone pain and inflammatory pain.[7,23,26]

Advanced Heart Failure

▶ *Palliative Care Considerations*

LO 3 Heart failure symptoms at the end of life may include hypotension, volume overload, edema, and fatigue. Patients should be assessed to confirm symptoms are related to heart failure rather than other disease states to ensure appropriate treatment.[31]

LO 5 Goals for advanced heart failure treatment differ from traditional heart failure management. Drug therapy focuses on symptom management rather than improving mortality. Prevention of cardiovascular disease through cholesterol reduction is no longer necessary at this point.

▶ *Nonpharmacologic Treatment*

LO 6 Patients should be maintained in a comfortable position with feet elevated to minimize lower leg fluid accumulation. Minimizing high-salt foods and limiting fluid intake can help reduce fluid accumulation. At this stage in heart failure, comfort becomes the primary initiative.

▶ *Pharmacotherapy*

LO 7 As patients approach the end of life, it is difficult to determine when certain medications for heart failure should be dose reduced or discontinued. The following general principles may help serve as a guide. However, each individual's history, prognosis, and current condition should be evaluated to determine appropriateness.

LO 5 LO 6 If a patient becomes symptomatic due to hypotension, angiotensin-converting enzyme (ACE) inhibitor, angiotensin receptor blocker (ARB), and/or β-adrenergic blocker doses should be reduced or discontinued. For β-adrenergic blockers, in particular, this should be done gradually to avoid significant clinical deterioration. If volume overload occurs or persists while taking β-adrenergic blocker therapy, consider tapering off the medication. Likewise, for patients experiencing fatigue while taking a β-adrenergic blocking agent, consider tapering down the dose *only if* their heart rate does not increase with exertion. Consider discontinuing the ACE inhibitor (or the angiotensin receptor blocker) if the patient's renal function deteriorates (eg, cardiorenal syndrome).

In patients with excessive fluid overload where sodium and water intake restrictions are not effective or not possible, consider increasing the dose of diuretic. However, vascular dehydration can occur in some patients with end-stage heart failure if the dose of diuretic is excessive.

Patient Encounter 3

JM is a 45-year-old man recently diagnosed with pancreatic cancer. He received several rounds of palliative chemotherapy with localized radiation over the past few months with the last chemotherapy and radiation administered 4 weeks ago. The interventions were unsuccessful in limiting tumor growth, which has now metastasized to liver, brain, and right intercostal bones. JM has jaundice with mild ascites with no reported pruritus. JM's chief complaint today is uncontrolled nausea and vomiting which worsens with meals and has been going on for a week. The oncologist prescribed ondansetron 8 mg by mouth every 8 hours as needed. JM has the prescription at home and has taken two doses without benefit or improvement in his nausea. Comorbidities include hypertension and depression with recent uncontrolled anxiety. Allergy: Codeine (reaction unknown). Medications include: hydrocodone/acetaminophen 5-325 1–2 tablets by mouth every 4–6 hours as needed for pain, ibuprofen 200 mg 1–2 tablets by mouth every 4–6 hours as needed for pain and acetaminophen 500 mg 1–2 tablets by mouth every 6 hours as needed, ondansetron 8 mg by mouth every 8 hours as needed for nausea, dexamethasone 4 mg by mouth twice daily (give after breakfast and after lunch).

What are potential causes of JM's nausea and vomiting? Based on this differential list, what questions would you ask JM during your assessment of his nausea and vomiting?

What potential drug–drug interactions and side effects exist in this patient?

What medications could be added, changed, and/or discontinued?

How does the patient's reported allergy to codeine impact potential treatment options?

LO 7 LO 8 Digoxin toxicity is common; therefore, patients should be carefully monitored and therapy adjusted or discontinued as appropriate. The symptoms of digoxin toxicity including complaints of anorexia, nausea and vomiting, visual disturbances, disorientation, confusion, or cardiac arrhythmias.[31]

LO 7 Hydroxymethylglutaryl coenzyme-A (HMG-CoA) reductase inhibitors (and other cholesterol-lowering medications) are likely to have a long-term effect rather than a palliative effect.

Figure 4–1 provides a list of agents that improve functional status in advanced heart failure patients.

OUTCOME EVALUATION

KEY CONCEPT Involving the patient, family, and caregivers in the development of the therapeutic plan demonstrates responsible palliative care. Before the implementation of drug therapy, LO 8 the patient, family, and caregiver should be involved with the decision-making process. The practitioner should provide information about all reasonable options for care so that the patient, family, and caregivers can collaborate with the health care team to meet their combined goals. KEY CONCEPT Positive therapeutic outcomes include resolution of symptoms while minimizing adverse drug events. When treating symptoms pharmacologically, adverse drug events must be avoided or minimized to prevent negative outcomes.

Patient Care Process

Collect Information:

- Evaluate physical examination, review of systems and relevant laboratory findings and assess for symptoms related to, or worsened by their current hospice diagnosis.
- Perform medication reconciliation (prescription, OTC medications, herbal).
- Determine the goal as they relate to the hospice plan of care.
- Identify cultural, spiritual, or ethnic traditions that impact patient care and incorporate those aspects into the plan of care.

Assess the Information:

- Ensure that medications confer benefit for functional status rather than only survival (see Figure 4–1) and that this approach supports the patient's goals.
- Establish realistic medication outcomes prior to initiating or titrating a medication for palliative care.
- Verify prescription coverage or institutional formulary when adding medications.
- Provide preventative care recommendations (ie, immunization, annual health screening, etc.), and discuss their health benefits.

Develop a Care Plan:

- Based on prognosis of a health condition, determine if continuing medication for preventative or long-term management is appropriate.
- If laboratory monitoring is discontinued, medications with a narrow therapeutic index may be discontinued.
- Ensure that medications are appropriate for the patient's functional status.
- Evaluate adherence strategies and monitor for side effects.
- Before adding a medication to treat symptoms, ensure that the symptom is not attributable to current medications.

Implement the Care Plan:

- Involve the patient, family, and caregivers in development of pharmacologic/nonpharmacologic strategies based on patient's goals.
- Share patient preferences, priorities, and goals with health care providers.
- Communicate resuscitation preferences with caregivers and health care providers.

Follow-up: Monitor and Evaluate:

- Monitor results following initiation of drug therapy, and discuss findings in context to symptom prioritization, goals, and outcomes.
- Continuous evaluation of therapy as functional status (ie, ambulation, swallowing, continence) changes, and ensure safe and effective medication use.
- Encourage the patient, family, and caregivers to contact the hospice or palliative team with questions.
- Bimonthly reviews of the patient's medical condition, medications, and goals occur during hospice interdisciplinary meetings.

LO 7 Patients with life-limiting diseases have emotional and spiritual issues that deserve attention by trained professionals. Addressing these concerns and providing support and coping skills can dramatically reduce the medication requirements for symptom control. Psychosocial and spiritual support is not only directed toward the patient in palliative care but also supports the family during the time of the illness and after the death of their loved one.

LO 8 KEY CONCEPT Patient and caregiver education is vital to ensuring positive outcomes. If the patient and caregiver are unaware of the purpose and goals for interventions used in palliative medicine, adherence to regimens will be hindered and outcomes will be compromised. Education regarding the role and value of the palliative care team will allow the patient and family to understand why palliative care is important to their overall quality of life. Patients will achieve the best possible outcomes when practitioners incorporate the interdisciplinary palliative care approach to care early in the disease progression of patients with life limiting illnesses.

Abbreviations Introduced in This Chapter

5-HT	5-Hydroxytryptamine (serotonin)
ACE	Angiotensin-converting enzyme
ALS	Amyotrophic lateral sclerosis
ARB	Angiotensin receptor blocker
CHF	Chronic heart failure
COPD	Chronic obstructive pulmonary disease
CTZ	Chemoreceptor trigger zone
CVA	Cerebral vascular accident
GERD	Gastroesophageal reflux disease
HMG-CoA	Hydroxymethylglutaryl coenzyme-A
NSAID	Nonsteroidal anti-inflammatory drug
PPI	Proton pump inhibitor
SSRI	Selective serotonin reuptake inhibitor
WHO	World Health Organization

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify guideline-based treatment goals for patients with hypertension.
2. Recognize underlying causes and contributing factors in the development of hypertension.
3. Describe the appropriate measurement of blood pressure (BP).
4. Classify BP levels after appropriate measurement.
5. Recommend appropriate lifestyle modifications.
6. Determine patient-centered pharmacotherapy for individuals with hypertension.
7. Identify specific conditions and populations requiring special consideration when designing a treatment plan for hypertension.
8. Construct an appropriate monitoring plan to assess hypertension treatment.

INTRODUCTION

It is well established that reducing elevated blood pressure (BP) in patients at sufficient risk provides significant cardiovascular benefit. However, despite efforts to promote awareness, treatment, and management of high BP, control remains suboptimal. Worldwide, approximately one-third of adults have controlled BP, and in the United States, slightly over one-half of adults experience control.[1] Based on clinical evidence, national and international organizations continually refine recommendations on the management of patients with high BP. The purpose of this chapter is to: (a) provide a summary of key issues associated with the management of hypertension; (b) discuss the basic approach to treating hypertension and provide a functional summary of the prevailing themes of contemporary guidelines; and (c) summarize pharmacotherapeutic issues essential for clinicians to consider when treating hypertension.

Various algorithms recommend nonpharmacologic and pharmacologic management, with the underlying premise that lowering elevated BP reduces target organ damage leading to reductions in stroke, myocardial infarction (MI), end-stage renal disease, and heart failure (HF). BP targets and treatment recommendations for a particular patient may vary based on different guidelines and/or position statements, depending on their interpretation of the clinical evidence available at the time of development. This chapter primarily focuses on the most recent comprehensive, evidence-based 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults, put forth by the American College of Cardiology/American Heart Association (ACC/AHA) Task Force on Clinical Practice Guidelines and hereafter referred to as the 2017 ACC/AHA guidelines.[2]

KEY CONCEPT The 2017 ACC/AHA guidelines classify BP and provide guidance on accurate assessment of BP as well as the nonpharmacologic and pharmacologic approaches to managing hypertension. Various guidelines recognize that the lowest risk of adverse cardiovascular or renal outcomes is at a BP around 115/75 mm Hg, with risk rising as BP increases. For each increase by 20 mm Hg in systolic BP (SBP), or approximate 10 mm Hg increase in diastolic BP (DBP), the risk of death from ischemic heart disease, stroke, and other vascular diseases increases by twofold in individuals aged 40 to 69 years. The risk is even greater in older individuals.

KEY CONCEPT The 2017 ACC/AHA guidelines classify elevations in BP beyond specific thresholds as elevated BP, stage 1 hypertension, and stage 2 hypertension (Table 5–1) to imply different levels of risk and the need for varying intensities of intervention with drug therapy.[2] Specific BP thresholds for treatment and BP goals of therapy are established based on cardiovascular risk assessment or the presence of specific comorbid conditions (Figure 5–1 and Table 5–2).[2] Recommendations for BP-lowering medications typically begin with one or two (in the case of stage 2 hypertension and average BP of 20/10 mm Hg above the BP target) antihypertensive drugs. In addition, recommendations

Table 5–1

Classification of Hypertension in Adults[a,2]

BP Classification	Systolic BP (mm Hg)		Diastolic BP (mm Hg)
Normal	< 120	AND	< 80
Elevated	120–129	AND	< 80
Stage 1 hypertension	130–139	OR	80–89
Stage 2 hypertension	≥ 140	OR	≥ 90

[a]Adults with SBP and DBP in two categories should be assigned to the higher BP classification.

BP, blood pressure.

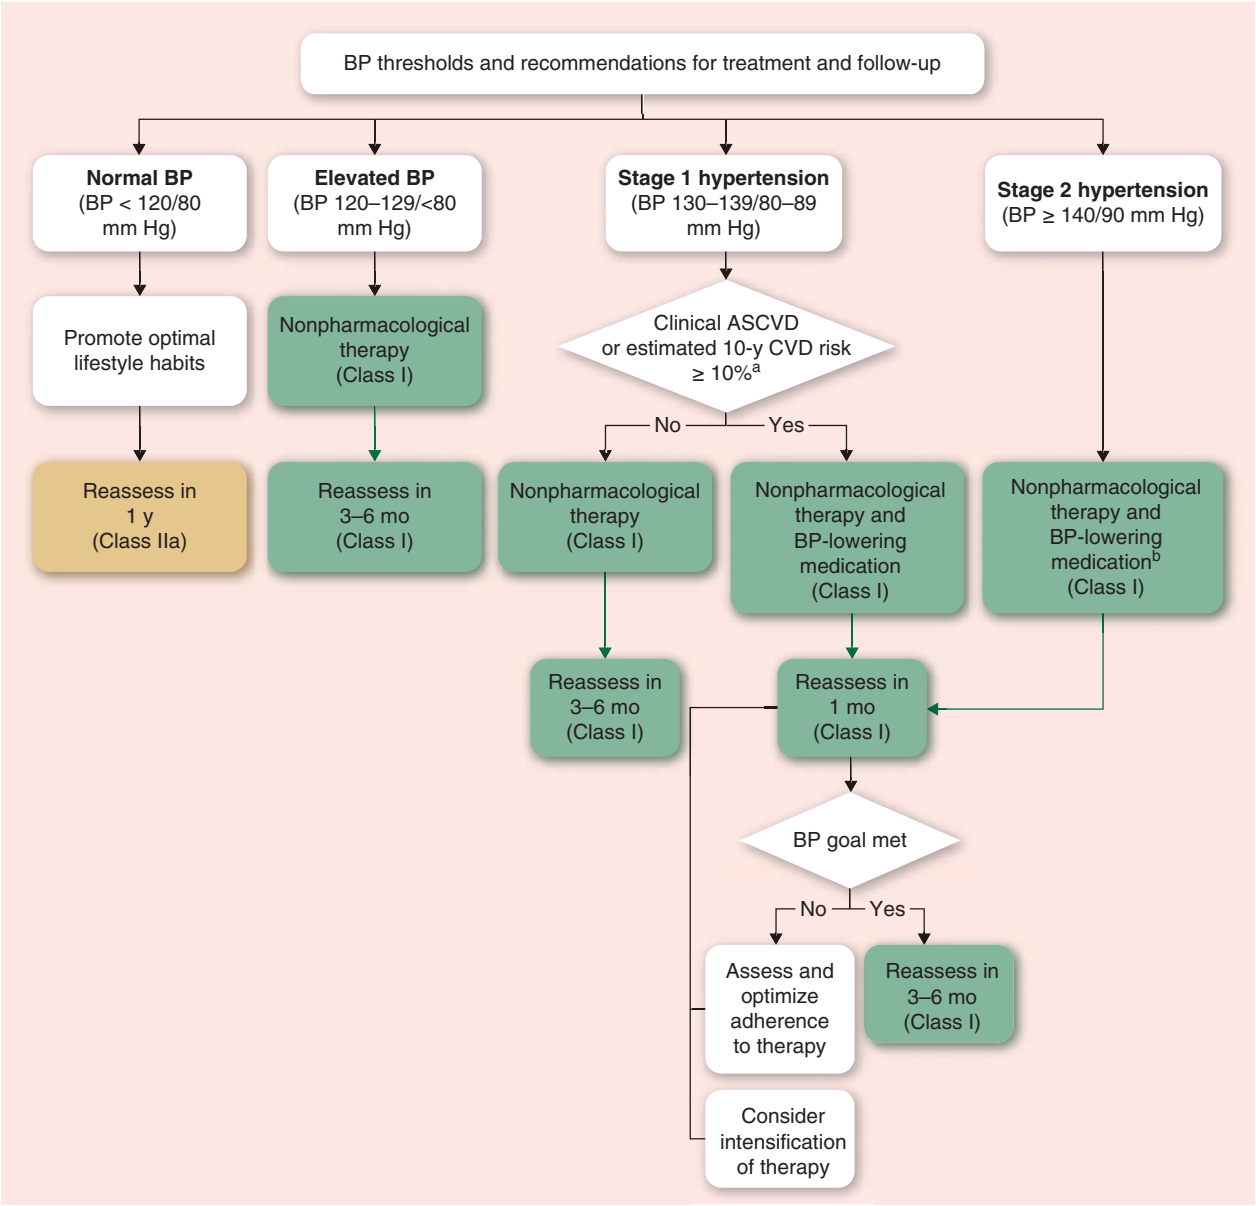

FIGURE 5–1. General recommendations for blood pressure (BP) threshold and recommendations for treatment and follow-up. Patients with elevated BPs should incorporate nonpharmacologic therapies to promote BP lowering. As BP reaches stage 1 hypertension thresholds for therapy are guided based on a patient's level of risk as determined by baseline presence of cardiovascular disease, chronic kidney disease (CKD) or diabetes mellitus (DM) (all placing patient at higher risk) and cardiovascular disease risk as calculated with the American College of Cardiology/American Heart Association (ACC/AHA) Pooled Cohort Equations (values ≥ 10% defining higher risk). Lower risk patients are reasonable for an initial trial of nonpharmacologic therapies while those with higher risk or stage 2 hypertension are initially begun on BP-lowering medications. Consideration may be given in patients with stage 2 to the initiation of combination therapy at treatment onset. "Class" indicates the strength of the recommendation, with Class I considered the strongest. [a]Using the ACC/AHA Pooled Cohort Equations. Note that patients with DM or CKD are automatically placed in the high-risk category. For initiation of renin–angiotensin system (RAS) inhibitor or diuretic therapy, assess blood tests for electrolytes and renal function 2 to 4 weeks after initiating therapy. [b]Consider initiation of pharmacological therapy for stage 2 hypertension with 2 antihypertensive agents of different classes. Patients with stage 2 hypertension and BP greater than or equal to 160/100 mm Hg should be promptly treated, carefully monitored, and subject to upward medication dose adjustment as necessary to control BP. Reassessment includes BP measurement, detection of orthostatic hypotension in selected patients (eg, older or with postural symptoms), identification of white coat hypertension or a white coat effect, documentation of adherence, monitoring of the response to therapy, reinforcement of the importance of adherence, reinforcement of the importance of treatment, and assistance with treatment to achieve BP target. (ASCVD, atherosclerotic cardiovascular disease; CVD, cardiovascular disease; mo, month; y, year.) (Whelton PK, Carey RM, Aronow WS, Casey DE, Collins KJ, et al. 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults. Hypertens. 2017.)

Table 5–2

Blood Pressure Thresholds and Goals of Pharmacologic Therapy in Patients with Hypertension According to Clinical Conditions[2]

Clinical Condition(s)	BP Threshold for Antihypertensive Therapy Initiation (mm Hg)	BP Goal (mm Hg)
General		
Clinical CVD or 10-year ASCVD risk ≥ 10%	≥ 130/80	< 130/80
No Clinical CVD and 10-year ASCVD risk < 10%	≥ 140/90	< 130/80
Older persons (≥ 65 years of age; noninstitutionalized ambulatory, community-living adults)	≥ 130 (SBP)	< 130 (SBP)
Specific Conditions		
Diabetes mellitus	≥ 130/80	< 130/80
Chronic kidney disease	≥ 130/80	< 130/80
Chronic kidney disease postrenal transplantation	≥ 130/80	< 130/80
Heart failure	≥ 130/80	< 130/80
Stable ischemic heart disease	≥ 130/80	< 130/80
Secondary stroke prevention	≥ 140/90	< 130/80
Secondary stroke prevention (lacunar)	≥ 130/80	< 130/80
Peripheral arterial disease	≥ 130/80	< 130/80

ASCVD, atherosclerotic cardiovascular disease (calculator available online at http://tools.acc.org/ascvd-risk-estimator/); BP, blood pressure; CVD, cardiovascular disease; SBP, systolic blood pressure.

Adapted from Whelton PK, Carey RM, Aronow WS, Casey DE, Collins KJ, et al. 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults. Hypertens. 2017, with permission.

for specific medications are provided by race and/or the presence of compelling indications (Table 5–3) for which explicit evidence in the literature exists to document the utility of a particular agent or class of agents.[2,3] Selection of subsequent drug therapy involves an iterative process of adding antihypertensive drugs as needed to achieve target BP, otherwise known as a stepped approach. Although calls for greater personalization in selecting drug therapy have been advocated, including plasma renin

Table 5–3

Compelling Indications for Individual Drug Classes[2,3]

	Recommended Drug Class						
Compelling Indication	**Diuretic**	**Ald Ant**	**BB**	**CCB**	**ACE-I**	**ARB**	**Dir Vaso**
Heart failure with reduced ejection fraction	X	X	X		X	X	X
Heart failure with preserved ejection fraction	X		X		X	X	
Stable ischemic heart disease[a]	X	X	X	X	X	X	
Chronic kidney disease[b]					X	X	
Post renal transplantation				X	X[c]		
Diabetes	X			X	X[d]	X[d]	
Secondary stroke prevention	X				X	X	
Atrial fibrillation						X	
Peripheral arterial disease	X			X	X	X	
Thoracic aortic disease			X				
Black race[e]	X			X			

[a]Recommended β-blockers for BP control or angina relief include carvedilol, metoprolol tartrate, metoprolol succinate, nadolol, bisoprolol, propranolol, and timolol. Avoid β-blockers with intrinsic sympathomimetic activity. Atenolol should not be used as it is less effective than placebo for reducing cardiovascular events. CCBs recommended (class I) if blood pressure goal not met with BB, ACE-I or ARBs, and angina pectoris present.

[b]Recommendations stronger (class IIa) for patients with chronic kidney disease (CKD) and albuminuria (≥ 300 mg/day or ≥ 300 mg/g creatinine) and weaker (class IIb) for CKD stage 3 or higher without albuminuria or stage 1 or 2 with albuminuria (≥ 300 mg/day or ≥ 300 mg/g creatinine).

[c]ACE-I may be reserved in the development of albuminuria or heart failure after transplantation.

[d]ACE-I or ARB may be considered in the presence of albuminuria.

[e]Black adults with or without diabetes mellitus but without heart failure or CKD.

ACE-I, angiotensin-converting enzyme inhibitor; Ald Ant, aldosterone antagonist; ARB, angiotensin receptor blocker; BB, β-blocker; CCB, calcium channel blocking agent; Dir Vaso, direct vasodilator.

Data from Whelton PK CR, Aronow WS, et al. 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults. J Am Coll Cardiol. 2017; and Chobanian AV, Bakris GL, Black HR, et al. Seventh report of the joint national committee on prevention, detection, evaluation, and treatment of high blood pressure. Hypertension. 2003;42(6):1206–1252.

activity (PRA) testing or noninvasive hemodynamic monitoring, these approaches are not widely used.[4,5] In contrast, the roles of 24-hour ambulatory BP monitoring (ABPM), home BP (HBP) monitoring, and ambulatory office-based BP (AOBP) monitoring have been increasingly clarified in the context of select patient groups.[6,7] Regardless of the guideline and strategy implemented in practice, it is imperative that clinicians consider patient-specific characteristics and preferences among other considerations when establishing BP targets and drug selection.

EPIDEMIOLOGY

KEY CONCEPT Hypertension is widely prevalent and significantly contributes to cardiovascular-related morbidity, mortality, and associated health care costs. Worldwide in 2014, around 22% of adults aged 18 years and over had hypertension.[8] In the United States, the prevalence of hypertension was estimated to include nearly 86 million individuals (one in three adults 20 years of age or older), with an estimated $51.2 billion spent annually in direct and indirect costs.[1] When applying the definition of hypertension in the 2017 ACC/AHA guidelines, the estimated prevalence of American adults with hypertension increases to nearly half (46%) of the US adult population.[2] The prevalence of hypertension differs based on age, sex, and ethnicity. As individuals age, risk of systolic hypertension increases. Hypertension is slightly more prevalent in men than women before the age of 35, similar between the ages of 35 and 64 years, and more prevalent in women than men 65 years and older. Age-adjusted prevalence of hypertension is highest in non-Hispanic blacks (40.3%–42.9%) when compared with non-Hispanic whites (30.4%–27.6%) and Mexican Americans (26.5%–27.2%).[1]

ETIOLOGY

KEY CONCEPT The cause of hypertension is usually unknown and referred to as primary hypertension in more than 90% of patients. However, in some patients there is an identifiable cause of hypertension, referred to as secondary hypertension. Causes of secondary hypertension include:[9]

LO 2

- Chronic kidney disease (CKD) (renal parenchymal disease)
- Coarctation of the aorta
- Cushing syndrome and other glucocorticoid excess states
- Drug induced/related (Table 5–4)
- Pheochromocytoma/paraganglioma
- Primary aldosteronism and other mineralocorticoid excess states
- Renovascular hypertension
- Obstructive sleep apnea
- Thyroid or parathyroid disease

The 2017 ACC/AHA guidelines recommend screening for secondary causes of hypertension for uncontrolled drug-resistant hypertension (three or more drugs), abrupt onset, age less than 30 years, excessive target organ damage, onset of diastolic hypertension in older adults or in the presence of unprovoked or excessive hypokalemia.[2] In addition to primary and secondary hypertension, the clinician may encounter what is referred to as resistant hypertension. KEY CONCEPT Patients failing to achieve goal BP despite adherence to optimal doses of three antihypertensive agents of different classes (ideally, one being a diuretic) have resistant hypertension and should be evaluated for secondary causes of hypertension.[10] Several causes of resistant hypertension are listed in Table 5–4 and should be carefully considered in such patients.[11] Additional consideration should be given to the clinical scenario of pseudohypertension, or elevated BP resulting from a myriad of potentiating factors including therapy adherence, white coat hypertension, or poor BP measurement technique.[10]

LO 2

Table 5–4

Causes of Resistant Hypertension[11]

Apparent Resistance
Improper blood pressure measurement
Failure to receive or take antihypertensive medication appropriately (nonadherence)
Inadequate doses (subtherapeutic)
Improper antihypertensive selection or combination
White coat hypertension

True Resistance
Secondary hypertension
Drug effects and interactions
- Adrenal steroid hormones
- Amphotericin B
- Cocaine, amphetamines, and other illicit drugs
- Cyclosporine and tacrolimus
- Erythropoietin
- Fluid retention from kidney disease or potent vasodilators (eg, minoxidil)
- Herbal products (ma huang, guarana, bitter orange, blue cohosh)
- Highly active antiretroviral therapy (HAART)
- Inadequate diuretic therapy
- Natural licorice (including some chewing tobacco)
- Neurologic and psychiatric agents (eg, venlafaxine, lithium, thioridazine hydrochloride)
- Nonsteroidal anti-inflammatory medications
- Oral contraceptive hormones
- Recent caffeine or nicotine intake
- Sympathomimetics (decongestants, anorectics, and stimulants)
- Vascular endothelial growth factor inhibitors (bevacizumab, sorafenib, sunitinib)

Volume overload
Excess sodium intake
Comorbidities
- Obesity
- Excess alcohol intake
- Chronic pain syndromes
- Intense vasoconstriction (arteritis)
- Anxiety-induced hyperventilation/panic attacks

Genetic variation
- Genetic differences in drug efficacy or metabolism

PATHOPHYSIOLOGY

KEY CONCEPT The pathophysiology of primary hypertension is heterogeneous but ultimately exerts its effects through two primary determinants of BP: cardiac output (CO) and peripheral vascular resistance (PVR). The processes influencing these two determinants are numerous and complex, and although the underlying cause of primary hypertension remains unknown, it is most likely multifactorial. As a review of these mechanisms is beyond the scope of this text, readers are referred to other sources.[9]

Patient Encounter 1

A 72-year-old white man comes into your clinic for an annual appointment. Seated BP measured in the left arm is 153/96 mm Hg and 157/89 mm Hg in the right arm. You request that the patient return in 1 week for a follow-up BP. His seated BPs in the right arm at follow-up are 156/92 mm Hg and 150/87 mm Hg. The patient's physical examination was unremarkable, but his electrocardiogram revealed evidence of left ventricular hypertrophy. His past medical history is significant for dyslipidemia. He does not smoke tobacco or drink alcohol and he walks daily for 30 minutes; however, he struggles with a heart healthy diet. He is currently taking aspirin 81 mg daily. His cholesterol panel revealed a high-density lipoprotein (HDL) cholesterol level of 40 mg/dL (1.03 mmol/L), triglyceride level of 140 mg/dL (1.58 mmol/L), and total cholesterol of 198 mg/dL (5.12 mmol/L). Calculated low-density lipoprotein cholesterol level is 130 mg/dL (3.36 mmol/L). All other laboratory values were within normal limits.

Based on the information above, what stage of hypertension does this patient have?

What is the patient's BP target?

What steps are involved in assuring that the patient's BP measurements are accurate?

The development of primary hypertension involves interplay between genetic and environmental factors interacting with multiple physiological systems including neural, renal, hormonal, and vascular. Further complicating this is that an individual's phenotype of primary hypertension (eg, diastolic hypertension in middle-aged individuals, isolated systolic hypertension in the elderly, and obesity-related hypertension) may have different contributing mechanisms.[9] Because of these complexities, no final common pathway has been identified and a single target for the treatment of primary hypertension remains elusive. Therefore, guidelines for the selection of specific therapeutic agents allow the clinician some flexibility in choices.

Genetic Factors

Although multiple genetic polymorphisms have been associated with relatively small effects on SBP, DBP, and response to antihypertensive medications, replications of these findings in large populations are elusive. Consequently, with very few exceptions, the information available to date is far from sufficient to provide any practical guidance for clinicians.[12] Nevertheless, genetic-based sources of variability in response to drug therapy continue.

Environmental Factors

Environmental factors contributing to hypertension are well-characterized. Nicotine use (including cigars and smokeless tobacco) and caffeine cause transient increases in BP via norepinephrine release and, in the case of caffeine, by its antagonism of vasodilatory adenosine receptors. Acute alcohol ingestion may have a transient variable effect (increased due to sympathetic nerve activity or lowering due to vasodilation), whereas chronic heavy consumption of alcohol and binge drinking raises the risk of hypertension.[9] Many other environmental factors have been implicated in the development of hypertension. These include obesity, physical inactivity, fetal environment, postnatal weight gain, premature birth and low birth weight, potassium and magnesium depletion, vitamin D deficiency, and environmental toxins (eg, lead).[9]

Neural Mechanisms

Over-activity of the sympathetic nervous system (SNS) in the early stages of primary hypertension manifests as increased heart rate, CO, and peripheral vasoconstriction. Despite this, outcome trials of agents targeting the SNS (α- and β-adrenergic blockers) have not performed as well as other drug classes. Nevertheless, strategies aimed at targeting the SNS continue with specific interest in invasive strategies aimed at resistant hypertension.[9]

Renal Mechanisms

The contribution of sodium to the development of primary hypertension is related to excess sodium intake and/or abnormal sodium excretion by the kidneys.[9] However, it is generally accepted that dietary salt is associated with increases in BP that can be lowered with reduction of sodium intake,[13] particularly in the approximately 30% of individuals deemed salt sensitive.[14]

Hormonal Mechanisms

Renin is produced and stored in the juxtaglomerular cells of the kidney, and its release is stimulated by impaired renal perfusion, salt depletion, and β_1-adrenergic stimulation. The release of renin is the rate-limiting step in the eventual formation of angiotensin II, which is a potent vasoconstrictor (Figure 5–2).[9] The role of

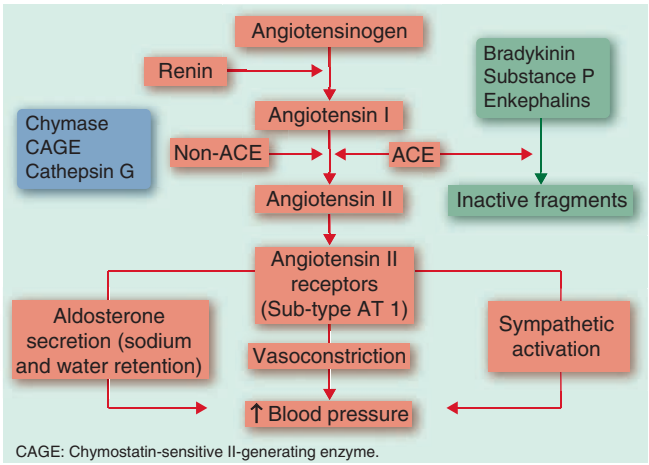

FIGURE 5–2. Diagram of the renin-angiotensin-aldosterone system (RAAS), a key system involved in the modulation of blood pressure. The diagram depicts the pathways involved in the action of various antihypertensive agents including angiotensin-converting enzyme (ACE) inhibitors, ARBs, diuretics, and aldosterone antagonists. By inhibiting the action of ACE, ACE inhibitors reduce both the formation of the vasoconstrictors angiotensin II and the degradation of vasodilating substances including bradykinin. ARBs primarily act through inhibition of the action of angiotensin II on the angiotensin-I receptors that modulate vasoconstriction. Aldosterone antagonists directly inhibit the action of aldosterone; diuretics affect sodium and water retention at a renal level. (ARB, angiotensin receptor blockers; AT1, angiotensin-1.) (From Victor RG, Kaplan NM. Kaplan's Clinical Hypertension, 10th ed. Philadelphia, PA: Wolters Kluwer Lippincott Williams & Wilkins Health; 2010, with permission.)

the renin-angiotensin-aldosterone system (RAAS) in primary hypertension is supported by the presence of high levels of renin, suggesting the system is inappropriately activated. Proposed mechanisms include increased sympathetic drive, defective regulation of the RAAS (nonmodulation), and the existence of a subpopulation of ischemic nephrons that release excess renin.[9] However, there are also patients with primary hypertension and low levels of renin which suggests alternative mechanisms, unrelated to renin levels or activity, may be in play. Thus, although uncommon in general practice, PRA measurements may be utilized to guide antihypertensive therapy selection. In fact, it has been demonstrated that patients with low PRA (< 0.65 ng/mL/hour [0.18 ng/L/s]) respond preferentially to diuretics, aldosterone antagonists, and calcium channel blockers (CCBs), whereas those with higher PRA levels respond preferentially to renin-mediated therapies such as β-blockers, angiotensin-converting enzyme inhibitors (ACE-Is), angiotensin receptor blockers (ARBs), and direct renin inhibitors.[5] However, use of PRA measurements to guide therapy is not without controversy and the reader is referred to other sources for more information.[12]

Vascular Mechanisms

Elevated PVR is the hemodynamic hallmark of primary hypertension. The increase in PVR typically observed may be due to a reduction in arterial lumen size as a result of vascular remodeling. This remodeling, or change in vascular tone, may be modulated by various endothelium-derived vasoactive substances, growth factors, and cytokines. This increase in arterial stiffness or reduced compliance results in an incremental rise in the systolic BP.[9]

Contributing Comorbidities

Several comorbidities have a high concurrence with the presence of hypertension leading to a higher risk of target organ damage, cardiovascular morbidity and mortality, and overall health care costs. Specifically, these include diabetes mellitus (DM), dyslipidemia, obesity, and CKD. As such, the assessment of atherosclerotic cardiovascular disease (ASCVD) risk in all patients with hypertension should be part of the management plan while pursuing target BPs through nonpharmacologic and pharmacologic means.[15]

MEASUREMENT OF BLOOD PRESSURE

KEY CONCEPT Appropriate technique in measuring BP is a vital component to the diagnosis and management of hypertension.

LO 3

Accurate measurement of a patient's BP requires control of factors that may influence variability in the measure. Failure to consider these factors, including body position, cuff size, device selection, auscultatory technique, and dietary intake prior to the visit, may lead to misclassification and thus inaccurate assessments of risk. Clinicians should instruct patients to avoid exercise, alcohol, caffeine, or nicotine 30 minutes before BP measurement. Patients should be sitting comfortably with their back supported and arm free of constrictive clothing with legs uncrossed and feet flat on the floor for a minimum of 5 minutes before the first reading. Systolic and diastolic BP tend to increase when the cuff size is too small. Ideally, the cuff bladder should encircle at least 80% of the arm's circumference to ensure a more accurate measurement of BP.[3]

To reduce deviations in BP measurement in the clinic, the patient and clinician should not talk during measurement. The measurement arm should be supported and positioned at heart level. If a mercury or aneroid device is used, then the palpatory method (inflate the cuff to approximately 80 mm Hg rapidly while palpating the radial pulse, then increase pressure slowly by 10 mm Hg increment every 2 to 3 seconds until the radial pulse is no longer felt [estimated SBP]; the cuff is then inflated further until the pressure is about 30 mm Hg higher) must be used first to estimate the SBP.[6] If an automated device is used, this is not necessary. After the patient's cuff is inflated above the systolic pressure, the pressure indicator should drop at a rate of 2 to 3 mm Hg/s. A stethoscope placed over the brachial artery in the antecubital fossa identifies the first and disappearance of audible **Korotkoff sounds**, which should be taken as systolic and diastolic pressure, respectively. A minimum of two readings at least 1 minute apart are then averaged. If measurements vary by more than 5 mm Hg between the two readings, then one or two additional BP measurements are collected (at least 1 minute apart from each measurement) and the multiple readings averaged. BP classification is based on the average of two or more properly measured BP readings on each of two or more office visits. Details and further recommendations for accurate measurement of BP in special populations can be found elsewhere.[3,15] Finally, the measurement of clinic or office BPs is often poorly correlated with assessments of BP in other settings. Consequently, under select circumstances, clinicians are increasingly using 24-hour ABPM, AOBP monitoring, and HBP monitoring. Corresponding values of systolic and diastolic BP for clinic, 24-hour ABPM, AOBP, and HBP measurements are provided in **Table 5–5**.[2] These methods of BP measurement are useful in identifying patients with white coat hypertension or in the case of 24-hour ABPM, elevations of BP during the

Table 5–5

Corresponding Values (mm Hg) of Systolic BP/Diastolic BP for Various Methods of BP Measurement[2]

Clinic	HBPM[a]	Daytime ABPM[a]	Nighttime ABPM[a]	24-Hour (Overall) ABPM[a]

Clinical Presentation and Diagnosis of Primary Hypertension

General

Prevalence of hypertension is likely to be highest with middle-aged or older patients
Gender: In the United States, hypertension is slightly more prevalent in men than women before the age of 35 years, similar between the ages of 35 and 64 years, and higher in women than men thereafter

Symptoms

The patient with primary hypertension may be asymptomatic yet still have major cardiovascular disease (CVD) risk factors

Signs

Adult patients have an average of two or more BP readings (SBP and DBP) on two or more occasions.
Classification of an individual's hypertension (Table 5–1) can be made based on the higher classification from either the SBP or DBP readings; for example, an individual whose readings are consistently 136/94 mm Hg would be classified as having stage 2 hypertension.

LO 4

Basic Testing (facilitates CVD risk factor profiling, establishes a baseline for monitoring medication use, and facilitates screening for select secondary causes of hypertension)

- Fasting lipid panel (to determine ASCVD risk and those who may benefit from statin therapy as described in Chapter 12, "Dyslipidemias")
- Hemoglobin A_{1C} or fasting plasma glucose (to identify patients with impaired fasting glucose or diabetes as described in Chapter 43, "Diabetes Mellitus")
- Complete blood count
- Serum sodium, potassium, calcium, creatinine with estimated glomerular filtration rate (GFR; may all be included as part of a comprehensive metabolic panel)
- Thyroid-stimulating hormone (simple test and hypo- or hyperthyroidism are remedial causes of hypertension)
- Urinalysis
- Electrocardiogram (ECG)

Optional Testing (may provide information on target organ damage)

- Echocardiogram
- Uric acid
- Urinary albumin to creatinine ratio

The following abnormal tests may indicate hypertension-related damage:

- Serum creatinine elevated (> 1.2 mg/dL [106 µmol/L])
- Microalbuminuria, which is diagnosed either from a 24-hour urine collection (20–200 mcg/min) or from elevated concentrations (30–300 mg/L) on at least two occasions. Use of the albumin-to-creatinine ratio (ACR) in a spot urine sample is becoming more common, and microalbuminuria is defined by this measure as 30 to 300 mg/g creatinine (3.4–34 mg/mmol creatinine)

Common Comorbidities and Factors Contributing to Cardiovascular Risk

- DM
- Metabolic syndrome
- Insulin resistance
- Dyslipidemia
- Microalbuminuria/CKD
- Family history
- Central obesity
- Physical inactivity
- Tobacco use

Cardiovascular Risk Assessment

Calculate with risk assessment tools, such as the ACC/AHA ASCVD Risk Estimator (http://tools.acc.org/ascvd-risk-estimator/)

Target Organ Damage

- Cerebrovascular disease (eg, stroke or transient ischemic attack)
- Ocular (hypertensive retinopathy)
- Cardiac (left ventricular hypertrophy, left ventricular dysfunction, coronary artery disease [CAD], HF)
- CKD (eg, albuminuria, nephrosclerosis)
- Peripheral arterial disease

night and masked hypertension, or hypertension not identified through traditional office measurement. They may also aid in the management of patients with refractory hypertension with minor target organ damage, suspected autonomic neuropathy, hypotensive symptoms, and patients with large differences between home and office BP measurements. Benefits derived from these additional methods of BP monitoring may be of greater prognostic significance than traditional office-based measurements.[7,16] Consequently, the 2017 ACC/AHA guidelines recommend utilizing out-of-office self-monitoring of BP to confirm hypertension diagnosis, and for titration of BP-lowering medications in conjunction with clinic and telehealth counseling.[2]

TREATMENT

Desired Outcomes

The goal of BP management is to reduce the risk of CVD-related morbidity and mortality manifested as target organ damage such as CAD, stroke, and kidney disease.

General Approach to Treatment

KEY CONCEPT Drug therapy for the management of patients with hypertension should be considered as adjunctive to nonpharmacologic approaches for BP lowering. Ultimately, the attainment of target BP in many cases may be more important

than the antihypertensive agent selected. Previous research has established the value of using individual antihypertensive drugs versus placebo to achieve reduction in morbidity and mortality by lowering BP. According to the 2017 ACC/AHA guidelines, the recommended BP target for the vast majority of patients is less than 130/80 mm Hg.[2] The BP threshold for treatment varies according to the patient's baseline cardiovascular risk. BP-lowering medications are recommended in patients with clinical CVD (defined as coronary heart disease, HF, or stroke) and an average SBP of 130 mm Hg or higher or an average DPB of 80 mm Hg or higher. In addition, BP-lowering medications are recommended for primary prevention in adults with an estimated 10-year ASCVD risk of 10% or higher and whose SBP/DBP exceeds 130/80 mm Hg. The recommended tool for calculating ASCVD risk is the ACC/AHA ASCVD Risk Estimator (http://tools.acc.org/ascvd-risk-estimator/). BP thresholds and goals for pharmacologic therapy in these patients and those with other clinical conditions are summarized in Table 5–2. Although these guidelines clearly recommend treatment thresholds for most individuals with or without CVD or select comorbidities, the benefits of aggressive BP control using pharmacotherapy remain debatable for certain patients. Examples where conflicting data require reconciliation include controlled studies, such as the SPRINT (Systolic Blood Pressure Intervention Trial),[17] ACCORD (Action to Control Cardiovascular Risk in Diabetes),[18] and SPS3 (Secondary Prevention of Small Subcortical Strokes; blood-pressure targets in patients with recent lacunar stroke)[19] trials, where improved outcomes across all major endpoints for patients achieving a more intensive BP-lowering goal were not consistently observed. Although these inconsistencies underscore the need for additional high-quality research with the aim of determining the most appropriate BP targets for specific patient groups, the 2017 ACC/AHA guidelines were generated by inclusion of many associations and groups representing a wide array of specialty populations.[2]

Evidence supports the position that the main benefits of pharmacologic therapy are related to achievement of BP lowering and are generally independent of the selection of an individual drug regimen. Inherent in this position is the realization that lifestyle changes or nonpharmacologic approaches alone are rarely successful in attaining target BPs, and multidrug therapy (sometimes as many as three or more agents) is necessary for most patients.[6,20] Given the need for multiple medications to control hypertension, clinicians should work to minimize pill burden, frequency of administration, and cost. When possible and appropriate, selecting fixed-combination drug therapies, longer acting formulations and generic or formulary-based medications may optimize adherence. The 2017 ACC/AHA guidelines state that it is reasonable to initiate pharmacologic therapy with a single agent in patients with stage 1 hypertension.[2] In those with stage 2 hypertension and an average BP more than 20/10 mm Hg above their BP target, it is recommended to start therapy simultaneously with two agents from different classes.[2] Furthermore, this guideline identifies black adults as a cohort who may be considered for two or more drugs to control hypertension. Both circumstances acknowledge the urgency to control hypertension with a high likelihood of needing multiple medications.

Another general consideration for antihypertensive therapy planning includes incorporation of chronotherapeutic principles. The timing of administration of antihypertensive medications may have relevance to the manifestations of adverse effects and/or optimizing therapeutic outcomes. A study of patients with CKD and diabetes demonstrated that moving the administration time of one antihypertensive agent to bedtime dosing significantly reduced composite cardiovascular events compared to administering all antihypertensive agents at one time in the morning.[21]

Nonpharmacologic Treatment: Lifestyle Modifications

Therapeutic lifestyle modifications consisting of nonpharmacologic approaches to BP reduction should be part of all treatment plans. The most widely studied interventions demonstrating effectiveness include:

- Dietary sodium restriction
- Increasing dietary potassium intake
- Low-fat diet, high in vegetables and fruits
- Weight reduction in overweight or obese individuals
- Regular physical activity
- Moderation of alcohol consumption

KEY CONCEPT Implementation of these lifestyle modifications successfully lowers BP, often with results similar to those of therapy with a single antihypertensive agent.[6,15] Combining multiple lifestyle modifications can have even greater BP-lowering effects. Sodium restriction to 2.4 g (100 mmol) of elemental sodium (6 g of sodium chloride or one teaspoon of table salt) per day lowers BP and has been recommended for the general population, especially individuals with hypertension.[22] Although controversy surrounds the optimal level of sodium intake and its cardiovascular benefits and risks,[23] adoption of an optimal dietary pattern that includes consuming fewer processed foods is expected to afford overall cardiovascular benefits.

Compared to the general population, BP lowering through sodium restriction is more pronounced in salt-sensitive individuals (low PRA), persons with diabetes, metabolic syndrome, or CKD, as well as older individuals and black people.[5,15] Simple dietary advice and instructions on reading nutrition labels should be introduced to patients initially and assessed and reinforced at subsequent visits. A diet high in fruits, vegetables, and low-fat dairy products, along with a reduced intake of total and saturated fat, can significantly reduce BP in as little as 8 weeks.[24] See Table 5–6.[3,22]

Smoking cessation should be encouraged for overall cardiovascular health despite its lack of chronic effects on BP.[15] Although BP-lowering lifestyle modifications have never been documented to reduce cardiovascular morbidity and mortality in patients with hypertension, they do effectively lower BP in most hypertensive patients and exhibit a favorable effect on other risk factors including dyslipidemia and insulin resistance. This may obviate the need for drug therapy in those with mild elevations in BP or minimize the doses or number of antihypertensive agents required in those on therapy.[15]

Pharmacologic Treatment

KEY CONCEPT An approach to selection of drugs for the treatment of patients with hypertension should be evidence-based with considerations regarding the individual's comorbidities, co-prescribed medications, and practical patient-specific issues including cost. The evidence-based 2017 ACC/AHA guidelines recommend drug therapy that is largely grounded in the best available evidence for superiority in outcomes—specifically morbidity and mortality.[2] The approach is often tempered

Table 5–6

Lifestyle Modifications to Manage Hypertension[a,3]

Modification	Recommendation	Approximate Systolic BP Reduction (Range)
Weight reduction	Maintain normal body weight (body mass index: 18.5–24.9 kg/m^2)	5–20 mm Hg/10 kg
Adopt DASH eating plan	Consume a diet rich in fruits, vegetables, and low-fat dairy products with a reduced content of saturated and total fat	8–14 mm Hg
Dietary sodium restriction	Reduce dietary sodium intake to no more than 100 mmol/day (2.4 g sodium or 6 g sodium chloride). If these targets cannot be achieved, an absolute reduction in 1 g sodium/day is recommended	2–8 mm Hg
Physical activity	Engage in regular aerobic physical activity such as brisk walking (at least 30 min/day, most days of the week)	4–9 mm Hg
Moderation of alcohol consumption	Limit consumption to no more than two standard drinks per day in most men and to no more than one standard drink per day in women and lighter weight persons[b]	2–4 mm Hg

[a]For overall cardiovascular risk reduction, stop smoking. The effects of implementing these modifications are dose and time dependent and could be greater for some individuals.

[b]One standard drink is defined as 12 oz (355 mL) beer, 5 oz (148 mL) wine, or 1.5 oz (44 mL) 80-proof whiskey.

BP, blood pressure; DASH, dietary approaches to stop hypertension.

with practical considerations related to competing options for specific comorbidities and issues regarding a patient's experience or tolerance for side effects and, in some cases, the cost of medications.

Landmark trials such as the Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial (ALLHAT) have provided some objective basis for comparisons between initiating antihypertensive drug therapy with one class of antihypertensives versus another; however, there is room for criticism of these studies.[20,25,26] Consequently, practical interpretations of their conclusions must leave room for individualization based on clinical judgment. Overall, current clinical guidelines provide a reasonable basis for guiding the selection of drug classes for individuals based on their stage of hypertension, comorbidities, and special circumstances. The following sections summarize key features of specific drug classes and guideline-based recommendations. An overview of specific oral antihypertensive drug classes in common use is summarized in Table 5–7.[3,6,27,28]

Diuretics

Diuretics have been advocated as initial therapy for uncomplicated patients with hypertension based on their practical attributes including cost, availability as combination agents and overall years of experience, as well as favorable outcomes in clinical trials for select populations. For example, patients randomized to chlorthalidone, a thiazide-type diuretic, as initial antihypertensive therapy had similar outcomes to those randomized to receive initial therapy with either amlodipine or lisinopril.[20] However, differences in outcomes for select secondary endpoints or special populations demonstrated superiority of chlorthalidone-based therapy over either ACE-I or CCB-based regimens. Criticism of the different BPs achieved in the various treatment groups, the artificial construct guiding the use of add-on drugs to base therapy, and the overrepresentation of African-Americans exhibiting select endpoints have weakened the interpretability of this trial.[20] Furthermore, other studies have challenged the status of diuretics as an ideal baseline choice for initial antihypertensive drug therapy for all patients[25,26] and even the choice of diuretic used,[29] supporting the debate over whether the means by which BP is lowered (specific drug selected) is more or less important than the extent and/or time taken to lower BP. Nonetheless, diuretics remain supported by many as acceptable baseline initial therapy for hypertensive patients without compelling indications to the contrary.

Key differences in the features of various subtypes of diuretics may also play a role in selection. The four subtypes include thiazides, loop diuretics, potassium-sparing agents, and aldosterone antagonists. The latter will be discussed separately. Each diuretic subtype has clinically-based properties that distinguish their roles in select patient populations. Thiazide diuretics are by far the most commonly prescribed with the greatest number of outcome-based studies supporting their use. This type of diuretic inhibits the sodium-chloride symporter in the renal distal convoluted tubule thus increasing sodium and chloride excretion. In the United States, hydrochlorothiazide and chlorthalidone represent the most commonly prescribed thiazide-type diuretics and have been the subject of large outcome-based studies. Although subtle differences in pharmacokinetics between these agents exist, practical differences are limited to their relative diuretic potency, with chlorthalidone being considered approximately 1.5 to 2 times more potent than hydrochlorothiazide for BP reduction.[29] Several recent analyses have demonstrated superiority of chlorthalidone over hydrochlorothiazide,[29] leading the 2017 ACC/AHA guidelines to specifically recommend chlorthalidone over other diuretics.[2,30]

Because the relationship between antihypertensive efficacy and metabolic/electrolyte-related side effects of thiazide diuretics is dose-related, attention to the differential in potency may be important. Specifically, select metabolic effects (hyperlipidemia and hyperglycemia) and electrolyte-related effects (hypokalemia, hypomagnesemia, hyperuricemia, and hypercalcemia) increase with higher doses. These effects may complicate the management of higher risk patients with common comorbidities such as dyslipidemia or diabetes, or even those likely to be sensitive to complications from hyperuricemia and the potassium- or magnesium-wasting effects of diuretics such as patients with dysrhythmias or those taking digoxin. Thiazide diuretic-induced development of new-onset diabetes remains debatable since the ALLHAT and Systolic Hypertension in the Elderly Program (SHEP) demonstrated no significant adverse cardiovascular

Table 5–7

Commonly Used Oral Antihypertensive Drugs by Pharmacologic Class[3,6,27,28]

Class	Brand	Dosage (mg/day) Low	Usual	Frequency	Select Adverse Events	Comments[a]
Diuretics						
Thiazides and thiazide-like	Chlorthalidone (Hygroton)	12.5	12.5–25	QDay	Hypokalemia and other electrolyte imbalances Negative effect on glucose and lipids	Thiazide diuretics are generally more effective antihypertensive agents than loop diuretics Ineffective in patients with estimated CrCL < 30 mL/min (0.5 mL/s), except metolazone Not first-line agents in pregnancy, but may be used with close monitoring for hypokalemia Monitor electrolytes (ie, decreased serum potassium) and metabolic abnormalities (ie, dyslipidemia, hyperglycemia) Use caution in patients with gout and severe renal impairment Contraindications include hypersensitivity and anuria
	Hydrochlorothiazide (Esidrix, HydroDiuril, Microzide, Oretic)	12.5	12.5–50	QDay		
	Indapamide (Lozol)	1.25	2.5	QDay		
	Metolazone (Zaroxolyn)	0.5	2.5–10	QDay		
Loops	Bumetanide (Bumex)	0.5	1	QDay or BID	Hypokalemia and other electrolyte imbalances	Preferred diuretic class in patients with estimated CrCL < 30 mL/min (0.5 mL/s) Monitor electrolytes (ie, decreased potassium) and metabolic abnormalities (ie, dyslipidemia, hyperglycemia) Use with caution in patients with gout Contraindications include hypersensitivity, anuria, acute renal insufficiency
	Furosemide (Lasix)	20	40	BID		
	Torsemide (Demadex)	5	10	QDay		
Potassium-sparing	Amiloride (Midamor)	5	20	QDay or BID	Potassium-sparing diuretics may enhance hyperkalemic effects of drug therapies (eg, ACE inhibitor, aldosterone antagonist)	Reserved for patients with diuretic-induced hypokalemia Monitor electrolytes (ie, potassium) Contraindications include hypersensitivity, acute renal insufficiency, hyperkalemia Avoid in patients with estimated CrCL < 30 mL/min (0.5 mL/s)
	Triamterene (Dyrenium)	100	100	QDay or BID		
Aldosterone antagonists	Eplerenone (Inspra)	25	50–100	QDay or BID	Hyperkalemia	Eplerenone contraindicated as an antihypertensive in patients with estimated CrCL < 50 mL/min (0.83 mL/s) or serum creatinine > 1.8 mg/dL (159 µmol/L) for women or 2 mg/dL (177 µmol/L) in men as well as type 2 diabetes mellitus with microalbuminuria. Also contraindicated in patients concomitantly receiving strong CYP3A4 inhibitors or a serum potassium > 5.0 mEq/L (mmol/L) at initiation
	Spironolactone (Aldactone)	12.5	25–50	QDay or BID	Gynecomastia (spironolactone)	
β-Blocker						
Cardioselective	Atenolol (Tenormin)	25	100	QDay or BID	Bradycardia Heart block Heart failure Dyspnea, bronchospasm Fatigue, dizziness, lethargy, depression	Caution with heart rate < 60 and respiratory disease Selectivity of β_1 agents is diminished at higher doses Abrupt discontinuation may cause rebound hypertension May mask signs/symptoms of hypoglycemia in diabetic patients
	Bisoprolol (Zebeta)	5	5–10	QDay		
	Metoprolol tartrate (Lopressor)	25	50–100	BID		
	Metoprolol succinate (Toprol XL)	25	50–100	QDay		

Nonselective	Nadolol (Corgard)	20	40–80	QDay	Hyper/hypoglycemia, hyperkalemia, hyperlipidemia	Contraindicated in hypersensitivity, sinus node dysfunction or severe sinus bradycardia (in the absence of a pacemaker), heart block (greater than first-degree), cardiogenic shock, acute decompensated heart failure
	Nebivolol (Bystolic)	2.5	5–10	QDay		
	Propranolol (Inderal)	40	40–160	BID		
	Propranolol long-acting (Inderal LA, InnoPran XL)	80	80–320	QDay		
	Timolol (Blocadren)	10	10–40	QDay		
Mixed α- and β-blocker	Carvedilol (Coreg)	3.125	6.52–25	BID		
	Carvedilol CR (Coreg CR)	10	20–80	QDay		
	Labetalol (Trandate)	100	100–300	BID		
CCB						
Nondihydropyridines	Diltiazem long-acting (Cardizem SR, Cardizem CD, others)	120	240–360	QDay	Bradycardia, heart block (nondihydropyridines) Constipation (nondihydropyridines) Peripheral edema, headache, flushing	Caution with heart rate < 60 (verapamil, diltiazem) Use caution in concomitant use with β-blocker; may potentiate heart block Extended-release formulations are preferred for once- or twice-daily medication administration
	Verapamil sustained-release (Calan SR, Isoptin SR, Verelan)	120	240–480	QDay		
Dihydropyridines	Amlodipine (Norvasc)	2.5	5–10	QDay	Gingival hyperplasia (dihydropyridines) Reflex tachycardia (dihydropyridines)	Contraindicated in hypersensitivity, sinus node dysfunction, or severe sinus bradycardia (in the absence of a pacemaker) (nondihydropyridines), heart block (greater than first degree) in the absence of a pacemaker (nondihydropyridines), atrial fibrillation/flutter associated with accessory bypass tract (nondihydropyridines), reduced ejection fraction (most CCBs except amlodipine)
	Felodipine (Plendil)	2.5	5–10	QDay		
	Isradipine SR (DynaCirc SR)	2.5	5–10	BID		
	Nicardipine SR (Cardene SR)	30	60–120	BID		
	Nifedipine long-acting (Adalat CC, Procardia XL)	30	30–90	QDay		
	Nisoldipine (Sular)	8.5	17–34	QDay		
ACE inhibitors	Benazepril (Lotensin)	5	10–40	QDay or BID	Cough Hyperkalemia Renal insufficiency Angioedema	Monitor electrolytes (ie, serum potassium) Monitor renal function Initial dose may be reduced in renal impairment, the elderly, patients who are volume depleted or maintained on diuretic therapy Use with caution in patients with baseline hyperkalemia Contraindicated in pregnancy and hypersensitivity, bilateral renal artery stenosis or unilateral renal artery stenosis in a solitary functional kidney
	Captopril (Capoten)	12.5	50–100	BID or TID		
	Enalapril (Vasotec)	5	10–40	QDay or BID		
	Fosinopril (Monopril)	10	10–40	QDay		
	Lisinopril (Prinivil, Zestril)	5	10–40	QDay		
	Moexipril (Univasc)	7.5	7.5–30	QDay or BID		
	Perindopril (Aceon)	4	4–8	QDay		
	Quinapril (Accupril)	5	10–40	QDay or BID		
	Ramipril (Altace)	2.5	5–10	QDay or BID		
	Trandolapril (Mavik)	1–2	2–8	QDay		

(*Continued*)

Table 5–7

Commonly Used Oral Antihypertensive Drugs by Pharmacologic Class[3,6,27,28] (*Continued*)

Class	Brand	Dosage (mg/day) Low	Usual	Frequency	Select Adverse Events	Comments[a]
ARBs	Azilsartan (Edarbi)	40	80	QDay	Hyperkalemia	Above comments to ACE inhibitors also apply to ARBs
	Candesartan (Atacand)	4	8–32	QDay or BID	Renal function deterioration	
	Eprosartan (Teveten)	400	600–800	QDay or BID	Angioedema	
	Irbesartan (Avapro)	150	150–300	QDay	Hypotension/syncope	
	Losartan (Cozaar)	50	50–100	QDay or BID		
	Olmesartan (Benicar)	10	20–40	QDay		
	Telmisartan (Micardis)	40	40–80	QDay		
	Valsartan (Diovan)	80	80–320	QDay		
Direct renin inhibitors	Aliskiren (Tekturna)	75	150–300	QDay	Hyperkalemia Hypotension	Use caution in patients with severe renal impairment and in patients with deteriorating renal function or renal artery stenosis, both bi- and unilateral Contraindicated in combination with ACE-Is or ARBs in patients with diabetes
Central α_2 agonists	Methyldopa (Aldomet)	125	250–500	BID	Transient sedation initially	First-line agent in pregnancy (methyldopa)
	Clonidine oral (Catapres)	0.1	0.1–0.2	BID	Hepatotoxicity, hemolytic anemia, peripheral edema (methyldopa)	Tolerance may occur 2–3 months after initiation of methyldopa; increase dose or add thiazide
	Clonidine patch (Catapres TTS)	0.1	0.1–0.3	Once weekly		Contraindications include hypersensitivity, concurrent use of MAO inhibitor (methyldopa), hepatic disease [methyldopa], pheochromocytoma (methyldopa)
	Guanfacine (Intuniv)	1	1–2	QDay	Orthostatic hypotension (methyldopa, clonidine) Dry mouth, muscle weakness (clonidine)	
α_1 Blockers	Doxazosin (Cardura)	1	1–8	QDay	Syncope, dizziness, palpitations, orthostatic hypotension	Contraindicated in hypersensitivity
	Prazosin (Minipress)	1	2–20	BID or TID		
	Terazosin (Hytrin)	1	1–20	QDay or BID		
Direct vasodilator	Isosorbide dinitrate 20 mg and hydralazine 37.5 (BiDil)	20/37.5	20–40/37.5–75	TID	Edema, hypertrichosis (minoxidil) Tachycardia	Give minoxidil with diuretic and β-blocker to mitigate side effects Contraindicated in hypersensitivity, pheochromocytoma (minoxidil), increased intracranial pressure [isosorbide dinitrate + hydralazine]
	Hydralazine (Apresoline)	10	25–100	BID	Lupus-like syndrome (hydralazine)	
	Minoxidil (Loniten)	2.5	5–100	QDay or BID		
Peripheral sympathetic inhibitors	Reserpine (generic only)	0.1	0.1–0.25	QDay	Mental depression Orthostatic hypotension Nasal congestion, fluid retention, peripheral edema Diarrhea, increased gastric secretion	Contraindications include hypersensitivity, peptic ulcer disease or ulcerative colitis, history of mental depression or electroconvulsive therapy

[a]Comments listed are not intended to be inclusive of all adverse effects, monitoring parameters, cautions, or contraindications, and may vary by source.

ACE, angiotensin-converting enzyme; ARB, angiotensin receptor blocker; CYP, cytochrome P450; BID, twice daily; CCB, calcium channel blocker; CrCL, creatinine clearance; MAO, monoamine oxidase; QDay, once daily; TID, three times daily. Modified from Reference 6 and Saseen JJ, Maclaughlin EJ. Hypertension. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York: McGraw-Hill; 2017:57–58, with permission.

events from new diuretic-associated diabetes versus other trials contradicting this observation.[31] Nonetheless, clinicians should generally not exceed 25 to 50 mg/day of hydrochlorothiazide or 25 mg/day of chlorthalidone.[32] In addition, regardless of the dose used, careful assessment of the potential for metabolic- or electrolyte-based effects is essential.

Additionally, it is important to recognize that when estimated creatinine clearance approaches or is less than 30 mL/min (0.50 mL/s), thiazide diuretics have limited efficacy, rendering loop diuretics to be preferred. Clinicians are advised to reevaluate the use of thiazide diuretics prescribed to individuals whose renal function has been declining with age and whose risk for the consequences of metabolic effects may be more significant.[33] Loop diuretics, such as furosemide, bumetanide, torsemide, and ethacrynic acid, have a common site of action in the thick ascending limb of the loop of Henle. As this region reabsorbs over 35% to 45% of filtered sodium, their diuretic efficacy is superior to that of thiazides, potassium-sparing diuretics, and aldosterone antagonists. With the exception of torsemide, which has a longer half-life, the loop diuretics should be administered twice daily (BID) when utilized primarily for their antihypertensive (vs diuretic) effect. The most significant adverse effect of loop diuretic use is excessive diuresis leading to hyponatremia or hypotension. Additionally, hypokalemia, hypomagnesemia, and hypocalcemia may develop over time and contribute to the potential for cardiac arrhythmias. Overall, relevance of drug–drug interactions and potential for aggravating select conditions (hyperglycemia, dyslipidemias, and hyperuricemia) should be routinely monitored.[9]

Potassium-sparing diuretics that do not act through mineralocorticoid receptors include triamterene and amiloride. These agents are often prescribed in combination with potassium-wasting diuretics to mitigate potassium loss. When administered alone or as a combination product, these agents result in modest diuresis given that their site of action on the distal tubule and collecting ducts has minimal impact on blocking sodium reabsorption. Their most significant risk is the potential for hyperkalemia. This is especially relevant in the context of those patients with moderate to severe renal impairment or those receiving nonsteroidal anti-inflammatory drugs (NSAIDs), potassium supplements, or other agents with potassium-sparing properties, such as ACE-Is or ARBs.[9]

Aldosterone Antagonists

Aldosterone antagonists such as spironolactone and eplerenone modulate vascular tone through a variety of mechanisms besides diuresis (Figure 5–2). Their potassium-sparing effects mediated through aldosterone antagonism counteract the potassium-wasting effects of other diuretics such as thiazide or loop diuretics. Patients with resistant hypertension (with or without primary aldosteronism) experience significant BP reductions with the addition of low-dose spironolactone (12.5–50 mg/day) to diuretics, ACE-Is, and ARBs.[34] Although a positive attribute, it is important to recognize the risk for hyperkalemia in patients with impaired or fluctuating renal function, or those who are receiving ACE-Is, ARBs, direct renin inhibitors, potassium supplements, potassium-containing salt substitutes, or NSAIDs. In addition, spironolactone is associated with **gynecomastia**, whereas eplerenone rarely causes this complication, presumably because of its greater aldosterone blocking specificity than spironolactone and minimal effects on androgens and progesterone.[6,9]

β-Blockers

Most contemporary guidelines refrain from supporting the use of β-blockers as first-line antihypertensive agents.[6,15,32] The basis of this position varies but often cites studies indicating inferior outcomes[35] and a lack of positive outcomes in elderly patients when compared to other antihypertensives. These analyses were conducted with a limited number of β-blockers (usually atenolol), and thus their findings may or may not apply to newer formulations of existing agents (eg, metoprolol succinate) or agents with unique properties such as carvedilol or nebivolol.[35] However, the role of β-blockers in patients with specific select comorbidities is well-established (Table 5–3).[3] Specific studies conducted in patients with comorbidities such as CAD, HF with reduced ejection fraction (HFrEF), or recent MI have clearly demonstrated morbidity and mortality benefits from β-blocker use.[36] Their hemodynamic effects and antiarrhythmic properties make them desirable for hypertensive patients who suffer from ischemic conditions including acute coronary syndromes (ACS). The mechanisms through which β-blockers affect BP are complex but most certainly include their modulation of renin, which appears to result in a reduction in CO and/or reduction in PVR along with their negative inotropic/chronotropic actions (Figure 5–2).

The specific pharmacologic properties of β-blockers are varied and diverse. An understanding of these properties may assist in the selection of one agent over others given a patient's specific condition(s) or comorbidities. One of these properties is cardioselectivity: the property of some β-blockers that preferentially block the β_1-receptor versus β_2-receptor. Some β-blockers exhibit membrane stabilization activity, which relates to the β-blocker's capacity to exhibit certain antiarrhythmic properties. Some β-blockers, as shown in **Figure 5–3**, possess properties referred to as intrinsic sympathomimetic activity (ISA). β-Blockers possessing this property effectively block the β-receptor at higher circulating catecholamine levels, such as during exercise, while having modest β-blocking activity at times of lower catecholamine levels, such as at rest.[37]

Cardioselectivity represents the most clinically relevant property of β-blockers, but β-blockers with ISA are not recommended for use in the post-ACS patient.[37] With regard to cardioselectivity, it is important to consider patients with asthma and/or chronic obstructive pulmonary disease. A β-blocker with relative cardioselectivity to block β_1-receptors may be more desirable in such a patient, whereas a nonselective β-blocker may be potentially disadvantageous. In such a patient, low doses of cardioselective β-blockers may achieve adequate blockade of β_1-receptors in the heart and kidneys while minimizing the undesirable effects of β_2-receptor blockade on the smooth muscle lining the bronchioles. In doing so, hypertension may be managed while avoiding complications of the coexisting reactive airway disease, which is mediated by β_2-receptor stimulation. Similarly, either because of a reduction in the β_2-mediated vascular blood flow or by enhanced unopposed α-agonist–mediated vasoconstriction, a patient with peripheral vascular disease and intermittent claudication may experience a worsening of symptoms with use of a nonselective β-blocker (Figure 5–3). It is important to remember that cardioselectivity depends on dose, with diminished selectivity exhibited with higher doses.

A limited number of β-blockers also possess vasodilatory properties that are either mediated through α_1-receptor blockade (carvedilol, labetalol) or via L-arginine/nitric oxide-induced release from endothelial cells, with subsequent increased nitric

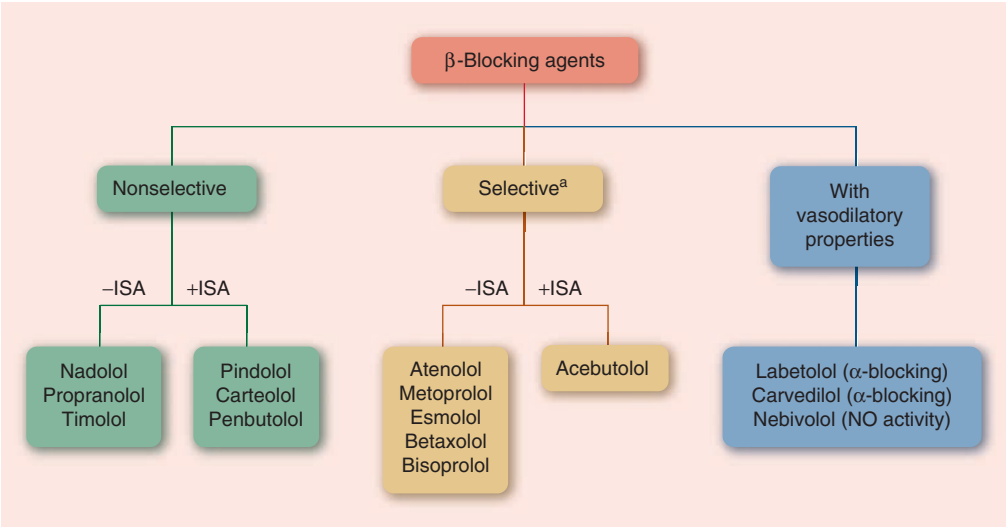

FIGURE 5–3. Flowchart listing various β-blocking agents separated by β-receptor activity and intrinsic sympathomimetic activity. [a]β-1 Cardioselective. (ISA, intrinsic sympathomimetic activity; NO, nitric oxide.)

oxide bioavailability in the endothelium (nebivolol). Although theoretically of benefit, there has been no proven evidence of superior outcomes from use of β-blockers with these vasodilatory properties.

The adverse effects of β-blockers follow their pharmacology. Their potential to precipitate bradycardia, various degrees of heart block, or signs and symptoms of HF may be of concern to those with a subclinical diagnosis of HF, the elderly, or those with reduced left ventricular ejection fraction (LVEF). Conversely, abrupt discontinuation of β-blockers has been cited as a precipitating factor in the development of ischemic syndromes, especially for those patients in whom β-blockers were used for extended periods of time, at higher doses, or who had underlying ischemic heart disease. In such cases, tapering the dose over a period of several days to 1 or even 2 week(s) is recommended. β-Blocker use in diabetics is usually a complex decision requiring consideration of their consequential effects on insulin, glucose availability, and blocking the signs and symptoms of hypoglycemia against their potential for morbidity/mortality benefits for select candidates with comorbidities such as HFrEF. Lastly, β-blockers, particularly first-generation agents (ie, those other than carvedilol, nebivolol), have a greater effect on glucose metabolism as well as other metabolic effects, and they should be used cautiously if at all with diuretics unless compelling indications exist for both.

The FDA-approved drug labeling for metoprolol, carvedilol, nebivolol, and propranolol states that when coadministered with drugs that affect cytochrome P450 (CYP) 2D6 metabolic pathways, their efficacy and/or toxicity may be altered. However, specific recommendations vary by agent. For example, recommendations for metoprolol state that dose titration or an alternative agent should be considered for individuals classified as CYP2D6 poor, intermediate, and ultra-rapid metabolizers. However, similar recommendations are not explicitly suggested for carvedilol, nebivolol, or propranolol.

Calcium Channel Blockers

Exhibiting considerable interclass diversity, CCBs are recognized as effective antihypertensives, particularly in the elderly.[6] Although the Valsartan Antihypertensive Long-term Use Evaluation (VALUE) trial comparing valsartan-based and amlodipine-based therapy failed to achieve its primary endpoint of cardiac morbidity and mortality, secondary endpoints including stroke and MI were reduced by amlodipine-based therapy.[26] In the Anglo-Scandinavian Cardiac Outcomes Trial-Blood Pressure Lowering Arm (ASCOT-BPLA), amlodipine-based therapy achieved greater BP-lowering and appeared to provide greater protection against stroke and MI versus atenolol-based therapy.[25]

The variety of pharmacologic properties among the subclasses of CCBs is significant and categorizes their expected effects on the cardiovascular system and potential risk of toxicities. Dihydropyridine CCBs such as nifedipine and amlodipine are commonly associated with edema, especially when used at higher doses. Nondihydropyridine CCBs such as verapamil and diltiazem are recognized for their electrophysiological effects, and negative chronotropic and inotropic effects. These pharmacologic properties may be exploited for their specific clinical utility. Verapamil and diltiazem effectively block cardiac conduction through the atrioventricular node, exhibiting value in the management of patients with atrial fibrillation in addition to hypertension. However, their negative inotropic effects can be detrimental to patients with reduced LVEF and should be avoided. In contrast, the dihydropyridine subclass of agents has no utility for managing patients with atrial dysrhythmias but may be used safely (exception being nifedipine) in patients with reduced ejection fraction. Similarly, all CCBs possess some coronary vasodilating properties and, therefore, may be used in select patients for the management of patients with angina, in addition to their antihypertensive benefits.[9]

ACE Inhibitors

ACE-Is have been extensively studied for the treatment of hypertension, and outcome-based trials generally support their use for a wide array of patients, especially with select comorbidities. These compelling indications include their qualified role in managing patients with hypertension who have a history of type 1 or 2 DM, HF, MI, CKD, or stroke.[15] Comparative trials using either ACE-Is or diuretics as initial drug therapy have demonstrated that diuretics may be superior to ACE-Is in regard to combined incidence of new onset CVD and HF,[20] but indistinguishable in terms of overall outcomes.[38] It is therefore

reasonable to conclude that both diuretics and ACE-Is represent appropriate choices as either first- or second-line hypertensive therapies that effectively achieve a target BP goal for most patients with or without comorbidities.

Although generally well-tolerated, ACE-Is are associated with two hallmark side effects: hyperkalemia and a persistent dry cough. Modest elevations in serum potassium should be anticipated when starting or increasing the dose of an ACE-I, particularly in patients with compromised renal function and those receiving any concurrent NSAIDs, potassium supplements, or potassium-containing salt substitutes. Hyperkalemia is rarely a reason for discontinuation of therapy. Nonetheless, periodic monitoring of serum potassium is prudent for patients receiving ACE-Is. The dry cough associated with ACE-Is is thought to be caused by accumulation of bradykinin resulting from a direct effect of inhibiting angiotensin-converting enzyme. If a cough jeopardizes compliance with the agent, ARBs should be considered as possible alternative agents because there is less incidence of cough.

Less common adverse effects of ACE-Is include acute kidney injury, particularly in patients with hemodynamically significant bilateral renal artery stenosis (or unilateral if one functioning kidney), preexisting kidney dysfunction, blood dyscrasias, or angioedema.

In general, effects of ACE-Is on renal function and potassium can be predicted given an understanding of their pharmacologic actions (Figure 5–2). Inhibition of angiotensin II synthesis through ACE inhibition (or direct blockage of the angiotensin II receptor by ARBs) naturally would reduce the efferent renal artery tone, thereby changing the intraglomerular pressure. Although changes in the afferent renal artery tone also occur, the overall effects usually produce a reduction in GFR with resulting decline in GFR of up to 30%.[9] Such reductions in GFR are not usually indications to discontinue use of the ACE-I; however, continued monitoring for further decreases in GFR and consideration of dose reduction remain prudent. Alternatively, should declines in GFR exceed 30%, dose reduction or discontinuation is warranted until further evaluation can be made.

Angiotensin Receptor Blockers

ARBs are inhibitors of the angiotensin-1 (AT1) receptors (Figure 5–2). AT1 receptor stimulation evokes a pressor response via a host of accompanying effects on catecholamines, aldosterone, and thirst.[9] Consequently, inhibition of AT1 receptors directly prevents this pressor response and results in upregulation of the RAAS. Upregulation of the RAAS results in elevated levels of angiotensin II, which have the added effect of stimulating the angiotensin-2 (AT2) receptors. AT2-receptor stimulation is generally associated with antihypertensive activity; however, long-term effects of AT2-receptor stimulation on cellular growth and repair mechanisms are relatively unknown. While the pharmacologic differences between ARBs and ACE-Is are clear, the therapeutic relevance resulting from these differences remains ambiguous. Previously, the clinical benefits of ARBs were considered less robust as compared to ACE-Is, but the Ongoing Telmisartan Alone and in Combination with Ramipril Global Endpoint Trial (ONTARGET) has demonstrated that in high-risk patients, telmisartan is noninferior to ramipril for the reduction of death from cardiovascular causes, MI, stroke, or hospitalization for HF.[39] This study also demonstrated that an ACE-I in combination with an ARB reduces proteinuria to a greater extent than either agent as monotherapy but increases the composite of dialysis, doubling of serum creatinine, and death.[40] Although better tolerated than ACE-Is, ARBs have not been shown to demonstrate superiority of outcomes relative to ACE-Is.

At this point, ARBs have emerged as an effective class of antihypertensives whose low incidence of side effects and demonstrated clinical role in patients with specific comorbidities have afforded them an attractive position in the antihypertensive armamentarium. However, as with ACE-Is, patients may develop angioedema. Although estimates of cross-reactivity are reportedly low,[41] one should always exercise caution when considering the use of an ARB in a patient with a known history of angioedema to an ACE-I. Like ACE-Is, the antihypertensive effectiveness of ARBs is greatly enhanced by combining them with diuretics. Combining an ACE-I with an ARB for treating hypertension should almost always be avoided. However, in select situations, the addition of ARBs to ACE-Is for patients with HF has demonstrated additional incremental benefits and may be considered if aldosterone antagonists are not indicated or tolerated.[41] Overall, ARBs have proven their value as reasonable first-line agents for uncomplicated patients with hypertension, well-tolerated alternatives to ACE-Is for patients with select comorbidities (CKD, DM, and prior MI [Table 5–3]) and alternatives when ACE-Is are not well-tolerated.

Renin Inhibitors

Aliskiren is the first agent in the newest class of antihypertensive agents. Although similar to ACE-Is and ARBs in that it acts

Patient Encounter 2

A 52-year-old Hispanic woman returns to your clinic for a follow-up visit. Her seated BP measurements are 160/90 mm Hg and 158/92 mm Hg. Her heart rate is 98 beats/min. She is currently on nebivolol 40 mg daily, hydrochlorothiazide 25 mg daily, amlodipine 10 mg daily, captopril 12.5 mg three times daily, terazosin 5 mg daily, and rosuvastatin 40 mg daily. She states that she has been adherent with all medications, but prescription bottles she brought in reveal she is overdue on refills yet she has at least 2 to 3 weeks worth of medication in each vial. She is not familiar with the names of her medications, smokes one pack of cigarettes per day, and does not consume any alcohol or illicit substances. She is overweight, does not exercise, and consumes mostly processed and/or fast foods. Past medical history is significant for prior MI 18 months ago treated medically, hypertension, obstructive sleep apnea, and osteoarthritis. Physical examination was unremarkable. Laboratory values were significant for serum creatinine of 0.8 mg/dL (71 µmol/L), a potassium level of 3.5 mEq/L (mmol/L), fasting glucose of 120 mg/dL (6.7 mmol/L), total cholesterol of 260 mg/dL (6.72 mmol/L), HDL cholesterol of 45 mg/dL (1.16 mmol/L), triglyceride level of 180 mg/dL (2.03 mmol/L), and calculated low-density lipoprotein (LDL) cholesterol of 179 mg/dL (4.63 mmol/L).

Based on the information provided, does the patient have resistant hypertension?
Based on the information presented, create a care plan for this patient's hypertension. This should include (a) goals of therapy, (b) a patient-specific therapeutic plan, and (c) a plan for appropriate monitoring to achieve goals and avoid adverse effects.

within the RAAS, it is unique in that it directly blocks renin, thereby reducing PRA and subsequently AT1 and AT2 with a resultant reduction in BP. This disruption of the negative feedback loop results in a compensatory increase in pro-renin and renin levels, the significance of which is not well-established. Aliskiren has been shown to be well-tolerated and effective in reducing BP when used as monotherapy and in combination with other antihypertensive agents, including thiazide diuretics, ARBs, and CCBs.[15] However, long-term clinical trials evaluating efficacy and safety have not been completed, and thus the effects of aliskiren on morbidity and mortality are as yet unknown. Additionally, the Aliskiren Trial In Type 2 Diabetes Using Cardio-renal End points (ALTITUDE) comparing ACE-I or ARB monotherapy to that in combination with aliskiren was stopped prematurely as the combination therapy did not reduce cardiovascular endpoints.[42] Therefore, combining two or more RAAS blocking agents (ACE-Is, ARBs, or renin inhibitors) for the treatment of hypertension is not recommended.[40,42] Because of aliskiren's role in the RAAS, recommendations and precautions for monitoring serum potassium and kidney function should be similar to those of ACE-Is and ARBs.

α_1-Blockers

Generally, α_1-blockers are considered inferior agents and should not be used as monotherapy. Further, doxazosin is associated with an increase in cardiovascular and cerebrovascular events.[20] However, α_1-blockers may be considered as add-on therapy to other agents (eg, fourth or fifth line) when hypertension is not adequately controlled. In addition, they may have a specific role in the antihypertensive regimen for elderly men with **prostatism**; however, their use is often curtailed by complaints of transient dizziness, palpitations, or syncope following the first dose and **orthostatic hypotension** with chronic use. Due to their ability to cross blood-brain barrier, α_1-blockers can also cause asthenia, vivid dreams, and depression. In addition, **priapism** may occur. When selected, however, combination therapy with thiazide is recommended to minimize potential edema resulting from the α_1-blocker's tendency to cause sodium and water retention. The roles of doxazosin, terazosin, and prazosin in management of patients with hypertension are limited due to the paucity of outcome data and absence of a unique role for special populations or compelling indications.[15]

Central α_2-Agonists

Limited by their tendency to cause **orthostasis**, sedation, dry mouth, and vision disturbances, clonidine, methyldopa, guanfacine, and guanabenz represent rare choices in contemporary treatment of patients with hypertension. However, adding clonidine to other antihypertensive agents may be used for individuals with resistant hypertension and methyldopa is a viable option for pregnancy. Their central α_2-adrenergic stimulation is thought to reduce sympathetic outflow and enhance parasympathetic activity, thereby reducing heart rate, CO, and total PVR. Occasionally used for cases of resistant hypertension, these agents may have a role when other more conventional therapies appear ineffective. The availability of a transdermal clonidine patch applied once-weekly may offer an alternative to hypertensive patients with adherence problems. Of particular importance is the potential for severe rebound hypertension when clonidine is abruptly discontinued. Rather, clonidine's dose should be gradually reduced when being discontinued. In patients concurrently taking a β-blocker, the β-blocker should be tapered to discontinuation first, ideally several days before initiating the clonidine taper. Because clonidine withdrawal results in an increase in SNS activity, patients withdrawing from clonidine while on a β-blocker could experience unbalanced α-mediated vasoconstriction.[9]

Other Agents

Direct vasodilators such as hydralazine and minoxidil represent alternative agents used for patients with resistant hypertension. They primarily act to relax smooth muscles in arterioles and activate baroreceptors. Because of the reflex tachycardia and fluid retention they cause, their use in the absence of concurrently administered β-blockers and diuretics such as furosemide is uncommon. Other side effects associated with minoxidil include pericardial effusion, nonspecific T-wave change on the ECG, and hypertrichosis (excessive body hair), particularly in women. Rarely, hydralazine-induced lupus-like syndrome can occur in some patients. Although uncommon, females, those receiving doses in excess of 200 mg/day, individuals with slow hepatic acetylation capacity, or having certain immunogenic factors appear to be at greater risk.[43] Because slow acetylation can increase the bioavailability of hydralazine leading to adverse effects, in 2013 the Food and Drug Administration (FDA) listed N-acetyltransferase-1 (NAT-1) and NAT2 genes as biomarkers for the effectiveness and/or toxicity of hydralazine. References describing the appropriate use and monitoring of these infrequently utilized agents should be consulted before use.[9] Finally, reserpine, although slow to act, reduces sympathetic tone and thus PVR by depleting norepinephrine from sympathetic nerve endings. Although included in the SHEP and ALLHAT trials,[20,44] reserpine's numerous side effects, including gastric ulceration, depression, and sexual side effects, have limited its utility. Two additional agents, guanethidine and guanadrel, act as postganglionic sympathetic inhibitors inhibiting the release of norepinephrine as well as depleting norepinephrine from these nerve terminals. However, these agents have little role in the management of hypertension because of significant adverse effects.[9]

Antihypertensive Toxicity and Management

Common adverse reactions and monitoring parameters with each class of antihypertensive agents are discussed in the earlier sections. Overdoses occurring from antihypertensive agents are relatively uncommon but their consequences, especially those involving β-blockers, CCBs, and vasodilators, can be profound.[45] This contrasts with the toxicities observed from diuretics, ACE-Is, ARBs, and direct renin inhibitors, which are generally more limited. Early gastrointestinal decontamination followed by routine supportive care, including intravenous (IV) crystalloid boluses, airway protection, and/or vasopressor administration should be initiated in patients manifesting significant bradycardia, hypotension, and/or seizures. If unresponsive to standard supportive care, glucagon and/or high dose insulin with glucose (if no response to glucagon) may be used when β-blocker toxicity is suspected or confirmed. The early use of high dose insulin and IV calcium can be effective for CCB poisonings. While administering calcium, one should monitor the ECG, avoid rapid infusions, and never infuse calcium in the same line as phosphate-containing solutions to prevent precipitation. Patients who ingest sustained-release formulations may experience delayed responses and prolonged toxicity and require 24-hour observation, even if asymptomatic upon presentation.

Patient Encounter 3

A 62-year-old black man with history of hypertension, gout, and CKD presents to clinic for his annual examination. Upon reviewing his medication history, you see the patient has been taking chlorthalidone 25 mg daily and allopurinol 200 mg daily. Physical examination is unremarkable. Laboratory values are remarkable for potassium 3.6 mEq/L (mmol/L), serum creatinine 1.4 mg/dL (124 µmol/L), serum uric acid 9.2 mg/dL (547 µmol/L), and proteinuria 600 mg/24 hours (0.6 g/day). Patient's average seated BP was 128/76 mm Hg with HR of 76 beats/min.

Based on the 2017 ACC/AHA guidelines, is this patient achieving his blood pressure goal?
Would you consider changes to current antihypertensive therapy given the patient's BP, laboratory values, and medical history?
How would you assess the effectiveness of your therapeutic recommendations for this patient?

SPECIAL PATIENT POPULATIONS

Compelling Indications and Special Considerations

KEY CONCEPT Specific antihypertensive therapy is warranted for certain patients with comorbid conditions that may elevate their level of risk for CVD. Clinical conditions and patient factors for which there is compelling evidence supporting one or more classes of drug therapy include:

LO 7

- Stable ischemic heart disease (SIHD)
- HF
- Diabetes
- CKD
- Valvular heart disease
- Atrial fibrillation
- Cerebrovascular disease
- Elderly
- Race

Compelling indications for specific drug therapies are summarized in Table 5–3.[6] The basis for recommendations for select patient populations may follow pharmacology and, in some cases, evidence of specific target values in select patient populations.

In patients with an ACS or stable angina and hypertension, β-blockers and possibly long-acting CCBs are indicated because of their antihypertensive and antianginal effects.[36] Nitrate therapy should also be considered in patients with persistent angina and hypertension, and in the setting of an ACS. In post-MI patients, especially those with reduced LVEF, β-blockers and ACE-Is or ARBs are indicated due to their proven reduction of cardiovascular morbidity/mortality in this population. Aldosterone antagonists are also indicated for the post-MI patient with reduced LVEF and either diabetes or symptoms of HF.[41] Patients with CAD were included in the SPRINT trial, which showed a reduction in major adverse cardiovascular events, including mortality, with intensive SBP reduction (SBP < 120 mm Hg) versus standard treatment (< 140 mm Hg) as measured via AOBP.[17] However, it should be noted that serious adverse events of hypotension, syncope, electrolyte abnormalities, and acute kidney injury or acute renal failure were more frequent in the intensive therapy arm and must weigh into decisions regarding application of the SPRINT findings. This data was considered by the 2017 ACC/AHA guidelines Committee as part of the evidence and rationale to support a lower BP target (< 130/80 mm Hg) in this patient population.[2]

Patients with HF represent a heterogeneous cohort of patients with specific recommendations for BP therapy depending on their classification. BP targets for patients with HF have been recently updated by the ACC/AHA with a target SBP less than 130 mm Hg recommended for stage A HF patients and those with stage C HF with either reduced or preserved LVEF, but with no clear update for stages B and D.[46] Patients with HFrEF and hypertension should be treated with evidence-based β-blockers (bisoprolol, carvedilol, or metoprolol succinate), ACE-Is or ARBs, and aldosterone antagonists as each has evidence supporting their morbidity/mortality benefits for such patients. In contrast, diuretics are recommended in HF patients with evidence of volume overload for symptom relief. African-Americans with HFrEF are ideal candidates for combination therapy with isosorbide dinitrate and hydralazine based on morbidity and mortality benefits and potential beneficial effects on lowering BP.[41] The dihydropyridine CCBs, amlodipine or felodipine, may be used in patients with HFrEF for uncontrolled BP; however, they offer no beneficial effect on morbidity and mortality and may increase the risk of edema.[41] For patients with HF with preserved ejection fraction (HFpEF), use of non-dihydropiridine CCBs (diltiazem and verapamil) is not discouraged in contrast to patients with HFrEF.[41] Updated HFpEF recommendations highlight the potential role for aldosterone antagonists in decreasing HF hospitalization in this cohort.[46]

Patients with diabetes and hypertension without CKD (regardless of age) represent a target population whose initial drug therapy depends on if they are Black or non-Black. Specifically, Black patients with diabetes and no CKD should be treated initially with thiazide-type diuretics or CCBs alone or in combination. In the presence of albuminuria in a patient with diabetes and hypertension, ACE-Is or ARBs can be considered initially. Non-Black patients with diabetes and no CKD are candidates for the same starting therapies but with expanded options including either ACE-Is or ARBs.[2]

In patients with CKD and hypertension (regardless of age, race, or presence of diabetes), ACE-Is or ARBs alone or in combination with other agents are preferred.[32] ACE-Is in combination with a thiazide diuretic are also preferred in patients with a history of prior stroke or transient ischemic attack. This therapy reduces the risk of recurrent stroke, making it particularly attractive in these patients for BP control.

Hypertension in patients with asymptomatic aortic stenosis can be treated with pharmacologic therapy, but therapy should be initiated with the use of low doses and carefully titrated upward as appropriate. In patients with chronic aortic dissection, β-blockers were associated with improved survival, whereas ACE-Is did not improve survival.[2]

In patients with atrial fibrillation, ARB therapy is suggested for reduction in recurrence of atrial fibrillation.[2] The use of an ARB versus CCBs or β-blockers has clinical superiority and may be an appropriate first-line therapy choice for antihypertensive therapy in patients with atrial fibrillation.[2] Of note, no data on the role of ACE-Is in this situation is available at this point.

LO 7

There are several situations in the management of hypertension requiring special considerations including, but not limited to:

- Hypertensive crisis
- Elderly populations
- Isolated systolic hypertension
- Minority populations
- Pregnancy
- Pediatrics

Hypertensive crisis includes both hypertensive emergencies and hypertensive urgencies. A hypertensive emergency occurs when severe elevations in BP are accompanied by acute or life-threatening target organ damage such as ACS, unstable angina with dynamic ST changes, encephalopathy, intracerebral hemorrhage, acute left ventricular failure with pulmonary edema, dissecting aortic aneurysm, rapidly progressive renal failure, accelerated malignant hypertension with papilledema, and eclampsia, among others. BP is generally greater than 180/120 mm Hg, although a hypertensive emergency can occur at lower levels, particularly in individuals without previous hypertension. The goal in most hypertensive emergency cases is to reduce SBP by up to 25% in the first hour; if stable, then lower to 160/100–110 mm Hg over the next 2 to 6 hours; and then carefully to normal over the following 24 to 48 hours. For individuals with compelling conditions, including aortic dissection, severe preeclampsia or eclampsia, or pheochromocytoma crisis, a more aggressive BP-lowering approach (reduce SBP to < 140 mm Hg in the first hour and < 120 mm Hg in aortic dissection) should be taken.[2] IV therapy is generally required and may consist of the agents listed in Table 5–8. A hypertensive urgency is manifested as a severe elevation in SBP greater than 179 mm Hg and DBP greater than 109 mm Hg without evidence of acute or life-threatening target organ damage.[47] In these individuals, BP can usually be managed with orally administered short-acting medications (ie, captopril, clonidine, or labetalol) and observation in the emergency department over several hours, with subsequent discharge on oral medications and follow-up in the outpatient setting within 24 hours.[2]

The target for BP in patients 65 years and older remains uncertain and in part depends on whether the patient is ambulatory, community dwelling, institutionalized, and able to tolerate therapy. A target BP of less than 130 mm Hg systolic is recommend in noninstitutionalized ambulatory community dwelling patients. In addition, if the patient has a high burden of comorbidity and limited life expectancy, a more personalized team-based approach taking into account potential risks and benefits of therapy is warranted.[2] The treatment of patients 60 years of age and older with hypertension should follow the same approach as other populations, with the exception that lower starting doses may be warranted to avoid adverse effects. Special attention should be paid to postural hypotension. This includes an approach that consists of careful assessment of orthostatic symptoms, measurement of BP in the upright position upon standing for 1 to 3 minutes, and caution to avoid volume depletion and rapid titration of antihypertensive therapy as was done in the Hypertension in the Very Elderly Trial (HYVET).[48] It should also be noted that in the HYVET trial, patients were excluded if standing SBP at baseline was less than 140 mm Hg. Newer data from the SPRINT suggests patients 75 years of age and older benefit in a similar fashion from intensive SBP reduction (< 120 mm Hg vs < 140 mm Hg as measured by AOBP) as did patients less than 75 years of age with regard to cardiovascular morbidity and mortality risk reduction.[17] In this situation, while some patients may benefit from pursuing intensive BP-lowering targets, tolerability must not be overlooked and aspects of patient selection and safety considerations are paramount when considering any BP-lowering strategy in the elderly.

In individuals with isolated systolic hypertension, the optimal level of diastolic pressure is not known, and although treated patients who achieve diastolic pressures less than 60 to 70 mm Hg had poorer outcomes in a landmark trial, their cardiovascular event rate was still lower than those receiving placebo.[33]

While the treatment approach of hypertension in minority populations is similar, special consideration should be paid to socioeconomic and lifestyle factors that may be important barriers to BP control. In addition, in patients of African origin, diminished BP responses have been seen with ACE-Is and ARBs compared with diuretics or CCBs.[3]

Hypertension in pregnancy is a major cause of maternal, fetal, and neonatal morbidity and mortality. There are four different categories of hypertension in pregnancy: preexisting chronic hypertension, gestational hypertension, preeclampsia-eclampsia, and preeclampsia superimposed on chronic hypertension. Each category is treated slightly differently. Table 5–9 summarizes oral drug therapy options for pregnant patients with chronic hypertension. Also refer to the American College of Obstetricians and Gynecologists task force on hypertension in pregnancy for detailed therapeutic options for acute severe hypertension in preeclampsia.[49]

In children and adolescents, three or more BP readings are compared with tables listing the 90th, 95th, and 95th + 12 mm Hg for BPs based on age, height, and gender that classify BP as normal, elevated BP, and stage 1 and stage 2 hypertension.[50] The prevalence of hypertension in adolescent populations is increasing. This, along with increases in obesity, sedentary lifestyle, or a positive family history, increases the risk of CVD. The clinician should be aware that secondary causes are common in adolescents with hypertension and the identification and aggressive modification of risk factors with nonpharmacologic and pharmacologic interventions is paramount for risk reduction of target organ damage. The 2017 Clinical Practice Guideline for Screening and Management of High Blood Pressure in Children and Adolescents published by the American Academy of Pediatrics provides specific recommendations to modify and treat risk factors in this population of patients.[50] The *Nelson Textbook of Pediatrics* is also recommended for a comprehensive review of treatment of congenital and pediatric hypertension, which is beyond the scope of this chapter.

OUTCOME EVALUATION

LO 8

Short-term goals are to achieve reduction in BP safely through the iterative process of using pharmacologic therapy, along with nonpharmacologic therapy and lifestyle changes. Key to achieving target BP goals is a comprehensive monitoring plan, which considers the following:

- In patients in whom healthy lifestyle changes alone are recommended (ie, elevated BP or stage 1 hypertension without clinical ASCVD, CKD, DM, and estimated 10-year CVD risk < 10%), BP should be reassessed every 3 to 6 months.
- In patients starting pharmacologic therapy, BP and HR should be measured at monthly intervals, or more frequently in patients with marked elevations or significant comorbidities (eg, HF, CKD) until BP goal is achieved.
- Monitor renal function and electrolytes within 2 to 4 weeks of initiating or increasing doses of antihypertensive

Table 5–8

Parenteral Antihypertensive Agents for Hypertensive Emergency and Special Conditions[28]

Drug	Dose Range[a]	Onset	Duration	Adverse Effects[b]	Special Indications
Adrenergic inhibitors					
Esmolol hydrochloride	500–1000 mcg/kg/min IV over 1 minute, then 50 mcg/kg/min by infusion; may repeat bolus after 5 minutes at 50 mcg/kg/min increment; maximum 200 mcg/kg/min	1–2 minutes	10–20 minutes	Nausea, asthma, first-degree heart block, HF	Preferred agent for acute aortic dissection, ACS and perioperative hypertension. Avoid use in combination with β-blocker therapy, bradycardia or decompensated HF.
Labetalol hydrochloride	0.3–1 mg/kg (maximum 20 mg) slow IV injection or 0.4–1 mg/kg/h IV infusion up to 3 mg/kg/h; may repeat every 4–6 hours; maximum total cumulative dose 300 mg	5–10 minutes	3–6 hours	Vomiting, scalp tingling, dizziness, asthma, COPD, nausea, heart block, orthostatic hypotension, HF	Most hypertensive emergencies, including eclampsia and preeclampsia. Avoid use in reactive airway disease, second- or third-degree heart block or bradycardia.
Phentolamine	5 mg IV bolus, may repeat every 10 minutes	1–2 minutes	10–30 minutes	Tachycardia, flushing, headache, nausea, vomiting	Catecholamine excess such as adrenergic crisis secondary to pheochromocytoma or cocaine or amphetamine overdose or clonidine withdrawal.
Angiotensin converting enzyme inhibitors					
Enalaprilat	1.25 mg IV over 5 minutes, may increase to 5 mg and repeat every 6 hours	15–30 minutes	6–12 hours	Precipitous fall in pressure in high-renin states; variable response	High plasma renin activity; avoid in acute MI, bilateral renal stenosis, pregnancy.
Dihydropyridine calcium channel blockers					
Clevidipine	Initial 1–2 mg/hour IV, doubling every 90 seconds until BP at target, then increasing by less than doubling every 5–10 minutes; maximum 32 mg/hour	2–4 minutes	5–15 minutes; maximum 72 hours	Atrial fibrillation, fever, insomnia, nausea, headache, vomiting, postprocedural hemorrhage, acute renal failure, respiratory failure	Most hypertensive emergencies. Avoid use if hypersensitivity to soy or egg products, pathological hyperlipidemia, lipoid nephrosis, or acute pancreatitis. Use low-end dose range for elderly.
Nicardipine hydrochloride	Initial 5 mg/hour IV, increasing by 2.5 mg/hour every 5 min; maximum 15 mg/hour	5–10 minutes	15–30 minutes, may exceed 4 hours	Tachycardia, headache, flushing, local phlebitis	Preferred agent for most hypertensive emergencies, pregnancy, except acute pulmonary edema. Avoid use in acute aortic dissection. No dose adjustment needed for elderly.
Dopamine$_1$-receptor agonist					
Fenoldopam mesylate	0.1–0.3 mcg/kg/min as IV infusion[c]	< 5 minutes	30 minutes	Tachycardia, headache, nausea, flushing	Preferred agent in acute renal failure. Avoid use in glaucoma, elevated intracranial pressure, and sulfite allergy.
Vasodilators					
Hydralazine hydrochloride	Initial 10 mg as slow IV infusion; maximum initial dose 20 mg; repeat every 4–6 hours as needed	10–20 minutes 20–30 minutes	1–4 hours IV	Tachycardia, flushing, headache, vomiting, aggravation of angina	Preferred agent in pregnancy. Not a first-line in most patients due to unpredictability of response and prolonged duration of action.

(*Continued*)

Table 5–8

Parenteral Antihypertensive Agents for Hypertensive Emergency and Special Conditions[28] (*Continued*)

Drug	Dose Range[a]	Onset	Duration	Adverse Effects[b]	Special Indications
Nitroglycerin	Initial 5 mcg/min as IV infusion; increase in increments of 5 mcg/min to achieve BP target; maximum dose 20 mcg/min	2–5 minutes	5–10 minutes	Headache, vomiting, methemoglobinemia, tolerance with prolonged use	Preferred agent in ACS, acute pulmonary edema, and perioperative hypertension
Sodium nitroprusside	Initial 0.3–0.5 mcg/kg/min as IV infusion[d]; increase in increments of 0.5 mcg/kg/min to achieve BP target; maximum dose 10 mcg/kg/min	Immediate	1–2 minutes	Nausea, vomiting, muscle twitching, sweating, thiocyanate and cyanide intoxication	Preferred agent in acute pulmonary edema. Use low dose range for elderly.

[a]These doses may vary from those in the *Physicians' Desk Reference.*

[b]Hypotension may occur with all agents.

[c]Requires special delivery system.

[d]Requires special delivery system. For infusion rates over or equal to 4–10 mcg/kg/min or duration more than 30 minutes, coadminister thiosulfate to prevent cyanide toxicity.

ACS, acute coronary syndrome; BP, blood pressure; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; HF, heart failure; IV, intravenous; MI, myocardial infarction.

Data from Whelton PK CR, Aronow WS, et al. 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCNA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults. J Am Coll Cardiol. 2017; and Saseen JJ, Maclaughlin EJ. Hypertension. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York: McGraw-Hill, 2017:74.

Table 5–9

Treatment of Chronic Hypertension in Pregnancy[3,49]

Agent	Category[a]	Comments
Methyldopa	B/C	Preferred first-line therapy on the basis of long-term follow-up studies supporting safety after exposure in utero. Surveillance data do not support an association between drug and congenital defects when the mother took the drug early in the first trimester
Labetalol	C	Increasingly preferred to methyldopa because of reduced side effects. The agent does not seem to pose a risk to the fetus, except possibly in the first trimester
β-Blockers	B/C/D	Generally acceptable on the basis of limited data. Reports of intrauterine growth restriction with atenolol in the first and second trimesters B: acebutolol, pindolol, sotalol C: esmolol, metoprolol, nadolol, nebivolol, penbutolol, propranolol, timolol D: atenolol
Clonidine	C	Limited data; no association between drug and congenital defects when the mother took the drug early in the first trimester, but number of exposures is small
Calcium channel antagonists	C	Limited data; nifedipine in the first trimester was not associated with increased rates of major birth defects, but animal data were associated with fetal hypoxemia and acidosis. This agent should probably be limited to mothers with severe hypertension
Thiazide-type diuretics	B	Not first-line agents; probably safe; available data suggest that throughout gestation, a diuretic is not associated with an increased risk of major fetal anomalies or adverse fetal-neonatal events
Angiotensin-converting enzyme inhibitors, angiotensin II receptor antagonists, and direct renin inhibitors	D	Should be discontinued as soon as possible. Can cause injury and death to the developing fetus

[a]Based on the US Food and Drug Administration (FDA) pregnancy risk categories. See additional information at the FDA website for the updated Pregnancy and Lactation Labeling.

therapy that may affect these parameters (eg, diuretics, aldosterone antagonists, ACE-Is, and ARBs). Earlier monitoring should be considered in those with CKD, baseline electrolyte abnormalities, or HF.

- Increase the dose of initial drug (replace with an alternative if adverse event or no significant reduction in BP) or add an additional drug to current regimen if BP goal is not reached.
- Once BP target is achieved, monitor patient every 3 to 6 months to assess BP control, electrolytes and renal function as appropriate, clinical status and target organ damage.
- Implement lifestyle changes that address risk factors for CVD such as obesity, physical inactivity, insulin resistance, dyslipidemia, smoking cessation, need for low dose aspirin, or statin therapy.
- Monitor for efficacy, adverse events, drug interactions, and adherence to therapy as keys to achieving the long-term goals of reducing risk of morbidity and mortality associated with CVD.

Patient Care Process

Collect Information:

- Perform a medication history including prescription and nonprescription medications, herbal products, and dietary supplements as well as history of allergies to medications or other substances.
- Obtain health data including personal and family medical history, past surgeries/procedures, immunization status, fall risk, health and wellness information, laboratory and physical assessment findings.
- Speak with patient and review records to obtain lifestyle habits (eg, sodium intake, cooking practices, physical activity, use of alcohol/tobacco/recreational drugs), preferences and beliefs, health literacy, cultural factors, health and functional goals, and socioeconomic factors that affect access to medications and other aspects of care.

Assess the Information:

- Document current BP and heart rate (office, HBP or 24 hour-ABPM or AOBP results if available).
- Identify any substances or lifestyle habits that could adversely affect BP control or negatively interact with current medications.
- Based on medical history, physical examination, laboratory results, and review of systems determine whether patient has any target organ damage or comorbidities related to or associated with high BP or if experiencing any signs or symptoms of high BP.
- Calculate patient's 10-year risk of a cardiovascular event to establish BP threshold for initiation of pharmacologic therapy if stage 1 hypertension and no clinical ASCVD, DM, or CKD, and candidacy for other cardioprotective therapies (eg, statin therapy, antiplatelet therapy).
- Establish an appropriate BP goal.
- Determine patient's awareness and knowledge (eg, health literacy) of health effects of high BP and benefits and risks of treatment.
- Identify compelling indications for specific antihypertensives (Table 5–3) or specific considerations (eg, pregnancy [Table 5–9]).
- Evaluate appropriateness, effectiveness, safety (adverse events, drug interactions), and patient adherence to current pharmacotherapy.
- Review immunization status and need for preventive care and other health care services, where appropriate.

Develop a Care Plan:

- Collaborate with patient to identify feasible lifestyle modifications (Table 5–6).
- If patient is not at BP goal, determine whether antihypertensive pharmacotherapy is indicated, and select appropriate therapy based on compelling indications (Tables 5–2 and 5–3), specific patient characteristics (eg, pregnancy [Table 5–9]), and patient preferences.
- Utilize medications with complementary mechanisms of action and at doses that are optimal for patient (Table 5–7).
- Determine affordability of medications (eg, insurance coverage) and availability on health care formulary, if applicable.
- Engage and empower the patient through education and self-management.

Implement the Care Plan:

- Educate and provide resources about implementing lifestyle modifications and changes in drug therapy including medication administration, storage, adherence, and potential adverse effects and their management.
- Help patient select a self-monitoring device and seek commitment on a mutually agreed upon frequency of measurements.
- Advise patient on how to monitor, document, and report BP measurements as well as when to seek medical advice or care.
- Address any patient concerns about management of hypertension.
- Arrange for preventive care (eg, immunizations) and other health care services that were previously identified as warranted.

Follow-up: Monitor and Evaluate:

- Follow at monthly intervals or more frequently in patients with marked elevations or significant comorbidities (eg, HF, CKD), until BP goal is achieved.
- Review medication and lifestyle adherence, BP measurements, adequacy of BP control, and laboratory and other diagnostic tests to assess changes in clinical status and target organ damage.
- Determine whether patient is experiencing any adverse reactions or drug interactions.
- Once BP is controlled, monitor patient every 3 to 6 months to assess BP control, electrolytes and renal function as appropriate, clinical status, and target organ damage.

Abbreviations Introduced in This Chapter

ABPM	Ambulatory blood pressure monitoring
ACCORD	Action to Control Cardiovascular Risk in Diabetes
ACE-I	Angiotensin-converting enzyme inhibitor
ACC	American College of Cardiology
ACR	Albumin-to-creatinine ratio
ACS	Acute coronary syndromes
AHA	American Heart Association
ALLHAT	Antihypertensive and Lipid-Lowering Treatment to Prevent Heart Attack Trial
ALTITUDE	Aliskiren Trial In Type 2 Diabetes Using Cardio-renal End points
AOBP	Ambulatory office-based blood pressure
ARB	Angiotensin receptor blocker
ASCOT-BPLA	Anglo-Scandinavian Cardiac Outcomes Trial-Blood Pressure Lowering Arm
ASCVD	Atherosclerotic cardiovascular disease
AT1	Angiotensin-1
AT2	Angiotensin-2
BID	Twice daily
BP	Blood pressure
CAD	Coronary artery disease
CCB	Calcium channel blocker
CKD	Chronic kidney disease
CO	Cardiac output
COPD	Chronic obstructive pulmonary disease
CrCl	Creatinine clearance
CVD	Cardiovascular disease
CYP	Cytochrome P450
DASH	Dietary Approaches to Stop Hypertension
DBP	Diastolic blood pressure
DM	Diabetes mellitus
ECG	Electrocardiogram
FDA	Food and Drug Administration
GFR	Glomerular filtration rate
HAART	Highly active antiretroviral therapy
HBP	Home blood pressure
HDL	High-density lipoprotein
HF	Heart failure
HFpEF	Heart failure with preserved ejection fraction
HFrEF	Heart failure with reduced ejection fraction
HYVET	Hypertension in the Very Elderly Trial
ISA	Intrinsic sympathomimetic activity
IV	Intravenous
LDL	Low-density lipoprotein
LVEF	Left ventricular ejection fraction
MAO	Monoamine oxidase
MI	Myocardial infarction
NAT-1	N-acetyltransferase-1
NSAID	Nonsteroidal anti-inflammatory drug
ONTARGET	Ongoing Telmisartan Alone and in combination with Ramipril Global Endpoint Trial
PRA	Plasma renin activity
PVR	Peripheral vascular resistance
QDay	Once daily
RAAS	Renin-angiotensin-aldosterone system
SBP	Systolic blood pressure
SHEP	Systolic Hypertension in the Elderly Program
SIHD	Stable ischemic heart disease
SPRINT	Systolic Blood Pressure Intervention Trial
SPS3	Secondary Prevention of Small Subcortical Strokes
SNS	Sympathetic nervous system
TID	Three times daily
VALUE	Valsartan Antihypertensive Long-term Use Evaluation

6 Heart Failure

Orly Vardeny and Tien M. H. Ng

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Differentiate between the common underlying etiologies of heart failure (HF), including ischemic, nonischemic, and idiopathic causes.
2. Describe the pathophysiology of HF as it relates to neurohormonal activation of the renin-angiotensin-aldosterone system and the sympathetic nervous system.
3. Identify signs and symptoms of HF and classify a given patient by New York Heart Association Functional Classification and American College of Cardiology/American Heart Association Heart Failure Staging.
4. Describe the goals of therapy for a patient with acute or chronic HF.
5. Develop a nonpharmacologic treatment plan that includes patient education for managing HF.
6. Develop a specific evidence-based pharmacologic treatment plan for a patient with acute or chronic HF based on disease severity and symptoms.
7. Formulate a monitoring plan for the nonpharmacologic and pharmacologic treatment of a patient with HF.

INTRODUCTION

Heart failure (HF) is defined as the inadequate ability of the heart to pump enough blood to meet the blood flow and metabolic demands of the body.[1] More commonly, HF is a result of low **cardiac output** (CO) secondary to impaired cardiac function. High-output HF is characterized by an inordinate increase in the body's metabolic demands that outpaces an increase in CO of a generally normally functioning heart. The term *heart failure* refers to low-output HF for the purposes of this chapter.

HF results from any structural or functional cardiac disorder that impairs the ability of the ventricle to fill with or eject blood, and can be classified based on the phase of the cardiac cycle leading to impaired ventricular function.[1] A normal cardiac cycle depends on two components: systole and diastole. Expulsion of blood occurs during systole, or contraction of the ventricles; diastole relates to filling of the ventricles. Ejection fraction (EF) is the fraction of the volume present at the end of diastole that is pushed into the aorta during systole. Abnormal ventricular filling (diastolic dysfunction) and/or ventricular contraction (systolic dysfunction) can result in similar decrease in CO and cause HF symptoms. HF is commonly associated with evidence of left ventricular (LV) systolic dysfunction (evidenced by a reduced EF, or left ventricular ejection fraction [LVEF] ≤ 40% [0.40]), and when accompanied by symptoms is also known as HF with reduced ejection fraction, or HFrEF. HF can occur with or without a component of diastolic dysfunction which coexists in up to two-thirds of patients. Isolated diastolic dysfunction, occurring in approximately one-third to one-half of HF patients, is diagnosed when a patient exhibits impaired ventricular filling without accompanying HF symptoms but normal systolic function, defined as LVEF 50% (0.50) or greater. When isolated diastolic dysfunction occurs with symptoms of HF, this is referred to as HF with preserved ejection fraction (HFpEF). Long-standing hypertension is the leading cause of HFpEF. Patients with symptoms of HF and an LVEF between 41% and 49% (0.41 and 0.49) are termed to have HF with mid-range ejection fraction (HFmrEF). Ventricular dysfunction can also involve either the left or right chamber of the heart or both. This has implications for symptomatology because predominant right-sided failure manifests as systemic congestion, whereas predominant left-sided failure results in pulmonary symptoms.

Thus, HF is a clinical syndrome characterized by a history of specific signs and symptoms related to congestion and hypoperfusion. Because HF can occur in the presence or absence of fluid overload, the term *heart failure* is preferred over the former term *congestive heart failure*. The term *acute heart failure* (AHF) is used to signify either an acute decompensation of a patient with a history of chronic HF or to refer to a patient presenting with new-onset HF symptoms. Many disorders, such as those of the pericardium, epicardium, endocardium, or great vessels, may lead to HF, but most patients develop symptoms due to impairment in LV myocardial function. Terms commonly associated with HF, such as ***cardiomyopathy*** and *LV dysfunction,* are not equivalent to HF but describe possible structural or functional reasons for the development of HF.

EPIDEMIOLOGY

HF is a major public health concern affecting approximately 6.5 million people in the United States. An additional 960,000 new cases are diagnosed each year. HF manifests most commonly in adults older than 60 years.[2] The growing prevalence of HF corresponds to (a) better treatment of patients with acute myocardial infarctions (MIs) who will survive to develop HF later in life, and (b) the increasing proportion of older adults due to the aging baby boomer population. The relative incidence of HF is lower in women compared with men, but there is a greater prevalence in women overall due to their longer life expectancy.

Acute HF accounts for 12 to 15 million office visits per year and 6.5 million hospitalizations annually, and HF is the most common hospital discharge diagnosis for Medicare patients and the most costly diagnosis in this population.[2] According to national registries, patients presenting with AHF are older (mean age: 75 years) and have numerous comorbidities such as coronary artery disease (CAD), renal insufficiency, and diabetes. Total estimated direct and indirect costs for managing both chronic and acute HF in the United States for 2012 was approximately $30.7 billion. Medications account for approximately 10% of that cost.[2]

The prognosis for patients hospitalized for AHF remains poor. Average hospital length of stay is estimated to be between 4 and 6 days, a number that has remained constant over the past decade.[3] In-hospital mortality rate has been estimated at approximately 4%, with ranges from 2% to 20%.[4] Readmissions are also high, with up to 30% to 60% of patients readmitted within 6 months of initial discharge date.[4] The 5-year mortality rate for chronic HF remains greater than 50%. Survival strongly correlates with severity of symptoms and functional capacity. Sudden cardiac death is the most common cause of death, occurring in approximately 40% of patients.[2] Although therapies targeting the upregulated neurohormonal response contributing to the pathophysiology of HF have clearly impacted morbidity and mortality, long-term survival remains low.

ETIOLOGY

LO 1

HF is the eventual outcome of numerous cardiac diseases or disorders (Table 6–1).[5] HF can be classified by the primary underlying etiology as ischemic or nonischemic, with 70% related to ischemia. KEY CONCEPT The most common causes of HF are CAD, hypertension, and dilated cardiomyopathy. CAD resulting in acute MI and reduced ventricular function is a common presenting history.

Table 6–1

Causes of Heart Failure

Systolic Dysfunction (Decreased Contractility)
- Reduction in muscle mass (eg, myocardial infarction)
- Dilated cardiomyopathies
- Ventricular hypertrophy
  - Pressure overload (eg, systemic or pulmonary hypertension, aortic or pulmonic valve stenosis)
  - Volume overload (eg, valvular regurgitation, shunts, high-output states)

Diastolic Dysfunction (Restriction in Ventricular Filling)
- Increased ventricular stiffness
- Ventricular hypertrophy (eg, hypertrophic cardiomyopathy, pressure and/or volume overload)
- Infiltrative myocardial diseases (eg, amyloidosis, sarcoidosis, endomyocardial fibrosis)
- Myocardial ischemia and infarction
- Mitral or tricuspid valve stenosis
- Pericardial disease (eg, pericarditis, pericardial tamponade)

Nonischemic Etiologies
- Hypertension
- Viral illness
- Thyroid disease
- Excessive alcohol use
- Illicit drug use
- Pregnancy-related heart disease
- Familial congenital disease
- Valvular disorders such as mitral or tricuspid valve regurgitation or stenosis

From Parker RB, Nappi JM, Cavallari LH. Chronic heart failure. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:80, with permission.

PATHOPHYSIOLOGY

A basic grasp of normal cardiac function sets the stage for understanding the pathophysiological processes leading to HF and selecting appropriate therapy for HF. CO is defined as the volume of blood ejected per unit of time (L/min) and is a major determinant of tissue perfusion. CO is the product of heart rate (HR) and stroke volume (SV): CO = HR × SV. The following sections describe how each parameter relates to CO.

HR is controlled by the autonomic nervous system, where sympathetic stimulation of β-adrenergic receptors results in an increase in HR, resulting in an increased CO. SV is the volume of blood ejected with each systole. SV is determined by factors regulating preload, afterload, and contractility. Preload is a measure of ventricular filling pressure, or the volume of blood in the left ventricle (also known as LV end-diastolic volume). Preload is determined by venous return as well as atrial contraction. An increase in venous return to the left ventricle results in the stretch of cardiomyocyte sarcomeres (or contractile units) and a subsequent increase in the number of cross-bridges formed between actin and myosin myofilaments. This results in an increase in the force of contraction based on the Frank-Starling mechanism.[6] Afterload is the resistance to ventricular ejection and is regulated by ejection impedance, wall tension, and geometry. Thus, elevated aortic and systemic pressures result in an increase in afterload and reduced SV. Contractility, also known as the inotropic state of the heart, is an intrinsic property of cardiac muscle incorporating fiber shortening and tension development. Contractility is influenced to a large degree by adrenergic nerve activity and circulating catecholamines such as epinephrine and norepinephrine.

Compensatory Mechanisms

In the setting of a sustained loss of myocardium (such as after an acute MI), a number of mechanisms aid the heart when faced with an increased hemodynamic burden and reduced CO. They include the Frank-Starling mechanism, tachycardia and increased afterload, and cardiac hypertrophy and remodeling (Table 6–2).[5,7]

▶ *Preload and the Frank-Starling Mechanism*

LO 2

In the setting of a sudden decrease in CO, the natural response of the body is to decrease blood flow to the periphery to maintain perfusion to vital organs such as the heart and brain. Therefore, renal perfusion is compromised due to both decreased CO as well as shunting of blood away from peripheral tissues. This results in activation of the renin-angiotensin-aldosterone system (RAAS). The decrease in renal perfusion is sensed by the juxtaglomerular cells of the kidneys leading to the release of renin and initiation of the cascade for production of angiotensin II. Angiotensin II stimulates the synthesis and release of aldosterone. Aldosterone in turn stimulates sodium and water retention in an attempt to increase intravascular volume and hence preload. In a healthy heart, a large increase in CO is usually accomplished with just a small change in preload. However, in a failing heart, alterations in the contractile filaments reduce the ability of cardiomyocytes to adapt to increases in preload. Thus, an increase in preload actually impairs contractile function in the failing heart and results in a further decrease in CO. See Figure 6–1.

Table 6–2

Beneficial and Detrimental Effects of the Compensatory Responses in Heart Failure[5,7]

Compensatory Response	Beneficial Effects of Compensation	Detrimental Effects of Compensation
Increased preload (through sodium and water retention)	Optimizes stroke volume via Frank-Starling mechanism	Pulmonary and systemic congestion and edema formation Increased MVO_2
Vasoconstriction	Maintains BP and perfusion in the face of reduced cardiac output	Increased MVO_2 Increased afterload decreases stroke volume and further activates the compensatory responses
Tachycardia and increased contractility (due to SNS activation)	Increases cardiac output	Increased MVO_2 Shortened diastolic filling time β_1-Receptor downregulation, decreased receptor sensitivity Precipitation of ventricular arrhythmias Increased risk of myocardial cell death
Ventricular hypertrophy and remodeling	Maintains cardiac output Reduces myocardial wall stress Decreases MVO_2	Diastolic dysfunction Systolic dysfunction Increased risk of myocardial cell death Increased risk of myocardial ischemia Increased arrhythmia risk

BP, blood pressure; MVO_2, myocardial oxygen consumption; SNS, sympathetic nervous system.

► *Tachycardia and Increased Afterload*

LO 2

Another mechanism to maintain CO when contractility is low is to increase HR. This is achieved through sympathetic nervous system (SNS) activation and the agonist effect of norepinephrine on β-adrenergic receptors in the heart. Sympathetic activation also enhances contractility by increasing cytosolic calcium concentrations. SV is relatively fixed in HF; thus HR becomes the major determinant of CO. Although this mechanism increases CO acutely, the **chronotropic** and inotropic responses to sympathetic activation increase myocardial oxygen demand, worsen underlying ischemia, contribute to proarrhythmia, and further impair both systolic and diastolic function.

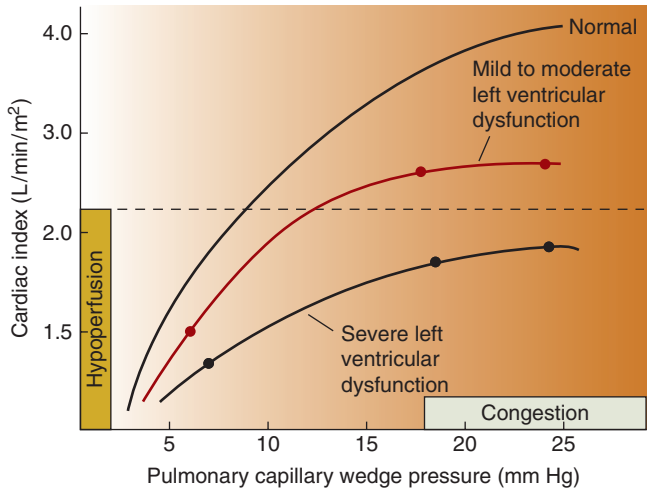

FIGURE 6–1. Relationship between cardiac output (shown as cardiac index) and preload (shown as pulmonary capillary wedge pressure). Cardiac index is expressed in conventional units of L/min/m², and can be converted to SI units of L/s/m² by multiplying by 0.0167. (Reproduced, with permission, from Parker RB, Nappi JM, Cavallari LH. Chronic heart failure. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:83.)

Activation of both the RAAS and SNS also contributes to vasoconstriction in an attempt to redistribute blood flow from peripheral organs such as the kidneys to coronary and cerebral circulation.[7] However, arterial vasoconstriction leads to impaired forward ejection of blood from the heart due to an increase in afterload. Arterial vasoconstriction results in a decrease in CO and continued stimulation of compensatory responses, creating a vicious cycle of neurohormonal activation.

► *Cardiac Remodeling and Ventricular Hypertrophy*

Cardiac remodeling occurs as a compensatory adaptation to a change in wall stress and is largely regulated by neurohormonal activation, with angiotensin II and aldosterone being key stimuli.[7] The process entails changes in myocardial and extracellular matrix composition and function that results in both structural and functional alterations to the heart. In HF, the changes in cardiac size, shape, and composition are pathological and detrimental to heart function. In addition to myocyte size and extracellular matrix changes, heart geometry shifts from an elliptical to a less efficient spherical shape. Even after remodeling occurs, the heart can maintain CO for many years. However, heart function continues to deteriorate until progression to clinical HF. The timeline for remodeling varies depending on the cardiac insult. For example, in the setting of an acute MI, remodeling starts within a few days.[6] Chronic remodeling, however, is what progressively worsens HF, and therefore is a major target of drug therapy.

Ventricular hypertrophy, an adaptive increase in ventricular muscle mass due to the growth of existing myocytes, occurs in response to an increased hemodynamic burden such as volume or pressure overload.[5] Hypertrophy can be concentric or eccentric. Concentric hypertrophy occurs in response to pressure overload such as in long-standing hypertension or pulmonary hypertension, whereas eccentric hypertrophy occurs after an acute MI. Eccentric hypertrophy involves an increase in myocyte size in a segmental fashion, as opposed to the global hypertrophy occurring in concentric hypertrophy. Although hypertrophy helps to reduce cardiac wall stress in the short term, continued hypertrophy accelerates myocyte cell death through an overall increase in myocardial oxygen demand.

Neurohormonal Model of Heart Failure

KEY CONCEPT Development and progression of HF involves activation of neurohormonal pathways including the SNS and the RAAS. This model begins with an initial precipitating event or myocardial injury resulting in a decline in CO, followed by the compensatory mechanisms previously discussed. Activation of neurohormonal pathways with pathological consequences include the RAAS, SNS, endothelin, and vasopressin, as well as those with counterregulatory properties such as the natriuretic peptides and nitric oxide. This model currently guides our therapy for chronic HF in terms of preventing disease progression and mortality.

▶ *Angiotensin II*

Angiotensin II is a key neurohormone in the pathophysiology of HF. The vasoconstrictive effects of angiotensin II lead to an increase in systemic vascular resistance (SVR) and blood pressure (BP). The resulting increase in afterload contributes to an increase in myocardial oxygen demand and opposes the desired increase in SV. In the kidneys, angiotensin II enhances renal function acutely by raising intraglomerular pressure through constriction of the efferent arterioles.[6] However, the increase in glomerular filtration pressure may be offset by a reduction in renal perfusion secondary to angiotensin II's influence over the release of other vasoactive neurohormones such as vasopressin and endothelin-1 (ET-1). Angiotensin II also potentiates the release of aldosterone from the adrenal glands and norepinephrine from adrenergic nerve terminals. Additionally, angiotensin II induces vascular hypertrophy and remodeling in both cardiac and renal cells. Clinical studies show that blocking the effects of the RAAS in HF is associated with improved cardiac function and prolonged survival. Thus, angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) are the cornerstone of HF treatment.

▶ *Aldosterone*

Aldosterone's contribution to HF pathophysiology is multifaceted. Renally, aldosterone causes sodium and water retention in an attempt to enhance intravascular volume and CO. This adaptive mechanism has deleterious consequences because excessive sodium and water retention worsen the already elevated ventricular filling pressures. Aldosterone also contributes to electrolyte abnormalities seen in HF patients. Hypokalemia and hypomagnesemia contribute to the increased risk of arrhythmias. In addition, evidence supports the role of aldosterone as an etiological factor for myocardial fibrosis and cardiac remodeling by causing increased extracellular matrix collagen deposition and cardiac fibrosis.[6] Aldosterone potentially contributes to disease progression via sympathetic potentiation and ventricular remodeling. In addition, the combination of these multiple effects is likely responsible for the increased risk of sudden cardiac death attributed to aldosterone. As elevated aldosterone concentrations have been associated with a poorer prognosis in HF, its blockade has become an important therapeutic target for improvement of long-term prognosis.

▶ *Norepinephrine*

Norepinephrine is a classic marker for SNS activation. It plays an adaptive role in the failing heart by stimulating HR and myocardial contractility to augment CO and by producing vasoconstriction to maintain organ perfusion. However, excess levels are directly cardiotoxic. In addition, sympathetic activation increases the risk for arrhythmias, ischemia, and myocyte cell death through increased myocardial workload and accelerated apoptosis. Ventricular hypertrophy and remodeling are also influenced by norepinephrine.[8]

Plasma norepinephrine concentrations are elevated proportionally to HF severity, with highest levels correlating to the poorest prognosis. Several mechanisms relate to diminished responsiveness to catecholamines (eg, norepinephrine) as cardiac function declines.[6] Adrenergic receptor desensitization and downregulation (decreased receptor number and postreceptor responses and signaling) occur under sustained sympathetic stimulation. The desensitization contributes to further release of norepinephrine. β-Adrenergic blocking agents, although intrinsically negatively inotropic, have become essential therapy for chronic HF.

▶ *Endothelin*

Endothelin-1 (ET-1), one of the most potent physiological vasoconstrictors, is an important contributor to HF pathophysiology.[9] ET-1 binds to two G-protein coupled receptors, endothelin-A (ET-A) and endothelin-B (ET-B). ET-A receptors mediate vasoconstriction and are prevalent in vascular smooth muscle and cardiac cells. ET-B receptors are expressed on the endothelium and in vascular smooth muscle, and receptor stimulation mediates vasodilation and endothelin clearance. Levels of ET-1 correlate with HF functional class and mortality.

▶ *Arginine Vasopressin*

Vasopressin exerts its effects through vasopressin type 1a (V_{1a}) and vasopressin type 2 (V_2) receptors.[5,7] V_{1a} stimulation leads to vasoconstriction, whereas actions on the V_2 receptor cause free water retention through aquaporin channels in the collecting duct. Vasopressin increases preload, afterload, and myocardial oxygen demand in the failing heart. Higher vasopressin concentrations are linked to dilutional hyponatremia and a poor prognosis in HF.

▶ *Counterreulatory Hormones (Natriuretic Peptides, Bradykinin, and Nitric Oxide)*

Atrial natriuretic peptide (ANP) and B-type natriuretic peptide (BNP) are endogenous neurohormones that regulate sodium and water balance. Natriuretic peptides decrease sodium reabsorption in the collecting duct of the kidney.[10] Natriuretic peptides also cause vasodilation through the cyclic guanosine monophosphate (cGMP) pathway. ANP is synthesized and stored in the atria, while BNP is produced mainly in the ventricles. Release of ANP and BNP is stimulated by increased cardiac chamber wall stretch usually indicative of volume load. Higher concentrations of natriuretic peptides correlate with a more severe HF functional class and prognosis. BNP is sensitive to volume status; thus the plasma concentration can be used as a diagnostic marker in HF.[10]

Bradykinin is part of the kallikrein-kinin system, which shares a link to the RAAS through ACE. Bradykinin is a vasodilatory peptide that is released in response to a variety of stimuli, including neurohormonal and inflammatory mediators known to be activated in HF.[9] As a consequence, bradykinin levels are elevated in HF patients and thought to partially antagonize the vasoconstrictive peptides.

Nitric oxide, a vasodilatory hormone released by the endothelium, is found in higher concentrations in HF patients and provides two main benefits in HF: vasodilation and neurohormonal antagonism of endothelin.[9] Nitric oxide's production is affected by the enzyme inducible nitric oxide synthetase (iNOS), which is upregulated in the setting of HF,

Table 6–3

Exacerbating or Precipitating Factors in Heart Failure (HF)[5]

Cardiac	Metabolic	Patient-Related
Acute ischemia Arrhythmia Endocarditis Myocarditis Pulmonary embolus Uncontrolled hypertension Valvular disorders	Anemia Hyperthyroidism/ thyrotoxicosis Infection Pregnancy Worsening renal function	Dietary/fluid nonadherence HF therapy nonadherence Use of cardiotoxins (cocaine, chronic alcohol, amphetamines, sympathomimetics) Offending medications (NSAIDs, COX-2 inhibitors, steroids, lithium, β-blockers, calcium channel blockers, antiarrhythmics, alcohol, thiazolidinediones)

COX-2, cyclooxygenase-2; NSAID, nonsteroidal anti-inflammatory drug.

likely due to increased levels of angiotensin II, norepinephrine, and multiple cytokines. In HF, the physiological response to nitric oxide appears to be blunted, which contributes to the imbalance between vasoconstriction and vasodilation.

▶ *Proinflammatory Cytokines*

Inflammatory cytokines have been implicated in the pathophysiology of HF.[9] Several proinflammatory cytokines (eg, tumor necrosis factor [TNF]-α, interleukin-1, interleukin-6, and interferon-γ) and anti-inflammatory cytokines (eg, interleukin-10) are overexpressed in the failing heart. The most is known about TNF-α, a pleiotropic cytokine that acts as a negative inotrope, stimulates cardiac cell apoptosis, uncouples β-adrenergic receptors from adenylyl cyclase, and is related to **cardiac cachexia**. The exact role of cytokines and inflammation in HF pathophysiology continues to be studied.

Precipitating and Exacerbating Factors in Heart Failure

HF patients exist in one of two clinical states. When a patient's volume status and symptoms are stable, their HF condition is said to be "compensated." In situations of volume overload or other worsening symptoms, the patient is considered "decompensated." Acute decompensation can be precipitated by numerous etiologies (Table 6–3).[5]

KEY CONCEPT The clinician must identify potential reversible causes of HF exacerbations including prescription and nonprescription drug therapies, dietary indiscretions, and medication nonadherence. Nonadherence with dietary restrictions or chronic HF medications deserves special attention because it is the most common cause of acute decompensation and can be prevented. As such, an accurate history regarding diet, food choices, and the patient's knowledge regarding sodium and fluid intake (including alcohol) is valuable in assessing dietary indiscretion. Nonadherence with medical recommendations such as laboratory and other appointment follow-up can also be indicative of nonadherence with diet or medications.

CLINICAL PRESENTATION AND DIAGNOSIS OF HEART FAILURE

In low-output HF, symptoms are generally related to either congestion behind the failing ventricle(s), or hypoperfusion (decreased tissue blood supply), or both. For example, a failing left ventricle causes fluid to back up in the lungs, and a patient with right ventricular failure (RVF) would exhibit systemic symptoms of congestion. Congestion is the most common symptom in HF, followed by symptoms related to decreased perfusion to peripheral tissues including decreased renal output, mental confusion, and cold extremities. Activation of the compensatory mechanisms occurs in an effort to increase CO and preserve blood flow to vital organs. However, the increase in preload and afterload in the setting of a failing ventricle leads to elevated filling pressures and further impairment of cardiac function, which manifests as systemic and/or pulmonary congestion. It is helpful to remember that congestion develops behind the failing ventricle, caused by the inability of that ventricle to eject the blood that it receives from the atria and venous return. As such, signs and symptoms may be classified as left sided or right sided. Symptoms of left-sided HF include dyspnea, ***orthopnea***, and paroxysmal nocturnal dyspnea (PND), whereas symptoms of right-sided HF include fluid retention, gastrointestinal (GI) bloating, and fatigue. Although most patients initially have left ventricular failure (LVF; pulmonary congestion), both ventricles eventually fail and contribute to the HF syndrome. Because of the complex nature of this syndrome, it has become exceedingly more difficult to attribute a specific sign or symptom as caused by either RVF (systemic congestion) or LVF.

LO 3

LO 3

General Signs and Symptoms

LO 3 Refer to the Clinical Presentation and Diagnosis of Chronic Heart Failure textbox for additional descriptions of signs and symptoms.

Patients can experience a variety of symptoms related to buildup of fluid. The most recognized finding of systemic venous congestion related to RVF is peripheral edema. It usually occurs in dependent areas of the body, such as the ankles (pedal edema) for ambulatory patients or the sacral region for bedridden patients. Patients may complain of swelling of their feet and ankles, which can extend up to their calves or thighs. Abdominal congestion may cause a bloated feeling, abdominal pain, early satiety, nausea, anorexia, and constipation. Abdominal edema can lead to delayed absorption of oral medications, including diuretics used to treat congestion. Often patients may have difficulty fitting into their shoes or pants due to edema. Weight gain often precedes signs of overt peripheral edema. Therefore, it is crucial for patients to weigh themselves daily even in the absence of symptoms to assess fluid status.

A clinically validated measure of venous congestion is assessment of the jugular venous pressure (JVP). This is performed by examining the right internal jugular vein for distention or elevation of the pulsation while reclining at a 45-degree angle. A JVP more than 4 cm above the sternal angle is indicative of elevated right atrial pressure. JVP may be normal at rest, but if application of pressure to the abdomen can elicit a sustained elevation of JVP, this is defined as hepatojugular reflux (HJR). A positive finding of HJR indicates hepatic congestion and results from displacement of volume from the abdomen into the jugular vein because the right atrium is unable to accept this additional blood. Hepatic congestion can cause abnormalities in liver function, which can be evident in liver function tests and/or clotting times. Development of hepatomegaly occurs infrequently and is caused by long-term systemic venous congestion. Intestinal or abdominal congestion can also be present, but it usually does not lead to characteristic signs unless overt ascites is evident.

It is important to note that in chronic severe HF, unintentional weight loss can occur that leads to a syndrome of cardiac

Clinical Presentation and Diagnosis of Chronic Heart Failure

General

Patient presentation may range from asymptomatic to cardiogenic shock.

Symptoms

- Dyspnea, particularly on exertion
- Orthopnea
- Shortness of breath (SOB)
- Paroxysmal nocturnal dyspnea
- Exercise intolerance
- Tachypnea
- Cough
- Fatigue
- Nocturia and/or polyuria
- Hemoptysis
- Abdominal pain
- Anorexia
- Nausea
- Bloating
- Ascites
- Mental status changes (confusion, hallucinations)
- Weakness
- Lethargy
- Insomnia

Signs

- Pulmonary rales
- Pulmonary edema
- S_3 gallop
- Pleural effusion
- Cheyne-Stokes respiration
- Tachycardia
- Cardiomegaly
- Peripheral edema (eg, pedal edema, which is swelling of feet and ankles)
- Jugular venous distension (JVD)
- Hepatojugular reflux (HJR)
- Hepatomegaly
- Cyanosis of the digits
- Pallor or cool extremities

Laboratory Tests

- BNP greater than 100 pg/mL (ng/L; 28.9 pmol/L) or N-terminal proBNP (NT-proBNP) greater than 300 pg/mL (ng/L; 35.4 pmol/L).
- Electrocardiogram (ECG): May be normal or could show numerous abnormalities including acute ST-T–wave changes from myocardial ischemia, atrial fibrillation, bradycardia, and LV hypertrophy.
- Serum creatinine: May be increased owing to hypoperfusion; preexisting renal dysfunction can contribute to volume overload.
- Complete blood count: Useful to determine if HF is due to reduced oxygen-carrying capacity.
- Chest x-ray: Useful for detection of cardiac enlargement, pulmonary edema, and pleural effusions.
- Echocardiogram: Used to assess LV size, valve function, pericardial effusion, wall motion abnormalities, and ejection fraction.

cachexia, defined as a nonedematous weight loss more than 6% of the previous normal weight over a period of at least 6 months. HF prognosis worsens considerably once cardiac cachexia has been diagnosed, regardless of HF severity. This results from several factors including loss of appetite, malabsorption due to GI edema, elevated metabolic rate, and elevated levels of norepinephrine and proinflammatory cytokines. Absorption of fats is especially affected, leading to deficiencies of fat-soluble vitamins.

Dyspnea, or shortness of breath (SOB), can result from pulmonary congestion or systemic hypoperfusion due to LVF. Exertional dyspnea occurs when patients experience breathlessness induced by physical activity or a lower level of activity than previously known to cause breathlessness. Patients often state that activities such as stair climbing, carrying groceries, or walking a particular distance cause SOB. Severity of HF is inversely proportional to the amount of activity required to produce dyspnea. In severe HF, dyspnea is present even at rest.

Orthopnea is dyspnea that is positional. Orthopnea is present if a patient is unable to breathe while lying flat on a bed (ie, in the recumbent position). It manifests within minutes of a patient lying down and is relieved immediately when the patient sits upright. Patients can relieve orthopnea by elevating their head and shoulders with pillows. The practitioner should inquire as to the number of pillows needed to prevent dyspnea as a marker of worsening HF. PND occurs when patients awaken suddenly with a feeling of breathlessness and suffocation. PND is caused by increased venous return and mobilization of interstitial fluid from the extremities leading to alveolar edema, and usually occurs within 1 to 4 hours of sleep. In contrast to orthopnea, PND is not relieved immediately by sitting upright and often takes up to 30 minutes for symptoms to subside.

Pulmonary congestion may also cause a nonproductive cough that occurs at night or with exertion. Not all patients with LVF will exhibit signs of pulmonary congestion if lymphatic clearance is intact. In cases of pulmonary edema, the most severe form of pulmonary congestion, patients may produce pink frothy sputum and experience extreme breathlessness and anxiety due to feelings of suffocation and drowning. If not treated aggressively, patients can become cyanotic and acidotic. Severe pulmonary edema can progress to respiratory failure, necessitating mechanical ventilation.

▶ *Patient History*

A thorough history is crucial to identify cardiac and noncardiac disorders or behaviors that may lead to or accelerate the development of HF. Past medical history, family history, and

Table 6–4

Drugs That May Precipitate or Exacerbate Heart Failure

Negative Inotropic Effect
- Antiarrhythmics (eg, disopyramide, flecainide, propafenone)
- β-Blockers (eg, propranolol, metoprolol, carvedilol)
- Calcium channel blockers (eg, verapamil, diltiazem)
- Itraconazole

Cardiotoxic
- Doxorubicin
- Epirubicin
- Daunomycin
- Cyclophosphamide
- Trastuzumab
- Bevacizumab
- Mitoxantrone
- Ifosfamide
- Mitomycin
- Lapatinib
- Sunitinib
- Imatinib
- Ethanol
- Amphetamines (eg, cocaine, methamphetamine)

Sodium and Water Retention
- NSAIDs
- COX-2 inhibitors
- Rosiglitazone and pioglitazone
- Glucocorticoids
- Androgens and estrogens
- Salicylates (high dose)
- Sodium-containing drugs (eg, carbenicillin disodium, ticarcillin disodium)

Uncertain Mechanism
- Adalimumab
- Etanercept
- Infliximab

COX-2, cyclooxygenase-2; NSAID, nonsteroidal anti-inflammatory drug.

From Parker RB, Nappi JM, Cavallari LH. Chronic heart failure. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:86, with permission.

social history are important for identifying comorbid illnesses that are risk factors for the development of HF or underlying etiological factors. A complete medication history (including prescription and nonprescription drugs, herbal therapy, and vitamin supplements) should be obtained each time a patient is seen to evaluate adherence, to assess appropriateness of therapy, to eliminate drugs that may be harmful in HF (Table 6–4), and to determine additional monitoring requirements.[5] For newly diagnosed HF, previous use of radiation or chemotherapeutic agents as well as current or past use of alcohol and illicit drugs should be assessed. In addition, for patients with a known history of HF, questions related to symptomatology and exercise tolerance are essential for assessing any changes in clinical status that may warrant further evaluation or adjustment of the medication regimen.

Heart Failure Classification

LO 3

There are two common systems for categorizing patients with HF. The New York Heart Association (NYHA) Functional Classification (FC) system is based on the patient's activity level and exercise tolerance. It divides patients into one of four classes, with functional class I patients exhibiting no symptoms or limitations of daily activities, and functional class IV patients who are symptomatic at rest (Table 6–5). The NYHA FC system reflects a subjective assessment by a health care provider and can change frequently over short periods of time. In general, anticipated survival declines in conjunction with a decline in functional ability.

Table 6–5

New York Heart Association (NYHA) Functional Classification and American College of Cardiology/ American Heart Association (ACC/AHA) Staging

NYHA Functional Class	ACC/AHA Stage	Description
N/A	A	Patients at high risk for heart failure but without structural heart disease or symptoms of heart failure.
I	B	Patients with cardiac disease but without limitations of physical activity. Ordinary physical activity does not cause undue fatigue, dyspnea, or palpitation.
II	C	Patients with cardiac disease that results in slight limitations of physical activity. Ordinary physical activity results in fatigue, palpitations, dyspnea, or angina.
III	C	Patients with cardiac disease that results in marked limitation of physical activity. Although patients are comfortable at rest, less than ordinary activity will lead to symptoms.
IV	C, D	Patients with cardiac disease that results in an inability to carry on physical activity without discomfort. Symptoms of heart failure are present at rest. Stage D refers to end-stage heart failure patients.

Patient Encounter Part 1

A 71-year-old man with a long-standing history of known hypertension and dyslipidemia presents for follow-up. His most bothersome complaint is coughing at night and an inability to lie down flat without feeling breathless. He has to sleep on a few pillows to get adequate rest and sometimes even that does not help as he wakes up in the middle of the night feeling short of breath. Although he used to be able to walk a few blocks and two to three flights of stairs comfortably before getting breathless, he has had increasing symptoms after one flight of stairs. He also notes his ankles are always swollen and his wedding ring feels tight on his finger. Additionally his appetite is decreased and he has difficulty finishing his meals, becoming full after only a few bites.

What information is suggestive of a diagnosis of HF?

What additional information do you need to create a treatment plan?

The American College of Cardiology/American Heart Association (ACC/AHA) have proposed another system based on the development and progression of the disease. Instead of classifications, patients are placed into stages A through D (Table 6–5).[1] Because the staging system is related to development and progression of cardiac function and the HF syndrome, it also proposes management strategies for each stage including risk factor modification. The staging system is meant to complement the NYHA FC system; however, patients can move between NYHA functional classes as symptoms improve with treatment, whereas HF staging does not allow for patients to move to a lower stage (eg, stage C patients will never revert to stage B, even after treatment). Currently, patients are categorized based on both systems. Functional classification and staging are useful from a clinician's perspective, allowing for longitudinal assessment of a patient's risk and progress, requirements for nonpharmacologic interventions, response to medications, and overall prognosis.

TREATMENT OF CHRONIC HEART FAILURE

Desired Therapeutic Outcomes

LO 4 There is no cure for HF. KEY CONCEPT The general therapeutic management goals for chronic HF include preventing the onset of clinical symptoms or reducing symptoms, preventing or reducing hospitalizations, slowing progression of the disease, improving quality of life, and prolonging survival. The ACC/AHA staging system provides a guide for application of these goals based on the clinical progression of HF for a given patient. The goals are additive as one moves from stage A to stage D.[1] For stage A, risk factor management is the primary goal because it reduces onset of clinical symptoms. Stage B includes the addition of pharmacologic therapies known to slow the disease progression in an attempt to prevent the onset of clinical symptoms. Stage C involves the use of additional therapies aimed at controlling symptoms and decreasing morbidity. Finally, in stage D, the focus shifts toward palliative care and other quality-of-life related issues. Only with aggressive management throughout all the stages can the odds of survival be improved. Attainment of these goals is based on designing a therapeutic approach that encompasses strategies aimed at control and treatment of contributing disorders, nonpharmacologic interventions, and optimal use of pharmacologic therapies.[11]

Control and Treatment of Contributing Disorders

All causes of HF must be investigated to determine the etiology of cardiac dysfunction. The most common etiology of HF in the United States is ischemic heart disease. An ischemic workup that includes stress testing, echocardiography, and coronary angiography is warranted with a history suggestive of underlying CAD, and may be considered in patients who newly exhibit reduced LVEF. Revascularization of those with significant CAD may help restore some cardiac function in patients with reversible ischemic defects. Aggressive control of hypertension (with BP-lowering medication required in most patients with HF and a BP of 130/80 mm Hg or higher), diabetes, and obesity is also essential because each of these conditions, uncontrolled, can cause further cardiac damage. Surgical repair of valvular disease or congenital malformations may be warranted if detected. Clinical HF partly depends on metabolic processes, so correction of imbalances such as thyroid disease, anemia, and nutritional deficiencies is important. Identifying and discontinuing medications that can exacerbate HF is also an important intervention.

Nonpharmacologic Interventions

LO 5 It is imperative that patients recognize the role of self-management in HF. KEY CONCEPT Nonpharmacologic treatment involves dietary modifications such as sodium and fluid restriction, risk factor reduction including smoking cessation, timely immunizations, and supervised regular physical activity. Patient education regarding monitoring symptoms, dietary and medication adherence, exercise and physical fitness, risk factor reduction, and immunizations are important for the prevention of AHF exacerbations.

Patients should be encouraged to become involved in their own care which includes self-monitoring. Home monitoring for fluid status should include daily assessment of weight and exercise tolerance. Daily weights should be done first thing in the morning upon arising and before any food intake to maintain consistency. Patients should record their weight daily in a journal and bring this log to each clinic or office visit. Changes in weight can indicate fluid retention and congestion prior to onset of peripheral or pulmonary symptoms. Individuals who have an increase of 3 pounds (1.4 kg) in a single day or 5 pounds (2.3 kg) over a week should alert their HF care provider. Some patients may be educated about self-adjusting diuretic doses based on daily weights. In addition to weight changes, a marked decline in exercise tolerance should also be reported to the HF care provider.

Nonadherence is an important issue because it may lead to an acute exacerbation of HF. Ensuring an understanding of the importance of each medication used to treat HF, proper administration, and potential adverse effects may improve adherence. Stressing the rationale for each medication is important, especially for NYHA FC I or ACC/AHA stage B patients who are asymptomatic yet started on drugs that may worsen symptoms initially. A clinician's involvement in emphasizing medication adherence, offering adherence suggestions such as optimal timing of medications or use of weekly pill containers, and providing intensive follow-up care has been shown to reduce AHF hospitalizations.

Dietary modifications in HF consist of initiation of an AHA step II diet as part of cardiac risk factor reduction, sodium restriction, and sometimes fluid restriction. Because sodium and water retention is a compensatory mechanism that contributes to volume overload in HF, salt and fluid restriction is often necessary to help avoid or minimize congestion. The normal American diet includes 3 to 6 g of sodium per day. Most patients with HF should limit salt intake to a maximum of 2 g/day. Patients should be educated to avoid cooking with salt and to limit intake of foods with high salt content, such as fried or processed food (lunch meats, soups, cheeses, salted snack foods, canned food, and some ethnic foods such as Asian or South American foods). Salt restriction can be challenging for many patients. Drastic dietary changes may lead to nonadherence due to an unpalatable diet. The clinician should counsel to restrict salt slowly over time. Substituting spices to flavor food is a useful recommendation. Salt substitutes should be used judiciously because many contain significant amounts of potassium that can increase the risk of hyperkalemia. Fluid restriction may not be necessary in many patients. When applicable, fluid intake is generally limited from all sources to less than 2 L/day.

LO 5 Exercise, although discouraged when the patient is acutely decompensated to limit cardiac workload, is recommended when patients are stable. The heart is a muscle that requires activity to prevent atrophy. In addition, exercise improves peripheral muscle conditioning and efficiency, which may contribute to better exercise tolerance despite the low CO state. Regular low intensity, aerobic exercise that includes light house/yard work,

Patient Encounter Part 2

Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension (unmanaged for at least a few years), dyslipidemia × 20 years, history of alcohol abuse × 30 years, history of migraines × 40 years

Allergies: No known drug allergies

Meds: Diltiazem CD 240 mg once daily, hydrochlorothiazide 25 mg once daily, atorvastatin 40 mg once daily for dyslipidemia, ibuprofen 600 mg twice daily as needed for headaches, vitamin B_{12} once daily, multivitamin daily, aspirin 81 mg once daily

FH: Significant for early heart disease in mother (MI at age 60)

SH: He is married, has one child, and runs his own business; he smokes 1½ packs per day and drinks at least 10 beers nightly.

PE:

BP 156/94 mm Hg, pulse 88 beats/min and regular, respiratory rate 16/min, Ht 5′8″ (173 cm), Wt 251 lb (114 kg), body mass index (BMI): 38.1 kg/m^2

Lungs: Rales bilaterally upon inspiration

CV: Regular rate and rhythm with normal S_1 and S_2; there is an S_3 and a soft S_4 present; there is a 2/6 systolic ejection murmur heard best at the left lower sternal border; point of maximal impulse is within normal limits at the midclavicular line

Abd: Soft, nontender, and bowel sounds are present, (+) HJR

Ext: 2+ pitting edema extending to below the knees is observed. JVP 13 cm

Chest x-ray: Cardiomegaly

Echocardiogram: EF = 30% (0.30)

Laboratory Values:

Hct: 41.1% (0.411)

WBC: 7.3 × 10^3/μL (7.3 × 10^9/L)

Sodium: 141 mEq/L (mmol/L)

Potassium: 4.2 mEq/L (mmol/L)

Bicarb: 30 mEq/L (mmol/L)

Chloride: 90 mEq/L (mmol/L)

Magnesium: 1.5 mEq/L (0.75 mmol/L)

Fasting blood glucose: 120 mg/dL (6.7 mmol/L)

Uric acid: 6 mg/dL (357 μmol/L)

BUN: 40 mg/dL (14.3 mmol/L)

SCr: 1.6 mg/dL (141 μmol/L)

Alk Phos: 120 IU/L (2.0 μkat/L)

Aspartate aminotransferase: 100 IU/L (1.67 μkat/L)

What other laboratory or diagnostic tests are required for assessment of the patient's condition?

How would you classify his NYHA FC and ACC/AHA HF stage?

Identify exacerbating or precipitating factors that may worsen his HF.

What are your treatment goals for the patient?

walking, swimming, or riding a bike is encouraged; heavy weight training is discouraged. The prescribed exercise regimen needs to be tailored to the individual's functional ability, and thus it is suggested that patients participate in cardiac rehabilitation programs, at least initially. It is important that patients not overexert themselves to fatigue or exertional dyspnea.

LO 5

Modification of classic risk factors, such as tobacco and alcohol consumption, is important to minimize the potential for further aggravation of heart function. Data from observational studies suggest that patients with HF who smoke have a mortality rate 40% higher than those who do not consume tobacco products.[1] All HF patients who smoke should be counseled on the importance of tobacco cessation and offered a referral to a cessation program. Patients with an alcoholic cardiomyopathy should abstain from alcohol. Whether patients with other forms of HF should abstain from any alcohol intake remains controversial. Proponents of moderation of alcohol base their rationale on the potential cardioprotective effects. However, opponents to any alcohol intake point out that alcohol is cardiotoxic and should be avoided.

In general, it is suggested that patients remain up-to-date on standard immunizations. Patients should be counseled to receive yearly influenza vaccinations. Additionally, pneumococcal vaccines are recommended.

Pharmacologic Treatment

LO 6

The ACC/AHA staging system delineates specific pharmacotherapy options based on disease progression.[1] For patients in stage A, every effort is made to minimize the impact of diseases that can injure the heart. Antihypertensive (specifically thiazide diuretics) and lipid-lowering therapies should be utilized when appropriate to decrease the risk for stroke, MI, and HF. ACE inhibitors should be considered in high-risk vascular disease patients. For stage B patients, the goal is to prevent or slow disease progression by interfering with neurohormonal pathways that lead to cardiac damage and mediate pathological remodeling. The goal is to prevent the onset of HF symptoms. The backbone of therapy in these patients includes ACE inhibitors or ARBs and β-blockers. In stage C patients with symptomatic LV systolic dysfunction (EF ≤ 40% [0.40]), the goals focus on alleviating fluid retention, minimizing disability, slowing disease progression, and reducing long-term risk for hospitalizations and death. Treatment entails a strategy that combines diuretics to control intravascular fluid balance with neurohormonal antagonists (including ACE inhibitors or ARBs or angiotensin receptor neprilysin inhibitor [ARNI], β-adrenergic blockers, and aldosterone receptor antagonists) to minimize the effects of the RAAS and SNS. In African American patients or patients with an allergy to ACE inhibitor/ARB, hydralazine and isosorbide dinitrate combination has been shown to be beneficial. Digoxin may be added to improve symptoms. Drug dosing and monitoring in the pharmacologic treatment of HF are described in Tables 6–6 and 6–7. Patients with advanced stage D disease are offered more modest goals, such as improvement in quality of life. Enhancing quality of life is often achieved at the expense of expected survival. Treatment options include mechanical support, transplantation, and continuous use of intravenous (IV) vasoactive therapies, in addition to maintaining an optimal regimen of chronic oral medications as possible.

Table 6–6

Drug Dosing in the Pharmacologic Treatment of Heart Failure

Drug	Brand Name	Initial Dose	Usual Range	Special Population Dose	Comments
Loop Diuretics					
Furosemide	Lasix®	20–40 mg once or twice daily	20–160 mg once or twice daily	CrCl 20–50 mL/min (0.33–0.83 mL/s): 160 mg once or twice daily CrCl < 20 mL/min (0.33 mL/s): 400 mg daily	Single doses exceeding those listed are unlikely to elicit additional response
Bumetanide	Bumex®	0.5–1.0 mg once or twice daily	1–2 mg once or twice daily	CrCl 20–50 mL/min (0.33–0.83 mL/s): 2 mg once or twice daily CrCl < 20 mL/min (0.33 mL/s): 8–10 mg daily	Single doses exceeding those listed are unlikely to elicit additional response
Torsemide	Demadex®	10–20 mg once daily	10–80 mg once daily	CrCl 20–50 mL/min (0.33–0.83 mL/s): 40 mg once daily CrCl < 20 mL/min (0.33 mL/s): 200 mg daily	Single doses exceeding those listed are unlikely to elicit additional response
ACE Inhibitors					
Captopril	Capoten®	6.25 mg three times daily	50 mg three times daily[a]		
Enalapril	Vasotec®	2.5 mg twice daily	10–20 mg twice daily[a]		
Lisinopril	Zestril®, Prinivil®	2.5–5.0 mg once daily	20–40 mg once daily[a]		
Quinapril	Accupril®	5 mg twice daily	20–40 mg twice daily		
Ramipril	Altace®	1.25–2.5 mg	5 mg twice daily[a]		
Fosinopril	Monopril®	5–10 mg once daily	40 mg once daily		Undergoes both hepatic and renal elimination
Trandolapril	Mavik®	0.5–1.0 mg once daily	4 mg once daily[a]		Undergoes both hepatic and renal elimination
Perindopril	Aceon®	2 mg once daily	8–16 mg once daily		Undergoes both hepatic and renal elimination
Angiotensin Receptor Blockers					
Candesartan	Atacand®	4 mg once daily	32 mg once daily[a]		
Valsartan	Diovan®	20–40 mg twice daily	160 mg twice daily[a]		
Losartan	Cozaar®	25–50 mg once daily	150 mg once daily[a]		
Angiotensin Receptor Neprilysin Inhibitor (ARNI)					
Sacubitril/valsartan	Entresto®	49/51 mg sacubitril/valsartan twice daily	97/103 mg sacubitril/valsartan twice daily[a]	For patients taking a low dose of or not taking an ACE inhibitor or ARB or if eGFR is < 30 mL/min/1.73 m^2, the starting dose is 24/26 mg sacubitril/valsartan twice daily	Discontinue ACE inhibitors at least 36 hours before initiating sacubitril/valsartan treatment; allow 36 hours between discontinuing ARNI and starting ACE inhibitor
β-Blockers					
Bisoprolol	Zebeta®	1.25 mg once daily	10 mg once daily[a]		
Carvedilol	Coreg®	3.125 mg twice daily	25 mg twice daily[a]	Target dose for patients weighing > 85 kg (187 lb) is 50 mg twice daily	Take with food
Carvedilol phosphate	Coreg CR®	10 mg once daily	80 mg once daily[a]		Take with food
Metoprolol succinate CR/XL	Toprol-XL®	12.5–25 mg once daily	200 mg once daily[a]		
Aldosterone Receptor Antagonists					
Spironolactone	Aldactone®	eGFR ≥ 50 mL/min/1.73 m^2: 12.5–25 mg once daily	25–50 mg once daily[a]	eGFR 30–49 mL/min/1.73 m^2: 12.5 mg once daily or every other day	The risk of hyperkalemia increases if serum creatinine is > 1.6 mg/dL (141 µmol/L). Avoid if baseline potassium is ≥ 5 mEq/L (mmol/L)

(*Continued*)

Table 6–6

Drug Dosing in the Pharmacologic Treatment of Heart Failure (*Continued*)

Drug	Brand Name	Initial Dose	Usual Range	Special Population Dose	Comments
Eplerenone	Inspra®	eGFR ≥ 50 mL/min/1.73 m^2: 25 mg once daily	50 mg once daily[a]	eGFR 30–49 mL/min/1.73 m^2: 25 mg every other day	The risk of hyperkalemia increases if serum creatinine is > 1.6 mg/dL (141 µmol/L). Avoid if baseline potassium is ≥ 5 mEq/L (mmol/L)
Other					
Hydralazine-Isosorbide Dinitrate	Bidil®	Hydralazine 37.5 mg three times daily; Isosorbide dinitrate 20 mg three times daily	Hydralazine 75 mg three times daily[a]; Isosorbide dinitrate 40 mg three times daily[a]		Indicated in conjunction with standard heart failure therapy to improve survival and reduce hospitalizations in self-identified African-American patients
Digoxin	Lanoxin®	0.125–0.25 mg once daily	0.125–0.25 mg once daily	Reduce dose in elderly patients with low lean body mass, and patients with impaired renal function	Target plasma concentration range is 0.5–0.9 ng/mL (mcg/L; 0.6–1.2 nmol/L). Does not improve survival in patients with HFrEF
Ivabradine	Corlanor®	5 mg twice daily	5–7.5 mg twice daily	Avoid if resting heart rate < 60 BPM before treatment	Indicated to reduce the risk of hospitalization in patients with HFrEF who are in normal sinus rhythm, with a resting heart rate ≥ 70 BPM receiving maximally tolerated β-blocker doses. Take with meals

[a]Regimens proven in large clinical trials to reduce mortality.

ACE, angiotensin-converting enzyme; ARB, angiotensin receptor blocker; BPM, beats per minute; CrCl, creatinine clearance; eGFR, estimated glomerular filtration rate; HFrEF, heart failure with reduced ejection fraction.

▶ *Diuretics*

LO 6 Diuretics have been the mainstay for HF symptom management for many years. KEY CONCEPT Diuretics are used for relief of acute symptoms of congestion and maintenance of euvolemia. These agents interfere with sodium retention by increasing urinary sodium and free water excretion. The primary rationale for the use of diuretic therapy is to maintain euvolemia in symptomatic or stages C and D HF. Diuretic therapy is recommended for all patients with clinical evidence of fluid overload. In mild HF, diuretics may be used on an as-needed basis. However, once the development of edema is persistent, regularly scheduled doses will be required.

Two types of diuretics are used for volume management in HF: thiazides and loop diuretics. Thiazide diuretics such as hydrochlorothiazide, chlorthalidone, and metolazone block sodium and chloride reabsorption in the distal convoluted tubule. Thiazides are weaker than loop diuretics in terms of affecting an increase in urine output and therefore are not utilized frequently as monotherapy. They are optimally suited for patients with hypertension who have mild congestion. Additionally, the action of thiazides is limited in patients with renal insufficiency (creatinine clearance [CrCL] < 30 mL/min [0.50 mL/s]) due to reduced secretion into their site of action. An exception is metolazone, which retains its potent action in patients with renal dysfunction. Metolazone is often used in combination with loop diuretics when patients exhibit diuretic resistance, defined as edema unresponsive to loop diuretics alone.

LO 6 Loop diuretics are the most widely used diuretics in HF. These agents, including furosemide, bumetanide, and torsemide, exert their action at the thick ascending loop of Henle. Loop diuretics are not filtered through the glomerulus, but instead undergo active transport into the tubular lumen via the organic acid pathway. As a result, drugs that compete for this active transport (eg, probenecid and organic by-products of uremia) can lower efficacy of loop diuretics. Loop diuretics increase sodium and water excretion and induce a prostaglandin-mediated increase in renal blood flow that contributes to their natriuretic effect. Unlike thiazides, they retain their diuretic ability in patients with poor renal function. The various loop diuretics are equally effective when used at equipotent doses, although there are intrinsic differences in pharmacokinetics and pharmacodynamics (Table 6–6).[5] The choice of which loop diuretic to use and the route of administration depends on clinical factors such as the presence of intestinal edema and rapidity of the desired effect. Oral diuretic efficacy may vary based on differing bioavailability, which is almost complete for torsemide and bumetanide but averages only 50% for furosemide. Oral torsemide can be considered an alternative to the IV route of administration for patients who do not respond to oral furosemide in the setting of profound edema. Onset of effect is slightly delayed after oral administration but occurs within a few minutes with IV dosing. Consequently, bioequivalent doses of IV furosemide are half the oral dose, whereas bumetanide and torsemide IV doses are generally equivalent to the oral doses.

In patients with evidence of mild to moderate volume overload, diuretics should be initiated at a low dose and titrated to achieve a weight loss of up to 2 pounds (0.9 kg) per day. Patients with severe volume overload should be managed in an inpatient

Table 6–7

Drug Monitoring

Drug Class	Adverse Effect	Monitoring Parameters	Comments
ACE inhibitors	Angioedema, cough, hyperkalemia, hypotension, renal dysfunction	BP, electrolytes, BUN, and creatinine	Contraindicated in patients with bilateral renal artery stenosis, history of angioedema, or pregnancy. Assess BP, BUN, creatinine, and electrolytes at baseline and 1–2 weeks after initiation or increase in dose. Goal is target dose from clinical trials or highest tolerated.
Angiotensin receptor blockers (ARB)	Hyperkalemia, hypotension, renal dysfunction	BP, electrolytes, BUN, and creatinine	Contraindicated in patients with bilateral renal artery stenosis or pregnancy. Assess BP, BUN, creatinine, and electrolytes at baseline and 1–2 weeks after initiation or increase in dose. Use with caution in patients with a history of ACE inhibitor-associated angioedema. Goal is target dose from clinical trials or highest tolerated.
Sacubitril/ valsartan	Angioedema, hyperkalemia, hypotension, dizziness, renal dysfunction	BP, electrolytes, BUN, and creatinine	Contraindicated in patients with a history of angioedema associated with ACE inhibitor or ARB therapy or in pregnancy. Assess BP, BUN, creatinine, and electrolytes at baseline and 1–2 weeks after initiation or increase in dose. Start with a low dose and double the dose every 2–4 weeks as tolerated based on BP, serum potassium, and renal function. Goal is target dose from clinical trials or highest tolerated.
Aldosterone receptor antagonists	Gynecomastia/breast tenderness/ menstrual irregularities (spironolactone), hyperkalemia, worsening renal function	BP, electrolytes, BUN, and creatinine	Assess BP, BUN, creatinine, and electrolytes at baseline. Check potassium 3 days and 1 week after initiation and then monthly for the first 3 months, then every 3 months. Change to eplerenone if gynecomastia develops with spironolactone.
β-Blockers	Bradycardia, heart block, bronchospasm, hypotension, worsening HF	BP, HR, ECG, signs and symptoms of worsening HF, blood glucose	Start with low dose and titrate upward no more often than every 2 weeks as tolerated based on BP, HR, and symptoms. Goal is target dose from clinical trials or highest tolerated. Patients may feel worse before they feel better.
Digoxin	GI and CNS adverse effects, brady- and tachyarrhythmias	Electrolytes, BUN, creatinine, ECG, serum digoxin concentration	Target serum digoxin concentration 0.5–0.9 ng/mL (mcg/L; 0.6–1.2 nmol/L).
Ivabradine	Bradycardia, hypertension, atrial fibrillation, luminous phenomena (phosphenes, transiently enhanced brightness in a portion of the visual field)	BP, HR, ECG	Start with 5 mg twice daily and after 2 weeks adjust dose to achieve a resting HR 50–60 BPM. Only use in patients in sinus rhythm.
Diuretics	Hypovolemia, hypotension, hyponatremia, hypokalemia, hypomagnesemia, hyperuricemia, renal dysfunction, thirst	BP, electrolytes, BUN, creatinine, glucose, uric acid, changes in weight, JVD	Dose should be adjusted based on volume status, renal function, electrolytes, and BP. Reassess these parameters 1–2 weeks after dose changes. Goal is lowest dose that maintains euvolemia.
Hydralazine	Hypotension, headache, rash, arthralgia, lupus, tachycardia	BP, HR	
Nitrates	Hypotension, headache, lightheadedness	BP, HR	

ACE, angiotensin-converting enzyme; BP, blood pressure; BPM, beats per minute; BUN, blood urea nitrogen; CNS, central nervous system; ECG, electrocardiogram; GI, gastrointestinal; HF, heart failure; HR, heart failure; JVD, jugular venous distention.

From Parker RB, Nappi JM, Cavallari LH. Chronic heart failure. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:96, with permission.

setting. Once diuretic therapy is initiated, dosage adjustments are based on symptomatic improvement and daily body weight. Because body weight changes are a sensitive marker of fluid retention or loss, patients should continue to weigh themselves daily. Once a patient reaches a euvolemic state, diuretics may be cautiously tapered and then withdrawn in appropriate patients. In stable, educated, and adherent patients, another option is self-adjusted diuretic dosing. Based on daily body weight, patients may temporarily increase their diuretic regimen to reduce the incidence of overt edema, or reduce diuretic doses in the setting of acute illness or exposure to hot temperatures such as during summer. Self-adjustment also avoids overuse of diuretics and possible complications of overdiuresis such as hypotension, fatigue, electrolyte imbalances, and renal impairment.

The maximal response to diuretics is reduced in HF, creating a "ceiling dose" above which there is limited added benefit. This diuretic resistance is due to a compensatory increase in sodium reabsorption in the distal tubules, which decreases the effect of blocking sodium reabsorption in the loop of Henle. In addition, there is a simultaneous increase in the reabsorption of sodium from the proximal tubule, allowing less to reach the site of action for loop diuretics. Apart from increasing diuretic doses, strategies to improve diuretic efficacy include increasing the frequency of dosing to two or three times daily, utilizing a continuous

infusion of a loop diuretic, and/or combining a loop diuretic with a thiazide diuretic. The latter strategy theoretically prevents sodium and water reabsorption at both the loop of Henle and the compensating distal convoluted tubule. Metolazone is used most often for this purpose because it retains its activity in settings of low CrCL. Metolazone can be dosed daily or as little as once weekly. This combination is usually maintained until the patient reaches his or her baseline weight. The clinician must use metolazone cautiously because its potent activity predisposes a patient to metabolic abnormalities as outlined next.

Diuretics cause numerous adverse effects and metabolic abnormalities, with severity linked to diuretic potency (Table 6–7). A particularly worrisome adverse effect is hypokalemia which can predispose patients to arrhythmias and sudden death. Hypomagnesemia often occurs concomitantly with diuretic-induced hypokalemia, and therefore both should be assessed and replaced in patients needing correction of hypokalemia. Magnesium is an essential cofactor for movement of potassium intracellularly to restore body stores. Patients taking diuretics are also at risk for renal insufficiency due to overdiuresis and reflex activation of the renin-angiotensin system. The potential reduction in renal blood flow and glomerular pressure is amplified by concomitant use of ACE inhibitors or ARBs.

► *Neurohormonal Blocking Agents*

KEY CONCEPT Agents with proven benefits in improving symptoms, slowing disease progression, and improving survival in chronic HF target neurohormonal blockade. These include ACE inhibitors, ARBs, ARNIs, β-adrenergic blockers, and aldosterone receptor antagonists (Tables 6–6 and 6–7).

LO 6

Angiotensin-Converting Enzyme Inhibitors ACE inhibitors are the cornerstone of treatment for HF. ACE inhibitors decrease neurohormonal activation by blocking the conversion of angiotensin I (AT_1) to angiotensin II (AT_2), a potent mediator of vasoconstriction and cardiac remodeling. The breakdown of bradykinin is also reduced. Bradykinin enhances the release of vasodilatory prostaglandins and histamines. These effects result in arterial and venous dilatation, and a decrease in myocardial workload through reduction of both preload and afterload. ACE inhibitors demonstrate favorable effects on cardiac hemodynamics such as long-term increases in **cardiac index** (CI) and SV index, SVR, mean arterial pressure, and HR.

There is extensive clinical experience with ACE inhibitors in systolic HF. Numerous clinical studies show ACE inhibitor therapy is associated with improvements in clinical symptoms, exercise tolerance, NYHA FC, LV size and function, and quality of life as compared with placebo.[12-14] ACE inhibitors significantly reduce hospitalization rates and mortality regardless of underlying disease severity or etiology. ACE inhibitors are also effective in preventing HF development in high-risk patients. Studies in acute MI patients show a reduction in new-onset HF and death with ACE inhibitors whether they are initiated early (within 36 hours) or started later. In addition, ACE inhibition decreases the risk of HF hospitalization and death in patients with asymptomatic LV dysfunction. The exact mechanisms for decreased HF progression and mortality are postulated to involve both the hemodynamic improvement and the inhibition of AT_2's growth promoting and remodeling effects. All patients with documented LV systolic dysfunction, regardless of existing HF symptoms, should receive ACE inhibitors unless a contraindication or intolerance is present.

LO 6

There is no evidence to suggest that one ACE inhibitor is preferred over another. ACE inhibitors should be initiated using low doses and titrated up to target doses over several weeks depending on tolerability (adverse effects and BP). The ACC/AHA 2013 guidelines advocate using doses that were proven to decrease mortality in clinical trials as the target doses (Table 6–6).[1] If the target dose cannot be attained, the highest tolerated dose should be used chronically. Although there is incremental benefit with higher doses of ACE inhibitors, it is accepted that lower doses provide substantial if not most of the effect.[15] Because ACE inhibitors are only one component of a mortality-reducing treatment plan in HF, targeting a high ACE inhibitor dose should be used cautiously to avoid a hypotensive effect that precludes starting a β-blocker or aldosterone receptor antagonist.

Despite their clear benefits, ACE inhibitors are still underutilized in HF. One reason is undue concern or confusion regarding absolute versus relative contraindications for their use. Absolute contraindications include a history of angioedema, bilateral renal artery stenosis, and pregnancy (Table 6–7). Relative contraindications include unilateral renal artery stenosis, renal insufficiency, hypotension, hyperkalemia, and cough. Relative contraindications provide a warning that close monitoring is required, but they do not necessarily preclude their use.

Clinicians are especially concerned about the use of ACE inhibitors in patients with renal insufficiency. It is important to recognize that ACE inhibitors can potentially contribute to the preservation or decline of renal function depending on the clinical scenario. Through preferential efferent arteriole vasodilation, ACE inhibitors can reduce intraglomerular pressure. Reduced glomerular pressures are renoprotective chronically; however, in situations of reduced or fixed renal blood flow, this leads to a reduction in filtration. In general, ACE inhibitors can be used in patients with serum creatinine less than 2.5 to 3.0 mg/dL (221–265 μmol/L). In HF, their addition can result in improved renal function through an increase in CO and renal perfusion. Although a small increase in serum creatinine (< 0.5 mg/dL [44 μmol/L]) is possible with the addition of an ACE inhibitor, it is usually transient or becomes the patient's new serum creatinine baseline level. However, ACE inhibition can also worsen renal function because glomerular filtration is maintained in the setting of reduced CO through AT_2's constriction of the efferent arteriole. Patients most dependent on AT_2 for maintenance of glomerular filtration pressure, and hence most susceptible to ACE inhibitor worsening of renal function, include those with hyponatremia, severely depressed LV function, or dehydration. The most common reason for creatinine elevation in a patient without a history of renal dysfunction is overdiuresis. Therefore, clinicians should consider decreasing or holding diuretic doses if an elevation in serum creatinine occurs concomitantly with a rise in blood urea nitrogen (BUN).

Hypotension occurs commonly at the initiation of therapy or with dosage increases but may happen anytime during therapy. Hypotension can manifest as dizziness, lightheadedness, presyncope, or syncope. The risk of hypotension due to possible volume depletion increases when ACE inhibitors are initiated or used concomitantly in patients on high diuretic doses. Therefore, in euvolemic patients, diuretic doses may often be decreased or withheld during ACE inhibitor dose titration. Initiating at a low dose and titrating slowly can also minimize hypotension. It may be advisable to initiate therapy with a short-acting ACE inhibitor, such as captopril, and subsequently switch to a longer-acting agent, such as lisinopril or enalapril, once the patient is stabilized.

Hyperkalemia results from reduced angiotensin II–stimulated aldosterone release. The risk of hyperkalemia with ACE inhibitors is also increased in HF due to a propensity for impaired renal function and additive effects with aldosterone receptor

antagonists. ACE inhibitor dose may need to be decreased or held if serum potassium increases above 5 mEq/L (mmol/L). Persistent hyperkalemia in the setting of renal insufficiency may preclude the use of an ACE inhibitor. Assessment of potential causes of hyperkalemia should include dietary intake as well as potassium-containing salt-substitutes.

Cough is commonly seen with ACE inhibitors (5%–15%) and may be related to accumulation of tissue bradykinins.[5] It can be challenging to distinguish an ACE inhibitor–induced cough from cough caused by pulmonary congestion. A productive or wet cough usually signifies congestion, whereas a dry, hacking cough is more indicative of a drug-related etiology. If a cough is determined to be ACE inhibitor–induced, its severity should be evaluated before deciding on a course of action. If the cough is truly bothersome, a trial with a different ACE inhibitor or switching to an ARB is warranted.

Angiotensin Receptor Blockers ARBs selectively antagonize the effects of AT_2 directly at the AT_1 receptor. AT_1 receptor stimulation is associated with vasoconstriction, release of aldosterone, and cellular growth promoting effects. By selectively blocking AT_1 but leaving AT_2 unaffected, ARBs block the detrimental AT_1 effects on cardiac function while allowing AT_2-mediated vasodilation and inhibition of ventricular remodeling. ARBs are considered an equally effective replacement for ACE inhibitors in patients who are intolerant or have a contraindication to an ACE inhibitor.

Prospective randomized trials suggest that the clinical efficacy of ARBs is similar to that of ACE inhibitors for reduction of hospitalizations for HF, sudden cardiac death, and all-cause mortality.[16-18] Despite poorer suppression of AT_2, comparable efficacy of ACE inhibitors may be due to the additional effects on the kallikrein-kinin system. Although ARBs produce hemodynamic and neurohormonal effects similar to those of ACE inhibitors, they are considered second-line therapy due to the overwhelming clinical trial experience with ACE inhibitors. LO 6

Because the mechanism for long-term benefit appears different for ACE inhibitors and ARBs, the combination has been studied for additive benefits. In one study, candesartan reduced the combined incidence of cardiovascular death and hospitalization for HF; however, the greatest benefit was noted in those not on an ACE inhibitor. Candesartan also significantly decreased mortality compared with placebo. Based on this study, the addition of an ARB to ACE inhibitor therapy can be considered in patients with evidence of disease progression despite optimal ACE inhibitor therapy and when aldosterone receptor antagonists are not tolerated, although this strategy is not widely applied.[1] LO 6

ARBs show similar tolerability to ACE inhibitors with regard to hypotension and hyperkalemia, but they are less likely to induce cough because ARBs do not cause an accumulation of bradykinin. ARBs can be considered in patients with ACE inhibitor–induced angioedema, but should be initiated cautiously because cross-reactivity has been reported. Many of the other considerations for use of ARBs are similar to those of ACE inhibitors, including the need for monitoring renal function, BP, and potassium. Contraindications are similar to those of ACE inhibitors (Table 6–7). In patients truly intolerant or contraindicated to ACE inhibitors or ARBs, the combination of hydralazine and isosorbide dinitrate should be considered. LO 6

Sacubitril/Valsartan Sacubitril/valsartan (formerly known as the compound LCZ696) is a first in class ARNI.[19] Neprilysin is a neutral endopeptidase responsible for the breakdown of natriuretic peptides, in addition to substance P, adrenomedullin, bradykinin, and AT_2. Blockade of neprilysin increases circulating natriuretic peptide levels. Because neprilysin inhibition alone would also result in elevated levels of AT_2, combination of a neprilysin inhibitor with a RAAS blocker prevents this potentially deleterious effect. Sacubitril/valsartan is a crystalline complex composed of equal parts of the neprilysin inhibitor sacubitril and the ARB valsartan. Shortly after ingestion, sacubitril/valsartan breaks apart into sacubitril, a prodrug which is cleaved to the active form sacubitrilat, and valsartan. The target dose is 97/103 mg twice daily, which was found to reduce the composite end point of cardiovascular death or hospitalization for HF by 20% compared to enalapril 10 mg twice daily in patients with symptomatic HF and reduced LVEF.[20] As such, the 2017 ACC/AHA/Heart Failure Society of America Focused Update of the 2013 American College of Cardiology Foundation/AHA Guideline for the Management of Heart Failure recommend that in patients with symptomatic HFrEF who are tolerating an ACE inhibitor or an ARB, replacement with sacubitril/valsartan is warranted to further reduce morbidity and mortality.[21] Compared to enalapril, patients taking sacubitril/valsartan experienced more symptomatic hypotension, necessitating caution with initiating or switching to this medication in patients with lower BP. Sacubitril/valsartan is contraindicated for use with an ACE inhibitor due to an increased risk for angioedema (Table 6–7), and a 36-hour washout period is necessary when switching to sacubitril/valsartan from an ACE inhibitor, or when switching from sacubitril/valsartan to an ACE inhibitor. The starting dose of sacubitril/valsartan is 49/51 mg twice daily, unless the patient has not previously been on an ACE inhibitor or ARB, or is taking a low dose of an ACE inhibitor, in which case the recommended initial dose is 24/26 mg twice daily (Table 6–6). Titration to a goal dose of 97/103 mg twice daily is recommended. LO 6

Hydralazine and Isosorbide Dinitrate Complementary hemodynamic actions originally led to the combination of nitrates with hydralazine. Nitrates reduce preload by causing primarily venous vasodilation through activating guanylate cyclase and a subsequent increase in cGMP in vascular smooth muscle. Hydralazine reduces afterload through direct arterial smooth muscle relaxation via an unknown mechanism. More recently, nitric oxide has been implicated in modulating numerous pathophysiological processes in the failing heart including inflammation, cardiac remodeling, and oxidative damage. Supplementation of nitric oxide via administration of nitrates has also been proposed as a mechanism for benefit from this combination therapy. The beneficial effect of an external nitric oxide source may be more apparent in the African American population, which appears to be predisposed to having an imbalance in nitric oxide production. In addition, hydralazine may reduce the development of nitrate tolerance when nitrates are given chronically.

The combination of hydralazine and isosorbide dinitrate was the first therapy shown to improve long-term survival in patients with systolic HF, but it has largely been supplanted by ACE inhibitors and ARBs.[22,23] Therefore, until recently, this combination therapy was reserved for patients intolerant to ACE inhibitors or ARBs secondary to renal impairment, angioedema, or hyperkalemia. New insight into the pathophysiological role of nitric oxide has reinvigorated research into this combination therapy. LO 6

The nitrate–hydralazine combination was first shown to improve survival compared with placebo,[22] but was inferior with respect to mortality reduction when compared to the ACE inhibitor enalapril.[23] Therefore, the combination is considered a third-line vasodilatory option for patients truly intolerant of ACE inhibitors and ARBs.

More recently, the value of adding the combination of isosorbide dinitrate 40 mg and hydralazine 75 mg three times daily to therapy including ACE inhibitors, β-blockers, digoxin, and diuretics was shown in a prospective randomized trial in African American patients.[24] KEY CONCEPT Combination therapy with hydralazine and isosorbide dinitrate is an appropriate substitute for AT_2 antagonism in those unable to tolerate an ACE inhibitor or ARB or as add-on therapy in African Americans. The ACC/AHA HF guidelines recommend considering the addition of isosorbide dinitrate and hydralazine in African Americans already on ACE inhibitors or ARBs.[1] Combination therapy with isosorbide dinitrate and hydralazine should be initiated and titrated as are other neurohormonal agents such as ACE inhibitors and β-blockers. Low doses are used to initiate therapy with subsequent titration of the dose toward target doses based on tolerability. Adverse effects such as hypotension and headache cause frequent discontinuations in patients taking this combination, and full doses often cannot be tolerated. Patients should be monitored for headache, hypotension, and tachycardia (Table 6–7). Hydralazine is also associated with a dose-dependent risk for lupus.

The frequent dosing of isosorbide dinitrate (eg, three to four times daily) is not conducive to patient adherence; therefore, a once-daily isosorbide mononitrate is commonly substituted for isosorbide dinitrate to simplify the dosing regimen.

β-Adrenergic Antagonists β-Adrenergic antagonists, or β-blockers, competitively block the influence of the SNS at β-adrenergic receptors. As recently as 15 to 20 years ago, β-adrenergic blockers were thought to be detrimental in HF due to their negative inotropic actions, which could potentially worsen symptoms and cause acute decompensations. Since then, the benefits of inhibiting the SNS have been recognized as far outweighing the acute negative inotropic effects. Chronic β-blockade reduces ventricular mass, improves ventricular shape, and reduces LV end-systolic and diastolic volumes.[6,8] β-blockers also exhibit antiarrhythmic effects, slow or reverse catecholamine-induced ventricular remodeling, decrease myocyte death from catecholamine-induced necrosis or apoptosis, and prevent myocardial fetal gene expression. Consequently, β-blockers improve EF, reduce all-cause and HF-related hospitalizations, and decrease all-cause mortality in patients with systolic HF.[25-27]

The ACC/AHA recommend that β-blockers be initiated in all HF patients with NYHA FC I to IV or ACC/AHA stages B through D if clinically stable.[1] To date, only three β-blockers have been shown to reduce mortality in systolic HF including the selective β_1-antagonists bisoprolol and metoprolol succinate, and the nonselective β_1-, β_2-, and α_1-antagonist carvedilol.[25-27] The positive findings of β-blockers are not a class effect because bucindolol did not exhibit a beneficial effect on mortality when studied for HF, and there is limited information with propranolol and atenolol.

Bisoprolol is not as commonly used since it is not Food and Drug Administration (FDA) approved for HF. Although metoprolol succinate and carvedilol are the most commonly used β-antagonists in HF, it is unknown whether one agent should be considered first line. Carvedilol was shown to lower all-cause mortality significantly more than metoprolol tartrate, but carvedilol has not been directly compared to metoprolol succinate.[28]

The key to utilizing β-blockers in systolic HF is initiation with low doses and slow titration to target doses over weeks to months. It is important that the β-blocker be initiated when a patient is clinically stable and euvolemic. Volume overload at the time of β-blocker initiation increases the risk for worsening symptoms. β-Blockade should begin with the lowest possible dose (Table 6–6), after which the dose may be doubled every 2 to 4 weeks depending on patient tolerability. β-Blockers may cause an acute decrease in LVEF and short-term worsening of HF symptoms upon initiation and at each dosage titration. After each dose titration, if the patient experiences symptomatic hypotension, bradycardia, orthostasis, or worsening symptoms, further increases in dose should be withheld until the patient stabilizes. After stabilization, attempts to increase the dose should be reinstituted. If mild congestion ensues as a result of the β-blocker, an increase in diuretic dose may be warranted. If moderate or severe symptoms of congestion occur, a reduction in β-blocker dose should be considered along with an increase in diuretic dose. Dose titration should continue until target clinical trial doses are achieved (Table 6–6) or until limited by repeated hemodynamic or symptomatic intolerance. Patient education regarding the possibility of acutely worsening symptoms but improved long-term function and survival is essential to ensure adherence.

Apart from possible clinical differences between the β-blockers approved for HF, selection of a β-blocker may also be affected by pharmacologic differences. Carvedilol exhibits a more pronounced BP-lowering effect, and thus causes more frequent dizziness and hypotension as a consequence of its β_1- and α_1-receptor blocking activities. Therefore, in patients predisposed to symptomatic hypotension, such as those with advanced LV dysfunction (LVEF < 20% [0.20]) who normally exhibit low systolic BP, metoprolol succinate may be the more desirable first-line β-blocker. In patients with uncontrolled hypertension, carvedilol may provide additional antihypertensive efficacy.

β-Blockers may be used by those with reactive airway disease or peripheral vascular disease but should be used with considerable caution or avoided if patients display active respiratory symptoms. Care must also be used in interpreting SOB in these patients because the etiology could be either cardiac or pulmonary. A selective β_1-blocker such as metoprolol succinate is a reasonable option for patients with reactive airway disease. The risk versus benefit of using any β-blocker in peripheral vascular disease must be weighed based on the severity of the peripheral disease, and a selective β_1-blocker is preferred.

Both metoprolol and carvedilol are metabolized by the liver through cytochrome P-450 (CYP) 2D6 and undergo extensive first-pass metabolism. β-Blockers should not be used in patients with severe hepatic failure.

There is some debate regarding which class of agents should be initiated first in a patient with HF, namely, ACE inhibitors or β-blockers. A recent study evaluated whether the order of initiation affects all-cause mortality or hospitalization and found no difference but that more events occurred during the 6-month single-treatment phase of the study.[29] These findings reinforce the importance of using both ACE inhibitors and β-blockers in the HF patient. As such, doses of the agent initiated first should not prohibit initiation of the second class of agents.

Mineralocorticoid Receptor Antagonists (MRAs) The MRAs currently available are spironolactone and eplerenone. Both agents are inhibitors of aldosterone that produce weak diuretic effects while sparing potassium concentrations. Eplerenone is selective for the mineralocorticoid receptor and hence does not exhibit the endocrine adverse effect profile commonly seen with spironolactone. The initial rationale for specifically targeting aldosterone for treatment of HF was based on the knowledge that ACE inhibitors do not suppress the chronic production and release of aldosterone. Aldosterone is a key pathological neurohormone that exerts multiple detrimental effects in HF. Similar to norepinephrine and AT_2, aldosterone levels are increased in HF and correlate with disease severity and patient outcomes.

MRAs improved clinical outcomes, including mortality, across the spectrum of HF in three separate clinical trials. These comprised patients who were post-MI with LVEF less than 40% (0.40), patients with NYHA FC II HF, and patients with NYHA FC III-IV HF.[30-32] It is postulated that MRAs reduce mortality at least in part through prevention of sudden cardiac death. Based on these studies, the ACC/AHA guidelines recommended MRAs in NYHA FC II through IV patients with LVEF less than or equal to 35% (0.35), unless contraindicated, in addition to patients post-MI with evidence of LV dysfunction. For individuals with mild symptoms (NYHA FC II), it is recommended they also exhibit a history of hospitalization or elevated BNP levels.[1]

LO 6

The major risk related to MRAs is hyperkalemia (Table 6–7). Therefore, the decision for use of these agents should balance the benefit of decreasing death and hospitalization from HF and the potential risks of life-threatening hyperkalemia. Before and within 1 week of initiating therapy, two parameters must be assessed: serum potassium and CrCL (or serum creatinine). MRAs should not be initiated in patients with potassium concentrations greater than 5.0 mEq/L (mmol/L). Likewise, these agents should not be given when CrCL is less than 30 mL/min (0.50 mL/s) or serum creatinine is greater than 2.5 mg/dL (221 μmol/L).

In patients without contraindications, spironolactone is initiated at a dose of 12.5 to 25 mg daily (Table 6–6), or occasionally on alternate days for patients with baseline renal insufficiency. Eplerenone is used at a dose of 25 mg daily, with the option to titrate up to 50 mg daily. Doses should be halved or switched to alternate-day dosing if CrCL falls below 50 mL/min (0.83 mL/s). Potassium supplementation is often decreased or stopped after MRAs are initiated, and patients should be counseled to avoid high-potassium foods. At any time after initiation of therapy, if potassium concentrations exceed 5.5 mEq/L (mmol/L), the dose of the MRA should be reduced or discontinued. In addition, worsening renal function dictates consideration for stopping the MRA. Other adverse effects observed mainly with spironolactone include gynecomastia for men and breast tenderness and menstrual irregularities for women. Gynecomastia leads to discontinuation in up to 10% of patients on spironolactone. Eplerenone is a CYP3A4 substrate and should not be used concomitantly with strong inhibitors of 3A4.

► *Digoxin*

Digoxin has been used for several decades in the treatment of HF. Traditionally, it was considered useful for its positive inotropic effects, but more recently its benefits are thought to be related to neurohormonal modulation. Digoxin exerts positive inotropic effects through binding to sodium- and potassium-activated adenosine triphosphate (ATP) pumps, leading to increased intracellular sodium concentrations and subsequently more available intracellular calcium during systole. The mechanism of digoxin's neurohormonal blocking effect is less well understood but may be related to restoration of baroreceptor sensitivity and reduced central sympathetic outflow.[5]

The exact role of digoxin in therapy remains controversial largely due to disagreement on the risk versus benefit of routinely using this drug in patients with systolic HF. Digoxin was shown to decrease HF-related hospitalizations but did not decrease HF progression or improve survival.[33] Moreover, digoxin was associated with an increased risk for concentration-related toxicity and numerous adverse effects. Post hoc study analyses demonstrated a clear relationship between digoxin plasma concentration and outcomes. Concentrations below 1.2 ng/mL (mcg/L; 1.5 nmol/L) were associated with no apparent adverse effect on survival, whereas higher concentrations increased the relative risk of mortality.[34]

LO 6

Current recommendations are for the addition of digoxin for patients who remain symptomatic despite an optimal HF regimen consisting of an ACE inhibitor or ARB, β-blocker, and diuretic. In patients with concomitant atrial fibrillation, digoxin may occasionally be added to slow ventricular rate; however, β-blockers are more effective at controlling ventricular rate, especially in the setting of exercise. Clinicians may also consider adding digoxin in patients with severe HF who have not responded symptomatically to neurohormonal blockade.

Digoxin is initiated at a dose of 0.125 to 0.25 mg daily depending on age, renal function, weight, and risk for toxicity (Table 6–6). The lower dose should be used if the patient satisfies any of the following criteria: older than 65 years, CrCL less than 60 mL/min (1.0 mL/s), or ideal body weight less than 70 kg (154 lb). The 0.125-mg daily dose is adequate in most patients. Doses are halved or switched to alternate-day dosing in patients with moderate to severe renal failure. The desired concentration range for digoxin is 0.5 to 0.9 ng/mL (mcg/L; 0.6–1.2 nmol/L), preferably with concentrations at or less than 0.8 ng/mL (mcg/L; 1.0 nmol/L). Routine monitoring of serum drug concentrations is not required but recommended in those with changes in renal function, suspected toxicity, or after addition or subtraction of an interacting drug.

Digoxin toxicity may manifest as nonspecific findings such as fatigue or weakness and other central nervous system (CNS) effects such as confusion, delirium, and psychosis (Table 6–7). GI manifestations include nausea, vomiting, or anorexia, and visual disturbances may occur such as halos, photophobia, and color perception problems (red-green or yellow-green vision). Cardiac findings include numerous types of arrhythmias related to enhanced automaticity, slowed or accelerated conduction, or delayed after-depolarizations. These include ventricular tachycardia and fibrillation, atrioventricular nodal block, and sinus bradycardia. Risk of digoxin toxicity, in particular, the cardiac manifestations, are increased with electrolyte disturbances such as hypokalemia, hypercalcemia, and hypomagnesemia. To reduce the proarrhythmic risk of digoxin, serum potassium and magnesium should be monitored closely and supplemented when appropriate to ensure adequate concentrations (potassium > 4.0 mEq/L [mmol/L] and magnesium > 2.0 mEq/L [1.0 mmol/L]). In patients with life-threatening digoxin toxicity due to cardiac or other findings, administration of digoxin-specific Fab antibody fragments usually reverses adverse effects within an hour in most cases.

► *Calcium Channel Blockers*

Treatment with nondihydropyridine calcium channel blockers (diltiazem and verapamil) may worsen HF and increase the risk of death in patients with advanced LV systolic dysfunction due to their negative inotropic effects. Conversely, dihydropyridine calcium channel blockers, although negative inotropes in vitro, do not appear to decrease contractility in vivo. Amlodipine and felodipine are the two most extensively studied dihydropyridine calcium channel blockers for systolic HF.[35,36] These two agents have not been shown to affect patient survival, either positively or negatively. As such, they are not routinely recommended as part of a standard HF regimen; however, amlodipine and felodipine can safely be used in HF patients to treat uncontrolled hypertension or angina once all other appropriate drugs are maximized.

LO 6

► *Antiplatelets and Anticoagulation*

Patients with HF are at an increased risk of thromboembolic events secondary to a combination of hypercoagulability, relative

stasis of blood, and endothelial dysfunction. However, the role of antiplatelets and anticoagulants remains debatable due to a lack of positive prospective clinical trials.

LO 6

Aspirin is generally used in HF patients with an underlying ischemic etiology, a history of ischemic heart disease, or other compelling indications such as history of embolic stroke. Routine use in nonischemic cardiomyopathy patients is currently discouraged because of a lack of data supporting any long-term benefit, as well as the potential negative drug–drug interaction with ACE inhibitors and ARBs. If aspirin is indicated, the preference is to use a low dose (81 mg daily).

LO 6

Current guidelines support chronic anticoagulation in patients with reduced LV systolic dysfunction and a compelling indication such as atrial fibrillation or prosthetic heart valves. For atrial fibrillation, a stronger level of evidence is given for use of anticoagulation in patients with an additional risk factor for cardioembolic stroke, such as history of hypertension, diabetes mellitus, previous stroke or transient ischemic attack, or age 75 years or older.[1] The choice of anticoagulant (warfarin vs novel anticoagulants) should be based on risk factors, tolerability, cost, and potential for drug–drug interactions. Patients with HF often have difficulty maintaining a therapeutic international normalized ratio (INR) due to fluctuating volume status and varying drug absorption.

▶ *Ivabradine*

Ivabradine is a novel medication that specifically targets lowering HR through blockade through the I_f channel (otherwise referred to as the "funny" current channel) in the sinoatrial node, without affecting BP or contractility. In one study, ivabradine was shown to reduce the composite of cardiovascular death or hospitalization for HF, although results were mainly driven by a reduction in hospitalizations.[37] Ivabradine is indicated in patients with HFrEF with an LVEF less than or equal to 35% (0.35), NYHA FC II-III, in normal sinus rhythm (without atrial fibrillation), taking maximally tolerated or target doses of β-blockers, and who have an HR 70 beats/min or greater. It is important that the β-blocker is optimized prior to initiating therapy with ivabradine, as β-blockers have proven benefits on lowering mortality; thus reaching target doses of a β-blocker takes priority. The starting dose of ivabradine is 5 mg twice daily (or 2.5 mg twice daily in those with conduction defects or those in whom a low HR could result in hemodynamic compromise), which may be titrated to 7.5 mg twice daily after 2 weeks (Table 6–6). Ivabradine is contraindicated for use in patients concomitantly taking strong CYP3A4 inhibitors. Frequently observed adverse effects in clinical trials included bradycardia, atrial fibrillation, hypertension, and visual phenomena (Table 6–7). Termed "phosphenes," these visual disturbances consist of temporarily enhanced brightness, usually in response to sudden variations in light (ie, headlights from other cars while driving). These occur in limited areas of the visual field and may also include halos, image decomposition (stroboscopic or kaleidoscopic effects), or colored bright lights. These visual effects may reduce in severity after a few months of therapy.

Heart Failure with Preserved Left Ventricular Ejection Fraction

It is now recognized that a significant number of patients exhibiting HF symptoms have normal systolic function or preserved LVEF (40%–60% [0.40–0.60]). It is believed that the primary defect in these patients is impaired ventricular relaxation and filling, commonly referred to as HF with preserved EF (HFpEF). HFpEF is more prevalent in older women and closely associated with hypertension or diabetes and, to a lesser extent, CAD and atrial fibrillation. Morbidity in HFpEF is comparable to those with reduced EF because both are characterized by frequent, repeated hospitalizations. However, HFpEF appears to be associated with slightly lower mortality. The diagnosis is based on findings of typical signs and symptoms of HF, in conjunction with echocardiographic evidence of abnormal diastolic function, absence of significant LV chamber dilation, and no valvular disease.

Unlike HFrEF, few prospective trials have evaluated the safety and efficacy of various cardiac medications in patients with HFpEF. The PEP-CHF (Perindopril in Elderly People with Chronic Heart Failure) study did not find differences in mortality and hospitalizations between perindopril and placebo, but premature withdrawal of many patients after 1 year could have contributed to the neutral findings.[38] The Candesartan in Heart Failure Assessment of Reduction in Mortality and Morbidity (CHARM) study demonstrated that angiotensin receptor blockade with candesartan resulted in beneficial effects on HF morbidity in patients with preserved LVEF similar to those seen in depressed LV function.[18] However, the largest clinical trial in HFpEF, the I-PRESERVE (Irbesartan in Patients with Heart Failure and Preserved Ejection Fraction) study did not find a reduction in the primary composite outcome of death or hospitalizations between irbesartan and placebo.[39] In the TOPCAT (Treatment of Preserved Cardiac Function Heart Failure with an Aldosterone Antagonist) trial, spironolactone did not reduce the composite end point of cardiovascular death, aborted cardiac arrest, or HF hospitalizations, but resulted in a reduction of the secondary end point, hospitalizations due to HF.[40] In the absence of more landmark clinical studies, the current treatment approach for HFpEF is: (a) correction or control of underlying etiologies (including optimal treatment of hypertension and CAD and maintenance of normal sinus rhythm); (b) reduction of cardiac filling pressures at rest and during exertion; (c) increased diastolic filling time, and (d) reduction of hospitalizations with spironolactone in select patients (LVEF 45% [0.45] or greater, elevated BNP levels or hospitalization for HF in the past year). Diuretics are frequently used to control congestion. β-Blockers and calcium channel blockers can theoretically improve ventricular relaxation through negative inotropic and chronotropic effects. Unlike in systolic HF, nondihydropyridine calcium channel blockers (diltiazem and verapamil) may be especially useful in improving diastolic function by limiting the availability of calcium that mediates contractility. A recent study did not find favorable effects with digoxin in patients with mild to moderate diastolic HF. Therefore, the role of digoxin for symptom management and HR control in these patients is not well established.

Patient Encounter Part 3

Based on the information presented and your problem-based assessment, create a care plan for the patient's HF. Your plan should include:

- Nonpharmacologic treatment options.
- Acute and chronic treatment plans to address symptoms and prevent disease deterioration.
- Monitoring plan for acute and chronic treatments.

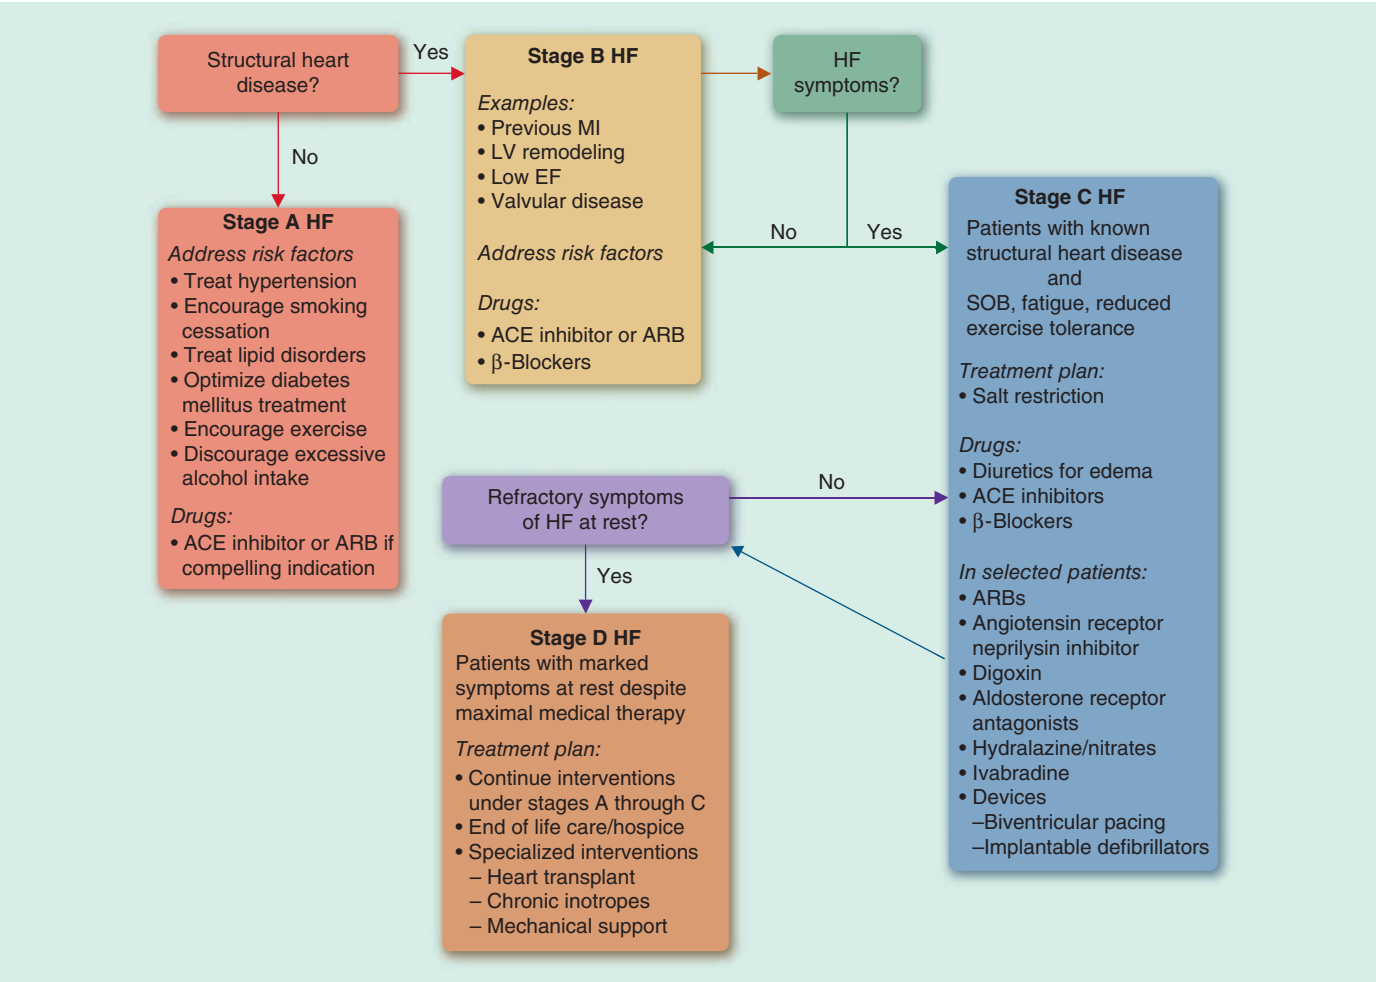

FIGURE 6–2. Treatment algorithm for heart failure with reduced ejection fraction. (ACE, angiotensin-converting enzyme; ARB, angiotensin receptor blocker; EF, ejection fraction; HF, heart failure; LV, left ventricular; MI, myocardial infarction; SOB, shortness of breath.) Table 6–5 describes the staging of heart failure.

Outcome Evaluation of Chronic Heart Failure

LO 7

- The evaluation of therapy is influenced by the ability of treatment to successfully reduce symptoms, improve quality of life, decrease frequency of hospitalizations for acute HF, reduce disease progression, and prolong survival (Figure 6–2).
- The major outcome parameters focus on (a) volume status, (b) exercise tolerance, (c) overall symptoms/quality of life, (d) adverse drug reactions, and (e) disease progression and cardiac function.
- Assess quality of life by evaluating patients' ability to continue their activities of daily living.
- Assess symptoms of HF such as dyspnea on exertion, orthopnea, weight gain, and edema, and abdominal manifestations such as nausea, bloating, and loss of appetite.
- If diuretic therapy is warranted, monitor for therapeutic response by assessing weight loss and improvement of fluid retention, as well as exercise tolerance and presence of fatigue.
- Once therapy for preventing disease progression is initiated, continue to monitor for symptomatic improvement.
- Keep in mind that patients' symptoms can worsen with β-blockers, and it may take weeks or months before patients notice improvement.
- Monitor BP to evaluate for hypotension caused by drug therapy.
- Occasional exercise testing is conducted to ascertain disease prognosis or suitability for heart transplant. Even though these tests can demonstrate improvement in heart function and therefore slowed disease progression, patient symptoms may not improve.

ACUTE AND ADVANCED HEART FAILURE

Clinical Presentation and Diagnosis of Acute Heart Failure

LO 3

Patients with AHF present with symptoms of worsening fluid retention or decreasing exercise tolerance and fatigue (typically worsening of symptoms presented in the chronic HF clinical presentation textbox). These symptoms reflect congestion behind the failing ventricle and/or hypoperfusion. Patients can be categorized into hemodynamic subsets based on assessment of physical signs and symptoms of congestion and/or hypoperfusion.[41] Patients can be described as "wet" or "dry" depending on volume status, as well as "warm" or "cool" based on adequacy of tissue perfusion. "Wet" refers to patients with volume/fluid overload (eg, edema and jugular venous distension [JVD]), whereas "dry" refers to euvolemic patients. "Warm" refers to patients with adequate CO to perfuse peripheral tissues (and

hence the skin will be warm to touch), whereas "cool" refers to patients with evidence of hypoperfusion (skin cool to touch with diminished pulses). Additionally, invasive hemodynamic monitoring can be used in some cases to provide objective data for assessing volume status (pulmonary capillary wedge pressure [PCWP]) and perfusion (CO). A CI below 2.2 L/min/m^2 (0.037 L/s/m^2) is consistent with hypoperfusion and reduced contractility, and a PCWP above 15 mm Hg (2.0 kPa) correlates with congestion and an elevated preload. The four possible hemodynamic subsets a patient may fall into are "warm and dry," "warm and wet," "cool and dry," or "cool and wet."

▶ *Precipitating Factors*

KEY CONCEPT It is important for the clinician to identify the cause(s) of AHF to maximize treatment efficacy and reduce future disease exacerbations. Cardiovascular, metabolic, and lifestyle factors can all precipitate AHF. The most common precipitating factors for acute decompensation and how they contribute pathophysiologically are listed in Table 6–3.

▶ *Laboratory Assessment*

Routine laboratory testing of patients with AHF includes electrolytes and blood glucose, as well as serum creatinine and BUN to assess renal function. Complete blood cell count is measured to determine if anemia or infection is present. Creatine kinase and/or troponin concentrations are used to diagnose ischemia, and hepatic transaminases are measured to assess hepatic congestion. Thyroid function tests are measured to assess hyperthyroidism or hypothyroidism as causes of AHF. A urinalysis is attained in patients with an unknown history of renal disease to rule out nephrotic syndrome. Lastly, a toxicology screen is obtained in patients in whom the use of illicit drugs is suspected.

Assays measuring BNP and its degradation product N-terminal proBNP (NT-proBNP) are being used with greater frequency in clinical practice. BNP is synthesized, stored, and released from the ventricles in response to increased ventricular filling pressures. Hence plasma levels of BNP can be used as a marker for volume overload. The most widely accepted indication for BNP measurement is as an adjunctive aid for diagnosing a cardiac etiology for dyspnea.[10] The current values for ruling out a cardiac etiology for dyspnea are a BNP less than 100 pg/mL (ng/L; 28.9 pmol/L) or an NT-proBNP less than 300 pg/mL (ng/L; 35.4 pmol/L). BNP measurements require cautious interpretation because numerous conditions can also elevate BNP concentrations. These include older age, renal dysfunction, pulmonary embolism, and chronic pulmonary disease. Nesiritide, a recombinant BNP drug, has an identical structure to native BNP and will interfere with the commercial BNP assay, resulting in a falsely elevated level. Therefore, blood for BNP determination should be obtained 2 hours after the end of a nesiritide infusion, or alternatively the NT-proBNP assay should be utilized. In addition, treatment with sacubitril/valsartan would also be expected to raise BNP levels based on the drug's inhibition of neprilysin. As such, monitoring of NT-proBNP should be utilized instead of BNP in patients taking sacubitril/valsartan, as NT-proBNP is not a substrate for neprilysin. Other diagnostic tests should also be obtained to rule out precipitating factors (chest radiograph) and to evaluate cardiac function (ECG).

Invasive hemodynamic monitoring in patients with HF entails placement of a right heart catheter or pulmonary artery catheter (PAC). The catheter is inserted percutaneously through a central vein and advanced through the right side of the heart to the pulmonary artery. Inflation of a balloon proximal to the end port allows the catheter to "wedge," yielding the PCWP, which estimates pressures in the left ventricle during diastole. Additionally, CO can be estimated and SVR calculated (Table 6–8).

There are no universally accepted guidelines dictating when invasive monitoring in HF is required, and invasive monitoring has not been shown to improve mortality or reduce hospitalizations in high-risk patients. Nonetheless, the use of a PAC remains a helpful component of management and monitoring of patients with signs significantly reduced cardiac output; however, use of inotropic agents does not mandate invasive monitoring. Invasive hemodynamic monitoring is most commonly used to aid in assessment of hemodynamics when there is disagreement between signs and symptoms and clinical response. In addition, invasive monitoring is helpful in guiding ongoing therapy for

Clinical Presentation of Acute Heart Failure

Subset I (Warm and Dry)

- CI *greater than* 2.2 L/min/m^2 (0.037 L/s/m^2), PCWP *less than* 18 mm Hg (2.4 kPa)
- Patients considered well compensated and perfused, without evidence of congestion
- No immediate interventions necessary except optimizing oral medications and monitoring

Subset II (Warm and Wet)

- CI *greater than* 2.2 L/min/m^2 (0.037 L/s/m^2), PCWP *greater than* or equal to 18 mm Hg (2.4 kPa)
- Patients adequately perfused and display signs and symptoms of congestion
- Main goal is to reduce preload (PCWP) carefully with loop diuretics and vasodilators

Subset III (Cool and Dry)

- CI *less than* 2.2 L/min/m^2 (0.037 L/s/m^2), PCWP *less than* 18 mm Hg (2.4 kPa)
- Patients are inadequately perfused and not congested
- Hypoperfusion leads to increased mortality, elevating death rates fourfold compared with those who are adequately perfused
- Treatment focuses on increasing CO with positive inotropic agents and/or replacing intravascular fluids
- Fluid replacement must be performed cautiously because patients can rapidly become congested

Subset IV (Cool and Wet)

- CI *less than* 2.2 L/min/m^2 (0.037 L/s/m^2), PCWP *greater than* 18 mm Hg (2.4 kPa)
- Patients are inadequately perfused and congested
- Classified as the most complicated clinical presentation of AHF with the worst prognosis
- Most challenging to treat; therapy targets alleviating signs and symptoms of congestion by increasing CI as well as reducing PCWP while maintaining adequate mean arterial pressure
- Treatment involves a delicate balance between diuretics, vasodilators, and inotropic agents
- Use of vasopressors is sometimes necessary to maintain BP

Table 6–8

Hemodynamic Monitoring: Normal Values

Hemodynamic Variable	Normal Value
Central venous (right atrial) pressure, mean	< 5 mm Hg[a] (0.7 kPa)
Right ventricular pressure	25/0 mm Hg[a]
Pulmonary artery pressure	25/10 mm Hg[a]
Pulmonary artery pressure, mean	< 18 mm Hg[a] (2.4 kPa)
Pulmonary artery occlusion pressure, mean[b]	< 12 mm Hg[a] (1.6 kPa)
Systemic arterial pressure	120/80 mm Hg[a]
Mean arterial pressure	70–110 mm Hg[a] (9.3–14.6 kPa)
Cardiac output	4–6 L/min (0.07–0.10 L/s)
Cardiac index	2.8–4.2 L/min/m^2 (0.047–0.070 L/s/m^2)
Stroke volume index	30–65 mL/beat/m^{2a} (0.030–0.065 L·$beat^{-1}$·m^{-2})
Systemic vascular resistance	900–1400 dyn·s·cm^{-5c} (90–140 MPa·s·m^{-3})
Pulmonary vascular resistance	150–250 dyn·s·cm^{-5c} (15–25 MPa·s·m^{-3})
Arterial oxygen content	20 mL/dL[c] (200 mL/L)
Mixed venous oxygen content	15 mL/dL[c] (150 mL/L)
Arteriovenous oxygen content difference	3–5 mL/dL[c] (30–50 mL/L)

[a]1 mm Hg = 0.133 kPa; 1 mL/beat per square meter = 0.001 L·$beat^{-1}$·m^{-2}.

[b]Also referred to as pulmonary artery wedge pressure (PCWP).

[c]1 dyn·s·cm^{-5} = 0.1 MPa·s·m^{-3}; 1 mL/dL = 10 mL/L.

From Rodgers JE, Reed BN. Acute decompensated heart failure. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:121, with permission.

AHF and offers the advantage of immediate hemodynamic assessment of an intervention, allowing for prompt adjustments. Risks with PACs include infection, bleeding, thrombosis, catheter malfunction, and ventricular ectopy.

Desired Therapeutic Outcomes

LO 4

The goals of therapy for AHF are to: (a) correct the underlying precipitating factor(s); (b) relieve the patient's symptoms; (c) improve hemodynamics; (d) optimize a chronic oral medication regimen; and (e) educate the patient, reinforcing adherence to lifestyle modifications and the drug regimen. The ultimate goal for a patient hospitalized for AHF is return to a compensated HF state and discharge to the outpatient setting on oral medications. Only through aggressive management to achieve all of these goals will a patient's prognosis be improved and future hospitalizations for acute decompensations be prevented.

Removal or control of precipitating factors is essential for an optimal response to pharmacologic therapy. Relief of symptoms should occur rapidly to minimize length of hospitalization. Although a rapid discharge from the hospital is desirable, a patient should not be discharged before ensuring that he or she is in a euvolemic, or nearly euvolemic, state with a body weight and functional capacity similar to before the acute decompensation. Oral agents such as β-blockers, ACE inhibitors or ARBs, and aldosterone antagonists should be initiated as soon as possible during the hospitalization. These chronic oral medications not only improve mortality and prevent readmissions, acutely they also contribute to improvement in hemodynamics. Patient education prior to discharge from the hospital is recommended to assist in minimizing adverse effects and nonadherence. Dissemination of written information, in addition to verbal information, is helpful for patient comprehension and retention. This can include therapy goals, lifestyle modifications, drug regimen, dosage information, and relevant adverse effects, as well as symptom and diary cards.

Pharmacologic Treatment

LO 6

KEY CONCEPT Treatment of AHF targets relief of congestion and optimization of CO utilizing oral or IV diuretics, IV vasodilators, and, when appropriate, inotropes based on presenting hemodynamics. Current treatment strategies in AHF target improving hemodynamics while preserving organ function. A specific treatment approach is formulated depending on the patient's symptoms (congestion vs hypoperfusion) and hemodynamic indices (CI and PCWP).[42] If the patient primarily exhibits signs and symptoms of congestion, treatment entails use of diuretics as first-line agents to decrease PCWP. Additionally, IV vasodilators are added to provide rapid relief of congestion and additional reductions in PCWP. By reducing congestion in the heart, cardiac contractile function may improve, which results in an increase in SV and CO, and hence perfusion to vital organs. The patient's presenting BP can also help guide the clinician on choice of diuretic, vasodilator, or both. For the patient with a systolic BP of 120 to 160 mm Hg in the setting of progressive worsening of chronic HF with pulmonary and systemic congestion, aggressive diuresis can be beneficial. In the patient with systolic BP greater than 160 mm Hg and abrupt onset of pulmonary congestion, IV vasodilators may be indicated in addition to diuretics. For patients primarily displaying symptoms of hypoperfusion, treatment relies on use of agents that increase cardiac contractility, known as positive inotropes. Some patients display both symptoms of congestion as well as hypoperfusion and thus require use of combination therapies. One of the current challenges to the treatment of AHF is achieving hemodynamic improvement without adversely affecting organ function. In the case of inotropes, the increased contractility occurs at the expense of an increase in cardiac workload and potential for proarrhythmia. In addition, high-dose diuretic therapy is associated with worsened renal function and possibly neurohormonal activation.

▶ *Diuretics*

Loop diuretics, including furosemide, bumetanide, and torsemide, are the diuretics of choice in the management of AHF. Furosemide is the most commonly used agent. Diuretics decrease preload by functional venodilation within 5 to 15 minutes of administration and subsequently by an increase in sodium and water excretion. This provides rapid improvement in symptoms of pulmonary congestion. Diuretics reduce PCWP but do not increase CI like positive inotropes and arterial vasodilators. Patients who have significant volume overload often have impaired absorption of oral loop diuretics because of intestinal edema or altered transit time. Therefore, doses are usually administered via IV boluses or continuous IV infusions (Table 6–9). Higher doses may be required for patients with renal insufficiency due to decreased drug delivery to the site of action in the loop of Henle. A good rule of thumb is to initiate the IV diuretic at twice the dose of the outpatient oral dose.

There is limited clinical trial evidence comparing the benefit of diuretics with other therapies for symptom relief or long-term outcomes. Careful monitoring of diuresis is needed as excessive preload reduction can lead to a decrease in CO resulting in reflex increase in sympathetic activation, renin release, and the expected consequences of vasoconstriction, tachycardia, and

Table 6–9

Intravenous Diuretics Used to Treat Heart Failure–Related Fluid Retention

	Onset of Action (minutes)	Duration of Action (hours)	Relative Potency	Intermittent Bolus Dosing (mg)	Continuous Infusion Dosing (bolus/infusion)
Furosemide	2–5	6	40	20–200+	20–40/2.5–10
Torsemide	< 10	6–12	20	10–100	20/2–5
Bumetanide	2–3	4–6	0.5	1–10	1–4/0.5–1
Ethacrynic acid	5–15	2–7		0.5–1 mg/kg per dose up to 100 mg/dose	

LO 7

increased myocardial oxygen demand. Monitoring of serum electrolytes such as potassium, sodium, and magnesium is done frequently to identify and correct imbalances. Monitor serum creatinine and BUN daily at a minimum to assess volume depletion and renal function.

Occasionally, patients with HF do not respond to a diuretic, defined as failure to achieve a weight reduction of at least 0.5 kg (or negative net fluid balance of at least 500 mL) after several increasing bolus doses. Several strategies are used to overcome diuretic resistance. These include using larger oral doses, converting to IV dosing, increasing the frequency of administration, or adding metolazone. A small study using low-dose continuous infusions of furosemide and torsemide has shown an increase in urine output compared with intermittent bolus dosing, but newer evidence suggests that there may be little difference between intermittent bolus dosing and continuous infusion strategies on symptom relief at 72 hours.[43] (See Table 6–9.) Another useful strategy is to combine two diuretics with different sites of action within the nephron. The most common combination is the use of a loop diuretic with a thiazide diuretic such as metolazone. Combining diuretics should be used with caution due to an increased risk for cardiovascular collapse due to rapid intravascular volume depletion. Strict monitoring of electrolytes, vital signs, and fluid balance is warranted. Also, poor CO may contribute to diuretic resistance. In these patients, it may become necessary to add vasodilators or inotropes to enhance perfusion to the kidneys. Care must be taken because vasodilators can decrease renal blood flow despite increasing CO through dilation of central and peripheral vascular beds.

▶ *Vasodilators*

IV vasodilators cause a rapid decrease in arterial tone, resulting in a decrease in SVR and a subsequent increase in SV and CO. Additionally, vasodilators reduce ventricular filling pressures (PCWP) within 24 to 48 hours, reduce myocardial oxygen consumption (MVO_2), and decrease ventricular workload.

LO 6

Vasodilators are commonly used in patients presenting with AHF accompanied by moderate to severe congestion. This class includes nitroglycerin, nitroprusside, and nesiritide. Hemodynamic effects and dosages for these agents are included in Tables 6–10 and 6–11, respectively. Although vasodilators are generally safe and effective, identification of the proper patient for use is important to minimize the risk of significant hypotension. In addition, vasodilators are contraindicated in patients whose cardiac filling (and hence CO) depends on venous return or intravascular volume, as well as patients who present with cardiogenic shock.

Nitroglycerin Nitroglycerin acts as a source of nitric oxide, which induces smooth muscle relaxation in venous and arterial vascular beds. Nitroglycerin is primarily a venous vasodilator at lower doses, but it exerts potent arterial vasodilatory effects at higher doses. Thus, at lower doses, nitroglycerin causes decreases in preload (or filling pressures) and improved coronary blood flow. At higher doses (> 100 mcg/min), additional reduction in preload is achieved, along with a decrease in afterload and subsequent increase in SV and CO. IV nitroglycerin is primarily used as a preload reducer for patients exhibiting pulmonary congestion or in combination with inotropes for congested patients with severely reduced CO.

LO 6

Continuous infusions of nitroglycerin should be initiated at a dose of 5 to 10 mcg/min and increased every 5 to 10 minutes until symptomatic or hemodynamic improvement. Effective doses range from 35 to 200 mcg/min. The most common adverse events reported are headache, dose-related hypotension, and tachycardia. Tachyphylaxis, or tolerance of effects, limits nitroglycerin's use within 12 hours of initiation. Nitroglycerin's effectiveness requires titration to higher doses.

Nitroprusside Nitroprusside, like nitroglycerin, causes the formation of nitric oxide and vascular smooth muscle relaxation. In contrast to nitroglycerin, nitroprusside is both a venous and arterial vasodilator regardless of dosage. Nitroprusside causes a pronounced decrease in PCWP, SVR, and BP, with a modest increase in CO. Nitroprusside has been studied to a limited extent in AHF, and no studies have evaluated its effects on mortality. Nitroprusside is initiated at 0.1 to 0.25 mcg/kg/min, followed by dose adjustments in 0.1 to 0.2 mcg/kg/min increments if necessary to achieve desired effect. Because of its rapid onset of action and metabolism, nitroprusside is administered as a continuous infusion that is easy to titrate and provides predictable hemodynamic effects. Nitroprusside requires strict monitoring

LO 6

of BP and HR. Nitroprusside's use is limited in AHF due to recommended hemodynamic monitoring with an arterial line and mandatory intensive care unit admission at many institutions. Abrupt withdrawal of therapy should be avoided because rebound neurohormonal activation may occur. Therefore, the dose should

Table 6–10

Usual Hemodynamic Effects of Commonly Used Intravenous Agents for Treatment of Acute or Severe Heart Failure

Drug	CO	PCWP	SVR	BP	HR
Diuretics	↑/ ↓/0	↓		↓	0

Table 6–11

Usual Doses and Monitoring of Commonly Used Hemodynamic Medications

Drug	Dose	Monitoring Variables[a]
Dopamine	0.5–10 mcg/kg/min	BP, HR, urinary output and kidney function, ECG, extremity perfusion (higher doses only)
Dobutamine	2.5–20 mcg/kg/min	BP, HR, urinary output and function, ECG
Milrinone	0.375–0.75 mcg/kg/min	BP, HR, urinary output and function, ECG, changes in ischemic symptoms (eg, chest pain), electrolytes
Nitroprusside	0.25–3 mcg/kg/min	BP, HR, liver and kidney function, blood cyanide and/or thiocyanate concentrations if toxicity suspected (nausea, vomiting, altered mental function)
Nitroglycerin	5–200+ mcg/min	BP, HR, ECG, changes in ischemic symptoms
Nesiritide	Bolus: 2 mcg/kg; Infusion: 0.01 mcg/kg/min	BP, HR, urinary output and kidney function, blood BNP/NT-proBNP concentrations

[a]In addition to pulmonary capillary wedge pressure and cardiac output.

BNP, B-type natriuretic peptide; BP, blood pressure; ECG, electrocardiogram; HR, heart rate; NT-proBNP, N-terminal proBNP.

be tapered slowly. Nitroprusside has the potential to cause cyanide and thiocyanate toxicity, especially in patients with hepatic and renal insufficiency, respectively. Toxicity is most common with use longer than 3 days and with higher doses. Nitroprusside should be avoided in patients with active ischemia because its powerful afterload-reducing effects within the myocardium can "steal" coronary blood flow from myocardial segments that are supplied by epicardial vessels with high-grade lesions.

Nesiritide Recombinant BNP, or nesiritide, binds to guanylate cyclase receptors in vascular smooth muscle and endothelial cells, causing an increase in cGMP concentrations leading to vasodilation (venous and arterial) and natriuresis. Nesiritide also antagonizes the effects of the RAAS and endothelin. Nesiritide reduces PCWP, right atrial pressure, and SVR. Consequently, it also increases SV and CO without affecting HR. Continuous infusions result in sustained effects for 24 hours without tachyphylaxis, although experience with its use beyond 72 hours is limited.

Nesiritide has been shown to improve symptoms of dyspnea and fatigue. In a randomized clinical trial, nesiritide was found to significantly decrease PCWP more than nitroglycerin and placebo over 3 hours.[44] Nesiritide improved patients' self-reported dyspnea scores compared with placebo at 3 hours, but there was no difference compared with nitroglycerin. In another study, nesiritide did not decrease death or rehospitalization for HF within 30 days, worsen renal function, or increase the risk for mortality, despite previous concerns regarding its association with elevations in serum creatinine.[45]

LO 6 Currently, nesiritide is indicated for patients with AHF exhibiting dyspnea at rest or with minimal activity. The recommended dose regimen is a bolus of 2 mcg/kg, followed by a continuous infusion for up to 24 hours of 0.01 mcg/kg/min. Because nesiritide's effects are predictable and sustained at the recommended dosage, titration of the infusion rate (maximum of 0.03 mcg/kg/min) is not commonly required nor is invasive hemodynamic monitoring. Nesiritide should be avoided in patients with systolic BP less than 90 mm Hg. Although nesiritide's place in AHF therapy is not firmly defined, it can be used in combination with diuretics for patients presenting in moderate to severe decompensation, and it offers a unique mechanism of action. One potential disadvantage compared with other vasodilators is its longer half-life. Combination therapy may result in hypotension, which can be prolonged (2 hours).

► *Inotropic Agents*

Currently available positive inotropic agents act via increasing intracellular cyclic adenosine monophosphate (cAMP) concentrations through different mechanisms. β-Agonists activate adenylate cyclase through stimulation of β-adrenergic receptors, which subsequently catalyzes the conversion of ATP to cAMP. In contrast, phosphodiesterase inhibitors reduce degradation of cAMP. The resulting elevation in cAMP levels leads to enhanced phospholipase activity, which then increases the rate and extent of calcium influx during systole, thereby enhancing contractility. Additionally, during diastole, cAMP promotes uptake of calcium by the sarcoplasmic reticulum, which improves cardiac relaxation. Routine use of inotropes during acute decompensations is less preferable to use of vasodilators, which should be attempted first for AHF.

Dobutamine Dobutamine has historically been the inotrope of choice for AHF. As a synthetic catecholamine, it acts as an agonist mainly on β_1- and β_2-receptors and minimally on α_1-receptors. The resulting hemodynamic effects are due to both receptor- and reflex-mediated activities. These effects include increased contractility and HR through β_1- (and β_2-) receptors and vasodilation through a relatively greater effect on β_2- than α_1-receptors. Dobutamine can increase, decrease, or cause little change in mean arterial pressure depending on whether the resulting increase in CO is enough to offset the modest vasodilation. Although dobutamine has a half-life of approximately 2 minutes, its positive hemodynamic effects can be observed for several days to months after administration. LO 6 The use of dobutamine is supported by several small studies documenting improved hemodynamics, but large-scale clinical trials in AHF are lacking.

Dobutamine is initiated at a dose of 2.5 to 5 mcg/kg/min, which can be gradually titrated to 20 mcg/kg/min based on clinical response. There are several practical considerations to dobutamine therapy. LO 6 First, owing to its vasodilatory potential, monotherapy with dobutamine is reserved for patients with systolic BP greater than 90 mm Hg. However, it is commonly used in combination with vasopressors in patients with lower systolic BP. Second, due to downregulation of β_1-receptors or uncoupling of β_2-receptors from adenylate cyclase with prolonged exposure to dobutamine, attenuation of hemodynamic effects has been reported to occur as early as 48 hours after initiation of a continuous infusion, although tachyphylaxis is more evident with use spanning longer than 72 hours. Full sensitivity to dobutamine's effects can be restored 7 to 10 days after the drug is withdrawn. Third, many patients with AHF will be taking β-blockers chronically. Because of β-blockers' high affinity for β-receptors, the effectiveness of β-agonists such as dobutamine will be reduced. LO 6 In patients on β-blocker therapy, it is recommended that consideration be given to the use of phosphodiesterase inhibitors such as milrinone, which do not depend on β-receptors for effect.[46,47] Although commonly practiced, use of high doses of dobutamine to overcome the β-blockade should be discouraged because this negates any of the protective benefits of the β-blocker and may increase risk for arrhythmias.

LO 6 **Dopamine** Dopamine is most commonly reserved for patients with low systolic BP and those approaching cardiogenic shock. Dopamine exerts its effects through direct stimulation of adrenergic receptors, as well as release of norepinephrine from adrenergic nerve terminals. Dopamine produces hemodynamic effects that differ based on dosing. At lower doses, dopamine stimulates dopamine type 1 (D1) receptors and thus increases renal perfusion. Positive inotropic effects are more pronounced at doses of 3 to 10 mcg/kg/min. CI is increased due to increased SV and HR. At doses higher than 10 mcg/kg/min, chronotropic and α_1-mediated vasoconstriction effects are evident. This causes an increase in mean arterial pressure due to higher CI and SVR. The ultimate effect on cardiac hemodynamics will depend largely on the dosage prescribed and must be individually tailored to the patient's clinical status. Dopamine is generally associated with an increase in CO and BP, with a concomitant increase in PCWP. Dopamine increases myocardial oxygen demand and may decrease coronary blood flow through vasoconstriction and increased wall tension. As with other inotropes, dopamine is associated with a risk for arrhythmias.

Phosphodiesterase Inhibitors Milrinone and inamrinone work by inhibiting phosphodiesterase III, the enzyme responsible for the breakdown of cAMP. The increase in cAMP levels leads to increased intracellular calcium concentrations and enhanced contractile force generation. Milrinone has replaced inamrinone as the phosphodiesterase inhibitor of choice due to the higher frequency of thrombocytopenia seen with inamrinone.

Milrinone has both positive inotropic and vasodilating properties and as such is referred to as an "inodilator." Its vasodilating activities are especially prominent on venous capacitance vessels and pulmonary vascular beds, although a reduction in arterial tone is also noted. IV administration results in an increase in SV and CO, and usually only minor changes in HR. Milrinone also lowers PCWP through venodilation. Routine use of milrinone during acute decompensations in NYHA FC II to IV HF is not recommended, and milrinone use remains limited to patients who require inotropic support.[48]

Dosing recommendations for milrinone may include a loading dose of 50 mcg/kg, followed by an infusion beginning at 0.5 mcg/kg/min (range: 0.23 mcg/kg/min for patients with renal failure up to 0.75 mcg/kg/min). A loading dose is not necessary if immediate hemodynamic effects are not required or if patients have low systolic BP (< 90 mm Hg). Decreases in BP during an infusion may necessitate dose reductions as well. Lower doses are also used in patients with renal insufficiency.

LO 6 Milrinone is a good option for patients requiring an inotrope who are also chronically receiving β-blockers because the inotropic effects are achieved independent of β-adrenergic receptors. However, milrinone exhibits a long distribution and elimination half-life compared with β-agonists. Potential adverse effects include hypotension, arrhythmias, and, less commonly, thrombocytopenia. Additionally, milrinone has been associated with increased risk for death in some studies. Milrinone should not be used in patients in whom vasodilation is contraindicated.

Mechanical, Surgical, and Device Therapies

▶ *Intraaortic Balloon Counterpulsation*

Intraaortic balloon counterpulsation (IABC) or intraaortic balloon pumps (IABPs) are widely used mechanical circulatory assistance devices for patients with cardiac failure who do not respond to standard therapies. An IABP is placed percutaneously into the femoral artery and advanced to the high descending thoracic aorta. Once in position, the balloon is programmed to inflate during diastole and deflate during systole. Two main beneficial mechanisms are: (a) inflation during diastole increases aortic pressure and perfusion of the coronary arteries; and (b) deflation just prior to the aortic valve opening reduces afterload. As such, IABP increases myocardial oxygen supply and decreases oxygen demand. This device has many indications, including cardiogenic shock, high-risk unstable angina in conjunction with percutaneous interventions, preoperative stabilization of high-risk patients prior to surgery, and in patients who cannot be weaned from cardiopulmonary bypass. Possible complications include infection, bleeding, thrombosis, limb ischemia, and device malfunction. The device is typically useful for short-term therapy due to its invasiveness, need for limb immobilization, and requirement for anticoagulation.

▶ *Ventricular Assist Device*

The ventricular assist device (VAD) is a surgically implanted pump that reduces or replaces the work of the right, left, or both ventricles. VADs are indicated for short-term support in patients refractory to pharmacologic therapies, as long-term bridge therapy (a temporary transition treatment) in patients awaiting cardiac transplant, or in some instances as destination therapy (for patients who are not appropriate candidates for transplantation).[1] The most common complications are infection and thromboembolism. Other adverse effects include bleeding, air embolism, device failure, and multiorgan failure.

▶ *Heart Transplant*

Heart transplantation represents the final option for refractory end-stage HF patients who have exhausted medical and device therapies. Heart transplantation should be considered a trade between a life-threatening syndrome and the risks associated with the operation and long-term immunosuppression. Assessment of appropriate candidates includes comorbid illnesses, psychosocial behavior, available financial and social support, and patient willingness to adhere to lifelong therapy and close medical follow-up.[1] Overall, the transplant recipient's quality of life may be improved, but not all patients receive this benefit. Posttransplant survival continues to improve due to advances in immunosuppression, treatment and prevention of infection, and optimal management of patient comorbidities.

Outcome Evaluation of Acute Heart Failure

LO 7
- Focus on (a) acute improvement of symptoms and hemodynamics due to IV therapies, and (b) optimization of oral therapy.
- Initially, monitor patients for rapid relief of symptoms related to the chief complaint on admission. This includes improvement of dyspnea, oxygenation, fatigue, JVD, and other markers of congestion or distress.
- Monitor for adequate perfusion of vital organs through assessment of mental status, creatinine clearance, liver function tests, and a stable HR between 50 and 100 beats/min. Additionally, adequate skin and muscle blood perfusion and normal pH are desirable.
- Monitor changes in hemodynamic variables if available. CI should increase, with a goal to maintain it above 2.2 L/min/m^2 (0.037 L/s/m^2). PCWP should decrease in volume-overloaded patients to a goal of less than 18 mm Hg (2.4 kPa).
- Closely monitor BP and renal function while decreasing preload with diuretics and vasodilators.

Patient Encounter Part 4

After 6 months, the patient returns to the clinic complaining of extreme SOB with any activity, as well as at rest. He sleeps sitting up due to severe orthopnea, feels too nauseous and bloated to eat, and states he has gained 25 lb (11.4 kg) from his baseline weight. He states that he does not feel his furosemide therapy is working. He is admitted to the cardiology unit.

SH: Admits to resuming previous alcohol intake; additionally, he has been eating out in restaurants more often in the past few weeks. He has also resumed smoking

Meds: Atorvastatin 40 mg once daily, lisinopril 10 mg once daily, carvedilol 6.25 mg twice daily, furosemide 80 mg twice daily, multivitamin daily, aspirin 81 mg daily

VS: BP 106/54 mm Hg, pulse 102 beats/min and regular, respiratory rate 22/min, temperature 37°C (98.6°F), Wt 276 lb (125.5 kg), BMI 41.9 kg/m^2

Lungs: Decreased breath sounds and rales present bilaterally

CV: Regular rate and rhythm with normal S_1 and S_2; there is an S_3 and an S_4; a 4/6 systolic ejection murmur is present and heard best at the left lower sternal border; point of maximal impulse is displaced laterally; jugular veins are distended, JVP is 14 cm above sternal angle

Abd: Hard, tender, and bowel sounds are present; 3+ pitting edema of extremities is observed

CXR: Bilateral pleural effusions and cardiomegaly

Echo: EF = 20% (0.20)

Pertinent labs: NT-proBNP 2210 pg/mL (ng/L; 261 pmol/L), K: 3.4 mEq/L (mmol/L), BUN 64 mg/dL (22.8 mmol/L), SCr 2.4 mg/dL (212 µmol/L), Mg 1.8 mEq/L (0.9 mmol/L); A pulmonary catheter is placed, revealing the following: PCWP 32 mm Hg (4.3 kPa); CI 2.3 L/min/m^2 (0.038 L/s/m^2)

What NYHA functional class, ACC/AHA stage, and hemodynamic subset is the patient currently in?

What are your initial treatment goals?

What pharmacologic agents are appropriate to use at this time?

Identify a monitoring plan to assess for efficacy and toxicity of the recommended drug therapy.

Once symptoms are improved, how would you optimize oral medication therapy for this patient's HF?

Patient Care Process

Collect Information:

- Obtain a thorough history of prescription, nonprescription, and herbal medication use.
- Review the patient's lifestyle habits including salt and alcohol intake, tobacco product use, exercise routine.
- Gather recent history of symptoms of congestion and hypoperfusion, including weight gain, swelling in extremities, etc.

Assess the Information:

- Assess the severity and duration of the patient's symptoms of HF and hypoperfusion, including limitations in activity. Rule out potential exacerbating factors. See Clinical Presentation and Diagnosis of Chronic Heart Failure textbox and Tables 6–1, 6–3, and 6–4.
- Review available diagnostic information from the chest radiograph, ECG, and echocardiogram. Investigate the patient's underlying etiology of HF.

Develop a Care Plan:

- Determine whether additional adjustment or new therapy is needed to address patient's acute and chronic conditions.
- Develop a treatment plan to alleviate symptoms and maintain euvolemia with diuretics (Tables 6–6 and 6–7). Daily weights to assess fluid retention are recommended.
- Develop a medication regimen to slow the progression of HF with the use of neurohormonal blockers such as vasodilators (ACE inhibitors, ARBs, sacubitril/valsartan, or hydralazine/isosorbide dinitrate), β-blockers, and aldosterone receptor antagonists (Tables 6–6 and 6–7). Utilize digoxin if the patient remains symptomatic despite optimization of the therapies just described, and ivabradine in patients with HRs of 70 beats/min or higher despite optimization of β-blocker.

Implement the Care Plan:

- Ensure the patient is at goal or maximally tolerated doses of vasodilator and β-blocker therapy (Table 6–6), or titrate to the next dosing level if possible.
- Educate the patient on lifestyle modifications such as salt restriction (maximum 2 g/day), fluid restriction if appropriate, limitation of alcohol, tobacco cessation, participation in a cardiac rehabilitation and exercise program, and proper immunizations such as the pneumococcal vaccine and yearly influenza vaccine.
- Stress the importance of adherence to the therapeutic regimen and lifestyle changes for maintenance of a compensated state and slowing of disease progression.

Follow-up: Monitor and Evaluate:

- Monitor patient, including appropriate hemodynamic monitoring for AHF (Table 6–8), for desired outcomes.
- Evaluate the patient for presence of adverse drug reactions, drug allergies, and drug interactions.
- Provide patient education with regard to disease state and drug therapy, and reinforce medication adherence and self-monitoring for symptoms of HF (eg, daily weights). Emphasize follow-up with health care practitioners.
- Assess changes in echocardiographic parameters from a follow-up echocardiography, ideally performed 2 months after medication optimization. Has the LVEF risen to above 40% (0.40)?

- Ensure patients are euvolemic or nearly euvolemic prior to discharge.
- Because oral therapies can both improve symptoms and prolong survival, optimizing outpatient HF management is a priority when preparing a patient for hospital discharge. Ensure the patient's regimen includes an ACE inhibitor, ARB, or ARNI, β-blocker, a diuretic at an adequate dose to maintain euvolemia, and aldosterone antagonist or digoxin if indicated.

Abbreviations Introduced in This Chapter

ACC/AHA	American College of Cardiology/American Heart Association
ACE	Angiotensin-converting enzyme
AHF	Acute heart failure
ANP	Atrial natriuretic peptide
ARB	Angiotensin receptor blocker
ARNI	Angiotensin receptor neprilysin inhibitor
AT_1	Angiotensin I
AT_2	Angiotensin II
ATP	Adenosine triphosphate
BMI	Body mass index
BNP	B-type natriuretic peptide
BPM	Beats per minute
BP	Blood pressure
BUN	Blood urea nitrogen
CAD	Coronary artery disease
cAMP	Cyclic adenosine monophosphate
cGMP	Cyclic guanosine monophosphate
CHARM	Candesartan in Heart Failure Assessment of Reduction in Mortality and Morbidity
CI	Cardiac index
CNS	Central nervous system
CO	Cardiac output
COX-2	Cyclooxygenase-2
CrCL	Creatinine clearance
CYP	Cytochrome P-450 isoenzyme
D1	Dopamine receptor type 1
ECG	Electrocardiogram
EF	Ejection fraction
eGFR	Estimated glomerular filtration rate
ET-1	Endothelin-1
ET-A	Endothelin-A
ET-B	Endothelin-B
FDA	Food and Drug Administration
GI	Gastrointestinal
HF	Heart failure
HFmrEF	Heart failure with mid-range ejection fraction
HFpEF	Heart failure with preserved ejection fraction
HFrEF	Heart failure with reduced ejection fraction
HJR	Hepatojugular reflux
HR	Heart rate
IABC	Intraaortic balloon counterpulsation
IABP	Intraaortic balloon pump
iNOS	Inducible nitric oxide synthetase
INR	International normalized ratio
I-PRESERVE	Irbesartan in Patients with Heart Failure and Preserved Ejection Fraction
IV	Intravenous
JVD	Jugular venous distention
JVP	Jugular venous pressure
LV	Left ventricular
LVEF	Left ventricular ejection fraction
LVF	Left ventricular failure
MI	Myocardial infarction
MRA	Mineralocorticoid receptor antagonist
MVO_2	Myocardial oxygen consumption
NSAID	Nonsteroidal anti-inflammatory drug
NT-proBNP	N-terminal proBNP
NYHA FC	New York Heart Association Functional Class
PAC	Pulmonary artery catheter
PCWP	Pulmonary capillary wedge pressure
PEP-CHF	Perindopril in Elderly People with Chronic Heart Failure
PND	Paroxysmal nocturnal dyspnea
RAAS	Renin-angiotensin-aldosterone system
RVF	Right ventricular failure
SCr	Serum creatinine
SNS	Sympathetic nervous system
SOB	Shortness of breath
SV	Stroke volume
SVR	Systemic vascular resistance
TNF-α	Tumor necrosis factor-α
TOPCAT	Treatment of Preserved Cardiac Function Heart Failure with an Aldosterone Antagonist
V_{1a}	Vasopressin type 1a
V_2	Vasopressin type 2
VAD	Ventricular assist device

7 Stable Ischemic Heart Disease

Dejan Landup and Robert J. DiDomenico

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify risk factors for the development of ischemic heart disease (IHD).
2. Differentiate between the pathophysiology of chronic stable angina and acute coronary syndromes (ACS).
3. Recognize symptoms and diagnostic criteria of IHD in a specific patient.
4. Compare and contrast the diagnostic criteria of IHD and ACS.
5. Identify treatment goals of stable IHD (SIHD).
6. Identify appropriate lifestyle modifications and pharmacologic therapy to address each treatment goal.
7. Design an appropriate treatment regimen for the management of SIHD based on patient-specific information.
8. Formulate a monitoring plan to assess effectiveness and adverse effects of a SIHD drug regimen.

INTRODUCTION

Ischemic heart disease (IHD) is also called coronary heart disease (CHD) or coronary artery disease (CAD). The term *ischemic* refers to a decreased supply of oxygenated blood to the heart muscle. IHD is caused by stenosis, or narrowing, in one or more of the major coronary arteries that supply blood to the heart, most commonly by atherosclerotic plaques. Atherosclerotic plaques may impede coronary blood flow to the extent that cardiac tissue distal to the coronary artery narrowing is deprived of sufficient oxygen to meet oxygen demand. KEY CONCEPT IHD results from an imbalance between myocardial oxygen supply and oxygen demand (Figure 7–1). Common clinical manifestations of IHD include chronic stable angina and the ACS of unstable angina (UA), non–ST-segment elevation myocardial infarction (NSTEMI), and ST-segment elevation myocardial infarction (STEMI).

Angina pectoris, or simply angina, is the most common symptom of IHD. Angina is discomfort in the chest that occurs when the blood supply to the myocardium is compromised. Chronic stable angina is a chronic occurrence of chest discomfort due to transient myocardial ischemia with physical exertion or other conditions that increase oxygen demand. The primary focus of this chapter is the management of stable IHD (SIHD), the most common manifestation of which is chronic stable angina. However, some information is also provided related to acute coronary syndrome (ACS), given the overlap between the two disease states. The American College of Cardiology (ACC), the American Heart Association (AHA), and several other organizations have jointly published practice guidelines for the management of SIHD. Refer to these and related guidelines for further information.[1-3]

EPIDEMIOLOGY AND ETIOLOGY

IHD affects over 16 million Americans and is the leading cause of death for both men and women in the United States.[4] The incidence of IHD is higher in middle-aged men compared with women. However, the rate of IHD increases twofold to threefold in women after menopause. Chronic stable angina is the initial manifestation of IHD in about 50% of patients, whereas ACS is the first sign of IHD in other patients. Patients with SIHD experience considerable morbidity and frequently require hospitalization for chest pain and evaluation for potential ACS. In addition, SIHD negatively impacts health-related quality of life. Thus, in patients with SIHD, it is important to optimize pharmacotherapy to reduce symptoms, improve quality of life, slow disease progression, and prevent ACS.

Conditions Associated with Angina

Figure 7–2 shows the anatomy of the coronary arteries. The major epicardial coronary arteries are the left main, left anterior descending, left circumflex, and right coronary arteries. Atherosclerosis leading to obstructive lesions in one or more of the major coronary arteries or their principal branches is the major cause of angina. Vasospasm at the site of an atherosclerotic plaque may further constrict blood flow and contribute to angina. Less commonly, vasospasm in coronary arteries with no or minimal atherosclerotic disease can produce angina and even precipitate ACS. This uncommon form of angina is referred to as variant or Prinzmetal angina. Other nonatherosclerotic conditions that can cause angina-like symptoms are listed in Table 7–1.[1] It is important to differentiate the etiology of chest discomfort because treatment varies depending on the underlying disease process.

Risk Factors

LO 1 Factors that predispose an individual to IHD are listed in Table 7–2. Optimization of modifiable risk factors can significantly reduce the risk of myocardial infarction (MI).[1]

LO 1 Hypertension, diabetes, dyslipidemia, and cigarette smoking are associated with endothelial damage and dysfunction and contribute to the development of atherosclerosis. Physical inactivity and obesity independently increase the risk for

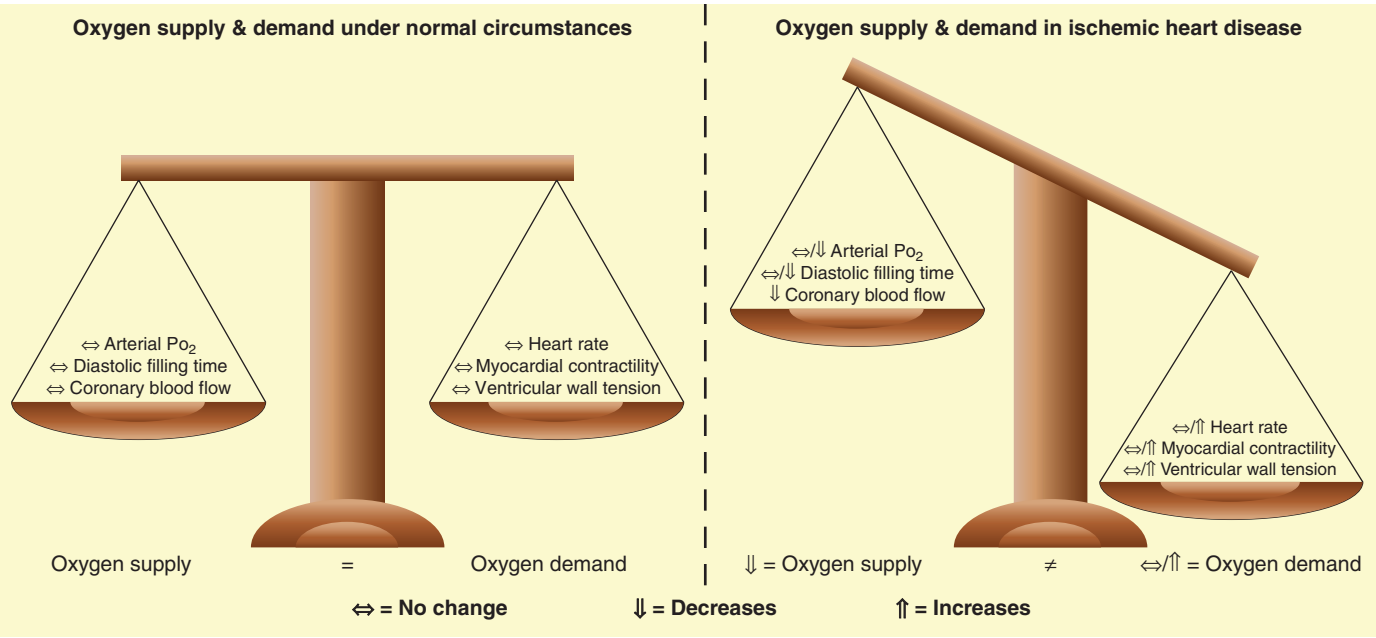

FIGURE 7–1. This illustration depicts the balance between myocardial oxygen supply and demand and various factors that affect each. It should be noted that diastolic filling time is not an independent predictor of myocardial oxygen supply per se, but rather a determinant of coronary blood flow. On the left is myocardial oxygen supply and demand under normal circumstances. On the right is the mismatch between oxygen supply and demand in patients with IHD. In patients without IHD, coronary blood flow increases in response to increases in myocardial oxygen demand. However, in patients with IHD, coronary blood flow cannot sufficiently increase (and may decrease) in response to increased oxygen demand, resulting in angina. (IHD, ischemic heart disease; Po_2, partial pressure of oxygen.)

IHD, in addition to predisposing individuals to hypertension, dyslipidemia, and diabetes.

Patients with multiple risk factors, particularly those with diabetes, are at the greatest risk for IHD, experiencing fivefold to sevenfold higher risk compared to individuals without risk factors.[4] Although alternative definitions exist, metabolic syndrome is generally considered a constellation of common cardiovascular risk factors including hypertension, abdominal obesity, dyslipidemia, and insulin resistance. Metabolic syndrome increases the risk of developing IHD and related complications by twofold.[5] According to a joint statement from the International Diabetes Federation, National Heart, Lung, and Blood Institute, AHA, World Heart Federation, International Atherosclerosis Society, and International Association for the Study of Obesity, patients must meet at least three of the following criteria for the diagnosis of metabolic syndrome[5]:

- Increased waist circumference (40 in [102 cm] or greater in men and 35 in [89 cm] or greater in women).
- Triglycerides of 150 mg/dL (1.70 mmol/L) or greater or active treatment to lower triglycerides.
- Low high-density lipoprotein (HDL) cholesterol (< 40 mg/dL [1.03 mmol/L] in men and < 50 mg/dL [1.29 mmol/L] in women) or active treatment to raise HDL cholesterol.
- Systolic blood pressure (BP) of 130 mm Hg or greater, diastolic BP of 85 mm Hg or greater, or active treatment with antihypertensive therapy.
- Fasting blood glucose of 100 mg/dL (5.6 mmol/L) or greater or active treatment for diabetes.

KEY CONCEPT Early detection and aggressive modification of risk factors are among the primary strategies for delaying IHD progression and preventing IHD-related events including death.

PATHOPHYSIOLOGY

The determinants of myocardial oxygen supply and demand are shown in Figure 7–1. Increases in heart rate, cardiac contractility, and left ventricular wall tension increase the rate of myocardial oxygen consumption (MVO_2). Ventricular wall tension is a function of BP, systemic vascular resistance, left ventricular end-diastolic volume, and ventricular wall thickness. Physical exertion increases MVO_2 and commonly precipitates symptoms of angina in patients with significant coronary atherosclerosis.

Reductions in coronary blood flow (secondary to atherosclerotic plaques, vasospasm, or thrombus formation) and arterial oxygen content (secondary to hypoxia) decrease myocardial oxygen supply. Because the coronary arteries fill during diastole, decreases in diastolic filling time (eg, tachycardia) can also reduce coronary perfusion and myocardial oxygen supply. Anemia, carbon monoxide poisoning, and cyanotic congenital heart disease are examples of conditions that can lead to diminished myocardial oxygen delivery and precipitate angina in the face of adequate coronary perfusion.

Coronary Atherosclerosis

The normal arterial wall is illustrated in panel A of Figure 7–3. The intima consists of a layer of endothelial cells that line the lumen of the artery and form a selective barrier between the vessel wall and blood contents. Vascular smooth muscle cells are found in the media. The vascular adventitia comprises the artery's outer layer. Atherosclerotic lesions form in the subendothelial space in the intimal layer.

LO 2 Endothelial damage and dysfunction, commonly caused by hypertension, diabetes, and smoking, allow low-density lipoprotein (LDL) cholesterol and inflammatory cells (eg,

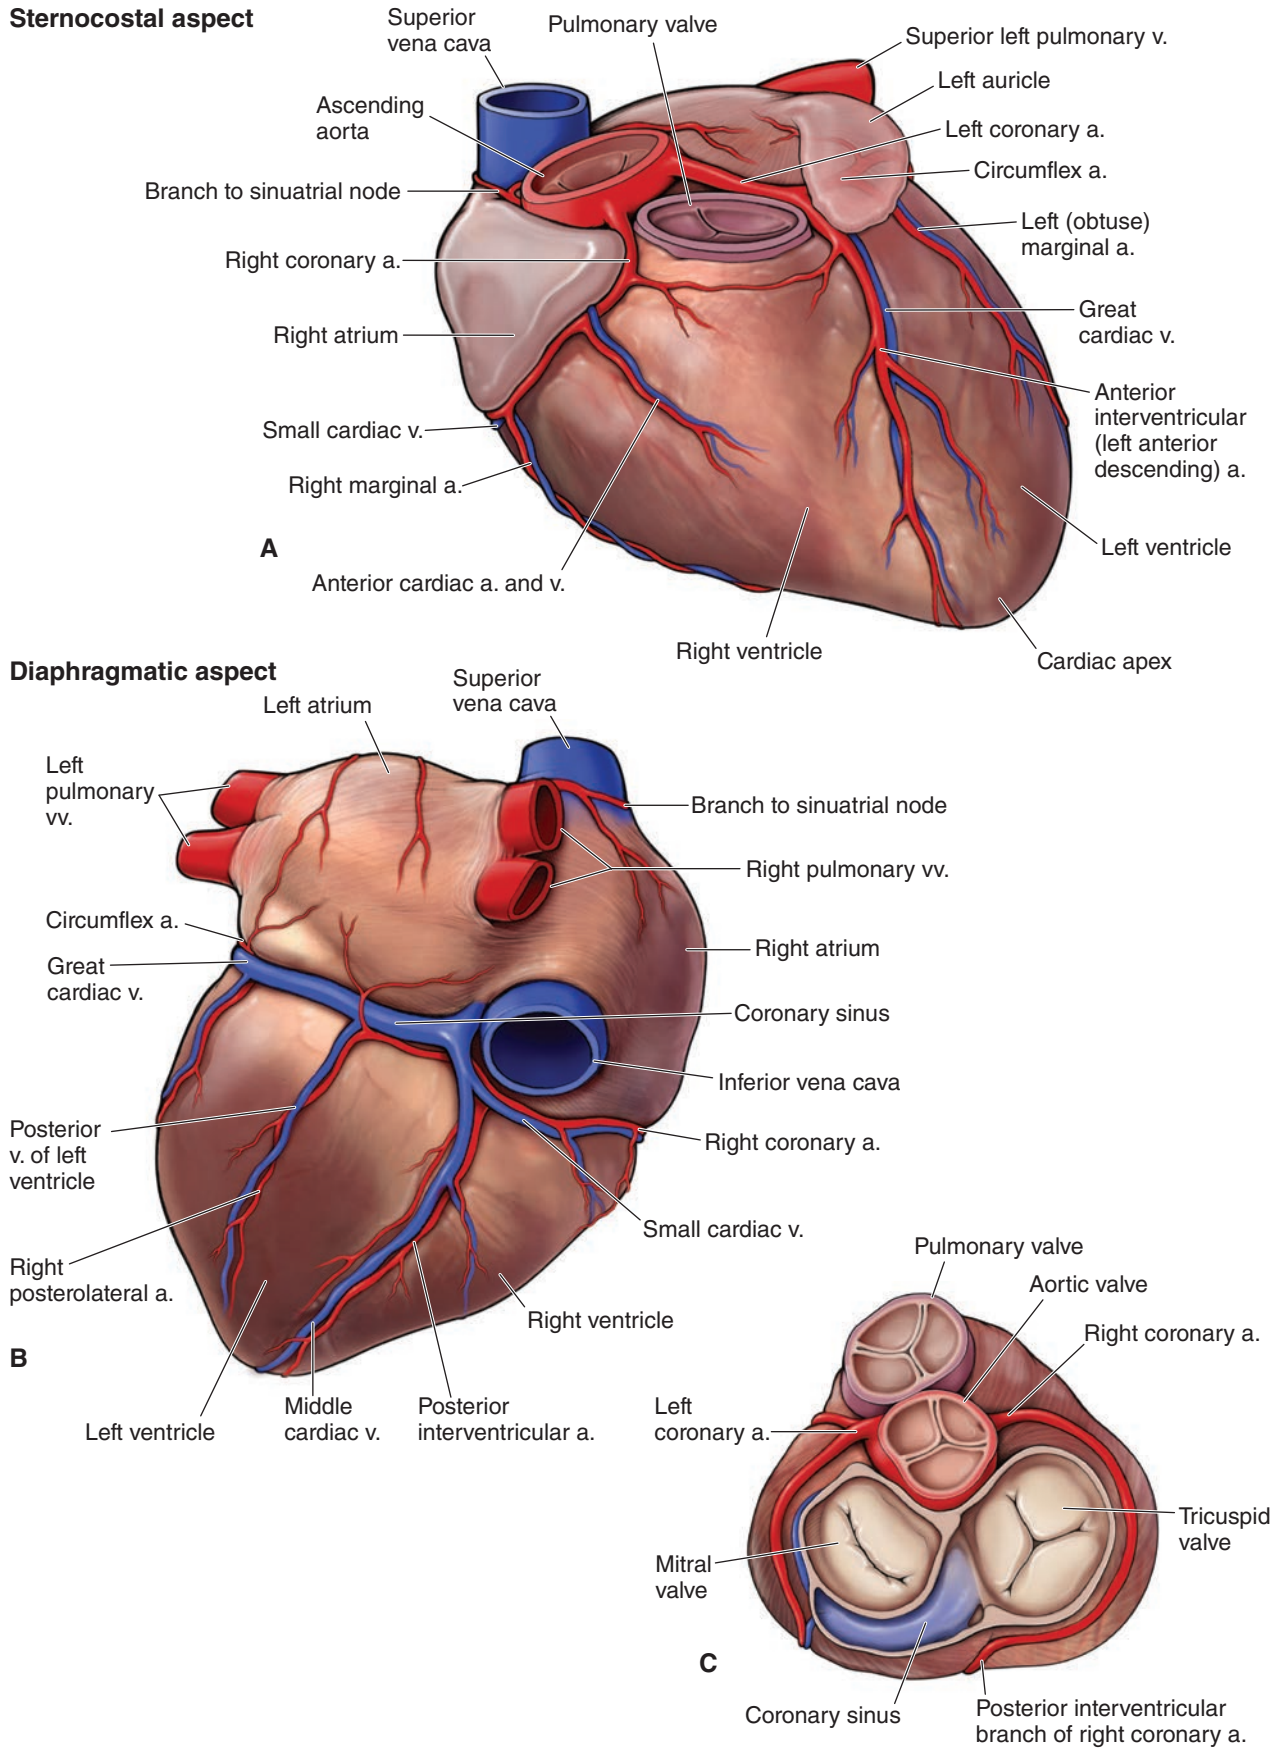

FIGURE 7–2. Coronary artery anatomy with sternocostal and diaphragmatic views. (a., artery; v., vein.) (Reproduced from Chapter 4. Heart. In: Morton DA, Foreman K, Albertine KH, eds. The Big Picture: Gross Anatomy. New York, NY: McGraw-Hill; 2011. http://accesspharmacy.mhmedical.com/content.aspx?bookid=381&sectionid=40140010, with permission.)

Table 7–1

Nonatherosclerotic Conditions That Can Cause Angina-Like Symptoms[1]

Organ System	Condition
Cardiac	Aortic dissection, aortic stenosis, coronary artery vasospasm, pericarditis, valvular heart disease, severe uncontrolled hypertension
Noncardiac	Anemia, anxiety disorders, carbon monoxide poisoning, chest wall trauma, cocaine use, esophageal reflux or spasm, peptic ulcer disease, pleuritis, pneumonia, pneumothorax, pulmonary embolus, pulmonary hypertension, thyrotoxicosis

monocytes and T lymphocytes) to migrate from the plasma to the subendothelial space, as illustrated in Figure 12–5 in Chapter 12, "Dyslipidemias." The process begins by monocyte-derived macrophages ingesting lipoproteins to form foam cells. Macrophages also secrete growth factors that promote smooth muscle cell migration from the media to the intima. The result is the development of early atherosclerosis in the form of a fatty streak consisting of lipid-laden macrophages and smooth muscle cells.

The fatty streak enlarges as foam cells, smooth muscle cells, and necrotic debris accumulate in the subendothelial space. A collagen matrix forms a fibrous cap that covers the lipid core of the lesion to establish an atherosclerotic plaque. The atherosclerotic plaque may progress until it protrudes into the artery lumen and impedes blood flow. When the plaque occludes 70% or more of a major coronary artery or 50% or more of the left main coronary artery, the patient may experience angina during activities that increase myocardial oxygen demand.

Compared with men, women with angina are more likely to present with microvascular disease. Microvascular angina, also called cardiac syndrome X, refers to disease of the smaller coronary vessels causing typical angina in the absence of obstructive CAD of the epicardial arteries. Endothelial dysfunction and reduced smooth muscle relaxation, resulting in reduced vasodilation and enhanced vasoconstriction, are proposed to contribute to microvascular disease.[6]

Table 7–2

Major Risk Factors for Ischemic Heart Disease

Modifiable	Nonmodifiable
Cigarette smoking	Age ≥ 45 years for men, age ≥ 55 years for women
Dyslipidemia • Elevated LDL or total cholesterol • Reduced HDL cholesterol	Gender (men and postmenopausal women)
Diabetes mellitus	Family history of premature cardiovascular disease, defined as cardiovascular disease in a male first-degree relative (ie, father or brother) < 55 years or a female first-degree relative (ie, mother or sister) < 65 years
Hypertension	
Physical inactivity	
Obesity (body mass index ≥ 30 kg/m^2)	
Low daily fruit and vegetable consumption	
Alcohol overconsumption	

HDL, high-density lipoprotein; LDL, low-density lipoprotein.

Stable versus Unstable Atherosclerotic Plaques

LO 2

The hallmark feature in the pathophysiology of SIHD is an established atherosclerotic plaque in one or more of the major coronary arteries that impedes coronary blood flow such that myocardial oxygen supply can no longer meet myocardial oxygen demand. In contrast, the hallmark feature in the pathophysiology of ACS is atherosclerotic plaque rupture with subsequent thrombus formation. Plaque rupture refers to fissuring of the fibrous cap and exposure of the plaque contents to elements in the blood. Plaque composition, rather than the degree of coronary stenosis, determines the stability of the plaque and the likelihood of rupture and ACS. As depicted in Figure 7–3B, a stable lesion characteristic of SIHD consists of a small lipid core surrounded by a thick fibrous cap that protects the lesion from the shear stress of blood flow. In contrast, an unstable plaque consists of a thin, weak cap covering a large lipid-rich core that renders the plaque vulnerable to rupture (Figure 7–3C). The transformation of a stable plaque into an unstable plaque involves the degradation of the fibrous cap by substances released from macrophages and other inflammatory cells. Following plaque rupture, platelets adhere to the site of rupture (Figure 7–3D), aggregate (Figure 7–3E), and generate thrombin leading to the development of a fibrin clot (Figure 7–3F). Coronary thrombi extend into the vessel lumen, where they partially or completely occlude blood flow, potentially resulting in UA or MI.

Unstable plaque often produces minimal occlusion of the coronary vessel, and the patient remains asymptomatic until the plaque ruptures. In fact, many ACS arise from vulnerable plaques that occlude less than 50% of the coronary lumen.[7]

Coronary Artery Vasospasm

Prinzmetal or variant angina results from spasm (or vasoconstriction) of a coronary artery in the absence of significant atherosclerosis. Variant angina usually occurs at rest, especially in the early morning hours. Although vasospasm is generally transient, it may persist long enough to cause myocardial ischemia and subsequent infarction. Patients with variant angina are typically younger than those with chronic stable angina and often do not possess the classic risk factors for IHD. The cause of variant angina is unclear but appears to involve vagal withdrawal, endothelial dysfunction, and paradoxical response to agents that normally cause vasodilation. Precipitants of variant angina include cigarette smoking, cocaine or amphetamine use, hyperventilation, and exposure to cold temperatures. The management of variant angina differs from that of classic angina, and thus it is important to distinguish between the two.

CLINICAL PRESENTATION AND DIAGNOSIS

History

LO 3

The evaluation of a patient with suspected IHD begins with a detailed history of symptoms. KEY CONCEPT The classic presentation of angina is described in the Clinical Presentation and Diagnosis text box. Chronic stable angina should be distinguished from UA because the latter is associated with a greater risk for MI and

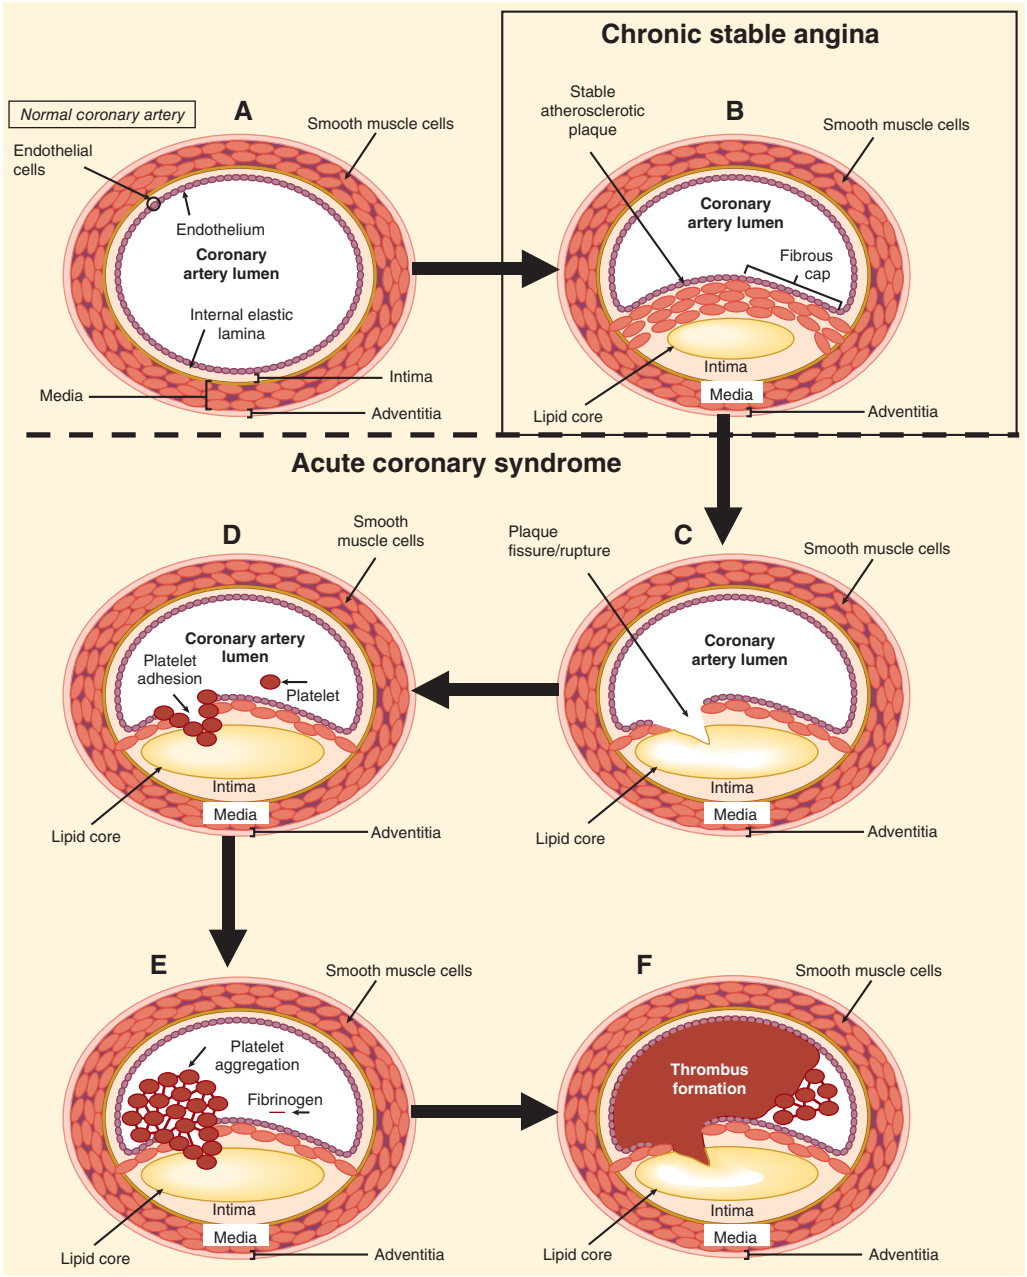

FIGURE 7–3. Pathophysiology of chronic stable angina versus acute coronary syndromes. **Panel A** depicts the cross-section of a normal coronary artery. **Panel B** depicts the cross-section of a coronary artery with a stable atherosclerotic plaque. Note that the lipid core is relatively small in size and the fibrous cap is made up of several layers of smooth muscle cells. **Panel C** depicts an unstable atherosclerotic plaque with a larger lipid core, and a thin fibrous cap composed of a single layer of smooth muscle cells with a fissure or rupture. **Panel D** depicts platelet adhesion in response to the fissured plaque. Platelet activation may ensue, leading to platelet aggregation as fibrinogen binds platelets to one another to form a mesh-like occlusion in the coronary lumen (**Panel E**). At this stage, patients may experience symptoms of acute coronary syndrome. If endogenous anticoagulant proteins fail to halt this process, platelet aggregation continues and fibrinogen is converted to fibrin, resulting in an occlusive thrombus (**Panel F**).

LO 3

death and requires hospitalization for more aggressive treatment. Because the pathophysiology of SIHD is due primarily to increases in oxygen demand rather than acute changes in oxygen supply, symptoms are typically reproducible when provoked by exertion, exercise, or stress. The exception may be a patient with coronary artery vasospasm, in whom symptoms may be more variable and unpredictable. In contrast to SIHD, ACS generally occurs in response to an acute decrease in coronary blood flow leading to inadequate oxygen supply.

LO 4

Consequently, ACS is marked by prolonged symptoms, often occurring at rest, or an escalation in the frequency or severity of angina over a short period of time. The presentation of UA is described in Table 7–3.[8]

Canadian Cardiovascular Society Classification System

LO 3

The Canadian Cardiovascular Society Classification System (Table 7–4) is commonly used to assess the degree of disability

Clinical Presentation and Diagnosis of Ischemic Heart Disease

General

- Patients with SIHD will generally be in no acute distress. In patients presenting in acute distress, the clinician should be suspicious of ACS.

Symptoms of Angina Pectoris

- The five components commonly used to characterize chest pain are: quality, location, duration, provoking factors, and mitigating factors.
- Patients typically describe pain as a sensation of pressure, heaviness, tightness, or squeezing in the anterior chest area. Sharp pain and pain reproducible by palpation are not typical symptoms of angina.
- Pain may radiate to the neck, jaw, shoulder, back, or arm.
- Pain may be accompanied by dyspnea, nausea, vomiting, or diaphoresis.
- Pain typically persists for several minutes.
- Symptoms are often provoked by exertion (eg, walking, climbing stairs, doing yard or housework) or emotional stress and relieved within minutes by rest or sublingual nitroglycerin. Other precipitating factors include exposure to cold temperatures and heavy meals. Pain that occurs at rest (without provocation) or that is prolonged and unrelieved by sublingual nitroglycerin is indicative of ACS.
- Some patients, most commonly women, the elderly, and patients with diabetes, may present with atypical symptoms including indigestion, gastric fullness, back pain, and shortness of breath. Patients with diabetes and the elderly may experience associated symptoms, such as dyspnea, diaphoresis, nausea, fatigue, and dizziness, without having any of the classic angina symptoms.
- In some cases, "silent ischemia" occurs in which patients are asymptomatic.

Signs

- Findings on physical examination are often normal with SIHD. However, during episodes of ischemia, patients may present with abnormal heart sounds, such as paradoxical splitting of the second heart sound, a third heart sound, or a loud fourth heart sound.

Laboratory Tests

- Cardiac troponin (troponin I or troponin T) is the most sensitive biomarker to detect myocardial damage and is elevated in MI but typically normal in chronic stable angina and UA.
- Hemoglobin, fasting glucose, and fasting lipid profile should be determined for assessing cardiovascular risk factors and establishing the differential diagnosis.

Other Diagnostic Tests

- A 12-lead electrocardiogram (ECG) recorded during rest is often normal in patients with SIHD in the absence of active ischemia. Significant Q waves may indicate prior MI. ST-segment changes (ST-segment depression or elevation) or T-wave inversion in two or more contiguous leads during symptoms of angina support the diagnosis of IHD. ST-segment depression or T-wave inversion may be observed in chronic stable angina, UA, and NSTEMI, whereas ST-segment elevation occurs with STEMI and Prinzmetal (variant) angina.
- Treadmill or bicycle exercise ECG, commonly referred to as a "stress test," is considered positive for IHD if the ECG shows at least a 1-mm deviation of the ST-segment (depression or elevation).
- Wall motion abnormalities or left ventricular dilation with stress echocardiography or cardiac magnetic resonance (MR) (exercise or pharmacological) are indicative of IHD.
- Perfusion abnormalities can be detected by stress myocardial perfusion imaging using either radionuclides technetium-99m sestamibi or thallium-201 or cardiac MR (with or without late gadolinium enhancement).
- Coronary angiography detects the location and degree of coronary atherosclerosis and is used to evaluate the potential benefit from revascularization procedures. Stenosis of at least 70% of the diameter of at least one of the major epicardial arteries (50% or greater for the left main coronary artery) on coronary angiography is indicative of significant IHD.
- Coronary angiography may be normal with microvascular angina.

Table 7–3

Presentations of Acute Coronary Syndromes[8]

- Angina at rest that is prolonged in duration, usually lasting over 20 minutes.
- Angina of recent onset (within 2 months) that markedly limits usual activity.
- Angina that increases in severity (ie, by Canadian Cardiovascular Society Classification System Class of one level or greater [Table 7–4]), frequency, or duration, or that occurs with less provocation over a short time period (ie, within 2 months).

resulting from IHD.[9] Patients are categorized into one of four classes depending on the extent of activity that produces angina. Grouping patients according to this or a similar method is commonly used to assess changes in IHD severity over time and the effectiveness of pharmacologic therapy.

Physical Findings and Laboratory Analysis

LO 3

A thorough medical history, physical examination, and laboratory analysis are necessary to ascertain cardiovascular risk factors and to exclude nonischemic and noncardiac conditions that could mimic angina-like symptoms. Laboratory analyses

Table 7–4

Canadian Cardiovascular Society Classification System of Angina[9]

Class	Description
I	Able to perform ordinary physical activity (eg, walking, climbing stairs) without symptoms. Strenuous, rapid, or prolonged exertion causes symptoms.
II	Symptoms slightly limit ordinary physical activity. Walking rapidly or for more than two blocks, climbing stairs rapidly, or climbing more than one flight of stairs causes symptoms.
III	Symptoms markedly limit ordinary physical activity. Walking less than two blocks or climbing one flight of stairs causes symptoms.
IV	Angina may occur at rest. Any physical activity causes symptoms.

should assess for glycemic control (ie, fasting glucose, glycated hemoglobin), fasting lipids, hemoglobin, and organ function (ie, blood urea nitrogen, creatinine, liver function tests, thyroid function tests). For patients with ACS, serial measurements of cardiac troponin (usually 2–3 measurements over a period of 3–12 hours) are performed to exclude the diagnosis of an acute MI. Cardiac findings on the physical examination are often normal in patients with SIHD. However, findings such as **carotid bruits**, abdominal and/or renal bruits, or abnormal peripheral pulses would indicate atherosclerosis in other vessel systems and raise the suspicion for IHD.

Diagnostic Tests

A resting 12-lead ECG is indicated in all patients with new or worsening symptoms of ischemia. Patients with characteristic chest discomfort, accompanied by ST-segment elevation in two or more contiguous leads, or a new left bundle branch block are often diagnosed with MI (STEMI) and are at the highest risk of death. Consequently, STEMI is treated as a medical emergency, often requiring expeditious percutaneous coronary intervention (PCI) or fibrinolytic therapy to restore blood flow in the occluded artery and reperfuse the myocardium. For patients with ACS, cardiac troponin is measured serially to distinguish between MI (elevated cardiac troponin) and either UA or noncardiac causes of chest discomfort (normal cardiac troponin).

"Stress" testing with either exercise or pharmacologic agents increases myocardial oxygen demand and is commonly used to evaluate the patient with suspected IHD. Approximately 50% of patients with IHD who have a normal ECG at rest will develop ECG changes with exercise on a treadmill (most commonly) or bicycle ergometer. Dobutamine is a common pharmacologic agent administered as an IV infusion to patients who are unable to exercise. Dobutamine increases oxygen demand by stimulating the β_1-receptor, increasing heart rate and contractility. Echocardiography is commonly performed along with exercise or dobutamine (eg, treadmill or dobutamine stress echocardiography) to identify stress-induced wall motion abnormalities of the left ventricle indicative of IHD.

Exercise or pharmacologic agents are also commonly combined with radionuclide myocardial perfusion imaging (nuclear imaging studies) or cardiac MR to detect IHD. An intravenous (IV) radioactive tracer is administered and accumulates in normal myocytes in proportion to coronary blood flow. Adenosine, dipyridamole, and regadenoson are coronary vasodilators that increase coronary blood flow in healthy arteries but not in atherosclerotic vessels. Radionuclide myocardial perfusion imaging is performed at rest and following exercise or pharmacologic stressor to detect perfusion defects indicative of IHD. Positive emission tomography, which utilizes a radioactive tracer that emits γ rays, is an alternative to conventional myocardial perfusion imaging that may be preferred in obese patients. Similar to other myocardial perfusion imaging, stress cardiac MR can detect wall motion abnormalities as well as perfusion defects, the latter often performed using late gadolinium enhancement, to determine the extent and severity of myocardial scarring that may be present.

Coronary artery calcium scoring via computed tomography (CT), also known as electron beam CT (EBCT) or "ultra-fast CT," may be performed as a noninvasive means to assess for CAD. Calcium deposits within the atherosclerotic coronary arteries are detected on CT, a calcium score is calculated, and the risk for IHD-related events is estimated.

Coronary angiography (also referred to as a cardiac catheterization or "cardiac cath") is indicated when stress testing results are either abnormal or inconclusive, symptoms of angina are poorly controlled, or in patients for whom the clinical suspicion of IHD remains high despite a normal stress test result. Angiography involves catheter insertion into either the femoral or radial artery with advancement of the catheter into the ascending aorta near the coronary ostia. Contrast medium is injected through the catheter into the coronary arteries and fluoroscopy is performed to visualize the coronary anatomy and detect IHD. Contrast medium must be used cautiously in patients with preexisting renal disease (especially in those with diabetes) to avoid contrast-induced nephropathy and often warrants prophylactic hydration periprocedurally. The decision to establish the diagnosis of IHD via stress testing, coronary angiography, or both is often individualized for each patient based on several factors including baseline assessment of IHD risk (eg, pretest probability), sensitivity and specificity of the diagnostic test, results of previous diagnostic tests, and risk for complications (eg, contrast nephropathy).

TREATMENT

Desired Outcomes

Once a patient is diagnosed with IHD, the clinician should provide counseling on lifestyle modifications, institute appropriate pharmacologic therapy, and evaluate the need for revascularization. Optimal medical therapy is essential for managing patients with SIHD. KEY CONCEPT The major goals for the treatment of SIHD are to:

- Prevent ACS and death
- Alleviate acute symptoms of angina
- Prevent recurrent symptoms of angina
- Prevent progression of the disease
- Reduce complications of IHD
- Avoid or minimize adverse treatment effects

The treatment approach to address these goals is illustrated in Figure 7–4.

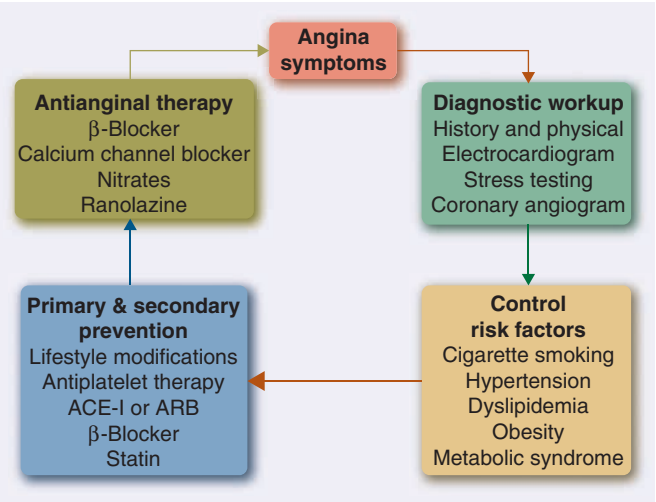

FIGURE 7–4. General treatment strategies for angina follow in clockwise fashion from the top center. (ACE-I, angiotensin-converting enzyme inhibitor; ARB, angiotensin receptor blocker.)

General Approach to Treatment

The primary strategies for preventing ACS and death (eg, primary or secondary prevention) are to:

- Aggressively modify cardiovascular risk factors
- Slow the progression of coronary atherosclerosis
- Stabilize existing atherosclerotic plaques

LO 6 The treatment algorithm in Figure 7–5 summarizes the appropriate management of IHD. Risk factor modification is accomplished through lifestyle changes and pharmacologic therapy. KEY CONCEPT Both 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors (HMG-CoA reductase inhibitors or statins) and angiotensin-converting enzyme (ACE) inhibitors possess vasculoprotective effects (eg, anti-inflammatory effects, antiplatelet effects, improvement in endothelial function, and/or improvement in arterial compliance and tone). Together with aspirin, these drugs reduce the risk of acute coronary events and death in patients with SIHD. In select patients with IHD (following hospitalization for ACS ± PCI and/or following intracoronary stent placement), dual antiplatelet therapy (DAPT) with aspirin and a $P2Y_{12}$ antagonist has also been shown to reduce ischemic events. Angiotensin receptor blockers (ARBs) may be used in patients who cannot tolerate ACE inhibitors because of side effects (eg, chronic cough). β-Blockers decrease morbidity and improve survival in patients who have suffered an MI, particularly in patients with concomitant heart failure with reduced ejection fraction (HFrEF).

The goal of therapies that alleviate and prevent angina is improving the balance between myocardial oxygen demand and supply. Drug treatment is primarily used to reduce oxygen demand, whereas revascularization by PCI and coronary artery bypass graft (CABG) surgery effectively restore coronary blood flow, improving myocardial oxygen supply.

Adverse treatment effects can be averted by avoiding drug interactions and the use of drugs that may have unfavorable effects on comorbid diseases. Appropriate drug dosing and monitoring reduces the risk for adverse treatment effects. Drugs should be initiated in low doses, with careful up-titration as necessary to control symptoms of angina and cardiovascular risk factors.

Patient Encounter Part 1

A 55-year-old black woman with a history of hypertension, diabetes, and a cerebral vascular accident presents to your clinic complaining of chest discomfort that occurred several times over the past few weeks. She describes her chest discomfort as indigestion, stating her "stomach feels full". She first noticed the discomfort while carrying her grandson to a second floor bedroom. Since then, she experienced the same symptoms while walking in the grocery store and carrying laundry upstairs. The discomfort was located in the substernal area and was associated with nausea and dyspnea. In each instance, the pain resolved after about 5 minutes of rest.

What information is suggestive of angina?

What tests would be beneficial in establishing a diagnosis?

What additional information do you need to create a treatment plan for this patient?

Lifestyle Modifications

LO 6 Lifestyle modifications (smoking cessation, avoidance of secondhand smoke, dietary modifications, increased physical activity, and weight loss) reduce cardiovascular risk factors, slow the progression of SIHD, and decrease the risk for SIHD-related complications. Cigarette smoking is the single most preventable cause of SIHD and SIHD-related death. Smoking may also attenuate the antianginal effects of drug therapy. Clinicians should counsel patients and/or family members who smoke on the importance of smoking cessation at each encounter and offer referral to smoking cessation programs. There are several pharmacologic aids for smoking cessation. Transdermal nicotine replacement therapy and bupropion have been studied in patients with SIHD and appear safe and effective.[10,11] Varenicline, a partial nicotine receptor agonist, is similarly efficacious but has been associated with worsening of preexisting depression and suicidal ideation.[12,13] Thus, it should be used cautiously, particularly in patients treated for depression, and the risk:benefit ratio should be discussed with patients. Weight loss, through caloric restriction and increased physical activity, should be encouraged in patients who have a body mass index greater than 25 kg/m^2. Dietary counseling should be provided to all patients with newly diagnosed angina regardless of weight. The AHA recommends a diet that includes a variety of fruits, vegetables, grains, low-fat or nonfat dairy products, fish, legumes, poultry, and lean meats.[14] The addition of plant stanols/sterols (2 g/day) and/or viscous fiber (over 10 g/day) are effective in lowering LDL cholesterol.[15] Specific dietary recommendations for patients with IHD should include the following[1,14]:

LO 6

- Limit cholesterol intake to less than 200 mg/day.
- Limit consumption of saturated fat to less than 7% and *trans* fatty acids to less than 1% of total calories.
- Limit daily sodium intake to 2.4 g (6 g of salt) for BP control.
- Limit alcohol consumption to 1 drink/day for women and 1 to 2 drinks/day for men unless otherwise contraindicated.

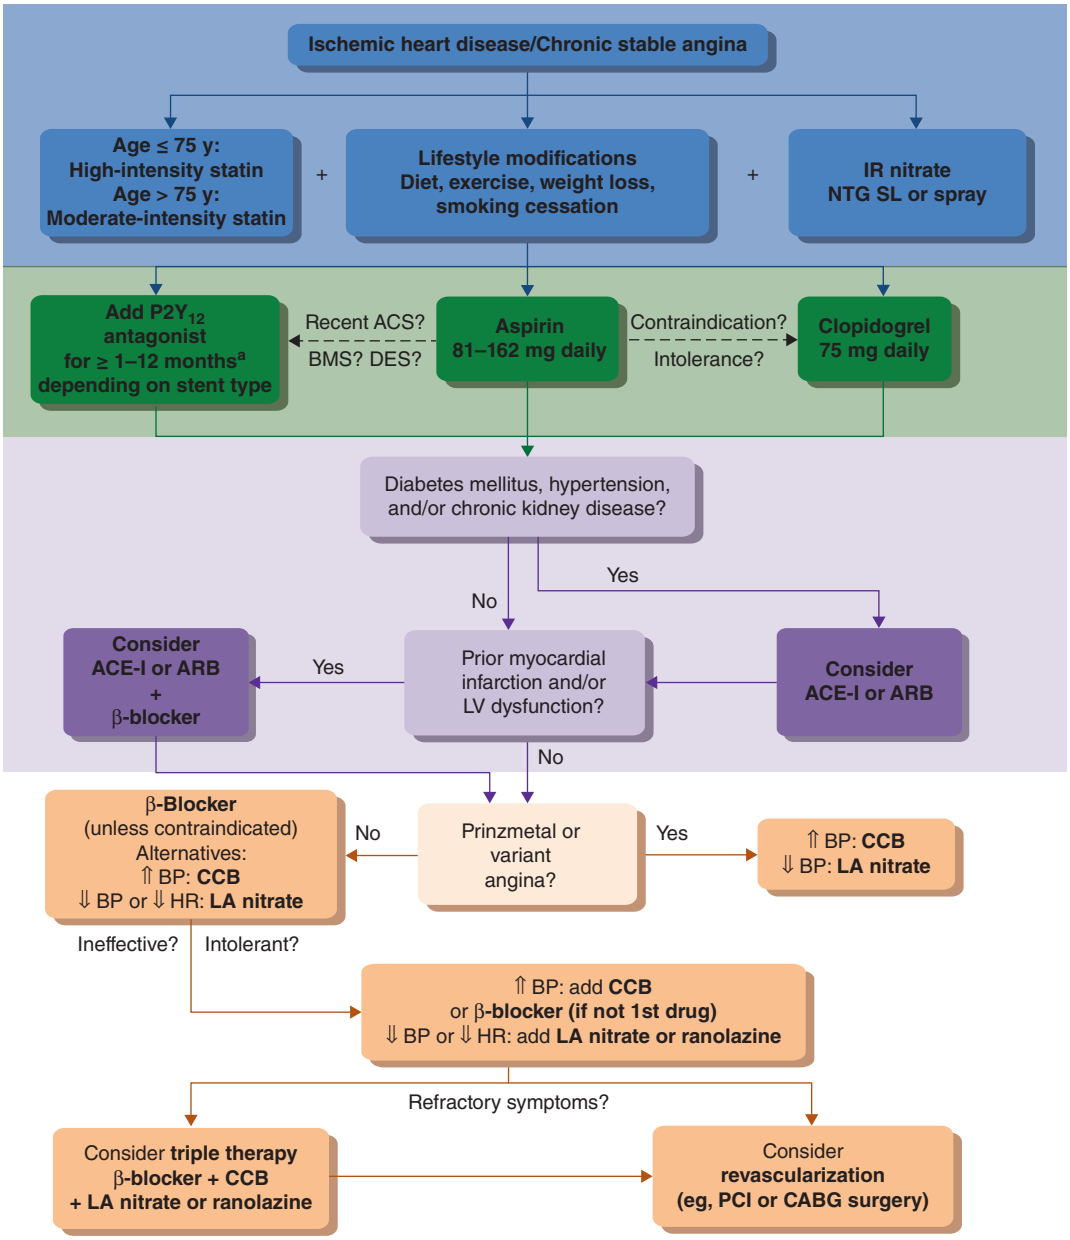

FIGURE 7–5. Treatment algorithm for ischemic heart disease. It begins at the top (blue section), which suggests risk factor modifications as the first treatment modality. Moving down to the green section, appropriate antiplatelet therapy is selected. The purple section identifies patients at high risk for major adverse cardiac events (MACE) and suggests appropriate drug therapy to decrease cardiovascular risk. The orange section at the bottom recommends appropriate antianginal therapy. [a]The minimum duration of $P2Y_{12}$ inhibitors in combination with aspirin (DAPT) following intracoronary stent placement is as follows: at least 1 month for BMSs and at least 6 months for DESs for patients with stable ischemic heart disease, at least 12 months in patients with stents placed for ACS regardless of stent type. (ACE-I, angiotensin-converting enzyme inhibitor; ACS, acute coronary syndrome; ARB, angiotensin receptor blocker; BMS, bare metal stent; BP, blood pressure; CABG, coronary artery bypass graft; CCB, calcium channel blocker; DES, drug-eluting stent; HR, heart rate; IR, immediate release; LA, long acting; LDL, low-density lipoprotein; LV, left ventricular; NTG, nitroglycerin; PCI, percutaneous coronary intervention; SL, sublingual.)

LO 6

Exercise facilitates weight loss, BP reduction, and glycemic control. In addition, regular exercise in patients with SIHD improves functional capacity, reduces symptoms of angina, and reduces mortality.[1,16] Guidelines recommend moderate intensity aerobic activity, such as brisk walking, ideally for 30 to 60 minutes at least 5 and preferably 7 days weekly.[1] Medically supervised cardiac rehabilitation programs are recommended for high-risk patients.

Interventional Approaches to Revascularization

▶ *Percutaneous Coronary Intervention*

LO 7

For patients with SIHD, optimal medical therapy is equivalent to PCI in reducing major adverse cardiac events (MACE), which include death, nonfatal MI, and revascularization.[17] Therefore, medical therapy is preferred as the initial treatment strategy. However, when optimal medical therapy fails, symptoms are

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension, diagnosed 13 years ago; diabetes, diagnosed 8 years ago; cerebral vascular accident, diagnosed 3 years ago

FH: Father with coronary artery disease, died of myocardial infarction at age 50 years; mother alive and well

SH: Active smoker, 40-year pack history; denies alcohol or illicit drug use; no regular exercise program

Meds: Aspirin 81 mg PO daily, hydrochlorothiazide 25 mg PO daily, metformin 500 mg PO twice daily, conjugated estrogen 0.625 mg PO daily, medroxyprogesterone 2.5 mg PO daily

Allergies/intolerances (reaction): No known drug allergies nor intolerances

PE:

VS: Blood pressure 152/98 mm Hg, HR 84 beats/min, RR 22 breaths/min, T 37°C (98.6°F), Ht 5′5″ (165 cm), Wt 212 lb (96.4 kg)

Cardiovascular: Regular rate and rhythm, normal S_1 and S_2, no S_3 or S_4; no murmurs, rubs, gallops

Lungs: Clear to auscultation and percussion

Abd: Nontender, nondistended, + bowel sounds

Ext: No clubbing, cyanosis, or edema

Labs: Fasting lipid profile: total cholesterol 206 mg/dL (5.33 mmol/L), HDL cholesterol 38 mg/dL (0.98 mmol/L), LDL cholesterol 119 mg/dL (3.08 mmol/L), triglycerides 246 mg/dL (2.78 mmol/L); fasting glucose 217 mg/dL (12.0 mmol/L); other labs within normal limits

Dobutamine stress echocardiography: Left ventricular ejection fraction at rest 35% (0.35), regional wall motion abnormalities during peak exercise suggestive of ischemia

Identify the patient's risk factors for stable ischemic heart disease.

How might her current drug regimen adversely affect the patient's stable ischemic heart disease?

Does she appear to have any SIHD-related complications?

What therapeutic alternatives are available to manage her stable ischemic heart disease?

unstable, or extensive coronary atherosclerosis is present (eg, > 70% occlusion of coronary lumen), PCI is often performed to restore coronary blood flow and relieve symptoms. Several catheter-based interventions may be used during PCI, including:

- Percutaneous transluminal coronary angioplasty (PTCA)
- Intracoronary bare metal stent (BMS) placement
- Intracoronary drug-eluting stent (DES) placement
- Rotational atherectomy

During PCI, a catheter is advanced into the diseased coronary artery, as described for cardiac catheterization. If PTCA is performed, a balloon at the end of the catheter is inflated inside the artery at the site of the critical stenosis, compressing the atherosclerotic plaque from the coronary lumen and restoring normal myocardial blood flow. Most PCI procedures involve the placement of a stent, a small metal scaffold-like device similar in size and shape to the spring at the tip of a ballpoint pen, at the site of angioplasty. Coronary stents are contained on special balloon catheters that are inflated at the site of stenosis to deploy the stent in the wall of the coronary artery, forming a sort of bridge to maintain a patent artery and improve coronary blood flow. Either a BMS or a DES may be used. DESs are impregnated with low concentrations of an antiproliferative drug (paclitaxel, everolimus, sirolimus, or zotarolimus), which is released locally over a period of weeks to inhibit **in-stent restenosis** of the coronary artery after PCI. Compared to BMS, DESs have been associated with a significant reduction in all-cause mortality for patients with IHD.[18] Stents are thrombogenic, especially until they become endothelialized (covered in endothelial cells like a normal coronary artery). To reduce the risk for in-stent thrombosis, MI, or death, DAPT (discussed later) is required until the stent becomes endothelialized. Lastly, rotational atherectomy may be performed wherein a special catheter is used to essentially cut away the atherosclerotic plaque, restoring coronary blood flow.

► *Coronary Artery Bypass Graft Surgery*

LO 7

As an alternative to PCI, CABG surgery, or open-heart surgery, may be performed if the patient is found to have extensive coronary atherosclerosis (generally > 70% occlusion of three or more coronary arteries) or is refractory to optimal medical treatment. In the former case, recent evidence suggests that CABG surgery is associated with a reduction in both the need for revascularization and mortality compared with PCI, particularly in patients with diabetes.[19] During CABG surgery, veins from the leg (ie, saphenous veins) and/or arteries from the chest wall (ie, internal mammary arteries) or less commonly from the arm (ie, radial artery) or stomach (gastroepiploic artery) are harvested and used as conduits to restore coronary blood flow. A median sternotomy, in which an incision is made the length of the sternum followed by surgical division of the sternum with an oscillating saw, is commonly required to gain access to the thoracic cavity and expose the heart. As the "new" blood vessels are being engrafted, the patient is typically placed on cardiopulmonary bypass (ie, heart-lung machine) to maintain appropriate myocardial and systemic perfusion. Alternative surgical approaches for advanced IHD may be used in some settings including "off-pump" CABG (cardiopulmonary bypass is not required) and minimally invasive CABG (ie, thoracoscopic surgery), although these techniques are uncommon. Because of its extremely invasive nature, CABG surgery is generally reserved for patients with extensive IHD or as a treatment of last resort in patients with symptoms refractory to medical therapy.

Pharmacologic Therapy

▶ *Pharmacotherapy to Prevent Acute Coronary Syndromes and Death*

LO 6 **Control of Risk Factors** A major component of any SIHD treatment plan is control of modifiable risk factors, including dyslipidemia, hypertension, and diabetes. Treatment strategies for dyslipidemia and hypertension in the patient with IHD are summarized in the following paragraphs. Visit chapters in this textbook on the management of hypertension (see Chapter 5) and dyslipidemias (see Chapter 12) for further information.

Because lipoprotein metabolism and the pathophysiology of atherosclerosis are closely linked, treatment of dyslipidemias is critical for both primary and secondary prevention of IHD-related cardiac events. In 2013, the ACC/AHA revised guidelines for the management of patients with dyslipidemia.[20] Unlike previous guidelines for dyslipidemia, current guidelines no longer recommend specific targets for LDL and non-HDL cholesterol and de-emphasize the use of non-statin therapies for the treatment of dyslipidemia. Rather, current guidelines focus on the use of statins stratified by presence of or 10-year risk for atherosclerotic cardiovascular disease (ASCVD). Recommendations for initiation of statin therapy for dyslipidemia include:[20]

LO 7

- High-intensity statin therapy in the presence of clinical ASCVD and for patients without clinical ASCVD in whom LDL cholesterol is 190 mg/dL (4.91 mmol/L) or greater; moderate-intensity therapy for elderly patients (age > 75 years) or those for whom safety concerns exist.
- Moderate to high-intensity statin therapy for patients at least 40 years of age with diabetes.
- Moderate to high-intensity statin therapy for patients with LDL cholesterol less than 190 mg/dL (4.91 mmol/L) who are at least 40 years of age and have a 10-year ASCVD risk of 7.5% or greater in the absence of diabetes; consideration may be given to moderate-intensity statin therapy in patients with a 10-year ASCVD risk between 5% and 7.5%.

Hypertension is another major, modifiable risk factor for the development of IHD and related complications. Aggressive identification and control of hypertension are warranted in patients with SIHD to minimize the risk of MACE. Most recently, the ACC and AHA released updated guidelines for the management of hypertension in adults, with specific recommendations for patients with SIHD.[21] Patients with SIHD and a BP of 130/80 mm Hg or higher should be started on antihypertensive therapy to reduce BP to a target of less than 130/80 mm Hg. Selection of initial agent is guided by the presence of compelling indications (eg, chronic stable angina, HFrEF, previous MI). β-Blockers (with the exception of atenolol and β-blockers with intrinsic sympathomimetic activity), ACE inhibitors, or ARBs are all recommended as first-line therapy in these patients. For patients who remain hypertensive (BP > 130/80 mm Hg) despite treatment with a β-blocker, ACE inhibitor, or ARB, additional medications should be added to further reduce BP to target. The choice of agent is dependent on the presence of angina symptoms. For patients with uncontrolled hypertension with angina, addition of a dihydropyridine calcium channel blocker (CCB) is recommended. For patients with SIHD whose angina symptoms are controlled, the addition of dihydropyridine CCBs, thiazide diuretics, and/or mineralocorticoid receptor antagonists (MRAs) may all be considered.

LO 7

Antiplatelet Agents Platelets play a major role in the pathophysiology of ACS. Thromboxane A_2 (TXA_2) is a potent platelet activator. Aspirin inhibits cyclooxygenase, an enzyme responsible for the production of TXA_2, thereby inhibiting platelet activation and aggregation. In patients with IHD, aspirin has been consistently shown to reduce the risk of MACE, particularly MI.[22] KEY CONCEPT Antiplatelet therapy with aspirin should be considered for all patients with SIHD, particularly in patients with a history of MI, in the absence of contraindications. Aspirin doses of 75 to 162 mg daily are recommended in patients with or at risk for SIHD.[1,3,23] Daily doses of aspirin above 162 mg offer no additional benefit but increase bleeding risk. If aspirin is contraindicated (eg, aspirin allergy) or is not tolerated by the patient, an alternative antiplatelet agent such as clopidogrel should be considered.[1]

LO 7

Binding of adenosine diphosphate to the $P2Y_{12}$ receptors on platelets activates glycoprotein IIb/IIIa receptors leading to platelet aggregation and thrombus formation. KEY CONCEPT Inhibition of the $P2Y_{12}$ receptor with either a thienopyridine (clopidogrel, prasugrel) or ticagrelor prevents platelet aggregation and is indicated in combination with aspirin in select patients with IHD. Ticlopidine is a $P2Y_{12}$ receptor inhibitor used historically in combination with aspirin, but is rarely used in practice because of hematologic toxicity. DAPT with aspirin and a $P2Y_{12}$ inhibitor is recommended following hospitalization for ACS and/or following PCI with stent placement to prevent ischemic events, although indications for specific drugs differ slightly.[3,24,25] Clopidogrel is a prodrug that is converted via a two-step process to its active thiol metabolite. The cytochrome P450 (CYP) 2C19 enzyme is involved in both steps of the biotransformation. Individuals with reduced CYP2C19 activity, either from inherited deficiencies of CYP2C19 or use of CYP2C19 inhibitors (eg, proton pump inhibitors), may produce less of the active thiol metabolite. These individuals are at increased risk for stent thrombosis and MACE during clopidogrel treatment compared to those with "normal" CYP2C19 activity.[26] The clopidogrel labeling now warns of reduced effectiveness in CYP2C19 poor metabolizers, who carry two dysfunctional *CYP2C19* gene alleles. The *CYP2C19*2* and *CYP2C19*3* alleles are the most common alleles leading to reduced CYP2C19 activity.

LO 6

LO 7

Prasugrel is a thienopyridine that also requires biotransformation to its active metabolite. However, unlike clopidogrel, CYP2C19 deficiency does not alter its effectiveness. Ticagrelor is a direct-acting $P2Y_{12}$ inhibitor that does not require biotransformation to exert its antiplatelet effects and is unaffected by CYP2C19 activity. Thus, prasugrel or ticagrelor may be suitable alternatives to clopidogrel when reduced CYP2C19 activity is suspected.

LO 7

Antiproliferative drugs in DES reduce the risk of in-stent restenosis but delay endothelialization. Until endothelialization occurs, platelets are exposed to the foreign surface of the stent and can stimulate platelet adhesion, activation, aggregation, and eventual thrombus formation within the implanted stent resulting in acute ischemia. Thus, a longer period of DAPT is recommended in patients with SIHD treated with DES compared with BMS to prevent in-stent thrombosis. Following BMS implantation, patients with SIHD should be treated with DAPT for a minimum of 1 month compared to a minimum of 6 months following DES implantation.[3] In contrast to patients with SIHD, a longer duration of DAPT (minimum of 12 months) is recommended for patients who have had stent implantation in the setting of ACS, regardless of the type of stent implanted.[3] Select patients with IHD who have not experienced a bleeding

LO 7

Table 7–5

"DAPT" Score Calculation to Guide Prolonged Dual Antiplatelet Therapy (DAPT) Following Stent Implantation[3,27]

Variable	Points
Age ≥ 75 years	−2
Age 65 to < 75 years	−1
Age < 65 years	0
Current cigarette smoker	1
Diabetes mellitus	1
Myocardial infarction (MI) at presentation	1
Prior percutaneous coronary intervention (PCI) or MI	1
Stent diameter < 3 mm	1
Paclitaxel-eluting stent	1
Heart failure of left ventricular ejection fraction < 30% (0.30)	2
PCI of saphenous vein graft	2

A score of ≥ 2 is associated with a favorable benefit:risk ratio for prolonged DAPT while a score of < 2 is associated with unfavorable benefit:risk ratio.

complication on DAPT and are not at high risk for bleeding (eg, prior bleeding on DAPT, coagulopathy, oral anticoagulant use) may be considered for "prolonged" or "extended" duration of DAPT (> 1 month in SIHD with BMS, > 6 months in SIHD with DES, > 12 months in ACS with either BMS or DES) to further reduce the risk of ischemic complications, including late in-stent thrombosis, but at the expense of an increased risk of bleeding.[3] Given the delicate balance between benefit and harm associated with prolonged DAPT following stent implantation, use of a "DAPT score" (Table 7–5) may be useful to individualize the decision to continue DAPT by predicting patients who will derive benefit.[3,27] Conversely, patients who experience a significant bleeding complication, are at high risk for bleeding, or have a high risk of severe bleeding complications (eg, major intracranial surgery) may be considered for a shorter duration of DAPT (3 months for SIHD with DES, 6 months after ACS with stent implantation).[3] Because the risk for in-stent thrombosis is increased with premature discontinuation of DAPT, it is imperative for clinicians to educate patients on this risk, and the need for continuation of combination antiplatelet therapy for the recommended duration.

LO 7 Clopidogrel, prasugrel, and ticagrelor are all indicated in combination with aspirin for at least 1 year in patients with ACS who undergo PCI.[3,24,25] Both clopidogrel and ticagrelor are also indicated in combination with aspirin in patients with NSTEMI who do not undergo PCI.[24] In patients with ACS, DAPT more effectively reduces the risk of death, MI, and stroke compared with aspirin alone even in patients who are managed medically (eg, in the absence of PCI).[28-30] Compared to clopidogrel, prasugrel and ticagrelor provide greater protection against cardiovascular events in ACS but increase risk for bleeding.[29,30] For more information regarding the use of DAPT in the setting of ACS, see Chapter 8.

Statins Statins are the preferred drugs to lower LDL cholesterol based on their potency and efficacy in preventing cardiac events. Several studies in tens of thousands of patients with or at high-risk for SIHD demonstrate that lowering cholesterol with statins reduces the risk of MACE by 21%.[31]

In addition to their LDL cholesterol-lowering effect, statins likely confer additional benefits in patients with SIHD.[32] Prompted by evidence that patients with "normal" LDL cholesterol derive benefit from statins, studies suggest statins modulate the following characteristics thought to stabilize atherosclerotic plaques and contribute to the cardiovascular risk reduction seen with these drugs:

- Shift LDL cholesterol particle size from predominantly small, dense, highly atherogenic particles to larger, less atherogenic particles.
- Improve endothelial function leading to more effective vasoactive response of the coronary arteries.
- Prevent or inhibit inflammation by lowering C-reactive protein and other inflammatory mediators implicated in atherosclerosis.
- Possibly improve atherosclerotic plaque stability.

LO 6 LO 7 KEY CONCEPT In summary, to control risk factors and prevent MACE, statin therapy should be considered in all patients with SIHD, particularly in those with elevated LDL cholesterol or diabetes. Statins are potent lipid-lowering agents, possess non–lipid-lowering effects that may provide additional benefit to patients with SIHD, and have been shown to reduce morbidity and mortality in patients with and at high risk for SIHD. LO 7 Moreover, because statins improve outcomes in patients with SIHD and "normal" LDL cholesterol, statins should be considered in all patients with SIHD, regardless of baseline LDL cholesterol.

ACE Inhibitors and Angiotensin Receptor Blockers

Angiotensin II, a neurohormone produced primarily in the kidney, is a potent vasoconstrictor and stimulates the production of aldosterone. Together, angiotensin II and aldosterone increase BP and sodium and water retention (increasing ventricular wall tension), cause endothelial dysfunction, promote thrombus formation, and cause myocardial fibrosis.

ACE inhibitors decrease angiotensin II production and have consistently been shown to decrease morbidity and mortality in patients with HFrEF or history of MI.[33,34] In addition, there is evidence that ACE inhibitors reduce the risk of vascular events in patients with chronic stable angina or risk factors for SIHD.[35,36] In patients with vascular disease (including SIHD) or risk factors for vascular disease, both ramipril and perindopril reduced the risk of MACE by 20% or more in separate studies.[35,36]

LO 7 KEY CONCEPT In the absence of contraindications, ACE inhibitors should be considered in all patients with SIHD, particularly those individuals who also have hypertension, diabetes mellitus, chronic kidney disease, left ventricular dysfunction, history of MI, or any combination of these.[1] Additionally, ACE inhibitors should also be considered in patients at high risk for developing SIHD based on findings from the studies summarized above. ARBs may be used in patients with indications for ACE inhibitors but who cannot tolerate them due to side effects (eg, chronic cough). ARBs also antagonize the effects of angiotensin II. In one large trial, valsartan was as effective as captopril at reducing morbidity and mortality in post-MI patients.[33] However, there are far more data supporting LO 7 the use of ACE inhibitors in SIHD. Therefore, ACE inhibitors are preferred over ARBs in patients with a history of MI, diabetes, chronic kidney disease, or left ventricular dysfunction. The ACE inhibitors and ARBs with indications for patients with or at risk for SIHD or IHD-related complications are listed in Table 7–6.

Side effects with ACE inhibitors and ARBs include hyperkalemia, deterioration in renal function, and angioedema. Serum potassium increases are secondary to aldosterone inhibition and are more likely in the presence of preexisting renal

Table 7–6

Doses of Angiotensin-Converting Enzyme Inhibitors and Angiotensin Receptor Blockers Indicated in Ischemic Heart Disease (IHD)

Drug	Indications	Usual Dosage in IHD[a]
Angiotensin-Converting Enzyme Inhibitors		
Captopril	HTN, HF, post-MI, diabetic nephropathy	6.25–50 mg three times daily
Enalapril	HTN, HF	2.5–40 mg daily in one to two divided doses
Fosinopril	HTN, HF	10–80 mg daily in one to two divided doses
Lisinopril	HTN, HF, post-MI	2.5–40 mg daily
Perindopril	HTN, IHD	4–8 mg daily
Quinapril	HTN, HF, post-MI	5–20 mg twice daily
Ramipril	HTN, high-risk for IHD, HF, post-MI	2.5–10 mg daily in one to two divided doses
Trandolapril	HTN, HF, post-MI	1–4 mg daily
Angiotensin Receptor Blockers		
Candesartan	HTN, HF	4–32 mg daily
Valsartan	HTN, HF, post-MI	80–320 mg daily in one to two divided doses
Telmisartan	HTN, high-risk for IHD	20–80 mg daily

[a]Reduce initial dose and gradually titrate upward as tolerated in renal impairment.

HF, heart failure; HTN, hypertension; MI, myocardial infarction.

impairment, diabetes, or concomitant therapy with nonsteroidal anti-inflammatory drugs (NSAIDs), potassium supplements, or potassium-sparing diuretics. Reductions in glomerular filtration may occur during ACE inhibitor or ARB initiation or up-titration due to inhibition of angiotensin II-mediated vasoconstriction of the efferent arteriole. This type of renal impairment is usually temporary and more common in patients with preexisting renal dysfunction or unilateral renal artery stenosis. Bilateral renal artery stenosis is a contraindication for ACE inhibitors and ARBs because of the risk for overt renal failure. Angioedema is a potentially life-threatening adverse effect that occurs in less than 1% of white patients but up to 8% of African Americans treated with ACE inhibitors. Angioedema may also occur with the administration of ARBs. Patients treated with ACE inhibitors may develop a chronic cough secondary to bradykinin accumulation. For patients who develop a persistent ACE inhibitor-induced cough or mild angioedema, substitution of an ARB for an ACE inhibitor may be appropriate. Both ACE inhibitors and ARBs can cause fetal injury and death and are contraindicated in pregnancy.

LO 7

LO 7

► *Nitroglycerin to Relieve Acute Symptoms*

LO 6

Short-acting nitrates are first-line treatment to terminate acute episodes of angina. KEY CONCEPT Patients with SIHD should have sublingual nitroglycerin tablets or spray to relieve acute ischemic symptoms. Nitrates undergo biotransformation to nitric oxide. Nitric oxide activates smooth muscle guanylate cyclase, leading to increased intracellular concentrations of cyclic guanosine monophosphate (cGMP), release of calcium from the muscle cell, and ultimately, to smooth muscle relaxation. Nitrates primarily cause venodilation, leading to reductions in preload. The resultant decrease in ventricular volume and wall tension leads to a reduction in myocardial oxygen demand. In higher doses, nitrates cause arterial dilation and reduce afterload and BP. In addition to reducing oxygen demand, nitrates increase myocardial oxygen supply by dilating the epicardial coronary arteries and collateral vessels, as well as relieving vasospasm.

Short-acting nitrates are available in tablet and spray formulations for sublingual administration. Sublingual nitroglycerin tablets are well absorbed across the oral mucosa, produce an antianginal effect within 1 to 3 minutes, and are less expensive than the spray. However, the spray is preferred for patients who have difficulty opening the tablet container or produce insufficient saliva for rapid dissolution of sublingual tablets. At the onset of an angina attack, a 0.3 to 0.4 mg dose of nitroglycerin (tablet or spray) should be administered sublingually, and repeated every 5 minutes up to three times or until symptoms resolve. Standing enhances venous pooling and may contribute to hypotension, dizziness, or lightheadedness. Sublingual nitroglycerin may be used to prevent effort- or exertion-induced angina. In this case, the patient should use sublingual nitroglycerin 2 to 5 minutes prior to an activity known to cause angina, with the effects persisting for approximately 30 minutes. Isosorbide dinitrate, also available in sublingual form, has a longer half-life with antianginal effects lasting up to 2 hours. The use of short-acting nitrates alone, without concomitant long-acting antianginal therapy, may be acceptable for patients who experience angina symptoms once every few days. However, for patients with more frequent attacks, other antianginal therapies are recommended.

LO 7

The use of nitrates within 24 to 48 hours of a phosphodiesterase type 5 inhibitor (eg, sildenafil, vardenafil, and tadalafil), commonly prescribed for erectile dysfunction, is contraindicated. Phosphodiesterase degrades cGMP, which is responsible for the vasodilatory effects of nitrates. Concomitant use of nitrates and phosphodiesterase type 5 inhibitors enhances cGMP-mediated vasodilation and can result in serious hypotension, decreased coronary perfusion, and even death. All patients with SIHD should be prescribed sublingual nitroglycerin and educated regarding its use. Points to emphasize when counseling a patient on sublingual nitroglycerin use include:

LO 7

- The seated position is generally preferred when using nitroglycerin because the drug may cause dizziness.
- Call 911 if symptoms are unimproved or worsen 5 minutes after the first dose.
- Keep nitroglycerin tablets in the original glass container and close the cap tightly after use.
- Nitroglycerin should not be stored in the same container as other medications because this may reduce nitroglycerin's effectiveness.
- Repeated use of nitroglycerin is not harmful or addictive and does not result in any long-term side effects. Patients should not hesitate to use nitroglycerin whenever needed.
- Nitroglycerin should not be used within 24 hours of taking sildenafil or vardenafil or within 48 hours of taking tadalafil because of the potential for life-threatening hypotension.

► *Pharmacotherapy to Prevent Recurrent Ischemic Symptoms*

LO 5

LO 6

The overall goal of antianginal therapy is to allow patients with IHD to resume normal activities without symptoms of angina and to experience minimal to no adverse drug effects. The drugs used to prevent ischemic symptoms are β-blockers, CCBs, nitrates, and ranolazine. These drugs exert their antianginal

Table 7–7

Effects of Antianginal Medications on Myocardial Oxygen Demand and Supply

	Oxygen Demand			
Antianginal Agent	**Heart Rate**	**Wall Tension**	**Cardiac Contractility**	**Oxygen Supply**
β-Blockers	↓	↔ or ↓	↓	↔
Calcium channel blockers				
Verapamil, diltiazem	↓	↓	↓	↑
Dihydropyridines	↔ or ↑	↓	↓	↑
Nitrates	↑	↓	↔	↑
Ranolazine[a]	↔	↓	↔	↔

[a]The exact mechanism of the anti-ischemic effects of ranolazine is not known.

↓ decreases; ↔, no change; ↑, increases.

effects by improving the balance between myocardial oxygen supply and demand, with specific effects listed in Table 7–7. β-Blockers, CCBs, nitrates, and ranolazine decrease the frequency of angina and delay the onset of angina during exercise. However, there is no evidence that any of these agents prevent ACS or improve survival in patients with SIHD. Combination therapy with two or three antianginal drugs is often needed.

β-Blockers β-Blockers antagonize β_1- and β_2-adrenergic receptors in the heart, reducing heart rate and cardiac contractility, and decreasing myocardial oxygen demand. β-Blockers may also reduce oxygen demand by lowering BP and ventricular wall tension through inhibition of renin release from juxtaglomerular cells. By slowing heart rate, β-blockers prolong diastole, thus increasing coronary blood flow. However, β-blockers do not improve myocardial oxygen supply.

β-Blockers with intrinsic sympathomimetic activity (eg, acebutolol, pindolol, and penbutolol) have partial β-agonist effects and cause lesser reductions in heart rate at rest. As a result, β-blockers with intrinsic sympathomimetic activity may produce lesser reductions in myocardial oxygen demand and should be avoided in patients with SIHD. Other β-blockers appear equally effective at controlling symptoms of angina. The properties and recommended doses of various β-blockers used to prevent angina are summarized in Table 7–8. The frequency of dosing and drug cost should be taken into consideration when choosing a particular drug. Most β-blockers are available in inexpensive generic versions. β-Blockers should be initiated in doses at the lower end of the usual dosing range, with titration according to symptom and hemodynamic response. The β-blocker dose is commonly titrated to achieve the following:

- Resting heart rate between 55 and 60 beats/min.
- Maximum heart rate with exercise of 100 beats/min or less or 20 beats/min above the resting heart rate.

KEY CONCEPT In the absence of contraindications, β-blockers are the preferred initial therapy to prevent symptoms of angina in patients with SIHD because of their potential cardioprotective effects (eg, after MI and/or in patients with HFrEF). The long-term effects of β-blockers on morbidity and mortality in patients with SIHD are largely unknown. Yet, β-blockers decrease the risk of reinfarction and death by 23% in patients who have suffered an MI.[37] However, controversy exists regarding the role of β-blockers as first-line therapy for all patients with SIHD. In a recent observational study, β-blockers did not lower the risk of MACE in patients with SIHD or IHD risk factors.[38] Additionally, recommendations for using β-blockers for risk reduction in patients with SIHD or other vascular disease, in the absence of MI or heart failure, were recently downgraded.[39]

β-Blockers are contraindicated in patients with severe bradycardia (heart rate < 50 beats/min) or atrioventricular (AV)

Table 7–8

Properties and Dosing of β-Blockers in Ischemic Heart Disease

Drug	Receptor Affinity	Usual Dose Range	Dose Adjust in Hepatic Impairment	Dose Adjust in Renal Impairment
Atenolol	β_1-Selective	25–200 mg once daily	No	Yes
Betaxolol	β_1-Selective	5–20 mg once daily	No	Yes
Bisoprolol	β_1-Selective	2.5–10 mg once daily	Yes	Yes
Carvedilol	α_1, β_1, and β_2	3.125–25 mg twice daily	Avoid in severe impairment	No
Carvedilol phosphate	α_1, β_1, and β_2	10–80 mg once daily	Avoid in severe impairment	No
Labetalol	α_1, β_1, and β_2	100–400 mg twice daily	Yes	No
Metoprolol	β_1-Selective	50–200 mg twice daily (once daily for extended release)	Yes	No
Nadolol	β_1 and β_2	40–120 mg once daily	No	Yes
Nebivolol	β_1-Selective	5–10 mg once daily	Yes, avoid in severe impairment	Yes
Propranolol	β_1 and β_2	20–120 mg twice daily (60–240 mg once daily for long-acting formulation)	Yes	No
Timolol	β_1 and β_2	10–20 mg twice daily	Yes	Yes

conduction defects in the absence of a pacemaker. β-Blockers should be used with particular caution in combination with other agents that depress AV conduction (eg, digoxin, verapamil, and diltiazem) because of the increased risk for bradycardia and heart block. Relative contraindications include asthma, bronchospastic disease, and severe depression. β_1-Selective blockers are preferred in patients with asthma or chronic obstructive pulmonary disease. However, selectivity is dose dependent, and β_1-selective agents may induce bronchospasm in higher doses.

There are several precautions to consider with the use of β-blockers in patients with diabetes or heart failure. All β-blockers may mask the tachycardia and tremor (but not sweating) that commonly accompany episodes of hypoglycemia in diabetes. In addition, nonselective β-blockers may alter glucose metabolism and slow recovery from hypoglycemia in insulin-dependent diabetes. β_1-Selective agents are preferred because they are less likely to prolong recovery from hypoglycemia. Importantly, β-blockers should not be avoided in patients with SIHD and diabetes, particularly in patients with a history of MI who are at high risk for recurrent cardiovascular events. β-Blockers are indicated in patients with chronic HFrEF who are euvolemic due to their mortality benefit in this population. However, β-blockers are negative inotropes (ie, they decrease cardiac contractility). Therefore, β-blockers may worsen symptoms of heart failure in patients with left ventricular dysfunction (ie, ejection fraction < 40% [0.40]) and initiation or titration should be delayed in patients with acute heart failure until symptoms have resolved. In particular, when used for the management of SIHD in a patient with heart failure, β-blockers should be initiated in very low doses with slow up-titration to avoid worsening heart failure symptoms.

LO 7

LO 7

Other potential adverse effects from β-blockers include fatigue, sleep disturbances, malaise, depression, and sexual dysfunction. Abrupt β-blocker withdrawal may increase the frequency and severity of angina, possibly because of increased receptor sensitivity to catecholamines after long-term β-blockade. If the decision is made to stop β-blocker therapy, the dose should be tapered over several days to weeks to avoid exacerbating angina.

LO 7

Calcium Channel Blockers CCBs inhibit calcium entry into vascular smooth muscle and cardiac cells, resulting in the inhibition of the actin-myosin complex and contraction of the cell. Inhibition of calcium entry into the vascular smooth muscle cells leads to systemic vasodilation and reductions in afterload. Inhibition of calcium entry into the cardiac cells leads to reductions in cardiac contractility. Thus, CCBs reduce myocardial oxygen demand by lowering both wall tension (through reductions in afterload) and cardiac contractility. The nondihydropyridine CCBs, verapamil and diltiazem, slow sinoatrial and AV nodal conduction, decrease heart rate, and further decrease myocardial oxygen demand. Because of their negative **chronotropic** effects, verapamil and diltiazem are generally more effective antianginal agents than the dihydropyridine CCBs. In contrast, dihydropyridine CCBs, nifedipine in particular, inhibit calcium in the vasculature and are potent vasodilators that can cause baroreflex-mediated increases in sympathetic tone and heart rate. In addition to decreasing myocardial oxygen demand, all CCBs increase myocardial oxygen supply by dilating coronary arteries, thus increasing coronary blood flow and relieving vasospasm.

CCBs are as effective as β-blockers at preventing ischemic symptoms. KEY CONCEPT CCBs are recommended as alternative treatment in SIHD when β-blockers are contraindicated or not tolerated. In addition, CCBs may be used in combination with β-blockers when initial treatment is unsuccessful. The combination of a β-blocker and a dihydropyridine CCB may improve symptoms better than either drug used alone.[40] However, the combination of a β-blocker with either verapamil or diltiazem should be used with extreme caution because both drugs decrease AV nodal conduction, increasing the risk for severe bradycardia or AV block when used together. If combination therapy is warranted, a long-acting dihydropyridine CCB is preferred. β-Blockers will prevent reflex increases in sympathetic tone and heart rate with the use of CCBs with potent vasodilatory effects. For patients with variable and unpredictable occurrences of angina, indicating possible coronary vasospasm, CCBs may be more effective than β-blockers in preventing angina episodes. The dosing of CCBs in IHD is described in Table 7–9.

LO 7

Table 7–9

Dosing of Calcium Channel Blockers in Ischemic Heart Disease

Drug	Usual Dose Range
Nondihydropyridines	
Diltiazem, extended release	120–360 mg once daily; consider dose adjustment in hepatic dysfunction
Verapamil, extended release	180–480 mg once daily; use initial dose of 120 mg in hepatic dysfunction
Dihydropyridines	
Amlodipine	5–10 mg once daily
Felodipine	5–10 mg once daily; use initial dose of 2.5 mg once daily in hepatic dysfunction
Nifedipine, extended release	30–90 mg once daily; dose adjust and monitor closely in hepatic dysfunction
Nicardipine	20–40 mg thrice daily; dose twice daily in hepatic dysfunction and up-titrate slowly in both hepatic and renal dysfunction

Verapamil and diltiazem are contraindicated in patients with bradycardia and preexisting conduction disease in the absence of a pacemaker. As previously noted, verapamil and diltiazem should be used with particular caution in combination with other drugs that depress AV nodal conduction (eg, β-blockers and digoxin). Because of their negative **inotropic** effects, CCBs may cause or exacerbate heart failure in patients with HFrEF and should be avoided in this population. The exceptions are amlodipine and felodipine that have less negative inotropic effects compared with other CCBs and appear to be safe in patients with left ventricular systolic dysfunction.[41,42] Finally, there is some evidence that short-acting CCBs (particularly short-acting nifedipine and nicardipine) may increase the risk of cardiovascular events.[43] Therefore, short-acting agents should be avoided in the management of SIHD.

Long-Acting Nitrates Nitrate products are available in both oral and transdermal formulations for chronic use. Commonly used products are listed in Table 7–10. All long-acting nitrate products produce effects within 30 to 60 minutes and are equally effective at preventing the recurrence of angina when used appropriately.

The major limitation of nitrate therapy is the development of tolerance with continuous use. The loss of antianginal effects may occur within the first 24 hours of continuous nitrate therapy.

Table 7–10

Nitrate Formulations and Dosing for Chronic Use

Formulation	Dose
Oral	
Nitroglycerin extended-release capsules	2.5 mg thrice daily initially, with up-titration according to symptoms and tolerance; allow a 10- to 12-hour nitrate-free interval
Isosorbide dinitrate tablets	5–20 mg two to three times daily, with a daily nitrate-free interval of at least 14 hours (eg, dose at 7 AM, noon, and 5 PM)
Isosorbide dinitrate slow-release capsules	40 mg one to two times daily, with a daily nitrate-free interval of at least 18 hours (eg, dose at 8 AM and 2 PM)
Isosorbide mononitrate tablets	5–20 mg twice daily initially, with up-titration according to symptoms and tolerance; doses should be taken 7 hours apart (eg, 8 AM and 3 PM)
Isosorbide mononitrate extended-release tablets	30–120 mg once daily
Transdermal	
Nitroglycerin extended-release film	0.2–0.8 mg/hour, on for 12–14 hours, off for 10–12 hours

Although the cause of tolerance is unclear, several mechanisms have been proposed, including the generation of free radicals that degrade nitric oxide. The most effective method to avoid tolerance and maintain the antianginal efficacy of nitrates is to allow a daily nitrate-free interval of at least 8 to 12 hours. Nitrates do not provide protection from ischemia during the nitrate-free period. Therefore, the nitrate-free interval should occur when the patient is least likely to experience angina, which is generally during the nighttime hours when the patient is sleeping and myocardial oxygen demand is reduced. Thus, it is common to dose long-acting nitrates so that the nitrate-free interval begins in the evening. For example, isosorbide dinitrate is typically dosed on awakening and again 6 to 7 hours later.

Monotherapy with nitrates for the prevention of ischemia should generally be avoided. Reflex increases in sympathetic activity and heart rate, with resultant increases in myocardial oxygen demand, may occur secondary to nitrate-induced venodilation. In addition, patients are unprotected from ischemia during the nitrate-free interval. β-Blockers and CCBs are dosed to provide 24-hour protection from ischemia. KEY CONCEPT Treatment with long-acting nitrates should be added to baseline therapy with either a β-blocker or CCB or a combination of the two. β-Blockers attenuate the increase in sympathetic tone and heart rate that occurs during nitrate therapy. As a result, the combination of β-blockers and nitrates is particularly effective at preventing angina and provides greater protection from ischemia than therapy with either agent alone. Monotherapy with nitrates may be appropriate in patients who have low BP at baseline or who experience symptomatic hypotension with low doses of β-blockers or CCBs.

Common adverse effects of nitrates include postural hypotension, dizziness, flushing, and headache secondary to venodilation. Headache often resolves with continued therapy and may be treated with acetaminophen. Hypotension is generally of no serious consequence. However, in patients with hypertrophic obstructive cardiomyopathy or severe aortic valve stenosis, nitroglycerin may cause serious hypotension and syncope. Therefore, long-acting nitrates are relatively contraindicated in these conditions. Because life-threatening hypotension may occur with concomitant use of nitrates and phosphodiesterase type 5 inhibitors, nitrates should not be used within 24 hours of taking sildenafil or vardenafil or within 48 hours of taking tadalafil. Skin erythema and inflammation may occur with transdermal nitroglycerin administration and may be minimized by rotating the application site.

Ranolazine Ranolazine is an anti-ischemic agent indicated for the management of chronic angina. The mechanism of action is unclear, but it is believed to inhibit the late inward sodium current during the plateau phase of the cardiac action potential. Under ischemic conditions, excess sodium may enter the myocardial cell during systole. The resultant intracellular sodium overload leads to intracellular calcium accumulation (calcium overload) through a sodium/calcium exchange mechanism. Calcium overload results in increases in left ventricular wall tension and MVO_2. By reducing intracellular sodium concentrations in ischemic myocytes, ranolazine decreases intracellular calcium overload, left ventricular wall tension, and MVO_2.

Similar to other antianginal drugs, ranolazine reduces angina and increases exercise capacity but does not reduce incidence of MACE. Ranolazine has minimal effects on heart rate or BP; thus, it may be an option in SIHD patients with low baseline BP or heart rate. Ranolazine is indicated as a first-line treatment for chronic stable angina. However, it is often reserved for patients with angina refractory to other antianginal medications due to its excessive cost. Ranolazine can prolong the QT interval. However, when used at recommended doses, the mean prolongation of QT interval is minimal (2.4 milliseconds [ms]).[44] The risk for QT interval prolongation is elevated in patients with hepatic impairment or taking other medications known to interact with ranolazine or prolong QT interval. Ranolazine should be started at a dose of 500 mg twice daily and increased to 1000 mg twice daily if needed for symptom relief. Higher doses are poorly tolerated and should be avoided. Contraindications to ranolazine are shown in Table 7–11. Common adverse effects with ranolazine include dizziness, constipation, headache, and nausea. Syncope may occur infrequently. Ranolazine is a CYP3A4 substrate, weak CYP2D6 substrate, CYP2D6 inhibitor, organic cation transporter 2 (OCT2) inhibitor, and both an inhibitor and substrate of P-glycoprotein (P-gp). Concomitant use of ranolazine with potent CYP3A4 inhibitors (eg, ketoconazole, clarithromycin, and nelfinavir) or inducers (eg, rifampin) is contraindicated. The use of ranolazine is contraindicated in patients with significant hepatic disease. The ranolazine dose should be limited to 500 mg twice daily when combined with moderate CYP3A4 inhibitors including diltiazem and verapamil. Ranolazine should be used cautiously with P-gp inhibitors (eg, cyclosporine) and substrates (eg, digoxin). The maximum doses of simvastatin (20 mg daily) and metformin (1700 mg daily) are lower during concomitant treatment with ranolazine.

► *Pharmacotherapy with No Benefit or Potentially Harmful Effects*

Hormone Replacement Therapy, Folic Acid, and Antioxidants Current guidelines recommend against the use of hormone replacement therapy (HRT), folic acid, or antioxidants for reducing cardiovascular risk.[1] Early evidence

Table 7–11

Contraindications and Precautions with Ranolazine

Contraindications	Precautions
Liver cirrhosis increases ranolazine plasma concentrations by 30%–80%, resulting in increased risk for QT interval prolongation	Treatment with moderate CYP3A4 inhibitors including diltiazem, verapamil, grapefruit juice, erythromycin, and fluconazole increases ranolazine plasma concentrations (twofold with diltiazem and verapamil)
Treatment with potent CYP3A4 inhibitors (including ketoconazole, clarithromycin, and nelfinavir) increases ranolazine concentrations (3.2-fold with ketoconazole)	Preexisting QT prolongation, history of torsades de pointes, or treatment with other QT-prolonging drugs as QT interval prolongation may occur with ranolazine
Treatment with CYP3A4 inducers (including rifampin, phenobarbital, phenytoin, carbamazepine, and St. John's wort) may significantly decrease the efficacy of ranolazine (by 95% with rifampin)	Treatment with a P-gp inhibitor, such as cyclosporine, may increase ranolazine absorption
	Up to a 50% increase in ranolazine plasma concentration has been observed in renal impairment
	Ranolazine may increase bioavailability of P-gp substrates (increases digoxin plasma concentrations by 1.5-fold)
	Ranolazine may cause reduced metabolism of CYP2D6 substrates
	Ranolazine may increase exposure to drugs transported by OCT2; metformin doses should not exceed 1700 mg/day in patients treated with ranolazine 1000 mg twice daily
	Ranolazine may reduce the metabolism of CYP3A3 substrates; the dose of simvastatin should not exceed 20 mg in patients treated with ranolazine

CYP, cytochrome P450; OCT2, organic cation transporter 2; P-gp, P-glycoprotein.

from observational studies with each of these suggested potential benefit in SIHD. However, no benefit was observed in randomized controlled clinical trials.[45-49] In the case of HRT, there was evidence of harm, with an increased risk of thromboembolic events and breast cancer with HRT in postmenopausal women.[46,47] Clinicians should consider discontinuing HRT therapy in women who suffer an acute coronary event while receiving such therapy.

LO 7

Herbal Supplements Herbal products are widely used for their purported cardiovascular benefits. Examples of such products include danshen, dong quai, feverfew, garlic, hawthorn, and hellebore. However, strong evidence supporting their benefits in cardiovascular disease is generally lacking. Furthermore, the potential for drug interactions and the lack of standardization limits the products' usefulness in clinical practice. Safety with herbal supplements in patients with SIHD is a major concern. Numerous case reports of adverse cardiovascular events led the Food and Drug Administration (FDA) to ban ephedra-containing products (eg, Ma huang) in 2004. However, other herbal supplements with potentially serious adverse cardiovascular effects remain easily accessible. Some herbal supplements, such as feverfew and garlic, may interact with antiplatelet and antithrombotic therapy and increase bleeding risk. Dietary supplements purported to enhance sexual performance may contain phosphodiesterase-like chemicals and increase risk for serious hypotension with nitroglycerin. Other agents may reduce the effectiveness of antianginal medications, such as St. John's wort with ranolazine. Thus, it is important to assess the use of herbal products in patients with SIHD and to counsel patients about the potential for drug interactions and adverse events with herbal therapies.

LO 7

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a specific plan for the management of the patient's stable ischemic heart disease. Your plan should include (a) the goals of therapy, (b) patient-specific nonpharmacologic and pharmacologic interventions to address these goals, and (c) a plan for follow-up to assess drug tolerance and whether the therapeutic goals have been achieved.

Cyclooxygenase-2 Inhibitors and Nonsteroidal Anti-inflammatory Drugs Data suggest that cyclooxygenase-2 (COX-2) inhibitors and nonselective NSAIDs may increase the risk for MI and stroke.[48] The cardiovascular risk with COX-2 inhibitors and NSAIDs may be greatest in patients with a history of, or with risk factors for, cardiovascular disease. The COX-2 inhibitors rofecoxib and valdecoxib were withdrawn from the market because of safety concerns. Product labeling for other COX-2 and nonselective NSAIDs (prescription and over-the-counter) now includes boxed warning about potential adverse cardiovascular effects. The AHA recommends the use of COX-2 inhibitors be limited to low-dose, short-term therapy in patients for whom there is no appropriate alternative.[50] Patients with cardiovascular disease should consult a clinician before using over-the-counter NSAIDs.

LO 7

Special Populations

▶ *Variant Angina*

Vasospasm as the sole etiology of angina (Prinzmetal or variant angina) is relatively uncommon. As a result, treatment options are not well studied. Nevertheless, based on the pharmacology of available drugs, several recommendations can be made. First, β-blockers should be avoided in patients with variant angina because of their potential to worsen vasospasm due to unopposed α-adrenergic receptor stimulation. In contrast, both CCBs and nitrates are effective in relieving vasospasm and are preferred in the management of variant angina. Because nitrates require an 8- to 12-hour nitrate-free interval, their role as monotherapy for prophylaxis of anginal attacks due to vasospasm is limited. However, immediate-release nitroglycerin is effective at terminating acute anginal attacks due to vasospasm. Therefore, all patients diagnosed with variant angina should be prescribed immediate-release nitroglycerin. CCBs are effective for monotherapy of variant angina. Because short-acting CCBs have been associated with increased risk of adverse cardiac events, they should be avoided.[41] Long-acting nitrates may be added to CCB therapy if needed.

LO 7

▶ *Microvascular Angina*

There are limited data on optimal therapy in patients with microvascular disease. Both ACE inhibitors and statins may produce beneficial effects on endothelial function and improve microvascular angina.[6] Short-acting nitrates remain the treatment of choice for relieving acute symptoms, although they may be less effective in microvascular disease. Similar to obstructive CAD, β-blockers are first line to control symptoms of angina in patients with microvascular disease and may be more effective than CCBs and long-acting nitrates in this setting.[4] Ranolazine may also produce favorable antianginal effects for patients with continued symptoms.

LO 7

▶ *Elderly Patients with IHD*

Elderly patients are more likely than younger patients to have other comorbidities that may influence drug selection for the treatment of angina. As a result, polypharmacy is more common in elderly patients, increasing the risk of drug–drug interactions, and perhaps decreasing medication adherence. Additionally, elderly patients are often more susceptible to adverse effects of antianginal therapies, particularly the negative chronotropic and inotropic effects of β-blockers and CCBs. Therefore, drugs should be initiated in low doses with close monitoring of elderly patients with IHD.

LO 7

▶ *Acute Coronary Syndromes*

Management of ACS is discussed in further detail in Chapter 8, "Acute Coronary Syndromes." It is important to educate patients with SIHD on the signs of ACS and steps to take if signs or symptoms occur. Importantly, patients should be instructed to seek emergent care if symptoms of angina last longer than 20 to 30 minutes, do not improve after 5 minutes of using sublingual nitroglycerin, or worsen after 5 minutes of using sublingual nitroglycerin. In patients with a history of ACS, it is crucial to select appropriate pharmacotherapy to prevent recurrent ACS and death. Appropriate pharmacotherapy for patients with a history of ACS includes aspirin (often in combination with a $P2Y_{12}$ inhibitor), ACE inhibitors or ARBs, β-blockers, statins, and sublingual nitroglycerin. In addition, control of cardiovascular risk factors (eg, dyslipidemia, hypertension, and diabetes) with lifestyle modifications and pharmacotherapy is critical.

LO 8

LO 7

OUTCOME EVALUATION

Assessing for Drug Effectiveness and Safety

LO 8

- In general, patients with SIHD should have follow-up evaluations every 4 to 12 months.[1] Early in the treatment course (eg, first year), more frequent evaluations (every 4–6 months) are recommended. For reliable patients whose symptoms are stable, less frequent evaluations are recommended after the first year of therapy. The length of the follow-up period may differ based on frequency and severity of symptoms, care coordination with other providers, regional practice patterns, patient preference, and physician availability.

LO 8

- KEY CONCEPT Monitor symptoms of angina at baseline and at each clinic visit for patients with SIHD to assess the effectiveness of antianginal therapy. In particular, assess the frequency and intensity of anginal symptoms.[1] Determining the frequency of sublingual nitroglycerin use is helpful in making this assessment. If angina is occurring with increasing frequency or intensity, adjust antianginal therapy and refer the patient for additional diagnostic testing (eg, coronary angiography) and possibly coronary intervention (eg, PCI or CABG surgery), if indicated.

LO 7

LO 8

- Assess the patient for IHD-related complications, such as heart failure and arrhythmias.[1] The presence of new comorbidities may indicate worsening SIHD requiring additional workup or pharmacologic therapy.
- Routinely monitor hemodynamic parameters to assess drug tolerance. Assess BP at baseline, after drug initiation and after dose titration. BP should be monitored periodically in patients treated with β-blockers, CCBs, nitrates, ACE inhibitors, and/or ARBs. BP reduction may be particularly pronounced after initiation and dose titration of β-blockers that also possess α-blocking effects (eg, labetalol and carvedilol).

LO 8

- Routinely assess adherence to medical therapy and recommended lifestyle changes.
- Because of the potential for postural hypotension, warn patients that dizziness, presyncope, and even syncope may result from abrupt changes in body position during initiation or up-titration of drugs with α-blocking effects.

LO 8

- Closely monitor heart rate in patients treated with drugs that have negative chronotropic effects (eg, β-blockers, verapamil, or diltiazem) or drugs that may cause reflex tachycardia (eg, nitrates or dihydropyridine CCBs). Treatment with β-blockers, verapamil, or diltiazem can usually be continued in patients with asymptomatic bradycardia. However, reduce or discontinue treatment with these agents in patients who develop symptomatic bradycardia or serious conduction abnormalities.

LO 7

LO 8

- Regularly assess control of existing risk factors and the presence of new risk factors for SIHD.[1] Routine screening for the presence of metabolic syndrome will help in assessing the control of known major risk factors and identifying new risk factors. If new risk factors are identified and/or the presence of metabolic syndrome is detected, modify the pharmacotherapy regimen, as discussed previously, to control these risk factors and lower the risk of SIHD and IHD-related adverse events.

LO 7

LO 8

- In patients treated with ACE inhibitors and/or ARBs, routinely monitor renal function and potassium levels at baseline, after drug initiation and dose titration, and periodically thereafter. This is particularly important when using these therapies in patients with preexisting renal impairment or diabetes because they may be more susceptible to these adverse events.

Duration of Therapy

LO 7

- Because these therapies reduce the risk for coronary events and death, treatment with antiplatelet (aspirin or clopidogrel), lipid-lowering, and neurohormonal-modifying medications for SIHD is generally lifelong.
- Antianginal therapy with a β-blocker, CCB, and/or nitrate is usually long term.
- A patient with severe symptoms managed with combination antianginal drugs who undergoes successful coronary revascularization may be able to reduce antianginal therapy. However, treatment with at least one agent that improves the balance between myocardial oxygen demand and supply is usually warranted.

Patient Care Process

Collect Information:

- Perform a thorough medication history; identify allergies and intolerances.
- Identify SIHD risk factors. (See Table 7–2.)
- Perform a physical examination; obtain vital signs.
- Collect laboratory and diagnostic information. (See Clinical Presentation and Diagnosis of Ischemic Heart Disease, and Figure 7–4.)

Assess the Information:

- Assess the patient's symptoms. (See Tables 7–3 and 7–4.)
- Determine quality, location, and duration of pain.
- Determine factors that provoke and relieve pain.
- Identify potential noncardiac conditions that can explain the patient's symptoms. (See Table 7–1.)
- Evaluate available laboratory and diagnostic information for SIHD. Do they suggest or confirm SIHD? Was PCI performed? Were there any stents placed and in what setting (ACS or SIHD)?
- Assess the efficacy and safety of the patient's previous SIHD drug regimen, if applicable.
- Identify medications that may interact with antianginal drug therapy.
- Assess adherence to medical therapy and recommended lifestyle modifications.
- Assess for the presence of SIHD-related complications.
- Assess preexisting and newly detected patient-specific risk factors for SIHD. (See Table 7–2 and Figure 7–4.)

Develop a Care Plan:

- Treat modifiable risk factors for SIHD; initiate appropriate lifestyle modifications.
- Treat hypertension, dyslipidemia, and diabetes.
- Initiate and/or modify therapy to prevent MACE. (See Figure 7–5.)
- Initiate and/or modify therapy to treat acute symptoms and prevent chronic angina symptoms. (See Figure 7–5.)

Implement the Care Plan:

- Refer patients with ACS to the hospital. (See Table 7–3.)
- Stress the importance of adherence to the care plan.
- Identify barriers that may affect adherence to the care plan; modify the care plan, if necessary.
- Provide education on the following: consequences of untreated SIHD, lifestyle modifications, medication administration, potential adverse effects, potential drug interactions, signs and symptoms of worsening angina, signs and symptoms of IHD-related complications, and when to seek emergent care.

Follow-up: Monitor and Evaluate:

- Reassess the care plan at least every 4 to 12 months, more often if necessary (eg, first year of therapy, persistent symptoms, intolerance to medical therapy).
- During each subsequent visit, assess control of preexisting risk factors and development of new risk factors, control of angina symptoms, presence of SIHD complications, adherence to the care plan, development of adverse drug reactions, and drug interactions.
- Reevaluate the efficacy and safety of the medical regimen assuring it includes appropriate therapy to prevent MACE and prevent angina symptoms. (See Figures 7–4 and 7–5.)
- Reassess barriers to treatment affecting adherence and modify the care plan, if necessary.

Abbreviations Introduced in This Chapter

ACC	American College of Cardiology
ACE	Angiotensin-converting enzyme
ACS	Acute coronary syndromes
AHA	American Heart Association
ARB	Angiotensin receptor blocker
ASCVD	Atherosclerotic cardiovascular disease
AV	Atrioventricular
BMS	Bare metal stent
BP	Blood pressure
CABG	Coronary artery bypass graft
CAD	Coronary artery disease
CCB	Calcium channel blocker
cGMP	Cyclic guanosine monophosphate
CHD	Coronary heart disease
COX-2	Cyclooxygenase-2
CT	Computed tomography
CYP	Cytochrome P450
DES	Drug-eluting stent
DAPT	Dual antiplatelet therapy
EBCT	Electron beam computed tomography
ECG	Electrocardiogram
FDA	Food and Drug Administration
HDL	High-density lipoprotein
HF	Heart failure
HFrEF	Heart failure with reduced ejection fraction
HMG-CoA	3-hydroxy-3-methylglutaryl coenzyme A
HRT	Hormone replacement therapy
HTN	Hypertension
IHD	Ischemic heart disease
IV	Intravenous
LDL	Low-density lipoprotein
MACE	Major adverse cardiac events
MI	Myocardial infarction
MR	Magnetic resonance
MRA	Mineralocorticoid receptor antagonist
Ms	Milliseconds
MVO_2	Myocardial oxygen consumption
NSTEMI	Non–ST-segment elevation myocardial infarction
NSAID	Nonsteroidal anti-inflammatory drug
OCT2	Organic cation transporter 2
PCI	Percutaneous coronary intervention
P-gp	P-glycoprotein
PTCA	Percutaneous transluminal coronary angioplasty
SIHD	Stable ischemic heart disease
STEMI	ST-segment elevation myocardial infarction
TXA_2	Thromboxane A_2
UA	Unstable angina

8 Acute Coronary Syndromes

Kelly C. Rogers, Shannon W. Finks, and Sarah A. Spinler

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Define the role of atherosclerotic plaque, platelets, and the coagulation system in an acute coronary syndrome (ACS).
2. List key electrocardiographic (ECG), biomarker, and clinical features identifying a patient with non–ST-segment elevation (NSTE)–ACS and ST-segment elevation myocardial infarction (STEMI).
3. Devise an initial, early pharmacotherapy treatment and monitoring plan for a patient presenting with either NSTE-ACS or STEMI given patient-specific data.
4. Devise an antithrombotic pharmacotherapy treatment and monitoring plan for a patient with NSTE-ACS or STEMI undergoing percutaneous coronary intervention (PCI) given patient-specific data.
5. Devise an antithrombotic pharmacotherapy treatment and monitoring plan for a patient with NSTE-ACS or STEMI not undergoing PCI given patient-specific data.
6. Develop a pharmacotherapy and risk factor modification treatment plan for secondary prevention of coronary heart disease (CHD) events in a patient following NSTE-ACS or STEMI.

INTRODUCTION

Cardiovascular disease (CVD) is the leading cause of death in the United States and one of the major causes of death worldwide. Acute coronary syndromes (ACSs), including **unstable angina** (UA) and **myocardial infarction** (MI), are a form of CHD that comprises the most common cause of CVD death.[1]

LO 1

KEY CONCEPT ACS is primarily caused by rupture of an atherosclerotic plaque with subsequent platelet adherence, activation, aggregation, and the activation of the clotting cascade. Ultimately, a thrombus composed of fibrin and platelets may develop, resulting in incomplete or complete occlusion of a coronary artery.[2] ACS is a spectrum of disease encompassing **ST-segment elevation MI** (STEMI) or **non-ST segment elevation** (NSTE)-ACS, which are classified according to ECG changes and underlying pathophysiology.[3,4] The American Heart Association (AHA), American College of Cardiology (ACC), and American College of Cardiology Foundation (ACCF) recommend strategies or guidelines for ACS patient care for STEMI and NSTE-ACS which includes both UA and non–ST-elevation MI (NSTEMI). In collaboration with the Society for Cardiovascular Angiography and Interventions (SCAI), the ACCF and AHA issue joint guidelines for **percutaneous coronary intervention** (PCI), including PCI in the setting of ACS. These practice guidelines are based on a review of available clinical evidence, have graded recommendations based on evidence and expert opinion, and are updated periodically. These guidelines form the cornerstone for quality care of the ACS patient.[3-5]

EPIDEMIOLOGY

Each year, approximately 695,000 Americans will have a new "coronary attack," defined as a first hospitalization for MI or CHD death, while 325,000 will have a recurrent hospitalization event.[1] The risks of CHD events, such as death, recurrent MI, and stroke, are higher for patients with established CHD and a history of MI than for patients with no known CHD.

The incidence rate of MI in the United States has been decreasing since 2007.[1] In particular, the number of patients presenting with STEMI has significantly decreased (from 133 to 50 cases per 100,000 person-years). Nevertheless, 114,019 Americans died of an MI in 2014. One in seven deaths is secondary to CHD, which is the leading cause of hospitalization in the United States.[1] With median length of hospital stay being 3.2 days, the cost of CHD is high.[6] Estimated direct and indirect costs are more than $199 billion and this figure is expected to double by 2030.[1]

Mortality rates have been declining since the 1990s. Improvements in care that may have contributed to this reduction include greater use of guideline-recommended drugs (eg, aspirin [ASA], β-blockers, angiotensin-converting enzyme [ACE] inhibitors, angiotensin receptor blockers [ARBs], 3-hydroxy-3-methylglutaryl coenzyme A (HMG CoA) reductase inhibitors [statins], $P2Y_{12}$ inhibitors); reductions in the median times for administering fibrinolytics and performing primary PCI; and increased use of early coronary angiography and PCI for high-risk patients with NSTE-ACS.[1] In patients with STEMI, in-hospital death rates are approximately 3% in patients receiving primary PCI, 7% for patients who are treated with fibrinolytics, and 16% for patients who do not receive reperfusion therapy. In patients with NSTEMI, in-hospital mortality is less than 5%. Other than persistent ST-segment changes and troponin, predictors of in-hospital mortality include older age, elevated serum creatinine (SCr), tachycardia, and heart failure (HF).[7]

ETIOLOGY

Endothelial dysfunction, inflammation, and formation of fatty streaks contribute to the formation of atherosclerotic coronary

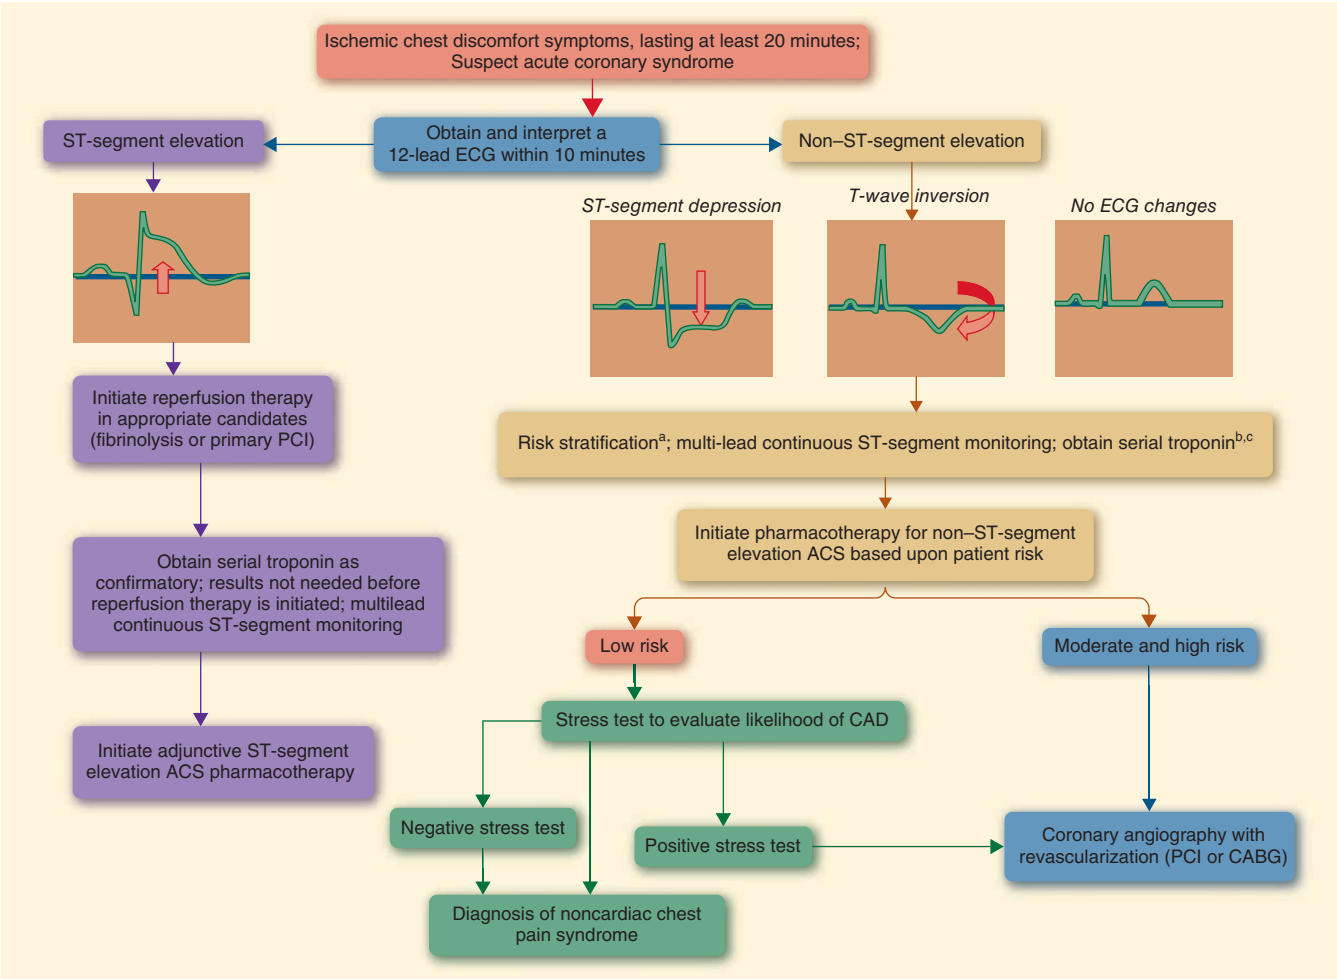

FIGURE 8–1. Evaluation of the acute coronary syndrome patient. [a]As described in Table 8–1. [b]"Positive": Above the myocardial infarction decision limit. [c]"Negative": Below the myocardial infarction decision limit. (ACS, acute coronary syndrome; CABG, coronary artery bypass graft; CAD, coronary artery disease; ECG, electrocardiogram; PCI, percutaneous coronary intervention.) (Reproduced with permission from: Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:167.)

artery plaques, the underlying cause of coronary artery disease (CAD).[8] KEY CONCEPT The predominant cause of ACS in more than 90% of patients is atheromatous plaque rupture, fissuring, or erosion of an unstable atherosclerotic plaque.[2,8] This is called an MI type 1, which generally occurs in coronary arteries where the stenosis occludes less than 50% of the lumen prior to the event, rather than a more stable 70% to 90% stenosis of the coronary artery.[4,9] Stable stenoses are characteristic of stable angina, are not considered an ACS, and are discussed in Chapter 7. MI type 2 is related to a reduction in myocardial oxygen supply or an increase in myocardial demand in the absence of a coronary artery process. MI type 3 is defined as MI resulting in death without the possibility of measuring biomarkers, while MI types 4 and 5 occur during revascularization procedures.[9]

LO 1

PATHOPHYSIOLOGY

LO 2

The term ACS encompasses all clinical syndromes compatible with acute myocardial ischemia and/or MI resulting from an imbalance between myocardial oxygen demand and supply. In contrast to stable angina, an ACS results primarily from diminished myocardial blood flow secondary to an occlusive or partially occlusive coronary artery thrombus. ACSs are classified according to ECG changes into STEMI or NSTE-ACS (NSTEMI and UA) (Figure 8–1).[3,4] An injury that transects the entire thickness of the myocardial wall results in a STEMI which will result in the release of biomarkers, mainly troponins T or I, from the necrotic myocytes into the bloodstream. An NSTEMI is limited to the subendocardial myocardium and is usually smaller and not as extensive as a STEMI. NSTEMI differs from UA in that ischemia is severe enough to result in the release of troponins. The clinical significance of serum markers is discussed in greater detail in later sections of this chapter.

Plaque Rupture and Clot Formation

LO 1

Plaques that rupture are generally characterized by a soft lipid-rich necrotic core, a thin fibrous cap, adventitial and perivascular inflammation, intraplaque hemorrhage, angiogenesis, and expansive vascular remodeling. The latter explains why these plaques only show minimal luminal obstruction, despite being larger than plaques that characterize stable angina which are associated with more severe luminal narrowing.[2,8] Following plaque rupture, a clot (a partially or completely occlusive thrombus) forms on top of the ruptured plaque. The thrombogenic contents of the plaque are exposed to blood elements. Exposure of collagen

and tissue factor induce platelet adhesion and activation, which promote the release of platelet-derived vasoactive substances, including adenosine diphosphate (ADP) and thromboxane A_2 (TXA_2).[8] These produce vasoconstriction and potentiate platelet activation. Furthermore, during platelet activation, a change in the conformation in the glycoprotein (GP) IIb/IIIa surface receptors of platelets occurs that cross-links platelets to each other through fibrinogen bridges. This is considered the final common pathway of platelet aggregation. Inclusion of platelets gives the clot a white appearance. Simultaneously, the extrinsic coagulation cascade pathway is activated as a result of exposure of blood components to the thrombogenic lipid core and disrupted endothelium, which are rich in tissue factor. This leads to the production of thrombin (factor IIa), which converts fibrinogen to fibrin through enzymatic activity. Fibrin stabilizes the clot and traps red blood cells, which gives the clot a red appearance. Therefore, the clot is composed of cross-linked platelets and fibrin strands.[2,8]

Ventricular Remodeling Following an Acute MI

Ventricular remodeling is a process that occurs in several cardiovascular (CV) conditions including HF and following an MI. It is characterized by left ventricular dilation and reduced pumping function of the left ventricle, leading to cardiac failure.[10] Because HF represents one of the principal causes of morbidity and mortality following an MI, preventing ventricular remodeling is an important therapeutic goal.

Use of ACE inhibitors, ARBs, β-blockers, and aldosterone antagonists can slow down or reverse ventricular remodeling through inhibition of the renin-angiotensin aldosterone system and/or through improvement in hemodynamics (decreasing preload or afterload).[10] These agents also significantly improve survival in ACS patients.

At some point during hospitalization, prior to discharge, patients with a definite ACS should have their left ventricular function (LVF) evaluated.[3,4] The most common way LVF is measured is using an echocardiogram to calculate the patient's left ventricular ejection fraction (LVEF, percent of blood pumped out of the left ventricle with each contraction). LVF is one of the strongest predictors of mortality following MI. Patients with LVEF less than 40% (0.40) are at high risk of death. LVEF is an important factor to consider when contemplating the use of several drugs, such as ACE inhibitors and aldosterone antagonists.

Complications

This chapter focuses on management of the uncomplicated ACS patient. However, it is important for clinicians to recognize complications of an acute MI as these may increase the risk of mortality. The most serious early complication of MI is cardiogenic shock, occurring in approximately 7% of hospitalized patients presenting with STEMI.[11,12] Mortality in cardiogenic shock patients with MI is high, approaching 60%.[12] Other complications that may result from MI are HF, valvular dysfunction, bradycardia, heart block, **pericarditis**, stroke secondary to left ventricular thrombus embolization, venous thromboembolism, left ventricular free wall rupture, and ventricular and atrial tachyarrhythmias.[3] In fact, many patients die, presumably from ventricular fibrillation, prior to reaching the hospital. Patients with ventricular fibrillation or sustained ventricular tachycardia occurring more than 2 days following MI (which are not due to transient and reversible ischemia, reinfarction, or metabolic abnormalities), those with LVEF less than 30% (0.30; measured at least 40 days after STEMI) regardless of symptoms, or those with LVEF less than or equal to 35% (0.35) with New York Heart Association functional classes II to III may experience a mortality benefit against sudden cardiac death from placement of an implantable cardioverter defibrillator (ICD).[3]

CLINICAL PRESENTATION AND DIAGNOSIS

Symptoms and Physical Examination Findings

LO 2

The classic symptom of an ACS is severe new-onset or increasing substernal angina that is at least 20 minutes in duration, most often occurring at rest. The pain may radiate to the shoulder, down the left arm, and to the back or jaw. Associated symptoms include nausea, vomiting, **diaphoresis**, or shortness of breath. Although similar to stable angina, the duration may be longer and the intensity may be greater.[3,4] Elderly, female patients, and diabetics may present with a more atypical presentation, including epigastric pain, shortness of breath, or indigestion symptoms in the absence of chest pain. Patients across the spectrum of ACS can present with symptoms. All health care professionals should review these warning symptoms with patients at high risk for CHD. On physical examination, no specific features are indicative of ACS. Patients with suspected ACS should be referred immediately to an emergency department (ED).

12-Lead ECG

KEY CONCEPT There are key features of a 12-lead ECG that identify and risk-stratify a patient with an ACS. Within 10 minutes of presentation to an ED with symptoms of ischemic chest discomfort, a 12-lead ECG should be obtained and interpreted. If the first ECG is not diagnostic, additional ECGs should be performed every 15 to 30 minutes for the first hour if the patient is still symptomatic and the clinician has a high suspicion of ACS.[4] KEY CONCEPT When possible, an ECG should be performed by emergency medical system providers to reduce the delay until myocardial reperfusion. If available, a prior ECG should be reviewed to identify whether ischemic changes are new or old, with new findings being more indicative of an ACS.

LO 2

Key findings on review of an ECG that indicate myocardial ischemia or infarction are ST-segment elevation (STE), ST-segment depression, and T-wave inversion (see Figure 8–1).[3,4] ST-segment and/or T-wave changes in certain groupings of ECG leads help to identify the location of the coronary artery that is the cause of the ischemia or infarction. In addition, the appearance of a new left bundle-branch block accompanied by chest discomfort is highly specific for acute STEMI. Approximately one-third of patients diagnosed with MI present with STE on their ECG, with the remainder having ST-segment depression, T-wave inversion, or in some instances, no ECG changes.[4] According to the latest guidelines, the diagnosis of STE, in the absence of left bundle-branch block or left ventricular hypertrophy, is a new STE in at least two contiguous leads of greater than or equal to 2 mm in men and greater than or equal to 1.5 mm in women in leads V_2-V_3 and/or of greater than or equal to 1 mm in other leads. Some parts of the heart are more "electrically silent" than others, and myocardial ischemia may not be detected on an ECG. Therefore, it is important to review findings from the ECG in conjunction with biochemical markers of myocardial necrosis, such as troponin I or T, clinical symptoms, and other risk factors for CHD to determine the patient's risk for experiencing a new MI or having other complications.

Clinical Presentation and Diagnosis

General

- The patient is typically in acute distress and may develop or present with acute HF, cardiogenic shock, or cardiac arrest.

Symptoms

- The classic symptom of ACS is substernal chest pain or discomfort. Accompanying symptoms may include radiation of pain to arm, back, or jaw, nausea, vomiting, diaphoresis, anxiety, or shortness of breath.
- Elderly, women, and diabetics are more likely to present with atypical symptoms such as indigestion, epigastric pain, shortness of breath, or anxiety and less likely to present with classic symptoms.

Physical Signs

- There are no "classic" signs for ACS.
- Patients with ACS may present with signs of acute HF, including edema, jugular venous distention, an S_3 sound on auscultation, or pulmonary edema on a chest X-ray.
- Patients may also present with arrhythmias such as tachycardia, bradycardia, or heart block.

Laboratory Tests

- Troponin I or T is measured at presentation and repeated 2 to 3 times at 3- to 6-hour intervals to ascertain heart muscle damage; confirmatory for the diagnosis of an infarction. For patients with NSTE-ACS, an elevated troponin is diagnostic for MI, differentiating NSTEMI from UA. Patients presenting with suspected NSTE-ACS who do not have an MI undergo further diagnostic testing to determine whether they have UA or are not experiencing an ACS.
- Blood chemistry tests are performed with particular attention given to potassium and magnesium, which may affect heart rhythm.
- SCr is measured, and creatinine clearance (CrCl) is used to identify patients who may need dosing adjustments for medications, as well as those who are at high risk of morbidity and mortality.
- Baseline complete blood count (CBC) and coagulation tests (activated partial thromboplastin time [aPTT] and international normalized ratio [INR]) should be obtained because most patients will receive antithrombotic therapy that increases the risk for bleeding.
- Fasting lipid panel within 24 hours.

Other Diagnostic Tests

- The 12-lead ECG is the first step in management. Patients are risk stratified into two groups: STEMI or NSTE-ACS.
- High-risk ACS patients, especially those with STEMI and those with recurrent chest discomfort will undergo coronary angiography via a left heart catheterization and injection of contrast dye into the coronary arteries to determine the presence and extent of coronary artery stenoses with possible PCI.
- During hospitalization, a measurement of LVF, such as an echocardiogram, is performed to identify patients with EF less than or equal to 40% (0.40) who are at high risk of death following hospital discharge.
- Selected low-risk patients may undergo early stress testing.

(Modified with permission from Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:168.)

Biochemical Markers/Cardiac Enzymes

LO 2

Biochemical markers of myocardial cell death are important for confirming the diagnosis of MI. KEY CONCEPT The diagnosis of MI is confirmed when the following conditions are met in a clinical setting consistent with myocardial ischemia: "Detection of a rise and/or fall of cardiac biomarkers with at least one value above the 99th percentile of the upper reference limit and with at least one of the following: (a) symptoms of ischemia; (b) ECG changes of new ischemia or development of pathological Q waves; (c) imaging evidence of new loss of viable myocardium; (d) new regional wall motion abnormality; or (e) identification of an intracoronary thrombus by angiography or autopsy."[9] The most recent guidelines indicate that only the use of troponin assays is recommended to assess myocardial necrosis. Typically, troponin levels are obtained at presentation, then 3 to 6 hours later in patients with a high suspicion of MI to identify variations (increase or decrease ≥ 20% if the initial value is increased). In patients with normal troponin levels with an intermediate or high suspicion of ACS, additional levels should be obtained after 6 hours.[4] Troponins are released into the bloodstream approximately 2 to 4 hours after an MI and generally peak around 18 to 24 hours. Troponins can stay elevated for up to two weeks. A single measurement of troponin is not adequate to exclude a diagnosis of MI, as up to 15% of values that were initially below the level of detection (a "negative" test) rise to the level of detection (a "positive" test) in subsequent hours. Additionally, a single "positive" troponin may not be secondary to an MI as elevations can occur in other clinical conditions, such as pulmonary embolus, tachyarrhythmias, pericarditis, myocarditis, and sepsis, which can complicate diagnosis. Measurement of N-terminal pro B-type natriuretic peptide (BNP) may help predict long-term risk of mortality in patients with ACS but does not aid with acute diagnosis.[4]

Risk Stratification

KEY CONCEPT Patient symptoms, past medical history, ECG, and troponins are utilized to stratify patients into low, medium, or high risk of death, MI, or likelihood of failing pharmacotherapy and needing urgent coronary angiography and PCI (Table 8–1). Initial treatment according to risk stratification is depicted in Figure 8–1.[3,4] Patients with STEMI are at the highest risk of death; therefore, immediate reperfusion strategies should be initiated. The ACCF/AHA/SCAI PCI guidelines define a target time to initiate reperfusion treatment as within 30 minutes of first medical contact for fibrinolytics (eg, alteplase, reteplase, and tenecteplase) and within 90 minutes from presentation for primary PCI.[5] The sooner the infarct-related coronary artery is opened, the lower

Table 8–1

Risk Stratification for Acute Coronary Syndromes[4]

TIMI Risk Score for NSTE-ACS

One point is assigned for each of the seven medical history and clinical presentation findings below. The point total is calculated, and the patient is assigned a risk for experiencing the composite endpoint of death, MI, or urgent need for revascularization.

- Age 65 years or older
- Three or more CHD risk factors: smoking, hypercholesterolemia, HTN, DM, family history of premature CHD death/events
- Known CAD (50% or greater stenosis of at least one major coronary artery on coronary angiogram)
- Aspirin use within the past 7 days
- Two or more episodes of chest discomfort within the past 24 hours
- ST-segment depression 0.5 mm or greater
- Positive biochemical marker for infarction

High-Risk	Medium-Risk	Low-Risk
TIMI Risk Score 5–7 points	TIMI Risk Score 3–4 points	TIMI Risk Score 0–2 points

TIMI Risk Score	Mortality, MI, or Severe Recurrent Ischemia Requiring Urgent Revascularization Through 14 Days
0/1	4.7%
2	8.3%
3	13.2%
4	19.9%
5	26.2%
6/7	40.9%

GRACE Risk Factors for Increased Mortality and the Composite of Death or MI in ACS

Signs and symptoms of HF
Low systolic BP
Elevated heart rate
Older age
Elevated SCr
Baseline risk factors on clinical evaluation: cardiac arrest at admission, ST-segment deviation, elevated troponin
A high-risk patient is defined as a GRACE Risk Score more than 140 points (for in-hospital mortality)
The clinical application tool is available at http://www.outcomes-umassmed.org/grace/

An online calculator for the GRACE Risk Model is available at http://www.outcomes-umassmed.org/GRACE/acs_risk/acs_risk_content.html (Accessed August 28, 2017).

ACS, acute coronary syndrome; BP, blood pressure; CAD, coronary artery disease; CHD, coronary heart disease; DM, diabetes mellitus; GRACE, Global Registry of Acute Coronary Events; HF, heart failure; HTN, hypertension; MI, myocardial infarction; NSTE, non–ST-segment elevation; SCr, serum creatinine; TIMI, thrombolysis in myocardial infarction.

the mortality and the greater the amount of myocardium that is preserved.[5] Although all patients should be evaluated for reperfusion therapy, not all patients may be eligible. Indications and contraindications for fibrinolytic therapy are described in the treatment section of this chapter. If patients with STEMI are not eligible for reperfusion therapy, additional pharmacotherapy should be initiated in the ED and the patient transferred to a coronary intensive care unit.

Risk-stratification of the patient with NSTE-ACS is more complex because outcomes vary. Patients with a high likelihood of coronary ischemia have a greater risk of adverse cardiac events.[4] Not all patients presenting with suspected NSTE-ACS have CAD. Some are eventually diagnosed with nonischemic chest discomfort. In general, among NSTE-ACS patients, those with ST-segment depression (see Figure 8–1) and/or elevated biomarkers are at higher risk of death or recurrent infarction. Various risk scores are available and should be used to assess the prognosis of patients presenting with NSTE-ACS (see Table 8–1).[4]

Based on this risk assessment, a management strategy is chosen and patients are either treated using: (1) an invasive strategy, which involves coronary angiography in patients classified as high-risk or very high-risk of CV events based on clinical characteristics (eg, high TIMI [Thrombolysis in Myocardial Infarction] score), or (2) an ischemia-guided strategy in which patients initially receive medication therapy alone and will undergo an invasive evaluation only if they fail medical therapy (eg, continued ischemia despite optimal medical treatment) or have objective evidence of ischemia on noninvasive stress testing.[4] The ischemia-guided strategy is generally reserved for patients stratified as low-risk. The timing of the diagnostic angiography in moderate- to high-risk patients is generally guided by the short-term risk of the patients, with the invasive strategy of early coronary angiography preferred in very-high and high-risk individuals.[4]

TREATMENT

Desired Outcomes

Short-term desired outcomes in a patient with ACS are: (a) early restoration of blood flow to the infarct-related artery to prevent infarct expansion (in the case of MI) or prevent complete occlusion and MI (in UA); (b) prevention of death and other MI complications; (c) prevention of coronary artery reocclusion; (d) relief of ischemic chest discomfort; and (e) resolution of ST-segment and T-wave changes on the ECG.

Long-term desired outcomes are control of CV risk factors, prevention of additional CV events, including reinfarction, stroke, and HF, and improvement in quality of life.

General Approach to Treatment

Selecting evidence-based therapies described in the guidelines for patients without contraindications results in lower mortality.[3,4] General treatment measures for all STEMI and high- and intermediate-risk NSTE-ACS patients include admission to hospital, oxygen administration (if oxygen saturation is low, < 90% [0.90] or respiratory distress), continuous multilead ST-segment monitoring for arrhythmias and ischemia, frequent measurement of vital signs, bed rest for 12 hours in hemodynamically stable patients, avoidance of the Valsalva maneuver (prescribe stool softeners routinely), and pain relief (Figures 8–2 and 8–3).[3,4]

Because risk varies and resources are limited, it is important to triage and treat patients according to their risk category. Initial approaches to treatment of STEMI and NSTE-ACS patients are outlined in Figures 8–2 and 8–3. Patients with STE are at high risk of death, and efforts to reestablish coronary perfusion as well as adjunctive pharmacotherapy should be initiated immediately (see Figure 8–2). Features identifying low-, moderate-, and high-risk NSTE-ACS patients are described in Table 8–1 and treatment efforts are outlined in Figure 8–3.[4]

Patient Encounter 1, Part 1

A 62-year-old, 87-kg (191-lb) Hispanic male developed substernal chest squeezing and left arm tingling while raking leaves. When it was not relieved by rest, his wife called 911. Local paramedics arrived and ST-segment elevation was found on 12-lead ECG. He was given a total of three 0.4 mg sublingual nitroglycerin tablets by mouth over three successive doses, 325 mg ASA by mouth, and morphine 2-mg IV push without relief of discomfort upon transport to the emergency department (ED). He was taken to a facility with a cardiac catheterization laboratory with the intent of performing primary PCI.

PMH: Hypertension (HTN) for 7 years; dyslipidemia for 7 years; diabetes mellitus (DM) type 2 for 5 years; chronic kidney disease (CKD) for 2 years

FH: Mother with stroke at age 65 years; father with myocardial infarction at age 55 years; siblings with HTN and DM

SH: Nonsmoker, never smoked

Allergies: NKDA

Meds: Lisinopril 20 mg by mouth once daily; amlodipine 10 mg by mouth once daily; ASA 81 mg by mouth once daily; rosuvastatin 5 mg by mouth once daily

ROS: substernal chest discomfort

PE:

HEENT: Normocephalic atraumatic

CV: Regular rate and rhythm; S_1, S_2, no S_3, no S_4; no murmurs or rubs

VS: BP 140/90 mm Hg; HR 88 beats/min; T 37°C (98.6°F)

Lungs: Fine crackles at the lower bases

Abd: Nontender, nondistended

GI: Normal bowel sounds

GU: Stool guaiac negative

Exts: No bruits, No peripheral edema, pulses 2+, femoral pulses present, good range of motion

Neuro: Alert and oriented × 3, cranial nerves intact

Labs: Sodium 139 mEq/L (mmol/L), potassium 3.7 mEq/L (mmol/L), chloride 103 mEq/L (mmol/L), bicarbonate 21 mEq/L (mmol/L), SCr 1.6 mg/dL (141 µmol/L), glucose 155 mg/dL (8.6 mmol/L), WBC 9.9 × 10^3/mm^3 (9.9 × 10^9/L), hemoglobin 14.7 g/dL (147 g/L or 9.12 mmol/L), hematocrit 43% (0.43), platelets 220 × 10^3/mm^3 (220 × 10^9/L), troponin I 4.8 ng/mL (4800 ng/L), oxygen saturation 96% (0.96) on room air, N-terminal proBNP 500 pg/mL (59 pmol/L)

ECG: Normal sinus rhythm, PR 0.16 seconds, QRS 0.08 seconds, QTc 0.38 seconds, 2-mm ST-segment elevation in 2 or more contiguous anterior leads

CXR: No active disease

Echo: Anterior wall dyskinesis, LVEF 40% (0.40)

What information is suggestive of acute MI?

Are any complications of MI present?

Reperfusion Strategies for ACS

▶ *Reperfusion Strategies for STEMIs*

KEY CONCEPT Early reperfusion therapy with primary PCI of the infarct artery within 90 minutes from the time of hospital presentation is the reperfusion treatment of choice for patients with STEMI who present within 12 hours of symptom onset (see Figure 8–2).[3] Patients may not often recognize the importance of seeking immediate medical care for a variety of reasons, which include self-treatment and preconception regarding the importance or presentation of a heart attack. Thus, education to patients and their families about the symptoms of ACS is paramount to reduce delays in reperfusion.

For primary PCI in STEMI, the patient is taken from the ED to the cardiac catheterization laboratory and undergoes coronary angiography with either balloon angioplasty or, preferably, placement of a bare metal or drug-eluting intracoronary stent in the artery associated with the infarct.[5] Results of biochemical marker tests do not need to be available when the decision to proceed to primary PCI is made. Findings from a meta-analysis of trials comparing fibrinolysis with primary PCI indicate a lower mortality rate with primary PCI.[13] One reason for the superiority of primary PCI compared with fibrinolysis is that more than 90% of occluded infarct-related coronary arteries are opened with primary PCI compared with fewer than 60% with fibrinolytics.[3,5] In addition, intracranial hemorrhage (ICH) and major bleeding risks from primary PCI are lower than the risks of severe bleeding events following fibrinolysis.[14] An invasive strategy of primary PCI is generally preferred in patients presenting to institutions with skilled interventional cardiologists and a catheterization laboratory immediately available, those in cardiogenic shock, those with contraindications to fibrinolytics, and those with continuing symptoms 12 to 24 hours after symptom onset.[3] Current guidelines indicate that the time from first medical contact-to-device should be less than or equal to 90 minutes, with every effort made to ensure the time to reperfusion is as short as possible.[3]

Patients presenting to facilities that do not have interventional cardiology services can be transferred when a protocol that minimizes delays has been established between institutions and if primary PCI can be performed within the first 120 minutes of first medical contact.[3,14] Immediate transfer to a PCI-capable facility is recommended for patients who develop cardiogenic shock or acute severe HF, irrespective of the timing of presentation. PCI during hospitalization for STEMI, or transfer to a PCI-capable hospital, is also appropriate in those in whom fibrinolysis is not successful and those with persistent rest ischemia or signs of ischemia on stress testing following MI.[3,5]

▶ *Fibrinolytic Therapy for STEMI*

LO 3

Administration of a fibrinolytic agent is indicated in patients with STEMI who present to the hospital within 12 hours of the onset of chest discomfort, who are initially seen at a non-PCI-capable hospital and who have an anticipated time from first medical contact-to-device greater than 120 minutes if transferred to a PCI capable hospital (see Figure 8–2).[3] The reduction in mortality with fibrinolysis is greatest with early administration and diminishes after 12 hours. The use of fibrinolytics between

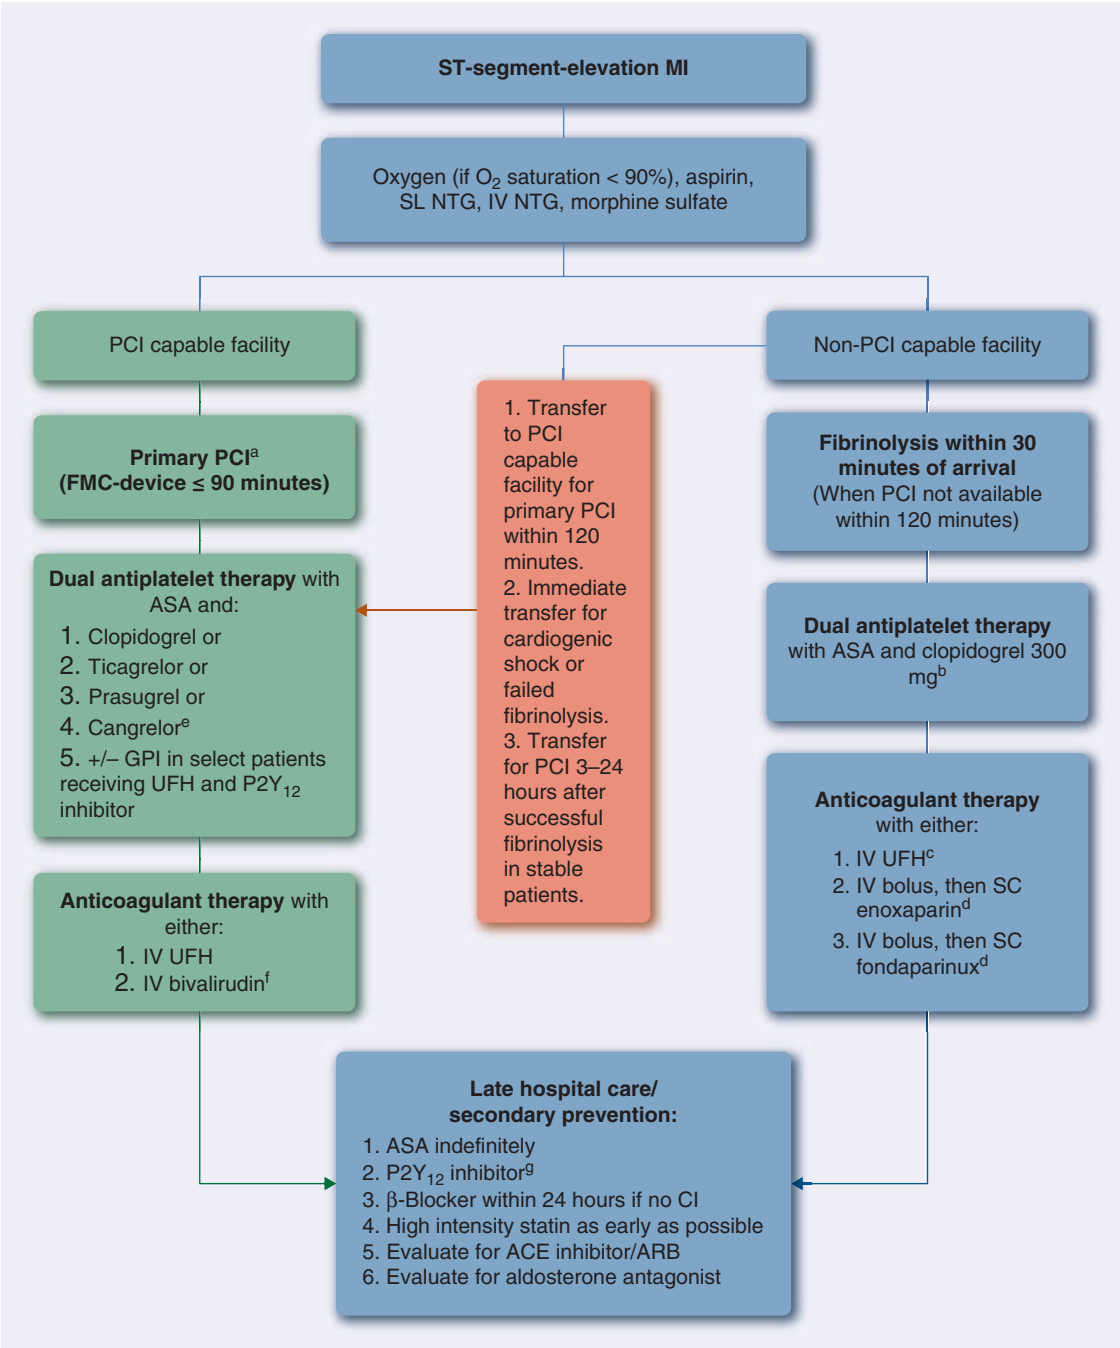

FIGURE 8–2. Initial pharmacotherapy for ST-segment elevation myocardial infarction. See Table 8–3 for dosing recommendations and contraindications to specific therapies. [a]Options after coronary angiography also include medical management alone or coronary artery bypass graft surgery. [b]Clopidogrel preferred $P2Y_{12}$ when fibrinolytic therapy is utilized. No loading dose recommended if age older than 75 years. [c]Given for up to 48 hours or until revascularization. [d]Given for the duration of hospitalization, up to 8 days or until revascularization. [e]For use as adjunct therapy during PCI only. Administer ticagrelor at any time prior to or during the cangrelor infusion. Administer prasugrel or clopidogrel after the cangrelor infusion. [f]If pretreated with UFH, stop UFH infusion for 30 minutes prior to administration of bivalirudin (bolus plus infusion). [g]In patients with STEMI receiving a fibrinolytic or who do not receive reperfusion therapy, administer clopidogrel for at least 14 days and ideally up to 1 year. (ACE, angiotensin-converting enzyme; ARB, angiotensin receptor blocker; ASA, aspirin; CI, contraindication; FMC, first medical contact; GPI, glycoprotein IIb/IIIa inhibitor; IV, intravenous; MI, myocardial infarction; NTG, nitroglycerin; PCI, percutaneous coronary intervention; SC, subcutaneous; SL, sublingual; UFH, unfractionated heparin.)

12 and 24 hours after symptom onset should be limited to patients with ongoing ischemia. Fibrinolytic therapy is preferred over primary PCI when there is no cardiac catheterization laboratory in a hospital and the delay from first medical contact-to-device would exceed 120 minutes if the patient was transferred to a PCI-capable hospital.[3] Guidelines recommend that the fibrinolytic agent be administered within 30 minutes of arrival.[3] All hospitals should have protocols addressing

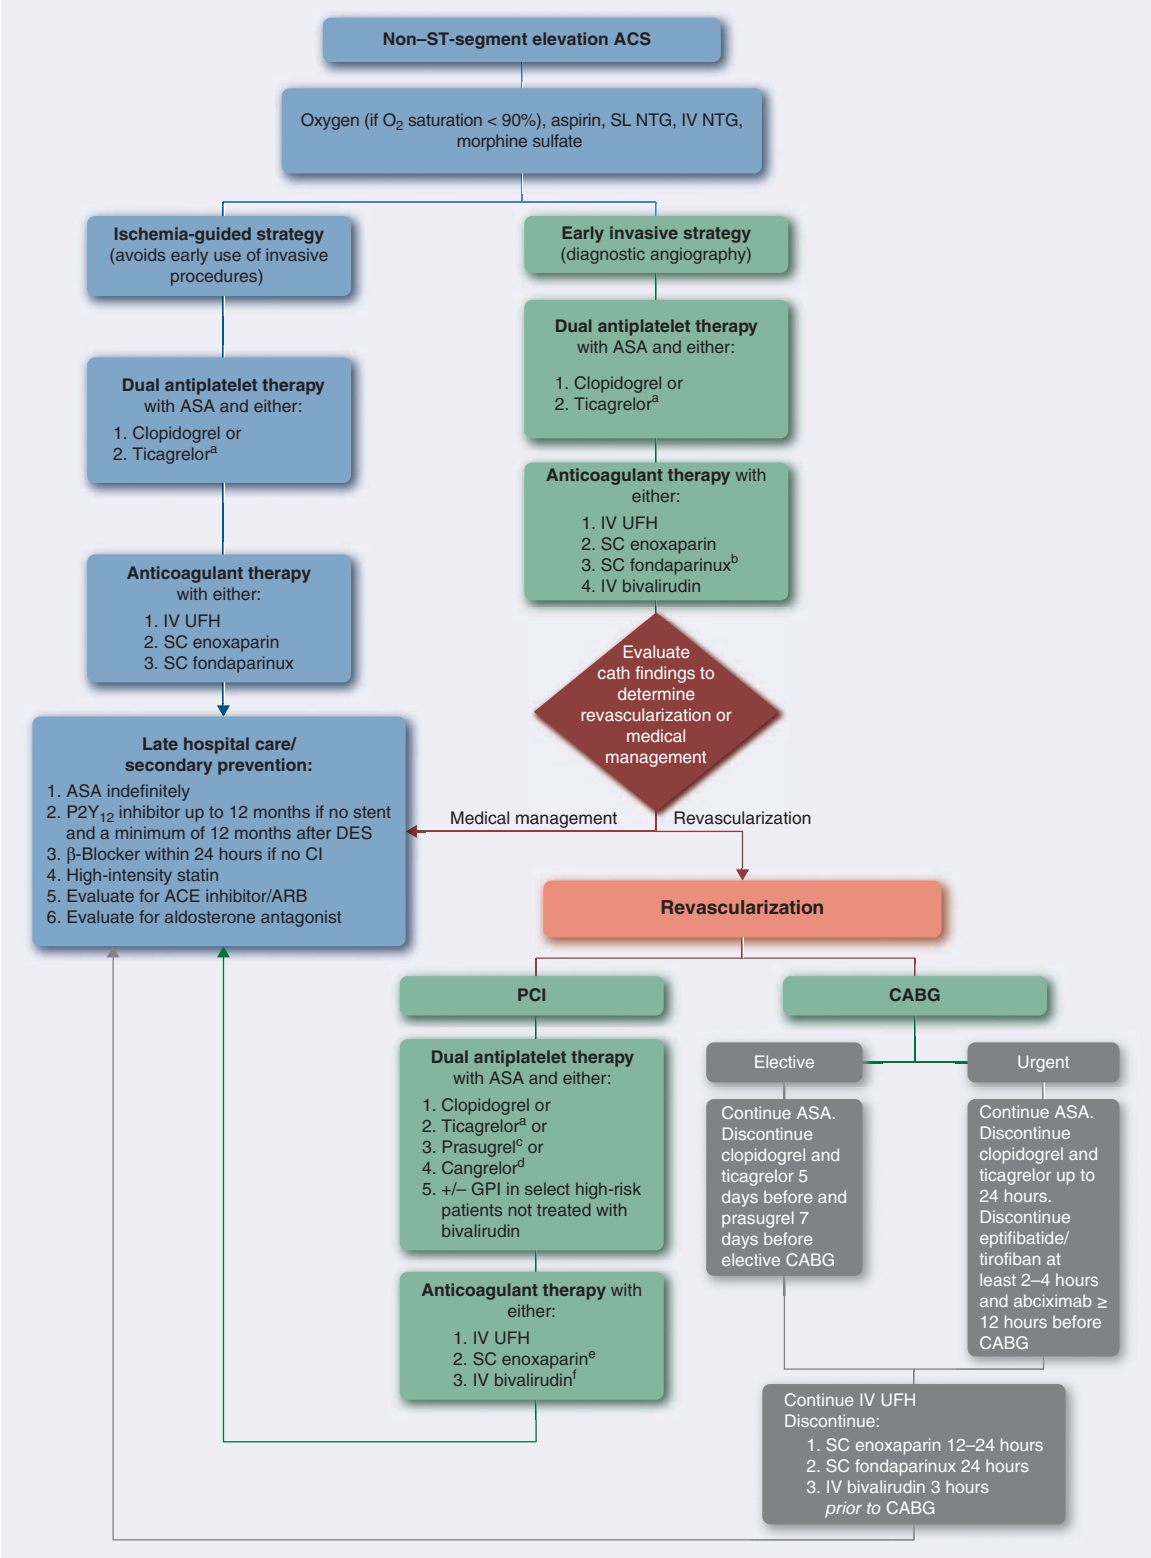

FIGURE 8–3. Initial pharmacotherapy for non–ST-segment elevation (NSTE) ACS. See Table 8–3 for dosing recommendations and contraindications to specific therapies. [a]Reasonable to choose ticagrelor over clopidogrel for maintenance $P2Y_{12}$ for NSTE-ACS patients treated with an early invasive or ischemia-guided strategy. [b]Not to be used as the sole anticoagulant during PCI. Give additional UFH 85 units/kg IV without GPI and 60 units/kg IV with GPI. [c]Reasonable to choose prasugrel over clopidogrel for maintenance $P2Y_{12}$ for NSTE-ACS patients undergoing PCI who are not at high risk for bleeding. Do not use if prior history of stroke/transient ischemic attack (TIA), age older than 75 years, or body weight less than or equal to 60 kg (132 lb). [d]Adjunct agent to be used during PCI only. Administer ticagrelor at any time prior to or during the cangrelor infusion. Administer prasugrel or clopidogrel after the cangrelor infusion. [e]May require IV supplemental dose of enoxaparin; see Table 8–3. [f]If pretreated with UFH, stop UFH infusion for 30 minutes prior to administration of bivalirudin bolus plus infusion. (ACE, angiotensin-converting enzyme; ACS, acute coronary syndrome; ARB, angiotensin receptor blocker; ASA, aspirin; CABG, coronary artery bypass graft; CI, contraindication; DES, drug-eluting stent; GPI, glycoprotein IIb/IIIa inhibitor; IV, intravenous; NTG, nitroglycerin; PCI, percutaneous coronary intervention; SC, subcutaneous; SL, sublingual; UFH, unfractionated heparin).

Table 8–2

Indications and Contraindications to Fibrinolytic Therapy for Management of ST-Segment Elevation Myocardial Infarction[3]

Indications

1. Ischemic chest discomfort at least 20 minutes in duration but 12 hours or less since symptom onset
   and
   ST-segment elevation of at least two contiguous leads of ≥ 2 mm in men and ≥ 1.5 mm in women in leads V_2-V_3 and/or of ≥ 1 mm in other leads, or new or presumed new left bundle-branch block
2. Ongoing ischemic chest discomfort at least 20 minutes in duration 12–24 hours since symptom onset
   and
   ST-segment elevation of at least two contiguous leads of ≥ 2 mm in men and ≥ 1.5 mm in women in leads V_2-V_3 and/or of ≥ 1 mm in other leads

Absolute Contraindications

- Active internal bleeding (not including menses)
- Previous intracranial hemorrhage at any time; ischemic stroke within 3 months (except acute ischemic stroke within 4.5 hours)
- Known intracranial neoplasm
- Known structural cerebral vascular lesion (eg, arteriovenous malformation)
- Suspected aortic dissection
- Significant closed head or facial trauma within 3 months
- Intracranial or intraspinal surgery within 2 months
- Severe uncontrolled hypertension (unresponsive to emergency therapy)
- For streptokinase, prior treatment within the previous 6 months

Modified with permission from: Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:177.

fibrinolysis eligibility, dosing, and monitoring. Indications and contraindications for fibrinolysis are listed in Table 8–2.[3] It is not necessary to obtain the results of biochemical markers before initiating fibrinolytic therapy.

Because administration of fibrinolytics results in clot lysis, patients who are at high risk of major bleeding (including ICH) presenting with an absolute contraindication should not receive fibrinolytic therapy; primary PCI is preferred.

Generally, a more fibrin-specific agent such as alteplase, reteplase, or tenecteplase is preferred over a non-fibrin-specific agent such as streptokinase.[3] Fibrin-specific fibrinolytics open a greater percentage of infarcted arteries. In a large clinical trial, administration of alteplase resulted in a 1% absolute reduction in mortality and cost about $30,000 per year of life saved compared with streptokinase.[15] Other trials compared alteplase with reteplase and alteplase with tenecteplase and found similar mortality between agents.[16,17] Therefore, either alteplase, reteplase, or tenecteplase is acceptable as a first-line agent. ICH and major bleeding are the most serious side effects of fibrinolytic agents. The risk of ICH is higher with fibrin-specific agents than with streptokinase.[18] However, the risk of systemic bleeding other than ICH is higher with streptokinase than with other more fibrin-specific agents and was higher with alteplase versus tenecteplase in one study.[3,16,18]

Fibrinolytic therapy is not indicated and should not be used in patients with NSTE-ACS because increased mortality has been reported with these agents compared with controls in clinical trials.[3]

Patient Encounter 1, Part 2

Identify your acute treatment goals for this patient with STEMI.

What adjunctive pharmacotherapy should be administered in the emergency department prior to proceeding to the cardiac catheterization laboratory?

What additional pharmacotherapy should be initiated on the first day of this patient's hospitalization following successful PCI/intracoronary stenting?

▶ *Early Invasive Therapy for NSTE-ACS*

KEY CONCEPT Clinical practice guidelines recommend coronary angiography followed by either PCI or coronary artery bypass graft (CABG) surgery revascularization as an early treatment (early invasive strategy) for patients with NSTE-ACS at an elevated risk for death or MI, including those with a high-risk score (see Table 8–1) or patients with refractory angina, hemodynamic instability or electrical instability (see Figure 8–3).[4,5] Several clinical trials support an "invasive" interventional strategy with early angiography and PCI or CABG versus an ischemia-guided approach, whereby coronary angiography with revascularization is reserved for patients with symptoms refractory to pharmacotherapy and patients with signs of ischemia on stress testing.[4,19] An early invasive approach results in a long-term reduction in the rates of CV death or MI, with the largest absolute effect seen in higher-risk patients.[4] Several studies have also shown less angina, fewer hospitalizations, and improved quality of life with an invasive strategy.[4]

LO 4

All patients undergoing PCI should receive ASA therapy indefinitely. A $P2Y_{12}$ inhibitor antiplatelet (clopidogrel, prasugrel, or ticagrelor) should be administered concomitantly with ASA for at least 12 months following PCI for a patient with ACS (Table 8–3).[3,4,20] A longer duration of $P2Y_{12}$ inhibitor therapy may be considered for select patients with a low-bleeding risk receiving a drug-eluting stent (DES) because the risk of stent thrombosis is greater upon cessation of dual antiplatelet therapy (DAPT).[3,4] This is because although DES reduce the rate of smooth muscle cell growth that causes stent restenosis, they induce a delay in endothelial cell regrowth at the site of the stent (re-epithelialization in arterial lumen) that places the patient at higher risk of thrombotic events following PCI, especially stent thrombosis. This explains why DAPT may be beneficial for a longer period of time following PCI with a DES when compared to patients receiving a bare metal stent (BMS). Nevertheless, recent trials have provided uncertain evidence regarding the benefit of continuing DAPT beyond 12 months for patients with an ACS, while the risk of bleeding persists.[21] Until data from larger trials evaluating the need for an extended duration (> 12 months) of $P2Y_{12}$ inhibitor therapy following PCI are available, the preferred duration of $P2Y_{12}$ therapy is at least a year regardless of whether a patient with NSTE-ACS or STEMI receives a stent.[4]

Ischemia-Guided Therapy for NSTE-ACS and STEMI

For patients with NSTE-ACS, an initial ischemia-guided strategy is recommended for patients with a low-risk score, normal

Table 8–3

Evidence-Based Pharmacotherapy for ST-Segment Elevation Myocardial Infarction and Non–ST-Segment Elevation Acute Coronary Syndrome[3,4,20]

Drug	Clinical Condition and Guideline Recommendations[a]	Contraindications[b]	Dose and Duration of Therapy
Aspirin	STEMI, class I recommendation for all patients. NSTE-ACS, class I recommendation for all patients.	Hypersensitivity, active bleeding, severe bleeding risk.	162–325 mg orally once on hospital day 1. 81–325 mg once daily orally starting hospital day 2 and continued indefinitely in all patients. Aspirin dose of 81 mg is preferred. Limit dose to < 100 mg if using ticagrelor.
Clopidogrel	NSTE-ACS, class I recommendation added to aspirin. STEMI, class I recommendation added to aspirin. PCI in STEMI and NSTE-ACS, class I recommendation. In patients with aspirin allergy, class I recommendation.	Hypersensitivity, active bleeding, severe bleeding risk.	300- to 600-mg oral loading dose on hospital day 1 followed by a maintenance dose of 75 mg once daily starting on hospital day 2 in patients with NSTE-ACS. 300-mg oral loading dose followed by 75 mg orally daily in patients receiving a fibrinolytic or who do not receive reperfusion therapy with a STEMI; avoid loading dose in patients ≥ 75 years. 600-mg (class I recommendation) loading dose before or when PCI performed (unless within 24 hours of fibrinolytic therapy, a dose of 300 mg should be given). Discontinue at least 5 days before CABG surgery if bleeding risk outweighs benefit (class I recommendation). Administer indefinitely in patients with aspirin allergy (class I recommendation). Continue for at least 12 months (class I recommendation) and possibly beyond 12 months (class IIb recommendation) in patients with ACS managed with PCI/stent. In patients with NSTE-ACS treated medically, administer for up to 12 months (class I recommendation). In patients receiving a fibrinolytic or who do not receive reperfusion therapy, administer for at least 14 days (class I recommendation) and ideally up to 12 months. Genetic testing might be considered to identify patients at high risk of poor response (class IIb recommendation). In these patients, an alternative $P2Y_{12}$ inhibitor might be considered (class IIb recommendation). The routine use of genetic testing is not recommended (class III recommendation).
Prasugrel	PCI in STE and NSTE-ACS, added to aspirin, class I recommendation. Class IIa as preference over clopidogrel for those not at high risk of bleeding and do not have a history of stroke/TIA.	Active bleeding, prior stroke or TIA.	Initiate in patients with known coronary artery anatomy only (so as to avoid use in patients needing CABG surgery; class I recommendation). Give no later than 1 hour after PCI. Patients who have history of prior stroke/TIA, are 75 years of age or more, or weigh < 60 kg (132 lb) have higher risk of bleeding and there's no added benefit compared with clopidogrel. 60-mg oral loading dose followed by 10 mg once daily for patients weighing 60 kg (132 lb) or more. Consider 5 mg once daily in patients weighing < 60 kg (132 lb) (based on limited data). Discontinue at least 7 days prior to CABG surgery if bleeding risk outweighs benefit (class I recommendation). Continue for at least 12 months (class I recommendation) and possibly beyond 12 months (class IIb recommendation) in patients with ACS managed with PCI/stent.
Ticagrelor	PCI in STEMI and NSTE-ACS, added to aspirin, class I recommendation. Class IIa as preference over clopidogrel.	Active bleeding.	180-mg (class I recommendation) oral loading dose in patients undergoing PCI or ischemia-guided management, followed by 90 mg twice daily for at least 12 months (class I recommendation) and possibly beyond 12 months (class IIb recommendation) in patients with ACS managed with PCI/stent. Current data are too limited to recommend use in patients with STEMI not undergoing primary PCI. Discontinue at least 5 days prior to CABG surgery if bleeding risk outweighs benefit (class I recommendation).
Cangrelor	PCI-adjunct in patients not treated with oral $P2Y_{12}$ inhibitor or GPI.	Active bleeding.	30 mcg/kg IV bolus initiated prior to PCI followed by 4 mcg/kg/min IV infusion for duration of PCI or 2 hours, whichever is longer. To maintain platelet inhibition after infusion, initiate oral $P2Y_{12}$ agent as follows: ticagrelor 180 mg at any time during or immediately after infusion; prasugrel 60 mg or clopidogrel 600 mg immediately after discontinuation of infusion. Do not administer prasugrel or clopidogrel during infusion of cangrelor. There is no antiplatelet effect of cangrelor 1 hour after discontinuation of infusion.

Unfractionated heparin	STEMI, class I recommendation in patients undergoing PCI and for those patients treated with fibrinolytics. NSTE-ACS, class I recommendation in combination with antiplatelet therapy for ischemia-guided or early invasive approach PCI, class I recommendation (NSTE-ACS and STEMI).	Active bleeding, history of heparin-induced thrombocytopenia, severe bleeding risk, recent stroke.	For STEMI with fibrinolytics, administer an initial 60-units/kg IV bolus (maximum 4000 units) heparin followed by a constant IV infusion at 12-units/kg/hour (maximum 1000 units/hour). Titrate to therapeutic aPTT. For STEMI primary PCI, administer 50- to 70-units/kg IV bolus if a GPI planned; 70–100 units/kg IV bolus if no GPI planned and supplement with IV bolus doses to maintain target ACT. For NSTE-ACS, administer 60-units/kg IV bolus (maximum 4000 units) followed by a constant IV infusion at 12 units/kg/hour (maximum 1000 units/hour). Titrated to maintain an aPTT of 1.5–2.0 times control (approximately 50–70 seconds) for STEMI with fibrinolytics and for NSTE-ACS. Titrated to ACT of 250–350 seconds for primary PCI without a GPI and 200–250 seconds in patients given a concomitant GPI. The first aPTT should be measured at 4–6 hours for NSTE-ACS and STEMI in patients not treated with fibrinolytics or undergoing primary PCI. The first aPTT should be measured at 3 hours in patients with STEMI who are treated with fibrinolytics. Continue for 48 hours or until revascularization.
Enoxaparin	STEMI class I recommendation in patients receiving fibrinolytics. NSTE-ACS, class I recommendation in combination with aspirin for ischemia-guided or early invasive strategy. For PCI, class IIa recommendation as an alternative to UFH in patients with NSTE-ACS.	Active bleeding, history of heparin-induced thrombocytopenia, severe bleeding risk, recent stroke, avoid enoxaparin if CrCl < 15 mL/min (0.25 mL/s), avoid if CABG surgery planned.	Enoxaparin 1 mg/kg SC every 12 hours for patients (CrCl ≥ 30 mL/min [0.50 mL/s]). Enoxaparin 1 mg/kg SC every 24 hours (CrCl 15–29 mL/min [0.25–0.49 mL/s]). For all patients undergoing PCI following initiation of SC enoxaparin for NSTE-ACS or STEMI, a supplemental 0.3-mg/kg IV dose of enoxaparin should be administered at the time of PCI if the last dose of SC enoxaparin was given 8–12 hours prior to PCI or received < 2 therapeutic SC doses. For patients with STEMI receiving fibrinolytics: • Age < 75 years: Administer enoxaparin 30-mg IV bolus followed in 15 minutes by 1 mg/kg. • SC every 12 hours (first two doses administer maximum of 100 mg for patients weighing > 100 kg). • Age ≥ 75 years: Administer enoxaparin 0.75-mg/kg SC every 12 hours (first two doses administer maximum of 75 mg). • Continue throughout hospitalization, up to 8 days, or until revascularization. Continue for duration of hospitalization for NSTE-ACS or until revascularization. Discontinue at least 12–24 hours before CABG surgery.
Bivalirudin	NSTE-ACS class I recommendation for invasive strategy. PCI in STEMI (class I recommendation).	Active bleeding, severe bleeding risk.	For NSTE-ACS, administer 0.1 mg/kg IV bolus followed by 0.25-mg/kg/hour infusion. For PCI in NSTE-ACS, administer a second bolus of 0.5 mg/kg IV and increase infusion rate to 1.75 mg/kg/hour. For PCI in STEMI, administer 0.75-mg/kg IV bolus followed by 1.75-mg/kg/hour infusion. If prior UFH given, discontinue UFH and wait 30 minutes before initiating bivalirudin. Adjust dose of infusion to 1 mg/kg/hr when CrCl < 30 mL/min (0.50 mL/s). Discontinue at end of PCI or continue at 0.25 mg/kg/hour if prolonged anticoagulation necessary. Lower bleeding rates are mitigated when administered with a GPI. Clopidogrel should be administered at least 6 hours before if a GPI is not used. Discontinue at least 3 hours prior to CABG surgery.
Fondaparinux	STEMI class I recommendation receiving fibrinolytics. NSTE-ACS class I recommendation for ischemia-guided or early invasive strategy. Class III as sole agent in PCI.	Active bleeding, severe bleeding risk, SCr ≥ 3.0 mg/dL (265 µmol/L) or CrCl < 30 mL/min (0.50 mL/s).	For STEMI, 2.5-mg IV bolus followed by 2.5-mg SC once daily starting on hospital day 2. For NSTE-ACS, 2.5-mg SC once daily. Continue throughout hospitalization, up to 8 days, or until revascularization. For PCI, give additional doses of either UFH or bivalirudin as recommended above. Discontinue at least 24 hours prior to CABG surgery.

(*Continued*)

Table 8–3

Evidence-Based Pharmacotherapy for ST-Segment Elevation Myocardial Infarction and Non–ST-Segment Elevation Acute Coronary Syndrome[3,4,20] (*Continued*)

Drug	Clinical Condition and Guideline Recommendations[a]	Contraindications[b]	Dose and Duration of Therapy
Fibrinolytic therapy	STEMI, class I recommendation for patients presenting within 12 hours following the onset of symptoms, class IIa in patients presenting between 12 and 24 hours following the onset of symptoms with continuing signs of ischemia. NSTE-ACS, class III recommendation.	Any prior ICH, known structural cerebrovascular lesions such as an arterial venous malformation, known intracranial malignant neoplasm, ischemic stroke within 3 months, active bleeding (excluding menses) or known bleeding diathesis, significant closed head or facial trauma within 3 months, severe uncontrolled HTN unresponsive to treatment.	Streptokinase: 1.5 MU IV over 60 minutes. Alteplase: 15-mg IV bolus followed by 0.75 mg/kg IV over 30 minutes (maximum 50 mg) followed by 0.5 mg/kg (max 35 mg) over 60 minutes (maximum dose 100 mg). Reteplase: 10 units IV × 2, 30 minutes apart. Tenecteplase: • < 60 kg (132 lb), 30-mg IV bolus • 60–69.9 kg (132–153 lb), 35-mg IV bolus • 70–80 kg (154–176 lb), 40-mg IV bolus
Glycoprotein IIb/IIIa receptor inhibitors	NSTE-ACS PCI, class I recommendation for abciximab, high-bolus dose tirofiban or double-bolus eptifibatide at the time of PCI in high-risk patients already receiving aspirin and not adequately pretreated with a $P2Y_{12}$ inhibitor and not receiving bivalirudin as the anticoagulant; class IIa at the time of PCI for high-risk patients already receiving aspirin and pretreated with a $P2Y_{12}$ inhibitor and receiving UFH; class IIb for early invasive strategies in high-risk patients already receiving DAPT; eptifibatide or tirofiban preferred. STEMI primary PCI, class IIa recommendation for abciximab, high-bolus dose tirofiban or double-bolus eptifibatide in patients receiving UFH; IIb for administration of upstream GPI when PCI is intended; IIb for intracoronary abciximab injection in select patients during PCI.	Active bleeding, thrombocytopenia, prior stroke, renal dialysis (eptifibatide).	**Drug** / **Dose** / **Dosing Adjustment for CKD** Abciximab: 0.25-mg/kg IV bolus followed by 0.125 mcg/kg/min (maximum 10-mcg/min) for 12 hours. None Eptifibatide: 180-mcg/kg IV bolus × 2, 10 minutes apart with an infusion of 2 mcg/kg/min for 18–24 hours after PCI. Reduce maintenance infusion to 1 mcg/kg/min for CrCl < 50 mL/min (0.83 mL/s); contraindicated if patient dependent on dialysis. Patients weighing 121 kg (267 lb) or more should receive a maximum infusion rate of 22.6 mg per bolus and a maximum rate of 15 mg/hour. Tirofiban: 25-mcg/kg IV bolus followed by an infusion of 0.15 mcg/kg/min for up to 18 hours. Reduce maintenance infusion to 0.075 mcg/kg/min for patients with CrCl ≤ 60 mL/min (1.0 mL/s).

Nitroglycerin	STEMI and NSTE-ACS, class I recommendation in patients with ongoing ischemic discomfort, control of HTN, or management of HF.	Hypotension, sildenafil, avanafil, tadalafil, or vardenafil are all contraindicated with nitrates.	0.4-mg SL, repeated every 5 minutes × 3 doses then assess need for IV infusion. 5- to 10-mcg/min IV infusion titrated up to 75–100 mcg/min until relief of symptoms or limiting side effects (headache) with a systolic BP < 90 mm Hg or > 30% below starting mean arterial pressure levels if significant HTN is present. Topical patches or oral nitrates are acceptable alternatives for patients without ongoing or refractory symptoms. Discontinue IV infusion after 24–48 hours.
β-Blockers[c]	STEMI and NSTE-ACS, class I recommendation for oral β-blockers in all patients without contraindications in the first 24 hours, class IIa for IV β-blockers in STEMI patients with HTN or those with ongoing ischemia. Class III for IV β-blockers in patients with risk factors for shock.	PR ECG interval > 0.24 seconds, second-degree or third-degree atrioventricular heart block, heart rate < 60 beats/min, systolic BP < 90 mm Hg, shock, left ventricular failure with decompensated HF, severe reactive airway disease.	Metoprolol 5-mg slow IV push (over 1–2 minutes), repeated every 5 min for a total of 15 mg followed in 1–2 hours by 25–50 mg orally every 6 hours; if a very conservative regimen is desired, initial doses can be reduced to 1–2 mg. Atenolol 5-mg IV dose followed in 5 minutes by a second 5-mg IV dose for a total of 10 mg followed in 1–2 hours by 50–100 mg orally once daily. Alternatively, initial IV therapy can be omitted and treatment started with oral dosing. For dosing of carvedilol, metoprolol succinate, and bisoprolol in patients with systolic HF, please refer to Chapter 6. Continue oral β-blocker for 3 years and possibly indefinitely.
Calcium channel blockers	NSTE-ACS class I recommendation for patients with ongoing ischemia or vasospasm who are already taking adequate doses of nitrates and β-blockers or in patients with contraindications or intolerance to β-blockers (diltiazem or verapamil preferred during initial presentation if EF > 40% [0.40]). NSTE-ACS, class IIb recommendation for diltiazem for patients with AMI.	Pulmonary edema, evidence of left ventricular dysfunction, systolic BP < 100 mm Hg, PR ECG segment to > 0.24 seconds second- or third-degree atrioventricular heart block for verapamil or diltiazem, pulse rate < 60 beats/min for diltiazem or verapamil.	Diltiazem 120–360 mg sustained release orally once daily. Verapamil 180–480 mg sustained release orally once daily. Amlodipine 5–10 mg orally once daily. Continue as indicated to manage angina, HTN, or arrhythmias.

ACE inhibitors	NSTE-ACS and STEMI, class I recommendation for patients with HF, left ventricular dysfunction and EF < 40% (0.40), DM, HTN, or stable CKD in the absence of contraindications. Consider in all patients with CAD (class I recommendation, class IIb in low-risk patients). Indicated indefinitely for all patients with EF < 40% (0.40) (class I recommendation).	Systolic BP < 100 mm Hg, history of intolerance to an ACE inhibitor, bilateral renal artery stenosis, serum potassium > 5.5 mEq/L (mmol/L), acute renal failure, pregnancy.	**Drug**	**Initial Dose (mg)**	**Target Dose (mg)**
			Captopril	6.25–12.5	50 twice daily orally to 50 three times daily
			Enalapril	2.5–5.0	10 twice daily orally
			Lisinopril	2.5–5.0	10–20 once daily orally
			Ramipril	1.25–2.5	5 twice daily or 10 once daily orally
			Trandolapril	1.0	4 once daily orally
Angiotensin receptor blockers	NSTEMI and STEMI, class I recommendation in patients with HF or left ventricular EF < 40% (0.40) and intolerant of an ACE inhibitor, class IIa recommendation in patients with clinical signs of HF or EF < 40% (0.40) and no documentation of ACE inhibitor intolerance. Class I in other ACE inhibitor–intolerant patients with HTN.	Systolic BP < 100 mm Hg, bilateral renal artery stenosis, serum potassium > 5.5 mEq/L (mmol/L), acute renal failure, pregnancy.	**Drug**	**Initial Dose (mg)**	**Target Dose (mg)**
			Candesartan	4–8	32 once daily orally
			Valsartan	40	160 twice daily orally
			Losartan	12.5–25	150 daily
			Continue indefinitely.

Table 8–3

Evidence-Based Pharmacotherapy for ST-Segment Elevation Myocardial Infarction and Non–ST-Segment Elevation Acute Coronary Syndrome[3,4,20] (*Continued*)

Drug	Clinical Condition and Guideline Recommendations[a]	Contraindications[b]	Dose and Duration of Therapy
Aldosterone antagonists	NSTEMI and STEMI class I recommendation in patients with EF ≤ 40% (0.40) and either DM or HF who are already receiving an ACE inhibitor and β-blocker.	Hypotension, hyperkalemia, serum potassium > 5.0 mEq/L (mmol/L), SCr ≥ 2.5 mg/dL (221 µmol/L) for men and ≥ 2.0 mg/dL (177 µmol/L) for women and/or CrCl ≤ 30 mL/min (0.50 mL/s) for spironolactone; SCr ≥ 2.0 mg/dL (177 µmol/L) for men or 1.8 mg/dL (159 µmol/L) for women or CrCl ≤ 50 mL/min (0.83 mL/s) for eplerenone.	**Drug** / **Initial Dose (mg)** / **Target Dose (mg)** Eplerenone / 25 / 50 once daily orally Spironolactone / 12.5 / 25–50 once daily orally Continue indefinitely.
Morphine sulfate	STEMI and NSTE-ACS class IIb recommendation for patients whose chest pain persists despite treatment with maximally tolerated anti-anginal drugs.	Hypotension, respiratory depression, confusion, obtundation.	1- to 5-mg IV bolus dose. May be repeated every 5–30 minutes as needed to relieve symptoms and maintain patient comfort.
Statins	NSTE-ACS and STEMI class I recommendation to initiate or continue high-intensity statin therapy during early hospital care.	Caution with use of fibrate and statin-specific drug interactions.	Atorvastatin 40–80 mg daily. Rosuvastatin 20–40 mg daily.

[a]Class I recommendations are conditions for which there is evidence and/or general agreement that a given procedure or treatment is useful and effective. Class II recommendations are those conditions for which there is conflicting evidence and/or divergence of opinion about the usefulness/efficacy of a procedure or treatment. For Class IIa recommendations, the weight of the evidence/opinion is in favor of usefulness/efficacy. Class IIb recommendations are those for which usefulness/efficacy is less well established by evidence/opinion. Class III recommendations are those where the procedure or treatment is not useful and may be harmful.

[b]Allergy or prior intolerance is a contraindication for all categories of drugs listed in this chart.

[c]Choice of the specific agent is not as important as ensuring that appropriate candidates receive this therapy. If there are concerns about patient intolerance due to existing pulmonary disease, especially asthma, selection should favor a short-acting agent, such as metoprolol, or the ultra short-acting agent esmolol. Mild wheezing or a history of chronic obstructive pulmonary disease should prompt a trial of a short-acting agent at a reduced dose (eg, 2.5-mg IV metoprolol, 12.5-mg oral metoprolol, or 25-mcg/kg/min esmolol as initial doses) rather than complete avoidance of β-blocker therapy.

ACE, angiotensin-converting enzyme inhibitor; ACS, acute coronary syndrome; ACT, activated clotting time; AMI, acute myocardial infarction; aPTT, activated partial thromboplastin time; BP, blood pressure; CABG, coronary artery bypass graft; CAD, coronary artery disease; CKD, chronic kidney disease; CrCl, creatinine clearance; DM, diabetes mellitus; ECG, electrocardiogram; EF, ejection fraction; GPI, glycoprotein IIb/IIIa inhibitor; HF, heart failure; HTN, hypertension; ICH, intracranial hemorrhage; IV, intravenous; NSTE, non–ST-segment elevation; PCI, percutaneous coronary intervention; SC, subcutaneous; SCr, serum creatinine; SL, sublingual; STEMI, ST-segment elevation myocardial infarction; TIA, transient ischemic attack; UFH, unfractionated heparin.

Modified with permission from Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:173–176.

ECGs, and negative troponin tests who are without recurrence of chest discomfort (see Figure 8–3).[4] An ischemia-guided strategy may also be the preferred approach in patients with extensive comorbidities in which the cumulative risks of comorbidities plus revascularization would outweigh the potential benefits of revascularization.

Stress testing (see Figure 8–1) is indicated in patients with NSTE-ACS when an initial ischemia-guided strategy is selected and for patients with STEMI where primary PCI was not performed and who do not have high-risk clinical characteristics for which earlier coronary angiography would be warranted.[3,4] Following the stress test, patients experiencing recurrent ischemia or symptoms despite optimal medical treatment or who are considered high-risk (see Table 8–1) should undergo left heart catheterization with coronary angiography and revascularization as indicated.[3,4] Patients with NSTE-ACS at low risk for recurrent CHD events following stress testing should be given ASA indefinitely and either clopidogrel or ticagrelor for up to 12 months following hospital discharge in addition to other secondary preventive pharmacotherapy described later in this chapter.[4] Patients with STEMI at low risk for recurrent CHD events should receive ASA indefinitely and clopidogrel for at least 14 days and up to 12 months in addition to other secondary preventive pharmacotherapy (see Figure 8–2).[3]

Early Pharmacologic Therapy for ACS

LO 3

Pharmacotherapy for early treatment of ACS is outlined in Figures 8–2 and 8–3 and Tables 8–2 and 8–3.[3-5] KEY CONCEPT According to ACC/ACCF/AHA STEMI and NSTE ACS practice guidelines, additional pharmacotherapy that all patients should receive within the first day of hospitalization, and preferably in the ED, are intranasal oxygen (if oxygen saturation is low), sublingual (SL) nitroglycerin (NTG), ASA, a $P2Y_{12}$ inhibitor (agent dependent on reperfusion strategy), and anticoagulation (agent dependent on reperfusion strategy). A GP IIb/IIIa inhibitor (GPI) may be administered with unfractionated heparin (UFH) for patients with STEMI undergoing primary PCI. High-risk patients with NSTE-ACS should proceed to early angiography (within 24 hours) and select high-risk patients may receive a GPI. Intravenous (IV) NTG may be given in select patients still experiencing pain despite SL NTG. It is reasonable to administer morphine to patients with refractory angina as an analgesic and a venodilator that lowers preload. Oral β-blockers should be initiated within the first day in patients without cardiogenic shock or other contraindications.[3,4] ACE inhibitors (or ARB in ACE inhibitor-intolerant patients) should be initiated in select patients during hospitalization with ACS.[3] High-intensity statin therapy should be initiated or continued during hospitalization in all patients without contraindications. Dosing and contraindications for SL and IV NTG, ASA, clopidogrel, β-blockers, ACE inhibitors, statins, anticoagulants, and fibrinolytics are listed in Table 8–3.[3,4,20]

► *Nitrates*

Nitrates promote the release of nitric oxide from the endothelium, which results in venous and arterial vasodilation. Venodilation lowers preload and myocardial oxygen demand. Arterial vasodilation may lower blood pressure (BP), thus reducing myocardial oxygen demand. Arterial vasodilation also relieves coronary artery vasospasm, dilating coronary arteries to improve myocardial blood flow and oxygenation. Randomized clinical trials failed to show a mortality benefit for IV nitrate therapy followed by oral nitrate therapy in acute MI.[4]

Patient Encounter 2, Part 1

A 56-year-old, 81-kg (178-lb) man presents to the ED by ambulance complaining of 5 hours of intermittent chest pressure while working at his office desk. His symptoms were not relieved with two antacid tablets. Local paramedics were called who gave the patient a total of three 0.4 mg sublingual nitroglycerin tablets over three successive doses and 325 mg ASA by mouth without relief of chest discomfort. The patient is transferred to the hospital where an early invasive strategy is chosen.

PMH: Dyslipidemia for 2 years

FH: Father died after myocardial infarction at age 65; mother and brother alive with HTN and dyslipidemia

SH: Nonsmoker

Allergies: NKDA

Meds: Atorvastatin 80 mg by mouth once daily at bedtime

ROS: Chest pressure

PE:

HEENT: Normocephalic atraumatic

CV: Regular rate and rhythm; S_1, S_2, no S_3, no S_4; no murmurs or rubs

VS: BP 138/88 mm Hg; HR 86 beats/min; T 37°C (98.6°F)

Lungs: Clear to auscultation and percussion

Abd: Nontender, nondistended

GI: Normal bowel sounds

GU: Stool guaiac negative

Exts: No bruits, no peripheral edema, pulses 2+, femoral pulses present, good range of motion

Neuro: Alert and oriented × 3, cranial nerves intact

Labs: Sodium 131 mEq/L (mmol/L), potassium 4.0 mEq/L (mmol/L), chloride 103 mEq/L (mmol/L), bicarbonate 23 mEq/L (mmol/L), SCr 0.8 mg/dL (71 µmol/L), glucose 88 mg/dL (4.9 mmol/L), WBC 4.9 × 10^3/mm^3 (4.9 × 10^9/L), hemoglobin 14.7 g/dL (147 g/L or 9.12 mmol/L), hematocrit 42% (0.42), platelets 226 × 10^3/mm^3 (226 × 10^9/L), troponin I 0.8 ng/mL (800 ng/L), oxygen saturation 99% (0.99) on room air, BNP 8600 pg/mL (2485 pmol/L)

ECG: Normal sinus rhythm, PR 0.16 seconds, QRS 0.08 seconds, QTc 0.38 seconds, 1-mm ST-segment depression in inferior leads

CXR: Normal

Echo: Inferior wall dyskinesis, LVEF 55% (0.55)

What type of ACS is this?

What information is suggestive of acute MI?

LO 3

In patients presenting with ACS, one SL NTG tablet should be administered every 5 minutes for up to three doses to relieve myocardial ischemia, unless contraindicated. IV NTG may be initiated in patients who have persistent ischemia, HF, or uncontrolled high BP in the absence of contraindications.[3,4] IV NTG is typically continued until revascularization is performed or for approximately 24 hours following ischemia relief.

The most significant adverse effects of nitrates are tachycardia, flushing, headache, and hypotension. Nitrate administration is contraindicated in patients who have received oral phosphodiesterase-5 inhibitors, such as sildenafil and vardenafil, within the past 24 hours, and tadalafil within the past 48 hours (see Table 8–3).[4]

▶ *Aspirin*

LO 3 ASA is the preferred antiplatelet agent in the treatment of ACS.[3,4] The antiplatelet effects of ASA are mediated by inhibiting the synthesis of TXA_2 through an irreversible inhibition of platelet cyclooxygenase-1.

In patients receiving fibrinolytics, ASA reduces mortality, and its effects are additive to fibrinolysis alone.[22] In patients undergoing PCI, ASA prevents acute thrombotic occlusion during the procedure. Additionally, in patients undergoing PCI, ASA, in addition to a $P2Y_{12}$ inhibitor, reduces the risk of stent thrombosis. ASA reduces the risk of death or MI by approximately 50% compared with no antiplatelet therapy in patients with NSTE-ACS.[22] Therefore, ASA remains the cornerstone of early treatment for all ACSs.

LO 3 In patients experiencing an ACS, an initial dose of at least 162 mg nonenteric-coated ASA is recommended to achieve a rapid platelet inhibition. Current guidelines for STEMI and NSTE-ACS recommend an initial ASA dose of 162 to 325 mg (see Table 8–3).[3,4] This first dose can be chewed to achieve high blood concentrations and platelet inhibition rapidly. Current data suggest that although an initial dose of 162 to 325 mg is required, long-term therapy with doses of 75 to 150 mg daily are as effective as higher doses. Therefore, a daily maintenance dose of 81 to 162 mg is generally preferred in most patients with ACS, including those patients also receiving a $P2Y_{12}$ inhibitor, to inhibit the 10% of the total platelet pool that is regenerated daily.[3,4,22] In patients receiving ticagrelor, the recommended maintenance dose of ASA is 81 mg.[4] ASA should be continued indefinitely following either STEMI or NSTE-ACS.[3,4]

The most frequent side effects of ASA are dyspepsia and nausea. Patients should be counseled about the risk of bleeding, especially gastrointestinal (GI) bleeding, with ASA (see Table 8–3).[22] Nonsteroidal anti-inflammatory agents other than ASA, as well as cyclooxygenase-2 (COX-2) selective anti-inflammatory agents, are contraindicated and should be discontinued at the time of ACS secondary to increased risk of death, reinfarction, HF, and myocardial rupture.[3,4]

▶ *Platelet $P2Y_{12}$ Inhibitors*

Clopidogrel, prasugrel, ticagrelor, and cangrelor block the $P2Y_{12}$ receptor, a subtype of ADP receptor, on platelets which prevents the binding of ADP to the receptor and subsequent expression of platelet GP IIb/IIIa receptors, and reduces platelet activation and aggregation. Both clopidogrel and prasugrel are thienopyridines and prodrugs that are converted to an active metabolite by a variety of cytochrome P-450 (CYP) isoenzymes, the most critical appearing to be CYP2C19 for clopidogrel (Table 8–4).[22] Both of these agents bind irreversibly to $P2Y_{12}$ receptors. Ticagrelor, which is not a thienopyridine, is a reversible, noncompetitive $P2Y_{12}$ receptor inhibitor. Ticagrelor's parent compound has antiplatelet effects and is also metabolized primarily by CYP3A4 to an active metabolite producing its antiplatelet effects. Cangrelor is the only intravenous $P2Y_{12}$ inhibitor approved as an adjunct to PCI in patients not receiving prior oral $P2Y_{12}$ inhibitors or planned GPIs to reduce the risk of periprocedural MI, revascularization, and stent thrombosis. Currently, there are no US guideline recommendations describing the role of cangrelor in ACS.

Both prasugrel and ticagrelor are more potent ADP inhibitors than clopidogrel. Prasugrel has the fewest significant drug–drug interactions of the oral agents. Moderate and strong inhibitors of CYP2C19 reduce the production of clopidogrel's active metabolite and consequently its antiplatelet effect, whereas strong inhibitors of CYP3A reduce ticagrelor's concentration. Cangrelor is an active drug that undergoes rapid dephosphorylation in the circulation and has no drug–drug interactions involving the CYP system. A more detailed discussion of the drug interactions with clopidogrel and proton pump inhibitors (PPIs) may be found in Chapter 7, "Stable Ischemic Heart Disease."

Genetic variations in the gene coding for *CYP2C19* significantly modulate the antiplatelet effects of clopidogrel. Specifically, carriers of reduced-function allele (ie, *2 or *3) are not able to convert clopidogrel to its active metabolite to the extent of carriers of the wild-type allele. This results in decreased antiplatelet effects, which could translate into higher rates of CV events, especially stent thrombosis and periprocedural MI.[22,23] The efficacy of prasugrel and ticagrelor is not associated with *CYP2C19* genotype.[3,4,22] Hence, ticagrelor or prasugrel may theoretically be considered preferred agents in carriers of *CYP2C19* reduced function alleles.[24] Nevertheless, in the absence of a large randomized trial demonstrating the benefit of such genotype-based approach, the most recent clinical practice guidelines of the ACC/AHA/SCAI have not endorsed routine genotyping to guide the prescription of $P2Y_{12}$ inhibitors.[3,4] Ongoing clinical trials should clarify the benefits of genotype-guided use of $P2Y_{12}$ receptor inhibitors.

LO 3 LO 4 Administration of a $P2Y_{12}$ receptor inhibitor, in addition to ASA, is recommended for all patients with ACS.[3,4] For patients with STEMI undergoing primary PCI, clopidogrel, prasugrel, ticagrelor, or cangrelor in addition to ASA, should be administered to prevent subacute stent thrombosis and long-term CV events (see Table 8–3 and Figure 8–2).[3-5] Although the most recent PCI and STEMI guidelines give no preference for any of the oral agents over the others, the NSTE-ACS guidelines indicate that ticagrelor may be preferred over clopidogrel for patients treated with either an ischemia-guided or early invasive approach, and both ticagrelor and prasugrel may be preferred over clopidogrel post PCI if patients are not at high risk of bleeding.[3-5] Cangrelor is only administered intravenously as an adjunct agent during PCI; an oral $P2Y_{12}$ agent must be initiated after PCI if cangrelor is used (see Table 8–4).

LO 4 LO 5 A large randomized double-blind study demonstrated that compared to clopidogrel, the addition of prasugrel to ASA for patients undergoing PCI significantly reduced the risk of CV death or MI by 19% (9.9% vs 12.1%), as well as MI and stent thrombosis, but increased the risk of major bleeding (not ICH) by 32% (2.4% vs 1.8%).[25] Patients with a history of prior stroke or transient ischemic attack (TIA) had an increased risk of ICH and net harm from prasugrel; therefore, prior stroke or TIA are contraindications to prasugrel. Patients 75 years and older as well as those weighing less than 60 kg (132 lb) are at increased risk of bleeding with prasugrel compared with clopidogrel and received no net clinical benefit from prasugrel.[25]

In a large randomized clinical trial, ticagrelor significantly reduced the rate of vascular death at 1 year by 22% (4.0% vs 5.1%), MI (5.8% vs 6.9%), and stent thrombosis (1.3% vs 1.9%) compared with clopidogrel.[26] There was no difference in the rate

Table 8–4

Clinical Considerations When Choosing a $P2Y_{12}$ Receptor Inhibitor[3-5,20]

	Clopidogrel	Prasugrel	Ticagrelor	Cangrelor
Pharmacologic class	Thienopyridine	Thienopyridine	Cyclopentyl triazolopyrimidine	Stabilized ATP analog
ADP receptor binding	Irreversible	Irreversible	Reversible	Reversible
Pharmacokinetics	Prodrug Converted twice to active metabolite primarily through CYP 2C19 Elimination half-life of active metabolite is approximately 30 minutes after a 75-mg dose Excretion is 50% urinary and 46% fecal	Prodrug Converted to active metabolite through CYP 3A4 and 2B6 Median elimination half-life of the active metabolite approximately 7.4 hours Excretion is primarily urinary (approximately 70%); fecal excretion < 30%	Active moiety Converted to active metabolite through CYP 3A4/5 Median elimination half-life of the parent compound is approximately 7 hours and active metabolite approximately 9 hours Excretion is primarily metabolism (84%); fecal excretion 58%, urinary excretion (26%)	Active drug Independent of hepatic function; rapidly dephosphorylzed to inactive metabolite Plasma half-life of 5–10 minutes; elimination half-life of 3–6 minutes Excretion is 58% renal and 35% fecal (presumed biliary)
	No dose adjustment necessary in CKD	Not recommended when eGFR < 15 mL/min/1.73 m^2	Not recommended when eGFR < 15 mL/min/1.73 m^2	No dose adjustment necessary in CKD
Dosing	300–600 mg loading dose; 75 mg daily	60 mg loading dose; 10 mg daily	180 mg loading dose; 90 mg twice daily. After 12 months, can use 60 mg twice daily in patients at low risk for bleeding	30 mcg/kg bolus; 4 mcg/kg/min IV infusion continued for at least 2 hours or the duration of PCI, whichever is longer
Onset of loading dose effect	Peak platelet inhibition occurs within 2 hours after 600 mg load and 6 hours after oral 300 mg load	Peak platelet inhibition reached within 1–1.5 hours after oral 60 mg load	Peak platelet inhibition within 1 hour after oral 180 mg load	Peak platelet inhibition within 2 minutes after 30 mcg/kg bolus
Duration of effect	3–10 days	7–10 days	3–5 days	1–2 hours
Drug and disease considerations	Genetic polymorphisms may influence efficacy Enhanced bleeding with NSAIDs; avoid use Enhanced bleeding with warfarin; monitor carefully for bleeding; target INR to 2.0–2.5 for most indications Avoid use with moderate or strong CYP2C19 inhibitors (omeprazole, esomeprazole, chloramphenicol, cimetidine, efavirenz, etravirine felbamate, fluoxetine, fluconazole, fluvoxamine, isoniazid, oxcarbazepine, ketoconazole, voriconazole); select alternative non-interacting $P2Y_{12}$ inhibitor or alternative non-interacting drug	Enhanced bleeding with warfarin and NSAIDs, avoid use	Enhanced bleeding with warfarin and NSAIDs Use aspirin doses < 100 mg daily Avoid use with strong CYP3A inhibitors (atazanavir, clarithromycin, indinavir, itraconazole, nefazodone, nelfinavir, ketoconazole, ritonavir, saquinavir, telithromycin, voriconazole) Avoid use with potent CYP3A inducers (carbamazepine, dexamethasone, phenobarbital, phenytoin, rifampin) Avoid simvastatin and lovastatin doses > 40 mg daily (ticagrelor inhibits CYP3A4 and increases statin concentration) Monitor digoxin serum concentrations with any change in ticagrelor dose (ticagrelor inhibits P-glycoprotein) Unique side-effects including dyspnea and bradycardia	Do not administer clopidogrel or prasugrel prior to the discontinuation of cangrelor infusion Ticagrelor may be given at any time during cangrelor infusion or immediately after the discontinuation of cangrelor infusion

(*Continued*)

Table 8–4

Clinical Considerations When Choosing a $P2Y_{12}$ Receptor Inhibitor[3-5,20] (*Continued*)

	Clopidogrel	Prasugrel	Ticagrelor	Cangrelor
Contraindications	Any active pathological bleeding	Any active pathological bleeding; any history of TIA/stroke	Any active pathological bleeding; ICH or severe hepatic disease	Significant active bleeding or hypersensitivity
Surgery hold time	5 days for elective surgery; 24 hours for urgent	7 days	5 days for elective surgery; 24 hours for urgent	1 hour
NSTE-ACS indication	May be used regardless of treatment strategy; additional non-ACS indications	Reasonable over clopidogrel in patients treated with PCI who are not at high risk for bleeding and who have no history of stroke/TIA	Reasonable over clopidogrel for NSTE-ACS patients treated with invasive or ischemia-guided approach	No US guideline recommendation; may be considered in $P2Y_{12}$ inhibitor–naïve patients undergoing PCI
STEMI indication	Preferred when fibrinolytics used	Superior to clopidogrel in STEMI or in other high-risk patients like DM; not studied in patients receiving fibrinolytic therapy	Superior to clopidogrel; not studied in patients receiving fibrinolytic therapy	No US guideline recommendation; may be considered in $P2Y_{12}$ inhibitor–naïve patients undergoing PCI
Risk benefit considerations	Gold standard for reducing CV death and stent thrombosis compared to placebo Consider alternative if documented clopidogrel ineffectiveness (ie, poor metabolism, stent thrombosis during clopidogrel therapy)	Superior to clopidogrel with a significant increase in bleeding risk (driven mainly by reductions in MI and stent thrombosis); no clinical benefit when age ≥ 75 years or weight < 60 kg (132 lb); Net harm in patients with history of TIA or stroke	Superior to clopidogrel with modest increase in major non-CABG related bleeding; associated with an all-cause mortality reduction; consider compliance with twice daily dosing	Demonstrated better efficacy than post-PCI clopidogrel with minor increases in bleeding Has potential use as a bridge to CABG surgery in high-risk patients

ACS, acute coronary syndrome; ADP, adenosine diphosphate; ATP, adenosine triphosphate; CABG, coronary artery bypass graft; CKD, chronic kidney disease; CV, cardiovascular; CYP, cytochrome P-450; DM, diabetes mellitus; eGFR, estimated glomerular filtration rate; ICH, intracranial hemorrhage; INR, international normalized ratio; IV, intravenous; MI, myocardial infarction; NSAIDs, nonsteroidal anti-inflammatory drugs; NSTE-ACS, non–ST-segment elevation acute coronary syndrome; PCI, percutaneous coronary intervention; STEMI, ST-segment elevation myocardial infarction; TIA, transient ischemic attack.

From Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:179–180, with permission.

of total stroke. Although no increase in study-defined major bleeding was noted with ticagrelor, the frequency of non-CABG major bleeding was increased compared with clopidogrel (4.5% vs 3.8%). Therefore, both of the more potent $P2Y_{12}$ inhibitors are more efficacious than clopidogrel but are also associated with an increased risk of bleeding. Patients with diabetes mellitus (DM) or those with STEMI appear to have a greater ischemic benefit with prasugrel and ticagrelor without an increase in major bleeding compared to clopidogrel.[27-30] No large randomized trial has directly compared ticagrelor to prasugrel. Figures 8–2 and 8–3 and Table 8–4 outline the role of antiplatelets and anticoagulants in ACS.[3,4]

LO 4 A clopidogrel loading dose of 600 mg is recommended over administration of 300 mg for patients undergoing PCI. A systematic review and meta-analysis of randomized and nonrandomized trials in more than 25,000 patients demonstrated a reduction in CV ischemic events with a loading dose of 600 mg compared with 300 mg in patients undergoing PCI.[31] Although a modest benefit of using a 7-day course of clopidogrel 150 mg compared to 75 mg daily has been suggested, it is also associated with a higher risk of major bleeding.[32] Thus, routine use of such dosing is not recommended in current clinical guidelines.[3,4]

LO 5 In STEMI patients receiving fibrinolysis, early therapy with clopidogrel 75 mg once daily administered during hospitalization and up to 28 days (mean: 14 days) reduced mortality and reinfarction without increasing the risk of major bleeding.[22] In adult patients 75 years or younger receiving fibrinolytics, a 300-mg loading dose (omit the load in those older than 75) of clopidogrel followed by 75 mg daily is recommended.[3] Clopidogrel should be continued for at least 14 days (and up to 1 year in the absence of bleeding) for patients presenting with STEMI who undergo reperfusion therapy with fibrinolysis.[3] Although prasugrel and ticagrelor are recommended in the setting of STEMI and primary PCI, no studies have evaluated their use in conjunction with fibrinolytics.

For patients with NSTE-ACS with an initial ischemia-guided approach, either clopidogrel (a 300- or 600-mg loading dose followed by 75 mg daily) or ticagrelor can be used (ticagrelor preferred). If an invasive management strategy is selected, either clopidogrel or ticagrelor can be used (ticagrelor may be preferred) either prehospital or in the ED. Following PCI, in patients not already treated with a $P2Y_{12}$ inhibitor, either clopidogrel, prasugrel, or ticagrelor can be used (in patients not at high risk of bleeding, ticagrelor and prasugrel may be preferred) and should

LO 4

be initiated within 1 hour following PCI. As in primary PCI for STEMI patients, cangrelor may be used in patients who have not received an oral $P2Y_{12}$ agent prior as an adjunct to PCI with an oral $P2Y_{12}$ agent initiated after cangrelor is discontinued. Specific dosing and contraindications of the $P2Y_{12}$ inhibitors are described in Tables 8–3 and 8–4.[3,4,22]

The recommended duration of $P2Y_{12}$ inhibitors for a patient undergoing PCI for ACS, either STEMI or NSTE-ACS, is at least 12 months for patients receiving either a BMS or DES.[3,4,20,22] The benefit of prolonging treatment beyond 12 months is uncertain. Trials evaluating the need for an extended duration greater than 12 months in patients with or without ACS undergoing PCI demonstrate a reduction in ischemic endpoints but an increased risk of bleeding.[20] For patients who are treated using an ischemia-guided approach, $P2Y_{12}$ inhibitors should be given for up to 12 months. Discontinuation of the $P2Y_{12}$ agent after 6 months may be considered for patients with ACS treated with a DES who have a high risk of bleeding.[20]

Nonadherence to $P2Y_{12}$ inhibitors is a major risk factor for stent thrombosis; therefore, the likelihood of compliance with DAPT (ASA and an oral $P2Y_{12}$ inhibitor) should be assessed prior to angiography.[5] The use of a BMS over a DES should be considered in patients who are anticipated to be nonadherent to 12 months of DAPT.[5] Adherence to twice-daily ticagrelor should also be a consideration.

To minimize the risk of CV events, elective noncardiac surgery should be delayed 4 to 6 weeks after angioplasty or BMS implantation, or 12 months after DES implantation if the discontinuation of the $P2Y_{12}$ inhibitor is required. If elective CABG surgery is planned, clopidogrel and ticagrelor should be withheld preferably for 5 days, and prasugrel at least 7 days, and cangrelor for 1 hour to reduce the risk of postoperative bleeding, unless the need for revascularization outweighs the bleeding risk. If urgent CABG is necessary, discontinue clopidogrel and ticagrelor up to 24 hours to reduce the risk of major bleeding.[4,5]

Although a variety of blood tests can assess functional platelet aggregation inhibition to $P2Y_{12}$ inhibitors, especially clopidogrel, there is no one gold standard test. Moreover, their benefit to personalize antiplatelet regimens has not been demonstrated. Therefore, the most recent practice guidelines do not recommend routine platelet aggregation testing to determine $P2Y_{12}$ inhibitor strategy.[3-5]

LO 4 LO 5 Bleeding should be carefully monitored when using $P2Y_{12}$ inhibitors.[25-27] Rarely, thrombotic thrombocytopenic purpura (TTP) has been reported with clopidogrel.[33] In addition, the use of ticagrelor is associated with dyspnea and, rarely, ventricular pauses and bradyarrhythmias. Small non-clinically significant increases in SCr and serum uric acid have also been reported with ticagrelor.[26]

▶ *Glycoprotein IIb/IIIa Receptor Inhibitors*

GP IIb/IIIa receptor inhibitors block the final common pathway of platelet aggregation, namely cross-linking of platelets by fibrinogen bridges between the GP IIb and IIIa receptors on the platelet surface. In patients with STEMI undergoing primary PCI who are treated with UFH, abciximab, eptifibatide, or tirofiban may be administered on an individual basis.[3,5] Investigations of GPIs precede the widespread use of oral DAPT and thus their benefit in modern settings is not as clear. Their use appears most appropriate and beneficial in patients who are not adequately treated with a $P2Y_{12}$ receptor antagonist or in those with a large thrombus burden. Routine use of a GPI is not recommended in patients who have received fibrinolytics or bivalirudin secondary to increased bleeding risk. For patients treated with bivalirudin as the anticoagulant, GPIs should only be used in select cases as clinically indicated. These agents should not be administered for medical management of patients with STEMI who will not be undergoing PCI.[3]

The role of GPIs in NSTE-ACS has diminished since $P2Y_{12}$ inhibitors are used earlier in therapy, and bivalirudin is commonly selected as the anticoagulant in patients receiving an early intervention approach. Current evidence indicates no benefit of routine use of GPIs in patients treated with an ischemia-guided approach because the bleeding risk exceeds the benefit.[4] Nevertheless, in select patients treated with an LO 5 ischemia-guided approach who experience recurrent ischemia (chest discomfort and ECG changes), HF, or arrhythmias after initial medical therapy necessitating a change in strategy to angiography and revascularization, a GPI may be added to ASA prior to the angiogram, particularly if the patient is (1) not adequately treated with clopidogrel or ticagrelor and (2) not treated with bivalirudin.

LO 4 In patients who undergo an early invasive strategy and are adequately treated with clopidogrel or ticagrelor, routine upstream (prior to coronary angiography) administration of a GPI is not recommended, although eptifibatide or tirofiban may be considered in select high-risk patients (eg, troponin positive). Indeed clinical trials have shown that eptifibatide (added to ASA and clopidogrel) prior to angiography and PCI (ie, "upstream" use) in NSTE-ACS does not reduce ischemic events and increases bleeding risk.[4,34] LO 4 In patients undergoing PCI, a GPI (abciximab, double-bolus eptifibatide, or high-dose bolus tirofiban) should be used in patients presenting with high-risk features who are not adequately pretreated with clopidogrel or ticagrelor (and who are not treated with bivalirudin as the anticoagulant), and may be considered in select individuals adequately pretreated with clopidogrel.[4]

Dosing and contraindications for GPIs are described in Table 8–3.[3,4] LO 4 LO 5 Bleeding is the most significant adverse effect associated with administration of GPIs; therefore, they should not be administered to patients with a prior history of hemorrhagic stroke or recent ischemic stroke. The risk of bleeding is increased in patients with CKD. Eptifibatide is contraindicated in patients dependent on dialysis and requires a 50% reduced infusion rate in patients with CrCl less than 50 mL/min (0.83 mL/s).[3] The rate of tirofiban infusion should also be halved in patients with CrCl less than or equal to 60 mL/min (1.0 mL/s).[3] No dosage adjustment for renal function is necessary for abciximab. An immune-mediated thrombocytopenia occurs in approximately 5% of patients with abciximab and less than 1% of patients receiving eptifibatide or tirofiban.[35]

▶ *Anticoagulants*

LO 3 LO 4 All patients should receive an anticoagulant in addition to DAPT regardless of ACS type or initial treatment strategy. Options for anticoagulant therapy are outlined in Figures 8–2 and 8–3.[3,4] For patients with STEMI undergoing primary PCI, either UFH or bivalirudin is preferred.[3] Bivalirudin monotherapy reduces CV and overall mortality while minimizing bleeding compared to UFH plus a GPI. However, direct head-to-head comparisons of monotherapy with UFH and bivalirudin have not shown this bleeding advantage.[36-38] Anticoagulant therapy is generally discontinued after primary PCI unless a compelling reason to continue exists. When fibrinolytic therapy is utilized in STEMI, LO 5 anticoagulation with either UFH, enoxaparin, or fondaparinux are administered concomitantly. In this case, anticoagulant

therapy should be maintained for a minimum of 48 hours (for UFH) and preferably for the duration of the hospitalization (with enoxaparin and fondaparinux) up to 8 days after fibrinolysis or until reperfusion is performed to support patency and prevent reocclusion of the affected artery.[3] Enoxaparin dosing is adjusted for body weight and renal function, and when administered in combination with fibrinolysis, it has special dosing requirements for older patients and those weighing more than 100 kg (220 lb) (see Table 8–3).

The choice of anticoagulant for a patient with NSTE-ACS is guided by risk stratification and initial treatment strategy, either an early invasive approach with coronary angiography and PCI or an ischemia-guided strategy with angiography in select patients guided by relief of symptoms and stress testing (see Figure 8–3). For patients treated by an early invasive strategy, UFH, enoxaparin, fondaparinux, or bivalirudin are options.[4] These same anticoagulants are continued after angiography if the decision is made to revascularize with PCI with one exception. Fondaparinux should not be used as the sole anticoagulant during PCI due to an increased risk of catheter-related thrombosis. Additional heparin must be administered during PCI if fondaparinux was initially chosen for anticoagulation. Clinical trials with bivalirudin have demonstrated similar efficacy in preventing CV ischemic events with a lower bleeding rate compared to UFH or enoxaparin plus a GPI in moderate- and high-risk patients with NSTE-ACS undergoing an early invasive strategy.[22] Use of enoxaparin during PCI is considered reasonable in patients treated with upstream subcutaneous enoxaparin. Dosing considerations for initial treatment and during PCI are outlined in Table 8–3.[4]

In NSTE-ACS patients in whom an initial ischemia-guided strategy is planned, enoxaparin, UFH, or low-dose fondaparinux is recommended.[4] Bivalirudin has not been studied as initial therapy in this setting. When added to ASA, UFH and low-molecular-weight heparins (LMWHs) reduce the frequency of death or MI in patients presenting with NSTE-ACS compared with control/placebo in patients primarily managed with an ischemia-guided strategy.[4,22] Compared with enoxaparin, fondaparinux showed similar ischemic outcomes with a lower bleeding rate in patients with NSTE-ACS primarily managed with an ischemia-guided strategy and may be preferred in patients at high risk for bleeding.[22] However, if fondaparinux is chosen for a patient who subsequently undergoes angiography and PCI, it should be administered in combination with UFH to avoid catheter thrombosis.[4] Guideline-recommended dosing and contraindications are described in Table 8–3.

UFH is preferred following angiography in patients proceeding to CABG during the same hospitalization because it has a short duration of action following discontinuation. Because enoxaparin is eliminated renally and patients with renal insufficiency generally have been excluded from clinical trials, UFH should be considered for patients with CrCl rates of less than 30 mL/min (0.50 mL/s) based on total patient body weight using the Cockroft–Gault equation.[4] Although recommendations for dosing adjustment of enoxaparin in patients with CrCl between 10 and 30 mL/min (0.17 and 0.50 mL/s) are listed in the product manufacturer's label, the safety and efficacy of enoxaparin in this patient population remain vastly understudied. Administration of enoxaparin should be avoided in dialysis patients with ACS. While the duration of bivalirudin infusion is generally short (several hours only), few patients with significant renal impairment have been included in clinical trials. Dose adjustments for bivalirudin in patients with CrCl less than 30 mL/min (0.50 mL/s) or on hemodialysis is recommended. Patients with SCr greater than 3.0 mg/dL (265 μmol/L) were excluded from ACS trials with fondaparinux. Fondaparinux is contraindicated in patients with CrCl less than 30 mL/min (0.50 mL/s).[4]

UFH is monitored and the dose adjusted to a target aPTT or antifactor Xa levels, whereas the dose of enoxaparin is based on actual body weight without routine monitoring of antifactor Xa levels. Some experts recommend antifactor Xa monitoring for LMWHs (eg, enoxaparin, fondaparinux) in patients with renal impairment during prolonged courses of administration of more than several days. No monitoring of coagulation is recommended for bivalirudin and fondaparinux.

Besides bleeding, the most serious adverse effect of UFH and enoxaparin is **heparin-induced thrombocytopenia**. ACS registry data indicate the frequency of heparin-induced thrombocytopenia is rare (< 0.5%).[11] Bivalirudin would be the preferred anticoagulant for patients with a history of heparin-induced thrombocytopenia undergoing PCI.[5]

► *β-Blockers*

Oral β-blockers should be administered early in the care of patients with an ACS and continued for at least 3 years in patients with normal LVF.[3,4,39] In ACS, the benefit of β-blockers results mainly from the competitive blockade of β_1-adrenergic receptors located on the myocardium. β_1-Blockade produces a reduction in heart rate, myocardial contractility, and BP, decreasing myocardial oxygen demand. In addition, the reduction in heart rate increases diastolic time, thus improving ventricular filling and coronary artery perfusion. As a result of these effects, β-blockers reduce the risk for recurrent ischemia, infarct size, risk of reinfarction, and occurrence of ventricular arrhythmias in the hours and days following MI.[3,4]

The role of early β-blocker therapy in reducing MI mortality was established in the 1970s and 1980s before routine use of early reperfusion therapy. Data in the reperfusion era are derived mainly from a large clinical trial that suggests IV initiation followed by oral β-blockers early in the course of MI is associated with a lower risk of reinfarction or ventricular fibrillation. However, there may be an early risk of cardiogenic shock in patients presenting with advanced age (> 70 years), heart rate greater than 100 beats/min, systolic BP less than 120 mm Hg, or late presentation.[4,40] Therefore, initiation of β-blockers (oral preferred) should be limited to patients who are hemodynamically stable, not at increased risk for cardiogenic shock, and without signs or symptoms of acute HF. Careful assessment for any contraindications to β-blockers should be performed following initiation and prior to any dose titration. The most serious side effects of β-blocker administration early in ACS are hypotension, acute HF, bradycardia, and heart block.[3,4]

Patients already taking β-blockers can continue taking them. Patients with contraindications to their use in the first 24 hours of presentation should be reevaluated and treated with β-blockers at a later time if they become eligible. In patients presenting with acute HF, use of β-blockers should be delayed until they are stabilized. Initiation of β-blockers may be attempted before hospital discharge in most patients following resolution of acute HF. Patients with HF secondary to reduced LVF should receive one of three β-blockers: bisoprolol, sustained-release metoprolol succinate, or carvedilol.[3,4]

► *Additional Therapies*

Oral ACE inhibitors have been shown to decrease nonfatal and fatal major CV events.[3,4] The benefit of ACE inhibitors in patients with MI most likely comes from their ability to prevent cardiac

remodeling and ultimately development of HF. The largest reduction in mortality is observed in patients with left ventricular dysfunction (low LVEF) or HF symptoms. Early initiation (within 24 hours) of an oral ACE inhibitor is recommended as benefit can be seen as early as 24 hours post MI, especially in patients with high-risk features such as HF, low LVEF, or STEMI in the anterior location.[3,4] However, these agents should be used cautiously in the first 24 hours to avoid renal dysfunction or hypotension.[4] The use of IV ACE inhibitors is not recommended because mortality may be increased. Administration of ACE inhibitors should be continued indefinitely in those patients without contraindications with LVEF less than 40% (0.40) and in those with HTN, stable CKD, or DM.[4,39]

To accurately assess baseline low-density lipoprotein (LDL), it is recommended to obtain a fasting lipid panel within 24 hours in patients presenting with an ACS.[41] The administration of high-intensity statins prior to PCI may reduce the risk of periprocedural MI, and hence statins should be initiated as early as possible in ACS.[5] Additionally, statins reduce the risk of CV death, recurrent MI, stroke, and the need for revascularization when initiated early in the treatment of ACS.[3,4,41] Although the primary effect of statins is to decrease LDL cholesterol, statins are believed to produce many non-lipid-lowering or "pleiotropic" effects such as anti-inflammatory and antithrombotic properties. Based on current evidence, the most recent guidelines for the treatment of cholesterol in adults recommend that patients who experience an ACS should receive high-intensity statin therapy (atorvastatin 40–80 mg daily; rosuvastatin 20–40 mg daily) if they are less than or equal to 75 years of age, and moderate-intensity statin therapy (eg, atorvastatin 10–20 mg; pravastatin 40–80 mg; rosuvastatin 5–10 mg; simvastatin 20–40 mg) if they are older than 75 years or not a candidate for high-intensity statins because of contraindications, at risk for statin intolerance, or have a history of statin-associated adverse drug reactions. Select patients older than 75 years may be candidates for high-intensity therapy to lower LDL cholesterol. High- and moderate-intensity statins defined as daily statin doses required to reduce LDL cholesterol greater than or equal to 50% and 30% to 49%, respectively.[42] Thus, in the absence of contraindications and depending on age, moderate- to high-intensity statin therapy should be initiated early during hospitalization to all patients experiencing ACS.[3,4]

▶ *Calcium Channel Blockers*

Calcium channel blockers in the setting of ACS are used for relief of continued ischemia despite β-blocker and nitrate therapy, vasospastic angina, additional need for BP lowering (ie, amlodipine), or in patients with contraindications to β-blockers. Data suggest little benefit on clinical outcomes beyond symptom relief for calcium channel blockers in the setting of ACS especially in patients with reduced LVEF.[3,4] Therefore, calcium channel blockers should be avoided in the acute management of ACS unless there is a clear symptomatic need or contraindication to β-blockers. Agent selection is based on presenting heart rate and left ventricular dysfunction (diltiazem and verapamil are contraindicated in patients with bradycardia, heart block, or reduced LVEF). Immediate-release nifedipine should be avoided because it has demonstrated reflex sympathetic activation, tachycardia, and worsened myocardial ischemia.[3,4] Dosing and contraindications are described in Table 8–3.

Secondary Prevention Following MI

The long-term goals following ACS are to: (a) control modifiable CHD risk factors; (b) prevent the development of HF; (c) prevent new or recurrent MI and stroke; (d) prevent death, including sudden cardiac death; and (e) prevent stent thrombosis following PCI. Pharmacotherapy, which has been proven to decrease mortality, HF, reinfarction, stroke, and stent thrombosis should be initiated prior to hospital discharge for secondary prevention.

KEY CONCEPT Secondary prevention guidelines suggest that following MI, all patients should receive long-term treatment with ASA, a β-blocker, an ACE inhibitor, and a statin for secondary prevention of death, stroke, or recurrent infarction.[39] A $P2Y_{12}$ inhibitor should be continued for at least 12 months for patients undergoing PCI and for patients with NSTE-ACS receiving an ischemia-guided treatment strategy.[3-5,20] Clopidogrel should be continued for at least 14 days and ideally up to 1 year in patients with STEMI receiving thrombolytics. Other $P2Y_{12}$ inhibitors have not been studied in combination with thrombolytics; however, prasugrel may be an alternative to clopidogrel in patients who undergo delayed PCI after thrombolytics.[3] An ARB and an aldosterone antagonist should be given to select patients. Dosing and contraindications of medication therapy are described in detail in Table 8–3. For all patients with ACS, treatment and control of modifiable risk factors such as HTN, dyslipidemia, obesity, smoking, and DM are essential.[3,4,39] Patients should receive proper counseling and education, both verbal and written, regarding these treatments and recommendations prior to discharge. At follow-up appointments, medication reconciliation and dose optimization improve drug adherence.[43] Use of ICDs for the prevention of sudden cardiac death following MI in patients with reduced LVF and nonsustained ventricular arrhythmias is discussed in more detail in Chapter 9, "Arrhythmias."

▶ *Aspirin*

ASA decreases the risk of death, recurrent infarction, and stroke following MI. All patients should receive daily ASA 81 to 162 mg indefinitely; those patients with a contraindication to ASA should receive clopidogrel.[3,4,39] The risk of major bleeding from chronic ASA therapy is approximately 2% and is dose related. Higher doses of ASA, 160 to 325 mg, are not more effective than ASA doses of 75 to 81 mg but have higher rates of bleeding.[44] Therefore, the guidelines recommend 81 mg daily as a preferred strategy in ACS patients with or without PCI.[3,4]

▶ *$P2Y_{12}$ Inhibitors*

For patients with either STEMI or NSTE-ACS, clopidogrel decreases the risk of CV events and stent thrombosis compared with placebo. Compared with clopidogrel, either prasugrel or ticagrelor lowers the risk of CV death, MI, or stroke by an additional 20% to 30% depending on the patient population studied. The frequency of stent thrombosis following PCI is also lower with prasugrel or ticagrelor compared with clopidogrel. However, the rate of bleeding not related to CABG surgery

Patient Encounter 2, Part 2

Is reperfusion therapy with fibrinolysis indicated at this time for this patient?

What adjunctive pharmacotherapy should be administered to this patient in the emergency department?

What additional pharmacotherapy should be initiated on the first day of this patient's hospitalization following successful reperfusion with PCI?

is higher with both prasugrel and ticagrelor compared with clopidogrel.[25,26]

LO 6 The ACC/AHA Dual Antiplatelet Therapy Focused Update recommends continuation of a $P2Y_{12}$ inhibitor for at least 12 months following PCI for ACS.[20] Continuation of $P2Y_{12}$ inhibitors longer than 12 months may be considered in patients who have not experienced any bleeding episodes and are not at high risk for bleeding.[20] For patients with STEMI receiving thrombolytics, clopidogrel should be continued for at least 14 days and ideally up to 1 year.[3] For NSTE-ACS patients who do not receive a coronary stent, clopidogrel or ticagrelor should be continued up to 1 year.[4,20]

Bleeding is an inherent risk with long-term DAPT. In fact, oral antiplatelet agents are the third leading cause of adverse drug reaction–associated hospital admissions after ED visits among seniors.[45] Therefore, patients should be counseled on the risks and sites of potential bleeding and should be told to seek medical care immediately if significant bleeding is noticed. Some patients who are at increased risk of GI bleeding may benefit from the addition of a PPI.[20,46]

► β-Blockers, Nitrates, and Calcium Channel Blockers

LO 6 Current treatment guidelines recommend that following an ACS, patients with normal LVF should receive a β-blocker for at least 3 years, indefinitely for those with reduced LVF, and may be considered longer if needed for the treatment of HTN or angina.[3,4,39,47] Overwhelming data support the use of β-blockers in patients with a previous MI to improve long-term survival. Currently, there are no data to support the superiority of one β-blocker over another in the absence of HF with reduced LVF.

Although β-blockers should be avoided in patients with decompensated HF from left ventricular systolic dysfunction complicating an MI, clinical trial data suggest it is safe to initiate β-blockers prior to hospital discharge in these patients once HF symptoms have resolved.[3,4] In patients who cannot tolerate or have a contraindication to a β-blocker, a calcium channel blocker can be used to prevent anginal symptoms but nondihydropyridines should not be used in patients with reduced LVF.[3,4]

Chronic long-acting nitrate therapy has not been shown to reduce CHD events following MI and is not indicated in ACS patients who have undergone revascularization, unless the patient has stable ischemic heart disease, refractory angina, coronary vasospasms, or significant coronary stenoses that were not revascularized. All patients should be prescribed short-acting SL NTG tablets or spray to relieve any anginal symptoms when necessary and instructed on its use.[3,4] If ischemic chest discomfort persists for more than 5 minutes after the first dose, the patient should be instructed to contact emergency medical services. Nitrates should not be administered to patients with hypotension or who have recently received a phosphodiesterase inhibitor (see Table 8–3).[3,4,48]

► ACE Inhibitors and ARBs

ACE inhibitors reduce mortality, decrease reinfarction, and prevent the development of HF with recent ACS, especially in those with reduced LVF.[3,4,39] Additional trials suggest that most patients with CAD, not just ACS or HF patients, benefit from ACE inhibitors. Therefore, ACE inhibitors should be considered in all patients (eg, those with HTN, DM, or stable CKD) following an ACS in the absence of a contraindication.

Besides hypotension, the most frequent adverse reaction to an ACE inhibitor is cough, which may occur in up to 30% of patients. Patients who cannot tolerate an ACE inhibitor may be prescribed an ARB. Other, less common but more serious adverse effects of ACE inhibitors and ARBs include acute renal failure, hyperkalemia, and angioedema.[3,39]

► Aldosterone Antagonists

LO 6 Aldosterone plays an important role in HF and in MI because it promotes vascular and myocardial fibrosis, endothelial dysfunction, HTN, left ventricular hypertrophy, sodium retention, potassium and magnesium loss, and arrhythmias. Aldosterone antagonists have been shown to attenuate these adverse effects and reduce mortality in patients who are already receiving an ACE inhibitor (or ARB) and β-blocker and have an LVEF less than or equal to 40% (0.40) and either HF symptoms or DM.[3,4]

Eplerenone and spironolactone are aldosterone antagonists that block the mineralocorticoid receptor. In contrast to spironolactone, eplerenone has no effect on the progesterone or androgen receptor, thereby minimizing the risk of gynecomastia, sexual dysfunction, and menstrual irregularities. In a large clinical trial, eplerenone significantly reduced mortality as well as hospitalization for HF in post–MI patients with an LVEF less than 40% (0.40) and symptoms of HF at any time during hospitalization.[49]

LO 6 The risk of hyperkalemia increases with the use of aldosterone antagonists when added to an ACE inhibitor or ARB. Therefore, patients with serum potassium concentrations greater than 5.0 mmol/L (mEq/L) should not receive these agents. Specific contraindications for spironolactone include SCr greater than or equal to 2.5 mg/dL (221 μmol/L) for men or 2.0 mg/dL (177 μmol/L) for women, or CrCl less than or equal to 30 mL/min (0.50 mL/s). Contraindications for eplerenone include SCr greater than or equal to 2.0 mg/dL (177 μmol/L) for men or 1.8 mg/dL (159 μmol/L) for women, or CrCl less than or equal to 50 mL/min (0.83 mL/s). Currently, there are no data to support that eplerenone is superior or preferred to spironolactone unless a patient has experienced gynecomastia, breast pain, or impotence while receiving spironolactone.

► Lipid-Lowering Agents

LO 6 Following MI, statins reduce total mortality, CV mortality, need for revascularization, and stroke. According to practice guidelines, all patients who have experienced ACS should receive high-intensity statin therapy provided that no contraindications exist.[4,42] Indeed, results from landmark clinical trials have unequivocally demonstrated the value of statins in secondary prevention. High-intensity statin therapy, which typically lowers LDL cholesterol by 50% or greater, is preferred because of the greatest reduction in outcomes. The current evidence indicates that higher-dose statin therapy, such as atorvastatin 40 to 80 mg daily and rosuvastatin 10 to 20 mg daily, produces a greater reduction in CV events such as MI, ischemic stroke, and revascularization than less intensive statin regimens (such as simvastatin 20–40 mg daily). Moderate intensity statin therapy is recommended for those who are 75 years of age or older if high-intensity therapy is not tolerated, or in those who have a high risk for statin-associated adverse effects such as those with drug–drug interactions.[4,42]

In patients for whom a 50% reduction of LDL cholesterol is not achieved by statin therapy alone (or, in whom LDL cholesterol remains ≥ 70 mg/dL [1.81 mmol/L]), nonstatin therapy may be added to the statin for therapy intensification. An expert consensus statement supports the addition of either ezetimibe or

a proprotein convertase subtilisin/kexin type (PCSK9) inhibitor to statin therapy in very high-risk patients after considering desired LDL reduction, potential for additional CV risk reduction, adverse events or drug–drug interactions, and patient preference.[41] Based on randomized data, ezetimibe added to statin therapy after ACS produced a modest benefit (~10% reduction) on CV outcomes.[41] Both evolocumab and alirocumab (PCSK9 inhibitors) have also demonstrated improved CV outcomes in patients with atherosclerotic cardiovascular disease (ASCVD) added to maximal statin therapy with or without ezetimibe.

▶ *Other Modifiable Risk Factors*

LO 6

Smoking cessation, managing HTN, weight loss, exercise, and glucose control for patients with DM, in addition to treatment of dyslipidemia, are important treatments for secondary prevention of CHD events.[39] Referral to a comprehensive CV risk reduction program for cardiac rehabilitation is recommended.[3,39] HTN should be strictly controlled according to published guidelines.[47] Patients who are overweight, hypertensive, or who require cholesterol lowering should be educated on the importance of regular exercise, healthy eating habits, and reaching and maintaining an ideal weight. Moderate-intensity aerobic exercise for at least 40 minutes, 3 to 4 days per week is recommended. Because patients with DM have up to a fourfold increased mortality risk compared with patients without DM, the importance of blood glucose control, as well as other CHD risk factor modifications, cannot be overstated.[39] Finally, influenza vaccination is recommended in all patients with CV disease. Additionally, vaccination with the 13- and 23-valent pneumococcal polysaccharide vaccines is recommended in those 65 years and older, as well as all high-risk individuals presenting with CV disease.[4,39]

LO 6

In patients who require treatment for musculoskeletal pain, a stepped-care approach should be taken in the selection of treatment. Acetaminophen, tramadol, and nonacetylated salicylates are preferred. Use of small doses of narcotics for short periods can be added if the aforementioned are not adequate to relieve the patient.[4] If these agents are insufficient, nonselective nonsteroidal anti-inflammatory drugs (NSAIDs) can be considered, and should be used at the lowest effective dose and for the shortest possible time. Existing evidence suggests that naproxen may have the lowest risk to induce CV ischemic events, but the quality of the evidence available limits the definitiveness of assessment of its safety, particularly when it is used for long term. Importantly, all NSAIDs increase the risk of HF. If NSAIDs are used in combination with antiplatelets, a PPI should be added to reduce risk of GI bleeding.[46]

Patient Encounter 2, Part 3

The patient undergoes coronary angiography and is found to have a 95% stenosis in his right coronary artery. PCI is performed and a drug-eluting stent is placed without complications.

Identify the long-term treatment goals for this patient.

What additional pharmacotherapy should be initiated prior to hospital discharge?

Create a care plan for this patient for hospital discharge that includes pharmacotherapy, desired treatment outcomes, and monitoring for efficacy and adverse effects.

OUTCOME EVALUATION

LO 3 LO 4 LO 5

- KEY CONCEPT To determine the efficacy of nonpharmacologic and pharmacotherapy for both STEMI and NSTE-ACS, monitor patients for: (a) relief of ischemic discomfort; (b) return of ECG changes to baseline; and (c) absence or resolution of HF signs and symptoms.
- Monitoring parameters for recognition and prevention of adverse effects from ACS pharmacotherapy are described in Table 8–5. KEY CONCEPT In general, the most common adverse reactions from ACS therapies are hypotension and bleeding. To treat bleeding and hypotension, discontinue the offending agent(s) until symptoms resolve. Severe bleeding resulting in

Table 8–5

Therapeutic Drug Monitoring of Pharmacotherapy for Acute Coronary Syndromes

Drug	Adverse Effects	Monitoring
Aspirin	Dyspepsia, bleeding, gastritis	Clinical signs of bleeding[a]; GI upset; baseline and every 6 months: Hgb, HCT, platelet count
Clopidogrel and prasugrel	Bleeding, diarrhea, rash, TTP (rare)	Clinical signs of bleeding[a]; baseline and every 6 months: Hgb, HCT, platelet count
Ticagrelor	Bleeding, dyspnea, diarrhea, rash, elevated SCr, elevated serum uric acid	Clinical signs of bleeding[a]; baseline and every 6 months: Hgb, HCT, platelet count
Unfractionated heparin	Bleeding, heparin-induced thrombocytopenia	Clinical signs of bleeding[a]; baseline aPTT, INR, Hgb, HCT, and platelet count; ACT during cardiac catheterization; aPTT every 6 hours until target then every 24 hours; daily Hgb, HCT, and platelet count
Enoxaparin	Bleeding, heparin-induced thrombocytopenia	Clinical signs of bleeding[a]; baseline SCr, aPTT, INR, Hgb, HCT, and platelet count; daily SCr, Hgb, HCT, and platelet count
Fondaparinux	Bleeding	Clinical signs of bleeding[a]; baseline SCr, aPTT, INR, Hgb, HCT, and platelet count; daily SCr, Hgb, HCT, and platelet count
Bivalirudin	Bleeding	Clinical signs of bleeding[a]; baseline SCr, aPTT, INR, Hgb, HCT, and platelet count
Fibrinolytics	Bleeding, especially ICH	Clinical signs of bleeding[a]; baseline aPTT, INR, Hgb, HCT, and platelet count; mental status every 2 hours for signs of ICH; daily Hgb, HCT, and platelet count

(*Continued*)

Table 8–5

Therapeutic Drug Monitoring of Pharmacotherapy for Acute Coronary Syndromes (*Continued*)

Drug	Adverse Effects	Monitoring
GPIs	Bleeding, acute profound thrombocytopenia	Clinical signs of bleeding[a]; baseline SCr (for eptifibatide and tirofiban), Hgb, HCT, and platelet count; platelet count at 4 hours after initiation; daily Hgb, HCT, and platelet count (and SCr for eptifibatide and tirofiban)
IV nitrates	Hypotension, flushing, headache, tachycardia	BP and HR every 2 hours
β-Blockers	Hypotension, bradycardia, heart block, bronchospasm, acute HF, fatigue, depression, sexual dysfunction	BP, RR, HR, 12-lead ECG, and clinical signs of HF every 5 minutes with bolus IV dosing; BP, RR, HR, and clinical signs of HF every shift with oral therapy, then BP and HR every 6 months following hospital discharge
Diltiazem and verapamil	Hypotension, bradycardia, heart block, HF, constipation, gingival hyperplasia	BP and HR every shift with oral therapy, then every 6 months following hospital discharge; dental examination and teeth cleaning every 6 months
Amlodipine	Hypotension, dependent peripheral edema, gingival hyperplasia	BP every shift with oral therapy, then every 6 months following hospital discharge; dental examination and teeth cleaning every 6 months
ACE inhibitors and ARBs	Hypotension, cough (with ACE inhibitors), hyperkalemia, prerenal azotemia, acute renal failure, angioedema (ACE inhibitors more so than ARBs)	BP every 4 hours × 3 for first dose, then every shift with oral therapy, then once every 6 months following hospital discharge; baseline SCr and potassium; daily SCr and potassium while hospitalized, then every 6 months (or 1–2 weeks after each outpatient dose titration); closer monitoring required in patients receiving spironolactone or eplerenone or if renal insufficiency; counsel patient on symptoms of angioedema including throat, tongue, and facial swelling
Aldosterone antagonists	Hypotension, hyperkalemia, increased SCr	BP and HR every shift with oral therapy, then once every 6 months; SCr and serum potassium concentration at baseline then at 48 hours, at 7 days, monthly for 3 months, then every 3 months thereafter
Morphine	Hypotension, respiratory depression	BP and RR 5 minutes after each bolus dose and resolution of pain
Statins	GI upset, myopathy, hepatotoxicity	Liver function tests at baseline. Lipid panel for adherence. CK if indicated. Only repeat if patients present with sign/symptoms of liver failure or muscle symptoms; counsel patient on myalgia; consider CK at baseline if adding a fibrate or niacin

[a]Clinical signs of bleeding include bloody stools, melena, hematuria, hematemesis, bruising, and oozing from arterial or venous puncture sites.

ACE, angiotensin-converting enzyme; ACT, activated clotting time; aPTT, activated partial thromboplastin time; ARB, angiotensin receptor blocker; BP, blood pressure; CK, creatine kinase; ECG, electrocardiogram; GI, gastrointestinal; GPI, glycoprotein IIb/IIIa inhibitor; HCT, hematocrit; HF, heart failure; Hgb, hemoglobin; HR, heart rate; ICH, intracranial hemorrhage; INR, international normalized ratio; IV, intravenous; RR, respiratory rate; SCr, serum creatinine; TTP, thrombotic thrombocytopenic purpura.

Modified with permission from Rogers KC, de Denus S, Finks SW, Spinler SA. Acute coronary syndromes. In: DiPiro JT, Talbert RL, Yee GC, et al. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:188.

Patient Care Process

Collect Information:

- Perform a medication history (including prescriptions, over-the-counter medications, and dietary supplements). Identify whether the patient has any drug allergies or is experiencing side effects from therapy.
- Review the medical history to identify possible causes of ACS (eg, HTN, hyperlipidemia).
- Review the medical history and physical assessment findings, specifically
  - Possible causes and risk factors for ACS (eg, tobacco use, HTN, hyperlipidemia)
  - Family history of premature ASCVD
  - Patient's description of chest pain, precipitating causes, other symptoms, and what may have relieved the chest pain
  - Results of the 12-lead ECG which should be performed and interpreted within 10 minutes (see Figure 8–1)
  - Serial cardiac troponin levels at presentation and 3–6 hours after symptom onset. (See Figure 8–1 and Clinical Presentation and Diagnosis textbox). Serial troponin measurements are not necessary if the patient is experiencing a STEMI (see Figure 8–1)
  - Vital signs (eg, BP and HR) to determine need for appropriate treatment

(*Continued*)

Patient Care Process (*Continued*)

- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Risk stratify the patient using available risk calculators for those with NSTE-ACS (see Table 8–1).
- If the patient is diagnosed with ACS, determine what pharmacotherapy is indicated.
- For STEMI patients in non-PCI facilities, assess for contraindications for fibrinolytic therapy if patient cannot be transferred and undergo PCI within 120 minutes.
- If patient is already receiving pharmacotherapy for ACS, assess efficacy and safety. Are there any significant drug interactions? Document existing contraindications and adverse events to medications (eg, aspirin, $P2Y_{12}$ inhibitors, β-blockers, ACE inhibitors, or aldosterone antagonists) in the medical record.
- Determine whether recommended agents are included on the institution's formulary.
- Discuss prescription coverage with the patient to determine any barriers to paying for medications.
- Talk with patient and assess refill history, if available, to determine medication adherence and to identify any barriers to adherence.
- Review relevant laboratory tests (eg, electrolytes, lipids, renal function, CBC).

Develop a Care Plan:

- Use risk stratification to select site of care, antithrombotic therapies, and invasive management for patients with NSTE-ACS (see Figure 8–3).
- Choose appropriate initial therapy and antithrombotic therapy for patients presenting with STEMI based on reperfusion strategy chosen (see Figure 8–2).
- Assess for potential contraindications for antiplatelet (active bleeding, history of TIA/stroke, renal function) and anticoagulant therapies (SCr, hemoglobin/hematocrit, platelet function). See Table 8–3.
- Initiate ACE inhibitors (or ARBs) and aldosterone antagonists as appropriate before discharge.
- Initiate prescription of PPI therapy as appropriate for those requiring triple therapy with aspirin, a $P2Y_{12}$ receptor inhibitor, and a vitamin K antagonist.
- Assess for appropriate vaccinations prior to discharge.

Implement the Care Plan:

- Verify orders for anti-ischemic (nitroglycerin [NTG], β-blockers), antiplatelet (aspirin), and analgesic (morphine) medications where appropriate early in care.
- Initiate appropriate antiplatelet and anticoagulant medications based on ACS type (STEMI vs NSTE-ACS) and strategy chosen (early invasive vs ischemia guided) (see Figures 8–2 and 8–3). If a patient has received fondaparinux and is going to the catheterization or cath laboratory, ensure that additional anticoagulation with UFH is given at time of intervention (see Figure 8–3).
- Review renal function and baseline coagulation tests (aPTT, platelets) to make appropriate dosing adjustments in antiplatelet and anticoagulant therapies given during early ACS.
- Appropriately adjust all medications based on renal function (see Table 8–3).
- Monitor for signs and symptoms of bleeding during hospitalization and prior to discharge.
- Ensure all patients without contraindications receive oral β-blockers, preferably within the first 24 hours.
- Patients with initial contraindications to β-blockers in the first 24 hours should be reevaluated for therapy prior to discharge.
- Ensure all patients receive aspirin and statins at discharge and continue indefinitely as long as no contraindication exists.
- Educate patient on discharge prescriptions for DAPT (with aspirin 81 mg plus a $P2Y_{12}$ inhibitor), which should be given for 12 months after ACS regardless of stenting. Also, discuss with the patient the importance of DAPT (especially in the patient receiving a stent).
- Ensure patients receive a prescription for SL NTG at the time of discharge with verbal and written instructions for use.
- Continue anti-ischemic medications at discharge in those with recurrent symptoms or in patients who do not undergo revascularization.
- Discontinue NSAIDs and select COX-2 inhibitor agents taken prior to ACS.
- Educate patients about appropriate cholesterol management, BP goals, smoking cessation, and lifestyle management with easily understandable and culturally sensitive verbal and written instructions.
- Address musculoskeletal pain control prior to discharge.
- Refer all patients to a comprehensive CV rehabilitation program.

Follow-up: Monitor and Evaluate:

- Follow-up within 2 weeks to assess angina symptoms and interventional success if applicable.
- Review medical history and physical examination findings, laboratory tests, and results of other diagnostic workup.
- Discuss adherence with medications and discover if the patient is experiencing any adverse events from medications.

hypotension secondary to hypovolemia may require blood transfusion.

LO 6

- Because poor medication adherence of secondary prevention medications following MI leads to worsened CV outcomes, patients should receive medication counseling (including counseling prior to hospital discharge) and be monitored for medication persistence.[3,4,43] Counseling should include assessment of health literacy level, assessment of barriers to adherence, assessment of access to medications, written and verbal instructions about the purpose of each medication, changes to previous medication regimen, optimal time to take each medication, new allergies or medication intolerances, need for timely prescription fill after discharge, anticipated duration of therapy, consequences of nonadherence, common and/or serious adverse reactions that may develop, drug–drug and drug–food interactions, and an assessment of instruction understanding.

ACKNOWLEDGMENT

The authors and editors wish to acknowledge and thank Dr. Simon de Denus, a co-author of this chapter in the first, second, third, and fourth editions of this book.

Abbreviations Introduced in This Chapter

ACC	American College of Cardiology
ACCF	American College of Cardiology Foundation
ACE	Angiotensin-converting enzyme
ACS	Acute coronary syndrome
ACT	Activated clotting time
ADP	Adenosine diphosphate
AHA	American Heart Association
aPTT	Activated partial thromboplastin time
ARB	Angiotensin receptor blocker
ASA	Aspirin
ASCVD	Atherosclerotic cardiovascular disease
BNP	B-type natriuretic peptide
BMS	Bare metal stent
BP	Blood pressure
CABG	Coronary artery bypass graft (surgery)
CAD	Coronary artery disease
CBC	Complete blood count
CHD	Coronary heart disease
CKD	Chronic kidney disease
COX-2	Cyclooxygenase-2
CrCl	Creatinine clearance
CV	Cardiovascular
CVD	Cardiovascular disease
CYP	Cytochrome P-450
DAPT	Dual antiplatelet therapy
DES	Drug-eluting stent
DM	Diabetes mellitus
ECG	Electrocardiogram
ED	Emergency department
GI	Gastrointestinal
GP	Glycoprotein
GPI	Glycoprotein IIb/IIIa inhibitor
HF	Heart failure
HMG CoA	3-hydroxy-3-methylglutaryl coenzyme A
HTN	Hypertension
ICD	Implantable cardioverter defibrillator
ICH	Intracranial hemorrhage
INR	International normalized ratio
IV	Intravenous
LDL	Low-density lipoprotein
LMWH	Low molecular weight heparin
LVEF	Left ventricular ejection fraction
LVF	Left ventricular function
MI	Myocardial infarction
NSAID	Nonsteroidal anti-inflammatory drug
NSTE	Non–ST-segment elevation
NSTEMI	Non–ST-elevation myocardial infarction
NTG	Nitroglycerin
PCI	Percutaneous coronary intervention
PCSK9	Proprotein convertase subtilisin/kexin type
PPI	Proton pump inhibitor
SCAI	Society for Cardiovascular Angiography and Interventions
SCr	Serum creatinine
SL	Sublingual
STE	ST-segment elevation
STEMI	ST-segment elevation myocardial infarction
TIA	Transient ischemic attack
TIMI	Thrombolysis in myocardial infarction
TTP	Thrombotic thrombocytopenic purpura
TXA_2	Thromboxane A_2
UA	Unstable angina
UFH	Unfractionated heparin

9 Arrhythmias

James E. Tisdale

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the phases of cardiac action potential, compare and contrast cardiac myocyte ion currents corresponding to each phase, and explain the relationship between the cardiac action potential and the electrocardiogram (ECG).
2. Describe the modified Vaughan Williams classification of antiarrhythmic drugs, and compare and contrast the effects of available antiarrhythmic drugs on ventricular conduction velocity, refractory period, automaticity, and inhibition of ion flux through specific myocyte ion channels.
3. Compare and contrast risk factors for and features, mechanisms, etiologies, symptoms, and goals of therapy of (a) sinus bradycardia, (b) atrioventricular (AV) block, (c) atrial fibrillation (AF), (d) paroxysmal supraventricular tachycardia (PSVT), (e) premature ventricular complexes (PVCs), (f) ventricular tachycardia (VT, including torsades de pointes [TdP]), and (g) ventricular fibrillation (VF).
4. Compare and contrast appropriate treatment options for sinus bradycardia and AV block.
5. Compare and contrast mechanisms of action of drugs used for ventricular rate control, conversion to sinus rhythm and maintenance of sinus rhythm in patients with AF.
6. Compare and contrast the advantages and disadvantages of warfarin and the non-vitamin K antagonist oral anticoagulants (NOACs) for prevention of stroke and systemic embolism in patients with AF.
7. Discuss nonpharmacologic methods for termination of PSVT, compare and contrast mechanisms of action of drugs used for acute termination of PSVT, and compare and contrast appropriate treatment options for long-term prevention of PSVT recurrence.
8. Describe the role of drug therapy for management of asymptomatic and symptomatic PVCs.
9. Compare and contrast mechanisms of action of drugs used for treatment of acute episodes of VT, and describe options and indications for nonpharmacologic treatment of VT and VF.
10. Design individualized drug therapy treatment plans for patients with (a) sinus bradycardia, (b) AV block, (c) AF, (d) PSVT, (e) PVCs, (f) VT (including TdP), and (g) VF.

NORMAL AND ABNORMAL CARDIAC CONDUCTION AND ELECTROPHYSIOLOGY

The heart functions via mechanical and electrical activity. Mechanical activity refers to atrial and ventricular contraction, the mechanism by which blood is delivered to tissues. When deoxygenated blood returns to the heart via venous circulation, the blood enters the right atrium. Right atrial contraction and right ventricular pressure changes result in delivery of blood to the right ventricle through the tricuspid valve. Right ventricular contraction pumps blood through the pulmonic valve and through the pulmonary arteries to the lungs, where blood becomes oxygenated. The oxygenated blood then flows through the pulmonary veins into the left atrium. Left atrial contraction and left ventricle (LV) pressure changes result in delivery of blood through the mitral valve into the LV, contraction of which results in pumping of blood through the aortic valve and to the tissues of the body.

Mechanical activity is stimulated by the electrical activity of the heart. The heart possesses an intrinsic electrical conduction system (Figure 9–1). Normal myocardial contraction cannot occur without normal function of the heart's electrical conduction system. Depolarization of the atria results in atrial contraction, and ventricular depolarization produces ventricular contraction. Perturbation of the heart's electrical conduction system may result in dysfunctional atrial and/or ventricular contraction and may reduce cardiac output.

Cardiac Conduction System

The sinoatrial (SA) node (frequently referred to as the sinus node), located in the upper portion of the right atrium, normally serves as the pacemaker of the heart and generates the electrical impulses that subsequently result in atrial and ventricular depolarization (see Figure 9–1). The sinus node serves as the heart's dominant pacemaker because it has the greatest degree of automaticity,

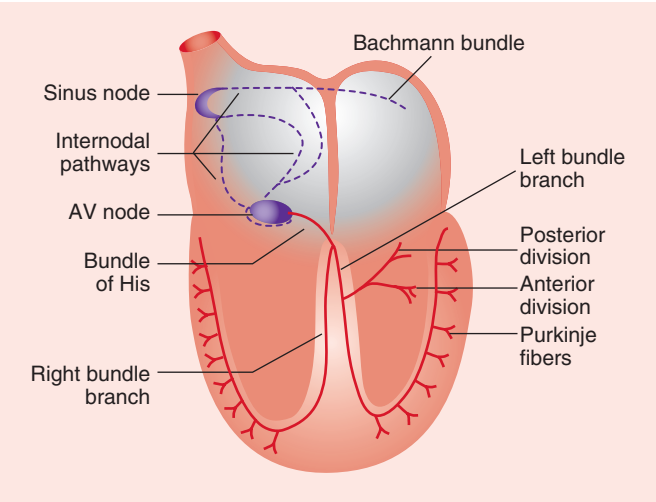

FIGURE 9–1. The cardiac conduction system. (AV, atrioventricular.)

defined as the ability of a cardiac fiber or tissue to initiate depolarizations spontaneously. In adults at rest, the normal intrinsic depolarization rate of the sinus node is 60 to 100 per minute. Other cardiac fibers also possess the property of automaticity, but normally the intrinsic depolarization rates are slower than that of the sinus node. For example, the normal depolarization rate of the atrioventricular (AV) node and ventricular tissue are 40 to 60 per minute and 30 to 40 per minute, respectively. Therefore, as a result of greater automaticity, the sinus node normally serves as the pacemaker of the heart. However, if the sinus node fails to generate depolarizations at a rate faster than that of the AV node, the AV node may take over as the pacemaker. If both the sinus node and AV node fail to generate depolarizations at a rate more than 30 to 40 per minute, ventricular tissue may take over.

Following initiation of the electrical impulse from the sinus node, the impulse travels through internodal pathways of the specialized atrial conduction system and the Bachmann bundle. The atrial conducting fibers do not traverse the entire breadth of the left and right atria; upon excitation via the internodal pathways and the Bachmann bundle, atrial depolarization spreads as a wave, conceptually similar to that which occurs upon throwing a pebble into water. As the impulse is conducted across the atria, each depolarized cell depolarizes the surrounding connected cells, until both atria have been completely depolarized. Atrial contraction follows normal atrial depolarization.

Following atrial depolarization, impulses are conducted through the AV node, located in the lower right atrium (see Figure 9–1). The impulse then enters the bundle of His and is conducted through the ventricular conduction system, consisting of the left and right bundle branches. The LV requires a larger conduction system than the right ventricle due to its larger mass; therefore, the left bundle branch bifurcates into the left anterior and posterior divisions (also known as "fascicles"). The bundle branches further divide into the **Purkinje fibers** through which impulse conduction results in ventricular depolarization, initiating ventricular contraction.

Ventricular Action Potential

LO 1

Ventricular **action potential** is depicted in **Figure 9–2**. Ventricular myocyte resting membrane potential is –70 to –90 mV, due to the function of the sodium–potassium adenosine triphosphatase (ATPase) pump, which maintains relatively high extracellular sodium concentrations and low extracellular potassium concentrations. During each action potential cycle, the membrane potential slowly increases due to a slow influx of sodium into the cell, raising the threshold to –60 to –80 mV. When the membrane potential reaches this threshold, the fast

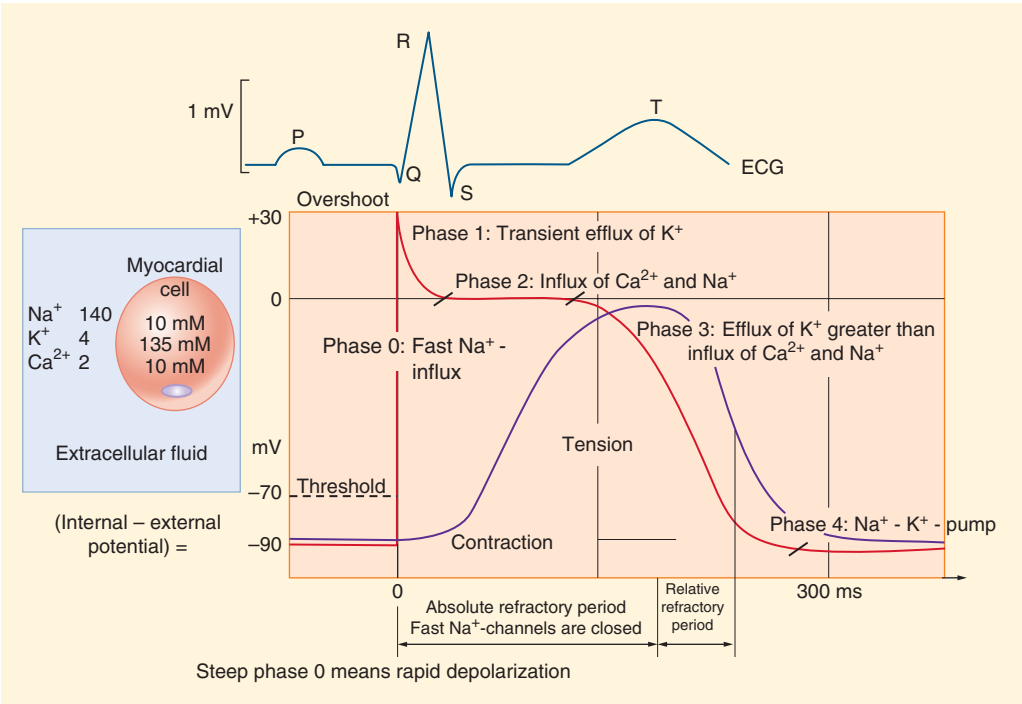

FIGURE 9–2. The ventricular action potential depicting the flow of specific ions responsible for each phase. The phases of the action potential that correspond to the absolute and relative refractory periods are portrayed, and the relationship between phases of the action potential and the ECG are shown. The red line represents the ventricular action potential and the purple line represents ventricular contraction. (Ca, calcium; K, potassium; Na, sodium.)

sodium channels open, allowing rapid entry of sodium ions into the cell. This rapid influx of positive ions creates a vertical upstroke of the action potential, which reaches 20 to 30 mV. This is phase 0, representing ventricular depolarization. At this point, the fast sodium channels become inactivated, and ventricular repolarization begins, consisting of phases 1 through 3. Phase 1 repolarization occurs primarily as a result of an efflux of potassium ions. During phase 2, potassium ions continue to exit the cell, but the membrane potential is balanced by an influx of calcium and sodium ions, transported through slow calcium and slow sodium channels, resulting in a plateau. During phase 3, the efflux of potassium ions greatly exceeds calcium and sodium influx, resulting in the major component of ventricular repolarization. During phase 4, sodium ions gradually enter the cell, increasing the threshold again to −60 to −80 mV and initiating another action potential. Understanding the ion fluxes responsible for each phase of the action potential facilitates understanding of the effects of specific drugs. For example, drugs that primarily inhibit ion flux through sodium channels influence phase 0 (ventricular depolarization), whereas drugs that primarily inhibit ion flux through potassium channels influence the repolarization phases, particularly phase 3.

Electrocardiogram

LO 1

The electrocardiogram (ECG) is a noninvasive means of measuring the heart's electrical activity. The relationship between the ventricular action potential and the ECG is depicted in Figure 9–2. The P wave on the ECG represents atrial depolarization (not depicted in Figure 9–2, which shows only the ventricular action potential). Phase 0 of the action potential corresponds to the QRS complex, which therefore is a noninvasive representation of ventricular depolarization. The T wave on the ECG corresponds to phase 3 ventricular repolarization. The interval from the beginning of the Q wave to the end of the T wave, known as the QT interval, is used as a noninvasive marker of ventricular repolarization time. Atrial repolarization is not visible on the ECG because it occurs during ventricular depolarization and is obscured by the QRS complex.

Several ECG intervals and durations are measured routinely. The PR interval represents the time of impulse conduction from the atria to the ventricles through the AV node; normal PR interval in adults is 0.12 to 0.2 seconds (120–200 ms). The QRS duration represents the time required for ventricular depolarization, which is normally 0.08 to 0.12 seconds (80–120 ms) in adults. The QT interval, measuring 0.32 to 0.4 seconds (320–400 ms), represents the time required for ventricular repolarization. The QT interval varies with heart rate—the faster the heart rate, the shorter the QT interval, and vice versa. Therefore, the QT interval is corrected for heart rate using the Bazett formula:

$$QTc = \frac{QT}{\sqrt{RR}}$$

where QTc is the QT interval corrected for heart rate, and RR is the interval from the onset of one QRS complex to the onset of the next QRS complex, measured in seconds (ie, the heart rate, expressed in different terminology). Normal QTc interval in adults is 0.36 to 0.47 seconds (360–470 ms) in men and 0.36 to 0.48 seconds (360–480 ms) in women.[1]

Refractory Periods

After an impulse is initiated and conducted, there is a period during which cells and fibers cannot be depolarized again, which is referred to as the absolute refractory period (see Figure 9–2) and corresponds to phases 1, 2, and approximately one-third of phase 3 repolarization. The absolute refractory period also corresponds to the period from the Q wave to approximately the first half of the T wave on the ECG (see Figure 9–2). During this period, if there is a premature stimulus for an electrical impulse, this impulse cannot be conducted because the tissue is absolutely refractory to conduction. However, there is a period following the absolute refractory period during which a premature electrical stimulus can be conducted and is often conducted abnormally, which is called the relative refractory period, corresponding roughly to the latter two-thirds of phase 3 repolarization on the action potential and to the latter half of the T wave on the ECG. The relative refractory period is also sometimes referred to as the "vulnerable period." If a premature electrical stimulus is initiated during the relative refractory period, it can be conducted abnormally, potentially resulting in an arrhythmia.

Mechanisms of Cardiac Arrhythmias

KEY CONCEPT Cardiac arrhythmias are caused by (a) abnormal impulse initiation, (b) abnormal impulse conduction, or (c) both.

▶ *Abnormal Impulse Initiation*

Abnormal initiation of electrical impulses occurs due to abnormal automaticity. A decrease in sinus node automaticity results in a reduced rate of impulse generation and a slow heart rate (sinus bradycardia). Conversely, an increase in sinus node automaticity results in an increased rate of impulse generation and a rapid heart rate (sinus tachycardia). If other cardiac fibers become abnormally automatic, such that the rate of spontaneous impulse initiation exceeds that of the sinus node, or premature impulses are generated, other tachyarrhythmias may occur. Many cardiac fibers possess the capability for automaticity, including atrial tissue, the AV node, the Purkinje fibers, and ventricular muscle. In addition, fibers with the capability of initiating and conducting electrical impulses are present in left atrial myocardial sleeves that extend into the pulmonary veins. Abnormal atrial automaticity may result in premature atrial depolarizations or may precipitate atrial tachycardia or atrial fibrillation (AF); abnormal AV nodal automaticity may result in "junctional tachycardia" (so named because the AV node is also sometimes referred to as the AV junction). Abnormal automaticity originating from the pulmonary veins is a precipitant of AF. In addition, abnormal automaticity in the ventricles may result in premature ventricular complexes (PVCs) or may precipitate ventricular tachycardia (VT) or ventricular fibrillation (VF).

Automaticity of cardiac fibers is controlled in part by activity of the sympathetic and parasympathetic nervous systems. Enhanced sympathetic nervous system activity may result in increased automaticity of the sinus node or other automatic cardiac fibers. Enhanced parasympathetic nervous system activity suppresses automaticity, while inhibition of parasympathetic nervous system activity increases automaticity. Other factors may lead to increases in automaticity of extra-sinus node tissues, including hypoxia, atrial or ventricular stretch (such as following long-standing hypertension or during and after development of heart failure [HF]), and electrolyte abnormalities such as hypokalemia or hypomagnesemia.

▶ *Abnormal Impulse Conduction*

The mechanism of abnormal impulse conduction is referred to as reentry. Reentry is often triggered as a result of an abnormal premature electrical impulse (abnormal automaticity); therefore, in these situations, the mechanism of the arrhythmia is both

abnormal impulse formation (automaticity) and abnormal impulse conduction (reentry). For reentry to occur, three conditions must be present. There must be: (a) at least two pathways down which an electrical impulse may travel (which is the case in most cardiac fibers); (b) a "unidirectional block" in one of the conduction pathways (this "unidirectional block" reflects prolonged refractoriness in this pathway, or increased "dispersion of refractoriness," defined as substantial variation in refractory periods between cardiac fibers); and (c) slowing of the velocity of impulse conduction down the other conduction pathway.

The process of reentry is depicted in Figure 9–3.[2] Normally, when a premature impulse is initiated, it cannot be conducted in either direction down either pathway because the tissue is in its absolute refractory period from the previous impulse. A premature impulse may be conducted down both pathways if it is only slightly premature and arrives after the tissue is no longer refractory. However, when refractoriness is prolonged down one of the pathways, a precisely timed premature beat may be conducted down one pathway but cannot be conducted in either direction in the pathway with prolonged refractoriness because the tissue is still in its absolute refractory period.[2] Refractoriness may be prolonged to a greater degree in one pathway than in the other as a result of increased dispersion of repolarization. When the third condition for reentry is present, the impulse traveling forward down the other pathway still cannot be conducted. However, because the impulse in one pathway is traveling more slowly than normal, by the time it circles around and travels upward along the other pathway, sufficient time has passed so the pathway is no longer in its absolute refractory period, and now the impulse may travel upward in that pathway. In other words, the electrical impulse "reenters" a previously stimulated pathway in the reverse (retrograde) direction. This results in circular movement of electrical impulses; as the impulse travels in this circular fashion, it depolarizes each cell around it, and if the impulse is traveling at a rate faster than the intrinsic rate of the sinus node, a tachycardia occurs. Reentry may occur in numerous tissues, including the atria, the AV node, and the ventricles.

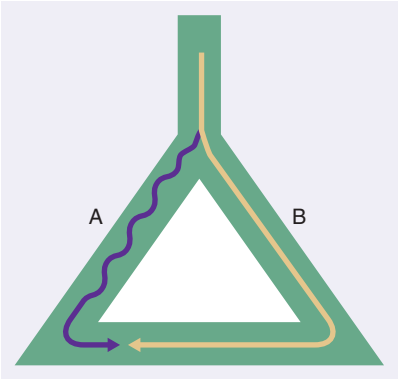

FIGURE 9–3. The process of initiation of reentry. There are two pathways for impulse conduction, slowed impulse conduction down pathway A and a longer refractory period in pathway B. A precisely timed premature impulse initiates reentry; the premature impulse cannot be conducted down pathway B because the tissue is still in the absolute refractory period from the previous, normal impulse. However, because of dispersion of refractoriness (ie, different refractory periods down the two pathways), the impulse can be conducted down pathway A. Because conduction down pathway A is slowed, by the time the impulse reaches pathway B in a retrograde direction, the impulse can be conducted retrogradely up the pathway because the pathway is now beyond its refractory period from the previous impulse. This creates reentry, in which the impulse continuously and repeatedly travels in a circular fashion around the loop.

Prolonged refractoriness and/or slowed impulse conduction velocity may be present in cardiac tissues for a variety of reasons. Myocardial ischemia may alter ventricular refractory periods or impulse conduction velocity, facilitating ventricular reentry. In patients with past myocardial infarction (MI), the infarcted myocardium is dead and cannot conduct impulses. However, there is typically a border zone of tissue that is damaged and in which refractory periods and conduction velocity are aberrant, facilitating ventricular reentry. In patients with left atrial or LV hypertrophy as a result of hypertension, refractory periods and conduction velocity are often perturbed. In patients with HF with reduced ejection fraction (HFrEF), ventricular refractoriness and conduction velocity are often altered due to LV hypertrophy, collagen deposition, and other anatomical and structural changes.

Vaughan Williams Classification of Antiarrhythmic Drugs

LO 2

The modified Vaughan Williams classification of antiarrhythmic drugs is presented in Table 9–1.[3-5] This classification is based on the effects of drugs on ventricular conduction velocity, repolarization/refractoriness, and automaticity. Class I drugs inhibit ventricular automaticity and decrease conduction velocity. However, due to differences in the potency of the drugs to reduce conduction velocity, the class I drugs are subdivided into classes IA, IB, and IC. The class IC drugs have the greatest potency for slowing ventricular conduction, class IA drugs have intermediate potency, and class IB drugs have the lowest potency, with minimal effects on conduction velocity at normal heart rates. Class II drugs are the adrenergic β-receptor inhibitors (β-blockers), class III drugs are those that delay ventricular repolarization and prolong refractoriness, and class IV drugs are the nondihydropyridine calcium channel blockers (CCBs) diltiazem and verapamil.

The Vaughan Williams classification of antiarrhythmic drugs has notable limitations. The classification is based on the effects of drugs on normal, rather than diseased, myocardium. In addition, many of the drugs may be placed into more than one class. For example, the class IA drugs prolong repolarization/refractoriness, either via the parent drug[6] or an active metabolite,[7] and therefore may also be placed in class III. Sotalol is also a β-blocker and therefore fits into class II. Amiodarone inhibits sodium and potassium conductance, is a noncompetitive inhibitor of β-receptors, and inhibits calcium channels, and therefore may be placed into any of the four classes. For this reason, drugs within each class cannot be considered interchangeable. Nonetheless, despite attempts to develop mechanism-based classifications that better distinguish the actions of antiarrhythmic drugs, the Vaughan Williams classification continues to be widely used because of its simplicity.

CARDIAC ARRHYTHMIAS

Arrhythmias are classified into two broad categories: supraventricular (those occurring above the ventricles) and ventricular (those occurring in the ventricles). Names of specific arrhythmias are generally composed of two words, the first of which indicates the location of the electrophysiological abnormality resulting in the arrhythmia (sinus node, AV node,

Table 9–1

Vaughan Williams Classification of Antiarrhythmic Agents[a,3-5]

Class	Drug	Conduction Velocity[b]	Repolarization/Refractoriness[b]	Automaticity[b]
IA	Quinidine Procainamide Disopyramide	↓	↑	↓
IB	Lidocaine Mexiletine	0/↓	↓/0	↓
IC	Flecainide Propafenone	↓↓	0	↓
II	β-Blockers[c] Acebutolol Atenolol Betaxolol Bisoprolol Carteolol Carvedilol[d] Esmolol Labetalol[d] Metoprolol Nadolol Nebivolol Penbutolol Pindolol Propranolol Timolol	0	0	0
III	Amiodarone[e] Dofetilide Dronedarone[e] Ibutilide Sotalol	0	↑	0
IV	CCBs[c] Diltiazem Verapamil	0	0	0

[a]Adenosine and digoxin are agents used for the management of arrhythmias that do not fit into the Vaughan Williams classification.

[b]In ventricular tissue only; effects may differ in atria, sinus node, or atrioventricular node.

[c]Slow conduction, prolong refractory period, and reduce automaticity in sinoatrial node and atrioventricular node tissue but generally not in the ventricles.

[d]Combined α- and β-blocker.

[e]Amiodarone and dronedarone also slow conduction velocity and inhibit automaticity.

CCB, calcium channel blocker; ↑, increase/prolong; ↓, decrease; 0, no effect; 0/↓, does not change or may decrease: ↓/0, decreases or does not change.

atrial, or ventricular), and the second describes the arrhythmia as abnormally slow (bradycardia) or fast (tachycardia), or the type of arrhythmia (block, fibrillation, or flutter).

SUPRAVENTRICULAR ARRHYTHMIAS

Sinus Bradycardia

Sinus bradycardia is defined by a sinus rate less than 60 beats/min.[8]

► *Epidemiology and Etiology*

LO 3

Many individuals, particularly those who engage in regular vigorous exercise, have resting heart rates less than 60 beats/min. For those individuals, sinus bradycardia is normal and healthy, and does not require evaluation or treatment. However, some people develop symptomatic sinus node dysfunction. In the absence of correctable underlying causes, idiopathic sinus node dysfunction is referred to as sick sinus syndrome. The prevalence of sick sinus syndrome is approximately 1 in 600 individuals older than 65 years, while the incidence is about 0.8 per 1000 person-years of follow-up.[9] The incidence of sick sinus syndrome increases with advancing age and is higher in white versus black individuals.[9] Sinus node dysfunction accounts for roughly 50% of all pacemaker implantations in the United States,[9] and may also manifest as the bradycardia-tachycardia syndrome (also known as tachy-brady syndrome) characterized by alternating periods of supraventricular tachyarrhythmias and bradycardia.[8]

LO 3

Sick sinus syndrome leading to sinus bradycardia may be caused by degenerative changes in the sinus node that occur with advancing age. However, there are other possible etiologies of sinus bradycardia including drugs (Table 9–2).[8,10]

► *Pathophysiology*

LO 3

Sick sinus syndrome leading to sinus bradycardia occurs as a result of fibrotic tissue in the sinus node, which replaces normal sinus node tissue.[8]

Table 9–2

Etiologies of Sinus Bradycardia[8,10]

Idiopathic ("sick sinus syndrome")
Myocardial ischemia
Carotid sinus hypersensitivity
Neurocardiac syncope
Electrolyte abnormalities: hypokalemia or hyperkalemia
Hypothyroidism
Hypothermia
Amyloidosis
Sarcoidosis
Systemic lupus erythematosus
Scleroderma
Sleep apnea
Drugs:

- Adenosine
- Amiodarone
- β-Blockers
- Cisplatin
- Citalopram
- Clonidine
- Cocaine
- Dexmedetomidine
- Digoxin
- Diltiazem
- Dipyridamole
- Disopyramide
- Donepezil
- Dronedarone
- Fingolimod
- Flecainide
- Fluoxetine
- Halothane
- Isradipine
- Ivabradine
- Ketamine
- Neostigmine
- Nicardipine
- Nitroglycerin
- Paclitaxel
- Pregabalin
- Propafenone
- Propofol
- Remifentanil
- Sotalol
- Succinylcholine
- Thalidomide
- Verapamil

Clinical Presentation and Diagnosis of Sinus Bradycardia

Symptoms

LO 3

- Many patients are asymptomatic, particularly those with normal resting heart rates less than 60 beats/min as a result of physical fitness due to regular exercise
- Susceptible patients may develop symptoms, depending on the degree of heart rate lowering
- Symptoms include dizziness, fatigue, light-headedness, syncope, chest pain (in patients with underlying coronary artery disease [CAD]), and shortness of breath and other symptoms of HF (in patients with underlying LV dysfunction)

Diagnosis

- Cannot be made on the basis of symptoms alone because the symptoms of all bradyarrhythmias are similar
- History of present illness, presenting symptoms, and 12-lead ECG that reveals sinus bradycardia
- Assess possible correctable etiologies, including myocardial ischemia, serum potassium concentration (for hyperkalemia), thyroid function tests (for hypothyroidism)
- Determine whether patient is taking any drugs known to cause sinus bradycardia. If the patient is currently taking digoxin, determine the serum digoxin concentration and ascertain whether it is supratherapeutic (> 2 ng/mL [2.6 nmol/L])

▶ *Treatment*

LO 3

Desired Outcomes Desired outcomes of treatment are to restore normal heart rate and alleviate patient symptoms.

Pharmacologic Therapy KEY CONCEPT Treatment of sinus bradycardia is only necessary in patients who become symptomatic. If the patient is taking any medication(s) that may cause symptomatic sinus bradycardia, they should be discontinued whenever possible. If the patient remains in sinus bradycardia after drug discontinuation and after five half-lives of the drug(s) have elapsed, then drug(s) can usually be excluded as the etiology. In certain circumstances, however, discontinuation may be undesirable, even if the drug may be the cause of symptomatic sinus bradycardia. For example, if the patient has a history of MI or HFrEF, discontinuation of a β-blocker may be necessary in the short term but undesirable long term because β-blockers reduce mortality and prolong life in patients with these diseases, and benefits of therapy outweigh risks associated with sinus bradycardia. In this situation, clinicians and patients may elect to implant a permanent pacemaker to allow continuation of therapy with β-blockers.

LO 4 LO 10

KEY CONCEPT Acute treatment of the symptomatic and/or hemodynamically unstable patient with sinus bradycardia includes administration of the anticholinergic drug atropine, which should be given in doses of 0.5 mg intravenous (IV) every 3 to 5 minutes to a maximum recommended total dose of 3 mg.[11] Atropine is generally used as a method of achieving acute symptom control while awaiting placement of a transcutaneous or transvenous pacemaker. Where necessary, transcutaneous pacing can be initiated during atropine administration. Atropine should be used cautiously in patients with myocardial ischemia or MI because increasing heart rate and myocardial oxygen demand may aggravate ischemia or extend the infarct.

In patients with hemodynamically unstable sinus bradycardia unresponsive to atropine, transcutaneous pacing may be initiated. In patients with hemodynamically unstable or severely symptomatic sinus bradycardia unresponsive to atropine and in whom temporary or transvenous pacing is not available or is ineffective, or while awaiting placement of a pacemaker, dopamine (2–10 mcg/kg/min, titrate to response), epinephrine (2–10 mcg/min, titrate to response), or isoproterenol (2–10 mcg/min, titrate to response) may be administered to increase heart rate.[11]

In patients with sinus bradycardia due to underlying correctable disorders (such as electrolyte abnormalities or hypothyroidism), management consists of correcting those disorders.

LO 4

Nonpharmacologic Therapy Long-term management of patients with sick sinus syndrome requires implantation of a permanent pacemaker.[8]

▶ *Outcome Evaluation*

- Monitor heart rate and alleviation of symptoms.
- Monitor for adverse effects of medications such as atropine (dry mouth, mydriasis, urinary retention, and tachycardia).

AV Block

LO 3

AV block occurs when conduction of electrical impulses through the AV node is impaired to varying degrees. AV block is classified into three categories. First-degree (1°) AV block is defined simply as prolongation of the PR interval to greater than 0.2 seconds. During 1° AV block, all impulses initiated by the sinus node resulting in atrial depolarization are conducted through the AV

node; the abnormality is simply that the impulses are conducted more slowly than normal, resulting in prolongation of the PR interval.[12] Second-degree (2°) AV block is further distinguished into two types: Mobitz type I (also known as Wenckebach) and Mobitz type II. In both types, some of the impulses initiated by the sinus node are not conducted through the AV node. This often occurs in a regular pattern; for example, there may be absence of AV nodal conduction of every third or fourth impulse. During third-degree (3°) AV block, also referred to as "complete heart block," none of the impulses generated by the sinus node are conducted through the AV node. This results in AV dissociation, during which the atria continue to depolarize normally as a result of normal impulses initiated by the sinus node; however, the ventricles initiate their own depolarizations because no sinus node-generated impulses are conducted to the ventricles. Therefore, on the ECG, there is no relationship (dissociation) between the P waves and the QRS complexes.

▶ *Epidemiology and Etiology*

LO 3

Overall incidence of AV block is unknown. AV block may be caused by degenerative changes in the AV node. In addition, there are many other possible etiologies of AV block including drugs (Table 9–3).[8,10,12]

▶ *Pathophysiology*

1° AV block is due to inhibition of conduction within the upper portion of the node.[12] Mobitz type I 2° AV block results from inhibition of conduction further down within the node.[8,12] Mobitz type II 2° AV block is caused by inhibition of conduction within or below the level of the bundle of His.[8,12] 3° AV block may be a result of inhibition of conduction either within the AV node or within the bundle of His or the His-Purkinje system.[8,12] AV block may occur as a result of age-related AV node degeneration.

Table 9–3

Etiologies of Atrioventricular (AV) Block[8,10,12]

Idiopathic degeneration of the AV node
Myocardial ischemia or infarction
Neurocardiac syncope
Carotid sinus hypersensitivity
Electrolyte abnormalities: hypokalemia or hyperkalemia
Hypothyroidism
Hypothermia
Infectious diseases: Chagas disease or endocarditis
Amyloidosis
Sarcoidosis
Systemic lupus erythematosus
Scleroderma
Sleep apnea
Drugs:
- Adenosine
- Amiodarone
- β-Blockers
- Bupivacaine
- Carbamazepine
- Chloroquine
- Digoxin
- Diltiazem
- Dronedarone
- Fingolimod
- Flecainide
- Hydroxychloroquine
- Paclitaxel
- Phenylpropanolamine
- Propafenone
- Propofol
- Sotalol
- Thioridazine
- Tricyclic antidepressants
- Verapamil

Clinical Presentation and Diagnosis of AV Block

LO 3

Symptoms

- 1° AV block is rarely symptomatic because it rarely results in bradycardia
- 2° AV block may cause bradycardia because not all impulses generated by the sinus node are conducted through the AV node to the ventricles
- In 3° AV block, or complete heart block, the heart rate is often 30 to 40 beats/min, resulting in symptoms
- Symptoms consist of dizziness, fatigue, light-headedness, syncope, chest pain (in patients with underlying CAD), and shortness of breath and other symptoms of HF (in patients with underlying HF)

Diagnosis

- Made on the basis of patient presentation, including history of present illness and presenting symptoms, as well as a 12-lead ECG that reveals AV block
- Assess potentially correctable etiologies, including myocardial ischemia, serum potassium concentration (for hyperkalemia), and thyroid function tests (for hypothyroidism)
- Determine whether the patient is taking any drugs known to cause AV block
- If the patient is currently taking digoxin, determine the serum digoxin concentration and ascertain whether it is supratherapeutic (> 2 ng/mL [2.6 nmol/L])

▶ *Treatment*

LO 3

Desired Outcomes Desired outcomes of treatment are to restore normal sinus rhythm and alleviate patient symptoms.

Pharmacologic Therapy KEY CONCEPT Treatment of 1° AV block is rarely necessary because symptoms rarely occur. However, the ECGs of patients with 1° AV block should be monitored to assess the possibility of progression to 2° or 3° block, which requires treatment because bradycardia often results in symptoms. If the patient is taking any medication(s) that may cause AV block, the drug(s) should be discontinued whenever possible. If the patient's rhythm still exhibits AV block after discontinuing the medication(s) and after five half-lives of the drug(s) have elapsed, then drug(s) can usually be excluded as the etiology. However, in certain circumstances, discontinuation of a medication that is inducing AV block may be undesirable. For example, if the patient has a history of MI or HFrEF, discontinuation of a β-blocker is undesirable, as the benefits of therapy outweigh risks associated with AV block. In these patients, clinicians and patients may elect to implant a permanent pacemaker to allow the patient to continue β-blocker therapy.

LO 4 LO 10

KEY CONCEPT Acute treatment of patients with 2° or 3° AV block consists primarily of administration of atropine, which may be administered in the same doses as recommended for management of sinus bradycardia. In patients with hemodynamically unstable or severely symptomatic AV block that is unresponsive to atropine and in whom temporary or transvenous pacing is not available or is ineffective, epinephrine (2–10 mcg/min, titrate to response) and/or dopamine (2–10 mcg/kg/min) may be administered.[11]

In patients with 2° or 3° AV block due to underlying correctable disorders (such as electrolyte abnormalities or hypothyroidism), management consists of correcting those disorders.

LO 4 **Nonpharmacologic Therapy** Long-term treatment of patients with 2° or 3° AV block due to idiopathic AV node degeneration requires implantation of a permanent pacemaker.[8]

▶ *Outcome Evaluation*

- Monitor for termination of AV block and restoration of normal sinus rhythm, heart rate, and alleviation of symptoms.
- If atropine is administered, monitor for adverse effects, including dry mouth, mydriasis, urinary retention, and tachycardia.

Atrial Fibrillation

AF is the most common arrhythmia encountered in clinical practice. It is important for clinicians to understand AF because it is associated with substantial morbidity and mortality, and because many strategies for drug therapy are available. Some drugs used to treat AF have a narrow therapeutic index and a broad adverse effect profile.

▶ *Epidemiology and Etiology*

Approximately 2.7–6.1 million Americans have AF,[9] and as many as 4.5 million in the European Union. Prevalence and incidence of AF increases with advancing age; roughly 8% of patients between 80 and 89 years old have AF. AF occurs more commonly in men than women.

LO 3 Etiologies of AF are presented in Table 9–4.[10,13-17] The common feature of the majority of etiologies is the development of left atrial hypertrophy. Hypertension may be the most important risk factor for AF development. However, AF also occurs commonly in patients with CAD. HF is increasingly recognized as a cause; approximately 25% to 30% of patients with New York Heart Association (NYHA) class III HF and as many as 50% of patients with NYHA class IV HF have AF.[14] AF is responsible for more than 467,000 annual hospitalizations in the United States.[17]

Drug-induced AF is relatively uncommon but has been reported (see Table 9–4).[10,15,16] Acute ingestion of large amounts of alcohol may cause AF. Recent evidence suggests that chronic moderate alcohol intake also may be associated with an increased risk of AF. In addition, recent reports have associated use of some bisphosphonate drugs with new-onset AF, but this potential relationship requires further study.[16]

Table 9–4

Etiologies of Atrial Fibrillation (AF)[10,13-17]

Older age
Hypertension
Myocardial infarction
Heart failure
Diabetes mellitus
Hyperthyroidism
Rheumatic heart disease
Diseases of the heart valves:
Mitral stenosis or regurgitation
Mitral valve prolapse
Obesity
Smoking
Obstructive sleep apnea
Pericarditis
Amyloidosis
Myocarditis
Pulmonary embolism
Idiopathic
Family history
Genetic predisposition
Thoracic surgery:
Coronary artery bypass graft surgery
Pulmonary resection
Thoracoabdominal esophagectomy
Drugs:
Adenosine
Albuterol
Alcohol
Alendronate
Dobutamine
Doxorubicin

▶ *Pathophysiology*

AF may be caused by both abnormal impulse formation and abnormal impulse conduction. Traditionally, AF was believed to be initiated by premature impulses initiated in the atria. However, it is now understood that in most patients AF is triggered by electrical impulses generated within the pulmonary veins.[18] These impulses initiate the process of reentry within the atria, and AF is believed to be sustained by multiple reentrant wavelets operating simultaneously within the atria. Some believe that, at least in some patients, the increased automaticity in the pulmonary veins may be the sole mechanism of AF and that the multiple reentrant wavelet hypothesis may be incorrect. However, the concept of multiple simultaneous reentrant wavelets remains the predominant hypothesis regarding the mechanism of AF.[17]

AF leads to electrical remodeling of the atria. Episodes that are of longer duration and occur with increasing frequency result in progressive shortening of atrial refractory periods, further

Patient Encounter Part 1

A 77-year-old man presents to the emergency department (ED) complaining that he can feel his heart fluttering and pounding in his chest. He states that this started several hours ago, and he waited to see if it would stop, but it has not. He also complains of feeling light-headed and says that he "nearly passed out." His pulse is irregular, with a rate of 140 beats/min.

What information is suggestive of AF?

What additional information do you need to develop a treatment plan?

potentiating atrial reentry.[19] Therefore, it is often said that "atrial fibrillation begets atrial fibrillation"; that is, AF causes atrial electrophysiologic alterations that further promote AF.[17,19] AF is associated with chaotic, disorganized atrial electrical activity, resulting in no completed atrial depolarizations and therefore no atrial contraction.

LO 3 AF occurs when structural and/or electrophysiologic abnormalities occur that promote abnormal atrial and/or pulmonary vein automaticity and/or atrial reentry.[17] Structural abnormalities of the atria may include fibrosis, dilation, ischemia, infiltration, and hypertrophy.[17] Other contributing factors may include inflammation, oxidative stress, activation of the renin-angiotensin-aldosterone system, autonomic nervous system activation, and genetic variants in myocardial ion channels and those leading to cardiomyopathy.[17] A substantial amount of the atrial electrical activity occurring during AF is conducted through the AV node into the ventricles, resulting in ventricular rates ranging from 100 to 200 beats/min.

AF is categorized into classifications.[17] Paroxysmal AF is defined as that which terminates spontaneously or with interventions within 7 days of onset.[17] Episodes begin suddenly and spontaneously, last minutes to hours, or sometimes as long as several days, and terminate suddenly and spontaneously. The frequency of recurrence in patients with paroxysmal AF is variable. Persistent AF is defined as continued AF of duration longer than 7 days.[17] Long-standing persistent AF is defined as continuous AF lasting longer than 12 months.[17] The term permanent AF is used when patient and clinician jointly decide to terminate further attempts to restore and/or maintain sinus rhythm.[17] Acceptance of AF represents a specific therapeutic viewpoint from the patient and clinician rather than a pathophysiological characteristic of the AF, and may change as symptoms, efficacy of treatments, and patient and clinician preferences develop and evolve.[17]

AF is associated with substantial morbidity and mortality, including risk of ischemic stroke of approximately 5% per year.[17] The risk of stroke is increased two- to sevenfold in patients with AF compared to patients without this arrhythmia.[9] AF is the cause of roughly one of every six strokes. During AF, atrial contraction is absent. Because atrial contraction is responsible for approximately 30% of LV filling, blood that is not ejected from the left atrium to the LV pools in the atrium, particularly in the left atrial appendage. Blood pooling facilitates the formation of a thrombus, which subsequently may travel through the mitral valve into the LV and may be ejected during ventricular contraction. The thrombus then may travel through a carotid artery into the brain, resulting in an ischemic stroke. Patients with AF are also at increased risk for systemic thromboembolism.

AF is associated with a threefold increase in the risk of HF as a result of tachycardia-induced cardiomyopathy.[17] AF increases the risk of dementia and mortality approximately twofold compared to patients without AF;[17] causes of death are likely stroke or HF.

Clinical Presentation and Diagnosis of AF

LO 3

Symptoms

- Approximately 20% to 30% of patients with AF remain asymptomatic
- Symptoms include fatigue, palpitations, dizziness, lightheadedness, dyspnea, chest pain (if underlying CAD is present), near-syncope, and syncope. Patients commonly complain of palpitations; often the complaint is "I can feel my heart beating fast" or "I can feel my heart fluttering" or "It feels like my heart is going to beat out of my chest"
- Other symptoms depend on the degree to which cardiac output is diminished, which in turn depends on ventricular rate and the degree to which stroke volume is reduced by the rapidly beating heart
- In some patients, the first symptom of AF is stroke

Diagnosis

- Because symptoms of all tachyarrhythmias depend on heart rate and are therefore essentially the same, diagnosis depends on the presence of AF on the ECG
- Characterized on ECG by an absence of P waves, an undulating baseline that represents chaotic atrial electrical activity, and an irregularly irregular rhythm, meaning the intervals between the R waves are irregular and there is no pattern to the irregularity
- Sometimes first diagnosed in patients presenting with ischemic stroke

▶ *Treatment*

LO 3 **Desired Outcomes** KEY CONCEPT The goals of individualized therapy for AF are: (a) ventricular rate control; (b) termination of AF and restoration of sinus rhythm (commonly referred to as "cardioversion" or "conversion to sinus rhythm"); (c) maintenance of sinus rhythm, or reduction in the frequency of episodes of paroxysmal AF; and/or (d) prevention of stroke and systemic embolism. These goals of therapy do not necessarily apply to all patients; the specific goal(s) that apply depend on the patient's AF classification (Table 9–5).

Hemodynamically Unstable AF For patients who present with an episode of AF that is hemodynamically unstable, emergent conversion to sinus rhythm is necessary using direct current

Table 9–5

Treatment Goals According to Atrial Fibrillation (AF) Classification

Paroxysmal AF	Persistent AF	Long-Standing Persistent AF	Permanent AF
Ventricular rate control Prevention of stroke and systemic embolism Maintenance of sinus rhythm *if ventricular rate control is not sufficient to control symptoms*	Ventricular rate control Prevention of stroke and systemic embolism Conversion to sinus rhythm	Ventricular rate control Prevention of stroke and systemic embolism Conversion to sinus rhythm	Ventricular rate control Prevention of stroke and systemic embolism

cardioversion (DCC). Hemodynamic instability may be defined as the presence of any one of the following: (a) acutely altered mental status; (b) hypotension (systolic blood pressure < 90 mm Hg) or other signs of shock; (c) ischemic chest discomfort; and/or (d) acute HF.[11]

DCC is the process of administering a synchronized electrical shock to the chest. The purpose of DCC is to simultaneously depolarize all of the myocardial cells, resulting in interruption and termination of the multiple reentrant circuits and restoration of normal sinus rhythm. The recommended initial energy level for conversion of AF to sinus rhythm is 120 to 200 joules (J) for biphasic shocks or 200 J for monophasic shocks. If the DCC attempt is unsuccessful, DCC energy should be increased in a stepwise fashion.[11] Delivery of the shock is synchronized to the ECG by the cardioverter machine, such that the electrical charge is not delivered during the latter portion of the T wave (ie, the relative refractory period) to avoid delivering an electrical impulse that may be conducted abnormally, which may result in a life-threatening ventricular arrhythmia.

The remainder of this section is devoted to pharmacologic management of hemodynamically stable AF.

LO 5 LO 10

Ventricular Rate Control Ventricular rate control can be achieved by inhibiting the proportion of electrical impulses conducted from the atria to the ventricles through the AV node. Therefore, drugs that are effective for ventricular rate control are those that inhibit AV node impulse conduction: β-blockers, diltiazem, verapamil, digoxin, and amiodarone (Tables 9–6[17] and 9–7).

In patients who present to the emergency department (ED) with an episode of symptomatic persistent AF or paroxysmal AF for which intervention is desired, ventricular rate control is usually initially achieved using IV drugs. A decision algorithm for selecting a specific drug for ventricular rate control is presented in Figure 9–4.[17] In general, an IV CCB or β-blocker is preferred for ventricular rate control in patients with normal LV function because ventricular rate control can often be achieved within several minutes. In patients with acutely decompensated HF (ADHF) or HFrEF, IV diltiazem and verapamil should be avoided, as these drugs confer negative inotropic effects and may exacerbate HFrEF.[17] An IV β-blocker may be administered in these patients, but only following stabilization of ADHF, due to potential for exacerbation.

For patients with paroxysmal or permanent AF requiring long-term rate control with oral medications, the treatment algorithm is the same (Figure 9–4). Although digoxin is effective for ventricular rate control in patients at rest, it is less effective than CCBs or β-blockers for ventricular rate control in patients undergoing physical activity, including activities of daily living. This is likely because activation of the sympathetic nervous system during exercise and activity overwhelms the stimulating effect of digoxin on the parasympathetic nervous system. Some recent evidence suggests digoxin therapy may be independently associated with an increased risk of mortality in patients with AF.[20,21] Overall, in patients with normal LV function, CCBs or β-blockers are preferred for long-term ventricular rate control. Diltiazem may be preferable to verapamil in older patients due to a lower incidence of constipation. However, in patients with HFrEF, oral diltiazem and verapamil are contraindicated as a result of their negative inotropic activity and propensity to exacerbate HFrEF. Therefore, the options in this population are β-blockers or digoxin. Most patients with HFrEF should be receiving therapy with an oral β-blocker with the goal of achieving mortality risk reduction. In patients with HFrEF who develop rapid AF while receiving therapy with β-blockers, digoxin can be administered for purposes of ventricular rate control. Fortunately, studies have found the combination of digoxin and β-blockers to be effective for ventricular rate control, likely as a result of β-blocker–induced attenuation of the inhibitory effects of the sympathetic nervous system on the efficacy of digoxin.[22]

Conversion to Sinus Rhythm Termination of AF in hemodynamically stable patients may be performed using antiarrhythmic drug therapy or elective DCC. Drugs that may be used for conversion to sinus rhythm are presented in Table 9–8.[17] These agents slow atrial conduction velocity and/or prolong refractoriness, facilitating interruption of reentrant circuits and restoration of sinus rhythm. DCC is generally more effective than drug therapy for conversion of AF to sinus rhythm. However, patients who undergo elective DCC must be sedated and/or anesthetized to avoid the discomfort associated with delivery of 120 to greater than or equal to 200 J of electricity to the chest. Therefore, it is important that patients scheduled to undergo elective DCC do not eat within approximately 8 to 12 hours of the procedure to avoid aspiration of stomach contents and resulting aspiration pneumonitis during the period of sedation/anesthesia. This often factors into the decision as to whether to use elective DCC or drug therapy for conversion of AF to sinus rhythm. If a patient presents with AF requiring nonemergent conversion to sinus rhythm, and the patient has eaten a meal that day, then pharmacologic conversion methods must be used on that day, or DCC must be postponed to the following day to allow for a period of fasting prior to the procedure.

A decision strategy for conversion of AF to sinus rhythm is presented in Figure 9–5.[17] The cardioversion decision strategy depends greatly on the duration of AF. If the AF episode began within 48 hours, conversion to sinus rhythm is safe and may be attempted with elective DCC or specific drug therapy. However, if the duration of the AF episode is 48 hours or longer, or if there is uncertainty regarding duration, two strategies for

Table 9–6

Drugs for Ventricular Rate Control in Atrial Fibrillation (AF)[17]

Drug	Mechanism of Action	Intravenous Administration	Usual Oral Maintenance Dose	Drug Interactions
Amiodarone	β-Blocker CCB	300 mg over 1 hour, then 10–50 mg/hour over 24 hours via continuous infusion	100–200 mg once daily	Inhibits clearance of digoxin, warfarin, some statins, and other drugs
β-Blockers[a]	Inhibit AV nodal conduction by slowing AV nodal conduction and prolonging AV nodal refractoriness	Esmolol 500 mcg/kg over 1 minute, then 50–300 mcg/kg/min continuous infusion Propranolol 1 mg over 1 minute, up to 3 doses at 2 minute intervals Metoprolol tartrate 2.5–5 mg over 2 minutes; up to 3 doses	Atenolol 25–100 mg once daily Bisoprolol 2.5–10 mg once daily Carvedilol 3.125–25 mg twice daily Metoprolol tartrate 25–100 mg twice daily Metoprolol XL (succinate) 50–400 mg once daily Nadolol 10–240 mg once daily Propranolol 10–40 mg three or four times daily	
Diltiazem	Inhibits AV nodal conduction by slowing AV nodal conduction and prolonging AV nodal refractoriness	0.25-mg/kg bolus over 2 minutes, then 5–15 mg/hour continuous infusion	120–360 mg once daily (extended release)	Increases carbamazepine, cyclosporine, midazolam, triazolam, theophylline, atorvastatin, cerivastatin, lovastatin, simvastatin concentrations Cimetidine, ranitidine, diazepam, grapefruit juice may increase serum diltiazem concentrations Dantrolene (combination may lead to ventricular arrhythmias)
Verapamil	Inhibits AV nodal conduction by slowing AV nodal conduction and prolonging AV nodal refractoriness	0.075–0.15-mg/kg bolus over 2 minutes. If no response after 30 minutes, may give an additional 10 mg, then 0.005 mg/kg/min continuous infusion	180–480 mg daily (extended release)	Increases digoxin, carbamazepine, cyclosporine, theophylline, atorvastatin, cerivastatin, lovastatin, simvastatin concentrations Dantrolene (combination may lead to ventricular arrhythmias)
Digoxin	Inhibits AV nodal conduction by (a) vagal stimulation (b) directly slowing AV nodal conduction, and (c) prolonging AV nodal refractoriness	0.25 mg every 2 hours, up to 1.5 mg over 24 hours	0.125–0.25 mg once daily	Amiodarone, verapamil inhibit digoxin elimination

[a]In patients with acute decompensated heart failure, therapy with intravenous β-blockers should be initiated only after the patient has been stabilized.

AV, atrioventricular; CCB, calcium channel blocker.

conversion may be considered. Data indicate that a thrombus may form in the left atrium during AF episodes of 48 hours or longer; if an atrial thrombus is present, the process of conversion to sinus rhythm, whether with DCC or drugs, can dislodge the atrial thrombus, leading to embolization and a stroke. Therefore, in patients experiencing an AF episode of 48 hours or longer, conversion to sinus rhythm should be deferred unless it is known that an atrial thrombus is not present. One option in patients with AF of duration 48 hours or longer, or of unknown duration, is to anticoagulate with warfarin (maintaining an **international normalized ratio** [INR] of 2–3), dabigatran, rivaroxaban, apixaban or edoxaban for 3 weeks, after which cardioversion may be performed. Patients should subsequently be anticoagulated for a minimum of 4 weeks following the restoration of sinus rhythm. An alternative approach is to perform a **transesophageal echocardiogram** (TEE) to determine whether an atrial thrombus is present; if such a thrombus is not present, DCC or pharmacologic cardioversion may be performed. If this strategy is selected, hospitalized patients should undergo anticoagulation with IV unfractionated heparin, with the dose targeted to an activated partial thromboplastin time (aPTT) of 60 seconds (range: 50–70 seconds), low molecular weight heparin, or oral anticoagulation therapy with warfarin (target INR: 2.5; range: 2–3), dabigatran, rivaroxaban, apixaban or

Table 9–7

Adverse Effects of Drugs Used to Treat Arrhythmias

Drug	Adverse Effects
Adenosine	Chest pain, flushing, dyspnea, transient sinus bradycardia/AV block
Amiodarone	IV: Hypotension, sinus bradycardia, phlebitis, QT interval prolongation, torsades de pointes Oral: Blue-gray skin discoloration, photosensitivity, corneal microdeposits, pulmonary fibrosis, hepatotoxicity, sinus bradycardia, hypo- or hyperthyroidism, peripheral neuropathy, weakness, AV block
Atenolol	Hypotension, bradycardia, AV block, HF exacerbation[a]
Atropine	Tachycardia, urinary retention, blurred vision, dry mouth, mydriasis
Bisoprolol	Hypotension, bradycardia, AV block, HF exacerbation[a]
Carvedilol	Hypotension, bradycardia, AV block, HF exacerbation[a]
Digoxin	Nausea, vomiting, anorexia, visual changes such as green-yellow halos around objects, AV block, ventricular arrhythmias
Diltiazem	Hypotension, sinus bradycardia, HF exacerbation, AV block
Dofetilide	Torsades de pointes
Dronedarone	Diarrhea, asthenia, nausea and vomiting, abdominal pain, bradycardia, GI distress, hepatotoxicity
Esmolol	Hypotension, sinus bradycardia, AV block, bronchospasm, HF exacerbation
Flecainide	Dizziness, blurred vision, HF exacerbation, torsades de pointes, life-threatening ventricular tachycardia (in patients with underlying CAD)
Ibutilide	Torsades de pointes
Lidocaine	Slurred speech, diminished consciousness, seizures, bradycardia
Metoprolol	Hypotension, sinus bradycardia, AV block, fatigue, bronchospasm, HF exacerbation[a]
Mexiletine	Nausea, vomiting, GI distress, tremor, dizziness, fatigue, seizures (if dose too high)
Nadolol	Hypotension, bradycardia, AV block, HF exacerbation[a]
Procainamide	Hypotension, HF exacerbation, QT interval prolongation, torsades de pointes
Propafenone	Dizziness, blurred vision, life-threatening ventricular tachycardia (in patients with underlying CAD)
Propranolol	Hypotension, sinus bradycardia, AV block, bronchospasm, HF exacerbation[a]
Sotalol	Sinus bradycardia, AV block, fatigue, torsades de pointes
Verapamil	Hypotension, HF exacerbation, bradycardia, AV block, constipation (oral)

[a]Associated with intravenous administration (metoprolol, propranolol), inappropriately high oral doses at initiation of therapy, or overly aggressive and rapid dose titration.

AV, atrioventricular; CAD, coronary artery disease; GI, gastrointestinal; HF, heart failure; IV, intravenous.

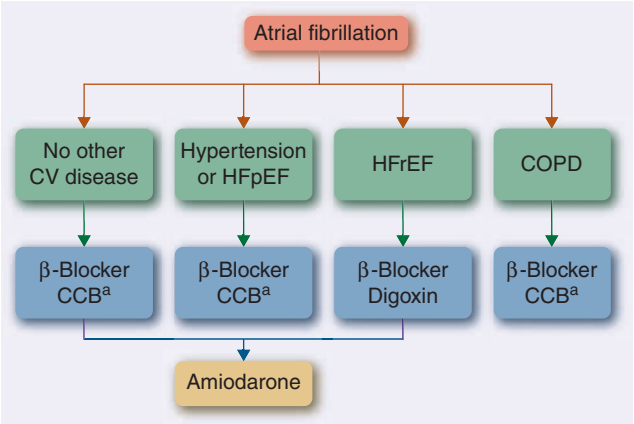

FIGURE 9–4. Decision algorithm for selecting drug therapy for ventricular rate control. In boxes where multiple medications are listed, drugs are listed alphabetically, not in order of preference. [a]When administered intravenously, diltiazem is generally preferred over verapamil because of a lower risk of severe hypotension. (CCB, calcium channel blocker [diltiazem or verapamil]; COPD, chronic obstructive pulmonary disease; CV, cardiovascular; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction.) edoxaban during the hospitalization period prior to the TEE and cardioversion procedure. If a thrombus is not present during TEE and cardioversion is successful, patients should remain on oral anticoagulation therapy for at least 4 weeks. If a thrombus is observed during TEE, then cardioversion should be postponed and anticoagulation should be continued indefinitely. Another TEE should be performed prior to a subsequent cardioversion attempt.[17]

Conversion of hemodynamically stable AF to sinus rhythm may be performed in patients with a symptomatic episode of persistent or paroxysmal AF. In patients who have been designated as being in permanent AF, a joint decision has been made by the patient and clinician to terminate further attempts to restore and/or maintain sinus rhythm.[17] Therefore, in patients with permanent AF, conversion to sinus rhythm is not attempted.

Maintenance of Sinus Rhythm/Reduction in the Frequency of Episodes of Paroxysmal AF In many patients, permanent maintenance of sinus rhythm after cardioversion is an unrealistic goal. Many patients experience recurrence of AF after cardioversion. Similarly, in patients with paroxysmal AF, complete maintenance of sinus rhythm without recurrent AF episodes is often not achievable. Therefore, a more realistic goal for many patients is not permanent maintenance of sinus rhythm, but rather reduction in the frequency of episodes of paroxysmal AF. Maintenance of sinus rhythm is more likely to be successful in patients with AF duration of less than 6 months.

LO 3

Table 9–8

Drugs for Conversion of Atrial Fibrillation (AF) to Normal Sinus Rhythm[17]

Treatment	IV Administration	Oral Administration	Drug Interactions
Amiodarone	Not recommended for conversion of AF to sinus rhythm	600–800 mg daily in divided doses up to a total load of 10 g, then maintenance dose of 200 mg daily	Inhibits elimination of digoxin, warfarin, some statins, and other drugs
Dofetilide	Not available IV	CrCl (mL/min)[a,b]: > 60 mL/min: 500 mcg twice daily 40–60 mL/min: 250 mcg twice daily 20–40 mL/min: 125 mcg twice daily < 20 mL/min: Not recommended	Cimetidine, hydrochlorothiazide, ketoconazole, medroxyprogesterone, promethazine, trimethoprim, verapamil (all inhibit dofetilide elimination, most by inhibition of renal cation transport)
Flecainide	Not available IV in the United States	200–300 mg × one dose[c]	Quinidine, fluoxetine, tricyclic antidepressants increase flecainide concentrations
Ibutilide	1 mg IV over 10 minutes, followed by a second 1 mg IV dose if necessary. If weight < 60 kg (132 lb), dose should be 0.01 mg/kg	Not available orally	—
Propafenone	Not available IV	450–600 mg × one dose[c]	Quinidine, fluoxetine, tricyclic antidepressants increase propafenone concentrations Increases serum digoxin concentrations Inhibits CYP2C9, inhibits warfarin metabolism

[a]Creatinine clearance of > 60, 40–60, 20–40, and < 20 mL/min corresponds to > 1.0, 0.67–1.0, 0.33–0.67, and < 0.33 mL/s, respectively.

[b]Dofetilide therapy must be initiated in the hospital, due to the risk of QT interval prolongation that may lead to torsades de pointes.

[c]It is recommended that a β-blocker or nondihydropyridine calcium channel blocker be administered ≥ 30 minutes prior to administering flecainide or propafenone to avoid accelerated AV node conduction and increased heart rate.

CrCl, creatinine clearance; CYP, cytochrome P450; IV, intravenous.

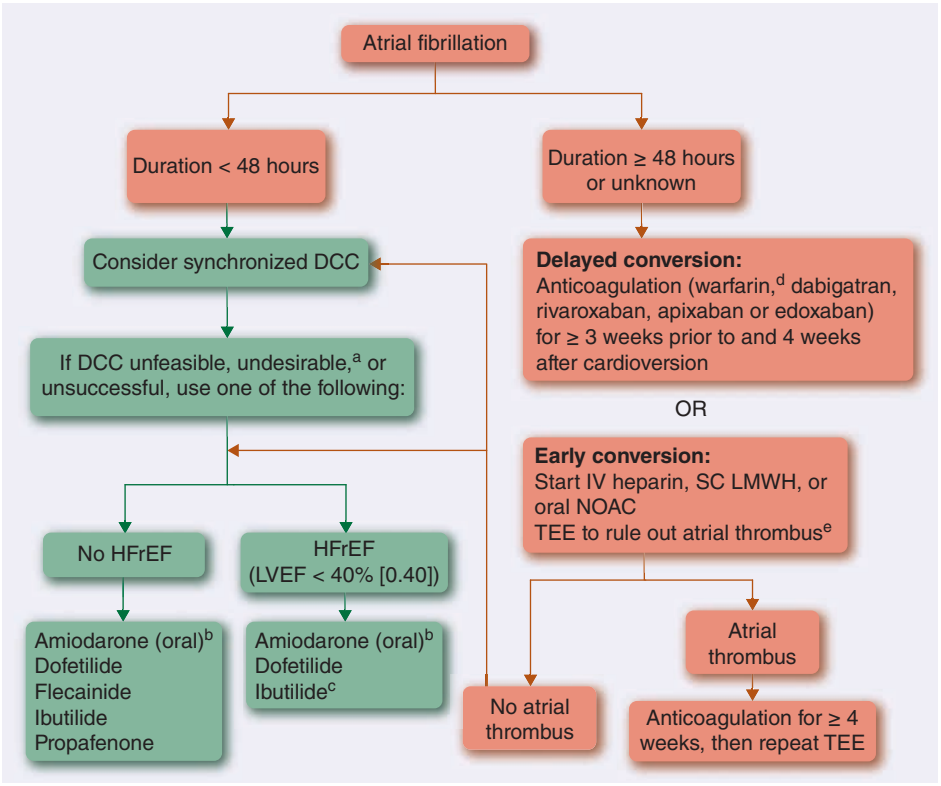

FIGURE 9–5. Decision algorithm for conversion of hemodynamically stable atrial fibrillation to normal sinus rhythm. [a]Patients should not be sedated for synchronized DCC if they have eaten a meal within 12 hours, due to risk of aspiration. [b]Drugs are listed in alphabetical order, not order of preference. [c]Ibutilide can be administered to patients with LVEF 30%–40% (0.30–0.40) but should be avoided in patients with LVEF < 30% (0.30) due to risk of ventricular proarrhythmia. [d]International normalized ratio (INR) of 2–3. [e]Anticoagulation must be achieved prior to TEE and maintained for more than or equal to 4 weeks after TEE. (DCC, direct current cardioversion; HFrEF, heart failure with reduced ejection fraction; IV, intravenous; LVEF, left ventricular ejection fraction; LMWH, low molecular weight heparin; NOAC, non-vitamin K antagonist oral antiacoagulant; SC, subcutaneous; TEE, transesophageal echocardiogram.)

In recent years, numerous studies have been performed to determine whether drug therapy for maintenance of sinus rhythm is preferred to drug therapy for ventricular rate control.[23-27] In these studies, patients were assigned randomly to receive therapy either with drugs for rate control or drugs for rhythm control (Table 9–9). These studies found no significant differences in mortality between the two strategies.[23-27] However, patients assigned to the rhythm control strategy were more likely to be hospitalized[23,25-27] and to experience adverse effects associated with drug therapy.[23,24]

LO 5 LO 10

KEY CONCEPT Therefore, drug therapy for the purpose of maintaining sinus rhythm or reducing the frequency of episodes of AF should be initiated only in those patients with episodes of paroxysmal AF who continue to experience symptoms despite maximum tolerated doses of drugs for ventricular rate control. A decision strategy for maintenance therapy of sinus rhythm is presented in Figure 9–6.[17] Therapy with dofetilide or sotalol should be initiated in the hospital with patients undergoing continuous ECG monitoring, due to the risk of torsades de pointes (TdP). Drug therapy for maintenance of sinus rhythm and/or reduction in the frequency of episodes of paroxysmal AF should not be initiated in patients with underlying correctable causes of AF, such as hyperthyroidism; rather, the underlying cause should be corrected. Drug therapy for maintenance of sinus rhythm should be discontinued when AF becomes designated as permanent.

The nonpharmacologic treatment strategy of catheter ablation is also an option for rhythm control in patients with paroxysmal AF. During this procedure, a catheter is introduced transvenously and directed to the left atrium under fluoroscopic guidance. Energy is delivered through the catheter to ablate, or destroy, reentrant circuits responsible for propagating the AF. The most common energy source for catheter ablation is radiofrequency energy, though cryoablation is sometimes used as an alternative to radiofrequency energy. Catheter ablation is often reserved for

Table 9–9

Drugs for Maintenance of Sinus Rhythm/Reduction in the Frequency of Episodes of Atrial Fibrillation

Drug	Dose
Amiodarone	400–600 mg orally in 2–3 divided doses for 2–4 weeks; maintenance dose 100–200 mg orally once daily
Dofetilide[a]	As described in Table 9–8
Dronedarone	400 mg orally every 12 hours
Flecainide	50–200 mg orally every 12 hours
Propafenone	Immediate release: 150–300 mg orally every 8 hours Extended release: 225–425 mg orally every 12 hours
Sotalol[a]	Initial dose, CrCl[b] > 60 mL/min: 80 mg orally twice daily Initial dose, CrCl[b] 40–60 mL/min: 80 mg orally once daily CrCl[b] < 40 mL/min: Contraindicated Maintenance dose: If 80 mg doses are tolerated and QTc interval remains < 500 ms after 3 days, patients can be discharged. Alternatively, dose can be increased to 120 mg orally once or twice daily as appropriate during hospitalization and patient followed for 3 days on this dose

[a]Dofetilide and sotalol therapy must be initiated in the hospital due to the risk of QT interval prolongation that may lead to torsades de pointes.

[b]CrCl of > 60, 40–60, and < 40 mL/min corresponds to > 1.0, 0.67–1.0, and < 0.67 mL/s, respectively.

CrCl, creatinine clearance; ms, milliseconds.

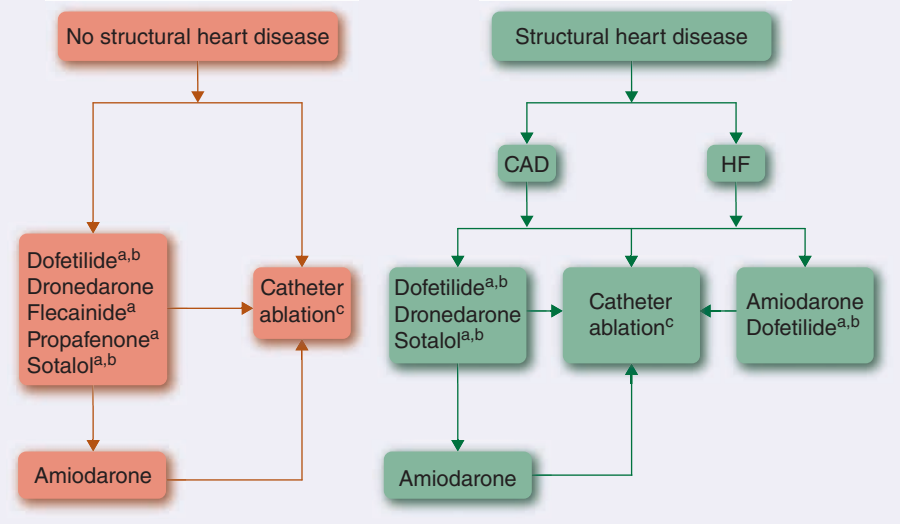

FIGURE 9–6. Decision algorithm for maintenance of sinus rhythm/reduction in the frequency of episodes of atrial fibrillation (AF) for patients with symptomatic paroxysmal or persistent AF despite rate control therapy. In boxes where multiple medications are listed, drugs are listed alphabetically, not in order of preference. [a]Not recommended in patients with severe left ventricular hypertrophy. [b]Should be used cautiously in patients at risk for torsades de pointes. [c]Catheter ablation is only recommended as first-line therapy in patients with paroxysmal AF and is recommended depending on patient preference when performed at experienced centers. (CAD, coronary artery disease; HF, heart failure.) (Adapted with permission from January CT, Wann LS, Alpert JS, et al. 2014 AHA/ACC/HRS guideline for the management of patients with atrial fibrillation. J Am Coll Cardiol. 2014;64:e1–e76.)

patients in whom symptomatic AF is refractory to, or the patient is intolerant of, at least one antiarrhythmic agent. However, some patients select catheter ablation as the preferred strategy, to avoid adverse effects of antiarrhythmic drugs.

LO 6 LO 10

Prevention of Stroke and Systemic Embolism Most patients with paroxysmal, persistent, or permanent AF should receive therapy for prevention of stroke and systemic embolism unless compelling contraindications exist. A decision strategy for assigning patients to receive anticoagulation for prevention of stroke or systemic embolism in AF is presented in Table 9–10.[17] In general, most patients require oral anticoagulation; however, in patients with nonvalvular AF and a CHA_2DS_2-VASc[17] score of 0, anticoagulation is not recommended.

Table 9–10

American Heart Association/American College of Cardiology/Heart Rhythm Society Recommendations for Prevention of Stroke and Systemic Embolism in Patients with Nonvalvular Atrial Fibrillation (AF)[a,17]

CHA_2DS_2-VASc Score	Recommended Stroke Prevention Strategy
0	Antithrombotic therapy is not recommended
1	No antithrombotic therapy or treatment with an oral anticoagulant or aspirin may be considered
≥ 2	Oral anticoagulation recommended. Options include: Warfarin (INR: 2.0–3.0) Dabigatran Rivaroxaban Apixaban Edoxaban[b]
CHA_2DS_2-VASc score calculated as follows:[17]	
Congestive heart failure	1 point
Hypertension	1 point
Age ≥ 75 years	2 points
Diabetes mellitus	1 point
History of **s**troke, TIA or thromboembolism	2 points
Vascular disease (prior MI, PAD or aortic plaque)	1 point
Age 65–74 years	1 point
Female **s**ex	1 point
Maximum score	9 points

[a]Patients with AF who have mechanical heart valves should receive warfarin titrated to an INR of 2.0–3.0 or 2.5–3.5 depending on the type and location of the prosthetic heart valve.

[b]Edoxaban is not recommended in the 2014 American Heart Association/American College of Cardiology/Heart Rhythm Society recommendations for prevention of thromboembolism in patients with nonvalvular AF, as data comparing its efficacy for prevention of thromboembolism in patients with AF had not been published at the time the guidelines were published. However, since 2014, data from a large study have shown edoxaban to be noninferior to warfarin for prevention of stroke and systemic embolism in patients with AF, with a lower rate of major bleeding. Therefore, edoxaban is an acceptable anticoagulant for patients with AF.

INR, international normalized ratio; MI, myocardial infarction; PAD, peripheral arterial disease; TIA, transient ischemic attack.

The landscape of anticoagulation for stroke prevention in AF has changed with the availability of the non-vitamin K antagonist oral anticoagulants (NOACs) dabigatran, rivaroxaban, apixaban, and edoxaban. Dabigatran, approved by the Food and Drug Administration (FDA) in 2010, is a direct thrombin inhibitor for reducing the risk of stroke and systemic embolism in patients with nonvalvular AF. Dabigatran is associated with lower rates of stroke and systemic embolism than warfarin in patients with AF, with a similar incidence of major bleeding.[28] Dabigatran should not be used in patients with end-stage kidney disease (creatinine clearance [CrCl] under 15 mL/min [0.25 mL/s]) or advanced liver disease (impaired baseline clotting function). The recommended dabigatran dose is 150 mg twice daily, except for patients with severe kidney disease (CrCl: 15–30 mL/min [0.25–0.50 mL/s]) for whom the recommended dose is 75 mg twice daily.

Advantages of dabigatran include the fact that INR monitoring is not required and the drug's onset of action is rapid, eliminating the need for bridging with unfractionated or low molecular weight heparins. In addition, there is a lower likelihood of drug interactions with dabigatran than with warfarin. Dabigatran is a P-glycoprotein (P-gp) substrate, and therefore concomitant administration with P-gp inhibitors such as ketoconazole, amiodarone, and verapamil may result in increases in plasma dabigatran concentrations; however, there is no recommendation for a change in dabigatran dose when administered concomitantly with these drugs. Similarly, concomitant administration of dabigatran with P-gp inducers such as rifampin may reduce plasma dabigatran concentrations. A previous disadvantage was that there was no antidote with which to reverse major bleeding associated with dabigatran. However, such an antidote is now available: idarucizumab is a humanized monoclonal antibody fragment with a high affinity for dabigatran, which binds to dabigatran and rapidly reverses its anticoagulant effects.[29] Finally, while none of the NOACs are recommended for administration to patients with AF that has occurred as a result of valvular heart disease, dabigatran is specifically contraindicated in patients with mechanical heart valves, due to higher risk of stroke, MI and thrombus formation on the mechanical valve compared with warfarin.

Rivaroxaban, an oral factor Xa inhibitor, was approved by the FDA in 2011 for reducing the risk of stroke and systemic embolism in patients with nonvalvular AF. Rivaroxaban was shown to be noninferior to warfarin for prevention of stroke or systemic embolism in patients with AF, and compared with warfarin, rivaroxaban was associated with a lower risk of intracranial and fatal bleeding.[30] Rivaroxaban is contraindicated in patients with end-stage renal disease (CrCl < 15 mL/min [0.25 mL/s]). The recommended rivaroxaban dose is 20 mg once daily with the evening meal. For patients with moderate-to-severe kidney disease (CrCl 15–50 mL/min [0.25–0.83 mL/s]), the dose should be reduced to 15 mg once daily with the evening meal. Rivaroxaban dose may require adjustment when used in combination with dual P-gp and strong cytochrome P-450 (CYP) 3A4 inducers or inhibitors.

Apixaban, an oral factor Xa inhibitor, was approved by the FDA in 2012 for reducing the risk of stroke and systemic embolism in patients with nonvalvular AF. Apixaban is superior to warfarin for prevention of stroke or systemic embolism in patients with AF, with lower bleeding risk.[31] The recommended dose of apixaban is 5 mg orally twice daily. In patients with moderate kidney disease (CrCl 30–50 mL/min [0.50–0.83 mL/s]), the dose should be reduced to 2.5 mg orally twice daily. There are

no data or dosage recommendations for patients with CrCl less than 30 mL/min (0.50 mL/s). Apixaban dose should be reduced to 2.5 mg orally twice daily when any two of the following characteristics are present: serum creatinine greater than 1.5 mg/dL (133 μmol/L), 80 years of age or older, body weight less than or equal to 60 kg (132 lb). Apixaban should not be administered to patients with severe liver disease.

Edoxaban, another oral factor Xa inhibitor, was approved by the FDA in 2015 for reduction in risk of stroke and systemic embolism in patients with nonvalvular AF. Edoxaban is noninferior to warfarin for prevention of stroke or systemic embolism in patients with AF, with a lower bleeding risk.[32] The recommended dose of edoxaban is 60 mg orally once daily in patients with CrCl greater than 50 mL/min (0.83 mL/s) to less than or equal to 95 mL/min (1.59 mL/s). In patients with kidney disease (CrCl 15–50 mL/min [0.25–0.83 mL/s]), the dose should be reduced to 30 mg orally once daily. There are no data or dosage recommendations for patients with CrCl less than 15 mL/min (0.25 mL/s). Interestingly, edoxaban is not recommended for administration to patients with CrCl greater than 95 mL/min (1.59 mL/s), as these patients had an increased risk of ischemic stroke associated with edoxaban 60 mg once daily compared to warfarin-treated patients. The most likely reason for this finding is that a higher dose of edoxaban is required in patients with CrCl greater than 95 mL/min (1.59 mL/s), but until the efficacy and safety of alternative doses of edoxaban are studied in these patients, the drug should be avoided in this patient population. Concomitant use of edoxaban and rifampin should be avoided, and edoxaban should not be administered to patients with moderate or severe liver disease.

For patients for whom warfarin is preferred over other oral anticoagulants (such as in patients with mechanical prosthetic heart valves, those with valvular AF, and patients with end-stage kidney disease), specific genetic tests to guide the initiation of therapy have been approved by the FDA. These tests assess single nucleotide polymorphisms of the gene that encodes CYP 2C9, the primary hepatic enzyme responsible for warfarin metabolism, and the gene *VKORC1*, which encodes vitamin K epoxide reductase complex subunit 1, the enzyme that is inhibited by warfarin as its mechanism of anticoagulation. Patients with specific polymorphisms of one or both of these genes may require adjustment of the initial warfarin dose to achieve adequate anticoagulation or avoid over-anticoagulation and toxicity; guidelines for pharmacogenetics-guided warfarin dosing have been published.[33] Genetic testing to guide the initiation of warfarin therapy has not yet become standard practice, and many have questioned the efficacy and cost effectiveness of incorporation of routine genetic testing into warfarin therapy. The role of routine genetic testing in selecting initial warfarin doses is likely to continue to evolve. However, in patients for whom *VKORC1* and/or CYP2C9 genotype information is available, the pharmacogenetics-guided warfarin dosing guidelines are useful for guiding selection of initial warfarin dose.[33] For patients in whom *VKORC1* and/or CYP2C9 genotype information is not available, a standard empirical dosing approach can be used, such as initiating warfarin at 5 mg once daily and titrating based on daily INR measurements until a stable therapeutic INR is achieved. Alternatively, for patients in whom *VKORC1* and/or CYP2C9 genotype information is not available, a clinical dosing algorithm such as those available at warfarindosing.org can be used to determine the initial dose of warfarin;[33] dose titration based on daily INR measurements is still required if this approach is employed.

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a care plan for the patient's acute AF episode and for long-term management of his AF.

Your plan should include (a) a statement of the drug-related needs and/or problems, (b) the goals of therapy, (c) a patient-specific detailed therapeutic plan, and (d) a plan for follow-up to determine whether the goals have been achieved and adverse effects avoided.

▶ *Outcome Evaluation*

- Monitor the patient to determine whether the goal of ventricular rate control is met. A target heart rate less than 80 beats/min is recommended for symptomatic patients and those with HFrEF. A target heart rate of less than 110 beats/min may be reasonable for patients who remain asymptomatic and have preserved LV systolic function.[17]
- Monitor ECG to assess continued presence of AF and determine whether conversion to sinus rhythm has occurred.
- In patients receiving warfarin, monitor INR approximately monthly to make sure it is therapeutic (target: 2.5; range: 2.0–3.0).
- Monitor for adverse effects of specific drug therapy (see Table 9–7). Monitor patients receiving oral anticoagulation for signs and symptoms of bruising or bleeding.

Paroxysmal Supraventricular Tachycardia

LO 3

Paroxysmal supraventricular tachycardia (PSVT) is a term that refers to a number of arrhythmias that originate above the ventricles and require atrial or AV nodal tissue for initiation and maintenance.[34] The most common of these arrhythmias is known as AV nodal reentrant tachycardia, in which the arrhythmia is caused by a reentrant circuit that involves the AV node or tissue adjacent to the AV node. Other types of PSVT include the relatively uncommon Wolff-Parkinson-White syndrome, which is caused by reentry through an accessory extra-AV nodal pathway. For the purposes of this section, the term *PSVT* refers to AV nodal reentrant tachycardia.

▶ *Epidemiology and Etiology*

LO 3

Approximately 570,000 persons in the United States have PSVT, with an estimated prevalence of 2.29 per 1000 individuals.[9,34] The incidence of PSVT is 35 per 100,000 person-years,[9] and there are roughly 89,000 new cases annually.[34] The average age of onset of PSVT is 57 years. PSVT occurs more commonly in women than men, and individuals older than 65 years of age have five times the risk of developing PSVT compared to younger people.[9,34] Although PSVT can occur in patients experiencing myocardial ischemia or MI, it sometimes occurs in individuals with no history of cardiac disease.

▶ *Pathophysiology*

PSVT is caused by reentry that includes the AV node as a part of the reentrant circuit. Typically, electrical impulses travel forward (antegrade, from atria to ventricles) down the AV node and then travel back up the AV node (retrograde, from

Clinical Presentation and Diagnosis of PSVT

LO 3

Symptoms

- Symptoms include palpitations, "neck-pounding," dizziness, light-headedness, shortness of breath, polyuria, chest pain (if underlying CAD is present), near-syncope, and syncope. Patients commonly complain of palpitations; often the complaint is "I can feel my heart beating fast" or "I can feel my heart fluttering" or "It feels like my heart is going to beat out of my chest"
- Other symptoms depend on the degree to which cardiac output is diminished, which in turn depends on heart rate and degree to which stroke volume is reduced by the rapidly beating heart

Diagnosis

- Because the symptoms of all tachyarrhythmias depend primarily on heart rate and are therefore similar, diagnosis depends on the presence of PSVT on the ECG, characterized by narrow QRS complexes (< 0.12 seconds). P waves are usually visible, but may be difficult to discern if the heart rate is extremely rapid
- PSVT is a regular rhythm and occurs at rates ranging from 100 to 250 beats/min

ventricles to atria) in a repetitive circuit. In some patients, the retrograde conduction pathway of the reentrant circuit may exist in extra-AV nodal tissue adjacent to the AV node. One of these pathways usually conducts impulses rapidly while the other usually conducts impulses slowly. Most commonly, during PSVT the impulse conducts antegrade through the slow pathway and retrograde through the faster pathway; in approximately 5% to 10% of patients, the reentrant circuit is reversed.[34]

▶ *Treatment*

LO 3

Desired Outcomes The desired outcomes for treatment are to terminate the arrhythmia, restore sinus rhythm, and prevent recurrence. Drug therapy is used to terminate the arrhythmia and restore sinus rhythm; nonpharmacologic measures are generally preferred to prevent recurrence, though some patients prefer drug therapy.

LO 3 LO 7 LO 10

Termination of PSVT KEY CONCEPT The primary method of termination of PSVT is inhibition of impulse conduction and/or prolongation of the refractory period within the AV node. Because PSVT is propagated via a reentrant circuit involving the AV node, inhibition of conduction within the AV node interrupts and terminates the reentrant circuit.

KEY CONCEPT Prior to initiation of drug therapy for termination of PSVT, some simple nonpharmacologic methods known as vagal maneuvers may be attempted.[11,34] Vagal maneuvers stimulate the activity of the parasympathetic nervous system, which inhibits AV nodal conduction, facilitating termination of the arrhythmia. Vagal maneuvers alone may terminate PSVT in up to 28% of cases.[34] The simplest vagal maneuver to perform is cough, which stimulates the vagus nerve. Instructing the patient to cough two or three times may successfully terminate the PSVT. Another vagal maneuver that may be attempted is carotid sinus massage; one of the carotid sinuses, located in the neck in the vicinity of the carotid arteries, may be gently massaged for 5 to 10 seconds, stimulating vagal activity. Carotid sinus massage should not be performed in patients with a history of stroke or transient ischemic attack, or in those in whom carotid bruits may be heard on auscultation. The Valsalva maneuver, during which patients bear down against a closed glottis for 10 to 30 seconds, may also be attempted. The Valsalva maneuver is more effective than carotid sinus massage.[34] If one vagal maneuver is unsuccessful, switching to another vagal maneuver may successfully terminate PSVT.[34]

If vagal maneuvers are unsuccessful, IV drug therapy should be initiated.[11,34,35] Drugs used for termination of hemodynamically stable PSVT are presented in Table 9–11.[11]

Table 9–11

Drugs for Termination of Paroxysmal Supraventricular Tachycardia[11,34]

Drug	Mechanism of Action	Dose
Adenosine	Direct AV node inhibition	6-mg IV rapid push followed by rapid saline flush. If no response in 1–2 minutes, 12-mg IV rapid push followed by rapid saline flush. If no response in 1–2 minutes, administer second 12 mg IV rapid push, followed by rapid saline flush
Diltiazem	Direct AV node inhibition	0.25 mg/kg IV over 2 minutes, followed by continuous IV infusion of 5–10 mg/hour, up to 15 mg/hour
Verapamil	Direct AV node inhibition	5–10 mg (0.75–0.15 mg/kg) IV over 2 minutes If no response, administer an additional 10 mg (0.15 mg/kg) IV, then continuous infusion of 0.005 mg/kg/min
β-Blockers	Direct AV node inhibition	Esmolol 500 mcg/kg IV over 1 minute Then 50 mcg/kg/min continuous infusion. If inadequate response, give second loading dose of 500 mcg/kg and increase maintenance infusion to 100 mcg/kg/min. Increment 50 mcg/kg/min dose increases in this manner as necessary to maximum infusion rate of 300 mcg/kg/min Propranolol 1 mg IV over 1 minute; if necessary, repeat 1 mg IV doses at 2 minute intervals, up to 3 doses Metoprolol 2.5–5 mg IV over 2 minutes; if necessary, repeat 2.5–5 mg IV bolus in 10 minutes, up to 3 doses
Digoxin	Vagal stimulation, direct AV node inhibition	0.25–0.5 mg IV bolus; if necessary, repeat 0.25 mg IV bolus every 6–8 hours, to a maximum dose of 1 mg (8–12 mcg/kg) over 24 hours

AV, atrioventricular; CCB, calcium channel blocker; IV, intravenous.

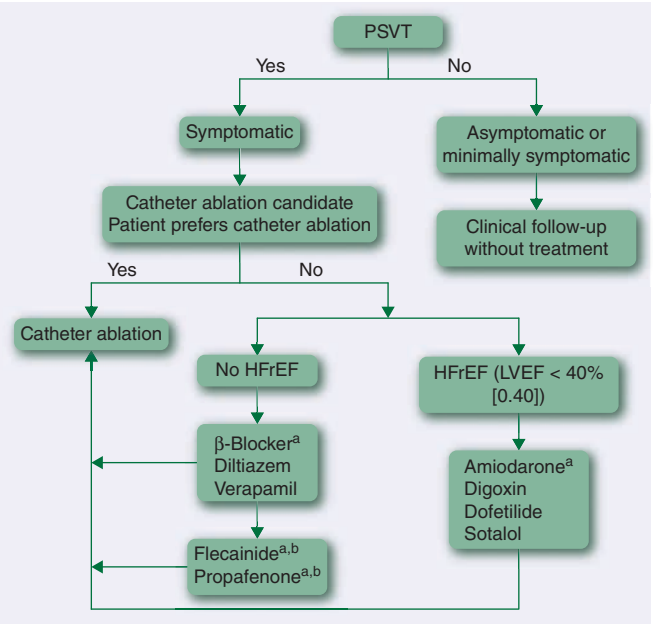

FIGURE 9–8. Decision algorithm for prevention of recurrence of PSVT. Drug doses as in Tables 9–6 and 9–9. [a]Drugs are listed alphabetically, not in order of preference. [b]Neither flecainide nor propafenone should be used in patients with known ischemic heart disease. (HFrEF, heart failure with reduced ejection fraction; LVEF, left ventricular ejection fraction; PSVT, paroxysmal supraventricular tachycardia.) (Adapted with permission from Page RL, Joglar JA, Caldwell MA, et al. 2015 ACC/AHA/HRS guideline for the management of adult patients with supraventricular tachycardia. A report of the American College of Cardiology/American Heart Association Task Force on Clinical Practice Guidelines and the Heart Rhythm Society. J Am Coll Cardiol. 2016;67:e27–e115.)

A decision strategy for pharmacologic termination of PSVT is presented in Figure 9–7.[34]

KEY CONCEPT Adenosine is the drug of choice for pharmacologic termination of PSVT and is successful in 95% of patients. Adenosine inhibits conduction transiently and is associated with adverse effects (see Table 9–7), including flushing, transient sinus bradycardia or AV block, and bronchospasm in susceptible patients. In addition, adenosine may cause chest pain that mimics the discomfort of myocardial ischemia but is not actually associated with ischemia. The half-life of adenosine is approximately 10 seconds, due to deamination in the blood; therefore, in the vast majority of patients, adverse effects are of short duration.

If adenosine therapy is unsuccessful for termination of PSVT, subsequent choices of therapy depend on whether the patient is hemodynamically stable or not. If the patient is hemodynamically unstable, synchronized DCC should be administered, using an initial energy level of 50 to 100 J; if the initial DCC attempt is unsuccessful, the shock energy should be increased in a stepwise fashion.[11] If the patient is hemodynamically stable, IV β-blockers, diltiazem or verapamil may be administered. β-Blockers are preferred if the patient has underlying HFrEF.

Prevention of Recurrence A decision strategy for prevention of recurrent PSVT is presented in Figure 9–8. If the patient's episodes of PSVT are asymptomatic or minimally symptomatic, long-term treatment may not be necessary. However, for patients with symptomatic episodes of PSVT, catheter ablation is a nonpharmacologic treatment option. During this procedure, a catheter is introduced transvenously and directed to the right atrium under fluoroscopic guidance. The catheter is advanced to the AV node, and energy is delivered through the catheter to ablate, or destroy, the extranodal pathway of the reentrant circuit. The most common energy source for catheter ablation is radiofrequency energy, though cryoablation is sometimes used as an alternative to radiofrequency energy to minimize damage to the AV node. This procedure usually achieves a complete cure of PSVT and therefore obviates the need for long-term antiarrhythmic drug therapy in this population. The complication rate associated with catheter ablation of PSVT is low (< 1%), and includes complete AV block (via inadvertent ablation of the AV node), perforation, pseudoaneurysm, bleeding at the site of catheter insertion in the groin, and pulmonary edema.

Despite the success rates achieved with catheter ablation and the relatively low risk of complications, some patients prefer not to undergo the procedure, while others are not considered suitable candidates. For these patients, drug therapy may be administered to prevent recurrence of PSVT or at least reduce the frequency of recurrent episodes. For patients with normal LV function, oral β-blockers, diltiazem, or verapamil are preferred agents. In patients for whom a trial of one or more of those drugs provides an unsatisfactory response, oral flecainide or propafenone may be administered; however, flecainide and propafenone are contraindicated in patients with a history of MI or any known underlying CAD, due to an increased risk of death associated with those drugs in that population. For patients with

HFrEF, diltiazem, verapamil, flecainide, and propafenone are contraindicated due to negative inotropic effects and the potential to exacerbate HF. In this patient population, oral amiodarone, digoxin, dofetilide, or sotalol may be used.

▶ *Outcome Evaluation*

- Monitor for termination of PSVT and restoration of normal sinus rhythm.
- Monitor for adverse effects of adenosine or any other antiarrhythmic agents administered (see Table 9–7).
- In patients taking drug therapy for long-term prevention of recurrence of PSVT, monitor for recurrence of symptoms and frequency of symptoms, as well as for adverse drug effects (Table 9–7).

VENTRICULAR ARRHYTHMIAS

Premature Ventricular Complexes

LO 3

PVCs are ectopic electrical impulses originating in ventricular tissue, resulting in wide, misshapen, abnormal QRS complexes. PVCs have also been known by other terms, ventricular premature beats (VPBs), ventricular premature contractions (VPCs), and ventricular premature depolarizations (VPDs).

▶ *Epidemiology, Etiology, and Pathophysiology*

PVCs occur with variable frequency, depending on underlying comorbid conditions. In a population of healthy individuals, the prevalence of PVCs was 0.8%.[9] In another study in which individuals without HF underwent ambulatory ECG monitoring (median duration 22 hours), 0.011% of all heartbeats were PVCs.[9] The prevalence of PVCs increases with age, and is approximately 0.5% in individuals less than 20 years of age and 2.2% in people older than 50 years of age. Roughly 60% of middle-aged men with or without heart disease had at least one PVC on a 6-hour continuous ECG recording. The prevalence of complex or frequent VPDs is approximately 33% and 12% in men with or without CAD, respectively;[35] in women, the prevalence of complex or frequent VPDs is 26% and 12% in those with or without CAD, respectively.[36]

PVCs occur as a result of abnormal ventricular automaticity due to enhanced activity of the sympathetic nervous system and altered electrophysiological characteristics of the heart during myocardial ischemia and following MI. In men without CAD, complex or frequent PVCs are associated with an increased risk of death and MI or death from CAD.[35] In patients with underlying CAD or a history of MI, the presence of complex or frequent PVCs is associated with an increased risk of mortality due to sudden cardiac death.[37] Therefore, in some patients, the occurrence of complex PVCs has negative prognostic implications.

▶ *Treatment*

Desired Outcomes Desired outcomes are to alleviate patient symptoms and reduce the risk of PVC-induced cardiomyopathy in patients with very frequent PVCs.

LO 8 LO 10

Pharmacologic Therapy KEY CONCEPT Asymptomatic PVCs should not be treated with antiarrhythmic drug therapy. Given that complex or frequent PVCs increase the risk of sudden cardiac death in patients with a history of MI, the Cardiac Arrhythmia Suppression Trials (CAST and CAST II) tested the hypothesis that suppression of asymptomatic PVCs with the drugs flecainide, encainide, or moricizine in patients with a relatively recent history of MI would lead to a reduction in the incidence of sudden cardiac death.[38,39] However, the results showed that not only did antiarrhythmic agents not reduce the risk of sudden cardiac death, there was a significant *increase* in the risk of death in patients who received therapy with encainide or flecainide compared with those who received placebo.[38] During the continuation of the study with moricizine (CAST II), there was a significantly higher incidence of death in the moricizine group compared to the placebo group during the first 2 weeks of therapy.[39] Additional evidence suggests that other Vaughan Williams class I agents, including quinidine, procainamide, and disopyramide, increase the risk of death in patients with complex PVCs following MI.[40]

KEY CONCEPT In patients with symptomatic PVCs who do not have structural heart disease, treatment with β-blockers or nondihydropyridine CCBs is recommended to reduce the frequency of recurrent PVCs and improve symptoms. Patients with symptomatic PVCs who do not have structural heart disease and in whom β-blockers or nondihydropyridine CCBs are ineffective or poorly tolerated can be treated with an antiarrhythmic drug. For patients with symptomatic PVCs and underlying structural heart disease, treatment with β-blockers is recommended. β-Blockers have been shown to reduce mortality in this population and to be effective for PVC suppression.[41] Patients with frequent symptomatic PVCs who do not respond adequately to β-blockers, nondihydropyridine CCBs or antiarrhythmic drugs, or who do not tolerate those medications, can undergo catheter ablation. Catheter ablation of infrequent PVCs is not recommended. For patients with PVC-induced cardiomyopathy, β-blockers or amiodarone are recommended to reduce the frequency of PVCs and improve symptoms and left ventricular function.

▶ *Outcome Evaluation*

- Monitor patients for PVC frequency and relief of symptoms.
- Monitor for adverse effects of β-blockers: bradycardia, hypotension, fatigue, masking symptoms of hypoglycemia, glucose intolerance (in diabetic patients), wheezing or shortness of breath (in patients with severe asthma or chronic obstructive pulmonary disease [COPD]).

Clinical Presentation and Diagnosis of PVCs

LO 3

- PVCs are usually categorized as simple or frequent/repetitive: simple PVCs are those that occur as infrequent, isolated single abnormal beats; frequent/repetitive PVCs are those that occur frequently (at least one PVC on a 12-lead ECG or ≥ 30 per hour) and/or in specific patterns. Very frequent PVCs are defined as greater than 10,000–20,000 per day
- Two consecutive PVCs are referred to as a couplet. The term *bigeminy* refers to a PVC occurring with every other beat; *trigeminy* means a PVC occurring with every third beat; *quadrigeminy* means a PVC occurring every fourth beat

Symptoms

- Most patients who experience simple or complex PVCs are asymptomatic. Occasionally, patients with complex or frequent PVCs may experience symptoms of palpitations, light-headedness, or dizziness

Digoxin	Thioridazine
Disopyramide	Trazodone
Flecainide	Venlafaxine
Ibutilide	

Ventricular Tachycardia

LO 3 VT is a series of three or more consecutive PVCs at a rate greater than 100 beats/min. VT is defined as nonsustained if it lasts greater than or equal to 3 beats and terminates spontaneously; sustained VT lasts greater than 30 seconds or requires termination because of hemodynamic instability in less than 30 seconds.[42] VT is usually monomorphic, meaning that each QRS complex displays the same shape, axis, and amplitude. VT may occasionally be polymorphic, with QRS complexes displaying various shapes, axes, and amplitudes.

▶ *Epidemiology, Etiology, and Pathophysiology*

The prevalence of monomorphic VT in the general population is unknown.[9] In populations at risk, the incidence of VT is variable, depending on underlying etiologies and comorbidities. Etiologies of VT are presented in Table 9–12. Up to 20% of patients who experience acute MI experience ventricular arrhythmias.[43] Approximately 7% to 8% of patients with MI develop VT during the period of hospitalization.[43] Nonsustained VT occurs in 20% to 80% of patients with HF.[44] Other etiologies of VT include electrolyte abnormalities such as hypokalemia, hypoxia, and drugs. VT that occurs in the absence of structural heart disease is referred to as "idiopathic" VT. Some patients with idiopathic VT have verapamil-sensitive VT, while others have outflow tract VT, indicating that the VT originates in the outflow tract of the right or left ventricle.[42] Verapamil-sensitive VT and outflow tract VT are generally differentiated based on the ECG morphology. VT is usually initiated by a precisely timed PVC, occurring during the relative refractory period, which provokes reentry within ventricular tissue. Sustained VT requires immediate intervention, because if untreated, the rhythm may cause sudden cardiac death via hemodynamic instability and the absence of a pulse (pulseless VT) or via degeneration of VT into VF.

▶ *Treatment*

Desired Outcomes

LO 3 Desired outcomes are to terminate the arrhythmia and restore sinus rhythm, and prevent sudden cardiac death.

Pharmacologic Therapy Hemodynamically unstable VT should be terminated immediately using synchronized DCC beginning with 100 J (for monophasic shocks) and increasing subsequent shocks to 200, 300, and 360 J.[11] In the event that VT is present but the patient does not have a palpable pulse (and therefore no blood pressure), asynchronous defibrillation should be performed, at 360 J for monophasic waveforms and starting at 120 to 200 J for biphasic waveforms.[11]

LO 9 LO 10 Drugs used for the termination of hemodynamically stable VT are presented in Table 9–13.[42] A decision algorithm for management of hemodynamically stable VT is presented in Figure 9–9. For patients with structural heart disease who develop VT, DCC is the preferred therapy as it is considered to be more effective than drug therapy. For patients in whom DCC is undesirable (ie, if patients have eaten a meal that day and cannot be safely sedated for DCC), IV procainamide is the drug of choice. IV amiodarone or sotalol are recommended for patients in whom VT is unresponsive to procainamide.[42]

For patients with idiopathic VT for which the arrhythmia is verapamil-sensitive, verapamil should be administered (Figure 9–9). For patients with outflow tract VT, IV β-blockers are preferred agents.[42]

Nonpharmacologic Therapy: Prevention of Sudden Cardiac Death KEY CONCEPT LO 9 LO 10 In patients who have experienced VT and are at risk for sudden cardiac death, an implantable cardioverter-defibrillator (ICD) is the treatment of choice.[42,45] An ICD is a device that provides internal electrical cardioversion of VT or defibrillation of VF. The ICD does not prevent the patient from developing the arrhythmia, but it reduces the risk that the patient will die of sudden cardiac death as a result of the arrhythmia. Whereas early versions of ICDs required a thoracotomy for implantation, these devices now may be implanted transvenously, similarly to pacemakers, markedly reducing the incidence of complications. ICDs are indicated for patients who are survivors of cardiac arrest due to hemodynamically unstable VT or VF.[42,45]

Clinical Presentation and Diagnosis of VT

Symptoms

LO 3
- Symptoms depend primarily on heart rate and include palpitations, dizziness, light-headedness, shortness of breath, chest pain (if underlying CAD is present), near-syncope, and syncope
- Patients with nonsustained VT may be asymptomatic if the duration of the arrhythmia is sufficiently short. However, if the rate is sufficiently rapid, patients with nonsustained VT may experience symptoms
- Patients with sustained VT are usually symptomatic, provided the rate is fast enough to provoke symptoms. Patients with rapid sustained VT may be hemodynamically unstable
- In some patients, sustained VT results in the absence of a pulse or may deteriorate to VF, resulting in sudden cardiac death

Diagnosis

- Diagnosis of VT requires ECG confirmation
- VT is characterized by wide, misshapen QRS complexes, with the rate varying from 140 to 250 beats/min
- In most patients with VT, the shape and appearance of the QRS complexes are consistent and similar, referred to as monomorphic VT. However, some patients experience polymorphic VT, in which the shape and appearance of the QRS complexes vary

Table 9–13

Drugs for Termination of Ventricular Tachycardia[42]

Drug	Loading Dose	Maintenance Dose
Procainamide	20–50 mg/min continuous IV infusion until maximum dose of 10–17 mg/kg is reached	Continuous IV infusion 1–4 mg/min
Amiodarone	150 mg IV over 10 minutes	1 mg/min continuous infusion for 6 hours, then 0.5 mg/min for 18 hours
Sotalol	75 mg IV every 12 hours	—
Verapamil	2.5–5 mg/kg IV bolus every 15–30 minutes	
β-Blockers	Esmolol – see Table 9–6	See Table 9–6
	Metoprolol – see Table 9–6	See Table 9–6
	Propranolol – see Table 9–6	See Table 9–6

IV, intravenous.

ICDs are significantly more effective than antiarrhythmic drugs such as amiodarone or sotalol for reducing the risk of sudden cardiac death, and therefore are preferred therapy.[46,47] However, many patients with ICDs receive concurrent antiarrhythmic drug therapy to reduce the frequency with which patients experience the discomfort of shocks and to prolong battery life of the devices. Combined pharmacotherapy with amiodarone and a β-blocker is more effective than monotherapy with sotalol or β-blockers for reduction in the frequency of ICD shocks.[48]

▶ *Outcome Evaluation*

- Monitor patients for termination of VT and restoration of normal sinus rhythm.
- Monitor patients for adverse effects of antiarrhythmic drugs (see Table 9–7).

Ventricular Fibrillation

LO 3

VF is irregular, disorganized, chaotic electrical activity in the ventricles resulting in the absence of ventricular depolarizations, and consequently, lack of pulse, cardiac output, and blood pressure.

▶ *Epidemiology and Etiology*

The annual incidence of out-of-hospital cardiac arrest in the United States is approximately 76 to 111 individuals per 100,000 population, or roughly 230,000 to 356,000 people.[9] Approximately 11% of individuals experiencing emergency medical services (EMS)-treated out-of-hospital cardiac arrest survive to hospital

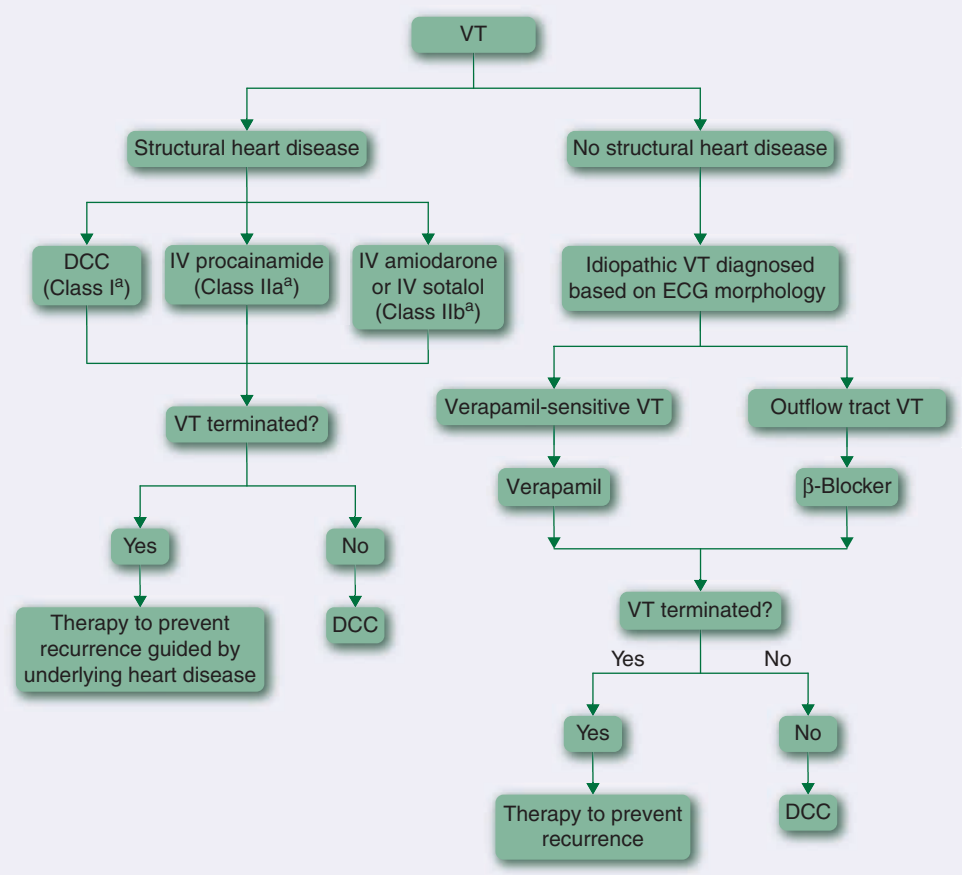

FIGURE 9–9. Decision algorithm for termination of hemodynamically stable ventricular tachycardia. [a]Class I recommendations represent strong level of evidence; Class IIa recommendations represent moderate level of evidence; and Class IIb recommendations represent weak level of evidence. (DCC, direct current cardioversion; ECG, electrocardiogram; IV, intravenous; VT, ventricular tachycardia.)

Clinical Presentation and Diagnosis of VF

Symptoms

LO 3

- VF results in immediate loss of pulse and blood pressure. Patients who are in the standing position at the onset of VF suddenly and immediately collapse to the ground.

Diagnosis

- The absence of a pulse does not guarantee VF because pulse may also be absent in patients with asystole, VT, or pulseless electrical activity.
- Confirmation of the diagnosis with an ECG is necessary to determine appropriate treatment. ECG reveals no organized, recognizable QRS complexes. If treatment is not initiated within a few minutes, death will occur, or at best, resuscitation of the patient with permanent anoxic brain injury.

discharge. Although some of these deaths occur as a result of asystole, the majority occur as a result of primary VF or VT that degenerates into VF. Etiologies of VF are presented in Table 9–12 and are similar to those of VT.

LO 3

▶ *Treatment*

Desired Outcomes Desired outcomes are to: (a) terminate VF, (b) achieve return of spontaneous circulation, and (c) achieve patient survival to hospital admission (in those with out-of-hospital cardiac arrest) and to hospital discharge.

LO 3

Pharmacologic and Nonpharmacologic Therapy VF is by definition hemodynamically unstable, due to the absence of a pulse and blood pressure. Initial management includes provision of basic life support, including calling for help and initiation of cardiopulmonary resuscitation (CPR).[11,49] Oxygen should be administered as soon as it is available. Most importantly, defibrillation should be performed as soon as possible. It is critically important to understand that the only means of successfully terminating VF and restoring sinus rhythm is electrical defibrillation. Defibrillation should be attempted using 360 J for monophasic defibrillators, and 120 to 200 J for biphasic shocks, after which CPR should be resumed immediately while the defibrillator charges. If the first shock was unsuccessful, subsequent defibrillation attempts should be performed at equivalent or higher energy doses.[11,49]

LO 9

If VF persists following two defibrillation shocks, drug therapy may be administered. KEY CONCEPT The purpose of drug administration for treatment of VF is to facilitate successful defibrillation. Drug therapy alone will not result in termination of VF. Drugs used for facilitation of defibrillation in patients with VF are listed in Table 9–14.[11,49] Drug administration should occur during CPR, before or after delivery of a defibrillation shock. The vasopressor agent epinephrine is administered initially because it has been shown that a critical factor in successful defibrillation is maintenance of coronary perfusion pressure, which is achieved via the vasoconstricting effects of this agent. A decision algorithm for the treatment of VF is presented in Figure 9–10. Vasopressin is no longer recommended as a vasopressor agent for cardiac arrest,

LO 9 LO 10

Table 9–14

Drugs for Facilitation of Defibrillation in Patients with Ventricular Fibrillation[11]

Drug	Dose
Epinephrine	1 mg IV/IO every 3–5 minutes
Amiodarone	300 mg IV/IO. One subsequent dose of 150 mg IV/IO may be administered

IO, Intraosseous; IV, intravenous.

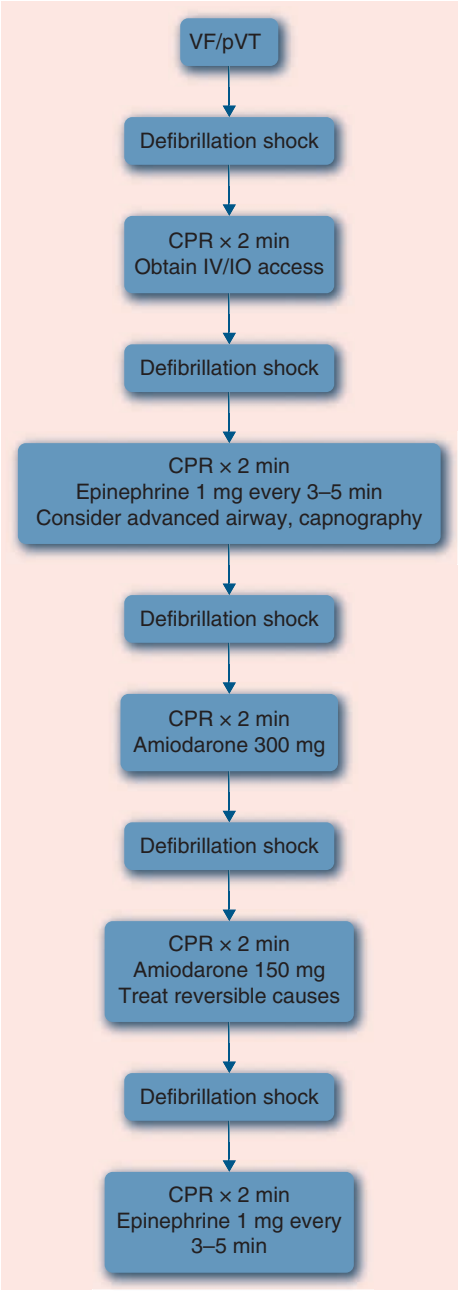

FIGURE 9–10. Decision algorithm for resuscitation of VF or pulseless VT. (CPR, cardiopulmonary resuscitation; IO, intraosseous; IV, intravenous; VF, ventricular fibrillation; pVT, pulseless ventricular tachycardia.) (Data from Link MS, Berkow LC, Kudenchuk PJ, et al. Part 7: adult advanced cardiovascular life support: 2015 American Heart Association Guidelines Update for Cardiopulmonary Resuscitation and Emergency Cardiovascular Care. Circulation. 2015;132(suppl 2):S444–S464.)

including that caused by VF; epinephrine is the sole vasopressor drug recommended for this indication.[49] Amiodarone is effective for facilitation of defibrillation leading to survival to hospital admission in patients with VF.[11,49] Note that amiodarone doses recommended for administration during a resuscitation attempt for VF (see Table 9–14) are different than those recommended for administration for termination of VT (see Table 9–13).

▶ *Outcome Evaluation*

- Monitor the patient for return of pulse and blood pressure, and for termination of VF and restoration of normal sinus rhythm.
- After successful resuscitation, monitor the patient for adverse effects of drugs administered (see Table 9–7).

Torsades de Pointes

LO 3 TdP is a specific polymorphic VT associated with prolongation of the QTc interval in the sinus beats that precede the arrhythmia.[1,50]

▶ *Epidemiology and Etiology*

Incidence of TdP in the population at large is unknown. Attempts to estimate incidence suggests there may be 1000 to 13,000 cases annually in the United States. Incidence of TdP associated with specific drugs ranges from less than 1% to as high as 8% to 10%, depending on dose and plasma concentration of the drug and presence of other risk factors for the arrhythmia.

LO 3 TdP may be inherited or acquired. Patients with specific genetic mutations may have an inherited long QT syndrome, in which the QTc interval is prolonged, and these patients are at risk for TdP. Acquired TdP may be caused by numerous drugs (Table 9–15);[1,50] the list of drugs known to cause TdP continues to expand.

Table 9–15

Some Drugs[a] Known to Cause Torsades de Pointes[1,50]

Amiodarone	Haloperidol
Arsenic trioxide	Ibutilide
Azithromycin	Levofloxacin
Chloroquine	Methadone
Chlorpromazine	Moxifloxacin
Ciprofloxacin	Ondansetron
Citalopram	Oxaliplatin
Clarithromycin	Pentamidine
Cocaine	Pimozide
Disopyramide	Procainamide
Dofetilide	Propofol
Donepezil	Quinidine
Dronedarone	Roxithromycin
Droperidol	Sevoflurane
Erythromycin	Sotalol
Escitalopram	Terlipressin
Flecainide	Thioridazine
Fluconazole	Vandetanib
Halofantrine	

[a]This table does not provide an exhaustive list of drugs that may cause torsades de pointes. For an exhaustive list, please consult reference 50.

Table 9–16

Risk Factors for Drug-Induced Torsades de Pointes (TdP)[1]

QTc interval > 500 ms
Increase in QTc interval by > 60 ms compared with the pretreatment value
Female sex
Age > 65 years
Heart failure
Electrolyte abnormalities: hypokalemia, hypomagnesemia, hypocalcemia
Bradycardia
Elevated plasma concentrations of QTc interval-prolonging drugs due to drug interactions or absence of dose adjustment for organ dysfunction
Rapid IV infusion of TdP-inducing drugs
Concomitant administration of more than one agent known to cause QTc interval prolongation/TdP
Concomitant administration of loop diuretics
Genetic predisposition
Sepsis
Previous history of drug-induced TdP

IV, intravenous; ms, milliseconds; QTc, corrected QT interval.

▶ *Pathophysiology*

TdP is caused by circumstances, often drugs, that lead to prolongation in the repolarization phase of the ventricular action potential (see Figure 9–2) manifested on the ECG by prolongation of the QTc interval. Prolongation of ventricular repolarization occurs via inhibition of efflux of potassium through potassium channels; therefore, drugs that inhibit conductance through specific potassium channels known as I_{Kr} (the rapid component of the delayed rectifier potassium current) may cause QTc interval prolongation and TdP. Prolongation of ventricular repolarization promotes the development of early ventricular afterdepolarizations during the relative refractory period, which may provoke reentry leading to TdP.

KEY CONCEPT Drug-induced TdP rarely occurs in patients without specific risk factors for the arrhythmia (Table 9–16).[1,50] In most cases, administration of a drug known to cause TdP is unlikely to cause the arrhythmia; however, the likelihood of the arrhythmia increases in patients with concomitant risk factors.

Onset of TdP associated with oral drug therapy is somewhat variable and in some cases may be delayed; often, a patient can be taking a drug known to cause TdP for months or longer without problem until another risk factor for the arrhythmia becomes present, which then may trigger the arrhythmia.

In some patients, TdP may be of short duration and may terminate spontaneously. However, TdP may not terminate on its own, and if left untreated, may degenerate into VF and result in sudden cardiac death.[1] Several drugs, including terfenadine, astemizole, cisapride, and grepafloxacin, have been withdrawn from the US market as a result of causing deaths due to TdP.

▶ *Treatment*

LO 3 **Desired Outcomes** Desired outcomes include (a) prevention of TdP, (b) termination of TdP, (c) prevention of recurrence, and (d) prevention of sudden cardiac death.

LO 10 **Pharmacologic and Nonpharmacologic Therapy** KEY CONCEPT In patients with risk factors for TdP, drugs with the potential to

Clinical Presentation and Diagnosis of TdP

LO 3

Symptoms

- Symptoms associated with TdP depend primarily on heart rate and arrhythmia duration, and include palpitations, dizziness, light-headedness, shortness of breath, chest pain (if underlying CAD is present), near-syncope, and syncope.
- TdP may be hemodynamically unstable if the rate is sufficiently rapid.
- Like sustained monomorphic VT, TdP may result in the absence of a pulse or may rapidly degenerate into VF, resulting in the syndrome of sudden cardiac death.

Diagnosis

- Diagnosis of TdP requires examination of the arrhythmia on ECG.
- TdP, or "twisting of the points," appears on ECG as apparent twisting of the wide QRS complexes around the isoelectric baseline.
- Associated with heart rates from 140 to 280 beats/min.
- Characteristic feature: a "long-short" initiating sequence that occurs as a result of a PVC followed by a compensatory pause followed by the first beat of the TdP.
- Episodes of TdP may self-terminate, with frequent recurrence.

cause QTc interval prolongation and TdP should be avoided or used with extreme caution, and diligent QTc interval monitoring should be performed.

A decision algorithm for management of TdP is presented in Figure 9–11. Management of drug-induced TdP includes discontinuation of the potential causative agent. Patients with hemodynamically unstable TdP should undergo immediate defibrillation, rather than synchronized DCC, because polymorphic arrhythmias are usually not responsive to DCC. In patients with hemodynamically stable TdP, electrolyte abnormalities such as hypokalemia, hypomagnesemia, or hypocalcemia should be corrected. Hemodynamically stable TdP should be treated with IV magnesium sulfate, irrespective of whether the patient is hypomagnesemic; magnesium has been shown to terminate TdP in normomagnesemic patients.[11,42] Magnesium sulfate should be administered IV in doses of 1 to 2 g,[42] diluted in 50 to 100 mL 5% dextrose in water (D_5W), administered over 15 minutes; doses may be repeated to a total of 6 g. Alternatively, a continuous magnesium infusion (0.5 to 1 g/hour) may be initiated after the first bolus. In addition, electrolyte repletion with potassium to greater than or equal to 4.0 mEq/L (4.0 mmol/L) and magnesium to greater than or equal to 2.0 mEq/L (1.0 mmol/L) is recommended.[42]

For hemodynamically stable TdP that is unresponsive to IV magnesium sulfate and is accompanied by bradycardia or triggered by pauses in rhythm, isoproterenol administered via continuous IV infusion 2 to 10 mcg/min may be administered or temporary transvenous atrial or ventricular pacing may be employed to increase the heart rate.[42]

▶ *Outcome Evaluation*

- Monitor vital signs (heart rate and blood pressure).
- Monitor the ECG to determine the QTc interval (maintain < 470 milliseconds [ms] in males and 480 ms in females)[1] and for the presence of TdP.
- Monitor serum potassium, magnesium, and calcium concentrations.
- Monitor for symptoms of tachycardia.

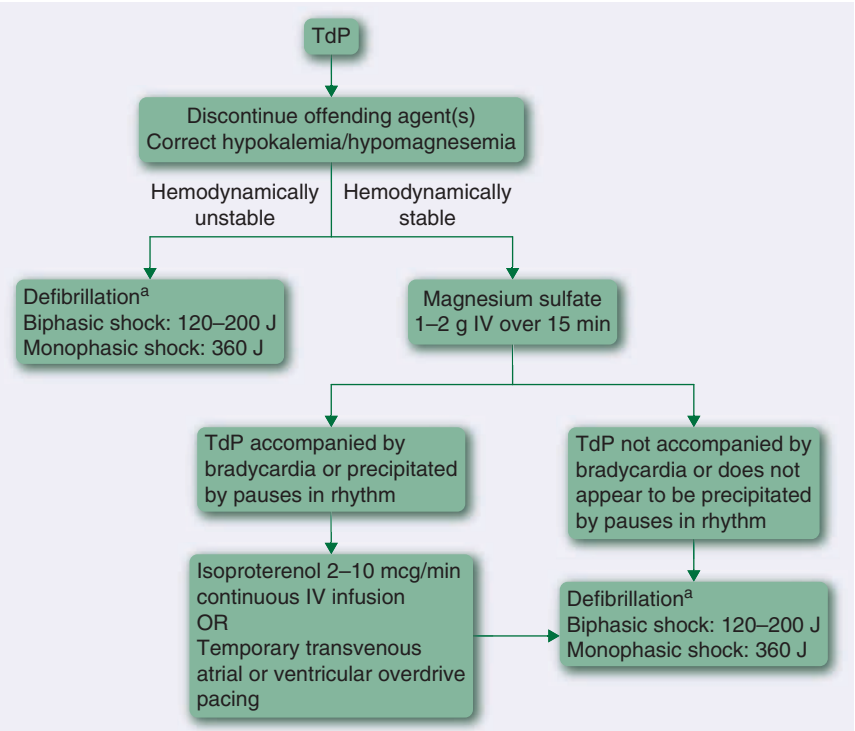

FIGURE 9–11. Decision algorithm for management of torsades de pointes. [a]As polymorphic arrhythmias do not permit synchronization, defibrillation is recommended, rather than synchronized direct current cardioversion. Administer sedation when possible. (IV, intravenous; J, Joules; TdP, torsades de pointes.) (Reprinted with permission from Erstad B, ed. Critical Care Pharmacotherapy. Lenexa, KS; American College of Clinical Pharmacy: 2016;730.)

Patient Care Process

Collect Information:

- Perform a thorough medication history to determine whether the patient is receiving prescription or nonprescription drugs that may cause or contribute to the development of an arrhythmia. See Tables 9–2, 9–3, 9–4, 9–12, and 9–15.
- Determine the patient's serum electrolyte concentrations to determine the presence of hypokalemia, hyperkalemia, hypomagnesemia, hypermagnesemia, or hypocalcemia.
- Consider the patient's heart rate, blood pressure, and symptoms to determine whether he or she is hemodynamically stable or unstable, and the degree to which symptoms are limiting function and quality of life.
- Review the patients' ECG(s) and/or ECG rhythm strips.

Assess the Information:

- Evaluate the patient for the presence of drug-induced diseases, drug allergies, and drug interactions.
- For patients with preexisting arrhythmias, assess the current drug therapy regimen for efficacy, side effects, and adherence.
- In patients currently receiving warfarin for AF, determine the INR and evaluate for appropriateness, adverse effects, and drug–drug and drug–food interactions.
- Assess adherence to current drug therapy regimens.
- Assess the patient's 12-lead ECG or single rhythm strips to determine if an arrhythmia is present, and identify the specific arrhythmia, and evaluate and monitor symptoms.
- Assess information from the chest X-ray, transthoracic echocardiograms or TEEs, and other physical examination and diagnostic information pertinent to arrhythmias.

Develop a Care Plan:

- Develop drug therapy treatment plans for management of the pertinent arrhythmia: sinus bradycardia, AV block, AF, PSVT, PVCs, VT (including TdP), or VF. See Figures 9–4 through 9–11 and Tables 9–6, 9–7, 9–8, 9–9, 9–10, 9–11, 9–13, and 9–14.

Implement the Care Plan:

- Educate the patient about changes in drug therapy, medication administration, potential new adverse effects, and how to manage adverse effects.
- Address patient concerns about arrhythmias and their management.
- Discuss importance of medication adherence and risk factor modification for management of arrhythmias.
- Determine whether the patient has prescription coverage and/or whether recommended agents are included on the institution's formulary.

Follow-up: Monitor and Evaluate:

- Develop specific drug therapy monitoring plans, including assessment of symptoms, ECG, adverse effects of drugs, and potential drug interactions.
- Monitor QTc interval in patients receiving QTc interval-prolonging drugs.
- Provide information regarding safe and effective oral anticoagulation:
  - Notify clinicians in the event of severe bruising, blood in urine or stool, melena, hemoptysis, hematemesis, or frequent epistaxis.
  - Patients taking warfarin should avoid radical changes in diet.
  - Avoid alcohol.
  - Do not take nonprescription medications or herbal/alternative/complementary medicines without notifying physician, pharmacist, and/or health care team members.
- Provide patient education regarding disease state and drug therapy.

Abbreviations Introduced in This Chapter

1°	First-degree
2°	Second-degree
3°	Third-degree
AF	Atrial fibrillation
ADHF	Acute decompensated heart failure
aPTT	Activated partial thromboplastin time
ATPase	Adenosine triphosphatase
AV	Atrioventricular
CAD	Coronary artery disease
CAST	Cardiac Arrhythmia Suppression Trial
CCB	Calcium channel blocker
COPD	Chronic obstructive pulmonary disease
CPR	Cardiopulmonary resuscitation
CrCl	Creatinine clearance
CYP	Cytochrome P450
DCC	Direct current cardioversion
D_5W	5% Dextrose in water
ECG	Electrocardiogram
ED	Emergency department
EMS	Emergency Medical Services
FDA	Food and Drug Administration
GI	Gastrointestinal
HF	Heart failure
HFrEF	Heart failure with reduced ejection fraction
ICD	Implantable cardioverter-defibrillator
INR	International normalized ratio
IO	Intraosseous
IV	Intravenous
J	Joule
LV	Left ventricle
LVEF	Left ventricular ejection fraction
MI	Myocardial infarction
ms	Milliseconds
NOAC	Non-vitamin K antagonist oral anticoagulant
NYHA	New York Heart Association
P-gp	P-glycoprotein
PAD	Peripheral arterial disease
PSVT	Paroxysmal supraventricular tachycardia

PVC	Premature ventricular complex
QTc	Corrected QT interval
SA	Sinoatrial
TdP	Torsades de pointes
TEE	Transesophageal echocardiogram
TIA	Transient ischemic attack
VF	Ventricular fibrillation
VPB	Ventricular premature beat
VPC	Ventricular premature contraction
VPD	Ventricular premature depolarization
VT	Ventricular tachycardia

10 Venous Thromboembolism

Edith A. Nutescu, James C. Lee, and Stuart T. Haines

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Identify risk factors and signs and symptoms of deep vein thrombosis (DVT) and pulmonary embolism (PE).
2. Describe the processes of hemostasis and thrombosis.
3. Determine a patient's relative risk of developing venous thrombosis.
4. Formulate an appropriate prevention strategy for a patient at risk for DVT.
5. Select and interpret laboratory test(s) to monitor antithrombotic drugs.
6. Identify factors that place a patient at high risk of bleeding while receiving antithrombotic drugs.
7. State at least two potential advantages of newer anticoagulants (ie, low molecular weight heparins [LMWHs], fondaparinux, oral direct thrombin inhibitors [DTIs], and oral direct factor Xa inhibitors) over traditional anticoagulants (ie, unfractionated heparin and warfarin).
8. Manage a patient with toxicity secondary to warfarin (elevated international normalized ratio [INR] with or without bleeding).
9. Identify anticoagulant drug–drug and drug–food interactions.
10. Formulate an appropriate treatment plan for a patient who develops a DVT or PE.

INTRODUCTION

Venous thromboembolism (VTE) is one of the most common cardiovascular disorders in the United States. VTE is manifested as deep vein thrombosis (DVT; ie, thrombus causing obstruction of a deep vein in the leg, pelvis, or abdomen) and pulmonary embolism (PE; ie, thrombus causing obstruction of a pulmonary artery or one of its branches and resulting in pulmonary infarction) (Figure 10–1).[1,2] A thrombus is a blood clot attached to the vessel wall composed of platelets, fibrin, and clotting factors that may partially or completely occlude the lumen of a blood vessel and compromise blood flow and oxygen delivery to distal tissue. It is often provoked by prolonged immobility and vascular injury and most frequently seen in patients hospitalized for a serious medical illness, trauma, or major surgery. VTE can also occur with little or no provocation in patients who have an underlying hypercoagulable disorder.

Although VTE may initially cause few or no symptoms, the first overt manifestation of the disease may be sudden death from PE, which can occur within minutes, before effective treatment can be given.[2,3] A history of VTE is a significant risk factor for recurrent thromboembolic events.[4-7] Postthrombotic syndrome (PTS) is a complication of VTE that occurs due to damage to the vein caused by a blood clot and leads to development of symptomatic venous insufficiency such as chronic lower extremity swelling, pain, tenderness, skin discoloration, and ulceration.

The treatment of VTE is fraught with substantial risks.[8] KEY CONCEPT Antithrombotic therapies (thrombolytics and anticoagulants) require precise dosing and meticulous monitoring, as well as ongoing patient assessment and education.[4,9,10] Well-organized anticoagulation management services improve quality of care and reduce overall cost. A systematic approach to drug therapy management reduces risks, but bleeding remains a common and serious complication.[10,11] Therefore, preventing VTE is paramount to improving outcomes. When VTE is suspected, a rapid and accurate diagnosis is critical to making appropriate treatment decisions. The optimal use of antithrombotic drugs requires not only an in-depth knowledge of their pharmacology and pharmacokinetic properties but also a comprehensive approach to patient management.[3,12]

EPIDEMIOLOGY AND ETIOLOGY

The true incidence of VTE in the general population is unknown because many patients, perhaps more than 50%, have no overt symptoms or go undiagnosed.[1,12,13] An estimated 2 million people in the United States develop VTE each year, of whom 600,000 are hospitalized and 60,000 die. The estimated annual direct medical costs of managing the disease are well over $1 billion. The incidence of VTE nearly doubles in each decade of life older than 50 years of age and is slightly higher in men. As the population ages, the total number of DVT and PE cases continues to rise.[1,2,13,14]

KEY CONCEPT The risk of VTE is related to several factors including age, history of VTE, major surgery (particularly orthopedic procedures of the lower extremities), trauma, malignancy, pregnancy, estrogen use, and hypercoagulable states (Table 10–1).[5-7] VTE risk factors can be categorized into one of the three elements of Virchow triad: stasis in blood flow, vascular endothelial injury, and inherited or acquired changes in blood constituents resulting in hypercoagulation states.[15-17]

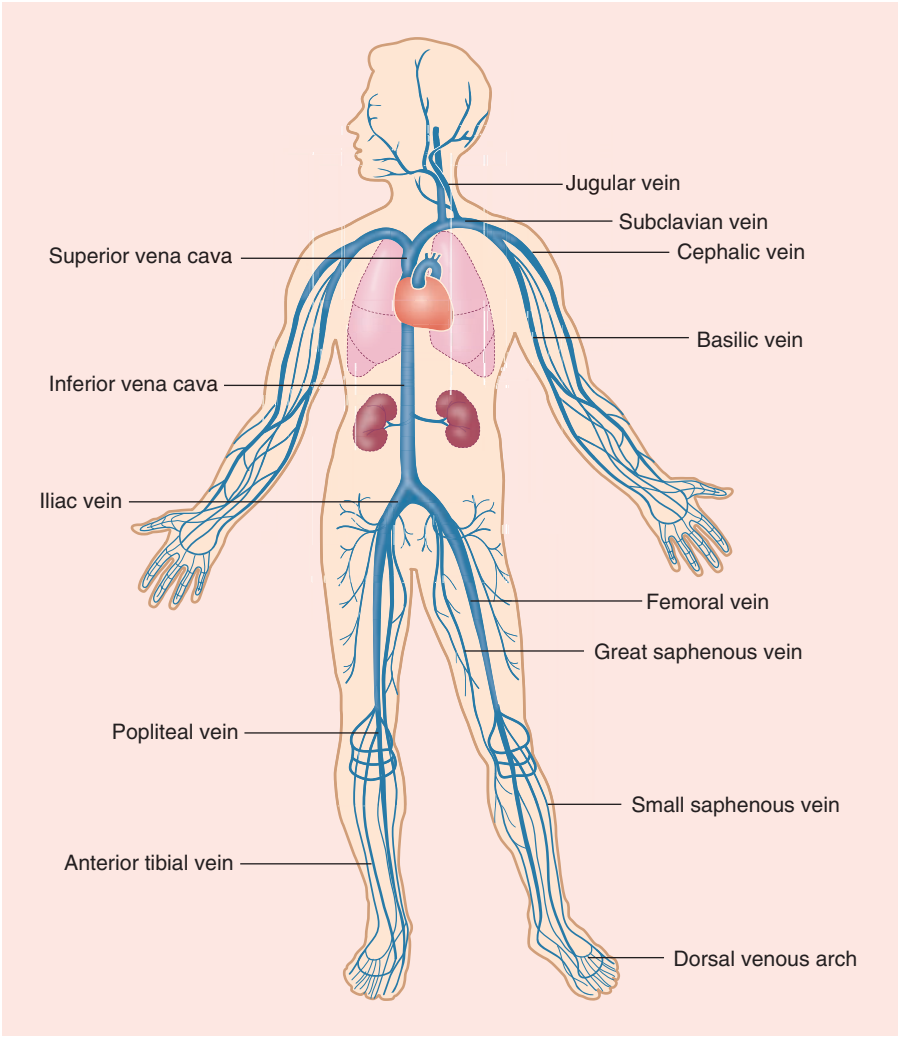

FIGURE 10–1. Venous circulation. (From Witt DM, Clark NP, Vazquez SR. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:232.)

LO 1

These risk factors are additive, and some can be easily identified in clinical practice.[1,3] A prior history of venous thrombosis (in which blood changes from a liquid to a solid state and produces a blood clot) is perhaps the strongest risk factor for recurrent VTE, presumably because of damage to venous valves and obstruction of blood flow caused by the initial event.[5-7] Rapid blood flow (as in arteries) has an inhibitory effect on thrombus formation, but a slow rate of blood flow (as in veins) reduces the clearance of activated clotting factors in the zone of injury and slows the influx of regulatory substances. Stasis tips the delicate balance of procoagulation and anticoagulation in favor of **thrombogenesis**. The rate of blood flow in the venous circulation, particularly in the deep veins of the lower extremities, is relatively slow. Valves in the deep veins of the legs, as well as contraction of the calf and thigh muscles, facilitate the flow of blood back to the heart and lungs. Damage to the venous valves and periods of prolonged immobility result in venous stasis. Vessel obstruction, either from a thrombus or external compression, promotes clot propagation. Numerous medical conditions and surgical procedures are associated with reduced venous blood flow and increase the risk of VTE. Greater than normal blood viscosity, seen in myeloproliferative disorders like **polycythemia vera**, may also contribute to slowed blood flow and thrombus formation.[5-7,16,17]

While a normal endothelium is antithrombotic, damage to the endothelium creates a substrate for platelet binding and activation that ultimately leads to clot formation. Major surgery, trauma, and indwelling central catheters can cause endothelial damage. Smoking and hypertension can also lead to endothelial dysfunction by shifting the balance between clot formation and clot breakdown toward thrombosis.[5-7,16,17]

A growing list of hereditary deficiencies, gene mutations, and acquired diseases has been linked to hypercoagulability (Table 10–1).[18,19] Some patients may have multiple genetic defects. Hereditary deficiencies include activated protein C resistance also known as factor V Leiden, the prothrombin gene 20210A mutation, deficiencies of the natural anticoagulants protein C, protein S, and antithrombin (AT), and high concentrations of factors VIII, IX, and XI. Acquired disorders of hypercoagulability include malignancy, antiphospholipid antibodies, estrogen use, and pregnancy.[20,21] Estrogen-containing contraceptives, estrogen replacement therapy, and many of the selective estrogen receptor modulators (SERMs) increase the risk of venous thrombosis.[20,22] Although the mechanisms are not clearly understood, estrogens increase serum **clotting factor** concentrations and induce activated protein C resistance. Increased serum estrogen concentrations may explain, in part, the increased risk of VTE during pregnancy and the postpartum period.[22]

Table 10–1

Risk Factors for Venous Thromboembolism (VTE)

Risk Factor	Considerations and Examples
Age	Risk doubles with each decade after age 50
History of VTE	Strongest known risk factor
Venous stasis	Major medical illness (eg, heart failure, acute myocardial infarction, ischemic stroke, acute infection)
	Major surgery (eg, general anesthesia for > 30 minutes)
	Paralysis (eg, due to stroke or spinal cord injury)
	Polycythemia vera
	Obesity
	Varicose veins
	Immobility (eg, bedrest for ≥ 3 days during hospital admission)
Vascular injury	Major orthopedic surgery (eg, knee and hip replacement)
	Trauma (especially fractures of the pelvis, hip, or leg)
	Indwelling venous catheters
Hypercoagulable states	Malignancy, diagnosed or occult
	Activated protein C resistance/ factor V Leiden
	Prothrombin (20210A) gene mutation
	Protein C deficiency
	Protein S deficiency
	Antithrombin deficiency
	Factor VIII excess (> 90th percentile)
	Factor XI excess (> 90th percentile)
	Antiphospholipid antibodies
	Dysfibrinogenemia
	Plasminogen activator inhibitor-1 (PAI-1) excess
	Pregnancy/postpartum
Drug therapy	Estrogen-containing oral contraceptive pills
	Estrogen replacement therapy
	Selective estrogen receptor modulators (SERMs)
	Heparin
	Chemotherapy

PATHOPHYSIOLOGY

Hemostasis, the arrest of bleeding following vascular injury, is essential to life.[23] Within the vascular system, blood remains in a fluid state, transporting oxygen, nutrients, plasma proteins, and waste. When a vessel is injured, a dynamic interplay between thrombogenic (activating) and antithrombotic (inhibiting) forces results in the local formation of a hemostatic plug that seals the vessel wall and prevents further blood loss (Figures 10–2 and 10–3). A disruption of this delicate system of checks and balances may lead to inappropriate clot formation within the blood vessel that can obstruct blood flow or embolize to a distant vascular bed.

LO 2 Under normal circumstances, the endothelial cells that line the inside of blood vessels maintain blood flow by producing a number of substances that inhibit platelet adherence, prevent the activation of the coagulation cascade, and facilitate fibrinolysis.[16,17,23] Vascular injury exposes the subendothelium. Platelets adhere to the subendothelium with their glycoprotein (GP) Ib surface receptors and facilitated by von Willebrand factor (vWF). This causes platelets to become activated, releasing a number of procoagulant substances that stimulate circulating platelets to expose GP IIb and IIIa surface receptors and subsequently allowing platelets to adhere to one another, resulting in platelet aggregation (Figure 10–2). The damaged vascular tissue releases tissue factor that activates the extrinsic pathway of the coagulation cascade (Figure 10–3).

The clotting cascade is a stepwise series of enzymatic reactions that results in the formation of a fibrin mesh.[12] Clotting factors circulate in the blood in inactive forms. Once a precursor is activated by specific stimuli, it activates the next clotting factor in the sequence. The final steps in the cascade are the conversion of prothrombin (factor II) to thrombin (factor IIa) and fibrinogen to fibrin. Thrombin plays a key role in the coagulation cascade; it is responsible not only for the activation of fibrin but also for the activation of factors V and VIII, creating a positive feedback loop that greatly accelerates the entire cascade. Thrombin also enhances platelet aggregation.

Traditionally, the coagulation cascade has been divided into three distinct parts: the intrinsic, the extrinsic, and the common pathways. This artificial division is misleading because there are numerous interactions between the three pathways.[16,17,23] A number of tempering mechanisms modulate coagulation (Figure 10–2).[23,24] Without effective self-regulation, the coagulation cascade would proceed unabated until all the clotting factors and platelets are consumed.

CLINICAL PRESENTATION AND DIAGNOSIS

Although a thrombus can form in any part of the venous circulation, most begin in the lower extremities. Once formed, a venous thrombus may (a) remain asymptomatic, (b) spontaneously lyse, (c) obstruct the venous circulation, (d) propagate into more proximal veins, (e) embolize, and/or (f) slowly incorporate into the endothelial layer of the vessel.[1,3,16] Most patients with VTE never develop symptoms.[3,25] However, even those who initially experience no symptoms may suffer long-term consequences, such as PTS and recurrent VTE.

Given that VTE can be debilitating or fatal, it is important to treat it quickly and aggressively.[1,2,12] However, because major bleeding induced by antithrombotic drugs can be equally harmful, it is also important to avoid treatment when the diagnosis is not reasonably certain. Assessment should focus on patient-specific LO 1 risk factors during the medical history (Table 10–1).[1,2,12] Venous thrombosis is uncommon in the absence of risk factors, and the effects of these risk factors are additive. If a patient has multiple risk factors, VTE should be strongly suspected even when the symptoms are very subtle.

KEY CONCEPT The symptoms of DVT or PE are nonspecific, and it is extremely difficult to distinguish VTE from other disorders on clinical symptoms alone.[1-3,25] Therefore, objective tests are required to confirm or rule out the diagnosis. Patients with DVT frequently present with unilateral leg pain on the affected leg, swelling that can persist after a night's sleep, and cyanosis of the skin in the affected leg (Table 10–2). Similarly, PTS, a long-term complication of DVT caused by damage to the venous valves, produces chronic lower extremity swelling, pain, and tenderness that lead to skin discoloration and ulceration. To distinguish LO 3 acute DVT from PTS and other possible diagnoses, a clinical prediction rule that incorporates signs, symptoms, and risk factors can be used to categorize the patient as at low, intermediate, or high probability of having acute DVT. This model, known as the Wells criteria, is summarized in Table 10–2.[2,3,12] If the clinical probability of DVT is low, the D-dimer test can be used to

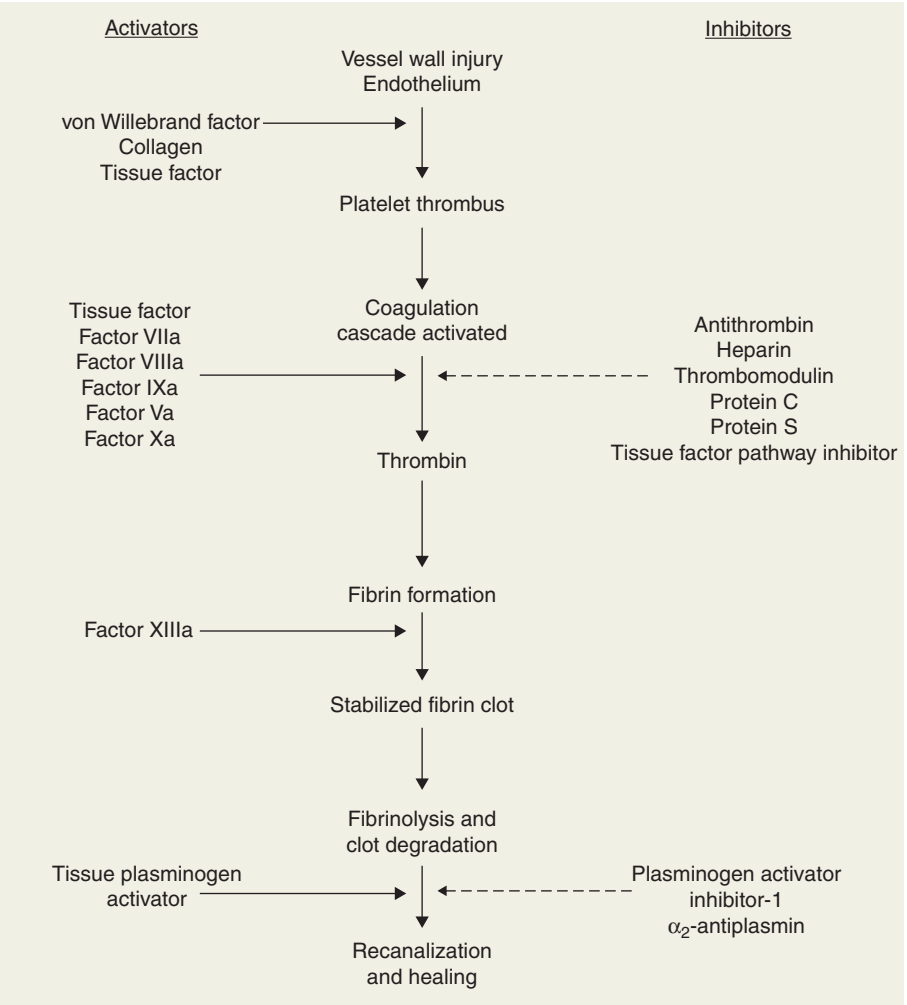

FIGURE 10–2. Hemostasis and thrombosis. (From Witt DM, Clark NP, Vazquez SR. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:234.)

confirm the patient does not have DVT. The D-dimer test is a quantitative measure of fibrin breakdown in the serum, and it is a marker of acute thrombotic activity. D-dimer assays are sensitive but not specific markers for VTE, so a negative D-dimer test can be used to rule out the diagnosis of DVT.

If the D-dimer test is positive in a low-probability patient, or if the patient has a moderate or high probability of DVT, then an objective radiographic test is used to confirm the diagnosis of DVT. Contrast venography allows visualization of the entire venous system in the lower extremities. This radiographic contrast study is the most accurate and reliable method for diagnosis of DVT and considered the gold standard in clinical trials.[3,25,26] However, venography is an expensive, invasive procedure that is technically difficult to perform and evaluate. Severely ill patients may be unable to tolerate the procedure, and many develop hypotension and cardiac arrhythmias. Furthermore, the contrast material is irritating to vessel walls and toxic to the kidneys. For these reasons, noninvasive testing using duplex ultrasonography is preferred. See the Clinical Presentation and Diagnosis of DVT textbox for further information.

LO 1

Like DVT, the nonspecific nature of the signs and symptoms of PE requires further evaluation. Table 10–3 describes the Wells criteria, a validated prediction model that can be used to stratify patients into high, moderate, and low probability of PE.[3,25-27] In patients with a low clinical probability of PE, diagnosis of PE can be ruled out if D-dimer testing is negative. If D-dimer testing is positive, or if the patient has a moderate or high clinical probability of PE, diagnostic imaging studies should be performed. Pulmonary angiography allows visualization of the pulmonary arteries and is the gold standard for diagnosing PE but is an extremely invasive procedure. Diagnosis of VTE can be made if there is a persistent intraluminal filling defect observed on multiple x-ray films. However, as with DVT, a noninvasive test is preferred, such as computed tomographic pulmonary angiography, magnetic resonance imaging (MRI), and ventilation/perfusion (V/Q) scans. See the Clinical Presentation and Diagnosis of PE textbox for further information.

LO 3

LO 1

PREVENTION

Given that VTE is often clinically silent and potentially fatal, prevention strategies have the greatest potential to improve patient outcomes.[5-7] The goal of an effective VTE prophylaxis program is to identify all patients at risk, determine each patient's level of risk, and select and implement regimens that provide sufficient protection for the level of risk.[5-7] KEY CONCEPT At the time of hospital admission, transition of care, and prior to discharge, all patients should be evaluated for risk of VTE, and appropriate prophylaxis strategies should be routinely used. Prophylaxis should be continued throughout the period of risk.

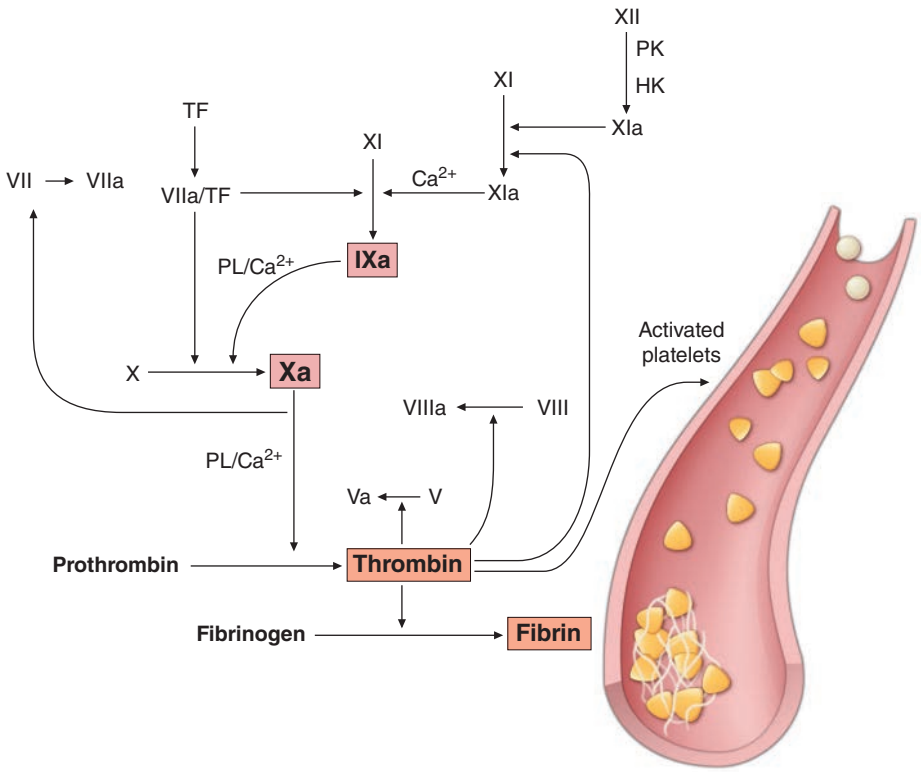

FIGURE 10–3. Summary of coagulation pathways. Specific coagulation factors ("a" indicates activated form) are responsible for the conversion of soluble plasma fibrinogen into insoluble fibrin. This process occurs via a series of linked reactions in which the enzymatically active product subsequently converts the downstream inactive protein into an active serine protease. The activation of thrombin leads to additional stimulation of platelets. (Ca^{2+}, Calcium; HK, high molecular weight kininogen; PK, prekallikrein; PL, phospholipid surface; TF, tissue factor.) (From Freedman JE, Loscalzo J. Arterial and venous thrombosis. In: Longo DL, Fauci AS, Kasper DL, et al., eds. Harrison's Principles of Internal Medicine, 18th ed. New York, NY: McGraw-Hill; 2012:985.)

Table 10–2

Clinical Model/Modified Wells Criteria for Evaluating the Pretest Probability of Deep Vein Thrombosis (DVT)

Clinical Characteristic	Score
Active cancer (cancer treatment within previous 6 months or currently on palliative treatment)	+1
Paralysis, paresis, or recent plaster immobilization of the lower extremities	+1
Recently bedridden for 3 days or more, or major surgery within the previous 12 weeks requiring general or regional anesthesia	+1
Localized tenderness along the distribution of the deep venous system	+1
Entire leg swollen	+1
Calf swelling at least 3 cm larger than that on the asymptomatic side (measured 10 cm below tibial tuberosity)	+1
Pitting edema confined to the symptomatic leg	+1
Collateral superficial veins (nonvaricose)	+1
Previously documented DVT	+1
Alternative diagnosis at least as likely as DVT	–2

Assess the patient for the presence of any of the 9 clinical characteristics listed above
Assign a score of "+1" for each characteristic that is present.
Tally the total score.
If an alternative diagnosis is at least as likely as DVT, then substract 2 points from the total points tallied above.
In patients with symptoms in both legs, the more symptomatic leg is used.

Risk Score Interpretation

Total Risk Score	Clinical Probability of DVT
0	Low
1	Moderate
2	Moderate
3 or higher	High

Clinical Presentation and Diagnosis of DVT

General

Most commonly develops in patients with identifiable risk factors (Table 10–1) during or following a hospitalization. Many patients have asymptomatic disease.

Symptoms

Patient may complain of persistent unilateral leg swelling, pain, warmth, and/or skin discoloration. Symptoms are nonspecific, and objective testing must be performed to establish the diagnosis.

Signs

- Superficial veins may be dilated and a "palpable cord" may be felt in the affected leg.
- May experience unilateral leg edema with measurable difference in leg circumference compared to the unaffected leg, erythema, increase in warmth, and tenderness with palpation of calf muscles.
- May experience pain in the popliteal or calf region in the affected leg when the examiner dorsiflexes the foot while the knee is flexed/slightly bent (Homans sign).
- Note: The physical examination signs can be unreliable. Homans sign can also be unreliable.

Clinical Probability

Apply the Wells criteria to determine the probability that the patient's signs, symptoms, and risk factors are the result of DVT (Table 10–2).

Laboratory Tests

- The initial laboratory evaluation should include complete blood count (CBC) with differential, coagulation studies (such as prothrombin time [PT]/international normalized ratio [INR], activated partial thromboplastin time [aPTT]), serum chemistries with renal and liver function, and urinalysis.
- Serum concentrations of D-dimer, a by-product of thrombin generation, will be elevated in an acute event. A negative D-dimer in a patient with low clinical probability of DVT can be used to rule out DVT.
- Patient may have an elevated erythrocyte sedimentation rate (ESR) and white blood cell (WBC) count.

Diagnostic Tests

- Duplex ultrasonography is the most commonly used test to diagnose DVT. It is a noninvasive test that can measure the rate and direction of blood flow and visualize clot formation in proximal veins of the legs. It cannot reliably detect small blood clots in distal veins. Coupled with a careful clinical assessment, it can confirm or rule out (exclude) the diagnosis in most cases. Repeat testing may be necessary if the first test is negative and the patient is still symptomatic.
- Venography (also known as phlebography) is the gold standard for the diagnosis of DVT. However, it is an invasive test that involves injection of radiopaque contrast dye into a foot vein. It is expensive and can cause anaphylaxis and nephrotoxicity.

LO 3

There are several risk assessment models available for estimating VTE risk specific to hospitalized medical and surgical patients.[5-7,12] While none of these models have been extensively validated, the Padua Prediction score is recommended for assessment of medical patients (Table 10–4) and the Caprini score is recommended for assessment of general surgical patients (Table 10–5). Bleeding risk should also be assessed to help identify patients in whom the risk of bleeding may outweigh benefits of pharmacologic prophylaxis.[5-7] Table 10–6 lists general and procedure-specific risk

Table 10–3

Clinical Model/Wells Criteria for Evaluating the Pretest Probability of Pulmonary Embolism (PE)

Clinical Characteristic	Score
Cancer	+1
Hemoptysis	+1
Previous PE or DVT	+1.5
Heart rate greater than 100 beats/min	+1.5
Recent surgery or immobilization	+1.5
Clinical signs of DVT	+3
Alternative diagnosis less likely than PE	+3

Risk Score Interpretation

Total Risk Score	Clinical Probability of PE
0–1	Low
2–6	Moderate
7 or higher	High

DVT, deep vein thrombosis.

Table 10–4

Risk Factors for Predicting Venous Thromboembolism (VTE) in Hospitalized Medical Patients (Padua Prediction Score)

Risk Factor	Points
Active cancer[a]	3
Previous VTE (with the exclusion of superficial vein thrombosis)	3
Reduced mobility[b]	3
Already known thrombophilic condition[c]	3
Recent (≤ 1 month) trauma and/or surgery	2
Elderly age (≥ 70 years)	1
Heart and/or respiratory failure	1
Acute myocardial infarction or ischemic stroke	1
Acute infection and/or rheumatologic disorder	1
Obesity (body mass index ≥ 30)	1
Ongoing hormonal treatment	1
Cumulative score of ≥ 4 points indicates high risk of VTE	

[a]Patients with local or distant metastases and/or in whom chemotherapy or radiotherapy had been performed in the previous 6 months.

[b]Anticipated bed rest with bathroom privileges (either because of patient's limitations or on physician's order) for at least 3 days.

[c]Carriage of defects of antithrombin, protein C or S, factor V Leiden, G20210A prothrombin mutation, antiphospholipid syndrome.

Adapted with permission from Kahn SR, Lim W, Dunn AS, et al. Prevention of VTE in nonsurgical patients: Antithrombotic Therapy and Prevention of Thrombosis, 9th ed: American College of Chest Physicians Evidence-Based Clinical Practice Guidelines. Chest. 2012;141(2 suppl):e195S–e226S.

Clinical Presentation and Diagnosis of PE

General

Most commonly develops in patients with risk factors for VTE (Table 10–1) during or following a hospitalization. Although many patients will have symptoms of DVT prior to developing a PE, many will not and some patients can be asymptomatic. Patients may die suddenly before effective treatment can be initiated.

Symptoms

- May complain of cough, pleuritic chest pain, chest tightness, shortness of breath with or without exertion, wheezing, orthopnea, or palpitations.
- May present with hemoptysis (spit or cough up blood).
- May complain of dizziness or experience syncope.
- May be misdiagnosed as a myocardial infarction (MI) or pneumonia, and objective testing must be performed to establish the diagnosis.

Signs

- May have tachypnea (increased respiratory rate) and tachycardia (increased heart rate).
- May appear diaphoretic (sweaty) and may have fever.
- Neck veins (external jugular veins) may be distended reflecting increased jugular venous pressure and increased heart pressure.
- The examiner may see use of accessory respiratory muscles and may hear diminished breath sounds, crackles, wheezes, or pleural friction rub during auscultation of the lungs. A parasternal lift or right ventricular S3, S4 may be found on the heart examination.
- In massive PE, the patient may appear cyanotic and hypotensive and may appear to have signs of right-sided heart failure. In such cases, oxygen saturation by pulse oximetry or arterial blood gas will likely indicate the patient is hypoxic.
- In the worst cases, the patient may go into circulatory shock and die within minutes.

Clinical Probability

Apply the Wells criteria to determine the probability that the patient's signs, symptoms, and risk factors are the result of PE (Table 10–3).

Laboratory Tests

- Serum concentrations of D-dimer, a by-product of thrombin generation, will be elevated. A negative D-dimer in a patient with low clinical probability of PE can be used to rule out PE.
- In patients with a low probability for PE, the PE rule-out criteria ("PERC rule") is an alternative to D-dimer testing. In patients who fulfill the following eight criteria the likelihood of PE is low and no further testing is required: age less than 50 years; heart rate less than 100 beats/min; oxyhemoglobin saturation at or above 95% (0.95); no hemoptysis; no estrogen use; no prior DVT or PE; no unilateral leg swelling; and no surgery/trauma requiring hospitalization within the prior 4 weeks.
- May have an elevated ESR and WBC count.
- May have elevated serum lactate dehydrogenase (LDH) or aspartate aminotransferase (AST; serum glutamic-oxaloacetic transaminase [SGOT]) with normal bilirubin.
- Serum troponin I and troponin T can be elevated in a large PE. These typically resolve within 40 hours if due to PE but persist longer after acute MI.
- Electrocardiogram may show nonspecific ST-segment and T-wave changes and tachycardia. Arterial blood gases may show acute respiratory alkalosis from hyperventilation.

Diagnostic Imaging Tests

- A computed tomography (CT) scan is the most commonly used test to diagnose PE, but some institutions still use a V/Q scan. Spiral CT scans can detect emboli in the pulmonary arteries. A V/Q scan measures the distribution of blood and air flow in the lungs. When there is a large mismatch between blood and air flow in one area of the lung, there is a high probability the patient has a PE.
- Pulmonary angiography is the gold standard for diagnosis of PE. However, it is an invasive test that involves injection of radiopaque contrast dye into the pulmonary artery. The test is expensive and associated with significant risk of mortality.

LO 4 factors for major bleeding complications. Patients with moderate to high risk of VTE should receive pharmacologic prophylaxis. If pharmacologic prophylaxis is contraindicated, such as in patients actively bleeding or at high risk of bleeding, nonpharmacologic prophylaxis should be used (Table 10–7).

Several pharmacologic and nonpharmacologic methods are effective for preventing VTE, and these can be used alone or in combination (Table 10–7).[5-7] Nonpharmacologic methods improve venous blood flow by mechanical means; drug therapy prevents thrombus formation by inhibiting the coagulation cascade.

Nonpharmacologic Therapy

LO 4 Ambulation as soon as possible following surgery lowers the incidence of VTE in low-risk patients.[5-7] Walking increases venous blood flow and promotes the flow of natural antithrombotic factors into the lower extremities. All hospitalized patients should be encouraged to ambulate as early as possible, and as frequently as possible.

Graduated compression stockings (GCS) are specialized hosiery that provide graduated pressure on the lower legs and feet to help prevent thrombosis. Compared with anticoagulant drugs, GCS are relatively inexpensive and safe; however, they are less effective and not recommended in moderate to higher risk patients.[2] They offer an alternate in low- to moderate-risk patients when pharmacologic interventions are contraindicated. When combined with pharmacologic interventions, GCS have an additive effect. However, some patients are unable to wear compression stockings because of the size or shape of their legs, and some patients may find them hot, confining, and very difficult to put on and remove.

LO 4 Similar to GCS, intermittent pneumatic compression (IPC) devices increase the velocity of blood flow in the lower extremities.[5-7] These devices sequentially inflate a series of

Table 10–5

Risk Factors for Predicting Venous Thromboembolism (VTE) in General Surgical Patients (Modified Caprini Risk Assessment Model for VTE in General Surgical Patients)

Risk Score			
1 Point	**2 Points**	**3 Points**	**5 Points**
Age 41–60 years	Age 61–74 years	Age ≥ 75 years	Stroke (< 1 month)
Minor surgery	Arthroscopic surgery	History of VTE	Elective arthroplasty
BMI > 25 kg/m^2	Major open surgery (> 45 minutes)	Family history of VTE	Acute spinal cord injury (< 1 month)
Swollen legs	Laparoscopic surgery (> 45 minutes)	Factor V Leiden	
Varicose veins	Malignancy	Prothrombin 20210A	
Pregnancy or postpartum	Confined to bed (> 72 hours)	Lupus anticoagulant	
History of unexplained or recurrent spontaneous abortion	Immobilizing plaster cast	Anticardiolipin antibodies	
Oral contraceptives or hormone replacement	Central venous access	Elevated serum homocysteine	
Sepsis (< 1 month)		Heparin-induced thrombocytopenia	
Serious lung disease, including pneumonia (< 1 month)		Other congenital or acquired thrombophilia	
Abnormal pulmonary function			
Acute myocardial infarction			
Heart failure (< 1 month)			
History of inflammatory bowel disease			
Medical patient at bed rest			

Risk Score Interpretation	
Total Risk Score	**Risk of VTE**
0	Very low (< 0.5%)
1–2	Low (1.5%)
3–4	Moderate (3%)
≥ 5	High (6%)

BMI, body mass index.

Table 10–6

Risk Factors for Major Bleeding Complications

General Risk Factors	Procedure-Specific Risk Factors	Procedures in Which Bleeding Complications May Have Especially Severe Consequences
Active bleeding	**Abdominal Surgery**	Craniotomy
Previous major bleeding	Male sex, preoperative hemoglobin level < 13 g/dL (130 g/L; 8.07 mmol/L), malignancy, and complex surgery defined as two or more procedures, difficult dissection, or more than one anastomosis	Spinal surgery
Known, untreated bleeding disorder	**Pancreaticoduodenectomy**	Spinal trauma
Severe renal or hepatic failure	Sepsis, pancreatic leak, sentinel bleed	Reconstructive procedures involving free flap
Thrombocytopenia	**Hepatic Resection**	
Acute stroke	Number of segments, concomitant extrahepatic organ resection, primary liver malignancy, lower preoperative hemoglobin level, and platelet counts	
Uncontrolled systemic hypertension	**Cardiac Surgery**	
Lumbar puncture, epidural, or spinal anesthesia within previous 4 hours or next 12 hours	Use of aspirin, use of clopidogrel within 3 days before surgery	
Concomitant use of anticoagulants, antiplatelet therapy, or thrombolytic drugs	BMI > 25 kg/m^2, nonelective surgery, placement of five or more grafts, older age, renal insufficiency, operation other than CABG, longer bypass time	
	Thoracic Surgery	
	Pneumonectomy or extended resection	

BMI, body mass index; CABG, coronary artery bypass graft.

Table 10–7

Thrombosis Risk Classification and Recommended Venous Thromboembolism Prevention Strategies[5-7]

Indication and Level of Risk	Prevention Strategies
Hospitalized Medical Patients	
Low thrombosis risk	Early ambulation
High thrombosis risk[a] (Padua Score > 4)	LMWH, LDUH, fondaparinux, betrixaban
Critically Ill Patients	
High thrombosis risk[a]	LMWH, LDUH
General Surgical Patients	
Very low thrombosis risk (Caprini Score 0)	Early ambulation
Low thrombosis risk (Caprini Score 1–2)	IPC
Moderate thrombosis risk[b] (Caprini Score 3–4)	LMWH, LDUH, IPC
High thrombosis risk[b] (Caprini Score ≥ 5)	LMWH, LDUH, plus GCS or IPC
Cancer Surgery	LMWH
Major Orthopedic Surgery	
Hip fracture surgery[b]	LMWH, fondaparinux, LDUH, adjusted dose warfarin, aspirin
Hip and knee arthroplasty[b]	LMWH, fondaparinux, LDUH, warfarin, aspirin, apixaban, dabigatran, rivaroxaban

[a]Mechanical methods of prophylaxis with IPC or GCS should be used in patients actively bleeding or those at high risk of bleeding complications (see Table 10–6 for risk factors for major bleeding).

[b]Mechanical methods of prophylaxis with IPC should be used in patients actively bleeding or those at high risk of bleeding complications (see Table 10–6 for risk factors for major bleeding).

GCS, graduated compression stockings; IPC, intermittent pneumatic compression; LDUH, low-dose unfractionated heparin; LMWH, low molecular weight heparin.

cuffs wrapped around the patient's legs from the ankles to the thighs and then deflate in 1- to 2-minute cycles. Although IPC has been shown to reduce the risk of VTE in surgical patients, most studies failed to define the type of device used. IPC was frequently used in combination with other prophylaxis methods, making it difficult to quantify their efficacy. Although IPC is safe to use in patients who have contraindications to pharmacologic therapies, it does have a few drawbacks: it is more expensive than GCS, it is a relatively cumbersome technique, some patients may have difficulty sleeping while using it, and some patients find the devices hot and uncomfortable. To be effective, IPC needs to be used throughout the day. In practice, this is difficult to achieve, and special efforts should be made to ensure the devices are worn and operational for most of the day.

Inferior vena cava (IVC) filters, also known as Greenfield filters, provide short-term protection against PE in very high-risk patients by preventing the **embolization** of a thrombus formed in the lower extremities into the pulmonary circulation.[5-7] Insertion of a filter into the IVC is a minimally invasive procedure. Despite the widespread use of IVC filters, there are very limited data regarding their effectiveness and long-term safety. The evidence suggests that IVC filters, particularly in the absence of effective antithrombotic therapy, are thrombogenic themselves and increase the long-term risk of recurrent DVT and of filter thrombosis. Although IVC filters can reduce the short-term risk of PE in patients at highest risk, they should be reserved for patients in whom other prophylactic strategies cannot be used. To further reduce the long-term risk of VTE in association with IVC filters, pharmacologic prophylaxis is necessary in patients with IVC filters in place, and warfarin therapy should begin as soon as the patient is able to tolerate it.[2] If used, retrievable filters are preferred, which can be removed once pharmacologic prophylaxis can be safely administered or once the patient is no longer at risk for VTE.

Pharmacologic Therapy

Appropriately selected drug therapies can dramatically reduce the incidence of VTE in medical and surgical patients (Table 10–7). The choice of medication and dose to use for VTE prevention must be based on the patient's level of risk for thrombosis and bleeding risk, as well as the cost and availability of an adequate drug therapy monitoring system.[5-7]

LO 4 The most extensively studied drugs for the prevention of VTE are unfractionated heparin (UFH), the low molecular weight heparins (LMWHs; dalteparin and enoxaparin), fondaparinux, and warfarin.[5-7] Generally the LMWHs provide improved protection against VTE when compared with low-dose UFH in most medical and surgical patients and when compared to low-dose UFH and warfarin in major orthopedic surgery patients. Fondaparinux is more effective than LMWH in patients undergoing high-risk orthopedic surgery, but it has a heightened risk of bleeding.

For hospitalized general surgical and medical patients, the available evidence supports the use of UFH 5000 Units subcutaneously (SC) every 8–12 hours, enoxaparin 40 mg SC daily, dalteparin 2500–5000 Units SC daily, or fondaparinux 2.5 mg SC daily. Betrixaban is also approved for extended VTE prophylaxis in hospitalized adult patients with acute medical illnesses and was found noninferior to prophylactic-dose enoxaparin with no differences in major bleeding. Betrixaban is given as an initial 160 mg dose followed by 80 mg daily, with the dose halved in the setting of severe renal impairment (creatinine clearance [CrCl] 15–30 mL/min [0.25–0.5 mL/s]) or concomitant use of P-glycoprotein (P-gp) inhibitors.[28]

LO 4 For the prevention of VTE following major orthopedic surgery, current evidence supports the use of UFH, LMWH, fondaparinux, adjusted dose warfarin, aspirin, and the direct oral anticoagulants (DOACs; apixaban, dabigatran, and rivaroxaban). The role of aspirin for VTE prevention is controversial as it produces a very modest reduction in VTE following orthopedic surgeries of the lower extremities.[5]

The effectiveness of UFH, aspirin, and warfarin is lower than LMWH and long-term safety data are lacking for apixaban, dabigatran, and rivaroxaban; thus the American College of Chest Physicians (ACCP) guidelines recommend the use of LMWH or fondaparinux preferentially over other pharmacologic options in major orthopedic surgery patients.[5] The appropriate prophylactic dose for each LMWH product in orthopedic surgery is indication specific; however, enoxaparin 30 mg SC twice daily or 40 mg SC daily, and dalteparin 5000 Units SC daily are the most commonly used regimens. The dose of fondaparinux is 2.5 mg SC daily.

The dose of warfarin, another commonly used option for prevention of VTE following orthopedic surgery, must be adjusted to maintain an INR between 2 and 3.[5] Oral administration and low drug acquisition cost give warfarin some advantages over the LMWHs and fondaparinux. However, warfarin does not achieve its full antithrombotic effect for several days and requires

Patient Encounter 1

An 80-year-old obese woman (BMI 42 kg/m^2) with a history of PE and ulcerative colitis is admitted to the hospital with severe abdominal pain, fever, fatigue, and diarrhea. She is diagnosed with peritonitis and started on antibiotic therapy.

PMH: PE 10 years ago; ulcerative colitis × 10 years; depression × 5 years; chronic hip pain × 3 years; hypertension × 3 years.

FH: Father died at 55 years due to MI; mother died at 74 years due to breast cancer.

SH: Occasional alcohol use. Employed in county government. Lives at home with spouse and pets.

Home Meds: Aspirin 81 mg by mouth once daily; atenolol 100 mg by mouth once daily; paroxetine 20 mg by mouth once daily.

Allergies: NKDA

VS: BP 135/70 mm Hg, HR 72 beats/min, RR 16 breaths/min, T 38.7°C (101.7°F), Wt 90 kg (198 lb).

Labs: WBC 22.4 × 10^3/mm^3 (22.4 × 10^9/L); estimated glomerular filtration rate (eGFR) 80 mL/min/1.73 m^2; CrCl 78 mL/min (1.30 mL/s).

Hospital Treatment: Nothing by mouth; metronidazole 500 mg IV every 8 hours; ceftriaxone 1 gm IV every 24 hours.

Which risk factor(s) predispose this patient to VTE?

What is her estimated risk for developing VTE?

Given her presentation and history, create an appropriate VTE prophylaxis plan including the pharmacologic agent, dose, route and frequency of administration, duration of therapy, and monitoring parameters.

frequent monitoring and periodic dosage adjustments, making therapy cumbersome. Warfarin should only be used when a systematic patient monitoring system is available.

LO 4

The oral factor Xa inhibitors rivaroxaban and apixaban are also options for VTE prevention following hip and knee replacement surgery and offer a convenient alternative to traditional anticoagulants.[5,29,30] Both agents have shown superior efficacy compared to LMWH with a similar rate of bleeding complications. Rivaroxaban is given at a fixed dose of 10 mg once daily, and apixaban is given at a fixed dose of 2.5 mg twice daily. Both are given without the need for routine laboratory monitoring and dosing adjustments (as with warfarin) and without the inconvenience of administration by injection (as with LMWH and fondaparinux).

The oral direct thrombin inhibitor (DTI) dabigatran is another option for VTE prevention following orthopedic surgery, but is only approved for use following hip replacement surgery. Dabigatran is given as an initial 110 mg dose, followed by 220 mg once daily. Dabigatran should not be used in those with CrCl less than 30 mL/min (0.50 mL/s) or concomitantly with P-gp inhibitors.

The optimal duration for VTE prophylaxis is not well established but should be given throughout the period of risk. For patients who have undergone total knee replacement, total hip replacement, or hip fracture repair, prophylaxis is recommended for a minimum of 10 to 14 days; however, extending it up to 35 days is recommended due to continued VTE risk up to 1 month postsurgery.[5-7]

TREATMENT

Desired Therapeutic Outcomes

The goal of VTE treatment is to prevent short- and long-term complications of the disease. The aim of initial therapy is to prevent propagation or local extension of the clot, embolization, hemodynamic collapse, and death. The goal of long-term and extended therapy is to prevent complications such as PTS, pulmonary hypertension, and recurrent VTE.[2,12]

General Treatment Principles

Anticoagulant drugs are considered the mainstay of therapy for patients with VTE, and the therapeutic strategies for DVT and PE are similar.[2,12] Management decisions are guided by balancing the risks and benefits of various treatment options. The treatment of VTE can be divided into three phases: acute (first 5–10 days), long term (first 3 months), and extended (beyond 3 months).[12] The acute treatment phase of VTE is typically accomplished by administering a fast-acting parenteral or a DOAC (Table 10–8). The long-term and extended phase treatments of VTE are usually accomplished using oral anticoagulant agents such as warfarin, or one of the DOACs (apixaban, dabigatran, edoxaban, and rivaroxaban).[2,12] In certain populations, such as patients with cancer and women who are pregnant, the LMWHs are the preferred agents during long-term and extended treatment phases due to better safety or efficacy.[2] The etiology of VTE will guide the duration of therapy. VTE can be provoked (by transient risk factors), unprovoked (or idiopathic), and cancer associated. Patients with unprovoked or cancer-associated VTE have a significantly higher risk of recurrence compared to patients with provoked VTE.[2,12]

KEY CONCEPT In the absence of contraindications, the treatment of VTE should initially include a rapid-acting injectable anticoagulant (eg, UFH, LMWH, fondaparinux) or a rapidly acting DOAC (eg, apixaban, rivaroxaban). If warfarin is used for oral anticoagulation, it should be initiated on the same day as the parenteral anticoagulant, and the parenteral agent should be overlapped for a minimum of 5 days and until the INR is greater than or equal to 2 for at least 24 hours. If dabigatran or edoxaban are used for oral anticoagulation, they should be initiated after 5 to 10 days of initial treatment with a parenteral anticoagulant. Anticoagulation therapy should be continued for a minimum of 3 months. However, the duration of anticoagulation therapy should be based on the patient's risk of VTE recurrence and major bleeding.[2,12]

Pharmacologic Therapy

▶ *Thrombolytics*

The role of thrombolysis in the treatment of VTE is controversial.[2,12,31] Compared with anticoagulants, thrombolytics restore venous patency more quickly; however, the bleeding risk associated with their use is significantly higher. In patients with DVT, thrombolytics decrease short-term pain and swelling and prevent destruction of the venous valves. While they may decrease the incidence and severity of PTS, clinical trials have failed to show reduction in recurrent DVT, PE, or death;[31] therefore, their use in most patients is not recommended.[2,12] In a select group of high-risk patients with massive iliofemoral DVT who are at risk of venous gangrene and limb loss, thrombolysis may be considered. See Table 10–9.

In patients with acute PE, the use of thrombolytics provides short-term benefits such as restoring pulmonary artery patency and hemodynamic stability.[2,12,31] However, systemic thrombolysis does not reduce mortality and is associated with a greater risk

Table 10–8

Pharmacologic Options for the Acute Phase Treatment of Venous Thromboembolism

Parenteral Anticoagulants

UFH

IV administration:[a] use weight-based dosing nomogram (Table 10–10)
Or
SC administration: 17,500 units (250 units/kg) given every 12 hours (an initial 5000 unit IV bolus dose is recommended to obtain rapid anticoagulation)
Adjust subsequent doses to attain a goal aPTT based on the institution-specific therapeutic range
Or
SC administration: 333 units/kg followed by 250 units/kg given every 12 hours (fixed-dose unmonitored dosing regimen)

LMWHs

Dalteparin: 200 units/kg SC once daily *or* 100 units/kg SC twice daily
Enoxaparin: 1.5 mg/kg SC once daily *or* 1 mg/kg SC twice daily; if CrCl < 30 mL/min (0.50 mL/s): 1 mg/kg SC once daily

Factor Xa Inhibitor

Fondaparinux[b]:
For body weight ≤ 50 kg (110 lb), use 5 mg SC once daily
For body weight 50–100 kg (110–220 lb), use 7.5 mg SC once daily
For body weight ≥ 100 kg (220 lb), use 10 mg SC once daily

Direct Oral Anticoagulants

Apixaban: 10 mg PO twice daily for the initial 7 days, then 5 mg PO twice daily[c]
Dabigatran: 150 mg PO twice daily after 5–10 days of parenteral anticoagulation[d]
Edoxaban: 60 mg PO once daily or 30 mg[e] PO once daily after 5–10 days of parenteral anticoagulation
Rivaroxaban: 15 mg PO twice daily for the initial 21 days, then 20 mg PO daily[d]

[a]IV administration preferred due to improved dosing precision.

[b]Contraindicated in patients with CrCl < 30 mL/min (0.50 mL/s).

[c]After the initial 6 months of therapy, the dose is reduced to 2.5 mg PO twice daily.

[d]Avoid in patients with CrCl < 30 mL/min (0.50 mL/s).

[e]Reduced dose for CrCl 15–50 mL/min (0.25–0.83 mL/s), body weight ≤ 60 kg (132 lb), or concomitant use of P-glycoprotein inhibitors.

aPTT, activated partial thromboplastin time; CrCl, creatinine clearance; IV, intravenous; LMWHs, low molecular weight heparins; SC, subcutaneous; UFH, unfractionated heparin.

of major bleeding.[12] Given the relative lack of data to support their routine use, thrombolytics should be reserved for select high-risk circumstances. Candidates for thrombolytic therapy are patients with acute massive **embolism** who are hemodynamically unstable (systolic blood pressure [SBP] < 90 mm Hg) and at low risk for bleeding. Current guidelines recommend a short infusion time (2 hours) over a prolonged infusion time (24 hours) and administration through a peripheral vein over a pulmonary artery catheter.[2,12]

▶ *Unfractionated Heparin*

UFH has traditionally been the drug of choice for indications requiring a rapid anticoagulation including the acute treatment

Patient Encounter 2

A 62-year-old woman with a new diagnosis of ovarian cancer is admitted to the hospital for debulking surgery.

PMH: Depression × 19 years; history of hip fracture 3 years ago with subsequent lower left extremity DVT, treated with LMWH and warfarin for 3 months.

FH: Brother 55 years old with type 2 diabetes; maternal grandmother died at 65 years due to breast cancer.

SH: Smoked half a pack per day for 25 years, quit 15 years ago; occasional alcohol use. Lives alone and expects to be discharged to a rehabilitation facility postoperatively before returning home.

Home Meds: Sertraline 100 mg by mouth daily; oxycodone 5–10 mg by mouth every 5 hours as needed for pain; St. John's Wort 2 capsules daily.

Allergies: NKDA

VS: BP 110/60 mm Hg, HR 55 beats/min, RR 18 breaths/min, T 37.0°C (98.6°F), Wt 127 kg (280 lb), BMI 41 kg/m^2.

Labs: All withinnormal limits; eGFR 96 mL/min/1.73 m^2; CrCl 94 mL/min (1.57 mL/s).

Which risk factor(s) predispose this patient to VTE?

How should postoperative VTE be prevented?

How long should she receive VTE prophylaxis?

What education about VTE prophylaxis should she receive?

of VTE. Unlike thrombolytics, UFH and other anticoagulants will not dissolve a formed clot but prevent its propagation and growth.[2,9] Heparin exerts its anticoagulant effect by augmenting the natural anticoagulant, AT. See **Figure 10–4**.

UFH can be administered via the intravenous (IV) or subcutaneous (SC) route.[2,9] See Table 10–8. When rapid anticoagulation is required, UFH should be administered IV and an initial bolus dose should be given. For the treatment of VTE, UFH is generally given as a continuous IV infusion. The half-life of UFH is dose dependent and ranges from 30 to 90 minutes but may be significantly longer, up to 150 minutes, with high doses. UFH is eliminated by two mechanisms: (a) enzymatic degradation via a saturable zero-order process, and (b) renally via a first-order process. Lower UFH doses are primarily cleared via enzymatic processes, whereas higher doses are primarily renally eliminated. Clearance of UFH can be impaired in patients with renal and hepatic dysfunction. Patients with active thrombosis may require higher UFH doses due to a more rapid elimination or variations in the plasma concentrations of heparin-binding proteins.

Certain patient-specific situations may require UFH higher doses to achieve a therapeutic anticoagulant effect. AT deficiency and elevated factor VIII levels are common in pregnant patients. AT deficiency has been linked to higher UFH dose requirements. The requirement of these higher UFH doses is termed *heparin resistance*. Factor VIII elevations can result in altered activated partial thromboplastin time (aPTT) response to UFH, and monitoring with antifactor Xa levels is recommended.[2,9,10]

The dose of UFH required to achieve a therapeutic anticoagulant response is correlated to the patient's weight.[2,9] Weight-based

Table 10–9

Thrombolysis for the Treatment of Venous Thromboembolism

- Thrombolytic therapy should be reserved for patients who present with PE with shock, hypotension, or massive DVT with limb gangrene
- Diagnosis must be objectively confirmed before initiating thrombolytic therapy
- Thrombolytic therapy is most effective when administered as soon as possible after PE diagnosis, but benefit may extend up to 14 days after symptom onset

FDA-Approved PE Thrombolytic Regimens

- Streptokinase 250,000 units IV bolus over 30 minutes followed by 100,000 units/hour for 12–24 hours[a]
- Urokinase 4400 units/kg IV bolus over 10 minutes followed by 4400 units/kg/hour for 12–24 hours[a]
- Alteplase (rt-PA) 100 mg IV over 2 hours

Non-FDA Approved Thrombolytic Regimens

- Reteplase two 10-unit IV boluses given 30 minutes apart
- Tenecteplase weight-adjusted IV bolus over 5 seconds (30–50 mg with a 5-mg step every 10 kg from < 60 to > 90 kg)

- Factors that increase the risk of bleeding must be evaluated before thrombolytic therapy is initiated (ie, recent surgery, trauma or internal bleeding, uncontrolled hypertension, recent stroke, or intracranial hemorrhage)
- Baseline labs should include CBC and blood typing in case transfusion is needed
- IV UFH should not be used during IV thrombolytic therapy. Neither the aPTT nor any other anticoagulation parameter should be monitored during the thrombolytic infusion
- aPTT should be measured following the completion of thrombolytic therapy:
  - If aPTT < 2.5 times the control value, UFH infusion should be started and adjusted to maintain aPTT in therapeutic range
  - If aPTT > 2.5 times the control value, remeasure every 2–4 hours and start UFH infusion when aPTT is < 2.5
- Avoid phlebotomy, arterial puncture, and other invasive procedures during thrombolytic therapy to minimize the risk of bleeding

[a]Two-hour infusions of streptokinase and urokinase are as effective and safe as alteplase; 2-hour infusion times are preferred over longer infusion times.

aPTT, activated partial thromboplastin time; CBC, complete blood count; DVT, deep vein thrombosis; FDA, Food and Drug Administration; IV, intravenous; PE, pulmonary embolism; rt-PA, recombinant tissue plasminogen activator; UFH, unfractionated heparin.

dosing regimens should be used to exceed the therapeutic threshold in the first 24 hours after initiating treatment.[9,10] Achieving a therapeutic aPTT in the first 24 hours after initiating UFH is critical because it has been shown to lower the risk of recurrent VTE. For nonobese patients, the actual body weight should be used to calculate the initial UFH dose (Table 10–10). For obese patients, using the actual body weight to calculate the initial dose is also generally recommended; however, data are limited in morbidly obese patients, that is, weight more than 150 kg (330 lb). Some experts recommend using an adjusted body weight (ABW) in these patients instead. The infusion rate is then adjusted based on laboratory monitoring of the patient's response.[9,10] (See Table 10–10.)

KEY CONCEPT Due to significant interpatient variability and changes in patient response over time, UFH requires close monitoring and periodic dose adjustment. The response to UFH can be monitored using a variety of laboratory tests including the aPTT, the whole blood clotting time, activated clotting time (ACT), antifactor Xa activity, and the plasma heparin concentration.[9,10] Although it has several limitations, the aPTT is the most widely used test in clinical practice to monitor UFH. Traditionally, therapeutic aPTT range is defined as 1.5 to 2.5 times the control aPTT value. However, due to variations in reagents and instruments used to measure the aPTT in different laboratories, each institution should establish a therapeutic range for UFH. The institution-specific therapy range should correlate with a plasma heparin concentration of 0.2 to 0.4 units/mL (kU/L) by protamine titration or 0.3 to 0.7 units/mL (kU/L) by an amidolytic antifactor Xa assay.[4,27] An aPTT should be obtained at baseline, 6 hours after initiating the heparin infusion, and 6 hours after each dose change because this is the time required to reach steady state. UFH dose is then adjusted based on the aPTT measurement and institutional-specific therapeutic range (Table 10–10). In patients with heparin resistance, antifactor Xa concentrations may be a more accurate method of monitoring the patient's response.[9,10]

LO 5

Side effects associated with UFH include bleeding, thrombocytopenia, hypersensitivity reactions, and with prolonged use, alopecia, hyperkalemia, and osteoporosis.[9,10]

KEY CONCEPT Bleeding is the most common adverse effect associated with antithrombotic drugs including UFH therapy.[8] A patient's risk of major hemorrhage is related to the intensity and stability of therapy, age, concurrent drug use, history of gastrointestinal bleeding, risk of falls or trauma, and recent surgery. Several risk factors can increase the risk of UFH-induced bleeding (Table 10–11). The risk of bleeding is related to intensity of anticoagulation. Higher aPTT values are associated with an increased risk of bleeding. The risk of major bleeding is 1% to 5% during the first few days of treatment.[2,9,10] In addition to the aPTT, hemoglobin, hematocrit, and blood pressure should be monitored. Concurrent use of UFH with other antithrombotic agents, such as thrombolytics and antiplatelet agents, also increases bleeding risk. Patients receiving UFH therapy should be closely monitored for signs and symptoms of bleeding, including epistaxis, hemoptysis, hematuria, hematemesis, **hematochezia**, **melena**, severe headache, and joint pain. If major bleeding occurs, UFH should be stopped immediately and the source of bleeding treated.[9,10] If necessary, use protamine sulfate as an antidote to reverse the effects of UFH. The usual dose is 1 mg protamine sulfate per 100 units of UFH, up to a maximum of 50 mg, given as a slow IV infusion over 10 minutes. The effects of UFH are neutralized in 5 minutes, and the effects of protamine persist for 2 hours. If bleeding is not controlled or the anticoagulant effect rebounds, repeated doses of protamine may be administered.[9,10]

LO 6

Heparin-induced thrombocytopenia (HIT) is a very serious adverse effect associated with UFH use. Platelet counts should be monitored every 2 to 3 days throughout the course of UFH therapy.[9,10] HIT should be suspected if the platelet count drops by more than 50% from baseline or to below $150 \times 10^3/mm^3$ ($150 \times 10^9/L$). HIT should also be suspected if thrombosis occurs despite UFH use. Immediate discontinuation of all heparin-containing products including the use of LMWHs and heparin-based flushes is required. Alternative anticoagulation with parenteral DTIs should be initiated. In patients with contraindications to anticoagulation therapy, UFH should not be administered (Table 10–12).

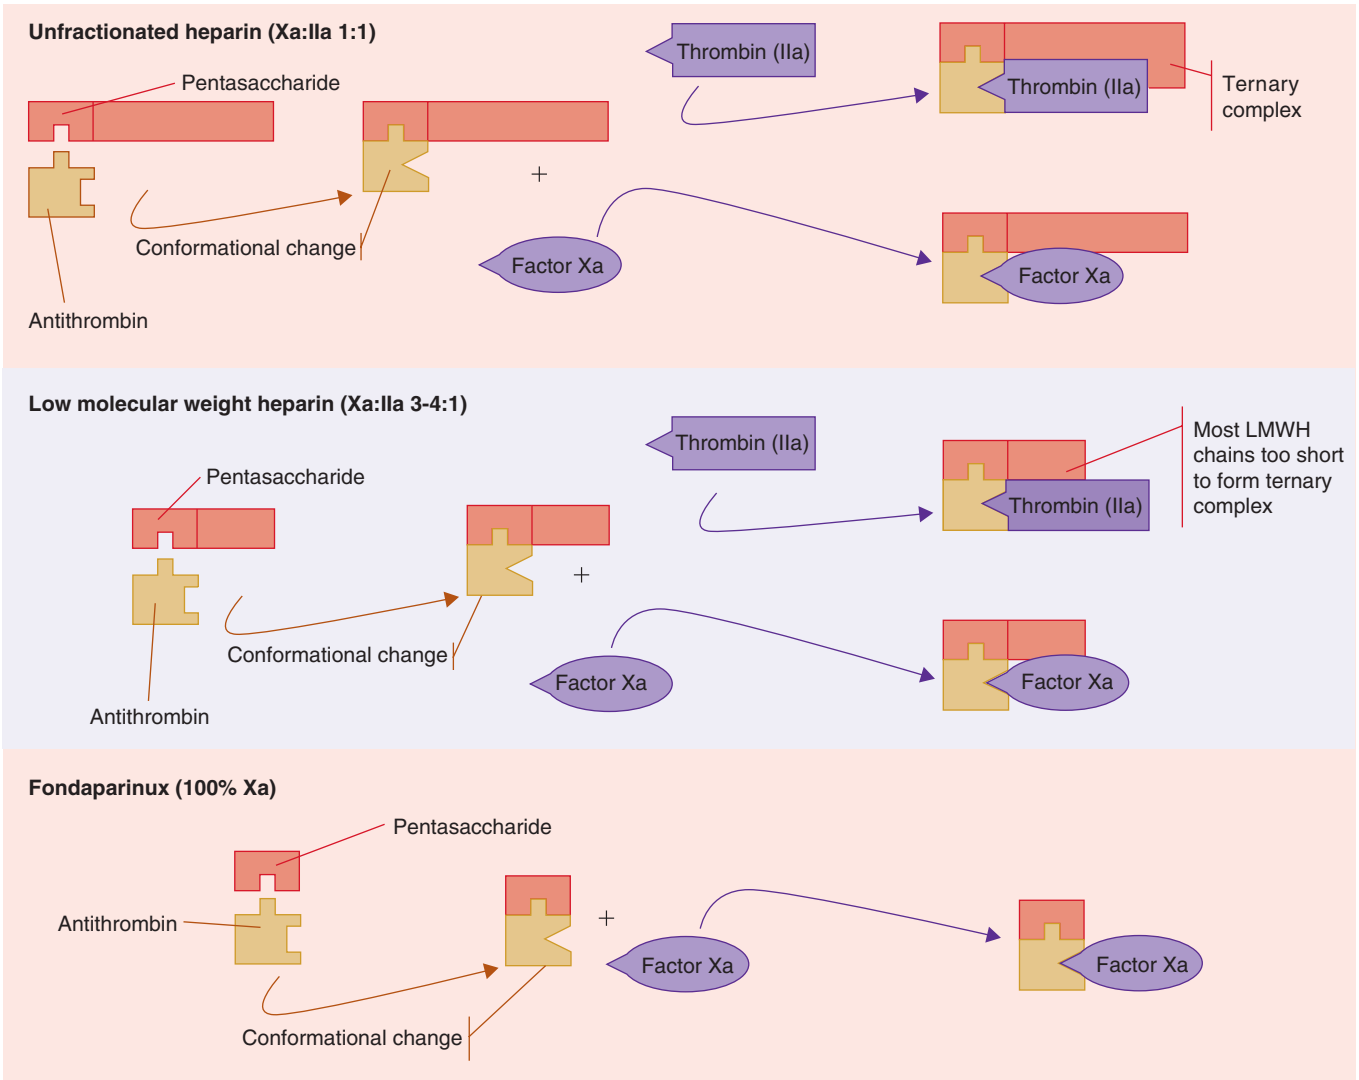

FIGURE 10–4. Mechanism of action of unfractionated heparin, low molecular weight heparin (LMWH), and fondaparinux. (From Witt DM, Clark NP. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014:266.)

UFH may be used to treat VTE during pregnancy. UFH should be used with caution in the peripartum period due to risk of maternal hemorrhage. UFH is not secreted into breast milk and is safe for use by women who wish to breastfeed.[2,9,10,20] For treatment of VTE in children, the UFH dose is 50 units/kg bolus followed by an infusion of 20,000 units/m^2 per 24 hours. Alternatively, a loading dose of 75 units/kg followed by an infusion of 28 units/kg/hour if younger than 12 months old and 20 units/kg/hour if older than 1 year may be considered.[32]

► *Low Molecular Weight Heparins*

LO 7

Compared with UFH, LMWHs have improved pharmacodynamic and pharmacokinetic properties.[9,10,12] They exhibit less binding to plasma and cellular proteins, resulting in a more predictable anticoagulant response. Consequently, routine monitoring of anticoagulation activity and dose adjustments are not required in most patients. LMWHs have longer plasma half-lives, allowing once- or twice-daily administration, improved SC bioavailability, and dose-independent renal clearance. In addition, LMWHs have a more favorable side-effect profile than UFH. They are also associated with a lower incidence of HIT and osteopenia. Two LMWHs are currently available in the United States: dalteparin and enoxaparin.

Like UFH, LMWHs prevent the propagation and growth of formed thrombi.[9] The anticoagulant effect is mediated through a specific pentasaccharide sequence that binds to AT. The primary difference in the pharmacologic activity of UFH and LMWH is their relative inhibition of thrombin (factor IIa) and factor Xa. Smaller heparin fragments (as in LMWHs) cannot bind AT and thrombin simultaneously (Figure 10–4). The SC bioavailability of the LMWHs is greater than 90%. Peak anticoagulant effect of the LMWHs is reached 3 to 5 hours after an SC dose. The elimination half-life is 3 to 6 hours and is agent specific. In patients with renal impairment, the half-life of LMWHs is prolonged.[9,10,12]

The dose of LMWHs for the treatment of VTE is determined based on the patient's weight and is administered SC once or twice daily (Table 10–8). Due to their predictable anticoagulant effect, routine monitoring is not necessary in most patients.[9] LMWHs have been evaluated in many randomized trials and

Table 10–10

Weight-Based[a] Dosing for UFH Administered by Continuous IV Infusion for Venous Thromboembolism

Initial Loading Dose	Initial Infusion Rate
80 units/kg (maximum = 10,000 units)	18 units/kg/hour (maximum = 2300 units/hour)
	Maintenance Infusion Rate
aPTT (seconds)	*Dose Adjustment*
< 37 (or < 12 seconds below institution-specific therapeutic range)	80 units/kg bolus then increase infusion by 4 units/kg/hour
37–47 (or 1–12 seconds below institution-specific therapeutic range)	40 units/kg bolus then increase infusion by 2 units/kg/hour
48–71 (within institution-specific therapeutic range)	No change
72–93 (or 1–22 seconds above institution-specific therapeutic range)	Decrease infusion by 2 units/kg/hour
> 93 (or > 22 seconds above institution-specific therapeutic range)	Hold infusion for 1 hour then decrease by 3 units/kg/hour

[a]Use actual body weight for all calculations. Adjusted body weight (ABW) may be used for morbidly obese patients (> 130% of ideal body weight [IBW]).

ABW = IBW + (Actual body weight – IBW) × 0.7

aPTT, activated partial thromboplastin time; IV, intravenous; UFH, unfractionated heparin.

have been shown to be at least as safe and effective as UFH for the treatment of VTE.[2,12] Indeed, the rate of mortality was lower in patients treated with an LMWH in clinical trials. This mortality benefit was primarily seen in patients with cancer.[33]

LO 5

Prior to initiating treatment with an LMWH, baseline laboratory tests should include PT/INR, aPTT, CBC, and serum creatinine (SCr). Monitor the CBC with platelet count every 3 to 5 days during the first 2 weeks of therapy, and every 2 to 4 weeks with extended use.[9,10] Use LMWHs cautiously in patients with renal impairment due to the potential of drug accumulation and risk of bleeding. Specific dosing recommendations for patients with a CrCl less than 30 mL/min (0.50 mL/s) are currently available for enoxaparin but are lacking for other LMWH agents (Table 10–8). Current guidelines recommend the use of UFH over LMWH in patients with severe renal dysfunction (CrCl < 30 mL/min [0.50 mL/s]).[2]

Table 10–11

Risk Factors for Major Bleeding While on Anticoagulation

- Increased anticoagulation intensity (eg, INR > 5, aPTT > 120 seconds)
- Initiation of therapy (first few days and weeks)
- Unstable anticoagulation response (eg, variable INR response)
- Age older than 65 years
- Concurrent antiplatelet drug use
- Concurrent NSAID or aspirin use
- History of gastrointestinal bleeding
- Recent surgery or trauma
- High risk for fall/trauma (eg, elderly, sedentary/bedbound, high risk medications)
- Heavy alcohol use
- Renal failure
- Cerebrovascular disease
- Active malignancy

aPTT, activated partial thromboplastin time; INR, international normalized ratio; NSAID, nonsteroidal anti-inflammatory drug.

Table 10–12

Contraindications to Anticoagulation Therapy

General
- Active bleeding
- Hemophilia or other hemorrhagic tendencies
- Severe liver disease with elevated baseline PT/INR
- Severe thrombocytopenia (platelet count < 20×10^3/mm^3 [20×10^9/L])
- Malignant hypertension
- Inability to meticulously supervise and monitor treatment

Drug-Specific Contraindications
- UFH
  - Hypersensitivity to UFH
  - History of HIT
- LMWHs
  - Hypersensitivity to LMWH, UFH, pork products, methylparaben, or propylparaben
  - History of HIT or suspected HIT
- Fondaparinux
  - Hypersensitivity to fondaparinux
  - Severe renal insufficiency (CrCl < 30 mL/min [0.50 mL/s])
  - Body weight < 50 kg (110 lb) for prophylaxis
  - Bacterial endocarditis
  - Thrombocytopenia with a positive in vitro test for antiplatelet antibodies in the presence of fondaparinux
- Lepirudin
  - Hypersensitivity to hirudins
- Argatroban
  - Hypersensitivity to argatroban
- Warfarin
  - Hypersensitivity to warfarin
  - Pregnancy
  - History of warfarin-induced skin necrosis
  - Inability to obtain follow-up PT/INR measurements
  - Inappropriate medication use or lifestyle behaviors
- Dabigatran
  - Mechanical prosthetic heart valves
  - Hypersensitivity to dabigatran
- Apixaban
  - Hypersensitivity to apixaban
- Rivaroxaban
  - Hypersensitivity to rivaroxaban

CrCl, creatinine clearance; HIT, heparin-induced thrombocytopenia; INR, international normalized ratio; LMWHs, low molecular weight heparins; PT, prothrombin time; UFH, unfractionated heparin.

KEY CONCEPT Most patients with an uncomplicated DVT and PE can be managed safely at home.[2] LMWHs can be easily administered in the outpatient setting, thus enabling the treatment of VTE at home. Several large clinical trials have demonstrated the efficacy and safety of LMWHs for outpatient treatment of DVT and PE, and this approach is commonly utilized in clinical practice.[2,33] Patients with DVT with normal vital signs, low bleeding risk, no other comorbid conditions requiring hospitalization, and who are stable may have anticoagulant initiated at home. Although the treatment of patients with PE

in the outpatient setting is more controversial, patients with submassive PE who are hemodynamically stable can be safely treated in the outpatient setting as well.[12] Patients considered for outpatient therapy must be reliable or have adequate caregiver support and must be able to strictly adhere to the prescribed treatment regimen and recommended follow-up visits. Close patient follow-up is critical to the success of any outpatient DVT treatment program. Home DVT treatment results in cost savings and improved patient satisfaction and quality of life.[2,12,33]

LO 5 Laboratory methods of measuring a patient's response to LMWH may be warranted in certain situations.[9,34] Although controversial, measurement of antifactor Xa activity has been the most widely used method in clinical practice. Monitoring of antifactor Xa activity may be considered in adult patients who are morbidly obese (weight > 150 kg [330 lb] or body mass index [BMI] > 50 kg/m^2), weigh less than 50 kg (110 lb), or have significant renal impairment (CrCl < 30 mL/min [0.50 mL/s]). Laboratory monitoring may also be useful in children, and pregnant women and those on long-term therapy.[34]

As with UFH, bleeding is the major complication associated with LMWHs. The incidence of major bleeding reported in clinical trials is less than 3%.[8,9] Minor bleeding, especially bruising at the injection site, occurs frequently. Protamine sulfate will partially reverse the anticoagulant effects of the LMWHs and should be administered in the event of major bleeding. Due to its limited binding to LMWH chains, protamine only neutralizes 60% of their antithrombotic activity. If the LMWH was administered within the previous 8 hours, give 1 mg protamine sulfate per 1 mg of enoxaparin or 100 antifactor Xa units of dalteparin. If bleeding is not controlled, give another 0.5 mg of protamine sulfate for every antifactor Xa 100 units of LMWH. Give smaller protamine doses if more than 8 hours have lapsed since the last LMWH dose.

The incidence of HIT is lower with LMWHs than with UFH.[9,10] However, LMWHs cross-react with heparin antibodies in vitro and should not be given as an alternative anticoagulant in patients with a diagnosis or history of HIT. Monitor platelet counts every few days during the first 2 weeks and periodically thereafter.

In patients undergoing spinal and epidural anesthesia or spinal puncture, spinal and epidural hematomas have been linked to the use of LMWHs. In patients with in-dwelling epidural catheters, concurrent use of LMWHs and all other agents that impact hemostasis should be avoided. When inserting and removing the in-dwelling epidural catheters, the timing of LMWH administration around catheter manipulation should be carefully coordinated. Catheter manipulation should only occur at minimal or trough anticoagulant levels.[9,10]

LMWHs are an excellent alternative to UFH for the treatment of VTE in pregnant women.[9,20] The LMWHs do not cross the placenta. Because the pharmacokinetics of LMWHs may change during pregnancy, monitoring of antifactor Xa activity every 4 to 6 weeks to make dose adjustments is recommended.[34] LMWHs have also been used to treat VTE in pediatric patients. Children younger than 1 year require higher doses (eg, enoxaparin 1.5 mg/kg SC every 12 hours). Monitor antifactor Xa activity to guide dosing in children.[32]

LO 5

LO 5

▶ *Factor Xa Inhibitors*

Parenteral Fondaparinux is an indirect inhibitor of factor Xa and exerts its anticoagulant activity by accelerating AT.[9,35,36] Due to its small size, fondaparinux exerts inhibitory activity specifically against factor Xa and has no effect on thrombin (Figure 10–4). After SC administration, fondaparinux is completely absorbed, and peak plasma concentrations are reached within 2 to 3 hours.[9,35,36] It has a half-life of 17 to 21 hours, permitting once-daily administration, but the anticoagulant effects of fondaparinux will persist for 2 to 4 days after stopping the drug. In patients with renal impairment, the anticoagulant effect persists even longer. Fondaparinux does not require routine coagulation monitoring or dose adjustments.

LO 5

Fondaparinux is not metabolized in the liver and therefore has few drug interactions.[9,35,36] However, concurrent use with other antithrombotic agents increases the risk of bleeding. Unlike the heparins, factor Xa inhibitors do not affect platelet function and do not react with the heparin platelet factor (PF)-4 antibodies seen in patients with HIT. Thus, they have a theoretical role in treatment and prevention of HIT. A few small observational studies report fondaparinux use in the management of patients with HIT. Based on these data some centers use fondaparinux in patients with subacute HIT or a history of HIT who require anticoagulation therapy.[9,35,36]

Fondaparinux is as safe and effective as IV UFH for the treatment of PE and SC LMWH for the treatment of DVT.[9,35,36] The recommended dose for fondaparinux in the treatment of VTE is based on the patient's weight (Table 10–8). Fondaparinux is renally eliminated, and accumulation can occur in patients with renal dysfunction. Due to the lack of specific dosing guidelines, fondaparinux is contraindicated in patients with severe renal impairment (CrCl < 30 mL/min [0.50 mL/s]). Baseline renal function should be measured and monitored closely throughout therapy. Based on limited data at this time, monitoring antifactor Xa activity to guide fondaparinux dosing is not recommended.[9,35,36]

LO 5

As with other anticoagulants, the major side effect associated with fondaparinux is bleeding. Fondaparinux should be used with caution in elderly patients because their risk of bleeding is higher. Patients receiving fondaparinux should be carefully monitored for signs and symptoms of bleeding. A CBC should be obtained at baseline and monitored periodically to detect the possibility of occult bleeding. In the event of major bleeding, fresh-frozen plasma and factor concentrates should be given. Fondaparinux is not reversed by protamine.[9,35,36]

LO 5

There are very limited data regarding the use of fondaparinux during pregnancy and its use in pediatric patients has not been studied.[35]

Oral Apixaban, rivaroxaban, edoxaban, and betrixaban are direct inhibitors of factor Xa, part of a newer generation of oral anticoagulants also referred to as direct oral anticoagulants (DOACs).[29,30,36,37] Apixaban and rivaroxaban have been evaluated and approved by the Food and Drug Administration (FDA) for the treatment of VTE (DVT and PE) and reduction in the risk of recurrence of DVT and PE. Edoxaban is also approved for VTE treatment. Rivaroxaban had similar efficacy and safety when compared to traditional therapy with LMWH and a vitamin K antagonist in the treatment of patients with VTE. Apixaban was noninferior in preventing recurrent VTE or VTE-related death but resulted in lower major bleeding events when compared to LMWH and warfarin therapy. Therefore, both agents can be used as monotherapy without parenteral anticoagulation overlap, allowing for a single oral regimen approach in the treatment and prevention of recurrent VTE. Edoxaban was noninferior to warfarin in recurrent VTE and associated with less major or clinically relevant nonmajor bleeding. Unlike the other oral factor Xa inhibitors, edoxaban is initiated after completing 5 to 10 days of initial treatment with a parenteral anticoagulant. See Table 10–13.

Table 10–13

Dosing of the Direct Oral Anticoagulants in the Treatment of Venous Thromboembolism (VTE)

	Dabigatran	Rivaroxaban	Apixaban	Edoxaban
Acute VTE	150 mg BID after 5–10 days of parenteral anticoagulation	15 mg BID × 3 weeks then 20 mg once daily with food	10 mg BID for 7 days, then 5 mg BID	60 mg once daily
Prevention of VTE recurrence	150 mg BID	20 mg once daily with food	2.5 mg BID	n/a
Dosage adjustments and/or thresholds for avoidance	Any P-gp *inducer*: avoid concurrent use Any P-gp *inhibitor* with CrCl < 50 mL/min (0.83 mL/s): avoid concurrent use CrCl < 30 mL/min (0.50 mL/s): avoid use	CrCl 30–50 mL/min (0.50–0.83 mL/s): use with caution CrCl < 30 mL/min (0.50 mL/s): avoid use	Dual strong CYP3A4 and P-gp inhibitors: If dose > 2.5 mg BID, decrease by 50% If already taking 2.5 mg BID and dual strong CYP3A4 and P-gp inhibitor: avoid use No dose adjustment in renal impairment required	CrCl 15–50 mL/min (0.25–0.83 mL/s) or body weight ≤ 60 kg (132 lb), or concurrent use with certain P-gp inhibitors: 30 mg once daily

CrCl, creatinine clearance; CYP, cytochrome P-450; P-gp, P-glycoprotein.

LO 7

The DOACs inhibit a serine protease single target within the common pathway of the coagulation cascade during the final stages of clot formation. See Figure 10–5. This specificity provides a linear dose response and wider therapeutic index that allows for fixed dosing and precludes the need for routine coagulation monitoring.[4,12,29,30,36,37] Apixaban, rivaroxaban, edoxaban, and betrixaban are competitive, selective, and potent direct inhibitors of factor Xa that bind in a reversible manner to the active site of both free-floating factor Xa and factor Xa within the prothrombinase complex, thereby attenuating thrombin generation. These agents have intrinsic anticoagulant activity, and do not require a cofactor to exert their effect as with UFH and the LMWHs.[4,12,29,30,36,37]

The pharmacokinetic and pharmacodynamic properties of DOACs are significantly different than those of warfarin. See Table 10–14. They have a more rapid onset and offset of action and shorter half-lives compared to warfarin. However, missed doses may be more prone to result in therapeutic complications than longer half-life therapies such as warfarin. They are all eliminated renally to varying degrees (see Table 10–14), and dose adjustment or avoidance in patients with renal impairment may be needed.[4,12,29,30,36,37] See Table 10–13. All DOACs are substrates of the P-gp transport system, and the Xa inhibitors are also substrates of the hepatic cytochrome P-450 (CYP) isoenzyme system. Any inhibition or induction of these metabolic systems will alter their absorption.[38] There are currently no readily available standardized laboratory assays to measure the anticoagulant effect of the DOACs, nor are there currently any FDA-approved specific antidotes to reverse the factor Xa inhibitors. This can cause challenges in situations where rapid

reversal of anticoagulation is required such as in cases of major bleeding or need for emergency surgery.[12,29,30,36,37,39] Fresh-frozen plasma, factor concentrates, or recombinant factor VIIa may be given in the event of a major life-threatening bleed.

Apixaban has dual pathways of elimination, with approximately 27% being cleared renally and the remainder eliminated via the fecal route. Elderly, low weight (< 50 kg [110 lb]), and patients with renal impairment can have increased exposure to apixaban, while gender and race do not appear to have clinically relevant influence. Apixaban pharmacokinetics are not significantly altered in patients with mild (Child Pugh A) to moderate (Child Pugh B) hepatic impairment. However, apixaban has not been studied in patients with severe hepatic impairment and is not recommended for use in these patients. There are no adequate studies in pregnant women, and its use during pregnancy is likely to increase bleeding risk. Use in pediatric patients has not been studied.[29]

Apixaban is a substrate of both the CYP 3A4/5 and P-gp systems, and it may be subject to a number of drug interactions (Table 10–15).[29,38] See Tables 10–13, 10–14, and 10–15 for pertinent drug interactions, monitoring, and dosing recommendations.

LO 5

While routine anticoagulation monitoring is not required, there may be clinical scenarios where knowing the patient's degree of anticoagulation may be necessary.[39] A drug-specific chromogenic anti-Xa assay may be used to measure apixaban plasma concentrations; however, this assay is not readily available in most laboratories. Other tests such as the PT, aPTT, and INR are not recommended to assess the anticoagulant effects of apixaban.[29,39] Baseline and periodic patient assessment including

Table 10–15

Drug Interactions and Monitoring Recommendations for Direct Oral Anticoagulants

	Apixaban	Rivaroxaban	Dabigatran	Edoxaban	Betrixaban
Drug interactions	Avoid concomitant use with strong dual inhibitors of CYP3A4 and P-gp (eg, ketoconazole, ritonavir, erythromycin) or reduce apixaban dose Avoid concomitant use with strong dual inducers of CYP3A4 and P-gp (eg, rifampin, phenytoin, carbamazepine) Concomitant use with antiplatelet agents, fibrinolytics, heparin, aspirin, and chronic NSAID increases bleeding risk	Avoid concomitant use with strong dual inhibitors of CYP3A4 and P-gp (eg, ketoconazole, ritonavir, erythromycin) Avoid concomitant use with strong dual inducers of CYP3A4 and P-gp (eg, rifampin, phenytoin, carbamazepine) Avoid concomitant use with other anticoagulants	Avoid concomitant use with P-gp inducers (eg, rifampin) P-gp inhibitors and impaired renal function can lead to increased exposure to dabigatran: Avoid concomitant use with severe renal impairment (CrCl < 30 mL/min [0.50 mL/s]) For moderate renal impairment, reduce dose to 75 mg twice daily when used concomitantly with dronedarone or systemic ketoconazole or avoid concomitant use	Avoid concomitant use with P-gp inducers (eg, rifampin) Concomitant use with coagulants, antiplatelet drugs, and thrombolytics may increase the risk of bleeding.	For concomitant use of P-gp inhibitors (eg, amiodarone, azithromycin, verapamil, ketoconazole, clarithromycin): reduce dose to 80 mg × 1 then 40 mg daily Concomitant use of anticoagulants, antiplatelet drugs, and thrombolytics may increase the risk of bleeding.
Monitoring	Baseline laboratory assessment: Hemoglobin/hematocrit, liver function, renal function, PT/INR At every visit: Adherence, signs/symptoms of bleeding or thromboembolism, side effects, concomitant medications (including over-the-counter) Annual laboratory assessment: Hemoglobin/hematocrit, renal function, liver function If CrCl 30–60 mL/min (0.50–1.0 mL/s), > 75 years, or fragile: renal function every 6 months If CrCl 15–30 mL/min (0.25–0.50 mL/s): renal function every 3 months If condition changes that might impact anticoagulation therapy: check renal and/or liver function				

CrCl, creatinine clearance; CYP, cytochrome P-450; INR, International Normalized Ratio; NSAID, nonsteroidal anti-inflammatory drug; P-gp, P-glycoprotein; PT, prothrombin time.

adherence, side effects, and renal and liver function should be conducted (Table 10–15).[40]

Rivaroxaban's bioavailability is dose dependent.[30] At a dose of 10 mg, bioavailability is 80% to 100% and may be taken without regard for food. At higher doses, bioavailability is approximately 66% in the fasted state, which is increased to greater than 80% by food intake. Thus, rivaroxaban 15 mg and 20 mg tablets should be taken with the largest meal of the day. See Table 10–14. Like apixaban, rivaroxaban does not induce or inhibit CYP isoenzymes, but may be affected by medications that are substrates for this enzymatic pathway.[30,38] Rivaroxaban has a dual mode of elimination, with approximately 35% excreted unchanged in the urine and the remaining two-thirds (in the form of inactive metabolites) excreted fairly equally between the renal and hepatobiliary route.[30] Rivaroxaban is a P-gp substrate, not only at the level of gut absorption, but also at the level of elimination in the kidney. Medications that are substrates for the P-gp transport system may impact plasma concentrations of rivaroxaban.[38,40]

While patients with renal impairment can have increased exposure to rivaroxaban, gender, race, age, and extremes of weight (< 50 kg [110 lb] or > 120 kg [265 lb]) have not been shown to significantly impact its pharmacokinetics or pharmacodynamics. Rivaroxaban should be avoided in patients with CrCl less than 30 mL/min (0.50 mL/s) when used in VTE treatment.[30] See Table 10–13. Mild hepatic impairment has minimal impact on the pharmacokinetics and pharmacodynamics of rivaroxaban. Patients with moderate hepatic impairment (Child-Pugh B) have significantly increased exposure to rivaroxaban and its use in patients with severe liver disease has not been studied.[30] There are no well controlled studies in pregnant women and pediatric patients and dosing of rivaroxaban in these patients has not been established.

Rivaroxaban should not be used concomitantly with medications that are dual P-gp and strong CYP3A4 inhibitors or inducers.[38,40] See Table 10–15. Use with weaker combined P-gp and CYP3A4 substrates should be undertaken with caution and only if benefit of use outweighs risk. Concomitant use of rivaroxaban with antiplatelet and nonsteroidal anti-inflammatory agents should be done with extreme caution due to the additive antithrombotic effects and heightened risk of bleeding. As with apixaban, a drug-specific chromogenic anti-Xa assay may be used to measure rivaroxaban activity. Rivaroxaban prolongs the aPTT and PT in a dose-dependent manner, but the PT is more sensitive to rivaroxaban than the aPTT.[29,39,40] Because it is widely available and has a low level of complexity, the PT may be used in a qualitative manner to quickly determine the presence of rivaroxaban. A normal result with most PT reagents would exclude clinically significant anticoagulant activity. The PT and INR are not suitable for measurement of rivaroxaban activity.

LO 5

Edoxaban is 62% orally bioavailable and dose dependent and is 55% bound to plasma protein. Edoxaban undergoes minimal CYP3A4 metabolism, hydrolysis, and conjugation, although an active primary metabolite is formed via hydrolysis

with renal elimination accounting for approximately half of edoxaban elimination. Edoxaban should not be used in those with moderate or severe hepatic impairment (Child-Pugh B and C). Individuals weighing 60 kg (132 lb) or less should receive a reduced dose of 30 mg daily. Similar to apixaban and rivaroxaban, chromogenic antifactor Xa can be considered to evaluate the presence of edoxaban. Edoxoban may affect PT and aPTT, but these measures should not be considered reliable measures of serum concentrations or anticoagulation intensity. Similar to the other DOACs, concomitant use of edoxaban with P-gp inducers, particularly rifampin, should be avoided.[36,39,40]

Betrixaban is 34% orally bioavailable and unlike rivaroxaban, administration with a low or high-fat meal leads to reduced betrixaban exposure. Betrixaban should thus be administered with food. Bextrixaban is mainly excreted through feces (85%), 11% through urine, and 1% metabolized via CYP1A1, 1A2, 2B6, 2C9, 2C19, 2D6, and 3A4. A reduced dose is recommended if severe renal impairment (CrCl 15–30 mL/min [0.25–0.50 mL/s]) or concomitant use of P-gp inhibitors is present. Betrixaban has not been evaluated in the setting of hepatic impairment, and its use in this patient population should be avoided. The recommended duration of treatment for betrixaban is 35 to 42 days.[37]

Reversal agents for oral factor Xa inhibitors are undergoing evaluation and approval.[41] Andexanet alfa, a recombinant modified human factor Xa decoy protein that binds to the active site of factor Xa inhibitors with high affinity thereby preventing DOAC-mediated factor Xa inhibition, has been found to effectively reverse the effects of rivaroxaban and apixaban utilizing DOAC-specific doses. Ciraparantag is a small synthetic molecule that utilizes noncovalent hydrogen bonds and charge–charge interactions to release factor Xa from a DOAC and has been studied with edoxaban use. Ciraparantag has also been proposed as a reversal agent for DTIs, UFH, and LMWH.

▶ *Direct Thrombin Inhibitors*

Given that thrombin is the central mediator of coagulation and amplifies its own production, it is a natural target for pharmacologic intervention.[9,42,43] DTIs bind thrombin and prevent interactions with their substrates (Figure 10–6).

Parenteral Parenteral DTIs are considered the drugs of choice for the treatment of VTE in patients with a diagnosis or history of HIT.[9,42,43] Several injectable DTIs are approved for use in the United States including lepirudin, bivalirudin, argatroban, and desirudin. All have been used to treat thrombosis in patients with HIT, but only lepirudin and argatroban are FDA approved for this indication. However, as of 2012, lepirudin is no longer commercially available in the United States. Data with some of the DTIs (desirudin, bivalirudin) in the treatment of HIT is limited and there are no high-quality studies that directly compare one DTI with another. DTIs differ in terms of their chemical structure, binding to the thrombin molecule and pharmacokinetic profiles. See Table 10–16. Unlike heparins, DTIs do not require AT as a cofactor and do not bind to plasma proteins. Therefore, they produce a more predictable anticoagulant effect. DTIs have a targeted specificity for thrombin, the ability to inactivate clot-bound thrombin, and an absence of platelet interactions that can lead to HIT.[9,42,43]

LO 7

Oral Small molecule DTIs have been structurally modified for oral administration.[42] One agent, dabigatran, is currently approved in the United States for treatment of VTE.[44] Dabigatran was found to be as effective and safe as warfarin in the treatment and prevention of recurrent VTE.[12,44] Like edoxaban, patients should be anticoagulated with UFH or LMWH for the initial 5 to 10 days of therapy and then transitioned to dabigatran for VTE treatment.[2,12,44] See Table 10–13. Similar to other DOACs, dabigatran can be given in fixed doses without the need for routine coagulation monitoring and has a fast onset and offset of action, offering more convenient anticoagulation options for patients and providers.[44]

LO 7

Dabigatran is a direct reversible, competitive inhibitor of thrombin and an oral prodrug of dabigatran etexilate.[42-44] Dabigatran is converted to its active form dabigatran etexilate by serum esterases that are independent of CYP pathways. See Table 10–14. Dabigatran has an oral bioavailability of approximately 3% to 7% and requires an acidic environment for absorption. The prodrug is contained in small pellets coated with an acid core. These pellets are enclosed in a capsule shell. This specific capsule formulation improves the dissolution and absorption of the prodrug, independent of gastric pH. Therefore, the capsules should not be broken, chewed, or opened before administration. Dabigatran demonstrates 35% protein binding and is a substrate of the efflux transporter P-gp. Although the absence of CYP metabolism decreases potential for many drug interactions, coadministration with P-gp substrates, inhibitors, or inducers may affect the efficacy of dabigatran.[38,40] See Table 10–15.

Approximately 80% of dabigatran is eliminated in the urine, and its use is not recommended in the treatment of VTE in patients with a CrCl less than 30 mL/min (0.50 mL/s) due to increased risk of drug exposure and bleeding.[44] Subjects with severe liver disease were excluded from clinical trials of dabigatran. In those with moderate hepatic impairment (Child-Pugh B), the pharmacokinetic profile of dabigatran is not affected. Gender, age, race, or extremes of weight (< 50 kg [110 lb] or > 110 kg [243 lb]) do not significantly impact dabigatran pharmacology.

Dabigatran prolongs the aPTT, PT, thrombin time (TT), and ecarin clotting time (ECT) assays in a dose-dependent manner.[39,44]

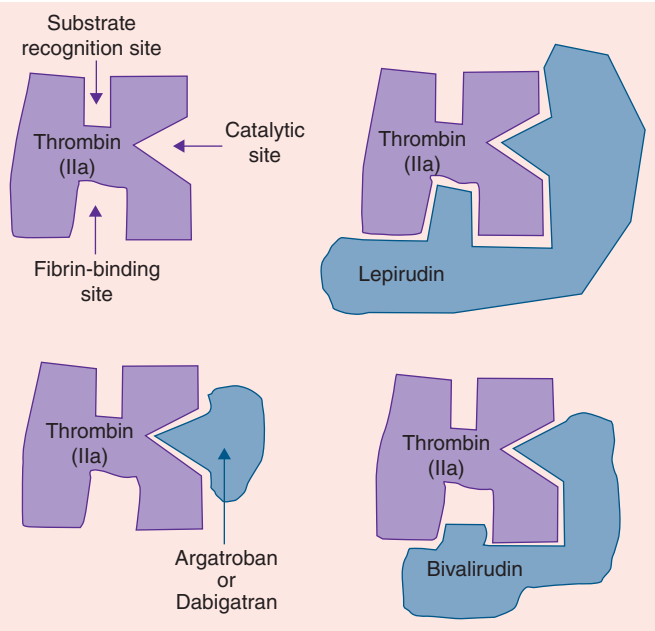

FIGURE 10–6. Mechanism of action of direct thrombin inhibitors. (From Witt DM, Nutescu EA, Haines S. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York, NY: McGraw-Hill; 2011:326.)

Table 10–16

Pharmacologic and Clinical Properties of Direct Thrombin Inhibitors Used in Treatment of Thrombosis in Patients with Heparin-Induced Thrombocytopenia (HIT)

	Lepirudin	Desirudin	Bivalirudin	Argatroban
Route of administration	IV	SC	IV	IV
FDA approved indication	Treatment of thrombosis in patients with HIT	VTE prevention after total hip arthroplasty	Patients with unstable angina undergoing percutaneous transluminal coronary angioplasty; PCI with provisional use of glycoprotein IIb-IIIa inhibitor; patients with or at risk of HIT or HITTS undergoing PCI	Prophylaxis or treatment of thrombosis in adult patients with HIT; patients with or at risk of HIT undergoing PCI
Binding to thrombin	Irreversible Catalytic site and exosite-1	Irreversible Catalytic site and exosite-1	Partially reversible Catalytic site and exosite-1	Reversible Catalytic site
Half-life in healthy subjects	80 minutes	2–3 hours	25 minutes	40–50 minutes
Monitoring	aPTT (IV) SCr/CrCl	aPTT SCr/CrCl	aPTT/ACT SCr/CrCl	aPTT/ACT Liver function
Elimination	Renal	Renal	Enzymatic (80%) and renal (20%)	Hepatobiliary
Antibody development	Anti-hirudin antibodies in up to 40%–60% of patients	Not reported	May cross-react with anti-hirudin antibodies	No

+ minimal effect

++ moderate effect

+++ significant effect

ACT, activated clotting time; aPTT, activated partial thromboplastin time; CrCl, creatinine clearance; FDA, Food and Drug Administration; HITTS, heparin-induced thrombocytopenia and thrombosis syndrome; INR, International Normalized Ratio; IV, intravenous; PCI, percutaneous coronary intervention; SC, subcutaneous; SCr, serum creatinine; VTE, venous thromboembolism.

Peak values greater than 2.5 times control may indicate supratherapeutic levels. A normal aPTT would indicate a lack of clinically relevant anticoagulant activity. The aPTT may be used in a qualitative manner to determine the presence of anticoagulation with dabigatran. It should not be used to quantitate dabigatran plasma concentrations. The PT is relatively insensitive to dabigatran, and the INR is not suitable for measurement of dabigatran due to significant variability. The TT, diluted thrombin time (dTT), and ECT exhibit a linear dose-response with therapeutic dabigatran plasma concentrations. Unfortunately, none of these assays are widely available in practice. It is important to note that quantitative thresholds beyond which a patient would be at increased risk of clotting or bleeding have not been established for any of the DOACs.[39,42,44]

LO 5

Contraindications to the use of DTIs and risk factors for bleeding are similar to those of other antithrombotic agents (Tables 10–11 and 10–12). Bleeding is the most common side effect reported. Concurrent use of DTIs with thrombolytics or antiplatelet agents significantly increases bleeding complications.[41] Idarucizumab, a humanized monoclonal antibody fragment specific to dabigatran and its acyl glucuronide metabolites, binds free and thrombin-bound dabigatran with 350-time higher affinity compared to thrombin and is indicated for dabigatran reversal.[45] Idarucizumab is administered as two consecutive 2.5 gram infusions or as a single bolus 5 gram IV injection. Serious adverse reactions include thromboembolic risk accompanying dabigatran reversal, hypersensitivity reactions, and serious adverse events in those with hereditary fructose intolerance. Fresh-frozen plasma, factor concentrates, or recombinant factor VIIa may also be given in the event of a major life-threatening bleed; however, their efficacy for this use has not been established. DTIs can increase PT/INR and interfere with the accuracy of monitoring and dosing of warfarin therapy. Data on use of DTIs in pregnancy are very limited. Use of DTIs in pediatric patients has not been established.[44]

LO 6

▶ *Warfarin*

KEY CONCEPT Warfarin has been the primary oral anticoagulant used in the United States when long-term or extended anticoagulation is required, but its use is gradually being supplanted in favor of DOACs. Warfarin is FDA approved for prevention and treatment of VTE.[46] Although very effective, warfarin has a narrow therapeutic index, requiring frequent dose adjustments and careful patient monitoring.[4,10,11,46]

Warfarin exerts its anticoagulant effect by inhibiting production of the vitamin K–dependent coagulation factors II (prothrombin), VII, IX, and X, as well as the anticoagulant proteins C and S (Figure 10–7). Warfarin has no effect on circulating coagulation factors that have been previously formed and its therapeutic antithrombotic activity is delayed for 5 to 7 days (potentially longer in slower metabolizers). This delay is related to half-lives of the clotting factors: 60 to 100 hours for factor II (prothrombin), 6 to 8 hours for factor VII, 20 to 30 hours for factor IX, and 24 to

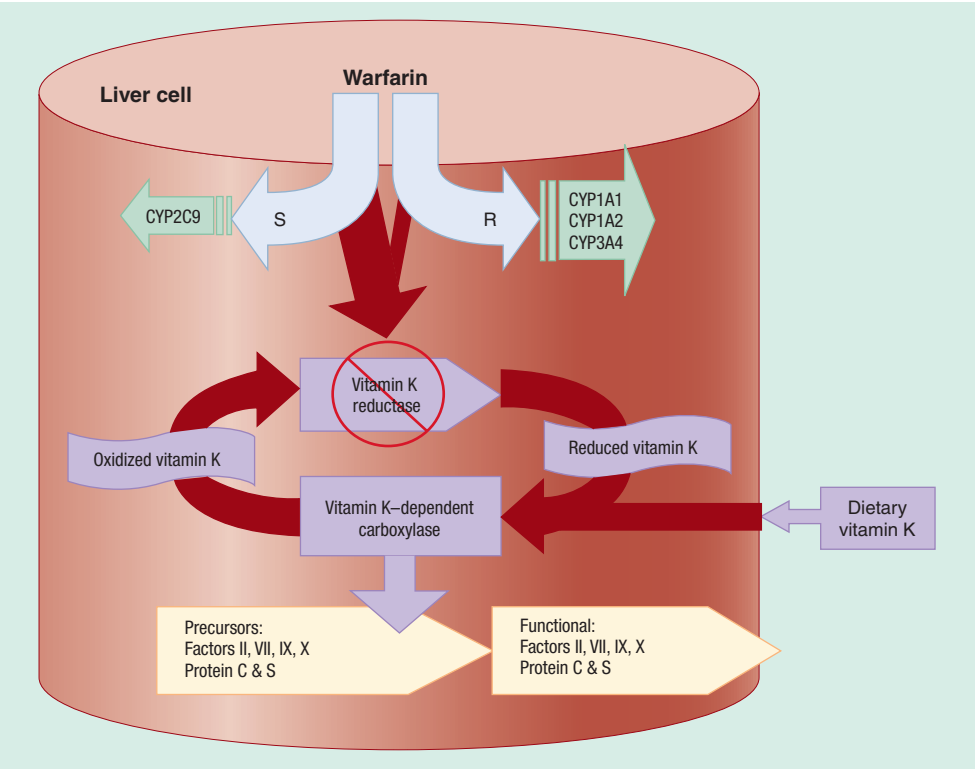

FIGURE 10–7. Pharmacologic activity and metabolism of warfarin. (CYP, cytochrome P-450 isoenzyme.) (From Witt DM, Nutescu EA, Haines S. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York, NY: McGraw-Hill; 2011:328.)

40 hours for factor X. Proteins C and S, the natural anticoagulants, are inhibited more rapidly due to their shorter half-lives, 8 to 10 hours and 40 to 60 hours, respectively. Reductions in the concentration of natural anticoagulants before the clotting factors are depleted can lead to a paradoxical hypercoagulable state during the first few days of warfarin therapy. It is for this reason that patients with acute thrombosis should receive a fast-acting anticoagulant (heparin, LMWH, or fondaparinux) while transitioning to warfarin therapy. The use of DOACs as a bridging agent has not been well evaluated or approved.[4,10,11,46]

Warfarin is metabolized in the liver via several isoenzymes including CYP 1A2, 3A4, 2C9, 2C19, 2C8, and 2C18 (Figure 10–7).[4,10,11,46] Hepatic metabolism of warfarin varies greatly among patients, leading to large interpatient differences in dose requirements and genetic variations in these isoenzymes. Multiple studies have demonstrated that VKORC1 and CYP2C9 genotypes influence the interpatient variability in warfarin dose requirements, together explaining up to 45% of overall dose variance. Several algorithms that incorporate CYP2C9 genotype and VKORC1 haplotype with other patient characteristics to predict warfarin maintenance dosing requirements have been developed and showed efficacy in better predicting warfarin stable doses when compared to clinical algorithms. Based on these data, the FDA recommends incorporating patient's genotype information in guiding warfarin dosing when such information is available.[46] See Table 10–17.[46] Guidelines published by the Clinical Pharmacogenetics Implementation Consortium are available to guide and apply CYP2C9 and VKORC1 genotype result interpretation to warfarin dosing.[47] Although randomized studies to date showed mixed results of pharmacogenomic-based warfarin dosing on clinical and health utilization outcomes, careful analyses of study design and single nucleotide polymorphisms tested in relation to the study patient population are necessary to appropriately interpret the implications and validity of genotype-guided dosing study outcomes. Therefore, pharmacogenomic-based dosing has not yet been widely adopted in clinical practice and some guidelines recommend against routine ordering of preemptive genetic testing.[2,4]

Warfarin displays nonlinear kinetics. Small-dose adjustments can lead to large changes in anticoagulant response.[4,10,11,46] The dose of warfarin is determined by each patient's individual response to therapy and the desired intensity of anticoagulation. In addition to hepatic metabolism and genotype, warfarin dose requirements are influenced by diet, drug–drug interactions, and health status. LO 5 Therefore, warfarin dose must be determined by frequent clinical and laboratory monitoring. Although there are conflicting data regarding the optimal warfarin induction regimen, when the patient's genotype is unknown, most patients can start with 5 mg daily and subsequent doses are determined based on INR response (Figure 10–8). When initiating therapy, it is difficult to predict the precise warfarin maintenance dose a patient will require. Patients who are younger (< 55 years) and otherwise healthy can safely use higher warfarin "initiation" doses (eg, 7.5–10 mg). A more conservative "initiation" dose (eg, 4 mg or less) should be given to patients older than 75 years, patients with heart failure, liver disease, or poor nutritional status, and patients who are taking interacting medications or are at high risk of bleeding. Loading doses of warfarin (eg, 15–20 mg) are not recommended. These large doses can lead to the false impression that a therapeutic INR has been achieved in 2 to 3 days and lead to potential future

Patient Encounter 3, Part 1

A 48-year-old woman presents to the emergency department complaining of shortness of breath, chest pain, and dizziness. She was in a car accident a week ago and injured her left leg. She started having left calf pain approximately 5 days ago and feeling short of breath and experiencing chest pain (7/10) last evening. She could not sleep, and her shortness of breath has gotten progressively worse in the last several hours. She was hospitalized because she was suspected to have a PE.

PMH: Obesity × 20 years; Asthma

FH: Mother died of an MI; paternal grandmother had clots (deep vein thrombosis) in her legs

SH: Full-time bus driver

Current Meds: Albuterol (salbutamol) metered-dose inhaler as needed; Ortho-Tri-Cyclen Lo by mouth daily; Ginseng one to two tablets by mouth daily as needed; multivitamin one tablet by mouth daily

Allergies: NKDA

PE:

VS: BP 104/64 mm Hg, HR 102 beats/min, RR 20 breaths/min, T 38.0°C (100.4°F), Wt 96 kg (211 lb; BMI 35.3 kg/m^2), Ht 65 in (165 cm)

Labs: Within normal limits; eGFR 101 mL/min/1.73 m^2; CrCl 99 mL/min (1.65 mL/s)

Procedures/Tests

ECG: Normal sinus rhythm; no ischemic changes

CXR: Cardiomegaly present

V/Q scan: High probability of PE

What symptoms are consistent with the diagnosis of PE? What are the most likely etiologies for PE in this case?

What are appropriate initial acute phase treatment and long-term and extended treatment options for PE in this patient?

If UFH is chosen as the initial acute phase anticoagulation treatment option for this patient's PE, what is the goal aPTT?

What is patient's goal INR for warfarin therapy?

How long should she remain on anticoagulation therapy?

Given the list of medications the patient took prior to hospitalization, should any of these be discontinued or changed? If changed, what alternative therapy would you recommend?

LO 6 overdosing.[4,10,11,46] Before initiating therapy, screen the patient for any contraindications to anticoagulation therapy and risk factors for major bleeding (Tables 10–11 and 10–12). Conduct a thorough medication history including the use of prescription and nonprescription drugs, and any herbal supplements to detect interactions that may affect warfarin dosing requirements.

In patients with acute VTE, a rapid-acting anticoagulant (UFH, LMWH, or fondaparinux) should be overlapped with warfarin for a minimum of 5 days and until the INR is greater than 2 and stable. This is important because the full antithrombotic effect will not be reached until 5 to 7 days or even longer after initiating warfarin therapy. The typical maintenance dose of warfarin for most patients will be between 25 and 55 mg per week, although some patients require higher or lower doses stemming from their genotype or other clinical factors. Adjustments in the maintenance warfarin dose should be determined based on the total weekly dose and by reducing or increasing the weekly dose by increments of 5% to 25%. When adjusting the maintenance dose, wait at least 7 days to ensure a steady state has been attained on the new dose before checking the INR again. Checking the INR too soon can lead to inappropriate dose adjustments and unstable anticoagulation status.[4,10,11,46]

LO 5 LO 8 KEY CONCEPT Warfarin requires frequent laboratory monitoring to ensure optimal outcomes and minimize complications. PT is the most frequently used test to monitor warfarin's anticoagulant effect. PT measures biological activity of factors II, VII, and X. Due to wide variation in reagent sensitivity, different **thromboplastins** will result in different PT results, potentially leading to inappropriate dosing decisions.[4,10,11,46] To standardize result reporting, the World Health Organization developed a reference thromboplastin and recommended the INR to monitor warfarin therapy. The INR corrects for the differences in thromboplastin reagents. Goal or target INR for each patient is based on the indication for warfarin therapy. For treatment and prevention of VTE, the INR target is 2.5 with an acceptable range of 2 to 3. Before initiating warfarin therapy, a baseline PT/INR and CBC should be obtained. After initiating warfarin therapy, the INR should be monitored at least every 2 to 3 days during the first week of therapy. Once a stable response to therapy is achieved, INR monitoring is performed less frequently, weekly for the first 1 to 2 weeks, then every 2 weeks, and every 4 to 6 weeks thereafter if the warfarin dose and the patient's health status are stable.[4,10,11,46,48] At each encounter, the patient should be carefully questioned regarding any factors that may influence the INR result. These factors include adherence to therapy, the use of interacting medications, consumption of vitamin K-rich foods, alcohol use, and general health status. Patients should also be questioned about symptoms related to bleeding and thromboembolic events. Warfarin dose adjustments should take into account not only the INR result but also patient-related factors that influence the result. Structured anticoagulation therapy management services (anticoagulation clinics) have been demonstrated to improve the efficacy and safety of warfarin therapy. Some patients engage in self-testing and self-management by using a point-of-care PT/INR device approved for home use. Highly motivated and well-trained patients are good candidates for self-testing or self-management.[48]

KEY CONCEPT Similar to other anticoagulants, warfarin's primary side effect is bleeding.[8] Warfarin can unmask an existing lesion. Incidence of warfarin-related bleeding appears to be highest during the first few weeks of therapy. The annual incidence of major bleeding ranges from 1% to 10% depending on the quality of warfarin therapy management. Bleeding in the gastrointestinal tract is most common. Intracranial hemorrhage (ICH) is one of the most serious complications because it often causes severe disability and death. The intensity of anticoagulation therapy is related to bleeding risk. Higher INRs result in higher bleeding risk, and risk of ICH increases when the INR exceeds 4.[4,10,11] Instability and wide fluctuations in the INR are also associated with higher bleeding risk. In cases of warfarin overdose or overanticoagulation, vitamin K may be used to reverse warfarin's effect. Vitamin K can

LO 8

Patient Encounter 3, Part 2

The patient is discharged home on warfarin therapy. She was referred to a local area antithrombosis center for monitoring of her oral anticoagulation therapy and has been maintained on warfarin 6 mg daily for the last 3 months. The patient presents today for a routine visit for anticoagulation monitoring and her INR is 10.5. She reports that 6 days ago she was started on Bactrim DS twice daily, which was prescribed by her primary care physician for a urinary tract infection. In addition, the primary care physician told the patient that her thyroid gland was enlarged and ordered some lab tests to determine if she has a thyroid problem. The patient has not heard what the results are. She also reports that she is trying to lose weight and her intake of vitamin K-rich foods (kale, turnip greens, brussels sprouts) has increased significantly over the last month. She has no other complaints today and denies any signs or symptoms of bleeding.

What is the most likely explanation for elevated INR?

Should she be given vitamin K? If yes, discuss the dose, route of administration, and an appropriate patient monitoring plan.

How will you manage the patient's warfarin therapy? Outline a plan including specific dose changes, timing of monitoring, and patient education.

be given by IV or oral route; the SC route is not recommended as vitamin K is erratically absorbed and frequently ineffective. The IV route is reserved for cases of severe warfarin overdose and when patients are actively bleeding. Anaphylactoid reactions have been reported with rapid IV administration; therefore, slow infusion is recommended. An oral dose of vitamin K will reduce INR within 24 hours. If INR is still elevated after 24 hours, another dose of oral vitamin K can be given. The dose of vitamin K should be based on the degree of INR elevation and whether bleeding is present. A dose of 2.5 to 5 mg orally is recommended when INR is greater than 10 and there is no active bleeding, while a higher dose 5 to 10 mg given via slow IV is recommended in cases when bleeding is present. Higher doses (eg, 10 mg) can lead to prolonged warfarin resistance. In cases of life-threatening bleeding, fresh-frozen plasma or clotting factor concentrates should also be administered, in addition to IV vitamin K. In patients in whom INR is less than 10 and there is no active bleeding or imminent risk of bleeding, simply withholding warfarin until INR decreases to within therapeutic range and reducing the weekly dose with more frequent monitoring is appropriate.[4,10,11,46]

Nonhemorrhagic side effects related to warfarin are rare but can be severe when they occur. Warfarin-induced skin necrosis (incidence < 0.1%) presents as an eggplant-colored skin lesion or a maculopapular rash that can progress to necrotic gangrene. It usually manifests in fatty areas such as the abdomen, buttocks, and breasts, and generally appears during the first week of therapy. Patients with protein C or S deficiency or those who receive large loading doses of warfarin are at greatest risk.[46] The mechanism is thought to be due to imbalances between procoagulant and anticoagulant proteins early in the course of warfarin therapy. Warfarin-induced purple toe syndrome is another rare side effect; patients present with a purplish discoloration of their toes. If these side effects are suspected, warfarin therapy should be discontinued immediately, and an alternative anticoagulant should be started.

Table 10–18

Clinically Significant Drug Interactions with Warfarin

Increase Anticoagulation Effect (↑ INR)	Decrease Anticoagulation Effect (↓ INR)	Increase Bleeding Risk
Acetaminophen	Amobarbital	Argatroban
Acute alcohol ingestion	Butabarbital	Aspirin
Allopurinol	Carbamazepine	Clopidogrel
Amiodarone	Cholestyramine	Danaparoid
Cephalosporins (with MTT side chain)	Chronic alcohol ingestion	Dipyridamole

There is a theoretical risk that warfarin may cause accelerated bone loss with long-term use, but to date there is no evidence to support this concern. Warfarin is teratogenic, it should be avoided during pregnancy, and women of childbearing potential should be instructed to use an effective form of contraception.

LO 9 KEY CONCEPT Warfarin is prone to numerous clinically significant drug–drug and drug–food interactions (Tables 10–18, 10–19, and 10–20).[10,11,46] Patients on warfarin should be questioned at every encounter to assess for any potential interactions with foods, drugs, herbal products, and nutritional supplements. When an interacting

Table 10–19

drug is initiated or discontinued, more frequent monitoring should be instituted. In addition, the dose of warfarin can be modified (increased or decreased) in anticipation of the expected impact on the INR.[10,11,46] Warfarin-related drug interactions can generally be divided into two major categories: pharmacokinetic and pharmacodynamic. Pharmacokinetic interactions are most commonly due to changes in hepatic metabolism or binding to plasma proteins. Drugs that affect the CYP2C9, CYP3A4, and CYP1A2 have the greatest impact on warfarin metabolism. Interactions that impact the metabolism of the S-isomer result in greater changes in the INR than interactions affecting the R-isomer. Pharmacodynamic drug interactions enhance or diminish the anticoagulant effect of warfarin, increasing the risk of bleeding or clotting, but may not alter the INR. There are increasing reports regarding dietary supplements, nutraceuticals, and vitamins that can interact with warfarin. Patients on warfarin may experience changes in the INR due to fluctuating intake of dietary vitamin K. Patients should be instructed to maintain a consistent diet and avoid large fluctuations in vitamin K intake rather than strictly avoiding vitamin K-rich foods.[4,10,11,46]

Nonpharmacologic Therapy

▶ *Thrombectomy*

Most cases of VTE can be successfully treated with anticoagulation. In some cases, removal of the occluding thrombus by surgical intervention may be warranted. Surgical or mechanical thrombectomy can be considered in patients with massive iliofemoral DVT when there is a risk of limb gangrene due to venous occlusion.[2,12] The procedure can be complicated by recurrence of thrombus formation. In patients who present with massive PE, pulmonary embolectomy can be performed in patients with contraindications to thrombolytic therapy, when thrombolysis has failed clinically, or when thrombolysis will not have sufficient time to take effect. The usual practice is to administer heparin by IV infusion to achieve a therapeutic aPTT during the operation, and postoperatively and thereafter give warfarin for the usual recommended duration.[2,12]

▶ *Inferior Vena Cava Filters*

An inferior vena cava (IVC) filter is indicated in patients with newly diagnosed proximal DVT or PE who have a contraindication to anticoagulation therapy.[2,12] IVC interruption is accomplished

Table 10–20

Vitamin K Content of Select Foods[a]

Very High (> 200 mcg)	High (100–200 mcg)	Medium (50–100 mcg)	Low (< 50 mcg)
Brussels sprouts	Basil	Apple, green	Apple, red
Chickpea	Broccoli	Asparagus	Avocado

[a]Approximate amount of vitamin K per 100 g (3.5 oz) serving.

through minimally invasive means by inserting a filter through the internal jugular vein or femoral vein and advancing it into the IVC using ultrasound or fluoroscopic guidance. One of the risks associated with these filters is development of thrombosis on the filter itself. Therefore, anticoagulation therapy should be resumed as soon as contraindications resolve. Temporary or removable filters are increasingly used, and filters should be removed once therapy is completed.[15]

APPROACH TO TREATING PATIENTS WITH VTE

LO 10

A treatment algorithm for VTE is presented in Figure 10–9. Note that LMWH or fondaparinux are preferred over UFH for acute VTE treatment; however, in patients with CrCl less than 30 mL/min (0.50 mL/s), UFH is the preferred treatment approach. For the long-term and extended treatment phases, DOACs are recommended over warfarin to prevent recurrent thrombosis not associated with a cancer diagnosis. However, in patients with cancer-associated thrombosis, the LMWHs are recommended for the acute, long-term, and extended phases of treatment due to better efficacy in preventing recurrent thromboembolic events.[2,33]

Anticoagulation therapy is continued for a minimum of 3 months but should be given longer depending on the underlying etiology of the VTE, thrombus location, and the patient's risk factors.[2,12] Determining the optimal duration of anticoagulation involves weighing the risk of recurrent VTE against the risk of bleeding associated with anticoagulation therapy and determining patient preference regarding treatment duration. Patients with provoked VTE by transient risk factors (eg, surgery, trauma) or an isolated distally located DVT require therapy for 3 months. Patients with unprovoked VTE have a recurrence risk of at least 10% after 1 year and at least 30% at 5 years, thus most such patients require extended if not indefinite anticoagulation, particularly in those with PE or proximally located DVT and PE, and if the patient carries low to moderate bleeding risk. Patients with low to moderate bleeding risk who have a second unprovoked VTE should receive extended or indefinite anticoagulation and those at high bleeding risk should be treated for three months. Patients who are recommended to receive indefinite anticoagulation should have periodic visits to assess bleeding risk and patient preference/quality of life to determine if anticoagulation should continue.

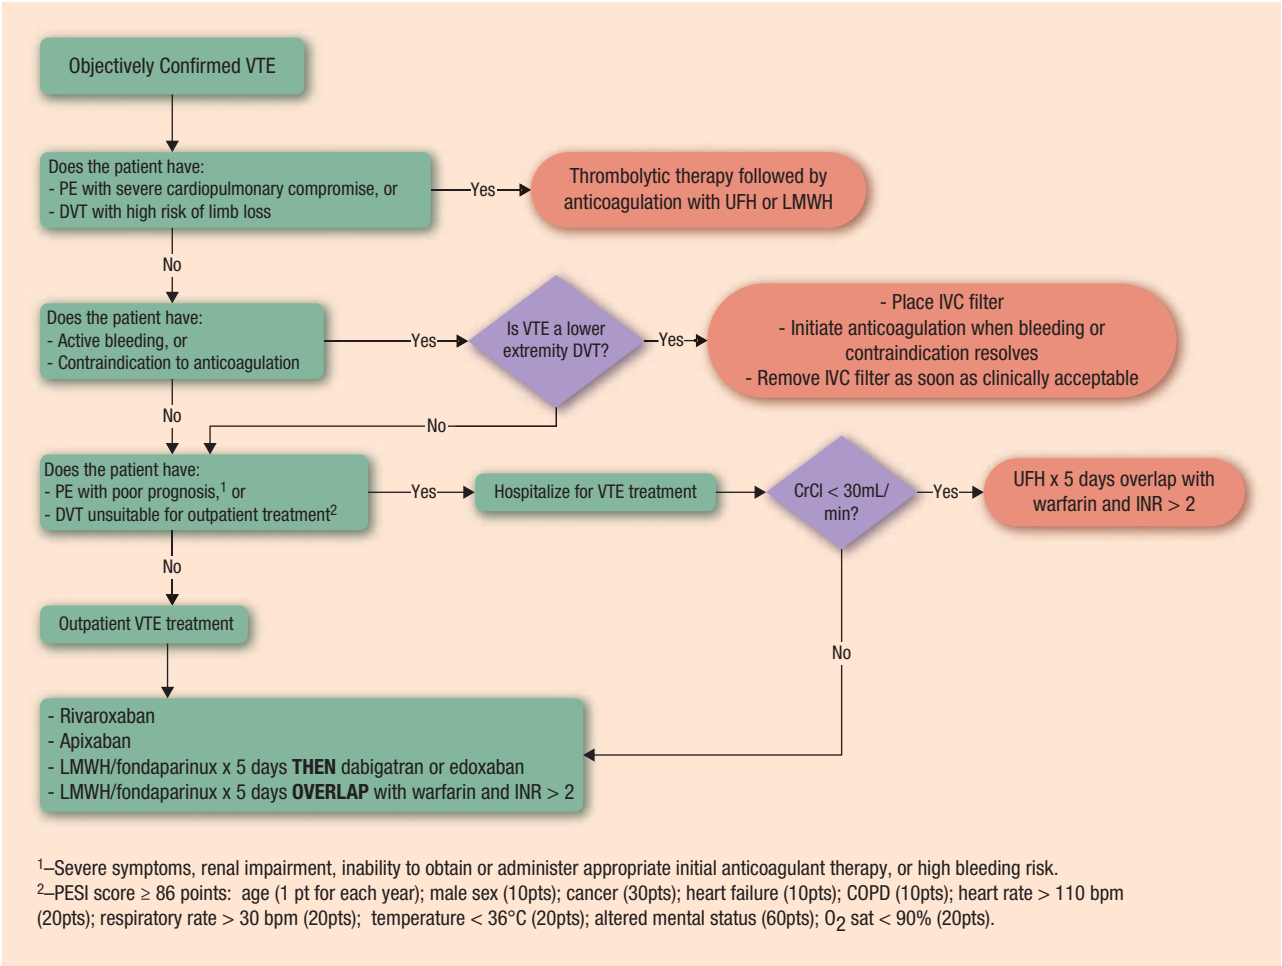

FIGURE 10–9. Treatment of VTE. (bpm, beats per minute; COPD, chronic obstructive pulmonary disease; CrCl, creatinine clearance [30 mL/min is equivalent to 0.50 mL/s]; DVT, deep vein thrombosis; INR, international normalized ratio; IVC, inferior vena cava; LMWH, low molecular weight heparin; O_2 sat, oxygen saturation [90% is equivalent to 0.90 when expressed as a fraction]; PE, pulmonary embolism; PESI, pulmonary embolism severity index; UFH, unfractionated heparin; VTE, venous thromboembolism.) (From Witt DM, Clark NP, Vazquez SR. Venous thromboembolism. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017:240.)

Patient preference should always be a strong consideration when deciding on extended duration anticoagulation.[2,12]

OUTCOME EVALUATION

- KEY CONCEPT Achieve optimal outcomes by: (a) preventing the occurrence of VTE in patients who are at risk, (b) administering effective treatments in a timely manner to patients who develop VTE, (c) preventing treatment-related complications, and (d) reducing the likelihood of long-term complications including recurrent events.
- Given that VTE is often clinically silent and potentially fatal, strategies to increase widespread use of prophylaxis have the

Patient Care Process

Collect Information:

- Obtain and review from the medical record the medical history, family history, social history, physical assessment findings, and laboratory and diagnostic testing results.
- Complete a medication history for use of prescription and nonprescription medications and dietary supplements. Identify any allergies to medications and other substances.
- Interview the patient and review records to identify lifestyle habits such as dietary patterns, alcohol and illicit drug use, smoking status, medication use–related preferences and beliefs, and socioeconomic factors that affect access to medications and health care.

Assess the Information:

- Based on clinical assessment and physical examination, determine whether the patient is experiencing signs or symptoms of VTE (Table 10–1 and Clinical Presentation and Diagnosis of DVT and PE).
- Apply the Wells criteria to determine the probability that the patient's signs, symptoms, and risk factors are the result of DVT and/or PE (Tables 10–2 and 10–3).
- Review relevant laboratory (eg, D-dimer, PT/INR, aPTT, antifactor Xa activity, SCr, CrCl, blood urea nitrogen [BUN], serum albumin, liver function tests, CBC with platelets) and diagnostic tests (eg, venous ultrasound, V/Q, or CT scan). See Clinical Presentation and Diagnosis of DVT and PE.
- Screen for pertinent family history (ie, hypercoagulable disorders, pregnancy loss, DVT, PE).
- Determine if diagnosis of VTE is confirmed based on clinical criteria and/or diagnostic testing.
- Assess whether the VTE is a new or recurrent event and whether the VTE is an idiopathic or triggered event.
- Assess severity of VTE and whether patient is a candidate for outpatient therapy.
- Assess risk of bleeding and check for any contraindications to anticoagulation therapy (Tables 10–6, 10–11, and 10–12).
- Screen dietary and medication profile including over-the-counter medications and herbal therapies used at home for potential drug–drug and drug–food interactions with anticoagulation therapy (Tables 10–15, 10–18, and 10–19).
- If patient is already receiving anticoagulation therapy, assess efficacy, safety, and adherence to therapy.

Develop a Care Plan:

- Once diagnosis of VTE has been confirmed with an objective test, initiate anticoagulation therapy in full therapeutic doses. If there is high clinical suspicion of VTE, anticoagulation therapy may be initiated while waiting for results of diagnostic tests (Figure 10–9).
- Determine the most appropriate anticoagulant therapy and dose options based on patient clinical characteristics, insurance coverage, plans for outpatient therapy, complexity of anticoagulation management, and patient preferences (Tables 10–8, 10–9, 10–10, and 10–13).
- Determine optimal duration of anticoagulation therapy by weighing the risk of recurrent VTE against the risk of bleeding and considering patient preferences regarding treatment duration.

Implement the Care Plan:

- Educate the patient on purpose of therapy and importance of proper monitoring, potential drug–drug and drug–food interactions, dietary consistency with vitamin K-containing foods if treated with warfarin, taking appropriate birth control measures in females, adherence with anticoagulants and with laboratory monitoring, potential side effects, and procedures to follow in case of emergency.
- Address any patient concerns about anticoagulation treatment and its management.
- Devise a structured plan for long-term monitoring of anticoagulation therapy; if treated with warfarin, determine if patient is candidate for anticoagulation self-testing.
- Refer the patient to a specialized anticoagulation monitoring service if available or another designated specialized provider.
- Evaluate patient's medical insurance status and assess coverage level for oral and injectable anticoagulant medications and coverage for follow-up monitoring visits and/or anticoagulation self-testing devices and supplies.

Follow-up: Monitor and Evaluate:

- Follow a structured plan for periodic long-term monitoring of anticoagulation therapy.
- Reevaluate risks and benefits of continuing anticoagulation therapy beyond the initial 3 months; patients who are recommended to receive indefinite anticoagulation should have periodic visits to assess bleeding risk and patient preference/quality of life to determine if anticoagulation should continue.
- Periodically reassess patient adherence, concurrent medications to screen for drug interactions, dietary habits to screen for drug–diet interactions, and renal and liver function tests.
- Monitor the patient to determine if there is worsening or new symptoms related to VTE.
- Evaluate the patient to determine if he/she is experiencing any side effects such as overt bruising or bleeding, as well as changes in stool or urine color.

greatest potential to improve patient outcomes. Thus, relying on early diagnosis and treatment of VTE is unacceptable because many patients will die before treatment can be initiated.

- Effective VTE prophylaxis programs screen all patients admitted to the hospital for VTE risk factors, determine each patient's level of risk, and select and implement prevention strategies that provide sufficient protection for the level of risk.
- Periodically evaluate patients who are receiving VTE prophylaxis for signs and symptoms of DVT, such as swelling, pain, warmth, and redness of lower extremities, and for signs and symptoms of PE, such as chest pain, shortness of breath, palpitations, and hemoptysis.
- Providing effective treatment in a timely manner is the primary goal for patients who develop VTE. Treat DVT and PE quickly and aggressively with effective doses of anticoagulant drugs.
- Short-term aims of therapy are to prevent propagation or local extension of the clot, embolization, and death.
- Regularly monitor patients for development of new symptoms or worsening of existing symptoms.
- All anticoagulant drugs require precise dosing and meticulous monitoring. Closely monitor patients receiving anticoagulant therapy for signs and symptoms of bleeding including epistaxis, hemoptysis, hematuria, hematemesis, bright red blood per rectum, tarry stools, severe headache, and joint pain. If major bleeding occurs, stop therapy immediately and treat the source of bleeding. In addition, closely monitor patients for potential drug–drug and drug–food interactions and adherence with the prescribed regimen.
- Long-term goals of therapy are to prevent complications such as PTS, pulmonary hypertension, and recurrent VTE.
- Continue long-term anticoagulation therapy for an appropriate duration based on etiology of the initial clot and presence of ongoing risk factors.

Abbreviations Introduced in This Chapter

ABW	Adjusted body weight
ACCP	American College of Chest Physicians
ACT	Activated clotting time
aPTT	Activated partial thromboplastin time
AST	Aspartate aminotransferase
AT	Antithrombin
BCRP	Breast cancer resistance protein
BMI	Body mass index
BUN	Blood urea nitrogen
CABG	Coronary artery bypass graft
CBC	Complete blood count
CrCl	Creatinine clearance
CT	Computed tomography
CYP	Cytochrome P-450
DOAC	Direct oral anticoagulant
DTI	Direct thrombin inhibitor
dTT	Diluted thrombin time
DVT	Deep vein thrombosis
ECT	Ecarin clotting time
eGFR	Estimated glomerular filtration rate
ESR	Erythrocyte sedimentation rate
FDA	Food and Drug Administration
FXa	Factor Xa
GCS	Graduated compression stockings
GP	Glycoprotein
HIT	Heparin-induced thrombocytopenia
HITTS	Heparin-induced thrombocytopenia and thrombosis syndrome
IBW	Ideal body weight
ICH	Intracranial hemorrhage
INR	International normalized ratio
IPC	Intermittent pneumatic compression (device)
IV	Intravenous
IVC	Inferior vena cava
LDH	Lactate dehydrogenase
LDUH	Low-dose unfractionated heparin
LMWH	Low molecular weight heparin
MI	Myocardial infarction
MRI	Magnetic resonance imaging
NSAID	Nonsteroidal anti-inflammatory drug
PAI-1	Plasminogen activator inhibitor-1
PCI	Percutaneous coronary intervention
PE	Pulmonary embolism
PF	Platelet factor
P-gp	P-glycoprotein
PT	Prothrombin time
PTS	Postthrombotic syndrome
rt-PA	Recombinant tissue plasminogen activator (alteplase)
SCr	Serum creatinine
SBP	Systolic blood pressure
SC	Subcutaneous
SGOT	Serum glutamic-oxaloacetic transaminase
SERM	Selective estrogen receptor modulator
TT	Thrombin time
UFH	Unfractionated heparin
V/Q	Ventilation/perfusion (scan)
VTE	Venous thromboembolism
vWF	von Willebrand factor
WBC	White blood cell

11 Stroke

Susan R. Winkler

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Differentiate types of cerebrovascular disease including transient ischemic attack (TIA), ischemic stroke (cerebral infarction), and hemorrhagic stroke.
2. Identify modifiable and nonmodifiable risk factors associated with ischemic stroke and hemorrhagic stroke.
3. Explain the pathophysiology of ischemic stroke and hemorrhagic stroke.
4. Describe the clinical presentation of TIA, ischemic stroke, and hemorrhagic stroke.
5. Formulate strategies for primary prevention of acute ischemic stroke.
6. Evaluate treatment options for acute ischemic stroke.
7. Determine whether fibrinolytic therapy is indicated in a patient with acute ischemic stroke.
8. Formulate strategies for secondary prevention of acute ischemic stroke.
9. Evaluate treatment options for acute hemorrhagic stroke.

INTRODUCTION

Cerebrovascular disease, or stroke, is the second most common cause of death worldwide, and is the fifth leading cause of death in the United States. Stroke can be either ischemic or hemorrhagic and is an acute medical emergency. Rapid treatment dependent on the type of stroke is critical. Treatment of risk factors and preventive measures are also paramount in the management of stroke. Decades of progress in treatment and prevention of stroke have resulted in a decrease in both stroke incidence and stroke case fatality rates.[1] Stroke mortality rates are higher in women than men and geographic variability exists, with higher mortality rates observed in the Southeastern United States, termed the "stroke belt."

EPIDEMIOLOGY

Approximately 795,000 strokes occur in the United States each year. New strokes account for 610,000 of this total; recurrent strokes account for the remaining 185,000. Stroke incidence increases with age, especially after age 55 years, resulting in an increased incidence in the elderly population.[2] Stroke is the leading cause of long-term disability in adults, with 90% of survivors having residual deficits. Moderate to severe disability is seen in 70% of survivors and 15% to 30% of stroke survivors are permanently disabled. The American Heart Association estimates there are currently over 7 million stroke survivors in the United States. Societal impact and economic burden is great, with total costs of $33.9 billion reported in the United States in 2013.

ETIOLOGY AND CLASSIFICATION

Strokes can either be ischemic (87% of all strokes) or hemorrhagic (13% of all strokes). KEY CONCEPT Ischemic stroke, which may be thrombotic or embolic, is the abrupt development of a focal neurological deficit that occurs due to inadequate blood supply to an area of the brain. A thrombotic occlusion occurs when a **thrombus** forms inside an artery in the brain. An embolic stroke typically occurs when a piece of thrombus, originating either inside or outside of the cerebral vessels, breaks loose and is carried to the site of occlusion in the cerebral vessels. An extracerebral source of emboli is often the heart, leading to cardioembolic stroke.

KEY CONCEPT Hemorrhagic stroke is a result of bleeding into the brain and other spaces within the central nervous system (CNS) and includes subarachnoid hemorrhage (SAH), intracerebral hemorrhage (ICH), and subdural **hematomas**. SAH results from sudden bleeding into the space between the inner and middle layers of the meninges, most often due to trauma or rupture of a cerebral **aneurysm** or **arteriovenous malformation** (AVM). ICH is bleeding directly into the brain parenchyma, often as a result of chronic uncontrolled hypertension. Subdural hematomas result from bleeding under the dura that covers the brain and most often occur as a result of head trauma. For hemorrhagic events associated with stroke, refer to the Clinical Presentation and Diagnosis of Stroke textbox.

Cerebral Ischemic Events

LO 1

There are two main classifications of cerebral ischemic events: transient ischemic attack (TIA) and ischemic stroke (cerebral infarction). A TIA is a transient episode of neurological dysfunction caused by focal brain, spinal cord, or retinal ischemia without acute infarction. TIAs have a rapid onset and short duration, typically lasting less than 1 hour and often less than 30 minutes. The symptoms vary depending on the area of the brain affected; however, no deficit remains after the attack.[3] KEY CONCEPT TIAs are

a risk factor for acute ischemic stroke, preceding acute ischemic stroke in approximately 15% of cases; therefore, preventive measures are the same for both TIA and ischemic stroke.[4]

LO1 Ischemic stroke is similar to TIA; however, tissue injury and infarction are present, and in many patients, residual deficits remain after the event. A standardized tissue-based definition of cerebral infarction has been established defining cerebral infarction as brain, spinal cord, or retinal cell death attributable to ischemia, based on neuropathological, neuroimaging, and/or clinical evidence of permanent injury.[5]

Risk Factors

Assessment of risk factors for ischemic stroke and hemorrhagic stroke is an important component of stroke prevention, diagnosis, and treatment. Major goals in the long-term management of ischemic stroke involve primary prevention (prevention of first stroke) and secondary prevention (prevention of a recurrent stroke). Risk factors for ischemic stroke are divided into modifiable and nonmodifiable (Table 11–1). Hypertension is one of the major risk factors for both ischemic and hemorrhagic stroke. Other risk factors for hemorrhagic stroke include trauma, cigarette smoking, cocaine use, heavy alcohol use, anticoagulant use, and cerebral aneurysm and AVM rupture.[6,7] Every patient should have risk factors assessed and treated, if possible, because management can decrease the occurrence and/or recurrence of stroke.[6,8]

LO2

Table 11–1

Nonmodifiable and Modifiable Risk Factors for Ischemic Stroke

Nonmodifiable Risk Factors
- Age (> 55 years)
- Gender (males more than females)
- Race and ethnicity (American Indian/Alaska Natives, African American, Asian/Pacific Islander, Hispanic)
- Genetic predisposition
- Low birth weight

Well Documented and Modifiable Risk Factors
- Hypertension (most important risk factor)
- Cardiac disease
  - Atrial fibrillation (most important and treatable cardiac cause of stroke)
  - Mitral stenosis
  - Mitral annular calcification
  - Left atrial enlargement
  - Structural abnormalities such as atrial-septal aneurysm
  - Acute myocardial infarction
- Transient ischemic attacks or prior stroke (major independent risk factor)
- Diabetes (independent risk factor)
- Dyslipidemia
- Asymptomatic carotid stenosis
- Oral contraceptive use (with estrogen content > 50 mcg)
- Postmenopausal hormone therapy
- Sickle cell disease
- Lifestyle factors
  - Cigarette smoking
  - Excessive alcohol use
  - Physical inactivity
  - Obesity
  - Diet
  - Cocaine and intravenous drug use
  - Low socioeconomic status

Less Well Documented or Potentially Modifiable Risk Factors
- Increased hematocrit
- Metabolic syndrome
- Hyperhomocysteinemia
- Migraine (risk not clear)
- Sleep disordered breathing (ie, sleep apnea)

PATHOPHYSIOLOGY

Ischemic Stroke

LO3 In ischemic stroke, there is an interruption of the blood supply to an area of the brain either due to thrombus formation or an embolism. Loss of cerebral blood flow results in tissue hypoperfusion, tissue hypoxia, and cell death. Thrombus formation usually starts with lipid deposits in the vessel wall that cause turbulent blood flow. This leads to vessel injury and vessel collagen becoming exposed to blood. This vessel injury initiates the platelet aggregation process due to the exposed subendothelium. Platelets release adenosine diphosphate (ADP), which causes platelet aggregation and consolidation of the platelet plug. Thromboxane A_2 is released, contributing to platelet aggregation and vasoconstriction. The vessel injury also activates the coagulation cascade, which leads to thrombin production. Thrombin converts fibrinogen to fibrin, leading to clot formation as fibrin molecules, platelets, and blood cells aggregate. Refer to Figures 7–3, 10–3, and 10–4 for a depiction of these processes.

After the initial event, secondary events occur at the cellular level that contribute to cell death. Regardless of the initiating event, the cellular processes that follow may be similar. Excitatory amino acids such as glutamate accumulate within the cells, causing intracellular calcium accumulation. Inflammation occurs and oxygen free radicals are formed resulting in the common pathway of cell death.

There is often a core of ischemia containing unsalvageable brain cells. Surrounding this core is an area termed the **ischemic penumbra**. In this area, cells are still salvageable; however, this is time-sensitive. Without restoration of adequate perfusion, cell death continues throughout a larger area of the brain, ultimately leading to neurological deficits.

Hemorrhagic Stroke

LO3 The pathophysiology of hemorrhagic stroke is not as well studied as that of ischemic stroke; however, it is more complex than previously thought. Much of the process is related to the presence of blood in the brain tissue and/or surrounding spaces resulting in compression. The hematoma that forms may continue to grow and enlarge after the initial bleed, and early growth is associated with a poor outcome. Brain tissue swelling and injury is a result of inflammation caused by thrombin and other blood products. This can lead to increased intracranial pressure (ICP) and **herniation**.[7] Delayed cerebral ischemia, or vasospasm, is a potential consequence of aneurysmal SAH that results in vasoconstriction of cerebral vessels and clinical symptoms of ischemia.

PRIMARY PREVENTION OF ISCHEMIC STROKE

Aspirin

LO5 Use of aspirin (ASA) in patients with no history of stroke or ischemic heart disease reduced the incidence of nonfatal myocardial infarction (MI) but not stroke. Primary prevention guidelines recommend ASA for general cardiovascular prophylaxis (not specific to stroke) in men and women with a

Clinical Presentation and Diagnosis of Stroke

General

- Patient may not be able to reliably report history due to cognitive or language deficits. A reliable history may have to come from a family member or another witness.

Symptoms of Ischemic Stroke

LO 4

- The patient may complain of weakness on one side of the body, inability to speak, loss of vision, vertigo, headache, or falling.

Signs of Ischemic Stroke

- Patients usually have multiple signs of neurologic dysfunction, and specific deficits are determined by the area of the brain involved.
- Hemiparesis or monoparesis occur commonly, as does a hemisensory deficit.
- Patients with vertigo and double vision are likely to have posterior circulation involvement.
- Aphasia is seen commonly in patients with anterior circulation strokes.
- Patients may also suffer from dysarthria, visual field defects, and altered levels of consciousness.

Signs and Symptoms of Hemorrhagic Stroke

- A sudden severe headache, nausea, vomiting, and photophobia may be the first signs and symptoms. Patients may complain the headache is "the worst headache of my life."
- Neck pain and nuchal rigidity (stiffness) may also be experienced.

**It is important to note that a diagnosis of type of stroke cannot be made solely on signs and symptoms because overlap occurs between types of stroke.

Laboratory Tests

- There are no specific laboratory tests for stroke.
- Tests for hypercoagulable states, such as protein C deficiency and antiphospholipid antibody, should be done only when cause of stroke cannot be determined based on presence of well-known risk factors.

Other Diagnostic Tests

- Computed tomography (CT) scan of the head will reveal an area of hyperintensity (white) identifying that a hemorrhage has occurred. CT scan will either be normal or hypointense (dark) in an area where an infarction has occurred. It may take 24 hours (and rarely longer) to reveal the area of infarction on a CT scan.
- Magnetic resonance imaging (MRI) of the head will reveal areas of ischemia earlier and with better resolution than a CT scan. Diffusion-weighted imaging can reveal an evolving infarct within minutes.
- Carotid Doppler studies will determine whether the patient has a high degree of stenosis (blockage of an artery) in the carotid arteries, which are the vessels that supply blood to the brain (extracranial disease).
- Electrocardiogram (ECG) will determine whether the patient has atrial fibrillation (AF), a major risk factor for cardioembolic stroke.
- Transthoracic echocardiogram will identify whether there are heart valve abnormalities or problems with wall motion of the heart resulting in emboli to the brain.

10-year cardiovascular risk of greater than 10% and in women who are at high risk for stroke. ASA may be considered for prevention of a first stroke in patients with chronic kidney disease, and cilostazol may be considered for prevention of a first stroke in patients with peripheral arterial disease. The benefits must be weighed against the risk of major bleeding. Due to lack of benefit observed in clinical trials, ASA is not recommended for primary prevention in patients with diabetes and asymptomatic peripheral arterial disease, or in those at low risk.[8]

Patient Encounter Part 1

An 83-year-old, 86.4 kg (190 lb), 5'4" (163 cm) white woman presents to the emergency department with weakness in her left arm and difficulty "getting the words out." She was last seen well by her neighbor approximately 3 hours prior to her neighbor noticing her symptoms. Her neighbor called 911 immediately after observing her symptoms. Her past medical history is significant for hypertension, dyslipidemia, and a previous stroke 3 years ago. She has experienced transient ischemic attacks in the past and has had two TIAs in the past week. Social history includes alcohol use of 3 to 4 drinks per week and obesity. Current medications include perindopril 4 mg once daily, atorvastatin 20 mg daily, aspirin 81 mg daily, and a multivitamin tablet once daily.

What signs and symptoms does the patient have that are suggestive of stroke?

What nonmodifiable and modifiable risk factors does she have for acute ischemic stroke?

▶ *Diabetes*

LO 5

Diabetes is an independent risk factor for stroke. Intensive glycemic control has not been shown to reduce stroke risk in either type 1 or type 2 diabetes mellitus. Adequate control of blood pressure (BP) to a target level of less than 130/80 mm Hg and management of dyslipidemia are recommended in individuals with diabetes. The use of a statin is also recommended to prevent a first stroke.[8,9] Hypertension guidelines recommend initial therapy that includes a thiazide-type diuretic, calcium channel blocker (CCB), angiotensin-converting enzyme inhibitor (ACE-I), or angiotensin receptor blocker (ARB).[9] The guidelines suggest that in black patients with diabetes, initial antihypertensive therapy should include a thiazide-type diuretic or a CCB.[9]

▶ *Dyslipidemia*

LO 5

Clinical studies have found a relationship between total cholesterol levels and stroke rate. Statin use, in addition to lifestyle modifications, is recommended for primary prevention

of ischemic stroke in patients estimated to have a high 10-year risk of cardiovascular events.[8] Treatment recommendations are based on current guidelines for treatment of blood cholesterol.[10] The benefit of other lipid-lowering therapies on stroke risk has not been established.[8]

▶ *Hypertension*

LO 5

Hypertension is the most important and well-documented risk factor for stroke. Lowering BP in hypertensive patients reduces the relative risk of both ischemic and hemorrhagic stroke. All patients should have BP monitored and controlled appropriately based on current guidelines for BP management released by the American College of Cardiology/American Heart Association in 2017.[9] In patients without cardiovascular disease (CVD), treatment with BP-lowering medications is recommended in patients with an estimated 10-year atherosclerotic CVD (ASCVD) risk of 10% or greater and systolic blood pressure (SBP) greater than or equal to 130 mm Hg or diastolic blood pressure (DBP) greater than or equal to 80 mm Hg, or in those patients with an estimated 10-year ASCVD risk less than 10% and an SBP greater than or equal to 140 mm Hg or a DBP greater than or equal to 90 mm Hg.[9] A recent meta-analysis of multiple trials found that more intensive BP lowering reduced the risk of stroke by 20% over a less-intensive BP-lowering strategy.[11] Many patients require two or more drug therapies to achieve BP control. For primary prevention of stroke, reduction in BP is the main goal because one antihypertensive agent has not been clearly shown to be more beneficial than any other. Refer to Chapter 5, "Hypertension."

▶ *Smoking Cessation*

LO 5

The relationship between smoking and both ischemic and hemorrhagic stroke is clear. Smoking status should be assessed at every patient visit. Patients should be assisted and encouraged in smoking cessation as stroke risk after cessation declines over time. Effective treatment options are available including counseling, nicotine replacement products, and oral agents.

▶ *Other Treatments*

A number of other disease states and lifestyle factors should be addressed as primary prevention of stroke. AF is an important and well-documented risk for stroke. See Chapter 9, "Arrhythmias," for information on stroke prevention in AF. Asymptomatic carotid stenosis, cardiac disease, sickle cell disease, obesity, excessive alcohol use, and physical inactivity are other risks that should be assessed and managed appropriately.

TREATMENT

Desired Outcomes

The short-term treatment goals for acute ischemic stroke include reducing secondary brain damage by reestablishing and maintaining adequate perfusion to marginally ischemic areas of the brain and protecting these areas from the effects of ischemia (ie, neuroprotection). KEY CONCEPT Long-term treatment goals for acute ischemic stroke include prevention of a recurrent stroke through reduction and modification of risk factors and by use of appropriate treatments.

Short-term treatment goals for hemorrhagic stroke include rapid neurointensive care to maintain adequate oxygenation, breathing, and circulation. Management of increased ICP and BP are important in the acute setting. Long-term management includes prevention of complications and of a recurrent bleed and delayed cerebral ischemia. Prevention of long-term disability and death related to stroke is important regardless of stroke type.

General Approach

KEY CONCEPT All patients should have a brain CT or MRI scan to differentiate an ischemic stroke from a hemorrhagic stroke because treatment differs and fibrinolytic therapy must be avoided until hemorrhagic stroke is ruled out. A CT or MRI scan is the most important initial diagnostic test in patients with acute stroke. For those with an ischemic stroke, an evaluation should be done to determine the appropriateness of reperfusion therapy. In hemorrhagic stroke, a surgical evaluation should be completed to assess the need for surgical clipping of an aneurysm or other procedure to control the bleeding and prevent rebleeding and other complications. Figure 11–1 provides an algorithm for initial management of the acute stroke patient.

Early Management of Acute Ischemic Stroke

Acute ischemic stroke is a medical emergency. Identification of the time of symptom onset and symptom presentation are important determinants in treatment. The time the patient was last without symptoms is used as the time of stroke onset. Because patients typically do not experience pain, determining the onset time can be difficult. It is also important to document risk factors, previous functional status, and the National Institutes of Health Stroke Scale (NIHSS) to assess stroke severity and current disability due to stroke. The NIHSS is a 42-point scale that quantifies neurological deficits in stroke patients. It is easy to perform and is used as a measure of daily functioning.

▶ *Supportive Measures*

LO 6

Acute complications of ischemic stroke include cerebral edema, increased ICP, seizures, and hemorrhagic conversion (ie, conversion of ischemic stroke into a hemorrhagic stroke). In the acute setting, supportive interventions and treatments to prevent acute complications should be initiated. Continuous cardiac monitoring, most commonly with a Holter monitor, should be continued for the first 24 hours to screen for AF and other cardiac diseases. Improved AF detection rates have been seen with extended monitoring times.[12] Tissue oxygenation should be maintained acutely. Measure the oxygen saturation using pulse oximetry and supplement the patient with oxygen if necessary. Oxygen saturation should be maintained at 94% (0.94) or greater.[13] Volume status and electrolytes should be corrected. If required, blood glucose should be corrected because both hyperglycemia and hypoglycemia may worsen brain ischemia. When blood glucose less than 60 mg/dL (3.3 mmol/L) is present, bolus with 25 mL of 50% dextrose immediately. Patients with elevated blood glucose poststroke have been documented to have worse outcomes; therefore, lowering blood glucose to between 140 and 180 mg/dL (7.8–10.0 mmol/L) with subcutaneous insulin is a reasonable approach.[14,15] If the patient is febrile, treat with acetaminophen because fever is associated with brain ischemia and increased morbidity and mortality after stroke. Alternatively, cooling devices can be used.[14,16] Low-dose unfractionated heparin (UFH) or low-dose low molecular weight heparin (LMWH) administered subcutaneously significantly decrease the risk of developing venous thromboembolism (VTE) poststroke. Low-dose UFH or LMWH should be initiated for VTE prophylaxis in patients who are not candidates for intravenous (IV) fibrinolytic therapy. In patients receiving fibrinolytic therapy, VTE prophylaxis with low-dose UFH or LMWH should be delayed until 24 hours after fibrinolytic administration to avoid bleeding complications.

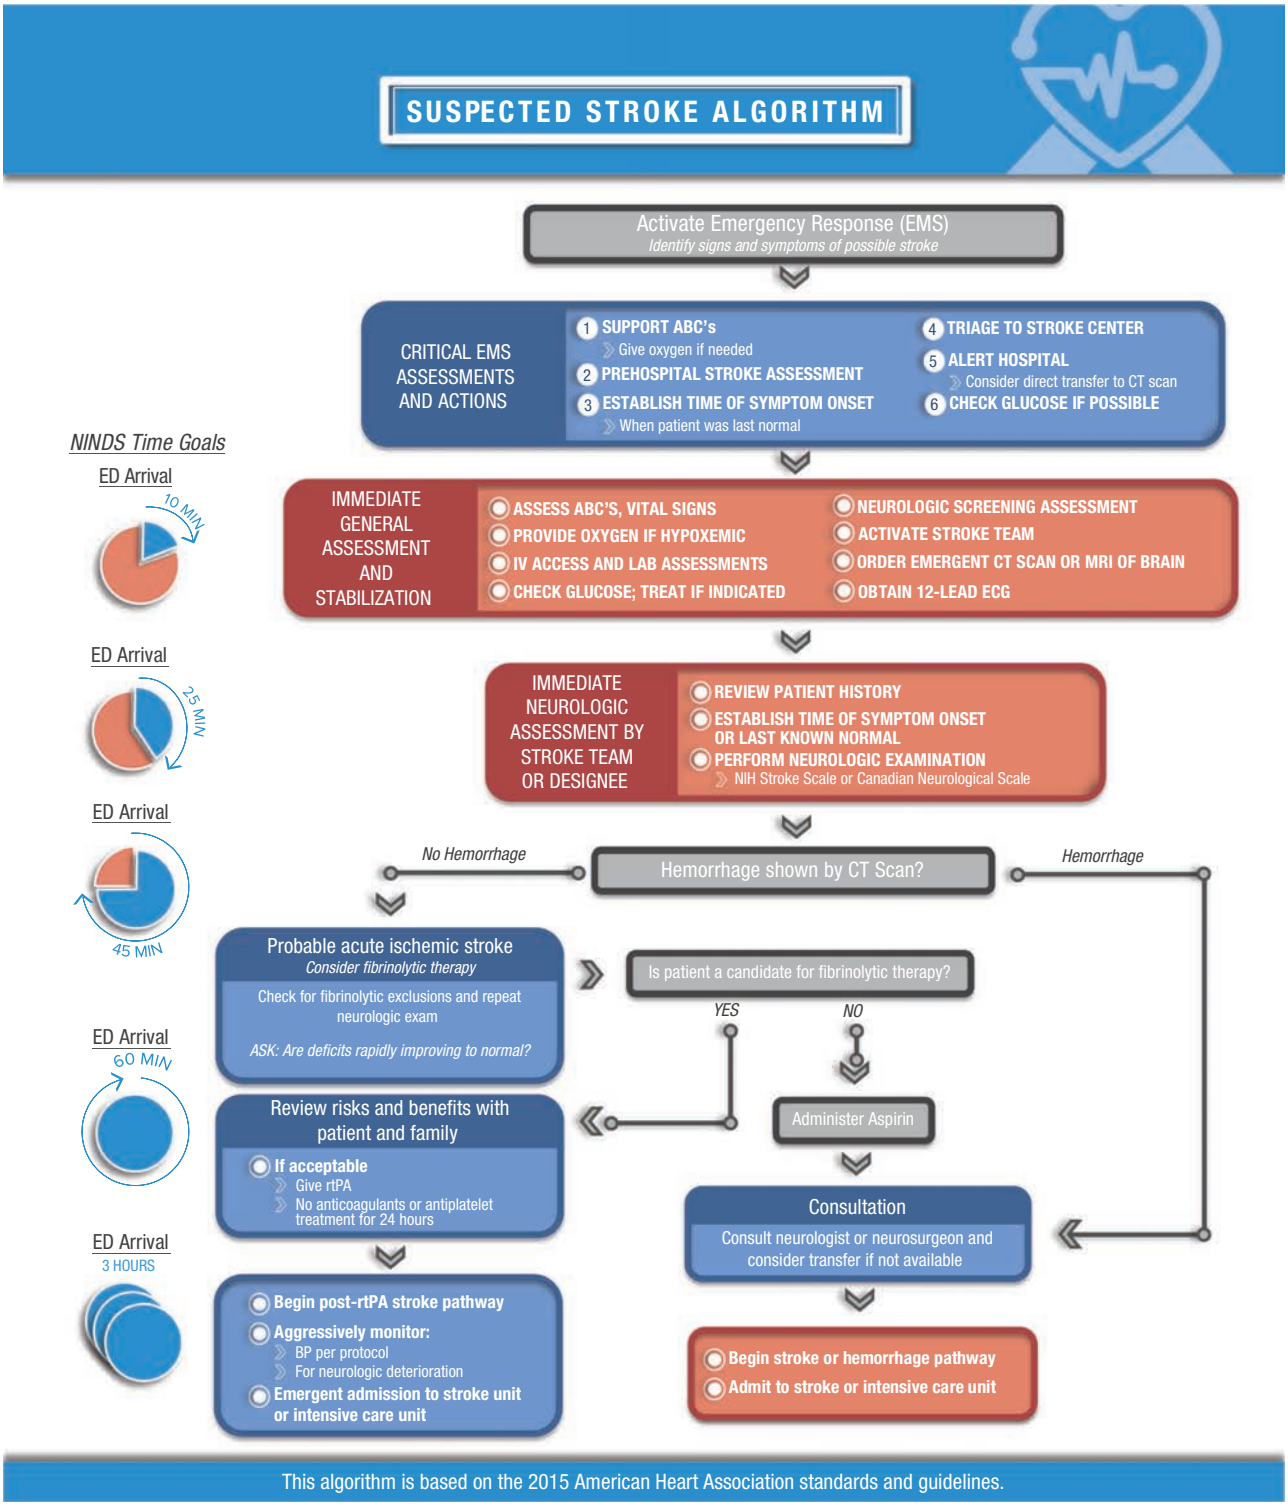

FIGURE 11–1. Suspected stroke treatment algorithm. (ABC, airway, breathing, and circulation; BP, blood pressure; CT, computed tomography; ECG, electrocardiogram; ED, emergency department; EMS, emergency medical services; IV, intravenous; MRI, magnetic resonance imaging; NIH, National Institutes of Health; NINDS, National Institute of Neurological Disorders and Stroke; rtPA, alteplase.) Available at https://promedcert.com/acls-algorithms/algorithm-acls-suspected-stroke.)

In the setting of acute ischemic stroke, up to 80% of patients have an elevated BP in the first 24 to 48 hours.[9] BP should be checked three times with each reading taken 5 minutes apart.

BP should be optimized; however, hypertension should generally not be treated in the acute period (12–24 hours) because it may cause decreased blood flow in ischemic areas, potentially increasing the infarction size. The cautious use of antihypertensive medications may be necessary in patients with severely elevated BP (SBP > 220 mm Hg or DBP > 120 mm Hg) who are otherwise candidates for fibrinolytic therapy. Antihypertensive therapy may also be used in patients with stroke and other medical disorders, including aortic aneurysm

Table 11–2

Blood Pressure (BP) Recommendations for Ischemic Stroke (Eligible for Alteplase)

Before treatment: If systolic BP > 185 mm Hg or diastolic BP > 110 mm Hg	May use either labetalol 10–20 mg IV over 1–2 minutes (may repeat after 10 minutes) or nicardipine infusion 5 mg/hour (titrate up by 2.5 mg/hour every 5–15 minutes; maximum dose 15 mg/hour) or may consider other agents (hydralazine, enalaprilat)
During and after treatment to maintain BP ≤ 180/105 mm Hg:	
If systolic BP > 180–230 mm Hg or diastolic BP > 105–120 mm Hg	Use either labetalol 10 mg IV over 1–2 minutes followed by labetalol infusion 2–8 mg/min or nicardipine infusion 5 mg/hour (titrate up by 2.5 mg/hour every 5–15 minutes; maximum dose 15 mg/hour)
If BP not controlled or diastolic BP > 140 mm Hg	Nitroprusside 0.3–0.5 mcg/kg/min titrated by 0.5 mcg/kg/min to response; maximum dose 10 mcg/kg/min

IV, intravenous.

rupture, MI and heart failure, requiring immediate lowering of BP. Tables 11–2 and 11–3 provide recommendations on BP management in those eligible and not eligible for fibrinolytic therapy. In those not eligible for fibrinolytic therapy, if BP reduction is necessary, aim for a 15% reduction in SBP and DBP in the first 24 hours after stroke onset.

▶ *Fibrinolytic Therapy*

Alteplase American Stroke Association guidelines recommend alteplase (rt-PA; Activase) as the only Food and Drug Administration (FDA)-approved acute treatment for ischemic stroke and strongly encourage early diagnosis and treatment of appropriate patients.[14] Alteplase is an IV fibrinolytic that was approved for acute ischemic stroke treatment within 3 hours of symptom onset based on the results of the National Institute of Neurological Disorders and Stroke (NINDS) rt-PA Stroke Trial.[17] Patients treated with alteplase were 30% more likely to have minimal or no disability at 3 months. Alteplase treatment resulted in an 11% to 13% absolute increase in patients with excellent outcomes at 3 months, independent of patient age, stroke subtype, stroke severity, or prior use of ASA.[18] ICH within 36 hours after stroke onset occurred in 6.4% of those given alteplase versus 0.6% in those given placebo. There was no significant difference in mortality between the two groups at 3 months or 1 year. A dose of 0.9 mg/kg (maximum 90 mg) is recommended; the first 10% is given as an IV bolus, and the remainder is infused over 1 hour.

Subsequent studies that followed the NINDS trial protocol have supported alteplase use in acute ischemic stroke and have shown similar rates for both response and ICH occurrence. When clinical trials are pooled, study results show that the sooner alteplase is given after onset of stroke symptoms, the greater the benefit seen in neurological outcome.[18-20] Alteplase has been shown to provide a benefit when administered from 3 to 4.5 hours after stroke onset in select patients. Additional exclusion criteria for alteplase use between 3 and 4.5 hours after symptom onset include age greater than 80, use of oral anticoagulants regardless of international normalized ratio (INR), NIHSS greater than 25, and the combination of stroke and diabetes.[20,21] KEY CONCEPT

LO 7 Current guidelines recommend alteplase use within 3 hours after stroke onset in appropriate patients and within 3 to 4.5 hours in patients meeting additional criteria. The guidelines recommend that alteplase be started as soon as possible within this window of time.[14,18,21] A **door-to-needle** time of 60 minutes is recommended. Alteplase is commonly withheld in patients with minor or rapidly improving stroke symptoms and in patients with stroke symptoms upon awakening. As many as one-third of patients with minor stroke may go on to have a poor outcome.[22] Although a recent observational study demonstrated a benefit to alteplase treatment in minor stroke, further research is underway in an effort to improve outcomes after ischemic stroke.[23,24] Table 11–4 LO 7 details the inclusion and exclusion criteria for administration of alteplase in acute ischemic stroke.

Efficacy is measured by elimination of existing neurological deficits and long-term improvement in neurological status and functioning based on neurological examinations and other outcome measures. BP measurements and neurological examinations should be completed every 15 minutes during and after the infusion of alteplase for 2 hours, every 30 minutes for the next 6 hours, and then every hour until 24 hours after alteplase administration. Patients should be assessed using the NIHSS at baseline and 24 hours after the administration of alteplase.

The major adverse effects of fibrinolytic therapy are bleeding, including ICH and serious systemic bleeding. Mental status changes and a severe headache may indicate ICH. Signs of systemic bleeding include easy bruising; hematemesis; guaiac-positive stools; black, tarry stools; hematoma formation; hematuria; bleeding gums; and nosebleeds. Angioedema is a potential side effect that may cause airway obstruction.

Antiplatelet agents, anticoagulants, and invasive procedures such as insertion of a central line, placement of a nasogastric tube, and bladder catheterization should be avoided for 24 hours after infusion of alteplase to prevent bleeding complications. A CT scan should be obtained 24 hours after IV infusion of alteplase before initiating anticoagulants or antiplatelet agents.

Other Fibrinolytics Aside from alteplase, no other fibrinolytics are FDA indicated for use in acute ischemic stroke. Trials evaluating streptokinase were stopped early due to a high

Table 11–3

Blood Pressure (BP) Recommendations for Ischemic Stroke (Not Eligible for Alteplase)

Systolic BP < 220 mm Hg and diastolic BP < 120 mm Hg	Observe unless other end-organ involvement
Systolic BP > 220 mm Hg or diastolic BP 121–140 mm Hg	Labetalol 10–20 mg IV over 1–2 minutes (may repeat every 10–20 minutes; maximum dose 300 mg) or nicardipine infusion 5 mg/hour titrated to response
Diastolic BP > 140 mm Hg	Nitroprusside 0.3–0.5 mcg/kg/min titrated by 0.5 mcg/kg/min to response; maximum dose 10 mcg/kg/min

IV, intravenous.

Table 11–4

Inclusion and Exclusion Criteria for Alteplase (rt-PA) Use in Acute Ischemic Stroke

Inclusion Criteria
- 18 years of age or older
- Clinical diagnosis of ischemic stroke causing a measurable neurological deficit
- Time of symptom onset well established to be < 4.5 hours before treatment would begin

Exclusion Criteria
- Evidence of multilobar infarction on CT scan of the brain (> 1/3 cerebral hemisphere) prior to treatment
- Clinical presentation suggestive of SAH even with a normal head CT
- Active internal bleeding
- Known bleeding diathesis, including but not limited to: (a) platelet count less than $100 \times 10^3/mm^3$ ($100 \times 10^9/L$); (b) heparin within 48 hours with an elevated aPTT; or (c) current oral anticoagulant use (eg, warfarin) or recent use with an elevated PT (> 15 seconds) or INR (> 1.7)
- Current use of direct thrombin inhibitors or direct factor Xa inhibitors with elevated sensitive laboratory tests (aPTT, INR, platelet count, and ECT; TT; or appropriate factor Xa activity assays)
- Blood glucose concentration < 50 mg/dL (2.8 mmol/L)
- Recent intracranial or intraspinal surgery, significant head trauma, or previous stroke within 3 months
- Recent arterial puncture at a noncompressible site in previous 7 days
- Lumbar puncture within 7 days
- History of previous intracranial hemorrhage
- Intracranial neoplasm, known AVM or aneurysm
- SBP > 185 mm Hg or DBP > 110 mm Hg at time of treatment, or patient requires aggressive treatment to reduce BP to within these limits

Relative Exclusion Criteria
- Consider risk to benefit of IV rt-PA if any relative contraindications are present:
  - Only minor or rapidly improving stroke symptoms
  - Pregnancy
  - Witnessed seizure at onset of stroke symptoms with postictal residual neurological impairments
  - Major surgery or serious trauma within 14 days
  - Recent gastrointestinal or urinary tract hemorrhage (within previous 21 days)
  - Recent acute MI (within previous 3 months)

Additional Exclusion Criteria for Treatment Between 3 and 4.5 Hours
- Age > 80 years
- Use of oral anticoagulants regardless of INR
- NIHSS > 25
- Combination of ischemic stroke and diabetes

aPTT, activated partial thromboplastin time; AVM, arteriovenous malformation; BP, blood pressure; CT, computed tomography; DBP, diastolic blood pressure; ECT, ecarin clotting time; INR, international normalized ratio; IV, intravenous; MI, myocardial infarction; NIHSS, National Institute of Health Stroke Scale; PT, prothrombin time; SAH, subarachnoid hemorrhage; SBP, systolic blood pressure; TT, thrombin time.

incidence of hemorrhage in streptokinase-treated patients. Desmoteplase has not demonstrated a clinical benefit when administered 3 to 9 hours after stroke onset.[25] Tenecteplase has demonstrated positive initial results. Trials evaluating extended treatment windows with tenecteplase and in comparison to alteplase are currently ongoing.[14,24] Fibrinolytic agents other than alteplase and the defibrinogenating agents are not recommended for treatment unless associated with a clinical trial.[14]

Intraarterial Fibrinolytics Early clinical trials evaluating intraarterial (IA) fibrinolytics evaluated pro-urokinase (r-pro UK) with heparin or heparin alone within 6 hours of symptom onset. Results from the first trial were not statistically significant, whereas results of the second trial showed a statistically significant benefit to r-pro UK.[26] Pro-urokinase is not FDA-approved for acute stroke treatment and is not available in the United States; however, this early work paved the way for continued advancements in acute stroke treatment. Progress has been made utilizing IA fibrinolytic therapy with alteplase administered via a catheter into the affected cerebral artery combined with embolectomy devices (ie, **endovascular** therapy) to remove the clot. Three randomized clinical trials comparing IA alteplase, first-generation embolectomy devices (ie, coil retrievers or aspiration devices using suction) or a combination to IV alteplase did not demonstrate a benefit.[27] Use of IA fibrinolytics without endovascular therapy is not recommended as first-line therapy in patients with acute ischemic stroke.[27]

Patient Encounter Part 2

The patient arrives in the emergency department 4 hours after the onset of her symptoms. In the emergency department, an IV line is placed, a physical and neurological examination is completed, and she is moved to the stroke unit. A head CT scan is negative for hemorrhagic stroke and reveals a diffuse hypodensity on the right. Her BP on admission to the stroke unit is 182/104 mm Hg. The patient denies other exclusions to IV alteplase. The neurologist is evaluating her for alteplase administration.

Identify your acute treatment goals for the patient.

Is she a candidate for IV alteplase at this time?

What acute management would be appropriate for the patient in the stroke unit?

▶ *Heparin*

Full-dose IV UFH has been previously used in acute stroke therapy; however, no adequately designed trials have been conducted to establish its efficacy and safety. Current acute ischemic stroke treatment guidelines do not recommend routine, urgent full-dose anticoagulation with UFH due to lack of a proven benefit in improving neurological function and the risk of intracranial bleeding.[14,18,28] The major complications of heparin include conversion of ischemic stroke into hemorrhagic stroke, bleeding, and thrombocytopenia. Occurrence of severe headache and mental status changes may indicate ICH. Signs of bleeding mirror those listed for alteplase therapy.

▶ *LMWHs and Heparinoids*

Full-dose LMWHs and heparinoids are not recommended in the treatment of acute ischemic stroke.[14,18,29] Studies with these agents have generally been negative, with no convincing evidence of improved outcomes after ischemic stroke. Increased risks of bleeding complications and hemorrhagic transformation have been observed.

▶ *Thrombin Inhibitors*

Several thrombin inhibitors have been approved for stroke prevention in patients with AF and may have a potential benefit in acute stroke treatment. Currently, use of these agents in acute stroke treatment is not well established, and it is recommended that their use be in conjunction with a clinical trial.[14] One recent clinical trial evaluated the use of dabigatran within 24 hours of stroke onset to prevent early stroke recurrence in patients without AF.[30] Further clinical trials are needed to establish the role of these agents in the acute setting.

▶ *Antiplatelet Agents*

ASA use in acute ischemic stroke has been studied in two large randomized trials. Patients who received ASA within 48 hours of onset of acute ischemic stroke symptoms were less likely to suffer early recurrent stroke, death, and disability. KEY CONCEPT ASA therapy with an initial dose of 160 to 325 mg is recommended in most patients with acute ischemic stroke within 24 to 48 hours after stroke symptom onset. ASA dose may then be decreased to 75 to 100 mg daily to reduce bleeding complications.[18] Administration should not replace other acute stroke treatments and should be delayed for 24 hours in patients receiving alteplase. In minor stroke or TIA, ASA plus clopidogrel has been compared to ASA alone started within 24 hours of stroke onset. Patients in the combination group demonstrated a reduced risk of recurrent stroke up to the 1-year follow-up.[31]

▶ *Nonpharmacologic Therapy*

Carotid Endarterectomy It is not well established whether carotid endarterectomy (CEA; removal of a thrombus from the carotid artery) is of value when performed emergently or urgently after stroke, meaning within the first 24 hours after symptom onset.[14] Recent trials have concluded that patients with TIA or mild to moderate stable stroke undergoing CEA within 48 hours may have an acceptable surgical risk. However, patients with unstable neurological status and more severe strokes demonstrated worse outcomes.[14,32] More research is needed to delineate the role of CEA in acute treatment.

Endovascular Treatment A focused update of the current stroke treatment guidelines was recently published to provide guidelines on the role of endovascular therapy in acute ischemic stroke.[27] These guidelines provide additional data on the safety and efficacy of endovascular therapy based on the results of recent clinical trials. IV alteplase should not be withheld if indicated, even if endovascular treatments are being considered. The majority of patients in these trials received IV alteplase initially followed by endovascular therapy. Patients meeting specific criteria should receive endovascular therapy, with new-generation **stent retrievers** preferred over the coil retriever and aspiration devices. Stent retrievers provide immediate restoration of blood flow through expansion of the stent at the site of occlusion and clot removal as the stent is removed. Criteria include a prestroke modified Rankin Score of 0 to 1, IV alteplase use within 4.5 hours of symptom onset, age 18 years and older, causative occlusion of the internal carotid artery or proximal middle cerebral artery, NIHSS score of 6 or greater, Alberta Stroke Program Early CT (ASPECT) score 6 or greater, and treatment within 6 hours of symptom onset. Endovascular therapy using stent retrievers plus standard care with IV alteplase, when appropriate, may improve outcomes in select patients with acute ischemic stroke due to large vessel occlusion, if administered within 6 hours of symptom onset. More rapid endovascular treatment has also shown better clinical outcomes.[27]

Secondary Prevention Following an Ischemic Stroke

Secondary prevention is aimed at preventing another stroke in patients that have had an initial stroke and is an important component of treatment. Once the acute ischemic stroke has been managed, typically within the first 24 to 48 hours after symptom onset, the focus shifts to secondary prevention and developing plans to prevent another stroke and manage risk factors. Antiplatelet and anticoagulant agents should be held for 24 hours following alteplase administration.

▶ *Nonpharmacologic Therapy*

LO 8

Carotid Endarterectomy The benefit of CEA for prevention of recurrent stroke has been studied in major clinical trials including a meta-analysis.[33,34] CEA is recommended to prevent **ipsilateral** stroke in patients with symptomatic carotid artery stenosis of 70% or greater when the surgical risk is less than 6%. In patients with symptomatic stenosis of 50% to 69%, a moderate reduction in risk is seen in clinical trials. CEA is recommended when anesthesia risk is low based on patient factors including age, sex, and comorbidities, and surgical risk is less than 6%. CEA is not beneficial for symptomatic carotid stenosis less than 50% and should not be considered in these patients. Patients with asymptomatic carotid artery stenosis of 70% or more may benefit from CEA if surgical complication rates for stroke, MI, and death are low.[35]

LO 8

Carotid Angioplasty Carotid angioplasty with **stenting** has evolved as a less invasive procedure with shorter recovery times for appropriate patients. Several trials have compared carotid angioplasty with stenting to CEA in symptomatic patients. Carotid angioplasty with stenting is an alternative to CEA in high-risk surgical candidates with greater than 50% stenosis by angiography and greater than 70% stenosis by noninvasive imaging when performed by skilled clinicians.[10] Age is an important factor when deciding between carotid angioplasty with stenting and CEA. Patients older than 70 years may have improved outcomes with CEA compared to carotid angioplasty with stenting. In patients younger than 70 years, CEA and carotid angioplasty with stenting have similar risks for stroke, MI, and death and also similar rates for ipsilateral stroke.[36]

▶ *Pharmacologic Therapy*

LO 8

Aspirin ASA decreases risk of subsequent stroke by approximately 22% in both men and women with previous TIA or stroke.[37] Therefore, ASA is an option for initial therapy for secondary prevention of ischemic stroke. A wide range of doses have been used (50–1500 mg/day); however, the FDA has approved doses of 50 to 325 mg for secondary ischemic stroke prevention. Current guidelines recommend varying ASA doses including 75 to 100 mg daily and 50 to 325 mg daily.[18,36] Lower ASA doses are currently recommended to decrease the risk of bleeding complications.[18] Adverse effects of ASA include gastrointestinal (GI) intolerance, GI bleeding, and hypersensitivity reactions.

Clopidogrel Clopidogrel is slightly more effective than ASA and similar in efficacy to the combination of extended-release (ER) dipyridamole plus ASA.[38,39] The usual dose is 75 mg orally taken once daily. There have been 11 case reports of **thrombotic thrombocytopenic purpura** (TTP) occurring secondary to clopidogrel. Most occurred within the first 2 weeks of therapy; therefore, clinicians need to be aware of the potential for the development of TTP with clopidogrel. Proton pump inhibitors may decrease the effectiveness of clopidogrel. An H_2-blocker

may be preferred in patients who require both acid suppression and clopidogrel.[40] Patients with a genetic variant of cytochrome P450 (CYP) 2C19 classified as poor metabolizers may have a decrease in the active metabolite of clopidogrel, potentially requiring increased doses.[41] Clopidogrel is an option for initial monotherapy for secondary prevention of ischemic stroke and is considered first-line therapy in patients who also have peripheral arterial disease or are allergic to ASA.

LO 8

Extended-Release Dipyridamole Plus Aspirin Combination therapy with ER dipyridamole plus ASA has been found to be more effective in preventing stroke than either agent alone.[42] Headache and diarrhea were common adverse effects of dipyridamole; bleeding was more common in all treatment groups that included ASA. A trial comparing the combination of ER dipyridamole plus ASA to clopidogrel found no difference in outcomes; however, adverse events occurred more frequently in the combination of ER dipyridamole plus ASA group.[38] The currently available formulation is a combination product containing 25 mg ASA and 200 mg ER dipyridamole. This combination is an option for initial therapy for secondary stroke prevention, but is not appropriate for patients who are intolerant to ASA.

LO 8

Current Clinical Trials Clinical trials have been completed to evaluate other combinations of antiplatelet agents and to compare them against one another. Low-dose ASA plus clopidogrel combination therapy did not show a significant benefit in reducing recurrent stroke compared with clopidogrel alone and increased the risk of major bleeding.[43]

More recently, two trials have evaluated early initiation (within 24 hours) of the combination of ASA and clopidogrel and its effect in the months following a TIA or minor stroke.[44,45] One trial demonstrated a trend toward a reduction in ischemic events; however, the trial was stopped early due to low enrollment.[44] The second trial demonstrated a reduced risk of stroke in the first 90 days after stroke onset in the combination group compared to ASA alone. Based on this trial, the combination of ASA and clopidogrel may be considered within 24 hours of a TIA or minor stroke and continued for 90 days.[45] Continuation beyond 90 days is not recommended due to an increased risk of hemorrhage and lack of benefits as seen in other trials.[43]

Summary of Antiplatelet Therapy for Secondary Stroke Prevention KEY CONCEPT Current stroke treatment guidelines recommend ASA or combination therapy with ER dipyridamole plus ASA as initial antiplatelet therapy for the secondary prevention of stroke. Clopidogrel is another option for initial treatment and is recommended in patients unable to tolerate ASA and those with peripheral arterial disease.[18,36] Initial choice of agent should be individualized based on patient factors and cost. Therapeutic failure in this patient population is challenging because no data are available to guide a treatment decision. When a patient is on therapeutic doses of ASA, yet experiences a recurrent TIA or stroke, switching to either clopidogrel or the combination of ER dipyridamole and ASA is a reasonable option. If failure occurs on either clopidogrel or the combination of ASA and ER dipyridamole, switching to the alternate drug may be appropriate.

Oral Anticoagulants Recent clinical trials have not found oral anticoagulation to be better than antiplatelet therapy in those patients without AF or carotid stenosis. In patients without AF, antiplatelet therapy is recommended over oral anticoagulants for secondary prevention of stroke. On the other hand, patients with AF and a previous TIA or stroke have the highest risk of recurrent stroke. Long-term anticoagulation with warfarin or other newer agents is effective and therefore recommended in the primary and secondary prevention of cardioembolic stroke.[18,36] The newer oral anticoagulants have only been studied for stroke prevention in nonvalvular AF. The goal INR when monitoring warfarin for this indication is 2 to 3. Refer to Chapter 9, "Arrhythmias," for more information on stroke prevention in AF.

Patient Encounter Part 3

The patient has been in the ICU for 24 hours and is still experiencing weakness in her left arm and continues to have difficulty speaking at times. She will be transferred out of the stroke unit and admitted to a medicine floor for medical management and discharge planning.

What treatments would you recommend to reduce the risk of another stroke in the next 24–48 hours?

What treatments would you recommend at discharge to reduce the risk of another stroke?

▶ *Blood Pressure Management*

Hypertension is a major risk factor for stroke, and BP control is an important strategy for secondary stroke prevention. Current stroke guidelines and the 2017 hypertension guidelines recommend initiation of antihypertensive treatment for untreated patients with TIA or stroke and an established BP of 140/90 mm Hg or greater. Patients previously treated with antihypertensives should be reinitiated on therapy several days after acute ischemic stroke. The optimal regimen to achieve the BP goal has not been established. Diuretics, either alone or in combination with an ACE-I, have been shown to be beneficial in reducing stroke recurrence.[9,36]

▶ *Other Recommendations*

Management of diabetes and lipids based on treatment guidelines, cessation of smoking, increased physical activity, and reducing alcohol use in heavy drinkers are additional recommendations for management of patients with previous stroke or TIA.[36] Statin therapy is recommended in patients with previous stroke or TIA, regardless of history of coronary heart disease. Table 11–5 provides drug and dosing recommendations for treatment of ischemic stroke.

Treatment of Acute Hemorrhagic Stroke

▶ *Supportive Measures*

Acute hemorrhagic stroke is considered to be a medical emergency due to ICH, SAH, or subdural hematoma. Initially, patients experiencing a hemorrhagic stroke should be transported to a neurointensive care unit. KEY CONCEPT There is no proven treatment for ICH. Management is based on neurointensive care treatment and prevention of complications. Treatment should be provided to manage the needs of the critically ill patient including management of increased ICP, seizures, infections, and prevention of rebleeding and delayed cerebral ischemia. In those with severely depressed consciousness, rapid endotracheal intubation and mechanical ventilation may be necessary. BP is often elevated after hemorrhagic stroke; appropriate management is important to prevent rebleeding and expansion of the hematoma. In patients presenting with SBP greater than 220 mm Hg, BP lowering using

LO 9

Table 11–5

Recommendations for Pharmacotherapy of Ischemic Stroke

	Primary Agents	Alternatives
Acute treatment	Alteplase 0.9 mg/kg IV (maximum dose 90 mg); 10% as IV bolus, remainder infused over 1 hour in select patients within 4.5 hours of onset	Alteplase (various doses) intraarterially within 6 hours after onset in select patients
	ASA 160–325 mg started within 48 hours of onset; hold for 24 hours if alteplase given (may reduce dose to 50–100 mg daily after 48 hours)	If minor stroke or TIA, ASA 75 mg plus clopidogrel 75 mg daily started within 24 hours of onset
Secondary prevention (noncardioembolic stroke)	ASA 50–325 mg daily ASA 25 mg + ER dipyridamole 200 mg twice daily	Clopidogrel 75 mg daily
Cardioembolic	Warfarin (INR 2–3) Dabigatran 150 mg twice daily; decrease to 75 mg twice daily if creatinine clearance is 15–30 mL/min (0.25–0.50 mL/s) Apixaban 5 mg twice daily; decrease to 2.5 mg twice daily if patient has at least two of the following: age ≥ 80 years, weight ≤ 60 kg (132 lb) or serum creatinine ≥ 1.5 mg/dL (133 µmol/L)	Rivaroxaban 20 mg daily with the evening meal; decrease to 15 mg daily with the evening meal if creatinine clearance 15–50 mL/min (0.25–0.83 mL/s)
All patients	BP control Statin therapy	

ASA, aspirin; BP, blood pressure; ER, extended-release; INR, international normalized ratio; IV, intravenous; TIA, transient ischemic attack.

continuous IV infusion is recommended.[9,46] When SBP is between 150 and 220 mm Hg, lowering of the SBP to less than 140 mm Hg does not improve outcomes and may cause harm compared to a less aggressive BP-lowering goal in the acute period.[9,47] BP can be controlled with IV boluses of labetalol 10 to 80 mg every 10 minutes up to a maximum of 300 mg or with IV infusions of labetalol (0.5–2 mg/min) or nicardipine (5–15 mg/hour). Deep vein thrombosis prophylaxis with intermittent compression stockings should be implemented early after admission. In those patients with SAH, once the aneurysm has been treated, heparin may be instituted. In ICH patients with lack of mobility after 1 to 4 days, heparin or LMWH may be started.[46,48]

► *Nonpharmacologic Therapy*

LO 9

Patients with hemorrhagic stroke are evaluated for surgical treatment of SAH and ICH. In SAH, either clipping of the aneurysm or coil embolization is recommended within 72 hours after the initial event to prevent rebleeding. Coil embolization, also called coiling, is a minimally invasive procedure in which a platinum coil is threaded into the aneurysm. The flexible coil fills up the space to block blood flow into the aneurysm thereby preventing rebleeding. Surgical removal of the hematoma in patients with ICH is controversial because trials have not consistently shown improved outcomes. Minimally invasive clot removal techniques have been evaluated; however, these procedures are considered investigational because outcomes are not certain. Current guidelines note that surgical treatment of ICH is uncertain and is not recommended except in specific patient situations.[46]

► *Pharmacologic Therapy*

LO 9

Calcium Antagonists Oral nimodipine is recommended in SAH to prevent delayed cerebral ischemia. It is recommended to begin oral nimodipine promptly after the initial event, but no later than 96 hours following SAH. Delayed cerebral ischemia occurs 4 to 14 days after the initial aneurysm rupture and is a common cause of neurological deficits and death. Nimodipine 60 mg orally every 4 hours for 21 days following aneurysmal SAH reduces the risk of a poor outcome and delayed cerebral ischemia.

Hemostatic Therapy A meta-analysis evaluating five clinical trials found that recombinant factor VIIa decreases the growth of the hematoma, but did not improve survival or functional outcome. A higher incidence of thromboembolic events was also seen.[49] Current guidelines do not recommend treatment with recombinant factor VIIa due to an uncertain benefit and increased risk of thromboembolic events.[46]

OUTCOME EVALUATION

- Stroke outcomes are measured based on neurological status and functioning of the patient after the acute event.
- Early rehabilitation can reduce functional impairment after a stroke. Stroke rehabilitation guidelines have been endorsed by the American Heart Association and American Stroke Association. These guidelines recommend that patients receive care in a multidisciplinary setting or stroke unit, receive early assessment using the NIHSS, and that rehabilitation is started as soon as possible after the stroke. Other recommendations include screening for dysphagia (difficulty in swallowing) and aggressive secondary stroke prevention treatments.[50]
- Continued effort has been placed on stroke systems of care and developing mechanisms for more urgent assessment and treatment of suspected stroke.
- Table 11–6 provides monitoring guidelines for the acute stroke patient.

Table 11–6

Monitoring the Stroke Patient

Treatment	Parameter(s)	Monitoring Frequency	Comments
Ischemic Stroke			
All stroke patients	CT scan	Upon arrival	
	Neurologic examination		
	BP	Every 5 minutes × 3	
Alteplase			
	CT scan	24 hours after alteplase infusion	
	BP	Every 15 minutes × 2 hours, every 30 min × 6 hours, every 1 hour × 16 hours; then every shift	
	Neurologic function	Neurological examination every 15 minutes × 2 hours, every 30 min × 6 hours, every 1 hour × 16 hours; NIHSS 24 hours after alteplase infusion and at discharge	
	Bleeding	Clinical signs of bleeding every 2 hours × 24 hours	
ASA	Bleeding Hb/Hct, platelets[a]	Daily	
Clopidogrel	Bleeding Hb/Hct, platelets[a]	Daily	
ASA/ER dipyridamole	Headache, bleeding Hb/Hct, platelets[a]	Daily	
Warfarin	Bleeding, INR, Hb/Hct[a]	INR daily × 3 days; weekly until stable; then monthly	
New oral anticoagulants	Bleeding Hb/Hct, renal and liver function	Each visit Yearly; if decreased renal function, every 3–6 months	
Hemorrhagic Stroke			
	BP, neurologic function, ICP	Every 2 hours in ICU	May require treatments to lower systolic BP to < 180 mm Hg
Nimodipine for SAH	BP, neurologic function, fluid status	Every 2 hours in ICU	

[a]Hb/Hct and platelets should be monitored at baseline and every 6 months for ASA, clopidogrel, ASA/ER dipyridamole, and warfarin treatment.

ASA, aspirin; BP, blood pressure; CT, computed tomography; ER, extended-release; Hb, hemoglobin; Hct, hematocrit; ICP, intracranial pressure; ICU, intensive care unit; INR, international normalized ratio; NIHSS, National Institutes of Health Stroke Scale; SAH, subarachnoid hemorrhage.

Patient Care Process

Collect Information:

- Assess signs and symptoms including time of symptom onset and time of arrival in the emergency department, obtaining information from patient or family members. Time the patient was last known to be well is used as the stroke onset time.
- Review results of completed prehospital stroke screening tests.
- Review the neurological and physical examination findings, including the NIHSS, evaluating for potential causes of stroke.
- Perform a comprehensive medication history, obtaining information from patient or family members.
- Determine the patient's baseline functional status.
- Determine the patient's risk factors for stroke.

Assess the Information:

- Determine if patient is experiencing an acute ischemic stroke.
- Determine if thrombolytic therapy is indicated based on inclusion and exclusion criteria.
- Review relevant laboratory tests (eg, BP, temperature, glucose, oxygen saturation).
- Assess the patient's weight.
- Review CT or MRI scan results to rule out a hemorrhagic stroke.
- Review the results of other diagnostic tests (eg, ECG, Doppler studies).
- Evaluate the inclusion and exclusion criteria for fibrinolytic therapy.
- Evaluate patient for IV and endovascular treatment acutely.

(*Continued*)

Patient Care Process (*Continued*)

Develop a Care Plan:

- Manage the patient's airway, breathing, and circulation (ABCs) initially in the acute phase of treatment.
- Transfer the patient to a stroke center if available.
- Begin IV alteplase if patient is within 4.5 hours of the onset of symptoms and meets the inclusion and exclusion criteria.
- Hold other anticoagulants and antiplatelet agents for 24 hours after the infusion of alteplase.
- Begin antiplatelet therapy to prevent a recurrent stroke.
- Manage patient's stroke risk factors.

Implement the Care Plan:

- If fibrinolytic therapy is indicated, initiate treatment protocol for alteplase administration and follow recommended monitoring plan.
- Develop a plan for long-term management of risk factors to prevent a recurrent stroke.
- Educate the patient on risk factors and lifestyle factors to reduce the risk of stroke recurrence.
- Educate the patient on the importance of adherence to their medication regimen.

Follow-up: Monitor and Evaluate:

- Monitor the patient's BP and neurological status every 15 minutes × 2 hours, every 30 minutes × 6 hours and then every hour for 24 hours after alteplase infusion.
- Obtain a follow-up CT scan 24 hours after the alteplase infusion.
- Evaluate functional status 24 hours after the alteplase infusion.
- Monitor patient's risk factors poststroke.

Abbreviations Introduced in This Chapter

ABCs	Airway, breathing, and circulation
ACE-I	Angiotensin-converting enzyme inhibitor
ADP	Adenosine diphosphate
AF	Atrial fibrillation
aPTT	Activated partial thromboplastin time
ARB	Angiotensin receptor blocker
ASA	Aspirin
ASCVD	Atherosclerotic cardiovascular disease
ASPECT	Alberta Stroke Program Early CT
AVM	Arteriovenous malformation
BP	Blood pressure
CCB	Calcium channel blocker
CEA	Carotid endarterectomy
CNS	Central nervous system
CT	Computed tomography
CVD	Cardiovascular disease
CYP	Cytochrome P450
DBP	Diastolic blood pressure
ECG	Electrocardiogram
ECT	Ecarin clotting time
ER	Extended-release
FDA	Food and Drug Administration
GI	Gastrointestinal
HB	Hemoglobin
HCT	Hematocrit
IA	Intraarterial
ICH	Intracerebral hemorrhage
ICP	Intracranial pressure
ICU	Intensive care unit
INR	International normalized ratio
IV	Intravenous
LMWH	Low molecular weight heparin
MI	Myocardial infarction
MRI	Magnetic resonance imaging
NIHSS	National Institutes of Health Stroke Scale
NINDS	National Institute of Neurological Disorders and Stroke
PT	Prothrombin time
rt-PA	Alteplase
r-pro UK	Pro-urokinase
SAH	Subarachnoid hemorrhage
SBP	Systolic blood pressure
TIA	Transient ischemic attack
TTP	Thrombotic thrombocytopenic purpura
TT	Thrombin time
UFH	Unfractionated heparin
VTE	Venous thromboembolism

12 Dyslipidemias

Joel C. Marrs

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Identify the common types of lipid disorders.
2. Identify the statin-benefit groups and intensity of statin therapy according to the American College of Cardiology/American Heart Association.
3. Recommend appropriate therapeutic lifestyle changes (TLC) and pharmacotherapy interventions for dyslipidemia.
4. Determine a patient's atherosclerotic cardiovascular disease risk and corresponding treatment goals according to the National Lipid Association, American Association of Clinical Endocrinologist/American College of Endocrinology, and American College of Cardiology.
5. Identify patients who are indicated for nonstatin therapy according to the American College of Cardiology.
6. Describe components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for dyslipidemias.
7. Educate patients about the disease state, appropriate TLC, and drug therapy required for effective treatment.

INTRODUCTION

KEY CONCEPT

Hypercholesterolemia or dyslipidemia play a major role in atherosclerosis and plaque formation leading to coronary heart disease (CHD) as well as other forms of atherosclerotic cardiovascular disease (ASCVD), such as carotid and peripheral artery disease.[1] CHD is the leading cause of death in adults in the United States and most industrialized nations. It is also the chief cause of premature, permanent disability in the US workforce.

EPIDEMIOLOGY AND ETIOLOGY

It is estimated that 94.6 million US adults have high cholesterol with a value of 200 mg/dL (5.17 mmol/L) or greater.[2] Further, one out of every three US adults has a high level of low-density lipoprotein (LDL) cholesterol.[2] Elevated cholesterol values are a major risk factor for the development of ASCVD. Annually, approximately 580,000 Americans experience a new heart attack and 210,000 will have a recurrent event.[2] Lowering cholesterol reduces atherosclerotic progression and mortality from CHD and stroke. The development of CHD is a lifelong process. Except in rare cases of severely elevated serum cholesterol levels, years of poor dietary habits, sedentary lifestyle, and life-habit risk factors (eg, smoking, overweight/obesity) contribute to the development of atherosclerosis.[3]

PATHOPHYSIOLOGY

Cholesterol and Lipoprotein Metabolism

Cholesterol, an essential substance manufactured by most cells in the body, is used to maintain cell wall integrity and for the biosynthesis of bile acids and steroid hormones. Cholesterol, triglycerides, and phospholipids circulate in the blood as lipoproteins (Figure 12–1). The major lipoproteins are chylomicrons, very low-density lipoprotein (VLDL), intermediate-density lipoprotein (IDL), LDL, and high-density lipoprotein (HDL). Each lipoprotein has various proteins called apolipoproteins (Apos) embedded on the surface (Figure 12–1) that serve four main purposes: (a) required for assembly and secretion of lipoproteins; (b) serve as major structural components of lipoproteins; (c) act as ligands for binding to receptors on cell surfaces; and (d) can be cofactors for inhibition of enzymes involved in the breakdown of triglycerides from chylomicrons and VLDL.[4]

A measured total cholesterol is the total cholesterol molecules in all these major lipoproteins. The estimated value of LDL cholesterol is found using the Friedewald equation (after fasting for 9–12 hours):

LDL cholesterol (mg/dL) = total cholesterol – (HDL cholesterol + triglycerides/5), when lipids are expressed in units of mg/dL;

or

LDL cholesterol (mmol/L) = total cholesterol – (HDL cholesterol + triglycerides/2.2), when lipids are expressed in units of mmol/L

Where triglycerides/5 or triglycerides/2.2 estimate VLDL cholesterol in units of mg/dL or mmol/L, respectively.

This formula becomes inaccurate if serum triglycerides are greater than 400 mg/dL (4.52 mmol/L), if chylomicrons are present, or the patient has familial dysbetalipoproteinemia.

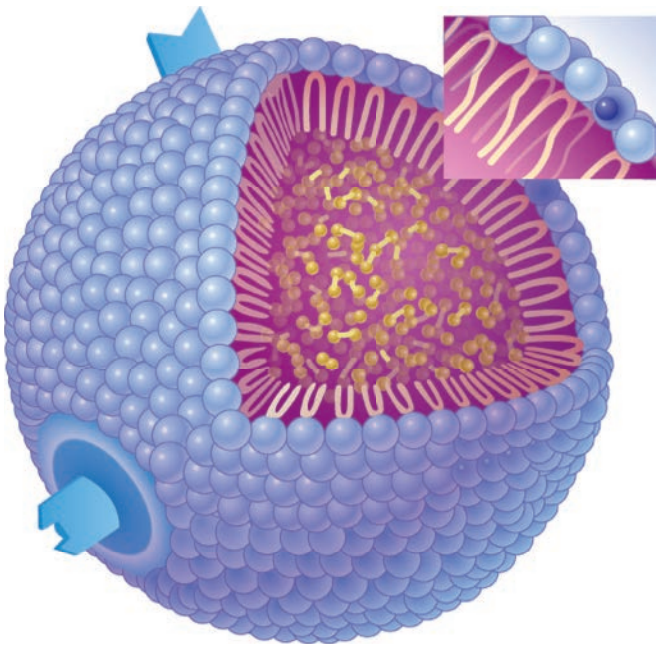

FIGURE 12–1. Lipoprotein structure. Lipoproteins are a diverse group of particles with varying size and density. They contain variable amounts of core cholesterol esters and triglycerides, and have varying numbers and types of surface apolipoproteins (Apos). The Apos function to direct the processing and removal of individual lipoprotein particles.

In each of these cases, LDL cholesterol must be directly measured, which can be done for any patient at most labs.[3] Non-HDL cholesterol is carried by all atherogenic Apos B-containing lipoproteins including VLDL, IDL, and LDL. It is calculated as:

Non-HDL cholesterol = total cholesterol – HDL cholesterol

Non-HDL cholesterol can be determined in a nonfasting state.

Cholesterol from the diet as well as from bile enters the small intestine and is emulsified by bile salts into micelles (Figure 12–2), which are microscopic particles of digested fat and cholesterol. These micelles interact with the **duodenal enterocyte** and **jejunal enterocyte** surfaces, and cholesterol is transported from the micelles into enterocytes by the Niemann-Pick C1 Like 1 (NPC1L1) transporter. Cholesterol within enterocytes is esterified and packaged into chylomicrons along with triglycerides, phospholipids, and Apos, which are then released into the **lymphatic** circulation. In the lymph and blood, chylomicrons are converted to chylomicron remnants. During this process, referred to as reverse cholesterol transport, chylomicrons also interact with HDL particles (Figure 12–3) and exchange triglyceride and cholesterol content (facilitated by cholesterol ester transfer protein, or CETP), and HDL particles acquire Apos A and C. Chylomicron remnant particles are then taken up by LDL-related protein (LRP).

In the liver, cholesterol and triglycerides are incorporated into VLDL along with phospholipids and Apo B-100 (Figure 12–4). VLDL loses its triglyceride content through interaction with

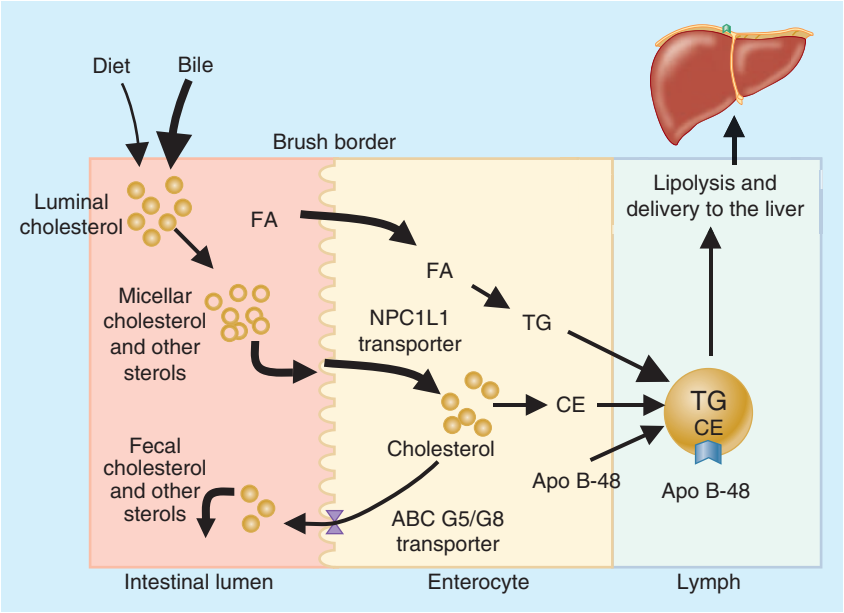

FIGURE 12–2. Intestinal cholesterol absorption and transport. Cholesterol from food and bile enters the gut lumen and is emulsified by bile acids into micelles. Micelles bind to the intestinal enterocytes, and cholesterol and other sterols are transported from the micelles into the enterocytes by a sterol transporter. Triglycerides synthesized by absorbed fatty acids, along with cholesterol and Apo B-48, are incorporated into chylomicrons. Chylomicrons are released into the lymphatic circulation and converted to chylomicron remnants (through loss of triglyceride), and then taken up by the hepatic LDL receptor-related protein (LRP). (ABC G5/G8, ATP-binding cassette G5/G8; Apo, apolipoprotein; CE, cholesterol ester; FA, fatty acid; LDL, low-density lipoprotein; NPC1L1, Niemann-Pick C1 Like 1; TG, triglyceride.)

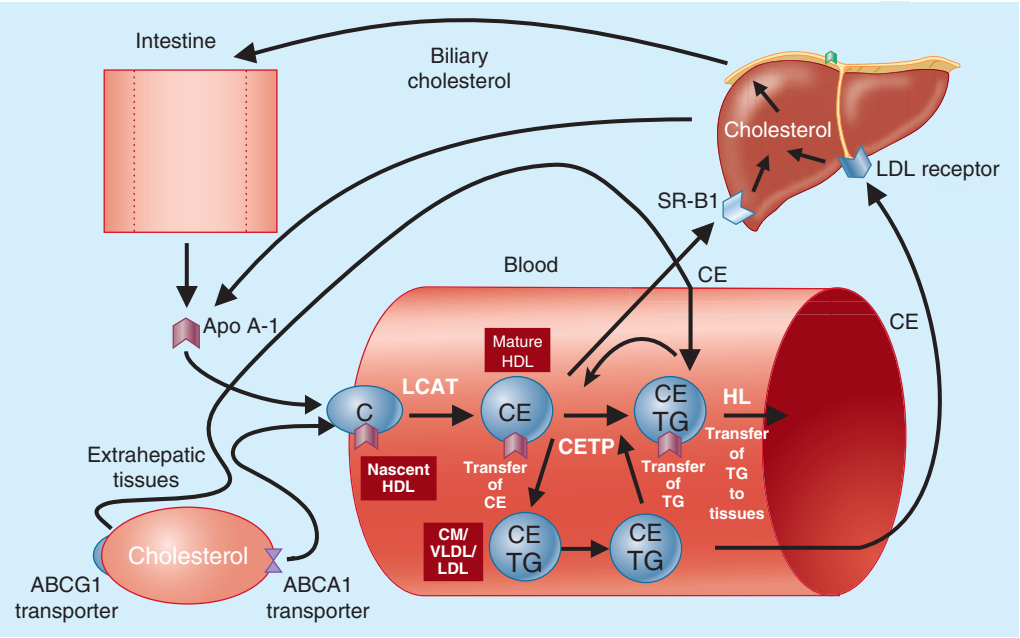

FIGURE 12–3. Reverse cholesterol transport. Cholesterol is transported from the arterial wall or other extrahepatic tissues back to the liver by HDL. Esterified cholesterol from HDL can be transferred to Apo B–containing particles in exchange for triglycerides. Cholesterol esters transferred from HDL to VLDL and LDL are taken up by hepatic LDL receptors or delivered back to extrahepatic tissue. (ABCA1, ATP-binding cassette A1; ABCG1, ATP-binding cassette G1; Apo, apolipoprotein; C, cholesterol; CE, cholesterol ester; CETP, cholesterol ester transfer protein; CM, chylomicrons; HDL, high-density lipoprotein; HL, hepatic lipase; LCAT, lecithin-cholesterol acyltransferase; LDL, low-density lipoprotein; SR-B1, scavenger receptors; TG, triglyceride; VLDL, very low-density lipoprotein.)

lipoprotein lipase (LPL) to form VLDL remnant and IDL. IDL can be cleared from the circulation by hepatic LDL receptors or further converted to LDL (by further depletion of triglycerides) through the action of hepatic lipases (HLs). Approximately 50% of IDL is converted to LDL. LDL particles are cleared from the circulation primarily by hepatic LDL receptors by interaction with Apo B-100. They can also be taken up by extrahepatic tissues or enter the arterial wall, contributing to atherogenesis. Biosynthesis of cholesterol is directly regulated by the amount of cholesterol present in an individual. Therefore, higher ingestion of cholesterol through food consumption results in decreased production of endogenous cholesterol in the liver. In the liver, cholesterol is produced through the mevalonate pathway (Figure 12–4) where the production of mevalonate is the rate-limiting and irreversible step in cholesterol synthesis. 3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) is converted to mevalonate by HMG-CoA reductase (site of action for statins).

Cholesterol is transported from the arterial wall or other extrahepatic tissues back to the liver by HDL (Figure 12–3). Triglyceride-rich HDL is hydrolyzed by HL, generating fatty acids (FA) and nascent (immature) HDL particles, or mature HDL can bind to scavenger receptors (SR-BI) on hepatocytes and transfer their cholesterol ester content for excretion in the bile.

LO 1

A variety of genetic mutations can occur during lipoprotein synthesis and metabolism that cause lipid disorders. The major genetic disorders and their effect on serum lipids are presented in Table 12–1. Disorders that increase serum cholesterol are generally those that affect the number or affinity of LDL receptors and are known as familial hypercholesterolemia (FH). These patients commonly present with **corneal arcus** of the eye, **xanthomas** of extensor tendons of the hand and Achilles tendon, premature CHD, and/or have a first or second degree relative with raised cholesterol and/or premature CHD. Elevations in triglycerides are generally associated with overproduction of triglyceride-rich VLDL, mutations in Apo E, or lack of LPL or Apo CII, which causes hyperchylomicronemia. Most individuals have mild to moderate elevations in cholesterol known as polygenic hypercholesterolemia, thought to be caused by various more subtle genetic defects as well as environmental factors such as diet, sedentary lifestyle, and overweight/obesity.[3]

Pathophysiology of Clinical Atherosclerotic Cardiovascular Disease

Lipoproteins are the "root cause" of atherosclerosis. The process begins when lipoproteins migrate between the **endothelial cells** into the arterial wall where they are modified by oxidation (Figure 12–5). Oxidized lipoproteins promote endothelial dysfunction by disturbing the production of nitric oxide, an endogenous vasodilator that maintains vasomotor tone, as well as increasing expression of cell-adhesion molecules on vascular endothelial cells leading to recruitment of monocytes (a variety of white blood cells) into the intima (inner layer of the wall of an artery or vein). Monocytes differentiate into macrophages (large scavenger cells) and express SR-BI, allowing enhanced uptake of these oxidized lipoproteins. The macrophages continue to accumulate lipoproteins and ultimately develop into lipid-laden **foam cells**. Accumulation of foam cells leads to formation of a lipid-rich core, which marks the transition to a more complicated atherosclerotic plaque. Such plaques may result in ischemic heart disease and **acute coronary syndromes**, further discussed in Chapters 7 and 8, respectively. Aggressive lipid lowering can restore endothelial function, decrease cardiovascular disease (CVD) risk, and improve patient cardiovascular (CV) outcomes.[3,5]

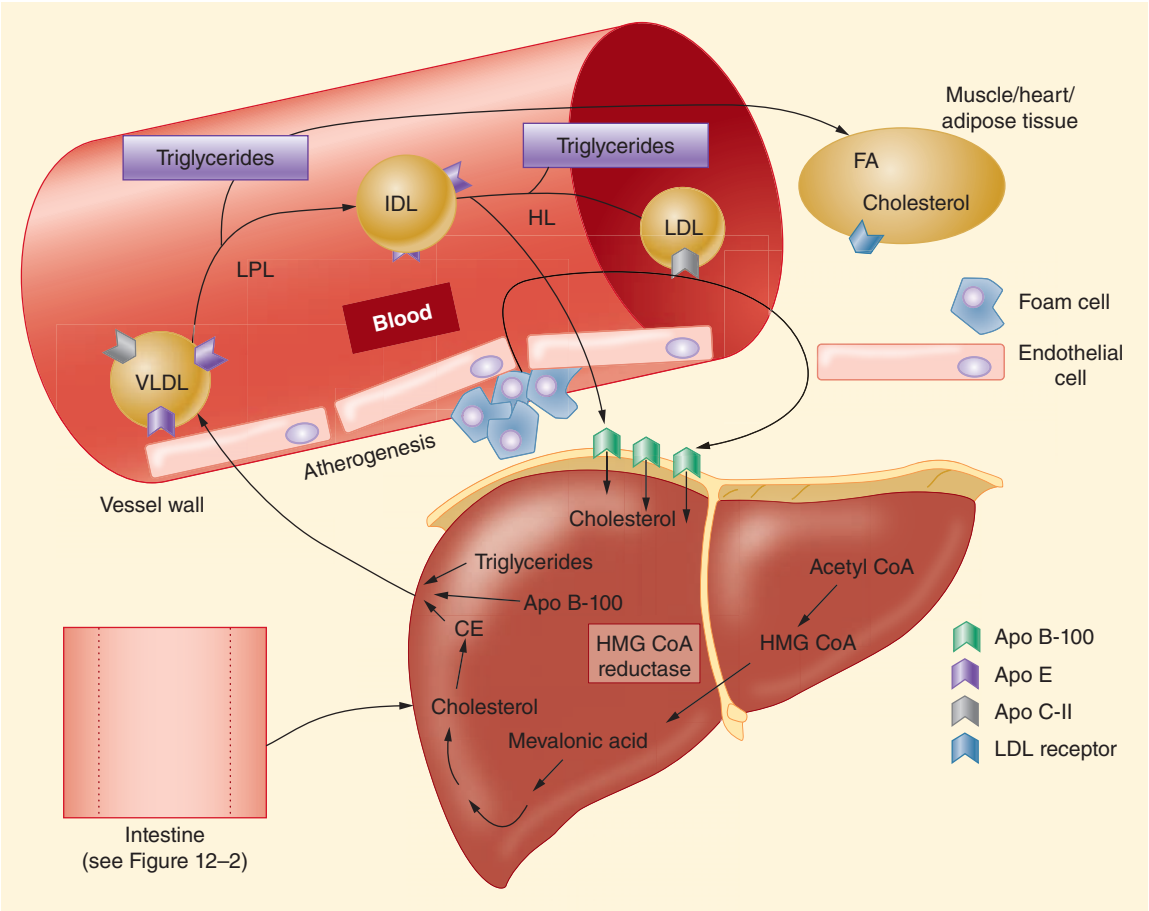

FIGURE 12–4. Endogenous lipoprotein metabolism. In liver cells, cholesterol and triglycerides are packaged into VLDL particles and exported into blood where VLDL is converted to IDL. Intermediate-density lipoprotein can be either cleared by hepatic LDL receptors or further metabolized to LDL. LDL can be cleared by hepatic LDL receptors or can enter the arterial wall, contributing to atherosclerosis. (Acetyl CoA, acetyl coenzyme A; Apo, apolipoprotein; CE, cholesterol ester; FA, fatty acid; HL, hepatic lipase; HMG-CoA, 3-hydroxy-3-methyglutaryl coenzyme A; IDL, intermediate-density lipoprotein; LDL, low-density lipoprotein; LPL, lipoprotein lipase; VLDL, very low-density lipoprotein.)

Table 12–1

Selected Characteristics of Primary Dyslipidemias

Disorder	Estimated Frequency	Metabolic Defect	Main Lipid Parameter
Autosomal dominant hypercholesterolemia			
Familial hypercholesterolemia homozygous	1/250,000–1/1 million	LDL-receptor negative	LDL-C > 500 mg/dL (12.93 mmol/L)
Heterozygous	1/250–1/500	Reduction in LDL receptors	LDL-C 250–500 mg/dL (6.47–12.93 mmol/L)
Familial defective Apo B-100	1/1000	Single nucleotide mutation	LDL-C 250–500 mg/dL (6.47–12.93 mmol/L)
PCSK9 gain of function mutations	Rare	Single nucleotide mutation	LDL-C 250–500 mg/dL (6.47–12.93 mmol/L)
Polygenic hypercholesterolemia	Common	Metabolic and environmental	LDL-C 160–250 mg/dL (4.14–6.47 mmol/L)
Familial combined dyslipidemia	1/200–300	Overproduction of VLDL and/or LDL	LDL-C 250–350 mg/dL (6.47–9.05 mmol/L) TG 200–800 mg/dL (2.26–9.04 mmol/L)
Familial hyperapobetalipoproteinemia	5%	Increase Apo B production	Apo B > 125 mg/dL (1.25 g/L)
Familial dysbetalipoproteinemia (Type III)	0.5%	Apo E2/2 phenotype	LDL-C 300–600 mg/dL (7.76–15.52 mmol/L)
Familial hypertriglyceridemia			
Type I	1/500,000–1/1 million	LPL-Apo CII system	TG > 1000 mg/dL (11.3 mmol/L)
Type IV	1/300	Unknown	TG 200–500 mg/dL (2.26–5.65 mmol/L)
Type V	1/205,000	Metabolic and environmental	TG > 1000 mg/dL (11.3 mmol/L)
Hypoalphalipoproteinemia	3%–5%	Defect in HDL catabolism	HDL-C < 35 mg/dL (0.91 mmol/L)

Apo, apolipoprotein; C, cholesterol; HDL, high-density lipoprotein; LDL, low-density lipoprotein; LPL, lipoprotein lipase; PCSK9, proprotein convertase subtilisin/kexin type 9; TG, triglyceride; VLDL, very low-density lipoprotein.

Clinical Presentation and Diagnosis

Physical Findings

- Dyslipidemia is usually asymptomatic.
- Corneal arcus of the eye and xanthomas may be seen in patients with genetic disorders that cause a marked increase in serum LDL cholesterol (> 250 mg/dL [6.47 mmol/L]).
- Those with extremely elevated serum triglycerides (> 1000 mg/dL [11.3 mmol/L]) can develop pancreatitis (inflammation of the pancreas) and tuberoeruptive xanthomas.

Indications for Lipid Panel

- All adults more than 20 years of age should be screened at least every 5 years using a fasting blood sample to obtain a lipid profile (total cholesterol, non-HDL cholesterol, LDL cholesterol, HDL cholesterol, and triglycerides). A fasting lipid profile is preferred so an accurate assessment of LDL cholesterol can be performed, but non-HDL cholesterol can accurately be assessed irrespective of fasting state.
- Children between 2 and 20 years old should be screened for high cholesterol if their parents have premature CHD or if one of their parents has a total cholesterol greater than 240 mg/dL (6.21 mmol/L). Early screening will help identify children at highest risk of developing CHD in whom early education and dietary intervention are warranted.

Lipid Panel

- Non-HDL cholesterol exceeding 130 mg/dL (3.36 mmol/L) or LDL cholesterol exceeding 100 mg/dL (2.59 mmol/L) should have an assessment of ASCVD risk.
- Serum triglycerides exceeding 150 mg/dL (1.70 mmol/L) and serum HDL cholesterol less than 40 mg/dL (1.03 mmol/L) in men and less than 50 mg/dL (1.29 mmol/L) in women may increase risk of ASCVD and should be evaluated.

Indications for Other Tests

- Conditions that may produce lipid abnormalities (such as those listed in **Table 12–2**) should be screened for using appropriate tests. If present, these conditions should be properly addressed as these can be secondary causes for dyslipidemia.

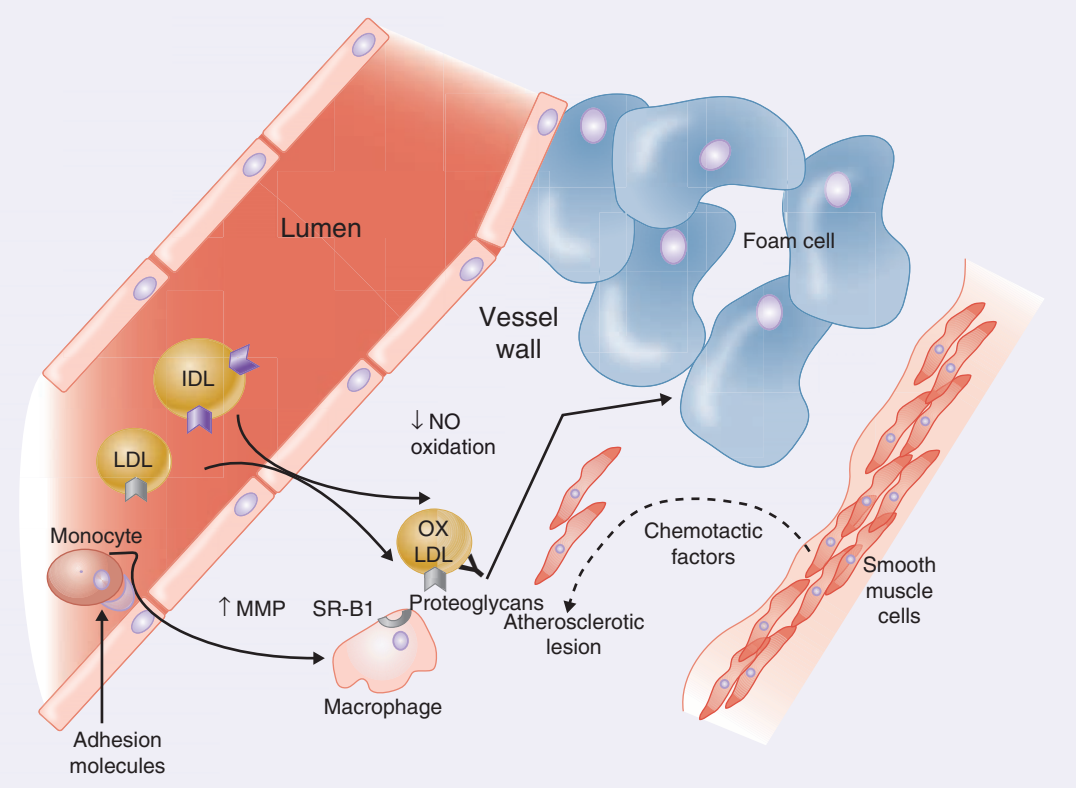

FIGURE 12–5. The process of atherogenesis. Atherosclerosis is initiated by the migration and retention of LDL and remnant lipoprotein particles into the vessel wall. These particles undergo oxidation and are taken up by macrophages in an unregulated fashion. The oxidized particles participate to induce endothelial cell dysfunction, leading to a reduced ability of the endothelium to dilate the artery and cause a prothrombotic state. The unregulated uptake of cholesterol by macrophages leads to foam cell formation and the development of a blood clot–favoring fatty lipid core. The enlarging lipid core eventually causes an encroachment of the vessel lumen. Early in the process, smooth muscle cells are activated and recruited from the media to the intima, helping to produce a collagen matrix that covers the growing clot protecting it from circulating blood. Later, macrophages produce and secrete matrix metalloproteinases that degrade the collagen matrix, leading to unstable plaque that may cause a myocardial infarction. (IDL, intermediate-density lipoprotein; LDL, low-density lipoprotein; MMP, matrix metalloproteinases; NO, nitric oxide; SR-B1, scavenger receptors.)

TREATMENT

The rate-limiting enzyme in cholesterol biosynthesis is HMG-CoA reductase. Isolation of a specific inhibitor of this enzyme resulted in the first marketed statin called lovastatin.[6,7] By reducing cholesterol synthesis, statins were shown to up-regulate the LDL receptor. Statins have now become the mainstay therapy for both familial and nonfamilial hypercholesterolemia.

In November 2013, the American College of Cardiology (ACC) and American Heart Association (AHA) released guidelines for treating high blood cholesterol to reduce risk of ASCVD in adults, which represented a paradigm shift in how clinicians had traditionally managed patients.[3] Major changes include identification of statin-benefit groups, removal of specific cholesterol treatment targets, and recommendations against nonstatin therapies in the general population due to lack of data supporting reduced ASCVD. The ACC/AHA guidelines shifted to a focus on statin-benefit groups versus other medical organizations recommending traditional cholesterol targets (eg, LDL goals, percent reduction in LDL) which are highlighted in Table 12–3.[3,8-11] In this chapter, the ACC/AHA guidelines,[3] the National Lipid Association (NLA) recommendations,[8] the 2016 ACC nonstatin expert consensus decision pathway (ECDP),[9] 2017 ACC updated ECDP,[10] and the American Association of Clinical Endocrinologists (AACE)/American College of Endocrinology (ACE) guidelines[11] will be reviewed.

LO 2

The ACC/AHA guidelines identify four groups of adult patients targeted for statin treatment (Figure 12–6), including:

- Established clinical ASCVD (secondary prevention)
- Primary prevention with elevation of LDL cholesterol levels 190 mg/dL (4.91 mmol/L) or higher

Table 12–3

2016 American College of Cardiology Expert Consensus Decision Pathway (EDCP) on the Role of Nonstatin Therapies for LDL-Cholesterol Lowering in the Management of Atherosclerotic Cardiovascular Disease Risk (2016)[9] and 2017 Update (2017)[10]	Yes	LDL cholesterol and % reduction and non-HDL cholesterol	LDL cholesterol ≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L) for patients > 21 years of age with stable ASCVD without comorbidities on statin ≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L) for patients > 21 years of age with stable ASCVD with comorbidities on statin ≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L) for patients > 21 years of age and baseline LDL cholesterol ≥ 190 mg/dL (4.91 mmol/L) on maximally tolerated statin for secondary prevention ≥ 50% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L) for patients > 21 years of age and baseline LDL cholesterol ≥ 190 mg/dL (4.91 mmol/L) on maximally tolerated statin for primary prevention ≥ 50% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L) for patients 40–75 years of age without clinical ASCVD and baseline LDL cholesterol 70–189 mg/dL (1.81–4.89 mmol/L) with diabetes on maximally tolerated statin for primary prevention 30%–49% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L) for patients 40–75 years of age without clinical ASCVD or diabetes with baseline LDL cholesterol 70–189 mg/dL (1.81–4.89 mmol/L) and ASCVD risk > 7.5% on maximally tolerated statin for primary prevention
American Association of Clinical Endocrinologists and American College of Endocrinology Guidelines for Management of Dyslipidemia and Prevention of Cardiovascular Disease (2017)[11]	Yes	Non-HDL cholesterol and LDL cholesterol and Apo B	LDL cholesterol: < 55 mg/dL (1.42 mmol/L) for extreme-risk patients < 70 mg/dL (1.81 mmol/L) for very high-risk patients < 100 mg/dL (2.59 mmol/L) for high-risk and moderate-risk patients < 130 mg/dL (3.36 mmol/L) for low-risk patients Non-HDL cholesterol: < 80 mg/dL (2.07 mmol/L) for extreme-risk patients < 100 mg/dL (2.59 mmol/L) for very high-risk patients < 130 mg/dL (3.36 mmol/L) for high-risk and moderate-risk patients < 160 mg/dL (4.14 mmol/L) for low-risk patients Apo B: < 70 mg/dL (0.70 g/L) for extreme-risk patients < 80 mg/dL (0.80 g/L) for very high-risk patients < 90 mg/dL (0.90 g/L) for high-risk and moderate-risk patients

Apo, apolipoprotein; ASCVD, atherosclerotic cardiovascular disease; LDL, low-density lipoprotein; non-HDL, non–high-density lipoprotein; %, percent.

- Primary prevention with diabetes mellitus (DM), age 40 to 75 years, with LDL cholesterol levels 70 to 189 mg/dL (1.81–4.89 mmol/L)
- Primary prevention without DM, age 40 to 75 years, with an estimated 10-year risk of 7.5% or greater, and LDL cholesterol levels 70 to 189 mg/dL (1.81–4.89 mmol/L)

A new pooled cohort risk estimator was developed to assist with decisions regarding initiation of statin therapy for primary prevention (http://tools.acc.org/ASCVD-Risk-Estimator-Plus/#!/calculate/estimate/). It should be emphasized that this risk estimator is part of the patient-clinician discussion regarding potential benefit of statin therapy and not the sole determinant

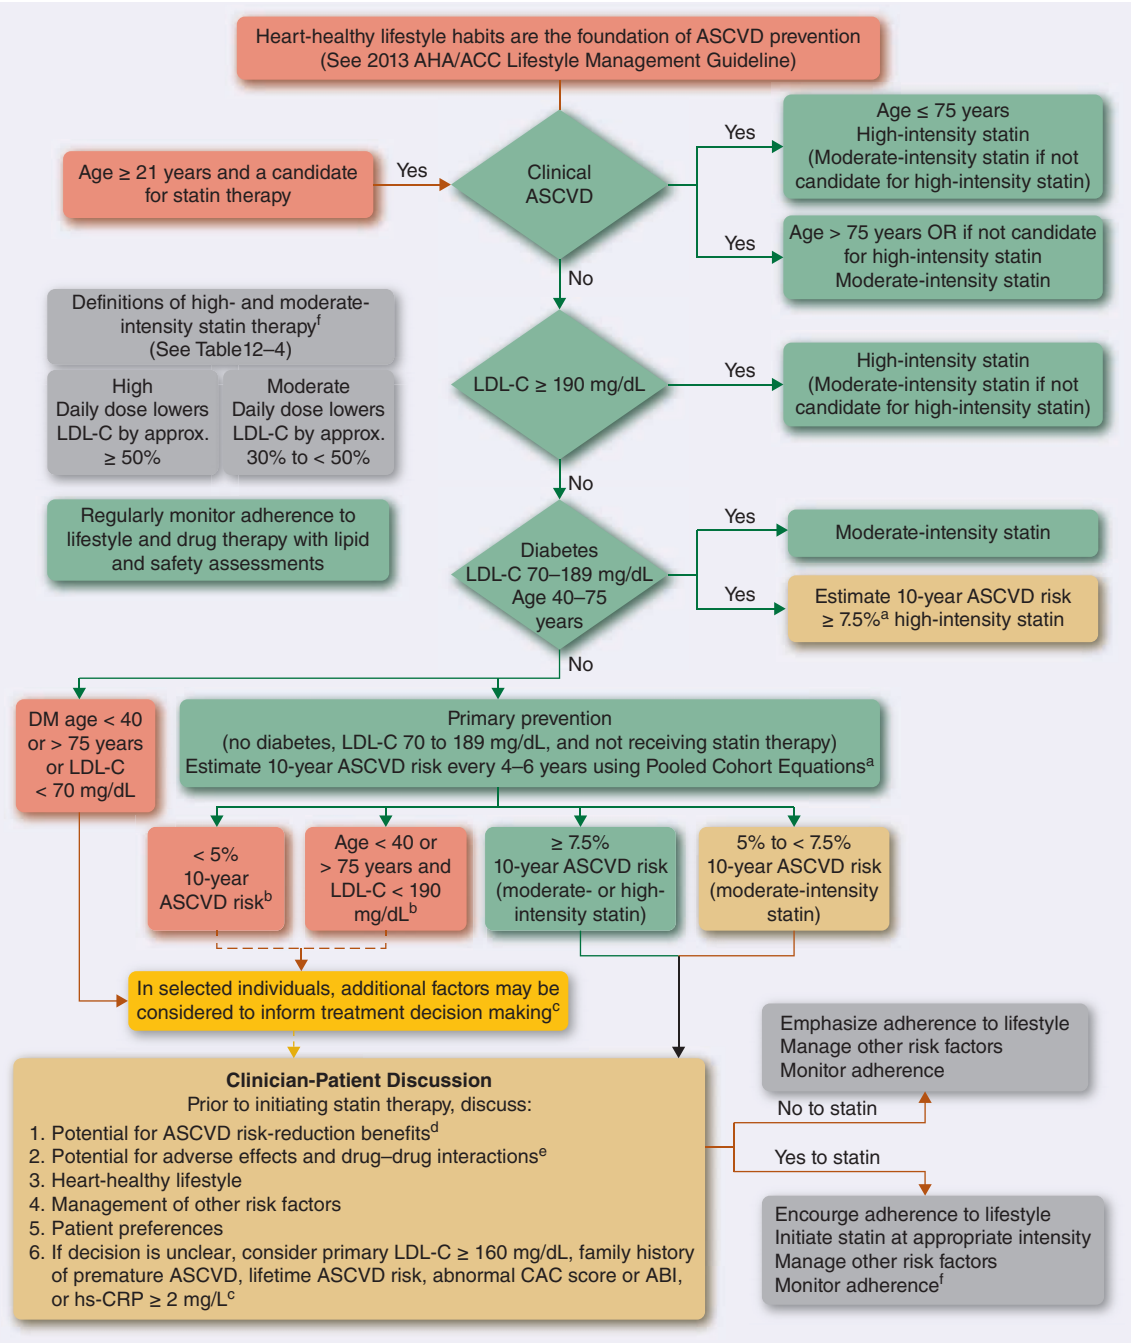

FIGURE 12–6. Summary of statin initiation recommendations for the treatment of blood cholesterol to reduce ASCVD risk in adults. [a]The Pooled Cohort Equation can be used to estimate 10-year ASCVD risk in individuals with or without DM. The estimator within this application should be used to inform decision making in primary prevention patients not on a statin. [b]Consider moderate-intensity statins as more appropriate in low-risk individuals. [c]For those in whom a risk assessment is uncertain, consider factors such as primary LDL-C greater than or equal to 160 mg/dL (4.14 mmol/L) or other evidence of genetic hyperlipidemias, family history of premature ASCVD with onset less than 55 years of age in a first-degree male relative or less than 65 years of age in a first-degree female relative, hs-CRP greater than or equal to 2 mg/L, CAC score greater than or equal to 300 Agatston units, or greater than or equal to 75th percentile for age, sex, and ethnicity, ABI less than 0.9, or lifetime risk of ASCVD. [d]Potential ASCVD risk reduction benefits. The absolute reduction in ASCVD events from moderate- or high-intensity statin therapy can be approximated by multiplying the estimated 10-year ASCVD risk by the anticipated relative-risk reduction from the intensity of statin initiated (~30% for moderate-intensity statin or ~45% for high-intensity statin). [e]Potential adverse effects. The excess risk of DM is the main consideration in ~0.1 excess cases per 100 individuals treated with a moderate-intensity statin for 1 year and ~0.3 excess cases per 100 individuals treated with a high-intensity statin for 1 year. In randomized controlled trials, both statin-treated and placebo-treated participants experienced the same rate of muscle symptoms. The actual rate of statin-related muscle symptoms in the clinical population is unclear. Muscle symptoms attributed to statin therapy should be evaluated. [f]Percent reduction in LDL-C can be used as an indication of response and adherence to therapy, but is not in itself a treatment goal. (ABI, ankle-brachial index; ACC, American College of Cardiology; AHA, American Heart Association; ASCVD, atherosclerotic cardiovascular disease; CAC, coronary artery calcium; DM, diabetes mellitus; hs-CRP, high-sensitivity C-reactive protein; LDL-C, low-density lipoprotein cholesterol.) The algorithm LDL-C values expressed in mmol/L are 4.91 mmol/L for 190 mg/dL, 4.89 mmol/L for 189 mg/dL, and 1.81 mmol/L for 70 mg/dL. (From Stone NJ, Robinson JG, Lichtenstein AH, et al. 2013 ACC/AHA guideline on the treatment of blood cholesterol to reduce atherosclerotic cardiovascular risk in adults: a report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines. J Am Coll Cardiol. 2014;63(25 Pt B):2889–2934, with permission.)

for initiation of therapy. A fasting lipid panel should be used for the initial calculation of the pooled cohort risk estimator. Clinical judgment, which includes risk and benefits, cost, and potential drug–drug interactions, must be exercised. This is especially important since the risk estimator has been shown to overestimate or underestimate risk in some patient populations. If initiation of statin therapy is uncertain based on quantitative risk assessment, additional factors such as LDL cholesterol 160 mg/dL (4.14 mmol/L) or higher, family history of premature ASCVD, high-sensitivity C-reactive protein (hs-CRP) of 2.0 mg/L or higher, coronary artery calcium (CAC) score of 300 Agatston units or higher, ankle brachial index (ABI) less than 0.9, or elevated lifetime ASCVD risk can be considered.

Once the decision to initiate statin therapy is made, the dose intensity is based on the patient's specific statin-benefit group (Figure 12–6). High-intensity statin therapy on average lowers LDL cholesterol by approximately 50% and moderate-intensity statin therapy lowers LDL cholesterol approximately 30% to 49% (see Table 12–4). The ACC/AHA expert panel concluded they could not find evidence for or against titration of drug therapy to specific LDL cholesterol and/or non-HDL cholesterol goals, thus no recommendations were given.[3] A follow-up LDL cholesterol 4 to 12 weeks after initiating therapy is used to assess response (percent LDL cholesterol lowering from baseline) and statin adherence, and not for determining if specific LDL cholesterol goals have been achieved.

In 2014, the NLA issued its recommendation for patient-centered management of dyslipidemia and reaffirmed the importance of setting cholesterol goals for prevention of ASCVD.[8] The NLA emphasized that non-HDL cholesterol is a better primary target for modification than LDL cholesterol, and is now considered a cotarget with LDL cholesterol. KEY CONCEPT The NLA recommendations for "desirable" cholesterol levels are presented in Table 12–5.

Table 12–4

High, Moderate, and Low-Intensity Statin Therapy as Indicated by the ACC/AHA

High-Intensity Statin Therapy	Moderate-Intensity Statin Therapy	Low-Intensity Statin Therapy
Daily dose lowers LDL cholesterol, on average, by approximately ≥ 50%	Daily dose lowers LDL cholesterol, on average, by approximately 30% to < 50%	Daily dose lowers LDL cholesterol, on average, by < 30%
Atorvastatin (40[a])–80 mg	**Atorvastatin 10 (*20*) mg**	*Simvastatin 10 mg*
Rosuvastatin 20 (*40*) mg	**Rosuvastatin (*5*) 10 mg**	**Pravastatin 10–20 mg**
	Simvastatin 20–40 mg	**Lovastatin 20 mg**
	Pravastatin 40 (*80*) mg	*Fluvastatin 20–40 mg*
	Lovastatin 40 mg	*Pitavastatin 1 mg*
	Fluvastatin XL 80 mg	
	Fluvastatin 40 mg twice daily	
	Pitavastatin 2–4 mg	

[a]Evidence from one RCT only: down-titration if unable to tolerate atorvastatin 80 mg.

Boldface type indicates specific statins and doses that were evaluated in randomized controlled trials (RCTs) by the ACC/AHA guideline committee.

Italic type indicates statins and doses that have been approved by the Food and Drug Administration but were not tested in RCTs reviewed by the ACC/AHA guidelines.

ACC, American College of Cardiology; AHA, American Heart Association; LDL, low-density lipoprotein.

Table 12–5

National Lipid Association Classifications of Cholesterol and Triglyceride Levels in mg/dL (mmol/L)

Lipids	
Non-HDL Cholesterol[a]	
< 130 (3.36)	Desirable
130–159 (3.36–4.11)	Above desirable
160–189 (4.14–4.89)	Borderline high
190–219 (4.91–5.66)	High
≥ 220 (5.69)	Very high
LDL Cholesterol	
< 100 (2.59)	Desirable
100–129 (2.59–3.34)	Above desirable
130–159 (3.36–4.11)	Borderline high
160–189 (4.14–4.89)	High
≥ 190 (4.91)	Very high
HDL Cholesterol	
< 40 (1.03) (men)	Low
< 50 (1.29) (women)	Low
Triglycerides	
< 150 (1.70)	Normal
150–199 (1.70–2.25)	Borderline
200–499 (2.26–5.64)	High
≥ 500 (5.65)	Very high[b]

[a]Non-HDL-C = total cholesterol minus HDL cholesterol.

[b]Severe hypertriglyceridemia is another term used for very high triglycerides in pharmaceutical product labeling.

HDL, high-density lipoprotein; LDL, low-density lipoprotein; non-HDL, non–high-density lipoprotein.

LO 3

KEY CONCEPT The ACC/AHA, NLA, and AACE/ACE guidelines emphasize that lifestyle therapies are an important element of risk reduction efforts in ASCVD prevention, whether or not pharmacotherapy is also used. Therapeutic lifestyle changes (TLC) should be the first approach tried in all patients (Table 12–6), but pharmacotherapy should be instituted concurrently in higher-risk patients. TLC includes dietary restrictions as well as regular exercise and weight reduction if overweight or obese. Additionally, consumption of plant stanols/sterols and dietary fiber should be encouraged as they may reduce LDL cholesterol by 20% to 25%.

Table 12–6

Essential Components of Therapeutic Lifestyle Changes

Component	Recommendation
Dietary cholesterol	< 200 mg/day (5.17 mmol/L)
Saturated fats	Total fat range should be 25%–35% for most cases < 7% of total calories and reduce intake of trans fatty acids
Therapeutic options for LDL-lowering plant stanols/sterols	2 g/day
Increased viscous (soluble) fiber	10–25 g/day
Total calories	Adjust caloric intake to maintain desirable body weight and prevent weight gain
Physical activity	≥ 150 min/week of moderate or higher intensity activity

LDL, low-density lipoprotein.

Table 12–7

American College of Cardiology Expert Consensus Decision Pathway for Nonstatin Therapy to Lower LDL-Cholesterol in the Management of Atherosclerotic Cardiovascular Disease (ASCVD) Risk

Risk Category	Treatment Target	1st Line After Statin	2nd Line After Statin
Primary Prevention			
> 21 years of age and baseline LDL cholesterol ≥ 190 mg/dL (4.91 mmol/L) on maximally tolerated statin	≥ 50% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L)	Ezetimibe or PCSK9 inhibitor as add-on therapy	BAS as add-on therapy if ezetimibe intolerant and TG < 300 mg/dL (3.39 mmol/L)
40–75 years of age without clinical ASCVD and baseline LDL cholesterol 70–189 mg/dL (1.81–4.89 mmol/L) with DM on maximally tolerated statin	≥ 50% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L)	Ezetimibe as add-on therapy	BAS as add-on therapy if ezetimibe intolerant and TG < 300 mg/dL (3.39 mmol/L)
40–75 years of age without clinical ASCVD or DM and baseline LDL cholesterol 70–189 mg/dL (1.81–4.89 mmol/L) and an ASCVD risk ≥ 7.5% on maximally tolerated statin	30%–49% reduction or < 100 mg/dL (2.59 mmol/L) or non-HDL cholesterol < 130 mg/dL (3.36 mmol/L)	Ezetimibe as add-on therapy	BAS as add-on therapy if ezetimibe intolerant and TG < 300 mg/dL (3.39 mmol/L)
Secondary Prevention			
> 21 years of age with stable clinical ASCVD without comorbidities on maximally tolerated statin	≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L)	Ezetimibe as add-on therapy	PCSK9 inhibitor as add-on therapy or replacing with PCSK9 inhibitor
> 21 years of age with stable clinical ASCVD with comorbidities on maximally tolerated statin	≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L)	Ezetimibe or PCSK9 inhibitor as add-on therapy	PCSK9 inhibitor as add-on therapy or replacing with PCSK9 inhibitor
> 21 years of age with stable clinical ASCVD and baseline LDL cholesterol ≥ 190 mg/dL (4.91 mmol/L) on maximally tolerated statin	≥ 50% reduction or < 70 mg/dL (1.81 mmol/L) or non-HDL cholesterol < 100 mg/dL (2.59 mmol/L)	Ezetimibe or PCSK9 inhibitor as add-on therapy	PCSK9 inhibitor as add-on therapy or replacing with PCSK9 inhibitor

BAS, bile acid sequestrant; DM, diabetes mellitus; LDL, low-density lipoprotein; non-HDL, non–high-density lipoprotein; PCSK9, proprotein convertase subtilisin/kexin 9; TG, triglycerides.

Recommendations for Treatment

▶ *Step 1: Screening and Classification of Initial Lipoprotein Lipid Levels*

Determine lipoprotein profile after fasting for 9 to 12 hours. KEY CONCEPT The NLA and AACE/ACE recommend that all adults older than 20 years are screened at least every 5 years to obtain a lipid profile (see Clinical Presentation and Diagnosis). Children between 2 and 20 years old should be screened for high cholesterol if their parents have premature CHD or if one of their parents has total cholesterol greater than 240 mg/dL (6.21 mmol/L).

▶ *Step 2: Rule Out Secondary Causes of Dyslipidemia*

Certain secondary causes (drugs and diseases) can cause abnormalities in serum lipids and should be evaluated (Table 12–2). Every effort should be made to correct or control underlying diseases such as hypothyroidism and DM. Concurrent medications known to induce lipid abnormalities should be evaluated for discontinuation if alternative medications can be used prior to instituting long-term lipid-modifying therapy.[8,10]

▶ *Step 3: Identify Patients with Very High-Risk Conditions*

LO3 LO4

Individuals with established clinical ASCVD (Table 12–7) or DM with greater or equal to two ASCVD risk factors (Table 12–8) or evidence of atherosclerosis mediated end-organ damage are considered very high risk or extreme risk. NLA, AACE/ACE, and ACC set non-HDL cholesterol and LDL cholesterol goals for very high-risk patients at less than 100 mg/dL (2.59 mmol/L) and less than 70 mg/dL (1.81 mmol/L), respectively.[8-11] The ACC ECDP for nonstatin therapy further set percent LDL cholesterol lowering targets (eg, 50%) in addition to LDL cholesterol and non-HDL cholesterol

Table 12–8

Risk Factors for Atherosclerotic Cardiovascular Disease (ASCVD) According to the National Lipid Association (NLA)[a]

Risk Factor	Definition
Age (years)	Male ≥ 45; female ≥ 55
Family history of premature CHD events[b]	Male first-degree relative at < 55 years Female first-degree relative at < 65 years
Hypertension[c]	SBP ≥ 140 mm Hg DBP ≥ 90 mm Hg
Low HDL cholesterol	< 40 mg/dL (1.03 mmol/L) in males < 50 mg/dL (1.29 mmol/L) in females
Cigarette smoking	Current

[a]Levels of non-HDL cholesterol and LDL cholesterol are not listed because these risk factors are used to assess risk category and treatment goals for atherogenic lipoprotein cholesterol levels. Diabetes is not listed because it is considered a high- or very high-risk condition for ASCVD risk assessment purposes.

[b]CHD is defined as myocardial infarction, coronary death, or a coronary revascularization procedure.

[c]Note, blood pressure values used by the NLA differ from the 2017 ACC/AHA/AAPA/ABC/ACPM/AGS/APhA/ASH/ASPC/NMA/PCMA Guideline for the Prevention, Detection, Evaluation, and Management of High Blood Pressure in Adults.

CHD, coronary heart disease; DBP, diastolic blood pressure; HDL, high-density lipoprotein; LDL, low-density lipoprotein; SBP, systolic blood pressure.

goals for both primary and secondary prevention patients based on risk levels.[9,10] The 2017 AACE/ACE guidelines set non-HDL cholesterol and LDL cholesterol goals for extreme-risk patients at less than 80 mg/dL (2.07 mmol/L) and less than 55 mg/dL (1.42 mmol/L), respectively.[11] NLA, AACE/ACE, and ACC state pharmacotherapy can be considered when non-HDL cholesterol or LDL cholesterol are equal to or above these targets. For patients with clinical ASCVD or DM, consideration can be given to use of moderate or high-intensity statin therapy, irrespective of baseline cholesterol levels.

▶ *Step 4: Identify Patients with High-Risk Conditions*

LO 3 LO 5 LO 4 LO 5

The ACC ECDP has set criteria for nonstatin therapy for patients with high residual risk after receiving maximum tolerated statin doses based on their statin benefit group and these are described in Table 12–7. The ACC, like the NLA and AACE/ACE, has set non-HDL cholesterol and LDL cholesterol goals for high-risk primary prevention patients at less than 130 mg/dL (3.36 mmol/L) and less than 100 mg/dL (2.59 mmol/L), and at less than 100 mg/dL (2.59 mmol/L) and less than 70 mg/dL (1.81 mmol/L) for secondary prevention patients, respectively.[8-11] Pharmacoltherapy can be considered when the desired LDL-cholesterol lowering is not achieved or LDL or non-HDL cholesterol is equal to or above the targets. If it is not possible to attain desirable LDL and non-HDL cholesterol levels in patients with severe hypercholesterolemia phenotype, a reduction of at least 50% is recommended.[9-11] For FH patients with multiple or poorly controlled other major ASCVD risk factors, clinicians may consider attaining even lower levels of atherogenic cholesterol.[9-11]

▶ *Step 5: Identify Patients with Two or Less ASCVD Risk Factors*

For individuals with two major ASCVD risk factors, quantitative risk scoring should be considered (eg, ASCVD risk calculation) and additional risk indicators (Table 12–9) may be useful for some patients. If quantitative risk score reaches the high-risk threshold, assign patient to high-risk category. If other risk indicators are present, consider assigning to the high-risk category. If no indication is present to assign to high risk, assign to moderate-risk category, with NLA and AACE/ACE goals for non-HDL cholesterol and LDL cholesterol of less than 130 mg/dL (3.36 mmol/L) and less than 100 mg/dL (2.59 mmol/L), respectively. Pharmacotherapy can be considered when non-HDL cholesterol or LDL cholesterol are equal to or above 160 mg/dL (4.14 mmol/L) and 130 mg/dL (3.36 mmol/L), respectively. For individuals with one or no major ASCVD risk factors, the NLA set goals for non-HDL cholesterol and LDL cholesterol level at less than 130 mg/dL (3.36 mmol/L) and less than 100 mg/dL (2.59 mmol/L), respectively. Pharmacotherapy can be considered when non-HDL cholesterol or LDL cholesterol are equal to or above 190 mg/dL (4.91 mmol/L) and 160 mg/dL (4.14 mmol/L), respectively. Consider assigning to a higher risk category based on other known risk indicators, when present.

▶ *Step 6: Treatment of Elevated Triglycerides*

KEY CONCEPT Patients with serum triglycerides exceeding 500 mg/dL (5.65 mmol/L) are at increased risk of pancreatitis, especially when levels exceed 1000 mg/dL (11.3 mmol/L).[8,11] Reducing triglycerides in these individuals becomes the primary target for intervention. Reduction in fats and carbohydrates and abstaining from ethanol should be considered, and secondary causes (Table 12–2) should be assessed. Increase in exercise should be encouraged. Weight loss should also be encouraged if the individual is overweight. When pharmacotherapy is instituted, the goal is to reduce triglycerides to less than 150 mg/dL (1.70 mmol/L). Once triglycerides are

Table 12–9

Risk Indicators (Other Than Major ASCVD Risk Factors) That Might Be Considered for Refinement[a]

Component
1. A severe disturbance in a major ASCVD risk factor, such as multipack per day smoking or strong family history of premature CHD
2. Indicators of subclinical disease, including coronary artery calcium ≥ 300 Agatston units[b] is considered high risk
3. LDL cholesterol ≥ 160 mg/dL (4.14 mmol/L) and/or non-HDL cholesterol ≥ 190 mg/dL (4.91 mmol/L)
4. High-sensitivity C-reactive protein ≥ 2.0 mg/L[c]
5. Lipoprotein (a) ≥ 50 mg/dL (500 mg/L; 125 nmol/L) using an isoform insensitive assay
6. Urine albumin/creatinine ratio ≥ 30 mg/g (3.4 mg/mmol)

[a]The presence of 1 or more of the risk indicators listed may be considered, in conjunction with major ASCVD risk factors, to reclassify an individual into a higher risk category. Except in the case of evidence of subclinical disease defining the presence of ASCVD, reclassification to a higher risk category is a matter of clinical judgment. Doing so will alter the threshold for consideration of pharmacotherapy and/or the treatment goals for atherogenic cholesterol.

[b]Or coronary artery calcium 75th percentile for age, sex, and ethnicity.

[c]Because of high intraindividual variability, multiple high sensitivity C-reactive protein (hs-CRP) values should be obtained before concluding that the level is elevated; hs-CRP should not be tested in those who are ill, have an infection, or are injured. If hs-CRP level is 0.10 mg/L, consider other etiologies such as infection, active arthritis, or concurrent illness.

ASCVD, atherosclerotic cardiovascular disease; CHD, coronary heart disease; LDL, low-density lipoprotein; non-HDL, non–high-density lipoprotein.

Patient Encounter 1

A 53-year-old Caucasian man with obesity (BMI: 34 kg/m^2) has been referred to you for a follow-up of his cholesterol. He has known hypertension for which he takes losartan 100 mg daily and hydrochlorothiazide 25 mg daily. His blood glucose is 115 mg/dL (6.4 mmol/L). His laboratory test results are within normal limits. His blood pressure today is 138/90 mm Hg with a heart rate of 68 beats/min. He is a nonsmoker. His fasting lipid profile: total cholesterol 240 mg/dL (6.21 mmol/L), triglycerides 200 mg/dL (2.26 mmol/L), HDL cholesterol 38 mg/dL (0.98 mmol/L), non-HDL cholesterol 202 mg/dL (5.22 mmol/L), and LDL cholesterol 162 mg/dL (4.19 mmol/L).

What is your assessment of the patient's cholesterol results?

Should an assessment of his risk factors for ASCVD or an ASCVD risk score be conducted?

Does this patient have clinical ASCVD?

What statin-benefit group does he fit according to ACC/AHA guidelines?

What additional information do you need to evaluate the patient?

Develop a care plan for the patient.

less than 500 mg/dL (5.65 mmol/L) and the risk of pancreatitis is reduced, the primary focus of intervention should once again be on non-HDL and LDL cholesterol. Niacin, fibrates, and long-chain omega-3 fatty acids (OM3FA) are the most effective agents in patients with fasting triglyceride concentrations greater than 1000 mg/dL (11.3 mmol/L).[8,11] For patients with triglycerides 500 to 999 mg/dL (5.65–11.29 mmol/L), a triglyceride-lowering agent or a statin (if no history of pancreatitis) may be reasonable. Individuals with triglycerides between 200 and 499 mg/dL (2.26 and 5.64 mmol/L) have increased triglyceride-rich remnant lipoproteins and small-dense LDL particles, which are considered more atherogenic than large buoyant LDL particles. For patients with high triglycerides between 200 and 499 mg/dL (2.26 and 5.64 mmol/L), statins will generally be first line since they are most effective in reducing non-HDL and LDL-cholesterol levels.

Pharmacotherapy

▶ *Statins (HMG-CoA Reductase Inhibitors)*

KEY CONCEPT Statins are very effective LDL-lowering medications and are proven to reduce the risk of CHD, stroke, and death. Thus, ACC/AHA, NLA, and AACE/ACE consider statins the preferred LDL-lowering medications. Statins are effective in reducing ASCVD and in some cases, mortality. This effectiveness has been demonstrated in both genders, the elderly, patients with DM and hypertension, those with or without preexisting ASCVD, and following an acute coronary syndrome.[12-24] Statins inhibit conversion of HMG-CoA to L-mevalonic acid and subsequently cholesterol. Statins lower LDL cholesterol levels by approximately 21% to 63% (Table 12–10), are moderately effective at reducing triglycerides, and modestly raise HDL cholesterol. Additionally,

Table 12–10

Effects of Lipid-Lowering Drugs on Serum Lipids at FDA-Approved Doses

Lipid-Lowering Drug	LDL Cholesterol	HDL Cholesterol	Triglycerides	Total Cholesterol
Statins				
Atorvastatin	–26% to –60%	+5% to +13%	–17% to –53%	–25% to –45%
Fluvastatin	–22% to –36%	+3% to +11%	–12% to –25%	–16% to –27%
Fluvastatin ER	–33% to –35%	+7% to +11%	–19% to –25%	–25%
Lovastatin	–21% to –42%	+2% to +10%	–6% to –27%	–16% to –34%
Lovastatin ER	–24% to –41%	+9% to +13%	–10% to –25%	–18% to –29%
Pitavastatin	–31% to –45%	+1% to +8%	–13% to –22%	–23% to –31%
Pravastatin	–22% to –34%	+2% to +12%	–15% to –24%	–16% to –25%
Rosuvastatin	–45% to –63%	+8% to +14%	–10% to –35%	–33% to –46%
Simvastatin	–26% to –47%	+8% to +16%	–12% to –34%	–19% to –36%
Cholesterol Absorption Inhibitor				
Ezetimibe	–18%	+1% to +2%	–7% to –9%	–12% to –13%
Bile Acid Sequestrants				
Cholestyramine	–15% to –30%	+3% to +5%	May increase in patients with elevated triglycerides	–10% to –25%

[a]Percent change relative to simvastatin 20 mg.

ER, extended-release; FDA, Food and Drug Administration; HDL, high-density lipoprotein; IR, immediate-release; LDL, low-density lipoprotein.

statins also inhibit other important by-products in the cholesterol biosynthetic pathway that affect intracellular transport, membrane trafficking, and gene transcription. This may explain some of the cholesterol-independent benefits (so-called pleiotropic effects) of statins such as reducing lipoprotein oxidation, enhancing endothelial synthesis of nitric oxide, and inhibiting **thrombosis**. These pleiotropic effects are thought to contribute to the early benefits of statins on CHD risk, while the decrease in serum lipids accounts for the later benefits.

LO 6

KEY CONCEPT Statins are well tolerated, with less than 4% of patients in clinical trials discontinuing therapy due to adverse side effects (Table 12–11). Elevations in liver function tests (LFTs) and **myopathy**, including **rhabdomyolysis**, are important adverse effects associated with statins. Liver toxicity, defined as LFT elevations greater than three times the upper limit of normal, is reported in less than 2% of patients. Incidence is higher at higher doses, but the progression to liver failure is exceedingly rare. LFTs should be obtained at baseline and as clinically indicated thereafter. Myopathy, defined as muscle weakness not necessarily associated with creatine kinase (CK) elevations, is reported to range from 0% to less than 0.5% for the currently marketed statins at approved doses. Rhabdomyolysis, defined as muscle symptoms with marked elevation in CK at 50 times the upper limit of normal and creatinine elevation usually associated with **myoglobinuria** and brown urine, is very rare.[25] The risks associated with statin-induced myopathy include the following:[25,26]

- Small body frame and frailty
- Multisystem disease (eg, chronic kidney disease, especially due to DM)
- Perioperative periods
- Multiple medications (see next bullet)
- Specific concomitant medications or consumptions (check specific statin package insert for warnings): fibrates (especially gemfibrozil, but other fibrates too), nicotinic acid (rarely), cyclosporine, azole antifungals, macrolide antibiotics, protease inhibitors, nefazodone, verapamil, amiodarone, large quantities of grapefruit juice (usually > 1 quart [about 950 mL] per day), and alcohol abuse (independently predisposes to myopathy).

Table 12–11

Formulation, Dosing, and Common Adverse Effects of Lipid-Lowering Drugs

Lipid-Lowering Drug	Dosage Forms	Usual Adult Maintenance Dose Range	Adverse Effects
Statins			
Atorvastatin	10-, 20-, 40-, 80-mg tablets	10–80 mg once daily (at any time of day). Dose adjustment in patients with renal dysfunction is not necessary	Most frequent side effects are constipation, abdominal pain, diarrhea, and nausea. Statins should be discontinued promptly if serum transaminase levels (liver function tests) rise to three times upper limit of normal or if patient develops signs or symptoms of myopathy. Approximate-equivalent doses of HMG-CoA reductase inhibitors are: atorvastatin 10 mg, fluvastatin 80 mg, lovastatin 40 mg, pitavastatin 2 mg, pravastatin 40 mg, simvastatin 20 mg, and rosuvastatin 5 mg
Fluvastatin	20-, 40-mg capsules; 80-mg extended-release tablets	20–40 mg/day as a single dose (evening) or 40 mg twice daily; 80 mg once daily (evening). Dose adjustments for mild to moderate renal impairment are not necessary	
Lovastatin	10-, 20-, 40-mg tablets	10–80 mg/day as a single dose (with evening meal) or divided twice daily with food. In patients with severe renal insufficiency (creatinine clearance less than 30 mL/min [0.5 mL/s]), dosage increases above 20 mg/day should be carefully considered and, if deemed necessary, implemented cautiously	
Lovastatin ER	20-, 30-, 60-mg tablets	20–60 mg/day as a single dose. In patients with severe renal insufficiency (creatinine clearance < 30 mL/min [0.5 mL/s]), dosage increases above 20 mg/day should be carefully considered and, if deemed necessary, implemented cautiously	
Pravastatin	10-, 20-, 40-, 80-mg tablets	10–80 mg/day as a single dose at bedtime. In patients with a history of significant renal or hepatic dysfunction, a starting dose of 10 mg daily is recommended	
Pitavastatin	1-, 2-, 4-mg tablets	1–4 mg/day as a single dose can be taken with or without food, at any time of day. Moderate renal impairment (glomerular filtration rate 30–60 mL/min/1.73 m^2 [0.29–0.58 mL/s/m^2]) and end-stage renal disease on hemodialysis: Starting dose of 1 mg once daily and maximum dose of 2 mg once daily	

(*Continued*)

Table 12–11

Formulation, Dosing, and Common Adverse Effects of Lipid-Lowering Drugs (*Continued*)

Lipid-Lowering Drug	Dosage Forms	Usual Adult Maintenance Dose Range	Adverse Effects
Rosuvastatin	5-, 10-, 20-, 40-mg tablets	5–40 mg/day (at any time of day); 40 mg reserved for those who do not achieve LDL cholesterol goal on 20 mg. In patients with history of significant renal dysfunction or Asian, starting dose of 5 mg daily is recommended	
Simvastatin	5-, 10-, 20-, 40-mg tablets	5–40 mg/day as a single dose in the evening, or divided. Recommended starting dose for patients at high risk of CHD is 40 mg/day. In patients with mild to moderate renal insufficiency, dosage adjustment is not necessary. However, caution should be exercised in patients with severe renal insufficiency; such patients should be started at 5 mg/day and be closely monitored. Due to increased risk of myopathy, including rhabdomyolysis, use of the 80 mg dose should be restricted to patients who have been taking simvastatin 80 mg chronically (eg, for 12 months or more) without evidence of muscle toxicity. Because of an increased risk for myopathy in Chinese patients taking simvastatin 40 mg coadministered with lipid-modifying doses (≥ 1 g/day niacin) of niacin-containing products, caution should be used when treating Chinese patients with simvastatin doses exceeding 20 mg/day coadministered with lipid-modifying doses of niacin-containing products. Because the risk for myopathy is dose related, Chinese patients should not receive simvastatin 80 mg coadministered with lipid-modifying doses of niacin-containing products	
Cholesterol Absorption Inhibitors			
Ezetimibe	10-mg tablets	10 mg once daily. No dosage adjustment is necessary in patients with renal or mild hepatic insufficiency	Overall incidence of adverse events reported with ezetimibe alone was similar to that reported with placebo and generally similar between ezetimibe with a statin and statin alone. The frequency of increased transaminases was slightly higher in patients receiving ezetimibe plus a statin compared with those receiving statin monotherapy (1.3% vs 0.4%)
Bile Acid Sequestrants			
Cholestyramine	4-g packets	4–24 g/day in two or more divided doses	Main side effects are nausea, constipation, bloating, and flatulence, although these may be less with colesevelam. Increasing fluid and dietary fiber intake may relieve constipation and bloating. Impair absorption of fat-soluble vitamins
Colesevelam	625-mg tablets	3750–4375 mg/day as a single dose or divided twice daily, with meals	
	3.75-g oral suspension packet	One packet once a day with meals	
Colestipol	5-g packets	5–30 g/day as a single dose or divided	
	1-g tablets	2–16 g/day as a single dose or divided	
Nicotinic Acid (Prescription Products)			
Niacin ER (Niaspan)	500-, 750-, 1000-mg extended-release tablets	1000–2000 mg once daily at bedtime. Use with caution in patients with renal impairment	Side effects include flushing, itching, gastric distress, headache, hepatotoxicity, hyperglycemia, and hyperuricemia

(*Continued*)

Table 12–11

Formulation, Dosing, and Common Adverse Effects of Lipid-Lowering Drugs (*Continued*)

Lipid-Lowering Drug	Dosage Forms	Usual Adult Maintenance Dose Range	Adverse Effects
Niacin IR (Niacor)	500-mg tablets	1–6 g/day in two to three divided doses. Do not exceed 6 g daily	
Fibric Acid Derivatives			
Fenofibrate	54-, 160-mg tablets[a]	54–160 mg/day; the dosage should be minimized in severe renal impairment	Most common side effects are nausea, diarrhea, abdominal pain, and rash. Increased risk of rhabdomyolysis when given with a statin. Fibric acids are associated with gallstones, myositis, and hepatitis
Gemfibrozil	600-mg tablets	1200 mg/day in two doses, 30 minutes before meals; should be avoided in hepatic or severe renal impairment	
Omega-3-Fatty Acids			
Lovaza	1-g capsule containing at least 0.9 g of OM3FA ethyl ester (EPA~0.465 g and DHA ~0.375 g)	4 g/day taken as single 4 g dose (four capsules) or two 2 g doses (two capsules twice daily)	All products are obtained from oil of fish. Should be used with caution in patients with known hypersensitivity to fish and/or shellfish. Side effects include: Side effects of Lovaza/Omtryg include: • Eructation, 4% • Dyspepsia, 3% • Taste perversion, 4% Side effects of Vascepa include: • Arthralgia, 2.3% Side effects of Epanova include: • Diarrhea, 15% • Nausea, 6% • Abdominal pain or discomfort, 5%
Vascepa	1-g capsule containing 1 g of icosapent ethyl	4 g/day taken as 2 g doses (two capsules twice daily)	
Epanova	1-g capsule containing at least 0.85 g OM3FFA (EPA~0.550 g and DHA~0.2 g)	2 or 4 g/day taken as single 2 g dose (2 capsules) or single 4 g dose (four capsules)	
Omtryg	1-g capsule containing at least 0.9 g of OM3FA ethyl ester (EPA ~0.465 g and DHA~0.375 g)	4 g/day taken as single 4 g dose (four capsules) or two 2 g doses (two capsules twice daily)	
Micosomal Transfer Protein Inhibitors			
Lomitapide	5-, 10-, and 20-mg capsules	5 mg once daily. Titrate dose based on acceptable safety/tolerability: increase to 10 mg daily after at least 2 weeks; and then, at a minimum of 4-week intervals, to 20 mg, 40 mg, and up to the maximum recommended dose of 60 mg daily	Gastrointestinal side effects and elevation in liver enzymes and hepatic fat are common
Antisense Oligonucleotide			
Mipomersen	200 mg subcutaneous injection	200 mg once weekly as a subcutaneous injection	Injection site reactions, hepatic fat, and liver enzyme elevations are common
Proprotein Convertase Subtilisin/Kexin Type 9 (PCSK9) Inhibitors			
Alirocumab	75 mg or 150 mg subcutaneous injection	75–150 mg once every 2 week subcutaneous injection or 300 mg once every month subcutaneous injection	Injection site reactions, nasopharyngitis, influenza, upper respiratory tract infections, urinary tract infection, elevation in liver enzymes
Evolocumab	140 mg or 420 mg subcutaneous injection	140 mg once every 2 week subcutaneous injection or 420 mg once every month subcutaneous injection	Injection site reactions, nasopharyngitis, influenza, upper respiratory tract infections, urinary tract infection, back pain
Combination Products			
Ezetimibe and atorvastatin	10 mg/10 mg, 10 mg/20 mg, 10 mg/40 mg, 10 mg/80 mg	Dosage range is 10/10 mg/day through 10/80 mg/day. Recommended usual starting dose is 10/10 or 10/20 mg/day. Recommended starting dose is 10/40 mg/day for patients requiring a > 55% reduction in LDL cholesterol	See previous entries for each drug (ezetimibe and atorvastatin)

(*Continued*)

Table 12–11

Formulation, Dosing, and Common Adverse Effects of Lipid-Lowering Drugs (*Continued*)

Lipid-Lowering Drug	Dosage Forms	Usual Adult Maintenance Dose Range	Adverse Effects
Ezetimibe and simvastatin	10 mg/10 mg, 10 mg/20 mg, 10 mg/40 mg, 10 mg/80 mg	Dosage range is 10/10 mg/day through 10/40 mg/day. Recommended usual starting dose is 10/10 or 10/20 mg/day. Initiation of therapy with 10/10 mg/day may be considered for patients requiring less aggressive LDL cholesterol reductions. Due to increased risk of myopathy, including rhabdomyolysis, use of the 10/80 mg dose of Vytorin should be restricted to patients who have been taking Vytorin 10/80 mg chronically (eg, for 12 months or more) without evidence of muscle toxicity. Because of an increased risk for myopathy in Chinese patients taking simvastatin 40 mg coadministered with lipid-modifying doses (≥ 1 g/day niacin) of niacin-containing products, caution should be used when treating Chinese patients with Vytorin doses exceeding 10/20 mg/day coadministered with lipid-modifying doses (≥ 1 g/day niacin) of niacin-containing products. Because the risk for myopathy is dose-related, Chinese patients should not receive Vytorin 10/80 mg coadministered with lipid-modifying doses of niacin-containing products	See previous entries for each drug (ezetimibe and simvastatin)

[a]Dose strengths vary depending on brand.

CHD, coronary heart disease; DHA, docosahexaenoic acid; EPA, eicosapentaenoic acid; ER, extended release; HMG-CoA, 3-hydroxy-3-methyglutaryl coenzyme A; IR, immediate-release; LDL, low-density lipoprotein; OM3FA, omega-3 fatty acid; OM3FFA, omega-3 free fatty acid.

It is reasonable to check a baseline CK in patients at risk for myopathy. Follow-up CK should only be obtained in patients complaining of muscle pain, weakness, tenderness, or brown urine. Patient assessment for symptoms of myopathy should be done 6 to 12 weeks after starting therapy and at each visit.

Some evidence suggests that statins increase the risk for development of DM. The Food and Drug Administration (FDA) warns of increased blood sugar and glycosylated hemoglobin (HbA_{1c}) levels on statin labels. In addition, the FDA has added to statin labels that cognitive impairment, such as memory loss, forgetfulness and confusion, has been reported by some statin users. It is suggested to look into other causes of cognitive impairment if this occurs while on statins and appears to be reversible, with symptoms disappearing approximately 3 weeks after statin discontinuation. The FDA continues to believe that the cardiovascular benefits of statins outweigh these small increased risks.

With the exception of pravastatin and pitavastatin, the other statins undergo biotransformation by the cytochrome P-450 (CYP) system with lovastatin and simvastatin having the highest risk of drug–drug interactions. Therefore, drugs known to inhibit statin metabolism should be used cautiously or avoided and are highlighted in a recent AHA scientific statement on statin drug interactions.[27] Medications such as cyclosporine and gemfibrozil can inhibit drug transporters in the gut and liver that can increase statin concentrations. The time until maximum effect on lipids for statins is generally 4 to 6 weeks.

► *Cholesterol Absorption Inhibitors*

Ezetimibe blocks biliary and dietary cholesterol as well as phytosterol (plant sterol) absorption by interacting with the NPC1L1 transporter (Figure 12–2).[5] Less cholesterol is delivered to the liver which leads to an upregulation of LDL receptors. This causes a reduction in serum cholesterol and a compensatory increase in cholesterol biosynthesis. Because statins inhibit cholesterol biosynthesis, this compensatory increase by ezetimibe can be blocked when coadministered with a statin.

KEY CONCEPT Ezetimibe reduces LDL cholesterol by an average of 18%. However, larger reductions can be seen in some individuals, presumably due to higher absorption of cholesterol. These individuals appear to have a blunted response to statin therapy. Ezetimibe lowers triglycerides by 7% to 9% and modestly increases HDL cholesterol. (See Table 12–10.)

LO 6 Ezetimibe is contraindicated in patients with active liver disease or unexplained persistent elevations in LFTs. Since statins are the standard of care, a placebo-controlled randomized trial of the effects of ezetimibe monotherapy on CHD morbidity and mortality has never been conducted. Ezetimibe combined with simvastatin was associated with a reduced incidence of ischemic cardiovascular events in low-risk patients with mild to moderate asymptomatic aortic stenosis compared with placebo,[28] as well as reduced incidence of major atherosclerotic events in a wide range of patients with advanced chronic kidney disease.[29] Most recently, ezetimibe combined with simvastatin was shown to further reduce ASCVD events in patients who have suffered a recent myocardial infarction (MI) compared to simvastatin alone.[30] Ezetimibe is primarily used in combination with a statin when adequate reductions in atherogenic cholesterol is not achieved (Table 12–7) or in those patients who are intolerant to statin therapy. The time until maximum effect on lipids for ezetimibe is generally 2 weeks.

Patient Encounter 2, Part 1

A 48-year-old, nonsmoking woman presents to your clinic for a physical examination. She states that she had an MI 1 year ago and she tries to take her medications every day. She has not had her cholesterol evaluated since her MI last year. She reports having chest pain rarely (less than once a month). She has one brother who is 42 years old with hypertension and diabetes but otherwise healthy. Her father had an MI when he was 50 and has elevated cholesterol. The patient is married with two children. She does not smoke and exercises regularly (3 times a week most weeks). She ate breakfast (eggs and bacon) approximately 3 hours ago.

Does this patient have clinical ASCVD?

Can the patient be evaluated today for non-HDL cholesterol?

Should an assessment of her risk factors for ASCVD or an ASCVD risk score be conducted?

What additional information do you need to evaluate the patient?

▶ Bile Acid Sequestrants

Cholestyramine, colestipol, and colesevelam are the oral bile acid-binding resins or sequestrants (BAS) currently available in the United States. Resins are highly charged molecules that bind to bile acids in the gut. The resin–bile acid complex is then excreted in the feces. The loss of bile causes a compensatory conversion of hepatic cholesterol to bile, reducing hepatocellular stores of cholesterol and resulting in an upregulation of LDL receptors which then results in a decrease in serum cholesterol. Resins have been shown to reduce CHD events in patients without CHD.[31]

KEY CONCEPT Resins are moderately effective in lowering LDL cholesterol but do not lower triglycerides. Moreover, in patients with elevated triglycerides, the use of a resin may increase triglycerides. This may be due to a compensatory increase in HMG-CoA reductase activity which results in an increase in secretion of VLDL. The increase in HMG-CoA reductase activity can be blocked with a statin, resulting in enhanced reductions in serum lipids. Resins reduce LDL cholesterol from 15% to 30%, with a modest increase in HDL cholesterol (3%–5%) (Table 12–10). Resins are most often used as adjuncts to statins in patients who require additional lowering of atherogenic cholesterol and are an option to add to statins based on the ACC nonstatin ECDP (Table 12–3).[9] Since these drugs are not absorbed, adverse effects are limited to the gastrointestinal (GI) tract (Table 12–11). About 20% of patients taking cholestyramine or colestipol report constipation and symptoms such as flatulence and bloating. A large number of patients stop therapy because of the GI effects. Resins should be started at the lowest dose and escalated slowly over weeks to months as tolerated until the desired response is obtained. Patients should be instructed to prepare the powder formulations in 6 to 8 ounces (~180–240 mL) of noncarbonated fluids, usually juice (enhances palatability) or water. Fluid intake should be increased to minimize constipation. Colesevelam is better tolerated with fewer GI side effects, although it is more expensive.[32] Colesevelam also has an indication for improvement of glycemic control in type 2 DM. All resins have the potential to prevent absorption of other drugs such as digoxin, warfarin, thyroxine, thiazides, β-blockers, fat-soluble vitamins, and folic acid. Potential drug interactions can be avoided by taking a resin either 1 hour before or 4 hours after these other agents. The time until maximum effect on lipids for resins is generally 2 to 4 weeks.

LO 6

LO 7

▶ Niacin

Niacin (vitamin B_3) has broad applications in the treatment of lipid disorders when used at doses higher than those used as a nutritional supplement. Niacin inhibits FA release from adipose tissue and FA and triglyceride production in liver cells. This results in a reduction in the number of VLDL particles secreted (Figure 12–4), which leads to an overall reduction in LDL cholesterol and a decrease in the number of small dense LDL particles. Niacin also reduces the uptake of HDL-Apo A1 particles and increases uptake of cholesterol esters by the liver, thus improving the efficiency of reverse cholesterol transport between HDL particles and vascular tissue (Figure 12–4). Niacin is indicated for patients with elevated triglycerides, low HDL cholesterol, and elevated LDL cholesterol.[8,11]

Several different niacin formulations are available: immediate-release (IR), sustained-release (SR), and extended-release (ER).[33,34] These formulations differ in terms of dissolution and absorption rates, metabolism, efficacy, and side effects. Limitations of niacin IR and SR are flushing and **hepatotoxicity**, respectively. These differences appear related to the dissolution and absorption rates of niacin formulations and their subsequent metabolism. Niacin IR is available by prescription (Niacor) as well as a dietary supplement, which is not regulated by the FDA.[33] Currently, all SR products are available only as dietary supplements.

Niacin ER (Niaspan) was developed as a once-daily formulation to be taken at bedtime, with the goal of reducing the incidence of flushing without increasing the risk of hepatotoxicity. Niaspan is the only long-acting niacin product approved by the FDA for dyslipidemia.

Niacin use is limited by cutaneous reactions such as flushing and pruritus of the face and body. The use of aspirin or a nonsteroidal anti-inflammatory drug (NSAID) 30 minutes prior to taking niacin can help alleviate these reactions because they are mediated by an increase in prostaglandin D2.[8,11] In addition, taking niacin with food and avoiding hot liquids or alcohol at the time niacin is taken is helpful in minimizing flushing and pruritus. Lastly, slow titration of the niacin dose to minimize and/or prevent flushing (eg, 500 mg/day to 1000 mg/day over 8 weeks).

In general, niacin reduces LDL cholesterol from 5% to 25%, reduces triglycerides by 11% to 60%, and increases HDL cholesterol by 14% to 39% (Table 12–10). Niacin monotherapy has been shown to reduce CHD events and total mortality,[35] as well as the progression of atherosclerosis when combined with a statin.[36] However, a recent trial that tested the effects of adding niacin ER or placebo in patients with CHD optimally treated (LDL cholesterol ~70 mg/dL [1.81 mmol/L]) on a statin was stopped earlier than planned because no apparent benefits by adding niacin ER were found. Moreover, a small and unexplained increase in ischemic stroke in the niacin ER group was seen.[37] Another trial also found no benefit by the addition of niacin ER plus an anti-flush medication (laropiprant).[38] These two trials have resulted in ambiguity in the role of niacin in lipid management. However, niacin is still a useful agent in the management of high triglycerides.

Niacin should be instituted at the lowest dose and gradually titrated to a maximum dose of 2 g daily for ER and SR products and no more than 6 g daily for IR products. FDA-approved niacin products are preferred because of product consistency. Moreover, niacin products labeled as "no flush" do not contain nicotinic acid and therefore have no therapeutic role in the treatment of lipid disorders.[33] The time until maximum effect on lipids for niacins is generally 3 to 5 weeks.

LO 6

LO 6

LO 7

▶ Fibrates

KEY CONCEPT The predominant effects of fibrates are a decrease in triglyceride levels by 20% to 60% and an increase in HDL cholesterol levels by 9% to 30% (Table 12–10). The effect on LDL cholesterol is less predictable. In patients with high triglycerides, however, LDL cholesterol may increase. Fibrates increase the size and reduce the density of LDL particles much like niacin. KEY CONCEPT Fibrates are the most effective triglyceride-lowering drugs and are used primarily in patients with elevated triglycerides and low HDL cholesterol.

Fibrates work by activating peroxisome proliferator-activated receptor-alpha (PPAR-α), a nuclear receptor involved in cellular function. This results in a reduction in triglyceride-rich lipoproteins (VLDL and IDL) and an increase in HDL.

Clinical trials of fibrate therapy in patients with elevated cholesterol and no history of CHD demonstrated a reduction in CHD incidence, although less than the reduction attained with statin therapy.[39] In addition, a large study of men with CHD, low HDL cholesterol, low LDL cholesterol, and elevated triglycerides demonstrated a 24% reduction in risk of death from CHD, nonfatal MI, and stroke with gemfibrozil.[40] Fibrates may be appropriate in prevention of CHD events for patients with established CHD, low HDL cholesterol, and triglycerides below 200 mg/dL (2.26 mmol/L). However, LDL-lowering therapy with statins should be the primary target if non-HDL and LDL cholesterol are elevated. Evidence of a reduction in CHD risk among patients with established CHD has not been demonstrated with fenofibrate.

LO 6 The fibric acid derivatives are generally well tolerated. The most common adverse effects include dyspepsia, abdominal pain, diarrhea, flatulence, rash, muscle pain, and fatigue (Table 12–11). Myopathy and rhabdomyolysis can occur, and the risk appears to increase with renal insufficiency or concurrent statin therapy. If a fibrate is used with a statin, fenofibrate is preferred because it appears to inhibit the glucuronidation of the statins less than gemfibrozil.[41] A CK level should be checked before therapy is started and if symptoms occur. Liver dysfunction has been reported, and LFTs should be monitored. Fibrates increase cholesterol in the bile and have caused gallbladder and bile duct disorders, such as cholelithiasis and cholecystitis. Unlike niacin, these agents do not increase glucose or uric acid levels. Fibrates are contraindicated in patients with gallbladder disease, liver dysfunction, or severe kidney dysfunction. The risk of bleeding is increased in patients taking both a fibrate and warfarin, specifically with gemfibrozil based on a CYP 2C9 interaction which can result in an increase in a patient's international normalized ratio (INR) if adding gemfibrozil to warfarin therapy. Increased INR monitoring is suggested after initiation of gemfibrozil in patients currently taking warfarin. The time until maximum effect on lipids is generally 2 weeks for fenofibrate and 3 to 4 weeks for gemfibrozil.

▶ Long-Chain Omega-3 Fatty Acids (OM3FA)

OM3FA (eicosapentaenoic acid and docosahexaenoic acid), the predominant long-chain FA in the oil of cold-water fish, lower triglycerides by as much as 45% (Table 12–10) when taken in large amounts (2–4 g). Long-chain OM3FA may be useful for patients with high triglycerides despite diet and weight loss, alcohol restriction, and fibrate therapy. This effect may be modulated through reduction in hepatic synthesis and release of VLDL triglycerides, increased β-oxidation of FA, and enhanced triglyceride clearance from triglyceride-rich lipoproteins. Long-chain OM3FA have other cardiac effects such as reduced platelet aggregation and antiarrhythmic properties. The current AHA Scientific Statement on fish consumption, fish oil, OM3FA, and cardiovascular disease recommends an increased intake of OM3FA in the diet.[42]

Prescription-grade long-chain OM3FA ethyl esters and free FA formulations are FDA approved at a dose of 2 to 4 g daily for the treatment of elevated triglycerides (≥ 500 mg/dL [5.65 mmol/L]). Use of high-quality OM3FA free of contaminants such as mercury and organic pollutants should be encouraged when using these agents. Common side effects associated with long-chain OM3FA are dyspepsia and eructation (Table 12–11). LO 6 Patients taking anticoagulant or antiplatelet agents should be monitored more closely when consuming these products because excessive amounts of long-chain OM3FA (eg, > 3 g daily) may lead to bleeding and may increase risk of hemorrhagic stroke.

▶ Microsomal Triglyceride Transport Inhibitors

Lomitapide is an oral inhibitor of microsomal triglyceride transfer protein, thereby inhibiting the normal transfer of triglycerides to Apo B in the lumen of the endoplasmic reticulum and preventing the assembly of Apo B–containing lipoproteins in enterocytes and hepatocytes.[8,11] Lomitapide reduces LDL cholesterol levels on average by 40% (Table 12–10) in homozygous FH patients on maximum tolerated lipid-lowering therapy and LDL apheresis. However, given its mechanism of action, GI side effects and elevation in liver enzymes and hepatic fat are common (Table 12–11). LO 6 Because of the risk of hepatotoxicity, lomitapide is available only through the Risk Evaluation and Mitigation Strategy (REMS) program and is currently FDA approved for the management of patients with homozygous FH. Gastrointestinal side effects are managed by strict adherence to a low-fat diet (< 20% of total calories from fat) and gradual dose escalation based on acceptable safety and tolerability. Lomitapide is primarily metabolized by CYP 3A4. Lomitapide interacts with numerous agents such as strong and moderate CYP 3A4 inhibitors and 3A4 inducers. Lomitapide is classified as pregnancy category X.

▶ Antisense Oligonucleotide Inhibitor of Apo B-100 Synthesis

Mipomersen is a once-weekly subcutaneous injectable antisense inhibitor of Apo B synthesis. When given in combination with maximum tolerated doses of lipid-lowering therapy, it can reduce LDL cholesterol by an additional 25% in homozygous FH patients (Table 12–10).[8,11] Injection site reactions, flu-like symptoms, hepatic fat, and liver enzyme elevations are common (Table 12–11). Because of the risk of hepatotoxicity similar to lomitapide, mipomersen is available only through a REMS program. Mipomersen is not a substrate for CYP metabolism and is metabolized by endonucleases and exonucleases. Therefore, LO 6 mipomersen has minimal clinically relevant drug–drug interactions. Mipomersen is pregnancy category B.

▶ Proprotein Convertase Subtilisin/Kexin Type 9 (PCSK9) Inhibitors

Alirocumab and evolocumab are subcutaneous injectable human monoclonal antibodies that bind to PCSK9. PCSK9 binds to the LDL receptors on hepatocyte surfaces to promote low-density lipoprotein receptor (LDLR) degradation. LDLR is the primary receptor that clears circulating LDL; therefore, the decrease in LDLR levels by PCSK9 results in higher blood levels of LDL. By inhibiting the binding of PCSK9 to LDLR, these agents increase the number of LDLRs available to clear LDL, thereby lowering LDL levels. In clinical trials, these agents have produced an additional

48% to 71% decrease in LDL levels when used in combination with statin therapy, compared with statin monotherapy. Both medications are FDA approved for heterozygous FH or ASCVD as an adjunct to diet and maximally tolerated statin therapy, when additional LDL lowering is required.[9,10] Evolocumab is also indicated as an adjunct in homozygous FH.[9,10] Recently, the results of the CV outcomes study for evolocumab and bococizumab (not currently FDA approved) were published.[43,44] The evolocumab CV outcome study demonstrated a reduction in the primary CV composite endpoint on top of statin therapy and was a primary driver for the updated ACC ECDP for nonstatin therapy presented in Table 12–7. Alirocumab's CV outcome trial demonstrated a reduction in major adverse cardiovascular events in post-acute coronary syndrome patients who were taking maximally tolerated statins compared to placebo.[45,46]

Combination Pharmacotherapy

A large proportion of the US population remains at a high risk for future CV events despite treatment with statin therapy. Reasons for high residual risk include inadequate starting doses, lack of dose escalation, and high baseline risk warranting lower treatment targets.[47] In addition, if lack of response is seen, patient adherence and adverse events should be assessed. Moreover, patients with concomitant elevations in triglycerides may need combination drug therapy to reach their non-HDL cholesterol goal. KEY CONCEPT Combination drug therapy is an effective means to achieve greater reductions in non-HDL and LDL cholesterol (statin plus ezetimibe or PCSK9 inhibitor) as well as lowering serum triglycerides (statin plus long-chain OM3FA or fibrate).

▶ *Combination Therapy for Elevated LDL Cholesterol*

LO 3 LO 5

For patients who do not achieve their non-HDL and LDL cholesterol goals with statin monotherapy and lifestyle modifications, including those unable to tolerate high doses due to adverse effects, combination therapy may be appropriate. The ACC ECDP for nonstatin therapy highlighted in Table 12–7 describes the first-line and second-line add-on therapies to statins for patients for both primary and secondary prevention of ASCVD. First-line add-on therapies include ezetimibe or PCSK9 inhibitors. Second-line add-on therapies include BAS. Ezetimibe, PCSK9 inhibitors, and BAS combine effectively with statins to augment further cholesterol reduction, with the largest LDL cholesterol and non-HDL cholesterol reductions seen with PCSK9 inhibitors combined with statins. Adverse events are similar to those of each product taken separately. The time until maximum effect on lipids for this combination is generally 2 to 6 weeks.

Some patients, in particular those with genetic forms of hypercholesterolemia such as FH (Table 12–1), require three or more drugs to manage their disorder. It is recommended that patients with FH obtain a minimum of greater than or equal to 50% reduction in LDL cholesterol.[8,11]

▶ *Combination Therapy for Elevated Cholesterol and Triglyceridemia with or Without Low HDL Cholesterol*

Fibrates are the most effective triglyceride-lowering agents and also raise HDL cholesterol levels. Combination therapy with a fibrate, particularly gemfibrozil, and a statin has been found to increase the risk for myopathy. Therefore, more frequent monitoring, thorough patient education, and consideration of factors that increase risk as reviewed previously should be considered.

KEY CONCEPT The evidence of reducing non-HDL and LDL cholesterol while substantially raising HDL cholesterol (statin plus niacin or fibrate) to reduce the risk of CHD related events to a greater degree than statin monotherapy remains in question. A recent trial found that the combination of fenofibrate and simvastatin did not reduce the overall rate of fatal cardiovascular events, nonfatal MI, or nonfatal stroke, as compared with simvastatin alone. However, in a prespecified subgroup analysis, incremental benefits of adding a fenofibrate to simvastatin therapy were noted in patients with triglycerides greater than or equal to 204 mg/dL (2.31 mmol/L) and HDL cholesterol less than or equal to 34 mg/dL (0.88 mmol/L).[48] Combining niacin with a statin augments the non-HDL and LDL cholesterol-lowering potential of niacin while enhancing both the HDL cholesterol-raising effects and triglyceride-lowering effects of the statin. A statin combined with niacin appears to offer greater benefits for reducing atherosclerosis progression compared with a statin

Patient Encounter 2, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: ST elevation MI 1 year ago with two drug eluting stents placed (one in left anterior descending artery and one in circumflex)

FH: Father and mother both alive. Father had MI at age 50. Brother has hypertension and type 2 DM

SH: Works for the post office as a letter sorter and exercises 3 times a week (rides bike 8–10 miles each time she exercises). Drinks alcohol (1–2 beers most nights)

Meds: Multivitamin once daily; lisinopril 20 mg once daily, metoprolol succinate 100 mg once daily, aspirin 81 mg daily, clopidogrel 75 mg daily, amlodipine 10 mg daily, simvastatin 20 mg daily

ROS: No chest pain, shortness of breath, or dizziness today in clinic

PE:

VS: BP 138/78 mm Hg, pulse 64 beats/min, RR 16 breaths/min, T 98.6°F (37°C), waist circumference 35 in (89 cm)

CV: RRR, normal S_1, S_2; no murmurs, rubs, or gallops

Abd: Soft, nontender, nondistended; positive for bowel sounds, no hepatosplenomegaly or abdominal aortic aneurysm

Exts: ABI 1.0

Neck: No carotid and basilar bruits

EENT: Within normal limits

Labs: Total cholesterol 205 mg/dL (5.30 mmol/L), triglycerides 220 mg/dL (2.48 mmol/L), HDL cholesterol 40 mg/dL (1.03 mmol/L), non-HDL cholesterol 165 mg/dL (4.27 mmol/L), LDL cholesterol 121 mg/dL (3.14 mmol/L), and glucose 110 mg/dL (6.1 mmol/L), all other labs within normal limits

Given this additional information, what is your assessment of the patient's ASCVD risk?

Identify your treatment goals for the patient based on the ACC/AHA guidelines.

What nonpharmacologic and pharmacologic alternatives are available for the patient?

Should her children be screened for high cholesterol and why?

Develop a care plan for the patient.

alone;[33] however, the incremental benefits on reducing CHD events remain in question.[40] Similar to fenofibrate, a subset of patients in both the highest triglyceride and lowest HDL cholesterol tertiles showed a trend toward benefit with addition of ER niacin. Formulations combining ER niacin and lovastatin (Advicor) and ER niacin and simvastatin (Simcor) are available, and are indicated for treatment of primary hypercholesterolemia and mixed dyslipidemia. The time until maximum effect on lipids for this combination is generally 3 to 6 weeks.

Compared with monotherapy, combination therapy may reduce patient adherence through increased side effects and increased costs. When used appropriately and with proper precautions, however, combination therapy is effective in normalizing lipid abnormalities, particularly in patients who cannot tolerate adequate doses of statin therapy for more severe forms of dyslipidemia.

OUTCOME EVALUATION

LO 6 LO 7

- The successful outcome in cholesterol management is to reduce cholesterol and triglycerides in an effort to alter the natural course of atherosclerosis and decrease future cardiovascular events and pancreatitis.
- Use an adequate trial of TLC in all patients, but institute pharmacotherapy concurrently in higher-risk patients.
- For patients in whom lipid-lowering drug therapy is indicated, statin treatment is the primary modality for reducing ASCVD risk because of their ability to substantially reduce non-HDL and LDL cholesterol, ability to reduce morbidity and mortality from atherosclerotic disease, convenient once-daily dosing, availability of inexpensive generics, and low risk of side effects.

Patient Care Process

Collect Information:

- Obtain fasting cholesterol profile.
- Obtain vital signs and physical examination findings.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.
- Obtain history of lipid-lowering therapy use (current and past).
- Obtain a family history for premature heart disease.
- Obtain a smoking history.
- Obtain a medical history for other comorbidities that may increase ASCVD risk.
- Obtain history of current diet and exercise regimen/pattern.

Assess the Information:

- Assess any abnormal lipid levels (Table 12–5).
- Assess lifestyle factors including diet and exercise habits.
- Assess if patient fits any of the four ACC/AHA statin benefit groups (Figure 12–6).
- Assess major risk factors for ASCVD (Table 12–8). Assign patient to risk category based on assessment and risk scoring as previously described (eg, Figure 12–6 and Tables 12–7 and 12–9).
- Assess if taking any medications that may contribute to abnormal lipid levels (Table 12–2).
- Assess concomitant diseases that may contribute to abnormal lipid levels (Table 12–2).
- Assess treatments for cholesterol the patient has used in the past (if any). If already receiving pharmacotherapy for dyslipidemia, assess efficacy, safety, and adherence. Are there any significant drug interactions?

Develop a Care Plan:

- Determine treatment goal for percent LDL cholesterol lowering, non-HDL cholesterol, and LDL cholesterol based on risk category (Table 12–7).
- Discuss importance of family screening if patient has FH.
- Select TLCs and educate patient on importance of TLCs and regular physical activity (Table 12–6).
- Consider starting pharmacotherapy in patients based on their risk category for ASCVD (eg, statin benefit groups in Figure 12–6). Consider potential disease and drug interactions that may affect choice or intensity of pharmacotherapy (Table 12–11).
- For patients with ASCVD or DM, consideration should be given to use of moderate or high-intensity statin therapy (Table 12–4), irrespective of baseline cholesterol levels.
- Determine patient's prescription coverage.

Implement the Care Plan:

LO 7

- Provide patient education and address concerns associated with ASCVD, hyperlipidemia, drug therapy, and therapy adherence.
- Educate patient on TLC interventions (eg, exercise, diet modifications).
- Start pharmacotherapy concordant with statin benefit group or overall ASCVD risk in collaboration with health care team.
- Develop a follow-up plan for the patient to assess efficacy and safety.

LO 7

- Stress the importance of medication adherence to the patient.
- Address any patient concerns about dyslipidemia and its management.

Follow-up: Monitor and Evaluate:

- Follow-up at regular intervals to assess cholesterol levels for attaining goals for dyslipidemia and monitoring of side effects (Table 12–11).
- Review medication adherence.
- Review physical examination, lab tests, and results of other diagnostic tests to assess changes in clinical status.
- For patients with FH, if it is not possible to attain desirable cholesterol levels, a reduction of at least 50% is recommended.
- Intensify TLC for those patients above cholesterol targets.
- Titrate therapy or add additional drug as needed.

- Use an individualized patient monitoring plan in an effort to promote medication safety, minimize side effects, maintain treatment adherence, and achieve lipid goals.
- Lipid goals should be assessed by determing if the patient has achieved their target LDL cholesterol reduction based on their statin benefit group (eg, clinical ASCVD patient on a high-intensity statin should achieve at least a 50% reduction in LDL cholesterol; if baseline LDL cholesterol values not available to calculate percent reduction then achieving an LDL cholesterol of less than 70 mg/dL [1.81 mmol/L] or a non-HDL cholesterol of less than 100 mg/dL [2.59 mmol/L] are additional targets).

ACKNOWLEDGMENT

The authors and editors wish to acknowledge and thank Dr. Matthew Ito, the primary author of this chapter in the first, second, third, and fourth editions of this book.

13 Hypovolemic Shock

Bradley A. Boucher and G. Christopher Wood

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. List the most common etiologies of decreased intravascular volume in hypovolemic shock patients.
2. Describe the major hemodynamic and metabolic abnormalities that occur in patients with hypovolemic shock.
3. Describe the clinical presentation including signs, symptoms, and laboratory test measurements for the typical hypovolemic shock patient.
4. Prepare a treatment plan with clearly defined outcome criteria for a hypovolemic shock patient that includes both fluid management and pharmacologic therapy.
5. Compare and contrast relative advantages and disadvantages of crystalloids, colloids, and blood products in the treatment of hypovolemic shock.
6. Outline the elements of damage control resuscitation in traumatic hemorrhagic shock patients.
7. Formulate a stepwise monitoring strategy for a hypovolemic shock patient.

INTRODUCTION

The primary function of the circulatory system is to supply oxygen and vital metabolic compounds to cells throughout the body, as well as removal of metabolic waste products. Circulatory shock is a life-threatening condition whereby this principal function is compromised resulting in inadequate cellular oxygen utilization.[1,2] When circulatory shock is caused by a severe loss of blood volume or body water, it is called hypovolemic shock. KEY CONCEPT By definition, hypovolemic shock occurs as a consequence of inadequate intravascular volume to meet the oxygen and metabolic needs of the body. Rapid and effective restoration of circulatory homeostasis using fluids, pharmacologic agents, and/or blood products is imperative to prevent complications of untreated shock and ultimately death.

ETIOLOGY AND EPIDEMIOLOGY

Practitioners must have a good understanding of cardiovascular physiology to diagnose, treat, and monitor circulatory problems in critically ill patients. The interrelationships among the major hemodynamic variables are depicted in Figure 13–1.[3] These variables include mean arterial pressure (MAP), cardiac output (CO), systemic vascular resistance (SVR), heart rate (HR), stroke volume (SV), left ventricular size, afterload, myocardial contractility, and preload. Although an oversimplification, Figure 13–1 is beneficial in conceptualizing where the major abnormalities occur in patients with circulatory shock as well as predicting the body's compensatory responses.

Hypovolemic shock is caused by a loss of intravascular volume either by hemorrhage or fluid loss (eg, dehydration). There is a profound deficit in preload, defined as the volume in the left ventricle at the end of diastole. Decreased preload results in subsequent decreases in SV, CO, and eventually, MAP. As such, restoration of preload becomes an overarching goal in the management of hypovolemic shock.

The prognosis of shock patients depends on several variables, including severity, duration, underlying etiology, preexisting organ dysfunction, and reversibility.[4] Data are not readily available on the incidence of hypovolemic shock, although hypovolemia due to hemorrhage is a major factor in 40% to 50% of trauma deaths annually.[5]

PATHOPHYSIOLOGY

The total amount of water in a typical 70-kg (154-lb) adult is approximately 42 L (Figure 13–2). About 28 of the 42 L are inside the cells of the body (intracellular fluid); the remaining 14 L are in the extracellular fluid space (fluid outside of cells, ie, interstitial fluid and plasma). Circulating blood volume for a normal adult is roughly 5 L (70 mL/kg) and is composed of 2 L of red blood cell fluid (intracellular) and 3 L of plasma (extracellular).

KEY CONCEPT Regardless of etiology, the most distinctive clinical manifestations of hypovolemic shock are arterial hypotension, clinical signs of hypoperfusion, and metabolic acidosis.[2] Metabolic acidosis is a consequence of an accumulation of lactic acid resulting from tissue hypoxia and anaerobic metabolism. If the decrease in MAP is severe and protracted, such hypotension will inevitably lead to severe hypoperfusion and organ dysfunction. Diminished intravascular volume can result from severe external or internal bleeding, profound fluid losses from gastrointestinal (GI) sources such as diarrhea or vomiting, or urinary losses such as diuretic use, diabetic ketoacidosis, or diabetes insipidus (Table 13–1).[1] Other sources of intravascular fluid loss can occur through damaged skin, as seen with burns, or via capillary leak into the interstitial space or peritoneal cavity, as seen with edema or ascites. This latter phenomenon

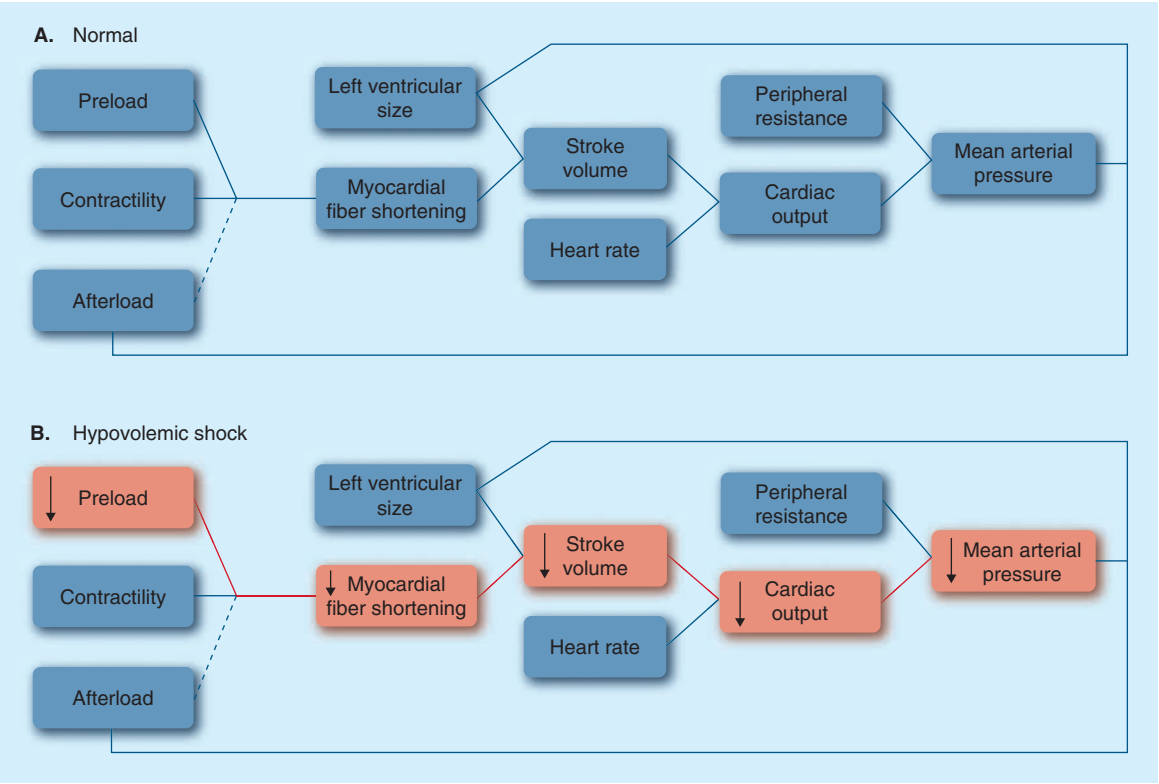

FIGURE 13–1. Hemodynamic relationships among key cardiovascular parameters (**A**). Solid lines represent a direct relationship; the broken line represents an inverse relationship. In (**B**), the alterations typically observed in hypovolemic shock are highlighted with arrows depicting the likely direction of the alteration. (Panel A from Braunwald E. Regulation of the circulation. I. N Engl J Med. 1974;290:1124–1129, with permission.)

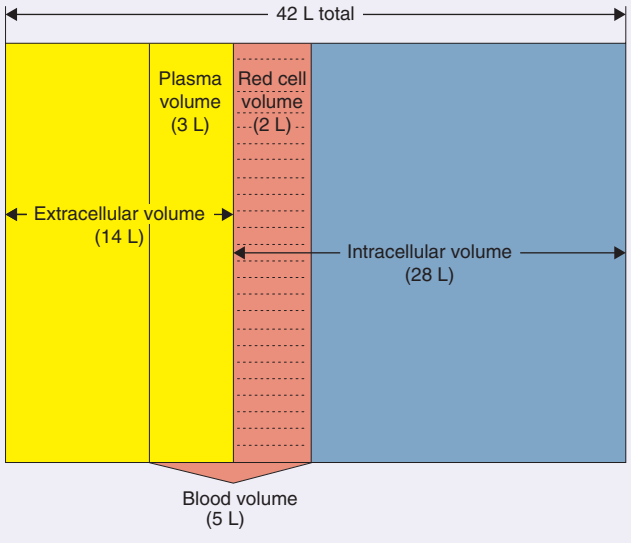

FIGURE 13–2. Distribution of body fluids showing the extracellular fluid volume, intracellular body fluid volume, and total body fluids in a 70-kg (154-lb) adult. Extracellular volume (ECV; yellow section of figure) comprises 14 L of total body fluid (42 L). Plasma volume makes up approximately 3 L of the 14 L of ECV. Intracellular volume (blue section of figure) accounts for the remaining 28 L of total body fluids, with roughly 2 L located within the red blood cells. Blood volume (~5 L) is also depicted and made up of primarily red blood cells and plasma (red section of figure). (From Guyton AC, Hall JE. Textbook of Medical Physiology, 8th ed. Philadelphia, PA: Saunders; 1991:275, with permission.)

is often referred to as third spacing because fluid accumulates in the interstitial space disproportionately to the intracellular and extracellular fluid spaces. Regional ischemia may also develop as blood flow is naturally shunted from organs such as the GI tract or the kidneys to more immediately vital organs such as the heart and brain.

Hypovolemic shock symptoms begin to occur with decreases in intravascular volume in excess of 750 to 1500 mL (about 1.5–3 pints) or 15% to 30% of the circulating blood volume (20–40 mL/kg in pediatric patients).[6] Decreases in preload result in decreases in SV. Initially, CO may be partially maintained by compensatory tachycardia. Similarly, reflex increases in SVR and myocardial contractility may diminish arterial hypotension. Regardless, rapid losses (eg, minutes) undoubtedly have more profound effects than losses over a longer period (eg, hours). This neurohumoral response to hypovolemia is mediated by the sympathetic nervous

Table 13–1

system in an attempt to preserve perfusion to vital organs such as the heart and brain. Two major end points of this response are to conserve water to maximize intravascular volume and to improve tissue perfusion by increasing MAP and CO (oxygen delivery). The body attempts to maximize its fluid status by decreasing water and sodium excretion through release of antidiuretic hormone (ADH), aldosterone, and cortisol. MAP is maintained by peripheral vasoconstriction mediated by catecholamine release and the renin-angiotensin system.[1] CO is augmented by catecholamine release and fluid retention.[1,7] Unfortunately, the increased sympathetic drive may become detrimental as tissue ischemia occurs with inconsistent microcirculatory flow.[1] Regardless, when intravascular volume losses exceed 1500 mL (about 3 pints), the compensatory mechanisms are inadequate, typically resulting in a fall in CO and MAP; acute losses greater than 2000 mL (about 4 pints) are life threatening (35 mL/kg in pediatric patients).[8] The decrease in CO results in a diminished delivery of oxygen to tissues within the body and activation of an acute inflammatory response.[1,5] Oxygen delivery can be further compromised by inadequate blood hemoglobin levels due to hemorrhage and/or diminished hemoglobin saturation due to impaired ventilation. Decreased delivery of oxygen and other vital nutrients results in diminished production of the energy substrate, adenosine triphosphate (ATP). Lactic acid is then produced as a by-product of anaerobic metabolism within tissues throughout the body.[7] Lactic acidosis is a key indicator that inadequate tissue perfusion has occurred.[7]

KEY CONCEPT Protracted tissue hypoxia sets in motion a downward spiral of events leading to organ dysfunction and eventual failure if untreated. Table 13–2 describes the effects of shock on the body's major organs. Relative failure of more than one organ is referred to as the multiple organ dysfunction syndrome (MODS). Involvement of the heart is particularly devastating considering the central role it plays in oxygen delivery and the potential for myocardial dysfunction to perpetuate the shock state. Preexisting organ dysfunction and buildup of inflammatory mediators can also exacerbate the effects of hypovolemic shock to the point of irreversibility.[5] For example, acute or chronic heart failure can lead to pulmonary edema, further aggravating gas exchange in the lungs and ultimately tissue hypoxia. Only about one-third of early-onset MODS is quickly reversible (within 48 hours) with proper fluid resuscitation. Thus it is imperative that hypovolemic shock be treated quickly to avoid MODS.[9]

LO 3

Clinical Presentation and Diagnosis

General

Patients will be in acute distress, although symptoms and signs will vary depending on the severity of the hypovolemia and whether the etiology is hemorrhagic versus nonhemorrhagic.

Symptoms

- Thirst
- Weakness
- Light-headedness

Signs

- Hypotension, arterial systolic blood pressure (SBP) less than 90 mm Hg or fall in SBP greater than 40 mm Hg
- Tachycardia
- Tachypnea
- Hypothermia
- Oliguria
- Dark, yellow-colored urine
- Skin color: pale to ashen; may be cyanotic in severe cases
- Skin temperature: cool to cold
- Mental status: confusion to coma
- Pulmonary artery (PA) catheter measurements: decreased CO, decreased SV, increased SVR, low pulmonary artery occlusion pressure (PAOP)
- Organ dysfunction (see Table 13–2)

Laboratory Tests

- Increased serum lactate
- Decreased arterial pH
- Decreased hemoglobin/hematocrit (hemorrhagic hypovolemic shock)
- Hypernatremia
- Elevated serum creatinine (SCr)
- Elevated blood urea nitrogen
- Hyperglycemia

TREATMENT

Desired Outcomes

KEY CONCEPT The major goals in treating hypovolemic shock are to restore effective circulating blood volume, as well as manage its underlying cause. In achieving this goal, the downward spiral of events that can perpetuate severe or protracted hypovolemic shock is interrupted. This is accomplished through the delivery of adequate oxygen and metabolic substrates such as glucose and electrolytes to the tissues throughout the body that will

optimally bring about a restoration of organ function and return to homeostasis. Evidence of the latter is a return to the patient's baseline vital signs, relative normalization of laboratory test results, and alleviation of other signs and symptoms of hypovolemic shock previously discussed. Concurrent supportive therapies are also warranted to avoid exacerbation of organ dysfunction associated with the hypovolemic shock event.

General Approach to Therapy

LO 4 Securing an adequate airway and ventilation is imperative in hypovolemic shock patients consistent with the "VIP Rule" of resuscitation: Ventilate (oxygen administration), Infuse (fluid resuscitation), and Pump (administration of a vasoactive agent).[2] Any compromise in ventilation only accentuates the tissue hypoxia occurring secondary to inadequate perfusion. Thus, early sedation, endotracheal intubation, and mechanical ventilation typically occur at this stage of resuscitation (Figure 13–3). Intravenous (IV) access is also essential for administration of fluids and medications, and is facilitated through the placement of peripheral IV lines or catheterization with central venous lines if rapid or large volumes of resuscitative fluids are indicated. Placement of an arterial catheter is advantageous to allow for accurate and continual monitoring of MAP, as well as arterial blood gas (ABG) sampling. A bladder catheter should be inserted for ongoing monitoring of urine output. Baseline laboratory tests that should be obtained immediately include complete blood cell count with differential, serum chemistry profile, liver enzymes, prothrombin and partial thromboplastin times, and serum lactate. A urinalysis and an ABG should also be obtained, and ongoing electrocardiogram (ECG) monitoring should be performed. In addition to restoring circulating blood volume, it is necessary to prevent further losses from the vascular space. This is especially true with hemorrhagic hypovolemic shock where identifying the bleeding site and achievement of hemostasis are critical in the successful resuscitation of the patient. This frequently involves surgical treatment of hemorrhages.

Upon stabilization, placement of a PA catheter may be indicated based on the need for more extensive cardiovascular monitoring than is available from noninvasive measurements such as vital signs, cardiac rhythm, and urine output.[10,11] Key measured parameters obtained from a PA catheter are the PAOP, which is a measure of left ventricular preload, and CO. From the CO values and simultaneous measurement of HR and MAP, one can calculate the left ventricular SV and SVR.[11] Placement of a PA catheter should be reserved for patients at high risk of death due to the severity of shock or preexisting medical conditions such as heart failure.[12] An alternative to the PA catheter is placement of a central venous catheter that typically resides in the superior vena cava to monitor central venous pressure (CVP). Central venous catheters are less expensive, can be more readily placed, and have been associated with comparable survival and fewer complications than PA catheters in select critically ill patient subsets (eg, acute lung injury).[13] Thus, movement has been away from the routine use of PA catheters.

▶ *Fluid Therapy*

The use of fluids is the cornerstone of managing hypovolemic shock.[1,2] KEY CONCEPT Three major therapeutic options are available to clinicians for restoring circulating blood volume: crystalloids (electrolyte-based solutions), colloids (large molecular weight solutions), and blood products.[14] Blood products are used only in instances involving hemorrhage (or severe preexisting anemia), thus leaving crystalloids and colloids as the mainstay of therapy in all types of hypovolemic shock, along with adjunctive vasopressor support. The aggressiveness of fluid resuscitation (rate and volume) is driven by the severity of the hypovolemic shock and the underlying cause. Warming of all fluids to 37°C (98.6°F) prior to administration is an important consideration to prevent hypothermia, arrhythmias, and coagulopathy because these complications will have a negative impact on the success of the resuscitation effort.[15]

Crystalloids Conventional crystalloid solutions are fluids with (a) electrolyte composition that approximates plasma known as balanced solutions (eg, lactated Ringer's solution [LR] or Plasma-Lyte), or (b) a total calculated osmolality similar to that of plasma (280–295 mOsm/kg [mmol/kg]), such as 0.9% sodium chloride (also known as normal saline [NS] or 0.9% NaCl) (Table 13–3).[14,16] Thus, conventional crystalloids distribute in normal proportions throughout the extracellular fluid space upon administration. In other words, expansion of the intravascular space only increases by roughly 200 to 250 mL for every liter of isotonic crystalloid fluid administered.[5] Hypertonic crystalloid solutions such as 3% NaCl or 7.5% NaCl have osmolalities substantially higher than plasma. The effect observed with these fluids is a relatively larger volume expansion of the intravascular space. By comparison with conventional crystalloids, administration of 250 mL of 7.5% sodium chloride results in an intravascular space increase of 500 mL.[5] This increase is a result of the fluid administered as well as osmotic drawing of intracellular fluid into the intravascular and interstitial spaces. This occurs because the hypertonic saline increases the osmolality of the intravascular and interstitial fluid compared with the intracellular fluid. Hypertonic saline also has the potential for decreasing the inflammatory response.[1] Despite these theoretical advantages, data are lacking demonstrating superiority of hypertonic crystalloid solutions compared with isotonic solutions.[17,18] Crystalloids are generally advocated as the initial resuscitation fluid in hypovolemic shock because of their availability, low cost, and equivalent outcomes compared with colloids.[10] A reasonable initial volume of an isotonic crystalloid (0.9% NaCl, LR, or Plasma-Lyte) in adult patients is 1000 to 2000 mL administered over the first hour of therapy.[6] Ongoing external or internal bleeding requires more aggressive fluid resuscitation. KEY CONCEPT In the absence of ongoing blood loss, administration of 2000 to 4000 mL of isotonic crystalloid normally reestablishes baseline vital signs in adult hypovolemic shock patients.[19]

LO 5

Patient Encounter Part 1

A 27-year-old man is admitted to the trauma center with a severely mangled right arm from a heavy equipment accident at work. He has extensive soft tissue damage, an open humerus fracture, and is actively bleeding. The first responders report heavy blood loss at the scene and in transit. The patient is in obvious pain and is only partially oriented. He is agitated so much that he is interfering with the trauma team's ability to assess and care for him. His initial blood pressure (BP) is 77/45 mm Hg.

Is this patient in shock? If so, what type of shock does the patient have and what is the cause?

Describe ways that the patient can be stabilized for a full assessment.

Describe the first nonpharmacologic steps in treating the patient.

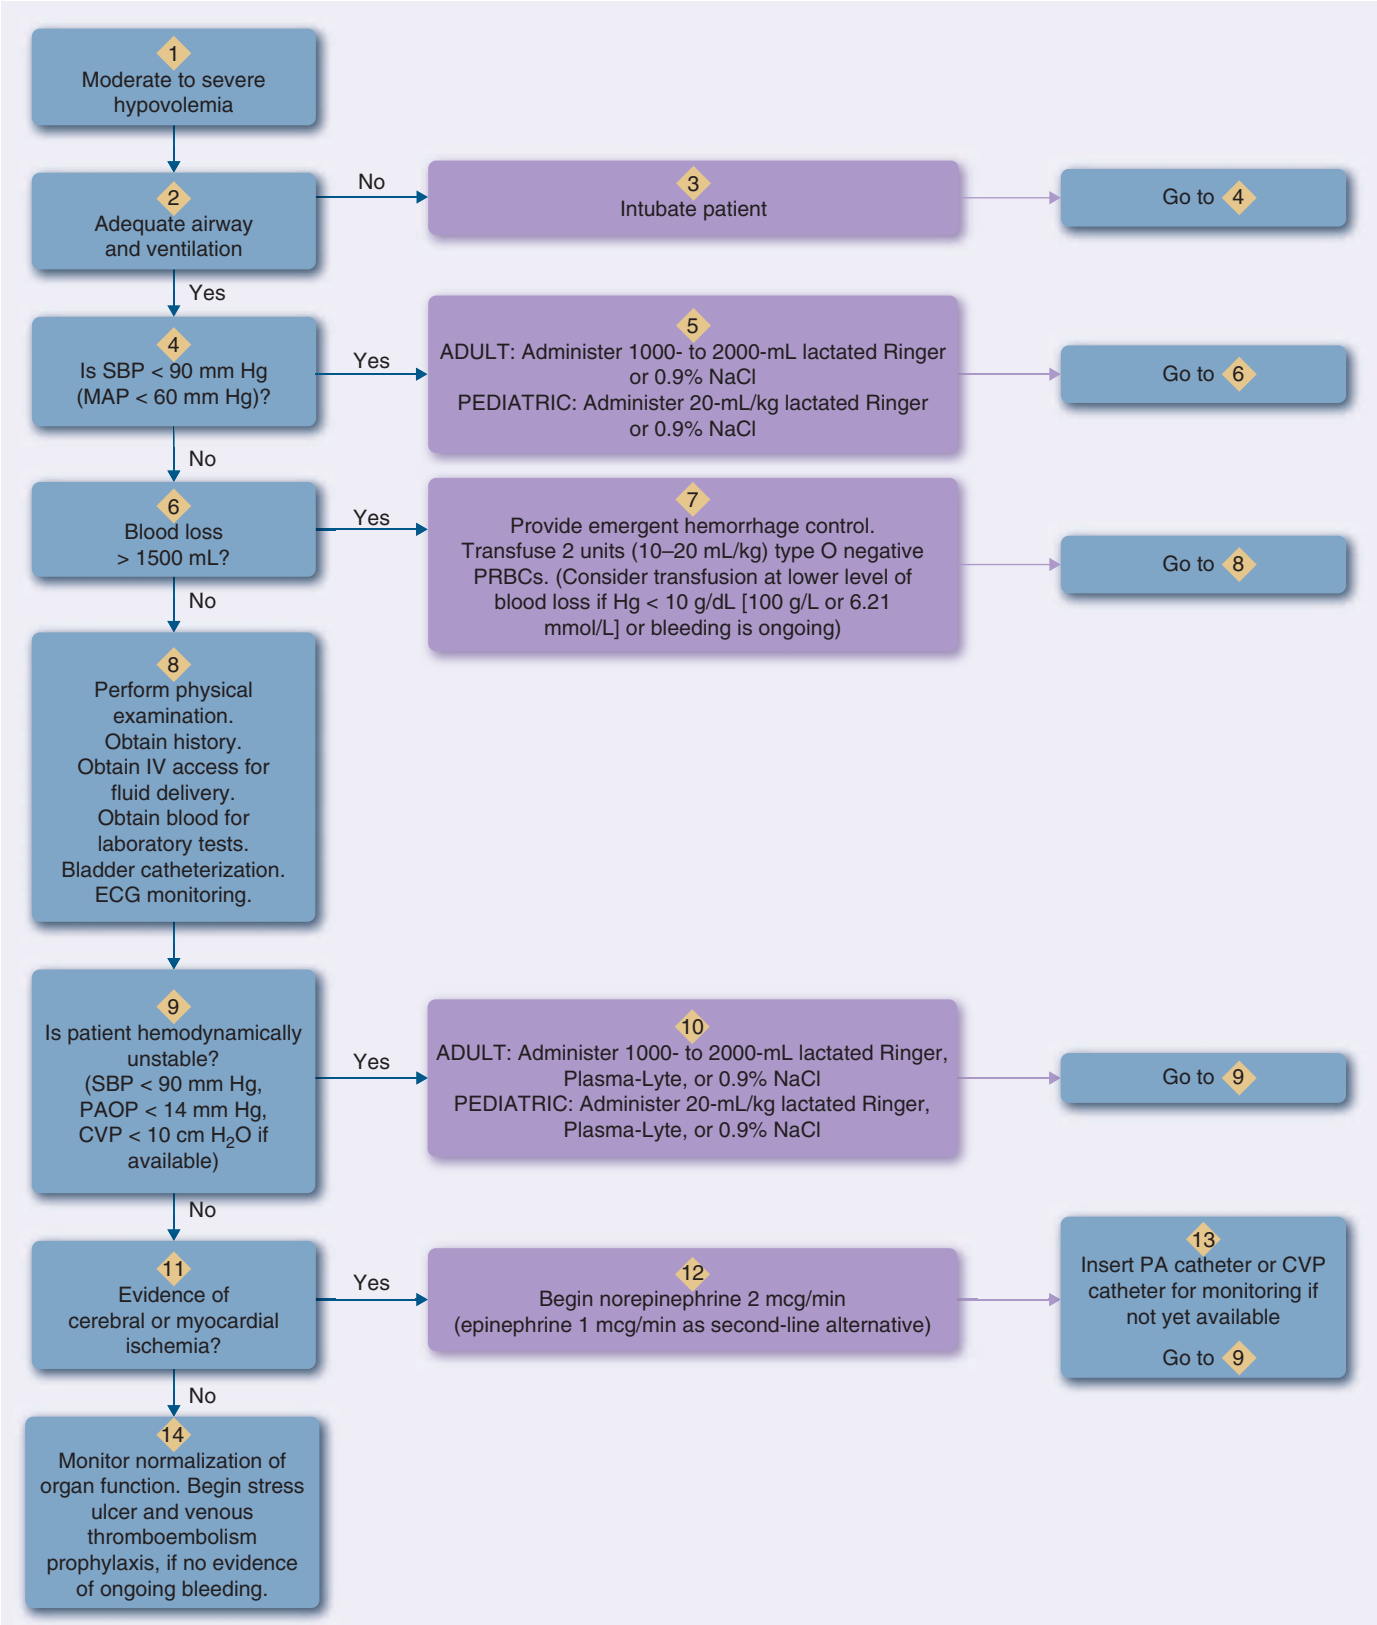

FIGURE 13–3. Treatment algorithm for the management of moderate to severe hypovolemia (balanced solution: lactated Ringer's solution, Plasma-Lyte). (CVP, central venous pressure; ECG, electrocardiogram; Hg, hemoglobin; IV, intravenous; MAP, mean arterial pressure; NaCl, sodium chloride or normal saline; PA, pulmonary artery; PAOP, pulmonary artery occlusion pressure; PRBCs, packed red blood cells; SBP, systolic blood pressure.) Hemoglobin concentration of 10 g/dL is equivalent to 100 g/L or 6.21 mmol/L.

Table 13–3

Composition of Common Resuscitation Fluids[14,16]

Fluid	Na (mEq/L)[a]	Cl (mEq/L)[a]	K (mEq/L)[a]	Mg (mEq/L)[b]	Ca (mEq/L)[b]	Lactate (mEq/L)[a]	Other	pH	Osmolality (mOsm/kg)[c]
0.9% NaCl	154	154						5.0	308
3% NaCl	513	513						5.0	1027
7.5% NaCl	1283	1283						5.0	2567
Lactated Ringer	130	109	4		2.7	28		6.5	273
Plasma-Lyte A	140	98	5	3			27 mEq/L (27 mmol/L) Acetate	7.4	294
Plasma-Lyte 148	140	98	5	3			27 mEq/L (27 mmol/L) Acetate	5.5	294
Hetastarch (Hextend)	143	124	3	0.9	5	28	Hetastarch 6 g/dL (60 g/L)	5.9	307
Hetastarch (Hespan)	154	154					Hetastarch 6 g/dL (60 g/L)	5.5	310
Pentastarch	154	154					Pentastarch 10 g/dL (100 g/L)	5.0	326
5% Albumin	130–160	130–160					Albumin 5 g/dL (50 g/L)	6.9	
25% Albumin	130–160	130–160					Albumin 25 g/dL (250 g/L)	6.9	
5% PPF	130–160	130–160	0.25				Plasma proteins 5 g/dL (50 g/L) (88% albumin)	7.0	
Dextran 40	154	154					Dextran 10 g/dL (100 g/L) (avg molecular weight 40 kDa)		
Dextran 70	154	154					Dextran 6 g/dL (60 g/L) (avg molecular weight 70 kDa)	5.5	308
Dextran 75	154	154					Dextran 6 g/dL (60 g/L) (avg molecular weight 75 kDa)	5.5	308

[a]For these values, mEq/L = mmol/L (eg, 154 mEq/L Na = 154 mmol/L).

[b]For these values, mEq/L × 0.5 = mmol/L (eg, 0.9 mEq/L Mg = 0.45 mmol/L Mg).

[c]For this value, mOsm/kg = mmol/kg (eg, 308 mOsm/kg = 308 mmol/kg).

avg, average; Ca, calcium; Cl, chloride; K, potassium; kDa, kilodalton; Mg, magnesium; Na, sodium; NaCl, sodium chloride or normal saline; PPF, plasma protein fraction.

Selected populations, such as burn patients, may require more aggressive fluid resuscitation.[20] In hemorrhagic shock patients, approximately three to four times the shed blood volume of isotonic crystalloids is needed for effective resuscitation.[20] Nevertheless, individualization of therapy is critical with well-defined endpoints to avoid excessive administration of crystalloids based on studies in trauma patients.[21]

Side effects from crystalloids primarily involve fluid overload and electrolyte disturbances of sodium, potassium, and chloride.[1] Dilution of coagulation factors can also occur resulting in a dilutional coagulopathy.[5] Two clinically significant differences between balanced solutions and NS is that the former contains potassium and has a lower sodium content (130 vs 154 mEq/L [mmol/L]). Therefore, balanced crystalloid solutions have a greater potential than NS to cause hyponatremia and/or hyperkalemia. Alternatively, NS can cause hypernatremia, hypokalemia, metabolic acidosis, and hyperchloremia. This latter adverse event is particularly concerning as a potential risk factor for acute kidney injury in critically ill patients.[22] Thus, based on their buffering capacity, lower chloride content, and respective side-effect profiles, balanced crystalloid solutions are deemed, in theory, to be the superior resuscitative fluid compared with NS by some authorities.[23,24] However, improvements in outcome have not been consistently documented with balanced crystalloid solutions nor a clear association of NS that contains a higher chloride content with acute kidney injury.[22,25] Therefore, currently there is no consensus in selecting a balanced crystalloid solution over NS.

Colloids Understanding the effects of colloid administration on circulating blood volume necessitates a review of those physiological forces that determine fluid movement between capillaries and the interstitial space throughout the circulation (Figure 13–4).[5,26] Relative hydrostatic pressure between the capillary lumen and the interstitial space is one of the major determinants of net fluid flow in or out of the circulation. The other major determinant is the relative colloid osmotic pressure between the two spaces (ie, oncotic pressure). Administration of exogenous colloids results in an increase in the intravascular colloid osmotic pressure. The effects of colloids on intravascular volume are a consequence of their relatively large molecular size (> 30 kilodaltons [kDa]), limiting their passage across the capillary membrane in large amounts. Alternately stated, colloids can be conceptualized as "sponges" drawing fluid into the intravascular space from the interstitial space. In the case of isooncotic colloids (5% albumin, 6% hetastarch, and dextran products), initial expansion of the intravascular space is essentially 65% to 75% of the volume of colloid administered, accounting for some "leakage" of the colloid from the intravascular space.[5]

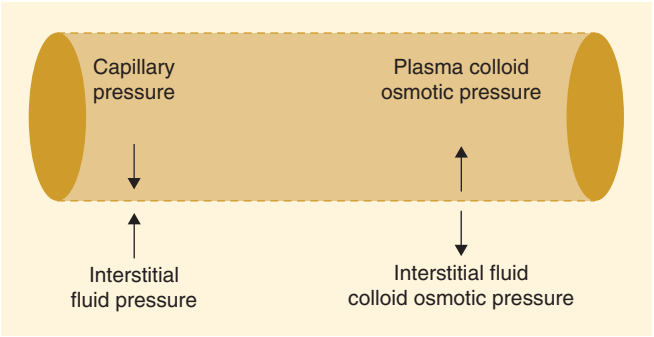

FIGURE 13–4. Operative forces at the capillary membrane tend to move fluid either outward or inward through the capillary membrane. In hypovolemic shock, one therapeutic strategy is the administration of colloids that can sustain and/or draw fluid from the interstitial space by increasing the plasma colloid osmotic pressure. (From Guyton AC, Hall JE. Textbook of Medical Physiology, 8th ed. Philadelphia, PA: Saunders; 1991:174, with permission.)

KEY CONCEPT Thus, in contrast to isotonic crystalloid solutions that distribute throughout the extracellular fluid space, the volume of isooncotic colloids administered remains relatively confined to the intravascular space. In the case of hyperoncotic solutions such as 25% albumin, fluid is pulled from the interstitial space into the vasculature, resulting in an increase in the intravascular volume that is much greater than the original volume of the 25% albumin that was administered. Although theoretically attractive, hyperoncotic solutions should not be used for hypovolemic shock because the expansion of the intravascular space is at the expense of depletion of the interstitial space. Exogenous colloids available in the United States include 5% albumin, 25% albumin, 5% plasma protein fraction (PPF), 6% hetastarch, 10% pentastarch, 10% dextran 40, 6% dextran 70, and 6% dextran 75 (see Table 13–3). The first three products are derived from pooled human plasma. Hetastarch and pentastarch are semisynthetic hydroxyethyl starches derived from amylopectin. The dextran products are semisynthetic glucose polymers that vary in terms of the average molecular weight of the polymers. Superiority of one colloid solution over another in terms of efficacy has not been clearly established.[27,28] Nonetheless, data suggests that albumin appears advantageous in septic patients while it should be avoided in patients with traumatic brain injury.[14]

For years within the critical care literature, a controversy known as the "colloid versus crystalloid debate" raged over the relative merits of these two types of resuscitation fluids. Largely in response to a major trial that demonstrated no difference in mortality between patients receiving saline versus albumin,[29] the Food and Drug Administration (FDA) issued a notice to health care providers declaring albumin safe for use in most critically ill patients.[30] However, based on previous data, there does not appear to be a clear-cut overall advantage relative to mortality for either crystalloids or colloids in these patient groups.[30] This was confirmed in a large study known as the CRISTAL (Colloids Versus Crystalloids for the Resuscitation of the Critically Ill) Randomized Trial published in 2013.[31] Thus, most clinicians today prefer using crystalloids based on their availability and inexpensive cost compared with colloids.[20,28] However, in addition to these factors, a shift in this debate has recently taken place focused on adverse events.

LO 5

Generally, the major adverse effects associated with colloids are fluid overload, dilutional coagulopathy, and anaphylactoid/anaphylactic reactions.[32] Because of direct effects on the coagulation system with the hydroxyethyl starch and dextran products, they should be avoided in hemorrhagic shock patients. Further, hetastarch has been associated with an increased risk of acute kidney injury in several recent clinical trials. As such, hydroxyethyl starch products are no longer recommended.[28] Despite these general limitations, there is a paradigm shift in a subset of hypovolemic shock patients, ie, traumatic hemorrhagic shock to minimize crystalloids, increase the use of blood products and plasma, as well as accepting lower MAP values (permissive hypotension). Collectively, this approach is referred to as damage control resuscitation (DCR).[33]

LO 6

▶ *Blood Products*

KEY CONCEPT Blood products are indicated in hypovolemic shock patients who have sustained blood losses from hemorrhage exceeding 1500 mL. This, in fact, is the only setting in which freshly procured whole blood is administered. In virtually all other settings, blood products are given as the individual components of whole blood units, such as packed red blood cells (PRBCs), fresh-frozen plasma (FFP), platelets, cryoprecipitate, and prothrombin complex concentrates (PCC).[34] This includes ongoing resuscitation of hemorrhagic shock when PRBCs can be transfused to increase oxygen-carrying capacity in concert with crystalloid solutions to increase blood volume. In patients with documented coagulopathies, FFP for global replacement of lost or diluted clotting factors, or platelets for patients with severe thrombocytopenia (< 20–50 × 10^3/mm^3 [20–50 × 10^9/L]) should be administered.[35,36] Data suggests that increasing the ratio of FFP to PRBC units may be associated with improved mortality and a reduction in the number of PRBC transfusions in patients requiring multiple transfusions.[37,38] Use of **viscoelastic testing** may also be a valuable tool for assessing coagulation defects and guiding FFP and PCC administration, especially emergently.[39] Type O negative blood or "universal donor blood" is given in emergent cases of hemorrhagic shock. Thereafter, blood that has been typed and cross-matched with the recipient's blood is given.

LO 5

The traditional threshold for PRBC transfusion in hypovolemic shock has been a serum hemoglobin of less than 10 g/dL (100 g/L [6.21 mmol/L]) and hematocrit (Hct) less than 30% (0.30). However, for critically ill patients who have received appropriate fluid resuscitation and have no signs of ongoing bleeding, a more restrictive transfusion threshold of 7 g/dL (70 g/L [4.34 mmol/L]) appears to be safe.[40] Traditional risks from allogeneic blood product administration include hemolytic and nonhemolytic transfusion reactions and transmission of blood-borne infections in contaminated blood. Recent large studies have also shown that transfusions are associated with increased infection and higher mortality, possibly because of adverse immune and inflammatory effects.[34,41] Increased thromboembolic events and mortality have been documented for patients receiving PRBCs stored longer than 28 days.[42] Thus administration of blood products should be restricted whenever possible and used as early as possible following donation.

▶ *Pharmacologic Therapy*

Vasopressor is the term used to describe any pharmacologic agent that can induce arterial vasoconstriction through stimulation of the α_1-adrenergic receptors or V_1 receptor. KEY CONCEPT Although replenishment of intravascular volume is undoubtedly the

Extremities: Right arm with open fracture, soft tissue damage, and moderate bleeding

Pertinent labs: pH 7.20, $PaCO_2$ 34 mm Hg (4.5 kPa), PaO_2 70 mm Hg (9.3 kPa), Na 133 mEq/L (mmol/L), Cl 98 mEq/L (mmol/L), HCO_3 16 mEq/L (mmol/L), K 5.2 mEq/L (mmol/L), Mg 2.8 mg/dL (1.15 mmol/L), lactate 6.0 mEq/L (mmol/L), SCr 1.5 mg/dL (133 µmol/L), Hct 28% (0.28)

What signs and symptoms of hypovolemic shock are present in this patient?

What laboratory abnormalities related to hypovolemic shock are present in this patient and why?

Describe treatment goals for the patient in the next hour.

Develop a pharmacologic and fluid therapy plan for initial therapy. Defend your selections compared to alternative agents.

Discuss the role in therapy for blood products, sodium bicarbonate, and hemostatic agents in the patient at this time.

Describe treatment goals for the patient in the next 24 hours.

cornerstone of hypovolemic shock therapy, use of vasopressors may be warranted as a temporary measure in patients with profound hypotension or evidence of organ dysfunction in the early stages of shock.[2,10] Vasopressors are typically used concurrently with fluid administration after the latter has not resulted in adequate restoration of MAP and/or tissue perfusion.[43] Table 13–4 lists those vasopressors recommended for use in the management of hypovolemic shock.[1] Although vasopressor therapy may improve the hemodynamic profile in shock patients, data are lacking that they improve mortality.[44] Furthermore, a study found that early use of vasopressors (ie, phenylephrine, norepinephrine, dopamine, vasopressin) in the resuscitation of patients with hemorrhagic shock may actually be associated with increased mortality.[45] Regardless, data suggest that if vasopressors are used, norepinephrine is preferable to dopamine secondary to increased incidence of arrhythmias associated with the latter agent in the treatment of shock patients.[46,47] Thus norepinephrine should be considered the first-line vasopressor therapy for these patients.[2,44] Epinephrine should be considered as a second-line vasopressor in patients with shock because of its association with tachyarrhythmias, impaired abdominal organ (splanchnic) circulation, and hypoglycemia.[2,43] In cases involving concurrent heart failure, an inotropic agent such as dobutamine may be needed, in addition to the use of a vasopressor.[2]

Vasopressors are almost exclusively administered as continuous infusions because of their very short duration of action and the need for close titration of their dose-related effects. Starting doses should be at the lower end of the dosing range followed by rapid titration upward if needed to maintain adequate MAP. Monitoring of end-organ function such as adequate urine output should also be used to monitor therapy. Once MAP is restored, vasopressors should be weaned and discontinued as soon as possible to avoid any untoward events.[2] The most significant systemic adverse events associated with vasopressors are excessive vasoconstriction

Table 13–4

Vasopressor Drugs

		Adrenergic Effects			
Drug	**Usual IV Dose**	**α**	**β_1**	**Dopaminergic**	**Potential to Cause Arrhythmias**
Dopamine	10–20 mcg/kg/min[a]	+++	++	+++	+++
Norepinephrine	0.5–80 mcg/min	+++	++	0	++
Epinephrine	1–200 mcg/min	++	+++	0	+++
Phenylephrine	0.5–9 mcg/kg/min	+++	0	0	0

[a]Lower dosages of dopamine may not produce desired α_1-adrenergic (vasopressor) effects.

+ = Low

++ = Moderate

+++ = High

IV, intravenous.

Patient Encounter Part 3

One hour after the initial fluid bolus, the patient's vital signs are BP 82/54 mm Hg, P 125 beats/min, RR 21 breaths/min, urine output 10 mL in the past hour. Pertinent new labs: lactate 4.5 mEq/L (mmol/L). He is weak and confused.

Assess the patient's condition compared to one hour ago.

Develop a plan for additional therapy, if any, that you recommend at this time.

Outline a plan for monitoring the patient over the next 24 hours.

What cultural beliefs, norms, or values should be considered when treating patients with hemorrhagic shock?

resulting in decreased organ perfusion and potential to induce arrhythmias (see Table 13–4). Central venous catheters should be used to minimize the risk of local tissue necrosis that can occur with extravasation of peripheral IV catheters.

▶ *Hemostatic Agents*

Several systemic pharmacologic agents have been used historically in patients with severe bleeding including the procoagulant, recombinant activated factor VII. Off-label use of this latter drug has fallen into disfavor due to uncertain efficacy, safety concerns, and high acquisition cost. In recent years, the greatest interest has shifted instead to the use of the antifibrinolytic drug, tranexamic acid. A recent study of tranexamic acid in trauma patients with or at risk of significant bleeding demonstrated a decrease in mortality compared with placebo.[48] As such, a recent European guideline recommends the use of tranexamic acid within 3 hours of injury (1 gram IV over 10 minutes then 1 gram over 8 hours) as an adjunctive agent in the management of bleeding trauma patients as well as spurring additional research including possible prehospital use.[35]

▶ *Supportive Care Measures*

Lactic acidosis, which typically accompanies hypovolemic shock as a consequence of tissue hypoxia, is best treated by reversal of the underlying cause. Administration of alkalizing agents such as sodium bicarbonate has not been demonstrated to have any beneficial effects and may actually worsen intracellular acidosis.[49] Noteworthy, however, the latter precautionary statement is based on limited retrospective data in a variety of patients with lactic acidosis. Because GI ischemia is a common complication of hypovolemic shock, prevention of stress-related mucosal disease should be instituted as soon as the patient is stabilized. The most common agents used for stress ulcer prophylaxis are the histamine$_2$-receptor antagonists and proton pump inhibitors. Prevention of thromboembolic events is another secondary consideration in hypovolemic shock patients. This can be accomplished with the use of external devices such as sequential compression devices and/or antithrombotic therapy such as the low-molecular-weight heparin products or unfractionated heparin. Sequential compression devices are preferred in any hypovolemic shock patient at risk of ongoing bleeding.

Patient Care Process

LO 7

Collect Information:

- Conduct medical history to determine the cause of shock to guide pharmacologic and nonpharmacologic therapy.
- Obtain pertinent laboratory tests (electrolytes, complete blood count [CBC], coagulation tests, ABG, serum lactate, liver function tests) to help determine shock severity and organ dysfunction.

Assess the Information:

- Assess airway/ventilation status to determine the need for supplemental oxygen/mechanical ventilation.
- Assess vital signs and urine output at least every 15 minutes (continuously if possible) to determine shock severity.
- Determine adequacy of current blood product therapy (if applicable).
- Determine adequacy of current vasopressor/inotropic therapy (if applicable).

Develop a Care Plan:

- Assure venous access to deliver fluid resuscitation.
- Determine fluid to be used including rate of administration.
- Determine if blood products are needed and dose. It should be noted that some religious denominations (eg, Jehovah's witnesses) object to transfusions of blood products including whole blood, PRBCs, and FFP, although certain products (eg, platelets, clotting factors, albumin) may be acceptable depending on the individual patient's choice. Cultural/religious preferences should be assessed and considered.
- Ascertain need for continued vasopressor therapy.
- Consider using tranexamic acid in bleeding trauma patients.

Implement the Care Plan:

- Start aggressive crystalloid IV fluid therapy if SBP is less than 90 mm Hg (MAP < 60 mm Hg).
- If required (see Figure 13–3), transfuse PRBCs and provide emergent control of ongoing hemorrhaging.
- Begin vasopressor therapy if there is evidence of cerebral or myocardial ischemia.
- Use the resulting data to optimize therapy if a PA catheter is placed.
- Avoid electrolyte disturbances and adverse drug events.

Follow-up: Monitor and Evaluate:

- Determine if appropriate treatment goals for the first hour and first 24 hours of therapy have been met (see Outcome Evaluation).
- Determine if the underlying cause of hypovolemic shock has been addressed (eg, control of bleeding or GI fluid losses).
- Ascertain if supportive care measures such as prophylaxis for stress ulcers and venous thromboembolism are indicated.

OUTCOME EVALUATION

KEY CONCEPT Successful treatment of hypovolemic shock is measured by the restoration of MAP to baseline values and reversal of associated organ dysfunction. The likelihood of a successful fluid resuscitation is directly related to the expediency of treatment. Therapy goals include:

- Arterial SBP greater than 90 mm Hg (MAP > 60–75 mm Hg) within 1 hour.
- Organ dysfunction reversal evident by increased urine output to greater than 0.5 mL/kg/hour (1.0 mL/kg/hour in pediatrics), return of mental status to baseline, and normalization of skin color and temperature over the first 24 hours.
- HR should begin to decrease reciprocally to increases in the intravascular volume within minutes to hours.
- Normalization of laboratory measurements expected within hours to days following fluid resuscitation. Specifically, normalization of base deficit and serum lactate is recommended within 24 hours and may be associated with decreased mortality.[50]
- Achievement of PAOP to a goal pressure of 14 to 18 mm Hg occurs (alternatively, CVP 8–12 mm Hg).

Abbreviations Introduced in This Chapter

ABG	Arterial blood gas
ADH	Antidiuretic hormone
ARDS	Acute respiratory distress syndrome
ATP	Adenosine triphosphate
BP	Blood pressure
Ca	Calcium
CBC	Complete blood count
Cl	Chloride
CO	Cardiac output
CRISTAL	Colloids Versus Crystalloids for the Resuscitation of the Critically Ill trial
CVP	Central venous pressure
DCR	Damage control resuscitation
ECG	Electrocardiogram
FDA	Food and Drug Administration
FFP	Fresh-frozen plasma
GI	Gastrointestinal
Hct	Hematocrit
HR	Heart rate
IV	Intravenous
K	Potassium
kDa	Kilodalton
LR	Lactated Ringer
MAP	Mean arterial pressure
Mg	Magnesium
MODS	Multiple organ dysfunction syndrome
Na	Sodium
NaCl	Sodium chloride
NS	Normal saline
PA	Pulmonary artery
$PaCO_2$	Partial pressure of arterial carbon dioxide
PaO_2	Partial pressure of arterial oxygen
PAOP	Pulmonary artery occlusion pressure
PCC	Prothrombin complex concentrate
PPF	Plasma protein fraction
PRBCs	Packed red blood cells
SBP	Systolic blood pressure
SCr	Serum creatinine
SV	Stroke volume
SVR	Systemic vascular resistance
VIP	Ventilate, infuse, pump

14 Asthma

Lori Wilken and Amanda Eades

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the pathophysiology and clinical presentation of acute and chronic asthma.
2. List the treatment goals for asthma.
3. Identify environmental factors associated with worsening asthma control.
4. Select inhaled drug delivery devices based upon patient characteristics.
5. List the steps to use a metered-dose inhaler correctly.
6. Recommend an asthma medication regimen for an adult patient based on symptoms.
7. Describe the purpose of an individualized asthma action plan.

INTRODUCTION

KEY CONCEPT Asthma is a complex disorder and has been defined as "a heterogeneous disease, usually characterized by chronic airway inflammation."[1] Airflow limitation results in wheezing, breathlessness, chest tightness, and coughing, particularly at night or early in the morning.[1] Severity of chronic asthma ranges from mild intermittent symptoms to a severe and disabling disease. Despite variability in the severity of chronic asthma, all patients with asthma are at risk of acute severe disease. International guidelines emphasize the importance of treating underlying airway inflammation to control asthma and reducing asthma-associated risks.[1–3]

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Asthma is the most prevalent chronic disease of childhood, and it causes significant morbidity and mortality in both adults and children. About 235 million adults and children worldwide have asthma.[4] In the United States, asthma affects 8.3% of adults (20.4 million) and 8.3% of children (6.1 million).[5] Asthma is the primary diagnosis for 6.3 million physician office visits, 2 million emergency department visits, and 3651 deaths annually.[5]

Asthma is also a significant economic burden in the United States, with costs totaling nearly $60 billion annually.[6] Prescription medications are the single largest direct medical expenditure and account for 71% of direct medical costs.[6]

Asthma results from a complex interaction of genetic and environmental factors. There appears to be an inherited component because the presence of asthma in a parent is a strong risk factor for developing asthma in a child. This risk increases when a family history of **atopy** is also present. The presence of atopy is a strong prognostic factor for continued asthma as an adult.

Environmental exposure also appears to be an important etiologic factor. Although asthma occurs early in life for most patients, those with occupational asthma develop the disease later upon exposure to specific allergens in the workplace. Exposure to secondhand smoke after birth increases the risk of childhood asthma.[7] Adult-onset asthma may be related to atopy, nasal polyps, aspirin sensitivity, occupational exposure, or recurrence of childhood asthma.

PATHOPHYSIOLOGY

LO 1

KEY CONCEPT Asthma is characterized by airway narrowing and inflammation primarily in medium-sized bronchi. A key feature of the pathophysiology is airway hyperresponsiveness, which is exaggerated narrowing of the airways in response to a trigger or allergen such as cold air, strong odors, pollen, or dust. Airway narrowing results from contraction of airway smooth muscle, increased mucus secretion, airway edema, and remodeling.[1]

Airway inflammation is initiated by an inhaled allergen or trigger such as dust, pollen, or animal dander inducing a type 2 T-helper $CD4^+$ (T_H2) response. This leads to B-cell production of antigen-specific immunoglobulin E (IgE), pro-inflammatory cytokines (eg, interleukin-5), and chemokines that recruit and activate eosinophils, neutrophils, and alveolar macrophages.[2] Further exposure to the antigen results in cross-linking of cell-bound IgE in mast cells and basophils, causing release of preformed inflammatory mediators such as histamine, cysteinyl leukotrienes, and prostaglandin D_2.[1]

Activation and degranulation of mast cells and basophils result in an early-phase response involving acute bronchoconstriction that lasts approximately 1 hour after allergen exposure. In the late-phase response, activated airway cells release inflammatory cytokines and chemokines, thereby recruiting more inflammatory cells into the lungs. The late-phase response occurs 4 to 6 hours after the initial allergen challenge and results in less intense bronchoconstriction as well as increased airway hyperresponsiveness and airway inflammation.[2]

CLINICAL PRESENTATION AND DIAGNOSIS

See accompanying box for the clinical presentation and diagnosis of asthma. Diagnosis is based on a detailed medical history, physical examination of the upper respiratory tract and skin, and spirometry. The clinician determines if episodic symptoms of airflow obstruction are present, whether airflow obstruction

is at least partially reversible, and that alternative diagnoses are excluded.[1–3] Spirometry is required for diagnosing asthma in patients older than 5 years because the medical history and physical examination are not reliable for characterizing the status of lung impairment or excluding other diagnoses.[1–3] Methacholine bronchoprovocation test is used to clinically evaluate airway hyperresponsiveness.

▶ *Chronic Asthma*

KEY CONCEPT In chronic asthma, initial classification of asthma severity is based on current disease impairment and future risk. The term *impairment* refers to the frequency and severity of symptoms, use of short-acting β_2-agonists (SABA) for quick relief of symptoms, pulmonary function, and impact on normal activity and quality of life. *Risk* refers to the potential for future severe exacerbations and asthma-related death, progressive loss of lung function (adults) or reduced lung growth (children), and the occurrence of drug-related adverse effects.[2]

▶ *Acute Asthma*

In acute asthma, symptoms of wheezing, coughing, and shortness of breath increase. Most exacerbations can be treated at home, while some mandate hospitalization. The severity of the asthma exacerbation does not depend upon the classification of the patient's chronic asthma. Patients with intermittent asthma can have life-threatening acute exacerbations.

Clinical Presentation and Diagnosis of Asthma

LO 1

General Findings

- Asthma presentation ranges from normal pulmonary function with symptoms only during acute exacerbations to significantly decreased pulmonary function with continuous symptoms of daily coughing, wheezing, and shortness of breath.
- Acute asthma can present rapidly (within 3–6 hours), but deterioration more commonly occurs over a longer period, even days or weeks. Acute asthma can be life threatening.
- Family history, social history, precipitating factors, history of exacerbations, and development of symptoms are important components of an asthma diagnosis.

LO 1

Symptoms

- Patients usually complain of wheezing, shortness of breath, coughing (usually worse at night), and chest tightness.
- Patients may be anxious and agitated. In acute severe asthma, patients may be unable to communicate in complete sentences.
- Mental status changes (eg, confusion, irritability, agitation) may indicate impending respiratory failure.
- The presence of precipitating factors (eg, smoke, mold, or viral illness) worsens symptoms.
- Symptoms usually have a pattern (eg, worse at night, seasonal symptoms).

LO 1

Signs

- Vital signs may reflect tachypnea, tachycardia, and hypoxemia.
- On inspection, there may be hyperexpansion of the thorax and use of accessory muscles.
- Auscultation of the lungs may detect end-expiratory wheezes in mild exacerbations or wheezing throughout inspiration and expiration in severe exacerbations.
- Bradycardia and absence of wheezing may indicate impending respiratory failure.
- In acute asthma, patients may present with pulsus paradoxus, diaphoresis, and cyanosis.

Laboratory Tests

- Spirometry may demonstrate airway limitation and excessive airway variability. Airway limitation is demonstrated by a decrease in the FEV_1/FVC (forced expiratory volume in the first second/forced vital capacity) less than 80% (0.80) and a decrease in the FEV_1 to less than 80% of the predicted value. Excessive airway variability is seen with: (a) a positive bronchodilator test, (b) positive bronchial or exercise challenge tests, (c) excessive variability in twice-daily peak expiratory flow (PEF) measurements, and (d) significant increases in FEV_1 after four weeks of an anti-inflammatory medication. Significant lung function improvement in adults is defined as an increase in greater than 200 mL and 12% in the FEV_1 from baseline. For children, lung function improvement is an increase in the FEV_1 greater than 12% of the predicted value. Spirometry may be normal if the patient is not symptomatic.
- A complete blood count with differential may show an elevated eosinophil count.
- Elevated serum immunoglobulin E (IgE) levels may be present.
- Immunoassays are serologic tests used to detect allergies in patients that may have sensitivities to molds, dust mites, pollen, and other triggers that worsen asthma control. The test is an interaction between antigens, in the form of a protein from the trigger and the patient's antigen-specific antibody. The test is used when skin testing is not available or cannot be used because it is a less sensitive test than skin testing.

Other Diagnostic Tests

- Full pulmonary function tests should be performed at baseline in patients 5 years or older to rule out other disorders.
- Arterial blood gases (to evaluate PCO_2) should be obtained for patients in severe distress, suspected hypoventilation, or when PEF or FEV_1 is at least 30% less than the percent predicted after initial treatment.
- Pulse oximetry is performed at each visit to assess for hypoxemia.
- Methacholine challenge test or bronchoprovocation may be performed if the diagnosis of asthma is questionable.
- Fraction of exhaled nitric oxide (FeNO) changes from baseline may indicate inflammation or a response to an inhaled corticosteroid (ICS). A normal value in adults is less than 25 parts per billion (ppb).

TREATMENT

Desired Outcomes

LO 2

The goals of treatment for asthma are directed at maintaining long-term control using the least amount of medications and minimizing adverse effects.[1,2] Treatment goals are to: (a) prevent chronic and troublesome symptoms, (b) require infrequent use (2 or fewer days/week) of SABA for quick relief of symptoms, (c) maintain normal or near-normal pulmonary function, (d) maintain normal activity levels, (e) meet patients' and families' expectations of satisfaction with asthma care, (f) prevent exacerbations of asthma and the need for emergency department visits or hospitalizations, (g) prevent progressive loss of lung function, and (h) provide optimal medications with minimal or no adverse effects.

Nonpharmacologic Therapy

Incorporating nonpharmacologic care and education is important for patients with asthma. Patient education begins at the time of diagnosis and meets the individual patient's needs. Components of education involve asthma trigger avoidance, proper administration of inhaled medications, and asthma self-management (Table 14–1).

Table 14–1

Nonpharmacologic Interventions to Improve Symptom Control in Patients with Asthma

LO 3

Tobacco use
- Strongly encourage smokers to quit
- Advise parents/caregivers of children with asthma to not smoke and not allow smoking in rooms or cars that children use
- Assess smokers/ex-smokers for COPD or overlapping features of asthma and COPD

Physical activity
- Encourage regular physical activity for its general health benefits
- If exercise-induced bronchospasm, use a SABA 5–30 minutes prior to physical activity
- Encourage stretching and warm-up exercises prior to physical activity

LO 3

Occupational exposures
- Ask patients with adult-onset asthma about work history and other exposures
- Record when work-related exposures and symptoms occur, when bronchodilator is needed, and peak airflow at work vs. home
- Use respiratory protective devices such as air-purifying masks to help protect against noxious occupational inhalants
- Identify and eliminate occupational sensitizers and remove sensitized patients from further exposure

Medications
- Ask about asthma before prescribing NSAIDs and advise patients to stop NSAIDs if asthma worsens after use
- If β-blockers are indicated, choose cardioselective agents (eg, atenolol). Asthma is not an absolute contraindication to β-blocker use, but consider the risk vs. benefit

LO 3

Indoor allergens
- Animal dander: Remove carpet from bedroom if possible; keep pets out of bedroom; consider removal of pets from the home
- Mold: Consider reducing indoor humidity to 30%–50%; dehumidify basements; fix water leaks and eliminate water sources associated with mold growth
- Dust mites: Encase mattress and pillows in allergen-impermeable covers; wash sheets and blankets in hot water weekly (> 130°F [54.4°C])
- Cockroaches: Do not leave food or garbage exposed; use poison bait or traps to control insects

Diet
- Encourage a diet high in fruits and vegetables for its general health benefits
- Avoid foods for which there is a confirmed allergy
- Encourage weight reduction if overweight or obese
- Avoid foods containing sulfites if they cause symptoms (eg, beer, wine, shrimp, dried fruit, processed potatoes)

Vaccinations
- Administer yearly influenza vaccine to patients with moderate-to-severe asthma[9]
- Follow CDC recommendations for administering the pneumococcal vaccine[10]

Emotional stress
- Identify goals and strategies (eg, relaxation, breathing exercises) to deal with emotional stress if it worsens asthma

LO 3

Weather conditions
- Avoid strenuous outdoor activities during unfavorable weather conditions
- Cover the nose and mouth with a scarf on cold or windy days

Outdoor allergens
- When pollen counts are high, remain indoors and keep windows and doors closed
- If time is spent outdoors, shower afterward to remove allergens on the skin
- Avoid being outdoors in areas of high pollution

CDC, Centers for Disease Control and Prevention; COPD, chronic obstructive pulmonary disease; NSAID, nonsteroidal anti-inflammatory drug; SABA, short acting β_2 agonist.

Patient Encounter Part 1

HPI: A 49-year-old man presents to the clinic with a chronic cough. He is frustrated that he can't sleep at night because of coughing. The cough is dry with clear sputum. He uses albuterol every night and multiple times a day. He is still able to work and feels better during the day. He has tried numerous medications and feels like nothing works. He took fluticasone propionate/salmeterol HFA once daily for 8 days and felt no relief. He now uses fluticasone propionate/salmeterol HFA intermittently. He has had oral prednisone bursts twice in the past 3 months with relief of his symptoms. He demonstrates use of an MDI using two consecutive puffs of his inhaler. He does rinse his mouth after use. He has tried using ranitidine and omeprazole in the past with no improvement in his nighttime cough. He tried using nasal corticosteroids for his allergies and sinuses with no relief.

PMH:

- Moderate, persistent asthma diagnosed during childhood; has never been hospitalized or intubated. Three prednisone bursts in the past year. Upper respiratory infections trigger worsening asthma symptoms. He has symptoms during all seasons, but winter is the worst. He is able to take NSAIDs without worsening his asthma.
- Allergic rhinitis
- Chronic sinusitis
- Nasal polyps

Family History: He has a cousin and an aunt with asthma.

Social History: He never smoked, and there are no smokers in the home; uses ETOH socially, 1–2 beers on special occasions. He has a dog that is allowed in the bedroom. He works as a patient transporter in a local hospital. His home has wood flooring with HVAC in the bedroom. There is some mold from flooding this past summer.

Allergies: Pollen, ragweed, trees, grass, roaches, dust mites, dogs and cats. No known medication allergies.

What symptoms are consistent with asthma?

What other common diseases can cause a cough?

Why is it important to ask about prednisone and albuterol use?

What nonpharmacologic interventions may help improve the patient's asthma control?

Pharmacologic Therapy

Treatment of chronic asthma involves avoidance of triggers known to precipitate or worsen asthma and use of long-term control and quick-relief medications. Long-term control medications include ICS, inhaled long-acting β_2-agonists (LABAs), oral leukotriene receptor antagonists (LTRAs), inhaled long-acting muscarinic antagonists (LAMA), and biologic agents. Quick-relief medications include SABAs, short-acting muscarinic antagonists (SAMAs), and short bursts of systemic corticosteroids.

▶ *Drug Delivery Devices*

LO 4

KEY CONCEPT Direct airway administration of asthma medications through inhalation is the most efficient route and minimizes systemic adverse effects. Inhaled asthma medications are available in metered-dose inhalers (MDIs), dry powder inhalers (DPIs), soft mist inhalers (SMIs), and nebulized solutions. Selection of the appropriate inhalation device depends on patient characteristics and medication availability (Table 14–2).

Poor inhaler technique results in increased oropharyngeal deposition of the drug, leading to decreased efficacy and increased adverse effects. Table 14–2 describes the steps for appropriate use of MDIs. Because MDIs are challenging to use correctly, use of valved-holding-chambers (VHCs) or spacers is recommended with the MDI to decrease the need for coordination of actuation with inhalation, decrease oropharyngeal deposition, and increase pulmonary drug delivery.[11,12]

▶ *β_2-Adrenergic Agonists*

β_2-Agonists relax airway smooth muscle by directly stimulating β_2-adrenergic receptors in the airway.[13] They also increase mucociliary clearance and stabilize mast cell membranes. Inhaled β_2-agonists are classified as either short-acting (SABA) or long-acting (LABA) based on duration of action. Oral β_2-agonists have increased adverse effects and are not recommended for asthma treatment.

The early-phase response to antigen in an asthma exacerbation is blocked by pretreatment with inhaled SABAs. The SABAs have a faster onset of action in acute asthma than muscarinic antagonists. Adverse effects of β_2-agonists include tachycardia, tremor, and hypokalemia, which are usually not troublesome with inhaled dosage forms.

Short-Acting Inhaled β_2-Agonists KEY CONCEPT Inhaled SABAs are the most effective agents for reversing acute airway obstruction caused by bronchoconstriction and are the drugs of choice for treating acute asthma and symptoms of chronic asthma as well as preventing exercise-induced bronchospasm.[1] Inhaled SABAs have an onset of action of less than 5 minutes and a duration of action of 4 to 6 hours. Using an MDI with a VHC or spacer has faster medication delivery and is as effective as administration by nebulization.

Albuterol (known as salbutamol outside the United States), the most commonly used inhaled SABA, is available as an MDI and solution for nebulization. Levalbuterol, the pure R-enantiomer of albuterol (and referred to as R-salbutamol outside the United States), is available as an MDI and solution for nebulization. Levalbuterol has similar efficacy to albuterol and is purported to have fewer side effects; however, clinical trials have not demonstrated this benefit.[14]

For both the albuterol and levalbuterol MDI, the typical dose is two inhalations every 4 hours as needed for asthma symptoms. During an asthma exacerbation, the usual SABA doses are increased to four inhalations every 4 hours until symptoms resolve. Scheduled chronic daily dosing of SABAs is not recommended for two reasons. First, the need to use an inhaled SABA is one key indicator of uncontrolled asthma. Therefore, patients are educated to record SABA use. Second, scheduled SABA use decreases the duration of bronchodilation provided by the SABA.

Long-Acting Inhaled β_2-Agonists LABAs provide 12 to 24 hours of bronchodilation after a single dose. Because of the long

LO 4 LO 5

Table 14–2

Age Recommendations and Proper Use of Inhalation Devices

Device Type	Recommended Age	Proper Use	Common Mistakes
Metered-dose inhaler (MDI)	≥ 5 years of age	1. Shake the inhaler well before use 2. Remove the cap 3. Exhale away from the inhaler 4. Tilt your head back slightly and place the mouthpiece into the mouth with lips sealed tightly around the inhaler 5. Press down on the inhaler to release medication as you start to breathe in slowly. Breathe in for a full breath (3–5 seconds) 6. Hold your breath for as long as possible, up to 10 seconds to allow the medicine to reach deeply into your lungs 7. If directed to take a second puff, wait 1 minute, then repeat steps 1–6	• Actuating 2 puffs at the same time • Actuating the inhaler, waiting and then inhaling • Exhaling immediately after inhalation
MDI plus valved-holding chamber (VHC)	If < 4 years old, use VHC with mask; If ≥ 4 years of age, use VHC alone	1. Shake the inhaler well before use 2. Remove the cap from inhaler and from the spacer, if it has one 3. Put the inhaler into the spacer 4. Breathe out, away from the spacer 5. Bring the spacer to your mouth, put the mouthpiece between your teeth, and close your lips around it 6. Press the top of your inhaler once 7. Breathe in slowly until you have taken a full breath. If you hear a whistle sound, you are breathing in too fast 8. Hold your breath for about 10 seconds, then breath out Use a spacer with mask for children under 5 years old, or for those unable to hold their breath. If a mask is used, take 6 normal breaths instead of one long breath.	• Inhaling too quickly and making the VHC whistle
Soft mist inhaler (SMI)	Respimat 6 years of age and older	1. Assemble and prime the device 2. Twist the base 3. Open the mouthpiece 4. Exhale away from the inhaler 5. Place the mouth on the mouthpiece and avoid covering the ventilation holes 6. Actuate the inhaler and inhale a slow steady breath 7. Hold your breath for 10 seconds 8. Exhale 9. Repeat steps 2–8 one time for complete dose	• Covering the ventilation holes with the mouth • Actuating the inhaler, waiting and then inhaling • Exhaling immediately after inhaling
Nebulizer	Any age, preferably infants or elderly	1. Add medication to the medication cup 2. Assemble the tubing to the air compressor 3. Assemble tubing to the medication cup 4. Assemble mouthpiece to the medication cup 5. Plug in air compressor and turn the nebulizer on 6. Place mouth on the mouthpiece and breathe in and out slow and steadily into the mouthpiece	• Using a mask unnecessarily • Not cleaning the mouthpiece and medication cup • Not replacing the tubing
Dry powder inhaler (DPI)	Diskus ≥ 4 years old Ellipta ≥ 12 years old Flexhaler ≥ 6 years old Respiclick ≥ 4 years old Twisthaler ≥ 4 years old	1. Open the inhaler 2. Exhale away from the inhaler 3. Place mouth on the mouthpiece 4. Inhale a quick, steady breath 5. Hold breath for 10 seconds or as long as comfortable 6. Exhale away from the inhaler	• Shaking the device • Exhaling into the inhaler • Inhaling too slowly

Table 14–3

Usual Doses of Long-Term Control Medications in Asthma

Medication	Dosage Form	Ages 0–11 Years	Adults and Children > 12 Years
Inhaled Corticosteroids (see Table 14–4)			
Long-Acting β_2-Agonists			
Salmeterol	DPI 50 mcg/blister	Ages 0–3 years: N/A Ages 4–11 years: One inhalation every 12 hours	One inhalation every 12 hours
Formoterol	DPI 12 mcg/capsule	Ages 0–4 years: N/A Ages 5–11 years: Inhalation of one capsule every 12 hours	Inhalation of one capsule every 12 hours
Long Acting Muscarinic Agents			
Tiotropium	SMI 1.25 mcg/actuation	Ages 0–5: N/A Ages 6–11: Two inhalation of 1.25 mcg once daily	Two inhalations of 1.25 mcg once daily
Leukotriene Modifiers			
Montelukast	4 mg or 5 mg chewable tablets 4 mg granule packets 10 mg tablet	Ages 1–5 years: 4 mg at bedtime Ages 6–11 years: 5 mg at bedtime	Ages 12–14 years: 5 mg at bedtime Ages 15 and older: 10 mg at bedtime
Zafirlukast	10 or 20 mg tablets	Ages 0–4 years: N/A Ages 5–11 years: 10 mg twice daily	20 mg tablet twice daily
Zileuton	600 mg extended-release tablet 600 mg immediate-release tablet	N/A: only approved for those 12 years of age and older	Extended-release tablets: 1200 mg twice daily after morning and evening meals Immediate-release tablets: 600 mg four times daily
Anti-IgE Monoclonal Antibody			
Omalizumab	SC injection, 150 mg/1.2 mL after reconstitution with 1.4 mL sterile water for injection	Ages 0–5: N/A Ages 6–11: 75–375 mg SC every 2–4 weeks, depending on body weight and pretreatment serum IgE level; see dosing chart[b]	150–375 mg SC every 2–4 weeks, depending on body weight and pretreatment serum IgE level; see dosing chart[b]
Anti-Interleukin-5 Receptor Monoclonal Antibodies			
Mepolizumab	SC injection, 100 mg/mL after reconstitution with 1.2 mL sterile water for injection	N/A	100 mg SC once every 4 weeks
Reslizumab	IV solution, 100 mg/10mL vial	N/A	3 mg/kg IV infusion over 20–50 minutes every 4 weeks
Benralizumab	SC injection, 30 mg/mL prefilled syringe	N/A	30 mg SC every 4 weeks for the first 3 doses, followed by once every 8 weeks thereafter

[a]Dosages are provided for products that have been approved by the US FDA or have sufficient clinical trial safety and efficacy data in the appropriate age ranges to support their use.

[b]https://www.xolair.com/pdf/dosingTables092916.pdf.

DPI, dry powder inhaler; IgE, immunoglobulin E; IV, intravenous; N/A, safety and efficacy not established; SC, subcutaneous; SMI, soft mist inhaler.

duration of bronchodilation, these agents are useful for patients experiencing nocturnal symptoms.

LABAs are indicated for chronic treatment of asthma as add-on therapy for patients not controlled on low to medium doses of ICS (see Table 14–3 for dosing). Adding a LABA is at least as effective in improving symptoms and decreasing asthma exacerbations as doubling the dose of an ICS or adding an LTRA to ICS.[3,15] Adding a LABA to ICS therapy also reduces the amount of ICS necessary for asthma control.[3]

LABAs should not be used as monotherapy for chronic asthma. There may be an increased risk of severe asthma exacerbations and asthma-related deaths when LABAs are used alone.[16] Labeling for all drugs containing LABAs includes a black box warning against their use without an ICS. The risk of increased severe asthma exacerbations does not appear to be increased in adults receiving both a LABA and ICS.[17]

Salmeterol is dosed twice daily and is available as a single-ingredient product and as a fixed-ratio combination product containing an ICS. Formoterol and vilanterol are available only in combination with inhaled corticosteroids (Table 14–4). Combination products may increase adherence because of the need for fewer inhalers and inhalations. Indacaterol, olodaterol, and arformoterol are LABAs approved only for COPD.

► *Corticosteroids*

Corticosteroids are the most potent anti-inflammatory agents available for asthma treatment and are available in inhaled, oral, and injectable dosage forms. They decrease airway inflammation, attenuate airway hyperresponsiveness, and minimize mucus production and secretion. Corticosteroids also improve the response to β_2-agonists.

Inhaled Corticosteroids KEY CONCEPT ICS are the preferred therapy for all forms of persistent asthma in all age groups.[1,2] ICS are more effective than LTRA in improving lung function and preventing emergency department visits and hospitalizations

[a]N/A in children 0–4 years of age.

[b]Doses based on clinical trials. Maximum of fluticasone/salmeterol 100/50 mcg, 1 inhalation twice daily is approved in children ages 4–11 years without specification of low, medium, or high dosage.

[c]Not FDA approved in children < 6 years of age.

[d]Maximum budesonide/formoterol 80/4.5 mcg, 2 inhalations twice daily is approved in children 6–11 years of age without specification of low, medium, or high dosage.

[e]FDA approved for adults 18 years and older.

DPI, dry powder inhaler; HFA, hydrofluoroalkane; MDI, metered-dose inhaler; N/A, safety and efficacy not established.

due to asthma exacerbations.[1,2] The primary advantage of using ICS compared with systemic corticosteroids is the targeted drug delivery to the lungs, which decreases the risk of systemic adverse effects. Product selection is based on preference for dosage form, delivery device, and cost.

All ICS are equally effective if given in equipotent doses (Table 14–5).[18] ICS have a flat dose-response curve; doubling the dose has a limited additional effect on asthma control.[19] Cigarette smoking decreases the response to ICS, and smokers require higher doses of ICS than nonsmokers.[20] Although some beneficial effect is seen within 12 hours of administration of an ICS, 2 weeks of therapy is necessary to see significant clinical effects. Longer treatment may be necessary to realize the full effects on airway inflammation.

For most delivery devices, the majority of the drug is deposited in the mouth and throat and swallowed. Local adverse effects of ICS include oral candidiasis, cough, and dysphonia. The incidence of local adverse effects can be reduced by using an MDI with a VHC and by having the patient rinse the mouth with water and expectorate after using the ICS. Decreasing the dose reduces the incidence of hoarseness.

Systemic absorption occurs via the pulmonary and oral routes. Systemic adverse effects include adrenal suppression, decreased bone mineral density, skin thinning, cataracts, and easy bruising, and occur more frequently with higher ICS doses.[2] Linear growth velocity is reduced by less than half a centimeter per year and height after 1 year of treatment is decreased by less than 1 cm

Patient Encounter Part 2

Home Medications:

- Albuterol MDI 2 puffs every 6 hours as needed for coughing. Last filled 2 weeks ago.
- Albuterol 2.5 mg solution for inhalation every 6 hours as needed for wheezing. Last filled 2 weeks ago.
- Cetirizine 10 mg PO daily for allergies. Last filled 3 months ago, #30.
- Fluticasone-salmeterol HFA 115/21 mcg, 2 inhalations twice daily to prevent asthma symptoms. Rinse after use. Last filled 2 months ago, #120 inhalations.
- Montelukast 10 mg PO once daily for allergies and to prevent asthma symptoms. Last filled 3 months ago, #30.
- Sodium chloride OTC nasal rinse (Sinus Rinse Kit nasal powder for reconstitution): Use as directed at bedtime for sinuses.

Vaccinations: He gets the influenza vaccine yearly.

What is the patient doing incorrectly with his MDI? What is he doing correctly?

Using motivational interviewing techniques, discuss adherence with medications.

Table 14–5

Estimated Comparative Daily Dosages for Inhaled Corticosteroids for Asthma

	Ages 0–11 Years			Ages 12 and Older		
Medication	**Low Dose**	**Medium Dose**	**High Dose**	**Low Dose**	**Medium Dose**	**High Dose**

in children treated with low and medium dose ICS.[21,22] Risk of pneumonia is also increased significantly with ICS use. [23]

A significant drug interaction causing Cushing syndrome and adrenal insufficiency occurs when potent inhibitors of CYP3A4 (ritonavir, itraconazole, ketoconazole) are administered with high doses of ICS.[18]

Poor adherence to ICS treatment is common and contributes to uncontrolled asthma.[24] The slow onset of action and concerns about side effects are major deterrents to using these highly effective medications.

Considerable variability in response to ICS exists, with up to 40% of patients not responding to ICS. This lack of response may be related to functional glucocorticoid-induced transcript 1 gene (*GLCCI1*) variant in some patients with asthma.[25]

Systemic Corticosteroids Prednisone, prednisolone, and methylprednisolone are the cornerstone of treatment for acute asthma not responding to a SABA (see Table 14–6 for recommended doses).[1,2] The onset of action for systemic corticosteroids is 4 to 12 hours. For this reason, systemic corticosteroids are started early in the course of acute exacerbations. The oral route is preferred in acute asthma; there is no evidence that intravenous corticosteroid administration is more effective. Therapy with systemic corticosteroids is continued until the PEF is 70% or more of the personal best measurement and asthma symptoms are resolved. The duration of therapy usually ranges from 3 to 10 days. Tapering the corticosteroid dose in patients receiving short bursts (up to 10 days) is usually not necessary because any adrenal suppression is transient and rapidly reversible.[2]

Because of serious potential adverse effects, systemic corticosteroids are avoided as long-term controller medication for asthma, if possible. If systemic therapy is necessary, once-daily or every-other-day therapy is used with repeated attempts to decrease the dose or discontinue the drug.

Table 14–6

Usual Dosages for Quick-Relief Medications for Asthma in Home Setting[a,b]

Medications	Dosage Form	Children 0–11 Years	Adults and Children 12 Years of Age and Older
Inhaled SABA			
Albuterol HFA	MDI (inhalation suspension) 90 mcg/inhalation, 200 inhalations/canister	0–3 years: N/A 4–11 years: 1–2 puffs every 4–6 hours as needed	2 puffs every 4–6 hours as needed
Albuterol	DPI (inhalation powder) 90 mcg/inhalation, 200 inhalations/canister	0–3 years: N/A 4–11 years: 1–2 puffs every 4–6 hours as needed	2 puffs every 4–6 hours as needed
Albuterol	Nebulizer solution 0.63 mg/3 mL, 1.25 mg/3 mL, 2.5 mg/3 mL, 5 mg/mL (0.5%)	0–4 years: 0.63–2.5 mg every 4–6 hours as needed 5–11 years: 1.25–5 mg every 4–8 hours as needed	2.5 mg every 6–8 hours as needed
Levalbuterol HFA	MDI (inhalation suspension) 45 mcg/puff, 200 puffs/canister	0–3 years: N/A 4–11 years: 1–2 puffs every 4–6 hours as needed	2 puffs every 4–6 hours as needed
Levalbuterol	Nebulizer solution 0.31 mg/3 mL, 0.63 mg/3 mL, 1.25 mg/0.5 mL, 1.25 mg/3 mL	0–4 years: 0.31–1.25 mg every 4–6 hours as needed 5–11 years: 0.31–0.63 mg every 8 hours as needed	0.63 mg every 6–8 hours as needed; may titrate to 1.25 mg every 8 hours if inadequate response
Systemic Corticosteroids			
Methylprednisolone	2, 4, 8, 16, 32 mg oral tablets	1–2 mg/kg/day by mouth in 2 divided doses (maximum 60 mg/day) for 3–10 days	40–60 mg/day by mouth as single or two divided doses for 3–10 days
Prednisolone	5 mg oral tablets; 5 mg/5 mL and 15 mg/5 mL oral liquid	1–2 mg/kg/day by mouth in 2 divided doses (maximum 60 mg/day) for 3–10 days	40–60 mg/day by mouth as single or two divided doses for 3–10 days
Prednisone	1, 2.5, 5, 10, 20, 50 mg oral tablets; 5 mg/mL and 5 mg/5 mL oral liquid	1–2 mg/kg/day by mouth in 2 divided doses (maximum 60 mg/day) for 3–10 days	40–60 mg/day by mouth as single or two divided doses for 3–10 days

[a]Dosages are provided for products that have been approved by the US FDA or have sufficient clinical trial safety and efficacy data in the appropriate age ranges to support their use.

[b]Doses are increased in the hospital/emergency department setting.

DPI, dry powder inhaler; HFA, hydrofluoroalkane; MDI, metered-dose inhaler; N/A; safety and efficacy not established; SABA, short-acting β_2-agonist.

▶ *Muscarinic Antagonists*

Muscarinic antagonists inhibit the effects of acetylcholine on muscarinic receptors in the airways and protect against cholinergic-mediated bronchoconstriction. The bronchodilator effects of the SAMAs are not as pronounced as SABAs in asthma.[1,2]

Ipratropium bromide is available as an MDI and solution for nebulization. Its onset of action is approximately 15 minutes, and the duration of action is 4 to 8 hours. The addition of ipratropium bromide to SABAs during a moderate to severe asthma exacerbation improves pulmonary function and decreases hospitalization rates in both adult and pediatric patients.[26] A SABA combined with ipratropium to increase bronchodilation is only indicated in the emergency department setting.

Tiotropium bromide is an inhaled LAMA available as a soft-mist inhaler for asthma. It has an onset of action of approximately 30 minutes and duration longer than 24 hours. Tiotropium is used as a long-term controller medication in patients with uncontrolled asthma already taking an ICS or an ICS and LABA combination.[27,28] Tiotropium decreases severe exacerbations, improves lung function, and is steroid sparing. Because of its safety and efficacy profile, tiotropium is the preferred LAMA for chronic asthma treatment. Aclidinium, glycopyrrolate, and umeclidinium are LAMAs approved only for COPD.

Muscarinic-antagonists may cause bothersome adverse effects such as blurred vision, dry mouth, and urinary retention. Increased cardiovascular events have been reported for ipratropium but not tiotropium.[29,30]

▶ *Leukotriene Receptor Antagonists*

The LTRAs are anti-inflammatory medications that either inhibit 5-lipoxygenase (zileuton) or competitively antagonize the effects of leukotriene D_4 (montelukast, zafirlukast). These agents improve FEV_1 and decrease asthma symptoms, SABA use, and asthma exacerbations. Although these agents offer the convenience of oral administration, they are significantly less effective than low ICS doses.[2,31] Combining an LTRA with an ICS is not as effective as an ICS plus a LABA but is considered steroid-sparing.[1,2] LTRAs are beneficial for asthma patients with allergic rhinitis, aspirin sensitivity, or exercise-induced bronchospasm.

Montelukast is generally well tolerated with minimal need for monitoring and few drug interactions. Zileuton and zafirlukast are less commonly used because of the risk of hepatotoxicity. Zileuton use requires liver function monitoring prior to use, monthly for 3 months, every 3 months for the first year of use, and periodically thereafter. Zileuton and zafirlukast are metabolized through the CYP 2C9 hepatic pathway and have significant drug interactions. All three agents have reports of neuropsychiatric events, such as sleep disorders, aggressive behavior, and suicidal thoughts.

▶ *Biologic Agents*

About 10% of patients have severe asthma requiring frequent, if not daily, oral corticosteroids and high doses of inhaled corticosteroids. Biologic agents target specific inflammatory sites and allow patients to reduce corticosteroid use.

Anti-IgE Monoclonal Antibody Omalizumab is a recombinant humanized monoclonal anti-IgE antibody that inhibits binding of IgE to receptors on mast cells and basophils, resulting in inhibition of inflammatory mediator release and attenuation of the early- and late-phase allergic response. Omalizumab is indicated for treatment of patients with moderate to severe persistent asthma whose asthma is not controlled by ICS and who have a positive skin test or in vitro reactivity to aeroallergens. Omalizumab significantly decreases ICS use, reduces the number and length of exacerbations, and increases asthma-related quality of life.[32]

Omalizumab is given as a subcutaneous injection every 2 to 4 weeks in the office or clinic. The initial dose is based on the patient's weight and baseline total serum IgE concentration. See Table 14–3 for dosing recommendations. Subsequent IgE levels are not monitored.

The most common adverse effects are injection site reactions and include bruising, redness, pain, stinging, itching, and burning. Anaphylactic reactions are rare but may occur at any time after medication administration. Monitoring the patient for an anaphylactic reaction for 2 hours after medication administration is recommended for the first 3 months; thereafter, monitoring time can be reduced to 30 minutes.[33] It is also important to issue a prescription for and provide patient education on the use of subcutaneous epinephrine for an anaphylactic reaction from omalizumab. Omalizumab has been associated with an increased risk of cardiovascular and cerebrovascular events (eg, myocardial infarction, transient ischemic attack, venous thrombosis) and perhaps cancer, but the magnitude of the increased risk is unclear.[34]

Anti-Interleukin-5 (IL-5) Receptor Monoclonal Antibodies Mepolizumab, reslizumab, and benralizumab are monoclonal antibodies that block the cytokine interleukin-5 (IL-5). IL-5 triggers the cascade of inflammation by activating eosinophils. By blocking eosinophils in patients with eosinophilic asthma, mepolizumab and benralizumab have significantly decreased asthma exacerbations and decreased the dose or need for oral corticosteroids.[35,36] Mepolizumab and benralizumab are both subcutaneous injections that need to be administered in a clinic setting because of the potential for anaphylactic reactions. Reslizumab has not shown the same clinical benefits as mepolizmab or benralizumab and is an intravenous infusion administered every 4 weeks in an infusion center.[37] See Table 14-3 for dosing. Common side effects include nasopharyngitis, headache, formation of positive anti-drug antibodies, and worsening asthma or upper respiratory tract infections. Because of the potential for anaphylactic reactions, consideration should be given to providing patients with epinephrine auto-injectors along with education. Long-term side effects of the anti-IL-5 receptor monoclonal antibodies, including opportunistic and parasitic infections, are unknown. Patients who have had or have an active helminth infection should avoid anti-IL-5 antibodies. Because of the immunosuppressive effects and case reports of anti-IL-5 receptor monoclonal antibody medications causing herpes zoster infections, the varicella vaccine and the recombinant zoster vaccine (Shingrix), if indicated, should be considered prior to initiation of treatment with an anti-IL-5 antibody. This drug class is not approved for children younger than age 12 or in patients who are pregnant or breastfeeding. All of these medications are very expensive, so identifying appropriate patients is important.

▶ *Macrolides*

Recent evidence indicates that azithromycin 500 mg orally three times weekly for 48 weeks decreases asthma exacerbations and improves quality of life for adults with asthma not controlled with an ICS and LABA.[38] Potential benefits result from anti-inflammatory and not antimicrobial properties. Screening for hearing impairment, cardiovascular arrhythmias, and drug interactions is recommended prior to initiating treatment.

Treatment of Chronic Asthma

KEY CONCEPT The intensity of pharmacotherapy for chronic asthma is based on disease severity for initial therapy and level of control for subsequent therapies. The least amount of medications necessary to meet the therapeutic goals is used.[2]

The first step in asthma management is evaluating the patient's asthma control and risk for future exacerbations (Tables 14–7 and 14-8). Pharmacologic treatment is initiated based on the recommendations for stepwise therapy (Table 14-9). Treatment

Table 14–7

Assessment of Asthma Control in Adults, Adolescents, and Children

Adults, Adolescents, and Children 6–11 Years		Children ≤ 5 Years	
Asthma Symptoms	**Level of Symptom Control**	**Asthma Symptoms**	**Level of Symptom Control**
In the past 4 weeks, has the patient had: • Daytime asthma symptoms more than twice per week • Nighttime awakening due to asthma • Reliever needed for symptoms more than twice per week • Activity limitation due to asthma	If yes to none of these = well controlled If yes to 1–2 of these = partly controlled If yes to 3–4 of these = uncontrolled	In the past 4 weeks, has the child had: • Daytime asthma symptoms for more than a few minutes, more than once a week • Nighttime awakening or nighttime coughing due to asthma • Reliever medication needed more than once per week • Activity limitation due to asthma	If yes to none of these = well controlled If yes to 1–2 of these = partly controlled If yes to 3–4 of these = uncontrolled

- If asthma is not well controlled, assess inhaler technique, adherence to therapies, and environmental controls before considering adjustment of therapy.
- Consider stepping up therapy if uncontrolled symptoms or recent exacerbations or high risk for exacerbations (see Table 14–8). Refer to Table 14–10 for stepwise approach to control asthma symptoms.
- Consider stepping down therapy if symptoms controlled for 3 months + low risk for exacerbations.

Data obtained from Global Initiative for Asthma. Global Strategy for Asthma Management and Prevention, 2017. www.ginasthma.org.

Table 14–8

Risk Factors for Asthma Exacerbation

- Uncontrolled asthma symptoms
- Frequent use of SABA (mortality increased if more than 1 × 200-dose canister used per month)
- Inadequate ICS therapy (not prescribed, poor adherence, poor technique)
- Low FEV_1 (especially if < 60% predicted)
- Major psychological or socioeconomic problems
- Exposures: smoking, allergen exposure if sensitized
- Comorbidities: Obesity, rhinosinusitis, confirmed food allergy
- Sputum or blood eosinophilia; elevated FeNO (in adults with allergic asthma)
- Pregnancy
- History of intubation or treatment in ICU for asthma
- 1 or more severe exacerbations in the past 12 months

FeNO, fraction of exhaled nitric oxide; FEV_1, forced expiratory volume in the first second; ICS, inhaled corticosteroid; ICU, intensive care unit; SABA, short-acting β_2-agonist.

Table 14–9

LO 6

GINA Recommendations for Initial Controller Treatment in Adults and Adolescents

Symptom Presentation	Preferred Option (Evidence Level)
• Asthma symptoms or need for SABA < 2×/month; no waking due to asthma in the past month; no risk factors for exacerbations; no exacerbations in the past year	No controller medication (D)
• Infrequent asthma symptoms, but patient has ≥ 1 risk factor for exacerbation	Low dose ICS (D)
• Asthma symptoms or need for SABA between twice a month and twice a week, or patient wakes due to asthma once or more a month	Low dose ICS (B)
• Asthma symptoms or need for SABA more than twice a week	Low dose ICS[a] (A)
• Troublesome asthma symptoms most days, or waking due to asthma once a week or more	Medium/high dose ICS (A) or low-dose ICS + LABA[b] (A)
• Severely uncontrolled asthma or patient presents with an acute exacerbation	Short course of OCS + high-dose ICS (A) or moderate-dose ICS/LABA[b] (D)

[a]Less effective option is LTRA.

[b]Not recommended for initial controller treatment in children 6–11 years.

Levels of evidence: A = randomized controlled trials (RCTs) and meta-analyses, rich body of data; B = RCTs and meta-analyses, limited body of data; C = nonrandomized trials, observational studies; D = panel consensus judgment.

GINA, Global Initiative for Asthma; ICS, inhaled corticosteroid; LABA, long-acting β_2-agonist, LTRA, leukotriene receptor antagonist; OCS, oral corticosteroid; SABA, short-acting β_2-agonist.

Data from Global Initiative for Asthma. Global Strategy for Asthma Management and Prevention, 2017. www.ginasthma.org.

recommendations involve two categories based on patient age: children 5 years of age and younger, and individuals 6 years of age and older. Therapeutic plans must be individualized.

▶ *Intermittent Asthma*

Patients with intermittent asthma only need SABAs. This asthma classification includes patients with exercise-induced bronchospasm (EIB), seasonal asthma, or asthma symptoms associated with infrequent trigger exposure. Patients pretreat with a SABA prior to exposure to a known trigger, such as exercise.

Exercise is one of the most common precipitants of asthma symptoms. Shortness of breath, wheezing, or chest tightness usually occur during or shortly after vigorous exercise, peak 5 to 10 minutes after stopping the activity, and resolve within 20 to 30 minutes. Warming up prior to exercise and covering the mouth and nose with a scarf or mask during cold weather may prevent exercise-induced asthma (Table 14–1). Pretreatment with a SABA 5 to 20 minutes prior to exercise is the treatment of choice and will protect against bronchospasm for 2 to 3 hours. Regular treatment with an ICS or LTRA is recommended if SABA treatment is needed daily for exercise and not working effectively.[39]

▶ *Persistent Chronic Asthma*

Patients with persistent chronic asthma require daily long-term control therapy. ICS are the long-term control medication of choice at all levels of severity (mild, moderate, and severe) and in all age groups.[2] SABAs are prescribed for all patients with asthma for use on an as-needed basis.

After initiating therapy, patients are monitored within 2 to 6 weeks to ensure that asthma control has been achieved. Before increasing therapy, the patient's inhaler technique and adherence to therapy are evaluated. Medication intensification is based on individualized response to therapy (Table 14–10).

Patients with controlled asthma are monitored at 1- to 6-month intervals to ensure that control is maintained. A gradual step-down in long-term controller therapy is attempted once control has been maintained for at least 3 months. Controversy exists about how best to taper long-term controller medication. The ICS dose can be decreased before removing the LABA, or the LABA can be discontinued while maintaining the same ICS dose.[2,40] Clinical trials are ongoing to resolve this issue.

Treatment of Acute Asthma

KEY CONCEPT In acute asthma, early and appropriate intensification of therapy is important to resolve the exacerbation and prevent relapse and future severe airflow obstruction. Early and aggressive treatment is necessary for quick resolution.[41]

The optimal treatment of acute asthma depends on the severity of the exacerbation. The patient's condition usually deteriorates over several hours, days, or weeks. Table 14–11 contains guidance for treating an asthma exacerbation.

Based on the initial response to SABA therapy, the severity of the exacerbation is assessed, and treatment is appropriately intensified. Patients deteriorating quickly or not responding to quick-relief medications should go to the emergency department for assessment and treatment of the exacerbation. Patients responding to therapy in the emergency department with a sustained response to a SABA are discharged home. Patients are discharged with a SABA, a 3- to 10-day course of oral corticosteroid, an ICS, and perhaps other appropriate long-term controller medications.

Table 14–10

GINA Stepwise Approach to Control Symptoms and Minimize Future Risk

Adolescents and Adults

Step	Preferred Controller Option	Other Controller Options
1	No controller As-needed SABA	May consider low-dose ICS if at risk for exacerbations
2	Low-dose ICS	LTRA
3	Low-dose ICS + LABA	Medium-dose ICS (preferred over addition of LABA for patients ages 6–11) High-dose ICS Low-dose ICS + LTRA
4	Medium/high dose ICS/LABA	Add tiotropium if history of exacerbations (not for children < 12 years old) High dose ICS + LTRA
5	Refer to specialist for consideration of add-on treatment such as tiotropium, anti-IgE, anti-IL5	Add low-dose OCS

Children Ages 5 Years and Younger

Step	Preferred Controller Option	Other Controller Options
1	No controller As-needed SABA	
2	Low dose ICS	LTRA Intermittent ICS
3	Moderate-dose ICS	Low-dose ICS + LTRA
4	Continue controller and refer to asthma specialist	Add LTRA Increase ICS frequency Add intermittent ICS

GINA, Global Initiative for Asthma; ICS, inhaled corticosteroid; LABA, long-acting β_2 agonist; LTRA, leukotriene receptor antagonist; OCS, oral corticosteroid; SABA, short-acting β_2 agonist.

Data from Global Initiative for Asthma. Global Strategy for Asthma Management and Prevention, 2017. www.ginasthma.org.

Patients who do not respond adequately to intensive therapy in the emergency department within 3 to 4 hours are admitted to the hospital. During hospitalization, oxygen, continuous nebulization of SABA, systemic corticosteroids, and alternative treatments such as magnesium and heliox may be used to treat the exacerbation.

Patients with oxygen saturation less than 90% (0.90; < 95% [0.95] in children, pregnant women, and patients with coexisting heart disease) receive oxygen with the dose adjusted to keep oxygen saturation above this level. Administration of low oxygen concentrations (< 30% [0.30] of the fraction of inspired oxygen or FiO_2) by nasal cannula or facemask is usually sufficient to reverse hypoxemia in most patients.

Asthma Self-Management

LO 7

Self-management plans give patients the freedom to adjust therapy based on personal assessment of disease control using predetermined written instructions from the physician. Written asthma action plans, a part of standard care, initiate early treatment of worsening asthma to potentially prevent hospitalizations and death.

The plan includes instructions on daily management and how to recognize and handle worsening asthma.[2] Asthma control is assessed by evaluating symptoms of worsening asthma and/or monitoring PEF. Early signs of deterioration include increasing nocturnal symptoms, increasing use of inhaled SABAs, or symptoms that do not respond to increased use of inhaled SABAs. Providing patients with a prescription for oral corticosteroids to use on an as-needed basis for the initiation of an asthma exacerbation is part of asthma self-management.

Measurement of PEF is considered for patients with moderate to severe persistent asthma, poor perception of worsening asthma or airflow obstruction, and those with an unexplained response to environmental or occupational exposures.[2] PEF measurements are not necessary for a patient to receive an asthma action plan. The plan can be based upon symptoms only. PEF is measured daily in the morning upon waking or when asthma symptoms worsen. For PEF-based action plans, the patient's personal best PEF is established over a 2- to 3-week period when the patient is receiving optimal treatment.[2] Subsequent PEF measurements are evaluated in relation to their variability from the patient's best PEF measurement. PEF measurements in the range of 80% to 100% of personal best (green zone) indicate that current therapy is acceptable. A PEF in the range of 50% to 79% of personal best (yellow zone) indicates an impending exacerbation, and therapy is intensified with SABA therapy, possibly oral corticosteroids, and a call to the physician. A PEF less than 50% (red zone) signals a medical alert; patients use their SABA immediately, take oral corticosteroids, and go to the emergency department.

Special Populations

▶ *Pregnancy*

Approximately 4% to 8% of pregnant women are affected by asthma with about one-third experiencing worsening asthma during pregnancy.[42] It is safer for pregnant women to have asthma treated with medications than to experience worsening asthma. Uncontrolled asthma is a greater risk to the fetus than asthma medication use. Consequently, asthma exacerbations should be managed aggressively with pharmacotherapy. The stepwise approach to asthma therapy in pregnancy is similar to that for the general population.

Budesonide has the most safety data in humans and is the preferred ICS. However, there are no data indicating that other ICS present increased risk to the mother or fetus. Albuterol is the drug of choice for treating asthma symptoms and exacerbations in pregnancy.

Table 14–11

Assessment and Treatment of Asthma Exacerbations in the Urgent or Emergency Care Setting

	Signs and Symptoms		
Severity	**> 5 Years of Age**	**Children ≤ 5 Years of Age**	**Clinical Course**
Mild to Moderate	Talks in sentences Prefers sitting to lying Not agitated Respiratory rate increased Accessory muscles not used Pulse rate 100–120 bpm O_2 saturation (on air) 90%–95% (0.90–0.95) PEF > 50% predicted or personal best	Talks in sentences Breathless Wheezing may be present May be agitated Pulse rate < 100 bpm if mild Pulse rate < 200 bpm (0–3yrs) or ≤ 180 bpm (4–5 yrs) if moderate O_2 saturation ≥ 92% (0.92)	• SABA by nebulizer or MDI + spacer • Ipratropium bromide may decrease need for hospitalization and improve FEV_1 compared to SABA alone • Systemic corticosteroid × 5–7 days for adult; 3–5 days for children • Oxygen (if needed); target saturation 93%–95% (0.93–0.95) for adults; 94%–98% (0.94–0.98) for children; > 95% (0.95) during pregnancy • Epinephrine indicated only if exacerbation is associated with anaphylaxis and angioedema
Severe	Talks in words, not sentences Sits hunched forward Respiratory rate > 30/min Accessory muscles in use Pulse rate > 120 bpm O_2 saturation (on air) < 90% (0.90) PEF < 50% predicted or personal best	Talks in words, not sentences Pulse rate > 200 bpm (0–3 yrs) or > 180 bpm (4–5 yrs) O_2 saturation < 92% (0.92) Marked subcostal and/or sub-glottic retractions	• Requires ED visit and likely hospitalization; immediate transfer to hospital is indicated if child ≤ 5 years of age • Give inhaled SABA + ipratropium bromide in ED setting; no benefit from adding ipratropium to SABA once hospitalized • Oxygen to maintain saturation 93–95% (0.93–0.95) for adults; 94%–98% (0.94–0.98) for children; > 95% (0.95) during pregnancy • Oral or IV systemic corticosteroids; oral preferred if possible • Consider IV magnesium[a] • Epinephrine indicated only if exacerbation is associated with anaphylaxis and angioedema
Subset: Life Threatening	Too dyspneic to speak Drowsiness Confusion Silent chest Central cyanosis Pulse rate > 200 bpm PEF < 25% predicted or personal best	Unable to speak or drink Central cyanosis Silent chest Confusion	• Transfer to ICU • While waiting, start SABA + ipratropium bromide, IV corticosteroids, and O_2 to maintain saturation 93%–95% (0.93–0.95) for adults; 94%–98% (0.94–0.98) for children; > 95% (0.95) during pregnancy • Prepare patient for intubation • Consider IV magnesium[a] • Epinephrine indicated only if exacerbation is associated with anaphylaxis and angioedema

[a]Intravenous magnesium sulfate is not recommended for routine use in asthma exacerbations; however, it reduces hospital admissions in some patients, including adults with FEV_1 < 25%–30% predicted at presentation; adults and children who fail to respond to initial treatment and have persistent hypoxemia; and children whose FEV_1 fails to reach 60% predicted after 1 hour of care. The role of magnesium sulfate is not established for children ages 5 years and younger but may be considered as an adjuvant to standard treatment in children 2 years or age and older with severe asthma.

bpm, beats per minute; ED, emergency department; FEV_1, forced expiratory volume in first second; ICU, intensive care unit; MDI, metered-dose inhaler; O_2, oxygen; PEF, peak expiratory flow; SABA, short acting β_2-agonist.

Data obtained from Global Initiative for Asthma. Global Strategy for Asthma Management and Prevention, 2017. Available from: www.ginasthma.org

▶ *Young Children*

Although asthma is the most common disease in children, its diagnosis and monitoring are challenging. Treatment in children 0 to 4 years of age is extrapolated from studies completed in adults and older children. Albuterol and ICS are the treatments of choice in this group. However, use of montelukast is common because it is available in an oral, chewable formulation and is not a corticosteroid. Route of delivery is an important issue. Nebulization treatment is commonly used, and MDI with VHC is becoming more popular due to its decreased time of administration compared with nebulization. Budesonide is the only corticosteroid available in nebulization form and is approved for use in this age group. If young patients are not controlled on as-needed SABA, they should be stepped up to low-dose ICS. LTRA are alternatives to ICS. If the patient continues to be uncontrolled on low-dose ICS, the ICS may be increased to medium dose or an LTRA may be added to the low-dose ICS.[1]

OUTCOME EVALUATION

Chronic Asthma

- Assess onset, duration, and timing of subjective symptoms such as wheezing, shortness of breath, chest tightness, cough, nocturnal awakenings, and activity level. Use validated questionnaires (such as the Asthma Control Test, Asthma Therapy Assessment Questionnaire, or Asthma Control Questionnaire) to objectively document control.
- Monitor the use of SABAs. Using a SABA more than twice a week in intermittent asthma may indicate the need to

Patient Encounter Part 3

ROS:

General: + fever and chills 2 days ago, now resolved. No night sweats

ENT: + allergic rhinitis, + nasal congestion, + postnasal drip, occasional mouth breathing, no sleep apnea

Respiratory: + asthma, + cough; no shortness of breath or wheezing

CV: No chest pain, palpitations, or history of coronary artery disease

Endocrine: No cold/heat intolerance or fatigue; no history of diabetes or thyroid disease

Heme: No easy bruising or bleeding

GI: No nausea, vomiting, diarrhea, or acid reflux

MS: No joint swelling or arthritis; some muscle aches/pains over the weekend; flu-like symptoms 2 days ago

GU: No dysuria

Derm: No hives, eczema, angioedema, or rash

Neuro: No dizziness, tingling, or numbness

PE:

VS: Temp 36.3°C, BP 158/84, Pulse 90, RR 20, SaO_2 98% (0.98), Ht 170 cm, Wt 79 kg, BMI 27.3 kg/m^2

Gen: NAD

Eyes: PERRL, EOMI

HEENT: OP clear, septal spur with deviation to the left noted, TMs clear

Lungs: CTA bilaterally, + slight wheezing at both bases

CV: RRR no m/r/g

Abd: Soft, NT/ND

Skin: No rash/hives, + hyper-pigmented cheeks

Neuro/Psych: Grossly normal, normal affect

Asthma Control Test: 8 out of 25 (goal above 20), very poorly controlled; 3 months prior to today's visit ACT: 15

PEFR: 350 L/min best. Not done in clinic today. Does not check at home.

FeNO: Today 55 ppb (< 25 ppb "normal"); FeNO at last visit 50 ppb

Review of RAST testing: + ragweed, trees, grass, roaches, dust mites, dogs, and cats

Spirometry from 1 month ago:

	Measured	% Predicted
FVC (L)	3.87	112.73
FEV_1 (L)	2.51	89.09
FEV_1/FVC (%)	64.8 (0.648)	
TLC (L)	5.93	92.47
DLCO (mL/min/mm Hg)	29.31	143.09

Summary: Reduced FEV_1/FVC. The FVC and FEV_1 are normal. There is a response to inhaled bronchodilator. The FRC, TLC, and diffusing capacity are normal.

Labs: Na 141 mEq/L (mmol/L) , K 3.6 mEq/L (mmol/L), Cl 104 mEq/L (mmol/L), CO_2 30 mEq/L (mmol/L), anion gap 7, Ca 9.3 mg/dL (2.33 mmol/L), Scr 0.92 mg/dL (81 µmol/L), estimated GFR 106 mL/min/1.73 m^2, IgE 90 IU/mL (kIU/L)

WBC 9.6 × 10^9/L, Hgb 15.4 g/dL (154 g/L; 9.56 mmol/L), Hct 43.9% (0.439) , MCV 83.9 µm^3 (fL), MCH 29.5 pg/cell, MCHC 35.1 g/dL (351 g/L), RDW 14.2% (0.142), Plt 216 ×10^9/L; absolute eosinophil count 0.9 × 10^9/L (high)

Aspergillus antibody: none detected

What risk factors does the patient have for an asthma exacerbation?

How do the above laboratory and procedures help to assess the patient's asthma?

What therapeutic alternative regimens are available for this patient?

Provide this patient with an asthma action plan.

Recommend monitoring and follow-up for this patient.

initiate long-term control therapy. Use of more than one canister per month indicates the need to step up long-term control therapy.

- Determine the frequency of patient exacerbations. Frequent exacerbations, unscheduled clinic visits, emergency department visits, and hospitalizations due to asthma may indicate the need to reassess the patient's asthma regimen and environment.
- Measure lung function using office spirometry yearly or after therapeutic changes have been made in patients older than 5 years.
- Identify environmental factors triggering asthma exacerbations and provide trigger avoidance recommendations.
- Perform medication reconciliation to identify discrepancies in medications prescribed and used by the patient and to determine drug and disease state interactions.
- Assess the patient's inhaler technique at every visit and always ensure proper technique before stepping up therapy.
- Determine adherence to long-term controller medications. Assess the patient's understanding of the indication for long-term controller medication and identify adverse events, cost issues, and need for refills.
- Review and update the patient's asthma action plan and provide the patient with a written copy of the plan.
- Update the patient's immunization status and provide an annual influenza vaccination.

Acute Asthma

In addition to the outcomes measured for chronic asthma, acute asthma monitoring also includes the following:

- Measure PEF and assess asthma symptoms. The goal PEF measurement is 70% of the patient's personal best peak flow after the first three doses of an inhaled SABA and

Patient Care Process: Chronic Asthma

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review previous full pulmonary function tests, RAST, CBC, IgE levels, and chemistry panel.
- Assess patient's peak flow measurement (if applicable).
- Collect current asthma control using validated questionnaire (eg, ACT or c-ACT) results.
- Document current height, weight, blood pressure, heart rate, and pulse oximetry.
- Auscultate the lungs for wheezing. Examine ears, eyes, nose, and throat. Look in the mouth for signs of oral candidiasis if on ICS.
- Identify asthma attacks since the last visit, including emergency room visits or hospitalizations or use of oral corticosteroid bursts.
- Ask about tobacco use and exposure to secondhand smoke (tobacco or marijuana).
- Ask the patient to demonstrate his/her inhaler use. Ask when the inhaler is used, how many times in the past week the inhaler was used, and when the inhaler was refilled.
- Identify the number of missed days of school or work because of asthma.
- Ask about patient (or caregiver) goals and satisfaction with asthma control.
- Collect diet and exercise information and use of SABA before exercise.
- Identify comorbid conditions that may affect asthma control including gastroesophageal reflux disease (GERD), allergic rhinitis, sleep apnea, anxiety, and depression.

Assess the Information:

- Evaluate medication side effects (rapid heart rate, jitteriness, bad taste, cough, dysphonia, lack of efficacy).
- Verify medication adherence. Examine the patient's inhaler for the number of doses remaining. Call the dispensing pharmacy to determine fill history of inhalers.
- Determine whether the patient is taking any medications (including prescription, OTC, or supplements) that may cause cough or worsen asthma control.
- Determine if patient's asthma medications are appropriate based on spirometry results, exacerbation history, and current asthma control (see Table 14–7 for assessing control).
- Identify changes in home, work, or school environment that may contribute to worsening asthma symptoms.
- Assess for worsening in comorbid conditions that may contribute to worsening asthma symptoms.
- Identify factors that may be affecting medication adherence including side effects, cost issues, formulary issues, and unclear understanding of purpose of inhalers.
- Assess inhaler technique. Identify if patient has any barriers that inhibit them from using their inhaler correctly.
- Determine if the patient needs the influenza or pneumococcal vaccines.
- Assess the patient's readiness to stop using tobacco or marijuana.

Develop a Care Plan:

- Document the patient's specific goals for asthma control, including no missed school/work, no hospitalizations or emergency department visits, no need for oral corticosteroids, increased ability to exercise on a daily basis, ACT above 20 or peak flow reading at least 80% of the patient's personal best measurement.
- If the patient is not controlled, before adding medications or increasing dosing, make sure the patient is using the current inhalers correctly and is willing to use the inhaler.
- If asthma is not controlled and patient is adherent to their asthma medications and using them correctly, consider a step up in therapy (Table 14–10.)
- Identify patient preference, ability to pay, and insurance coverage for MDI, DPI, SMI, or nebulization.
- If the patient is controlled and has been on the current regimen for 3 months or longer, consider discontinuing or lowering the dose of controller medications.

Implement the Care Plan:

- Educate the patient about changes in drug therapy, medication administration, potential new adverse effects, and how to manage and report adverse effects that may occur.
- Review patient's technique with new inhalers. Use pictures and videos of inhalers. (http://use-inhalers.com/)
- Treat oral candidiasis if present. Discuss rinsing and spitting after ICS use and possibly the need for a spacer to decrease side effects.
- Provide an updated medication list with indication and use of each inhaler device.
- Provide an updated asthma action plan with medication changes.
- Review environmental asthma triggers and avoidance plans.
- Administer and update vaccinations.
- Discuss diet and exercise (using SABA prior to exercise if needed).
- Refill all asthma-related medications, including medications to treat allergic rhinitis and GERD.

Follow-up: Monitor and Evaluate:

- Schedule follow-up physician visits depending on asthma control (2 weeks–6 months).
- Check spirometry yearly.
- Review inhaler technique and use at every visit.
- Update asthma action plan yearly or with each medication change.
- Monitor ACT quarterly.
- Monitor medication refill history.
- Evaluate asthma-related hospitalizations, emergency department visits, and oral corticosteroid use.

improved asthma symptoms. Spirometry is not usually conducted in the emergency department.

- Check respiratory rate and measure oxygenation using pulse oximetry and provide oxygen via nasal cannula if needed. The goal oxygen saturation is greater than 90% (0.90) in adults and greater than 95% (0.95) in children, pregnant women, and patients with coexisting cardiovascular disease.
- Obtain a PCO_2 measurement via arterial blood gases in patients with severe asthma exacerbations. An increased PCO_2 indicates the potential for respiratory failure.
- Monitor serum potassium for hypokalemia upon admission and periodically throughout the admission in patients receiving high dose or continuous nebulization of SABA.

Abbreviations Introduced in This Chapter

CYP	Cytochrome P-450 isoenzyme
DPI	Dry powder inhaler
FeNO	Fraction of exhaled nitric oxide
FEV_1	Forced expiratory volume in 1 second
FVC	Forced vital capacity
HFA	Hydrofluoroalkane
ICS	Inhaled corticosteroid
IgE	Immunoglobulin E
LABA	Long-acting β_2-agonist
MDI	Metered-dose inhaler
NHLBI	National Heart, Lung, and Blood Institute
NSAID	Nonsteroidal anti-inflammatory drug
PCO_2	Partial arterial pressure of carbon dioxide
PEF	Peak expiratory flow
ppb	Parts per billion
SABA	Short-acting β_2-agonist
SMI	Soft mist inhaler
TH2	Type 2 T-helper $CD4^+$ cell

15 Chronic Obstructive Pulmonary Disease

Jon P. Wietholter and Tara R. Whetsel

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the pathophysiology of chronic obstructive pulmonary disease (COPD).
2. Identify signs and symptoms of COPD.
3. List the treatment goals for a patient with COPD.
4. Design an appropriate COPD maintenance treatment regimen based on patient-specific data.
5. Design an appropriate COPD exacerbation treatment regimen based on patient-specific data.
6. Develop a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for COPD.
7. Formulate an appropriate education plan for a patient with COPD.

INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is a progressive disease characterized by airflow limitation that is not fully reversible. Previous definitions of COPD included chronic bronchitis and emphysema. Chronic bronchitis is defined clinically as a chronic productive cough for at least 3 months in each of two consecutive years in a patient in whom other causes have been excluded.[1] Emphysema is defined pathologically as destruction of alveoli.[1] The major risk factor for both conditions is cigarette smoking, and many patients share characteristics of each one. Therefore, current guidelines focus instead on chronic airflow limitation.

The Global Initiative for Chronic Obstructive Lung Disease (GOLD) is an expert panel of health professionals who developed consensus guidelines for the diagnosis and care of patients with COPD that are updated annually.[1]

EPIDEMIOLOGY AND ETIOLOGY

COPD is a major cause of morbidity and mortality and a significant cause of disability worldwide. In 2013, 15.7 million US adults were estimated to have COPD.[2] Chronic lower respiratory diseases are the third leading cause of death in the United States. In 2014, more than 151,000 adults died from COPD.[3] Personal health care spending in the United States on COPD was estimated to be $53.8 billion in 2013.[4]

COPD is caused by repeated inhalation of noxious particles or gases, most commonly cigarette smoke. Marijuana and other forms of tobacco, including secondhand smoke, are also risk factors.[1] Not all smokers develop clinically significant COPD, which suggests that genetic susceptibility plays a role. The best documented genetic factor is a rare hereditary deficiency of α_1-antitrypsin (AAT). Severe deficiency of this enzyme results in premature and accelerated development of emphysema. Factors that potentially reduce maximal attained lung function (eg, maternal smoking, preterm birth, early childhood lung infections, air pollution, childhood asthma, and active smoking during adolescence) increase the risk of COPD.[1,5] Other COPD risk factors include occupational exposure to dusts and chemicals (vapors, irritants, and fumes), biomass smoke inhalation, asthma, and bronchial hyperresponsiveness. Outdoor air pollution has been implicated as a cause, but its exact role is unclear.

PATHOPHYSIOLOGY

LO 1

Repeated exposure to noxious particles and gases causes chronic inflammation, resulting in pathologic changes in the central and peripheral airways, lung **parenchyma**, and pulmonary vasculature that lead to obstruction.[1,6,7] An imbalance between **proteases** and **antiproteases** in the lungs and oxidative stress are also important in the pathogenesis of COPD (**Figure 15–1**).

Inflammation is present in the lungs of all smokers, yet not all smokers develop COPD. In patients with COPD the inflammatory response is amplified, likely due to a genetic predisposition, although the exact mechanisms are unknown. KEY CONCEPT The inflammation of COPD differs from that seen in asthma, so the use of and response to anti-inflammatory medications is different. The inflammation of asthma is mainly mediated through eosinophils and mast cells. In COPD, the primary inflammatory cells are neutrophils, macrophages, and $CD8^+$ T lymphocytes.[6,7] A subset of patients with COPD also have increased eosinophils, which appears to predict a more favorable response to bronchodilators and corticosteroids and may indicate co-existing asthma.[6] Activated inflammatory cells release mediators (eg, interleukin-1, interleukin-8 [CXCL8], tumor necrosis factor-α) and secrete proteases (eg, elastase, proteinase-3, matrix metalloproteinase-9) which sustain and amplify inflammation and damage lung structures.[1,6]

Proteases and antiproteases are part of the normal protective and repair mechanisms in the lungs. An imbalance of protease-antiprotease activity in COPD results from either increased production or activity of destructive proteases or inactivation or reduced production of protective antiproteases. AAT (an antiprotease) inhibits trypsin, elastase, and several other proteolytic enzymes. Deficiency of AAT results in unopposed

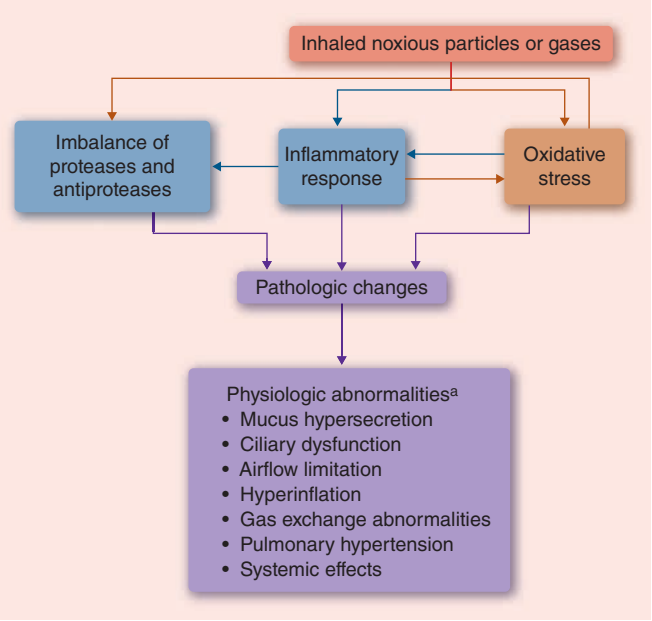

FIGURE 15–1. Pathophysiology of COPD.
[a]The physiologic abnormalities usually develop in this order.

protease activity, which promotes destruction of alveolar walls and lung parenchyma, leading to emphysema.

Oxidative stress occurs from smoke exposure and an increase in activated neutrophils and macrophages. Oxidative stress promotes inflammation and contributes to the protease-antiprotease imbalance by reducing antiprotease activity. In addition, oxidants constrict airway smooth muscle, contributing to reversible airway narrowing.

In the central airways (the trachea, bronchi, and larger bronchioles), inflammatory cells and mediators stimulate mucus gland hyperplasia and mucus hypersecretion. Mucus hypersecretion and ciliary dysfunction lead to chronic cough and sputum production. The major site of airflow obstruction is the peripheral airways (small bronchi and bronchioles). Narrowing of small airways results from **fibrosis**, increased mucus, and accumulation of inflammatory debris.[1,6,7] The reduced airway diameter causes increased resistance to airflow. Parenchymal destruction leads to loss of elasticity and structural support resulting in closure of small airways during expiration, further obstructing airflow.

As airflow obstruction worsens, the rate of lung emptying slows and the interval between inspirations does not allow expiration to the relaxation volume of the lungs. This leads to pulmonary hyperinflation, which initially only occurs during exercise but later is also seen at rest. Hyperinflation contributes to the discomfort associated with airflow obstruction by flattening the diaphragm and placing it at a mechanical disadvantage.

In advanced COPD, airflow obstruction, damaged bronchioles and alveoli, and pulmonary vascular abnormalities lead to impaired gas exchange, resulting in **hypoxemia** and eventually **hypercapnia**. Hypoxemia is initially present only during exercise but occurs at rest as the disease progresses. Inequality in the **ventilation/perfusion ratio (V_A/Q)** is the major mechanism underlying hypoxemia. As hypoxemia worsens, the body may increase erythrocyte production in an attempt to increase oxygen delivery to tissues.

Pulmonary hypertension develops late in the course of COPD, usually after development of severe hypoxemia. It is the most common cardiovascular complication of COPD and can result in **cor pulmonale**, or right-sided heart failure. Progressive loss of skeletal muscle mass in longstanding COPD contributes to exercise limitation and declining health status.

CLINICAL PRESENTATION AND DIAGNOSIS

See accompanying box for the clinical presentation of COPD.

Diagnosis

A suspected diagnosis of COPD should be based on patient symptoms and history of exposure to risk factors. **Spirometry** is required to confirm the diagnosis, using the ratio of **forced expiratory volume in the first second (FEV_1)** to **forced vital capacity (FVC)**. A postbronchodilator FEV_1/FVC ratio less than 70% (0.70) confirms airflow limitation that is not fully reversible.[1] Spirometry results can further be used to classify severity of airflow limitation in these patients. The GOLD classification categories of severity based on postbronchodilator FEV_1 are as follows: GOLD 1, Mild = 80% predicted or greater; GOLD 2, Moderate = 50% to 79% predicted; GOLD 3, Severe = 30% to 49%

Clinical Presentation of COPD

LO 2

General

- Patients are initially asymptomatic. COPD is usually not diagnosed until declining lung function leads to significant symptoms and prompts patients to seek medical care.

Symptoms

- Symptom onset is variable and does not correlate well with severity of airflow limitation measured by FEV_1.[1]
- Initial symptoms include chronic cough (for more than 3 months) that may be intermittent at first, chronic sputum production, and dyspnea on exertion. Patients may complain of a sensation of chest heaviness or increased effort to breathe.
- As COPD progresses, dyspnea at rest and/or orthopnea develop, and ability to perform activities of daily living declines.

Signs

- Inspection may reveal use of accessory muscles of respiration (paradoxical movements of the chest and abdomen in a seesaw-type motion), pursed-lips breathing, and hyperinflation of the chest with increased anterior–posterior diameter ("barrel chest").
- On lung auscultation, patients may have distant breath sounds, wheezing, a prolonged expiratory phase, and **rhonchi**.
- In advanced COPD, signs of hypoxemia may include **cyanosis** and tachycardia.
- Signs of cor pulmonale include increased pulmonic component of the second heart sound, jugular venous distention (JVD), lower extremity edema, and hepatomegaly.

predicted; GOLD 4, Very Severe = less than 30% predicted.[1] Full pulmonary function tests (PFTs) with lung volumes and diffusion capacity and arterial blood gases (ABGs) are not necessary to establish the diagnosis or severity of COPD.

Pulse oximetry should be obtained in patients with signs or symptoms suggestive of cor pulmonale or respiratory failure.[1] If oxygen saturation is less than 92% (0.92), ABGs should be assessed.[1] Patients may exhibit increased arterial carbon dioxide tension ($Paco_2$) and decreased arterial oxygen tension (Pao_2).

A complete blood count (CBC) may reveal an elevated hematocrit that may exceed 55% (0.55; **polycythemia**). An AAT level is recommended in all COPD patients, especially in areas with a high prevalence of AAT deficiency.[1] Chest radiography may show lung hyperinflation and signs of emphysema.

It is important to distinguish COPD from asthma because treatment and prognosis differ. Differentiating factors include age of onset, smoking history, triggers, occupational history, and degree of reversibility measured by prebronchodilator and postbronchodilator spirometry. In some patients, a clear distinction between asthma and COPD is not possible. Management of these patients should be similar to that of asthma.

TREATMENT

Desired Outcomes

LO 3

The goals of COPD management include: (a) smoking cessation if applicable, (b) reducing symptoms, and (c) preventing and treating exacerbations.

General Approach to Treatment

LO 4

KEY CONCEPT An integrated approach of health maintenance (eg, smoking cessation), drug therapy, and supplemental therapy (eg, oxygen and pulmonary rehabilitation) should be used via an individualized approach. Symptom severity, risk of COPD exacerbations, adverse effects, comorbidities, and the patient's response and/or desires should be used to guide therapy decisions.[1]

Either the modified Medical Research Council Questionnaire (mMRC) or COPD Assessment Test (CAT) is recommended for symptom assessment. The CAT is preferred because it provides a more comprehensive assessment.[1] An mMRC grade of 0 or 1 or a CAT score less than 10 indicates fewer symptoms. Patients with more symptoms will have an mMRC grade of 2 or more or a CAT score of 10 or more. These patients require inhaled long-acting bronchodilators on a scheduled basis.[1]

Patient Encounter, Part 1

A 56-year-old African-American man with a past medical history of COPD, type 2 diabetes mellitus, hypertension, gout, tobacco abuse (25 pack year history), and marijuana abuse (over the last 10 years) presents to the clinic complaining of shortness of breath with moderate physical activity, a "heavy" chest, chronic cough, and chronic sputum production for more than 1 year.

What symptoms and/or risk factors does he have that are suggestive of COPD?

What additional information do you need before creating a treatment plan for this patient?

Risk of future COPD exacerbation is assessed using number of exacerbations per year. Patients with a history of two or more exacerbations per year or one or more exacerbation(s) requiring hospitalization are at high risk for future exacerbations. Patients at high risk of COPD exacerbations also require inhaled long-acting bronchodilators on a scheduled basis to reduce the frequency of exacerbations.[1] **Figure 15–2** provides an overview of the management of stable COPD.

Nonpharmacologic Therapy

▶ *Smoking Cessation*

KEY CONCEPT Smoking cessation slows the rate of decline in pulmonary function in patients with COPD.[8,9] Cessation can also reduce cough and sputum production and decrease all-cause mortality.[8] Therefore, it is a critical part of any treatment plan. Unfortunately, achieving and maintaining cessation is a major challenge. A clinical practice guideline from the US Public Health Service recommends a specific action plan depending on the current smoking status and desire to quit (**Figure 15–3**).[10] Brief interventions are effective and can increase cessation rates significantly. The 5 As and the 5 Rs can be used to guide brief interventions (**Table 15–1**).

All tobacco users should be assessed for their readiness to quit and appropriate strategies implemented. Those who are ready to quit should be treated with a combination of behavioral and cognitive strategies and pharmacotherapy. Combination pharmacotherapy is more effective than monotherapy and should be considered in patients with moderate to very severe tobacco dependence.[8] Refer to Tobacco Cessation in Chapter 36.

▶ *Pulmonary Rehabilitation*

Pulmonary rehabilitation results in significant and clinically meaningful improvements in dyspnea, exercise capacity, health status, and health care utilization.[11] Initiating pulmonary rehabilitation within 4 weeks of hospitalization for an acute exacerbation can reduce readmissions and mortality.[1] Benefits have been observed in all grades of COPD severity.[1] A comprehensive pulmonary rehabilitation program should include exercise training, education, and self-management interventions aimed at behavior change.

Rehabilitation programs may be conducted in the inpatient, outpatient (most common), community, or home setting. The minimum length of an effective program is 6 weeks; the longer the program, the more sustained the results.[12] It is important for patients to continue with a home exercise program to maintain the benefits gained from the pulmonary rehabilitation program.

▶ *Long-Term Oxygen Therapy*

Long-term oxygen administration (> 15 hours/day) to patients with chronic respiratory failure has been shown to reduce mortality and improve quality of life.[1,7] Oxygen therapy should be initiated in stable patients with COPD who have severe resting hypoxemia as determined by Pao_2 at or below 55 mm Hg (7.3 kPa) or oxygen saturation (Sao_2) at or below 88% (0.88), or with evidence of pulmonary hypertension, peripheral edema suggesting heart failure, or polycythemia.[1] Patients should be reassessed with repeat ABG or oxygen saturation after 60 to 90 days.

The dual-prong nasal cannula is the standard means of delivering continuous oxygen flow. The goal is to increase the baseline oxygen saturation to at least 90% (0.90) and/or Pao_2 to at least 60 mm Hg (8.0 kPa), allowing adequate oxygenation of vital organs. The flow rate, expressed as liters per minute (L/min),

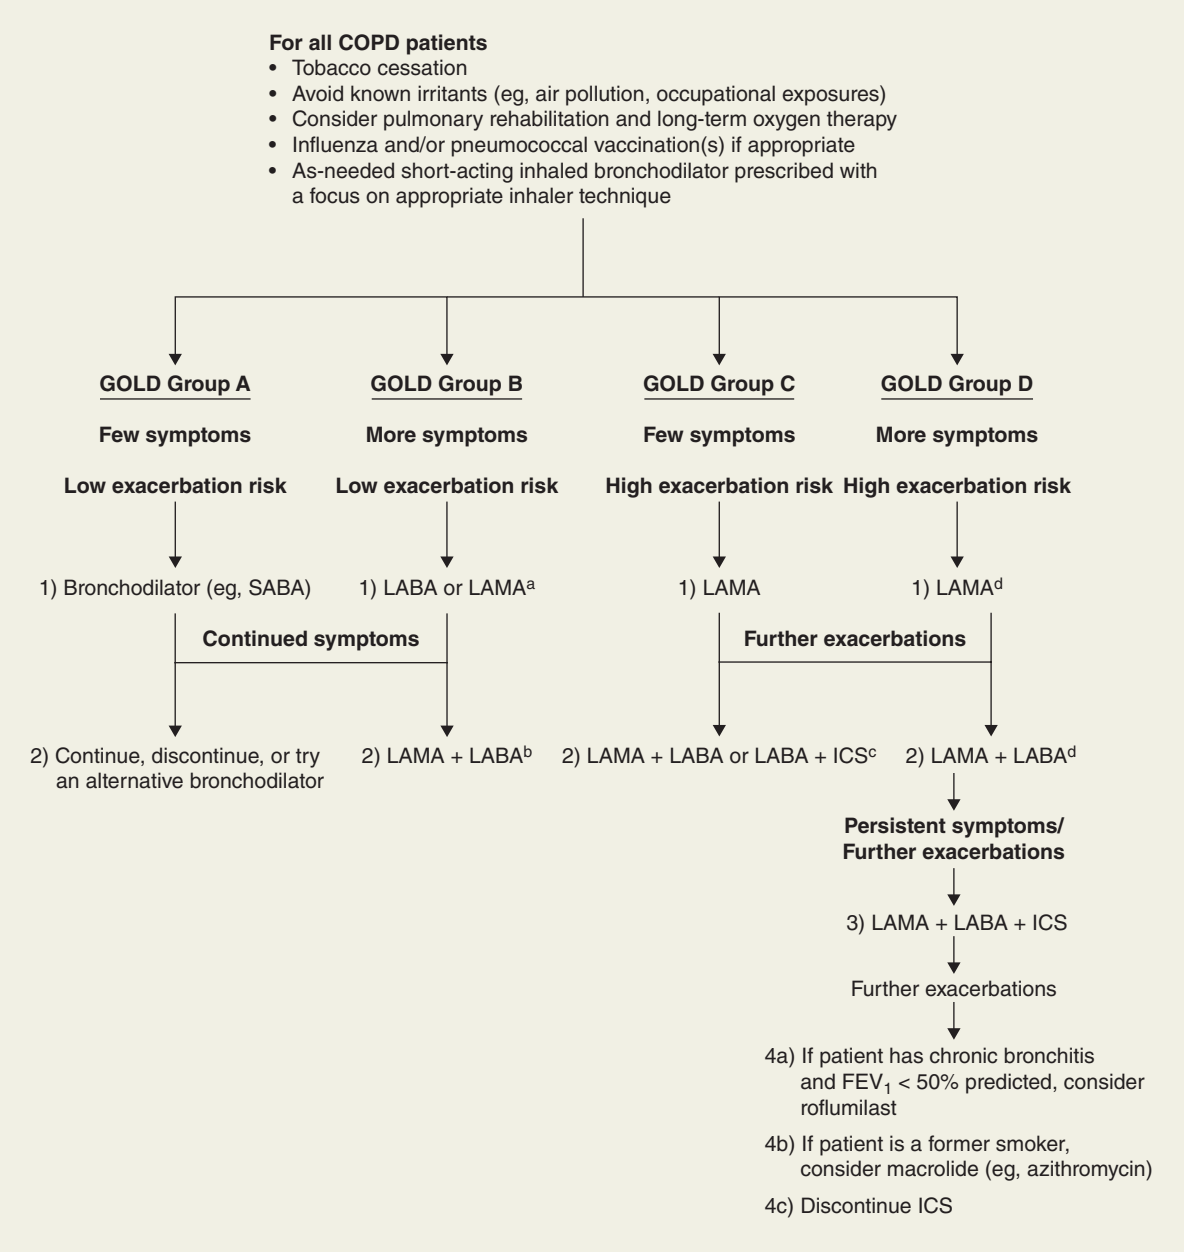

FIGURE 15–2. Treatment algorithm for stable COPD.[1] (ICS, inhaled corticosteroid; LABA, long-acting β-agonist; LAMA, long-acting muscarinic-antagonist; SABA, short-acting β_2-agonist.)
[a]If patient is experiencing severe breathlessness, may start with combination LABA/LAMA therapy.
[b]If patient does not improve on combination LABA/LAMA therapy, can de-escalate to a single agent.
[c]ICS therapy increases the risk for development of pneumonia, so LABA/LAMA combination therapy is preferred.
[d]GOLD guidelines suggest starting with combination LABA/LAMA therapy, but if monotherapy is desired, LAMA is the preferred option.

must be increased during exercise and sleep and can be adjusted based on pulse oximetry. Hypoxemia also worsens during air travel; patients requiring oxygen should generally increase their flow rate by 3 L/min during flight.[1]

▶ *Surgery*

Bullectomy, lung volume reduction surgery, and lung transplantation are surgical options for very severe COPD. These procedures may result in improved spirometry, lung volumes, exercise capacity, dyspnea, health-related quality of life, and possibly survival. Patient selection is critical because not all patients benefit.

Pharmacologic Therapy of Stable COPD

Medications available for COPD are effective for reducing or relieving symptoms, improving exercise tolerance, reducing the number and severity of exacerbations, and improving health status. Evidence that medications slow the rate of decline in lung function or improve mortality is inconclusive. An individualized evaluation of symptoms, activity limitation,

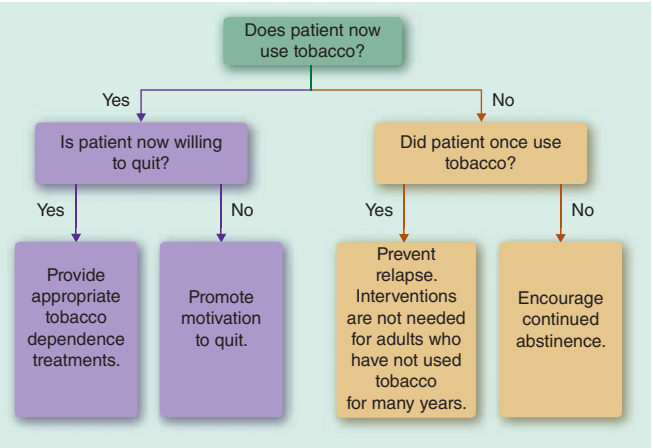

FIGURE 15–3. Algorithm for routine assessment of tobacco use status.[10] (From Fiore MC, Jaén CR, Baker TB, et al. Treating tobacco use and dependence. Clinical Practice Guideline. U.S. Department of Health and Human Services, 2008, http://www.ahrq.gov/professionals/clinicians-providers/guidelines-recommendations/tobacco/clinicians/update/index.html.)

and a patient's future risk for exacerbations should be the guiding principles to determine appropriate pharmacologic management of COPD.[1]

▶ *Bronchodilators*

KEY CONCEPT Bronchodilators are the mainstay of treatment for symptomatic COPD. They can increase FEV_1, reduce symptoms, reduce exacerbation and hospitalization rates, and improve exercise tolerance, pulmonary rehabilitation efficacy, and health status.[1] They can be used as needed for symptoms or on a scheduled basis to prevent or reduce symptoms. The inhaled route is preferred, but attention must be paid to proper inhaler technique. Long-acting bronchodilators are more expensive than short-acting bronchodilators but are superior on important clinical outcomes, including frequency of exacerbations, degree of dyspnea, and health-related quality of life.[1] Importantly, lung function may continue to worsen even with appropriate therapy.

β_2-Agonists These agents cause airway smooth muscle relaxation by stimulating adenyl cyclase to increase formation of cyclic adenosine monophosphate (cAMP). They may also improve mucociliary transport. β_2-Agonists are available in inhalation, oral, and parenteral dosage forms; the inhalation route is preferred because of fewer adverse effects.

These drugs are available in short-acting and long-acting formulations (Table 15–2). The short-acting β_2-agonists (SABAs) used in COPD include albuterol (known as salbutamol outside the United States) and levalbuterol (known as R-salbutamol outside the United States). They are used as "rescue" therapy for acute symptom relief or in those with only occasional symptoms. SABAs are inconvenient as maintenance therapy because of the need for frequent dosing.

Long-acting β_2-agonists (LABAs) include salmeterol, formoterol, arformoterol, indacaterol, olodaterol, and vilanterol. Arformoterol and formoterol are both available for nebulization, providing an alternative for patients with poor inhaler technique. Indacaterol, olodaterol, and vilanterol (only available in combination) are long acting, allowing for once-daily dosing (Table 15–2). While certain studies suggest potential spirometric benefits of one long-acting inhaler over another, definitive data on actual patient outcome differences among long-acting agents is lacking.[13,14] Insurance coverage, patient response, patient preference for type of inhaler device, and prescriber preference are considerations when selecting a LABA. Patients treated with LABAs should also have a SABA such as albuterol for as-needed use ("rescue" medication) but should be advised to avoid excessive use.

Adverse effects of both LABAs and SABAs are dose related and include palpitations, tachycardia, cough, hypokalemia, and tremor. Sleep disturbance may also occur and appears to be worse with higher doses of inhaled LABAs. Increasing doses beyond those clinically recommended is without benefit and could be associated with increased adverse effects.

Antimuscarinics Ipratropium, tiotropium, aclidinium, glycopyrrolate (also known as glycopyrronium bromide), and umeclidinium are all bromide salts available for inhalation treatment of COPD. They produce bronchodilation by competitively blocking muscarinic receptors in bronchial smooth muscle and may also decrease mucus secretion. Tiotropium and umeclidinium have long half-lives allowing for once-daily dosing and are considered long-acting muscarinic antagonists (LAMAs). Other LAMAs include aclidinium and glycopyrrolate, which have shorter half-lives requiring twice-daily dosing. While certain studies suggest potential spirometric benefits of one LAMA over another, definitive data on actual patient outcome differences among LAMAs is still lacking.[15] Choice of LAMA should be based on insurance coverage, patient response and preferences, and prescriber preferences. Ipratropium is not typically recommended because it has a longer onset of action than SABAs and decreased efficacy compared to tiotropium.[16]

LAMAs may be more effective than LABAs for reducing exacerbations in patients with moderate to very severe COPD.[1,17] Patients using a LAMA as maintenance therapy should be prescribed a SABA as their rescue therapy; ipratropium is not recommended as an alternative to albuterol because of the risk of excessive anticholinergic effects when combined with LAMAs.[18]

Inhaled antimuscarinics are well tolerated with the most common adverse effect being dry mouth. Occasional metallic taste has also been reported, most commonly with ipratropium. Other anticholinergic adverse effects include constipation, tachycardia, blurred vision, and precipitation of narrow-angle glaucoma symptoms. Urinary retention could be a problem, especially for patients with concurrent bladder outlet obstruction. Early studies

Components of Brief Interventions for Tobacco Users

The 5 As for Brief Intervention

Ask: Identify and document tobacco-use status for every patient at every visit
Advise: Urge every tobacco user to quit
Assess: Is the tobacco user willing to make a quit attempt at this time?
Assist: Use counseling and pharmacotherapy to help patients willing to make a quit attempt
Arrange: Schedule follow-up contact, preferably within the first week after the quit date

The 5 Rs to Motivate Smokers Unwilling to Quit at Present

Relevance: Tailor advice and discussion to each smoker
Risks: Help the patient identify potential negative consequences of tobacco use
Rewards: Help the patient identify the potential benefits of quitting
Roadblocks: Help the patient identify barriers to quitting
Repetition: Repeat the motivational message at every visit

Table 15–2

Maintenance Medications for COPD

	Medication	Onset	Peak	Duration	Usual Dose
Short-Acting β_2-Agonists	**Albuterol**[a]				
	Nebulization	5–8 min	1–2 hours	2–6 hours	1.25–5 mg every 4–8 hours as needed
	Inhalation	5–8 min	0.5–1 hour	2–6 hours	MDI (90 mcg/puff) one to two puffs every 4–6 hours as needed
	Oral	30 min	2–3 hours	4–6 hours ER: Up to 12 hours	2–4 mg three to four times a day as needed ER: 4–8 mg every 12 hours (max: 32 mg/day)
	Levalbuterol[a]				
	Nebulization	10–17 min	1.5 hours	5–8 hours	0.63–1.25 mg three times per day, 6–8 hours apart as needed
	Inhalation	5–10 min	1–1.5 hours	3–6 hours	MDI (45 mcg/puff) one to two puffs every 4–6 hours as needed
Long-Acting β_2-Agonists	**Formoterol**				
	Inhalation	1–3 min	1–3 hours	8–12 hours	Only in combination inhalers
	Nebulization	1–3 min	1–3 hours	8–12 hours	20 mcg every 12 hours
	Salmeterol				
	Inhalation	10 min to 1 hour	2–3 hours	12 hours	Powder (50 mcg/inhalation) one inhalation every 12 hours
	Indacaterol				
	Inhalation	5 min	1–4 hours	24 hours	Powder (75 mcg/inhalation) one inhalation every 24 hours
	Olodaterol				
	Inhalation	5 min	10–20 minutes	24 hours	2.5 mcg/inhalation two inhalations every 24 hours
	Vilanterol				
	Inhalation	15–30 min	2 hours	24 hours	Only in combination inhalers
	Arformoterol				
	Nebulization	7–20 min	1–3 hours	12 hours	15 mcg every 12 hours
Short-Acting Muscarinic Antagonists	**Ipratropium**				
	Nebulization	15 min	1–2 hours	4–8 hours	500 mcg every 6–8 hours as needed
	Inhalation	15 min	1–2 hours	2–4 hours	MDI (17 mcg/puff) two puffs four times/day as needed
Long-Acting Muscarinic Antagonists	**Tiotropium**				
	Inhalation	60 min	1.5–3 hours	24 hours	Powder (18 mcg/inhalation) one inhalation every 24 hours Aerosol solution (2.5 mcg/inhalation) two inhalations every 24 hours
	Aclidinium				
	Inhalation	30 min	2–3 hours	12 hours	Powder (400 mcg/inhalation) one inhalation every 12 hours
	Umeclidinium				
	Inhalation	60 min	1–3 hours	24 hours	Powder (62.5 mcg/inhalation) one inhalation every 24 hours
	Glycopyrrolate				
	Inhalation	5 min	5 minutes	12–24 hours	Powder (15.6 mcg/inhalation) one inhalation every 12 hours
	Nebulization	5 min	< 20 minutes	12–24 hours	25 mcg every 12 hours
Methylxanthine	**Theophylline**				
	Oral	15–30 min	Up to 24 hours, depending on formulation	6–24 hours	400–600 mg/day divided every 6–24 hours based on formulation (max: 600 mg/day)[b] Adjust dose to serum concentrations of 5–15 mcg/mL (mg/L; 28–83 µmol/L)
Phosphodiesterase-4 Inhibitor	**Roflumilast**	4 wks	—	—	500 mcg daily[c]
	Oral				

(*Continued*)

Table 15–2

Maintenance Medications for COPD (*Continued*)

Inhaled Corticosteroids	**Beclomethasone**	1–14 days	3–4 weeks	MDI (40, 80 mcg/puff) 40–160 mcg every 12 hours
	Budesonide	1 day	1–2 weeks	Powder (90, 180 mcg/inhalation) 90–180 mcg every 12 hours
	Fluticasone	Variable	1–2 weeks	MDI (44, 110, 220 mcg/puff) 88–440 mcg every 12 hours Powder (50, 100, 250 mcg/inhalation) 50–250 mcg every 12 hours

In elderly patients, start with the lowest recommended dose and increase as necessary.

[a]Albuterol is known as salbutamol and levalbuterol is known as levosalbutamol (or R-salbutamol) outside the United States.

[b]Maximum dose of 400 mg in patients with decreased hepatic function.

[c]Not recommended in patients with moderate or severe hepatic impairment.

ER, extended-release; MDI, metered-dose inhaler.

suggested an increased cardiovascular risk with ipratropium or tiotropium, but subsequent large trials of tiotropium found no increased cardiovascular risk.[1,17,19]

Methylxanthines Theophylline is an oral methylxanthine derivative and nonselective phosphodiesterase inhibitor that increases intracellular cAMP within airway smooth muscle resulting in bronchodilation and may also improve inspiratory function. Its use is limited due to a narrow therapeutic index, multiple drug interactions, and adverse effects. Theophylline should be reserved for patients who cannot use inhaled medications or who remain symptomatic despite appropriate use of inhaled bronchodilators.

Therapeutic drug monitoring is needed to optimize therapy because of wide interpatient variability. Serum concentrations from 5 to 15 mcg/mL (mg/L; 28–83 μmol/L) provide adequate clinical response with a greater margin of safety than the previously recommended range of 10 to 20 mcg/mL (mg/L; 55–111 μmol/L). However, bronchodilatory effects are small when the serum concentration is below 10 mcg/mL (mg/L; 55 μmol/L).[20] Multiple factors can alter theophylline clearance including concomitant medications (through CYP450 interactions), disease states, tobacco smoke, and marijuana. Chemicals in tobacco smoke induce theophylline metabolism and increase its clearance. The most common adverse effects of theophylline include headache, heartburn, insomnia, tachycardia, palpitations, and tremor. Dose-related adverse effects include nausea and vomiting, seizures, and arrhythmias.

▶ *Corticosteroids*

Inhaled corticosteroids (ICS) in combination therapy improve symptoms, lung function, health status, and exacerbation rates in patients with moderate to very severe COPD.[1] However, there appears to be a limited response of COPD-associated inflammation, and the long-term safety of ICS in COPD patients is unclear.[1]

KEY CONCEPT ICS are currently recommended solely for patients with severe to very severe COPD with increased exacerbation risk who are not adequately controlled by first-line long-acting bronchodilators and may be most beneficial in patients with elevated serum eosinophils.[1] Monotherapy with ICS is less effective than combined therapy with a LABA and is therefore not recommended. Combination inhaler devices are convenient and ensure that patients receive both medications (Table 15–3).

The most common adverse effects from ICS include oropharyngeal candidiasis and hoarse voice. These can be minimized by rinsing the mouth after use and by using a spacer device with metered-dose inhalers (MDIs). Increased bruising, decreased bone density, increased risk of diabetes, cataracts, and mycobacterial infections have been reported; an increased pneumonia risk exists with ICS usage and appears to be higher in elderly patients, smokers, or underweight patients.[1,21]

Long-term use of systemic corticosteroids should be avoided due to an unfavorable risk-to-benefit ratio. The steroid myopathy that can result from long-term use of oral corticosteroids weakens muscles, further decreasing the respiratory drive in patients with advanced disease.

▶ *Phosphodiesterase-4 (PDE-4) Inhibitors*

Roflumilast is an oral PDE-4 inhibitor approved for prevention of moderate and severe COPD exacerbations in patients with severe COPD associated with chronic bronchitis and a history of exacerbations.[9] Roflumilast is believed to reduce inflammation by inhibiting breakdown of cAMP but does not cause direct bronchodilation. Roflumilast has more frequent adverse events than inhaled medications, is expensive, and has little effect on quality of life.[22] Adverse effects typically occur early during treatment and include diarrhea, weight loss, nausea, headache, insomnia, decreased appetite, and abdominal pain; neuropsychiatric effects (eg, insomnia, anxiety, depression, suicidal ideation) have also been reported. Roflumilast can be considered in patients with chronic bronchitis, an FEV_1 less than 50%, and exacerbations while being treated with two or three classes of long-acting inhaled medications, particularly if they have had a hospitalization within the previous year.[1,9] It should not be combined with theophylline because both inhibit PDE-4, and it should be avoided in underweight patients or those with depression.[1,20]

▶ *Combination Therapy*

For patients who remain symptomatic on monotherapy, a combination of bronchodilators can be used.[1,9] Combining long-acting inhaled medications is preferred over short-acting agents or theophylline. Combination therapy should include

Table 15–3

FDA-Approved Combination Inhalers for Management of COPD

Inhaled Corticosteroid/Long-acting β_2-Agonist (ICS/LABA)

Brand Name	Corticosteroid	β_2-Agonist	Dosage Strengths	Frequency
Advair Diskus	Fluticasone propionate	Salmeterol	100, 250, 500 mcg/50 mcg	Twice daily
Symbicort	Budesonide	Formoterol	80, 160 mcg/4.5 mcg	Twice daily
Breo	Fluticasone furoate	Vilanterol	100 mcg/25 mcg	Daily

Long-acting Muscarinic Antagonist/Long-acting β_2-Agonist (LAMA/LABA)

Brand Name	Antimuscarinic	β_2-Agonist	Dosage Strengths	Frequency
Anoro	Umeclidinium	Vilanterol	62.5 mcg/25 mcg	Daily
Stiolto	Tiotropium	Olodaterol	2.5 mcg/2.5 mcg	Daily
Bevespi	Glycopyrrolate	Formoterol	9 mcg/4.8 mcg	Twice daily
Utibron	Glycopyrrolate	Indacaterol	15.6 mcg/27.5 mcg	Twice daily

Short-acting Muscarinic Antagonist/Short-acting β_2-Agonist (SAMA/SABA)

Brand Name	Antimuscarinic	β_2-Agonist	Dosage Strengths	Frequency
Combivent	Ipratropium	Albuterol	20 mcg/100 mcg	Four times daily

Long-acting Muscarinic Antagonist/Long-acting β_2-Agonist/Inhaled Corticosteroid (LAMA/LABA/ICS)

Brand Name	Antimuscarinic	β_2-Agonist	Corticosteroid	Dosage Strengths	Frequency
Trelegy	Umeclidinium	Vilanterol	Fluticasone furoate	62.5 mcg/25 mcg/100 mcg	Daily

medications with different mechanisms, which can lower the risk of side effects versus increasing the dose of a single agent.[1] Combining a LABA with a LAMA produces a greater change in spirometry, reduces symptoms and exacerbations, and has a lower pneumonia risk when compared to a LABA/ICS combination.[1,23,24]

Triple therapy with ICS, LABA, and LAMA is commonly used in patients who remain symptomatic on dual therapy. Adding a LAMA to existing LABA/ICS therapy appears to improve lung function and patient reported outcomes including exacerbation risk, while adding ICS to existing LABA/LAMA did not show similar benefits.[1,25] Recent data suggest that ICS may not decrease exacerbation rates more than LABA monotherapy after an exacerbation. Additionally, while spirometry could potentially worsen in the short term, exacerbation rates may not increase when ICS are withdrawn from patients with moderate to severe COPD.[26,27,28] Based on these results, a step-down in therapy can be considered in patients with stable COPD.[29] Potential benefits and risks of any combination therapy should be considered on a case-by-case basis. When combination therapy is indicated, multi-ingredient inhalers should be selected over single-ingredient inhalers to reduce medication administration and cost burden to the patient (Table 15–3).

▶ *Vaccinations*

COPD exacerbations, serious illness, and death in COPD patients can be reduced with annual influenza vaccination. The optimal time for vaccination is usually from early October through mid-November.

Pneumococcal polysaccharide vaccine (PPSV23) should be administered to all adults with COPD. Patients older than 65 years should be revaccinated if it has been more than 5 years since initial vaccination and they were younger than 65 years at the time. Pneumococcal conjugate vaccine (PCV13) is recommended for all persons 65 years old and older who have not previously received PCV13. PCV13 should be administered first, with PPSV23 administered at least 12 months after PCV13 and at least five years after the most recent PPSV23 dose.[30]

▶ *α_1-Antitrypsin Augmentation Therapy*

Augmentation therapy consists of weekly transfusions of pooled human AAT with the goal of maintaining adequate plasma levels of the enzyme. It is recommended for nonsmokers with AAT deficiency and an FEV_1 less than or equal to 65% predicted. In these patients, augmentation therapy appears to minimize the progression of lung disease and slow decline in FEV_1, although large randomized controlled trials are limited. Augmentation therapy appears to be most beneficial in patients with an FEV_1 of 35% to 49% predicted and can be considered even in those with an FEV_1 greater than 65%. It is not recommended for individuals with AAT deficiency who do not have lung disease.[1,31]

▶ *Other Pharmacologic Therapies*

N-acetylcysteine has antioxidant and mucolytic activity, and it may reduce exacerbations and improve health status.[1] While the exact COPD patient population that may benefit from *N*-acetylcysteine has not been defined, it may offer benefits in select patients.[9,32]

Prophylaxis with daily macrolides (eg, azithromycin) significantly reduced exacerbations in select subgroups of COPD patients.[33] However, they are associated with cardiovascular adverse effects, hearing loss, and bacterial resistance. Electrocardiography should be considered prior to starting therapy to detect a prolonged QTc interval, which may predispose to cardiac arrhythmias with macrolide therapy.[34] Their ideal utility appears to be in former smokers with continued exacerbations while on appropriate inhaled therapy.[1,9,34]

Opioids may be effective for dyspnea in severe COPD and may be used to manage symptoms in terminal patients potentially by reducing air hunger. Serious adverse effects are possible, so close monitoring is necessary.[1]

Traditionally, β-blockers were avoided in patients with COPD due to concerns of worsening respiratory status. However, β-blocker use may actually be beneficial in COPD patients because they have been associated with reduced mortality and exacerbation rates without negatively impacting pulmonary function even in patients without overt cardiovascular disease.[35]

While much of their benefit may be derived from cardioprotective properties, other hypotheses include upregulation of β_2-receptors or pleiotropic and/or antioxidant properties. They appear to be safe (particularly β_1-selective agents) and can be continued, particularly when used to treat comorbidities such as coronary artery disease and atrial fibrillation.

Multiple traditional Chinese medicines (eg, Buzhong Yiqi Tang, Bu-Fei Yi-Shen) have reduced exacerbations and improved lung function when added to standard therapy. However, most have been small, flawed studies and large randomized controlled trials are needed to confirm their efficacy.[36]

COPD Exacerbations

An exacerbation is defined as "an acute worsening of respiratory symptoms that result in additional therapy."[1] Exacerbations negatively impact health status, hasten lung function decline, increase rates of hospitalization, and have a reported mortality rate of 10% to 64% when requiring hospitalization.[1,37,38] While it is often difficult to discern what causes an exacerbation, many precipitating factors have been identified, including air pollution and viral (usually rhinovirus) and bacterial (usually *Haemophilus influenzae*) respiratory tract infections; exacerbations associated with viral infections are often more severe.[1,34,37,38]

Exacerbations are classified as mild (only short-acting bronchodilators needed), moderate (additional antibiotics and/or corticosteroids needed), or severe (hospitalization or emergency room visit required, often with acute respiratory failure present) and are based on the patient's clinical status.[1] During an exacerbation, patients often have increased inflammation, increased mucus production, increased gas trapping, and reduced expiratory function, which leads to increased dyspnea with symptoms typically lasting 7 to 10 days.[1,37] Factors associated with an increased risk of exacerbation include a history of exacerbation(s), worsening airflow limitation, and old age.[1,37]

The treatment goals for exacerbations are to limit the impact of the current exacerbation and to prevent future exacerbations. It is estimated that greater than 80% of exacerbations are managed on an outpatient basis.[1] Patients presenting with signs of a severe COPD exacerbation often use accessory muscles to breathe and are tachypneic, hypoxemic, and hypercarbic. Additionally, patients may be cyanotic and have peripheral edema. Life-threatening signs and symptoms include mental status changes, worsening respiratory status despite ventilatory support, hemodynamic instability, and acidosis. Presence of these signs and symptoms should prompt evaluation for hospital and/or intensive care unit admission.

▶ *Nonpharmacologic Management*

Pulse oximetry may be useful for determining whether supplemental oxygen therapy is needed during a COPD exacerbation. If necessary, oxygen should be titrated to a saturation of 88% to 92% (0.88–0.92).[1,37] Blood gases should be checked frequently to confirm appropriate oxygenation without compensatory carbon dioxide retention or acidosis.[1]

If mechanical ventilation is required, it can be provided by noninvasive (nasal or face mask) or invasive (orotracheal tube or tracheostomy) methods. Noninvasive mechanical ventilation (NIV) decreases acute respiratory acidosis, respiratory rate,

Patient Encounter, Part 2: The Medical History, Physical Examination, and Diagnostic Tests

PMH: COPD × 8 years, Hypertension × 15 years, type 2 diabetes mellitus × 10 years, gout × 5 years

Allergies: Anaphylaxis to penicillin and doxycycline

SH: Smokes one pack per day; social intake of alcohol (4–5 drinks per week); use of marijuana on a daily basis; no other illicit drug use

FH: Noncontributory

Meds: Carvedilol 6.25 mg twice daily, albuterol MDI one to two puffs every 4 to 6 hours as needed, metformin 500 mg twice daily, allopurinol 300 mg daily

ROS: (–) fever, chills, or night sweats; (–) nasal congestion, drainage; (–) chest pain, paroxysmal nocturnal dyspnea; (+) orthopnea; (+) shortness of breath, chest heaviness, cough with clear phlegm; (–) wheezing; (–) hemoptysis; (–) heartburn, reflux symptoms, N/V/D, change in appetite, change in bowel habits; (–) pedal edema

PE:

VS: BP 165/100 mm Hg, P 56 beats/min, RR 21/min, T 35.8°C (96.4°F), Wt 90 kg (198 lb), Ht 72 in. (183 cm), BMI 26.9 kg/m^2

HEENT: EOMI; moist mucous membranes; no JVD; no palpably enlarged cervical lymph nodes

Lungs: Clear breath sounds; expiratory phase is diminished; no wheezes or crackles; (+) rhonchi

CV: RRR, normal S_1, S_2; no murmur, gallop, or rub

Abd: Soft, nontender, normoactive bowel sounds, no hepatomegaly

Ext: No cyanosis, edema, or finger clubbing

Pulmonary Function Tests

	Prebronchodilator		Postbronchodilator	
	Actual	% Predicted	Actual	% Predicted
FVC (L)	4.44		4.45	
FEV_1 (L)	1.99	52%	2.01	53%
FEV_1/FVC			45% (0.45)	

CXR: Upper lobe bullous emphysema with hyperexpansion bilaterally

COPD Assessment Test score: 16

History of Exacerbations: 2 previous COPD exacerbations (3 years ago and 6 months ago, both requiring hospitalization)

Given this additional information, what is your assessment of the patient's condition?

What nonpharmacologic and pharmacologic alternatives are available for managing this patient's COPD?

With the data provided, create a care plan for managing the patient's COPD.

length of hospital stay, intubation rates, and mortality and should be attempted prior to invasive methods.[1,37,38]

▶ *Pharmacologic Management*

LO 5

Bronchodilators Administration of a SABA with or without ipratropium is considered standard bronchodilator therapy during a COPD exacerbation.[1,37] Increased doses and/or frequency may provide benefit during an exacerbation, and an MDI with or without a spacer or a nebulizer can be used.[1,37] Maintenance bronchodilator therapy should be continued during an exacerbation or initiated once stable. However, LAMAs should be discontinued if ipratropium is used as part of the exacerbation bronchodilator regimen.

Corticosteroids Systemic corticosteroids, while not having a defined mortality benefit, have been shown to shorten recovery time, improve lung function, reduce the risk of early relapse, reduce the risk of treatment failure, and hasten symptomatic improvement during COPD exacerbations, particularly in patients with higher levels of blood eosinophils (> 2% [0.02]).[1,38,40] A 5-day course of oral prednisone or prednisolone 40 mg daily is recommended, and patients should be monitored closely for hyperglycemia.[1,37,38,41] IV corticosteroids should be used only if the oral route is not tolerated because there is no clinical benefit over oral therapy.[1,40] Nebulized budesonide is more expensive but may be used as an alternative in some patients (eg, those unable to take systemic corticosteroids due to lack of availability or significant systemic adverse effects).[1]

Antibiotics Exacerbations with purulent sputum production have shown increased bacteria, but routine antibiotic use is controversial due to the possibility of nonbacterial causes.[1,42] Approximately 50% of exacerbations are caused by bacterial infections, and there may be benefit to treating most COPD exacerbations with antibiotics.[34,38] Antibiotics, given for 5 to 7 days, reduce recovery time, risk of early relapse, risk of treatment failure, hospitalization duration, and mortality when indicated, particularly in ICU patients.[1,37,38] Procalcitonin, the prohormone of calcitonin, may have value in determining whether to use antibiotics in exacerbations because it has been shown to be elevated in the presence of bacterial respiratory infections.[37,43] Current guidelines recommend antibiotics for patients with increased sputum purulence and either increased sputum volume or increased dyspnea, patients with all three of these symptoms, or patients who require mechanical ventilation.[1] Appropriate antibiotic selections for COPD exacerbations are included in Table 15–4. The oral route is preferred whenever possible, and severity of exacerbation and local resistance patterns should be considered when selecting an antimicrobial regimen.

Other Therapies Hospitalized patients with COPD exacerbations should receive thromboprophylaxis due to increased risk of venous thromboembolism.[1] Fluid balance should be closely monitored. Medication reconciliation, proper inhaler technique, vaccination status evaluation, and patient counseling on the importance of smoking cessation are necessary both during the exacerbation and upon hospital discharge. Patients are at a high risk for recurrence during the first 8 weeks after an exacerbation.[38]

Table 15–4

Recommended Antibiotics for Acute Exacerbations of COPD[1,34]

Suspected Pathogens Causing COPD Exacerbation	Commonly Used Antibiotics[a]
Haemophilus influenzae *Streptococcus pneumoniae* *Moraxella catarrhalis*	Amoxicillin ± β-lactamase inhibitor Azithromycin or clarithromycin Doxycycline
Pseudomonas aeruginosa	Ciprofloxacin[b] or levofloxacin Piperacillin–tazobactam or ticarcillin–clavulanate Cefepime or ceftazidime Meropenem, imipenem–cilistatin, or doripenem Gentamicin, tobramycin, or amikacin[c]
Methicillin-resistant Staphylococcus aureus (MRSA)	Vancomycin[d] Linezolid[d]

[a]Refer to local antibiogram to determine which antibiotic selection is most appropriate.

[b]Limited efficacy against *Streptococcus pneumonia.*

[c]Aminoglycosides are not effective against *Streptococcus pneumoniae.*

[d]Not effective against *Haemophilus influenzae* or *Moraxella catarrhalis.*

OUTCOME EVALUATION

LO 6

- Monitor patients for improvement in symptoms. Ask if there is a difference since starting treatment and if so, is it meaningful to them? Are they less breathless? Can they do more activities and/or sleep better? If treatment response was inadequate and the patient was using the medication correctly, consider discontinuing the medication and selecting another agent.
- Changes in FEV_1 should not be the main outcome assessed because FEV_1 changes correlate weakly with symptoms, exacerbations, and health-related quality of life. The GOLD guidelines recommend annual spirometry to identify patients who are declining quickly.[1]
- The CAT is an eight-item questionnaire that can be used to assess for trends and changes in symptoms and disease impact on daily life.[1] Higher CAT scores may also be predictive of future exacerbations, depression, and mortality.[44] The test can be accessed at www.catestonline.org.
- The Medical Research Council dyspnea scale can be used to monitor physical limitation due to breathlessness. The scale is simple to administer, correlates well with health status, and predicts future mortality risk. However, the CAT is preferred because it is more comprehensive.[1]

Patient Encounter, Part 3

Three months after his last clinic appointment, the patient arrives at the local emergency department complaining of significant shortness of breath even while resting, increasing sputum production, and change in sputum color. Upon examination, he is using accessory muscles and pursed lips to breathe and has an oxygen saturation of 83% (0.83). Based on these findings alone, he is diagnosed with a COPD exacerbation and is admitted to the hospital.

What additional signs and symptoms should be evaluated to determine the severity of his exacerbation?

What nonpharmacologic and pharmacologic alternatives are available for this patient?

With the data provided, create a care plan for managing this COPD exacerbation.

Patient Care Process

Collect Information:

- Review medical history, physical assessment findings, and PFTs.
- Assess the type, frequency, and severity of the patient's symptoms. Use the CAT to measure symptom impact.
- Ask about disease impact on the patient's life, including limitation of activity, missed work, and feelings of depression or anxiety.
- Obtain a thorough history of prescription, nonprescription, and dietary supplement use.
- Speak with the patient and review records to identify smoking history, exacerbation history (number in previous 12 months and whether required hospitalization), immunization status, preferences, health goals, and socioeconomic factors that affect access to medications and/or health care.

Assess the Information:

- Assess efficacy, safety, inhaler technique, and patient adherence.
- Assess appropriateness of each COPD medication based on patient symptoms and exacerbation risk (Figure 15–2).
- Determine symptom burden using the CAT.
- Identify any significant adverse drug effects or interactions.
- Assess for barriers to medication access. COPD medications can be costly even for patients with insurance.
- Assess immunization records for influenza and pneumococcal vaccinations.
- Determine if current smokers are ready to quit.

Develop a Care Plan:

- Design a therapeutic plan including lifestyle modifications (eg, smoking cessation) and optimal drug therapy (Figure 15–2). Consider the need for pulmonary rehabilitation, oxygen therapy, and/or surgery.
- Use combination inhalers when appropriate to minimize drug administration burden.
- Review insurance formularies for medication coverage. Use manufacturer patient assistance programs as needed to ensure medication access.

Implement the Care Plan:

- Provide annual influenza vaccination and pneumococcal vaccination if needed.
- Provide patient education and self-management training: LO 7
  - Smoking cessation including behavioral and cognitive strategies for quitting and proper use of pharmacotherapy.
  - Maintaining or increasing physical activity, ensuring adequate sleep, maintaining a healthy diet.
  - How and when to take medications, importance of adherence, adverse effects and how to minimize them.
  - Signs and symptoms of an exacerbation and what to do if one occurs; provide written action plan.
  - Advanced directives and end-of-life issues for patients with severe disease.
- Address any patient concerns about COPD and its management.
- Refer to pulmonary rehabilitation program, if indicated.

Follow-up: Monitor and Evaluate:

- Follow up within 1 month after an acute exacerbation.
- For stable patients, follow up every 3 to 6 months to assess effectiveness and safety of therapy.
- Review smoking status, oxygen saturation, symptoms, exacerbation frequency and severity, and medication regimen (adherence, inhaler technique, adverse reactions, drug interactions, issues affecting medication access).
- Obtain spirometry annually to assess disease progression.

- Monitor theophylline levels with goal serum concentrations of 5 to 15 mcg/mL (mg/L; 28–83 µmol/L). Obtain trough levels 1 to 2 weeks after initiation of treatment and after any dosage adjustment. Routine levels are not necessary unless toxicity is suspected or symptoms have worsened.
- Monitor the patient for adverse effects of the medications selected.

Abbreviations Introduced in This Chapter

AAT	α_1-Antitrypsin
ABG	Arterial blood gas
cAMP	Cyclic adenosine monophosphate
CAT	COPD Assessment Test
COPD	Chronic obstructive pulmonary disease
FEV_1	Forced expiratory volume in the first second
FVC	Forced vital capacity
GOLD	Global Initiative for Chronic Obstructive Lung Disease
ICS	Inhaled corticosteroid
LABA	Long-acting β_2-agonists
LAMA	Long-acting muscarinic antagonist
MDI	Metered-dose inhaler
mMRC	Modified Medical Research Council
NIV	Noninvasive mechanical ventilation
$Paco_2$	Partial pressure of arterial carbon dioxide
Pao_2	Partial pressure of arterial oxygen
PCV13	Pneumococcal conjugate vaccine
PDE-4	Phosphodiesterase-4
PFTs	Pulmonary function tests
PPSV23	Pneumococcal polysaccharide vaccine
SABA	Short-acting β_2-agonist
SAMA	Short-acting muscarinic antagonist
SaO_2	Arterial oxygen saturation
V_A/Q	Ventilation/perfusion ratio

16 Cystic Fibrosis

Kimberly J. Novak

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the pathophysiology of cystic fibrosis (CF) and its multiorgan system involvement.
2. Describe the common clinical presentation and diagnosis of CF.
3. Consider long-term treatment goals with respect to clinical course and prognosis of CF.
4. Identify nonpharmacologic therapies for CF management.
5. Recommend appropriate pharmacologic therapies for chronic CF management.
6. Design appropriate antibiotic regimens for acute pulmonary exacerbations of CF.
7. Apply pharmacokinetic principles when calculating drug doses in CF patients.
8. Formulate monitoring plans for acute and chronic CF pharmacotherapy.

INTRODUCTION

Cystic fibrosis (CF) is an inherited multiorgan system disorder affecting children and, increasingly, adults. It is the most common life-shortening genetic disease among whites and the major cause of severe chronic lung disease and pancreatic insufficiency in children. Disease generally manifests as mucosal obstruction of exocrine glands caused by defective ion transport within epithelial cells. Due to the array of affected organ systems and complicated medical therapies, appropriate CF treatment necessitates interprofessional team collaboration.

EPIDEMIOLOGY AND ETIOLOGY

In the United States, CF most commonly occurs in whites, affecting approximately 1 in 3200 individuals. CF is less common in Hispanics (1 in 9200 to 13,500), African Americans (1 in 15,000), and Asian Americans (1 in 35,000).[1] CF is inherited as an autosomal recessive trait, and approximately 1 in 25 whites are **heterozygous** carriers. Offspring of a carrier couple (each parent being heterozygous) have a 1 in 4 chance of having the disease (**homozygous**), a 1 in 2 chance of being a carrier (heterozygous), and a 1 in 4 chance of receiving no trait. The *CFTR* gene mutation is found on the long arm of chromosome 7 and encodes for the CF transmembrane regulator (CFTR) protein, which functions as a chloride channel to transport water and electrolytes. Over 2000 mutations have been described in the *CFTR* gene; however, the *Phe508del* mutation (also known as *F508del* or *ΔF508*) is most common and is present in approximately 70% to 90% of CF patients.[1-5]

PATHOPHYSIOLOGY

LO 1

CF is a disease of exocrine gland epithelial cells where CFTR expression is prevalent. Normally, these cells transport chloride through CFTR chloride channels with sodium and water accompanying this flux across the cell membrane (**Figure 16–1**). CFTR is regulated by protein kinases in response to varying levels of the intracellular second messenger cyclic-3′,5′-adenosine monophosphate (cAMP). CFTR also downregulates the epithelial sodium channel and regulates calcium-activated chloride and potassium channels, and it may function in exocytosis and formation of plasma membrane molecular complexes and proteins important in inflammatory responses and mucociliary clearance.[2,6] KEY CONCEPT In CF, the CFTR chloride channel is dysfunctional and usually results in decreased chloride secretion and increased sodium absorption, leading to altered viscosity of fluid excreted by the exocrine glands and mucosal obstruction. *CFTR* gene mutations are assigned to classes (I–VI) based on degree of residual CFTR protein function. Class I (absent CFTR synthesis), II (blocked CFTR trafficking), and III (blocked CFTR regulation or gating) mutations result in no CFTR function. Class IV (altered CFTR conductance), Class V (reduced CFTR synthesis), and Class VI (shortened CFTR life span) mutations have some remaining functional protein.[1,2,5]

Pulmonary System

Chronic lung disease leads to death in 90% of patients. KEY CONCEPT Pulmonary disease is characterized by thick mucus secretions, impaired mucus clearance, chronic airway infection and colonization, obstruction, and an exaggerated neutrophil-dominated inflammatory response.[1,4] This process leads to air trapping, **atelectasis**, mucus plugging, **bronchiectasis**, cystic lesions, pulmonary hypertension, and eventual respiratory failure. Pulmonary function declines approximately 1% to 2% per year; an individual's rate of decline depends on severity of CFTR dysfunction and comorbidities.[7] Sinusitis and nasal polyps are also common, and microbial colonization is similar to that of the lungs.

Bacterial pathogens are often acquired in age-dependent sequence. Early infection is most often caused by *Staphylococcus aureus* (usually methicillin sensitive) and nontypeable

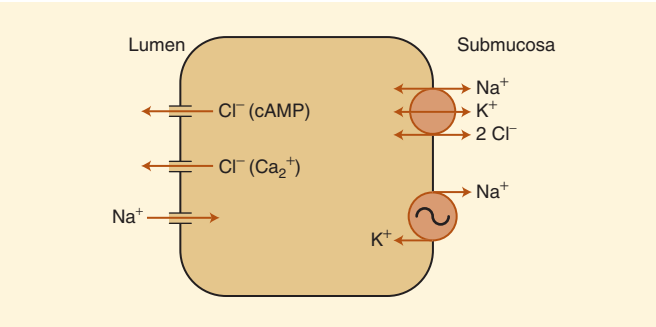

FIGURE 16–1. Electrolyte transport in the airway epithelial cell. (Ca, calcium; cAMP, cyclic-3′, 5′-adenosine monophosphate; Cl, chloride; Na, sodium; K potassium.) (From Milavetz G, Smith JJ. Cystic fibrosis. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 7th ed. New York, NY: McGraw-Hill; 2008:536.)

Haemophilus influenzae. *Pseudomonas aeruginosa* infection is the most significant CF pathogen among all age groups. *P. aeruginosa* expresses extracellular toxins that perpetuate lung inflammation. Mucoid strains of *P. aeruginosa* produce an alginate biofilm layer that interferes with antibiotic penetration. Methicillin-resistant *S. aureus* (MRSA) is also a significant CF pathogen, and incidence is on the rise in some geographic areas. Organisms identified later in the disease course include *Stenotrophomonas maltophilia*, *Achromobacter xylosoxidans*, *Burkholderia cepacia* complex, fungi including *Candida* and *Aspergillus* species, and nontuberculous mycobacteria among others.[2,7] Cultured organisms may represent initial infection, chronic colonization, or microbial overgrowth in an acute exacerbation.

Gastrointestinal System

Gastrointestinal (GI) involvement often presents as **meconium** ileus, small-bowel obstruction shortly after birth due to abnormally thick meconium. Older CF patients may develop distal intestinal obstruction syndrome (DIOS) due to fecal impaction in the terminal ileum and cecum.

Maldigestion due to pancreatic enzyme insufficiency is present in 85% to 90% of CF patients.[1,8] Thick pancreatic secretions and cellular debris obstruct pancreatic ducts and lead to fibrosis. Volume and concentration of pancreatic enzymes and bicarbonate are reduced, leading to maldigestion of fat and protein and subsequent malabsorption of fat-soluble vitamins (A, D, E, and K). Symptoms include abdominal distention, **steatorrhea**, flatulence, and malnourishment despite voracious appetite. Maldigestion is progressive and may develop later in a previously pancreatic-sufficient patient. Other complications may include GI reflux, dysmotility, salivary dysfunction, **intussusception**, **volvulus**, **atresia**, **rectal prolapse**, complications related to corrective surgery for meconium ileus, and an increased risk of GI cancers later in life.

Hepatobiliary disease occurs due to bile duct obstruction from abnormal bile composition and flow. Hepatomegaly, splenomegaly, and cholecystitis may be present. Hepatic **steatosis** may be present due to effects of malnutrition. Progression from cholestasis (impaired bile flow) to cirrhosis, esophageal varices, and portal hypertension takes several years. Many patients are compensated and asymptomatic but may be susceptible to acute decompensation in the event of extrinsic hepatic insult from viruses, medications, or other factors.[1,9]

Endocrine System

CF-related diabetes (CFRD) occurs in 20% of adolescents and 40% to 50% of adults, disproportionally affecting women. Although it shares characteristics of both type 1 and type 2 diabetes mellitus, CFRD is categorized separately. Reduced functional pancreatic islet cells and increased islet **amyloid** deposition results in insulin insufficiency, the primary cause of CFRD. Insulin secretion is delayed in response to glucose challenge, and absolute insulin secretion over time is reduced. Some insulin resistance may also be present in CFRD and may fluctuate in relation to infection and inflammation.[2,7,10,11]

Postprandial hyperglycemia is common, but because some basal insulin secretion is maintained, fasting hyperglycemia is less severe and ketosis is rare. Diet, acute and chronic infection, and corticosteroid use lead to fluctuation in glucose tolerance over time.[10] CFRD is associated with greater nutritional failure, increased pulmonary disease, and earlier mortality. Pulmonary function decline and nutritional consequences associated with progressive CFRD have historically overshadowed risks of long-term macrovascular and microvascular complications; however, these complications are now emerging with longer life expectancy.[7]

Reproductive System

CF patients often experience delayed puberty. In females, menarche occurs 18 months later than average; menstrual irregularity is common, and fertility is reduced due to increased cervical mucus viscosity. Due to increasing life expectancy, pregnancy is becoming more common; however, outcomes depend on prepartum nutritional and pulmonary status. Almost all males with CF are **azoospermic** due to congenital absence of the vas deferens with resultant obstruction; however, conception still occurs occasionally. Conception can also occur through application of assisted reproductive technologies.[12]

Musculoskeletal System

Several factors contribute to development of bone disease in CF: (a) malabsorption of vitamins D and K and calcium, (b) poor nutrition and decreased body mass, (c) physical inactivity, (d) corticosteroid therapy, and (e) delayed puberty. Chronic pulmonary infection, through release of inflammatory cytokines, can increase bone resorption and decrease formation. Osteopenia, osteoporosis, pathological fractures, and **kyphosis** can occur.[13,14] Episodic or chronic arthritis may occur due to immune complex formation in response to chronic inflammation.[7] Digital **clubbing** is common and is a marker for chronic hypoxia.[1]

Hematological System

Anemia may be present due to impaired erythropoietin regulation, nutritional factors (vitamin E and iron malabsorption), or chronic inflammation. Increased cytokine production can lead to shortened red blood cell survival, reduced erythropoietin response, and impaired mobilization of iron stores. Additionally, with chronic hypoxia, normal hemoglobin and hematocrit values may represent relative anemia.[15] Increased red blood cell production is a physiological response to hypoxia; however, this response may be blunted in CF and may result in symptoms of anemia despite normal lab values.

Abnormal bleeding or clotting may also be observed as a result of vitamin K malabsorption, antibiotic-associated depletion of GI flora and vitamin K synthesis, reduced coagulation factor synthesis due to liver disease, and/or a procoagulant state due to inflammation.

Clinical Presentation of Cystic Fibrosis

General

- Usually diagnosed in neonates (meconium ileus or newborn screening) or during early childhood. May present later in life due to less severe symptoms or misdiagnosis.

Symptoms

- Pulmonary: Chronic cough, sputum production, decreased exercise tolerance, and recurrent pneumonia and sinusitis. Exacerbations may be marked by increased cough, sputum changes (darker, thicker), hemoptysis, dyspnea, and fever.
- GI: Numerous large, foul-smelling loose stools (steatorrhea), flatulence, and abdominal pain. Intestinal obstruction may present as abdominal pain and distention and/or decreased bowel movements.
- Nutritional: Poor weight gain despite voracious appetite and hunger. Dry skin, skin rash, and visual disturbances may be noted in vitamin deficiency.
- CFRD: Weight loss, increased thirst, and more frequent urination.

Signs

- Obstructive airways disease: Tachypnea, dyspnea, cyanosis, wheezes, crackles, sternal retractions, digital clubbing, and barrel chest.
- Failure to thrive: Below age-based normal of both height and weight in children; adults may be near/below ideal body weight or have a low body mass index (BMI).
- Salty taste to the skin.
- Hepatobiliary disease: Hepatomegaly, splenomegaly, and prolonged bleeding may occur.
- Recurrent pancreatitis (usually in pancreatic-sufficient patients): Episodic epigastric abdominal pain, persistent vomiting, and fever.

Laboratory Tests

- Leukocytosis with increase in polymorphonuclear (PMN) leukocytes and bands may occur in acute pulmonary exacerbations.
- Maldigestion: Decreased serum levels of fat-soluble vitamins (A, D, E, and K). Decreased vitamin K levels may result in elevated prothrombin time (PT) and international normalized ratio (INR).
- Glucose intolerance: Blood glucose between 140 and 199 mg/dL (7.8–11 mmol/L) 2 hours after an oral glucose-tolerance test.
- CFRD: Blood glucose 200 mg/dL (11.1 mmol/L) or higher 2 hours after an oral glucose-tolerance test or fasting hyperglycemia (fasting blood glucose 126 mg/dL [7 mmol/L] or more regardless of the post-glucose challenge level).
- Hepatobiliary disease: Serum aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, γ-glutamyltransferase, and bilirubin may be elevated.

Other Tests

- Microbial cultures (sputum, throat, bronchoalveolar lavage, or sinus): Isolation of *P. aeruginosa, S. aureus, S. maltophilia,* and other CF-related organisms.
- Pulmonary function tests (PFTs): Decreased forced expiratory volume in 1 second (FEV_1) and forced vital capacity (FVC), typically lower during acute pulmonary exacerbations.
- Chest x-ray or CT scan: Infiltrates, atelectasis, bronchiectasis, and mucus plugging.
- Abdominal x-ray or CT scan: Intestinal obstruction may be manifested as meconium ileus, DIOS, or intussusception. Rectal prolapse may be noted on physical examination.
- Maldigestion: Elevated fecal fat content, reduced pancreatic stool elastase (< 200 mcg/g of feces).

Integumentary System

Sweat contains abnormally high concentrations of sodium and chloride due to impaired reabsorption within the sweat duct from loss of CFTR channels. This may impart a characteristic salty taste to the skin. Patients are usually otherwise asymptomatic.[4] In rare instances such as hot weather or excessive sweating during physical activity, patients may become dehydrated and experience symptoms of hyponatremia (nausea, headache, lethargy, and confusion).

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

See the accompanying box for the clinical presentation of CF.

Diagnosis

Testing for CF is part of required newborn screening panels in all US states in an effort to identify patients prior to symptom development, initiate early treatment, and improve long-term outcomes.[16] A positive newborn screen for CF is not diagnostic (due to false-positive results among CF carriers), nor does a negative screen universally exclude the diagnosis. All "positive screens," as well as individuals presenting with signs and symptoms of CF, are referred to a CF care center for sweat chloride test and genetic evaluation. Diagnosis of CF is based on two separate elevated sweat chloride concentrations of 60 mEq/L (mmol/L) or greater obtained through pilocarpine **iontophoresis** ("sweat test"). Genetic testing (*CFTR* mutation analysis) is performed to confirm the diagnosis and determine eligibility for precision medicine therapy, screen in utero, or detect carrier status. More than 70% of diagnoses are made by 12 months of age.[1,16]

Clinical Course and Prognosis

Clinical course varies because of multiple genetic mutations and the heterogeneous profile of the *Phe508del* mutation. Some patients develop severe lung disease early in childhood and reach end-stage disease by adolescence, whereas others maintain near-normal lung function into adulthood. Newly diagnosed adults tend to have *CFTR* mutations associated with residual CFTR function and may present with milder respiratory symptoms, pancreatitis, or infertility.[2]

Life expectancy has greatly increased from a predicted survival of 16 years of age in 1970 to more than 40 years for patients born in the 1990s.[1,2,7] According to the Cystic Fibrosis Foundation Registry, 51.6% of patients are over 18 years of age.[17]

Patient Encounter Part 1

A 6-week-old female term neonate is being evaluated at CF clinic due to an abnormal newborn screen (elevated immunoreactive trypsinogen; one copy of gene mutation *G551D* on initial testing). Sweat chloride testing is performed on bilateral thighs with results reported as follows:

Sample 1: Sweat chloride 112 mEq/L (mmol/L)

Sample 2: Sweat chloride 98 mEq/L (mmol/L)

Upon parental interview, the infant is a voracious eater and has six to nine loose stools per day that have an oily appearance. She is mostly breastfed, with some supplemental 20 kcal/ounce (0.67 kcal/mL; 2.8 kJ/mL) infant formula, and she weighs 3.25 kg (birth weight of 3.6 kg). Parents also report that she needed oral laxatives and enemas to help pass her meconium while in the newborn nursery.

What information is consistent with a diagnosis of CF?

What are the next steps in the CF diagnostic process?

The parents are overwhelmed with the diagnosis of CF and are very worried about life expectancy. How would you explain the infant's prognosis?

TREATMENT

Desired Outcomes

LO 3 Therapeutic outcomes in CF care relate to chronic and acute treatment goals. With chronic management, the primary goals are to delay disease progression and optimize quality of life. KEY CONCEPT Maximizing nutritional status through pancreatic enzyme replacement and vitamin and nutritional supplements is necessary for normal growth and development and for maintaining long-term lung function. Reduction of airway inflammation and infection and aggressive preventive therapies minimize acute pulmonary exacerbations and delay pulmonary decline. In pulmonary exacerbations, therapy is directed toward reducing acute airway inflammation and obstruction through aggressive airway clearance and antibiotic therapy with a goal of returning lung function to pre-exacerbation levels or greater.

Nonpharmacologic Therapy

▶ *Airway Clearance Therapy*

KEY CONCEPT Airway clearance therapy is a necessary routine for all CF patients to clear secretions and control infection, even at diagnosis prior to becoming symptomatic. Waiting until development of a first pulmonary exacerbation or daily symptoms delays benefits and may accelerate pulmonary decline. The LO 4 traditional form of chest physiotherapy (CPT) is percussion and postural drainage. Areas of the patient's chest, sides, and back are rapidly "clapped" by hand in different patient positions, followed by cough or forced expiration to mobilize secretions. Patients may also be taught autogenic drainage, which consists of deep breathing exercises followed by forced cough.

Several airway clearance devices are also available. Flutter valve devices use oscillating positive expiratory pressure (OPEP) to cause vibratory airflow obstruction and an internal percussive effect to mobilize secretions. Intrapulmonary percussive ventilation (IPV) provides continuous oscillating pressures during inhalation and exhalation. High-frequency chest compression (HFCC) with an inflatable vest that provides external oscillation is most commonly used and often preferred because patients can perform therapy independently from an early age.[1,18]

Effective cough and expectoration of mucus are essential for good clearance technique. Airway clearance therapy is typically performed once or twice daily for maintenance care and is increased to three or four times per day during acute exacerbations.

▶ *Nutrition*

Most CF patients have increased caloric needs due to increased energy expenditure through increased work of breathing, increased basal metabolism, and maldigestion. Prevention LO 4 of malnutrition requires early patient-specific nutritional intervention. Caloric requirements to promote age-appropriate weight gain or maintenance are typically 110% to 200% of the recommended daily allowance (RDA) for age, gender, and size and increase as disease progresses.[11]

Nutrition in malnourished patients consists of baseline required calories plus additional calories for weight gain via a high-calorie high-fat diet. Even with aggressive diet and oral supplements, placement of a **gastrostomy** or **jejunostomy** tube for nighttime supplemental feeds may be necessary.[11] Patients with refractory malabsorption, CFRD, and/or tube feedings have unique caloric needs. Collaboration with dieticians specially trained in CF nutrition is essential.

Pharmacologic Therapy

▶ *Airway Clearance Therapy*

LO 5 Airway clearance therapy is often accompanied by bronchodilator treatment with albuterol (known as salbutamol outside the United States) to stimulate mucociliary clearance and prevent bronchospasm associated with therapy (Table 16–1).

A mucolytic agent is administered subsequently to reduce sputum viscosity and enhance clearance. Dornase alfa (Pulmozyme) is a recombinant human (rh) DNase that selectively cleaves extracellular DNA released during neutrophil degradation in viscous CF sputum. Nebulization of dornase alfa improves daily pulmonary symptoms and function, reduces pulmonary exacerbations, and improves quality of life.[19,20] Daily dosing is most common, but some patients benefit from twice daily administration.[20] Hypertonic saline for inhalation (HyperSal) 7% or 3.5% is often used as an alternative or add-on mucolytic agent for osmotic effects in airway surface liquid or sputum. It must be preceded by a bronchodilator due to greater incidence of bronchospasm and may not be tolerated by some patients.[19,20] *N*-acetylcysteine is another mucolytic agent, but its unpleasant odor and taste limit patient acceptance.

CF guidelines do not recommend β_2-agonists or inhaled corticosteroids in patients without asthma or allergic bronchopulmonary aspergillosis (ABPA).[19] Inhaled corticosteroids may attenuate reactive airways and reduce airway inflammation in some patients; however, clear benefit in CF has not been established.[19-21] Patients with asthma or recurrent wheezing or dyspnea who improve with albuterol (salbutamol) should be considered for maintenance asthma therapy, as should patients with bronchodilator-responsive PFTs. Drug delivery to the site of inflammation is limited by mucus plugging, which may limit efficacy. Patients on asthma therapies should administer these medications after airway clearance to optimize drug delivery.

LO 5 Montelukast, antihistamines, and/or intranasal steroids are used for CF patients with allergic or rhinosinusitis symptoms.

Table 16–1

Common Medications Used in Cystic Fibrosis

Medication	Pediatric Dose	Adult Dose
Albuterol (salbutamol)	2.5 mg nebulized with chest physiotherapy two to four times daily; alternatively, two puffs via metered-dose inhaler may be substituted	2.5 mg nebulized with chest physiotherapy two to four times daily; alternatively, two puffs via metered-dose inhaler may be substituted
Dornase alfa	2.5 mg nebulized once or twice daily	2.5 mg nebulized once or twice daily
Hypertonic saline 7%, 3.5%, or 3%	4 mL nebulized one to four times per day	4 mL nebulized one to four times per day
Ibuprofen[a]	20–30 mg/kg/dose given twice daily	20–30 mg/kg/dose given twice daily
Azithromycin	Body weight 25–39 kg: 250 mg on Mondays, Wednesdays, and Fridays	Body weight 40 kg or more: 500 mg on Mondays, Wednesdays, and Fridays
Ivacaftor[b]	50–150 mg every 12 hours	150 mg every 12 hours
Lumacaftor/ivacaftor[c]	200–400 mg/250 mg every 12 hours	400 mg/250 mg every 12 hours

[a]Adjusted to achieve peak serum concentrations of 50 to 100 mcg/mL (243–485 µmol/L). Maintain chronic dosing with same dosage form and manufacturer. Note that therapy is not always continued into adulthood.

[b]Dose may require adjustment in patients with moderate or severe hepatic impairment and/or when coadministered with moderate or strong CYP3A inhibitors.

[c]Dose may require adjustment in patients with moderate or severe hepatic impairment and/or when coadministered with strong CYP3A inhibitors.

Long-term systemic corticosteroids reduce airway inflammation and improve lung function. However, beneficial effects diminish upon discontinuation, and concern for long-term adverse effects limits use as maintenance therapy.[19,21] Systemic corticosteroids may be used short term in acute exacerbations or for treatment of allergic response to *Aspergillus* colonization (ABPA); however, dose and duration of therapy should be minimized.

High-dose ibuprofen targeting peak concentrations of 50 to 100 mcg/mL (243–485 µmol/L) has been shown to slow disease progression, particularly in children 6 to 17 years of age with mild lung disease (FEV_1 > 60% predicted). At high doses, ibuprofen inhibits the lipoxygenase pathway, reducing neutrophil migration and function as well as release of lysosomal enzymes. At lower concentrations achieved with analgesic dosing, neutrophil migration increases, potentially increasing inflammation.[19] A dose of 20 to 30 mg/kg given twice daily is usually needed to attain target levels, but interpatient variability necessitates serum concentration monitoring.[21] Due to monitoring requirements and concerns regarding long-term safety and tolerability, only a few CF centers prescribe high-dose ibuprofen.

Azithromycin is a macrolide antibiotic commonly used in CF as an anti-inflammatory agent to improve overall lung function and reduce exacerbations in patients colonized with *Pseudomonas* and to reduce exacerbations in those without *Pseudomonas*.[19,20,22] Proposed mechanisms include interference with *Pseudomonas* alginate biofilm production, bactericidal activity during stationary *Pseudomonas* growth, neutrophil inhibition, cytokine inhibition, and reduction in sputum viscosity.[22] Due to its long tissue half-life, azithromycin is typically dosed 3 days/week (Monday, Wednesday, and Friday). Alternatively, patients may take 500 or 250 mg either daily or only Monday through Friday, based on the same weight parameters.[22] Patients should have a screening acid-fast bacillus sputum culture prior to initiation and then every 6 to 12 months, because isolation of nontuberculous mycobacteria is a contraindication to chronic azithromycin therapy.[19]

▶ *Antibiotic Therapy*

KEY CONCEPT Antibiotic therapy is used in three distinct situations: (a) eradication and delay of colonization in early lung disease (treatment of positive cultures regardless of symptoms), (b) suppression of bacterial growth once colonization is present, and (c) reduction of bacterial load in acute exacerbations in an attempt to return lung function to pre-exacerbation levels or greater.[23] KEY CONCEPT Antibiotic selection is based on periodic culture and sensitivity data, typically covering all organisms identified during the preceding year. If no culture data are available, empirical antibiotics should cover the most likely organisms for the patient's age group. Due to altered pharmacokinetics and microorganism resistance, dose optimization is key (Table 16–2).

Oral Antibiotic Therapy Severity of pulmonary symptoms also guides antibiotic selection. For recent-onset or mild symptoms, patients may be treated with outpatient oral and inhaled antibiotics for 10 to 14 days. Oral fluoroquinolones are a mainstay for *P. aeruginosa* treatment in CF, even in children. Despite concerns regarding cartilage and tendon toxicity in young animals, clinical practice has not shown an increased risk in human children.[24] Inhaled tobramycin, aztreonam, or colistin is usually continued or added for double coverage if the patient is not on suppressive inhaled antibiotics. Methicillin-sensitive *S. aureus* (MSSA) may be treated with oral amoxicillin–clavulanic acid, dicloxacillin, first- or second-generation cephalosporins, trimethoprim–sulfamethoxazole, clindamycin, doxycycline, or minocycline, depending on sensitivity. MRSA may be treated with oral trimethoprim–sulfamethoxazole, clindamycin, doxycycline, minocycline, or linezolid. *H. influenzae* often produces β-lactamases but can usually be treated with amoxicillin–clavulanic acid, a cephalosporin, or trimethoprim–sulfamethoxazole. Oral trimethoprim–sulfamethoxazole or minocycline may be used to treat *S. maltophilia*.

Intravenous Antibiotic Therapy For severe infections or patients failing outpatient therapy, IV antibiotic therapy is often prescribed for 10 to 21 days as inpatient therapy. Some patients may be discharged to finish their IV course or even receive their entire IV course at home. KEY CONCEPT Typical regimens for severe infections include an antipseudomonal β-lactam plus an aminoglycoside for added synergy and delay of resistance development.[25,26] Cephalosporins tend to be better tolerated and offer the benefit of less frequent administration. Extended-spectrum penicillins have been associated with a higher incidence of allergy. Aztreonam offers little cross-reactivity in penicillin- or cephalosporin-allergic patients; however, it has no gram-positive coverage. Meropenem should be reserved for organisms resistant to all other antibiotics to minimize development of resistance in the carbapenem drug class.

Table 16–2

Selected Antibiotic Dosing in Cystic Fibrosis[a]

Antibiotic	Pediatric Dose (mg/kg/day)	Adult Maximum Daily Dose	Interval (hours)
Intravenous			
Tobramycin, gentamicin[b]	10–15	None	8–24
Amikacin[b]	30–45	None	8–24
Ceftazidime	150–400	8–12 g	6–8
Cefepime	150–200	6–8 g	8
Piperacillin–tazobactam[c]	400–600	18–24 g	6
Ticarcillin–clavulanate[c]	400–600	12–18 g	4–6
Meropenem	120	6 g	8
Imipenem–cilastatin[c]	100	2–4 g	6
Aztreonam	200–300	8–12 g	6
Ciprofloxacin	30	1.2 g	8–12
Levofloxacin	10–20	750 mg	12–24
Nafcillin	200	12 g	4–6
Vancomycin[b]	60–80	None	6–12
Linezolid	30	1.2 g	8–12
Colistin	5–8	480 mg	8–12
Chloramphenicol[b]	60–80	4 g	6
Oral			
Amoxicillin ± clavulanic acid[c]	90	4 g	12
Dicloxacillin	100	2 g	6
Cephalexin	50–100	4 g	6–8
Trimethoprim–sulfamethoxazole[d]	12–20	1280 mg	6–12
Clindamycin	30	1.8 g	6–8
Ciprofloxacin	40	2 g	12
Levofloxacin	10–20	750 mg	12–24
Doxycycline[e]	4	200 mg	12–24
Minocycline[e]	4	200 mg	12
Linezolid	30	1.2 g	8–12
Inhaled			
Tobramycin	160–600 mg/day	600 mg	12
Aztreonam lysine	225 mg/day	225 mg	8
Colistin	75–150 mg/day	300 mg	12

[a]All doses assume normal renal and hepatic function. Consult a specialized drug reference for dosage adjustment if function is impaired. Dose and/or interval may require adjustment.

[b]Empirical starting doses only. Adjust dose per therapeutic drug monitoring.

[c]Dose based on β-lactam component.

[d]Dose based on trimethoprim component.

[e]Children older than 8 years.

Tobramycin IV is generally the first-line aminoglycoside. Isolates are usually resistant to gentamicin, and amikacin is reserved for tobramycin-resistant strains. Pharmacokinetic targets are listed in Table 16–3. Higher peak serum concentrations are desired to maximize efficacy, whereas lower trough levels reduce risk of toxicity. Once-daily dosing targets higher peaks and lower troughs, optimizing the concentration-dependent killing of aminoglycosides (eg, tobramycin 10–15 mg/kg/day or amikacin 30–45 mg/kg/day) and is preferred over three times daily dosing.[25] However, time below the minimum inhibitory concentration (MIC) is prolonged with once-daily administration in some children, possibly leading to loss of synergy for a substantial portion of the dosing interval or development of resistance. Traditional dosing may be used in these patients. Incorporation of patient-specific pharmacokinetic history is essential for optimal aminoglycoside dosing. Long-term studies are needed to examine the efficacy and resistance patterns associated with once-daily aminoglycosides in CF patients.[25,26]

As with Pseudomonas infections, most other serious gram-negative infections are also treated with combination therapy. *S. maltophilia* is highly resistant and most often treated with trimethoprim–sulfamethoxazole, minocycline, or ticarcillin–clavulanate (if available). There are few therapeutic options for *A. xylosoxidans* and *B. cepacia*.

An oral fluoroquinolone may be substituted for an IV aminoglycoside based on sensitivity data or presence of renal dysfunction and/or ototoxicity. Due to excellent bioavailability, fluoroquinolones, trimethoprim–sulfamethoxazole, doxycycline, minocycline, and linezolid should be used orally for most patients able to take enteral medications. Due to toxicity risk, colistin IV and chloramphenicol IV are reserved for life-threatening or highly resistant infections.

Inpatient treatment of MRSA can consist of IV vancomycin or oral agents as previously described, depending on the severity of infection and concomitant organisms.

LO 5

Inhaled Antibiotic Therapy Chronic or rotating inhaled antibiotic maintenance therapy may be used to suppress *P. aeruginosa* colonization in CF patients of all ages; however, long-term systemic antibiotics are not recommended due to emergence of resistance.[19,27,28] Inhaled antibiotic therapy is also recommended for eradication of initial *P. aeruginosa* infection.[29] Inhaled tobramycin (TOBI, Bethkis) is typically administered to patients 6 years of age and older in alternating 28-day cycles of 300 mg nebulized twice daily, followed by a 28-day washout period to minimize development of resistance. Long-term cyclical administration improves pulmonary function, decreases microbial burden, and reduces hospitalization for IV therapy.[20] A dry powder formulation of tobramycin (TOBI Podhaler, 112 mg inhaled twice daily) can also be used in 28-day on/off cycles with reduced administration time.[30] Due to minimal systemic absorption, pharmacokinetic monitoring is not necessary with normal renal function. Lower doses of nebulized tobramycin solution for injection have been used in younger children, and *Pseudomonas* eradication studies used 300 mg twice daily in children as young as 6 months.[31]

Aztreonam lysine for inhalation (Cayston) is also used for *P. aeruginosa* suppression in 28-day on/off cycles for CF patients 6 years of age and older.[19] It has been used in children as young as 3 months of age for *P. aeruginosa* eradication.[32] A dose of 75 mg three times daily is given via the Altera nebulizer system, a high-efficiency drug delivery device with shorter administration time.

Nebulized colistin using the IV formulation may be an option in patients with tobramycin-resistant strains or intolerance to inhaled tobramycin or aztreonam lysine.[33] Pretreatment with albuterol is necessary due to increased risk of bronchoconstriction.

Selection of inhaled antibiotics is based on culture data and patient preference. Alternating inhaled antibiotic regimens are sometimes used in patients with more advanced lung disease.[20] Inhaled antibiotics are typically stopped during acute exacerbations requiring IV therapy because drug delivery is reduced with increased sputum production, and concomitant use of IV aminoglycosides may increase risk of toxicity.[25]

Table 16–3

Target Intravenous Antibiotic Serum Concentrations in Cystic Fibrosis

	Traditional Units of Measurement		SI Units of Measurement	
Antibiotic	**Goal Peak[a] (mcg/mL)**	**Goal Trough[b] (mcg/mL)**	**Goal Peak[a] (μmol/L)**	**Goal Trough[b] (μmol/L)**
Tobramycin, gentamicin	10–12[c]	< 1.5[c]	21–26[c]	< 3.2[c]
	20–40[d]	< 1[d]	42–84[d]	< 2.1[d]
Amikacin	30–40[c]	< 5[c]	51–68[c]	< 8.6[c]
	60–120[d]	< 3[d]	103–206[d]	< 5.1[d]
Vancomycin	–[e]	15–20	–[e]	10–14

Note: Values reported in mcg/mL are numerically equivalent to mg/L.

[a]Peaks calculated 30 minutes after end of infusion for aminoglycosides.

[b]Troughs calculated immediately prior to the time the dose is due.

[c]Goals refer to traditional dosing (every 8 or 12 hours). Higher peaks may be targeted with corresponding lower trough concentrations for aminoglycosides based on center practice.

[d]Goals refer to once-daily (high-dose extended interval) dosing (preferred).

[e]Not routinely measured.

LO 7

Pharmacokinetic Considerations KEY CONCEPT CF patients have larger volumes of distribution for many antibiotics due to an increased ratio of lean body mass to total body mass and lower fat stores. CF patients also have enhanced total body clearance, although the exact mechanism has not been determined; both renal and extrarenal processes have been proposed.[26]

Because of these pharmacokinetic changes, higher doses of aminoglycosides are needed to achieve target serum levels and adequate tissue penetration.[26] Higher doses of β-lactam antibiotics are also needed to achieve and sustain levels above the MIC.[26] Trimethoprim–sulfamethoxazole displays enhanced renal clearance and hepatic metabolism in the CF population. Higher doses of fluoroquinolones, vancomycin, and linezolid may also be needed to attain inhibitory serum and tissue concentrations against CF pathogens.[26,34]

Although most CF patients have shorter drug half-lives and larger volumes of distribution than non-CF patients, some patients exhibit decreased renal clearance because of concomitant nephrotoxic medications, diabetic nephropathy, or other reasons.

► *Gastrointestinal Therapy*

LO 5

Pancreatic Enzyme Replacement This is the mainstay of GI therapy. Most enzyme products available in the United States are formulated as capsules containing enteric-coated microspheres or microtablets that escape enzyme inactivation by gastric acid and promote dissolution in the more alkaline duodenum (Table 16–4). Capsules may be opened and the microbeads swallowed with food (for infants and young children), as long as they are not chewed or mixed with alkaline or hot foods (which denature enzymes). Although products may contain similar enzyme ratios, they are not bioequivalent and cannot be interchanged.

Pancreatic enzymes are initiated at 1000 units/kg/meal of lipase component (because fats are most difficult to digest) with half-doses given for snacks. Enzymes should be taken at the beginning or divided throughout the meal and must be given with any fat-containing snack. Infants are typically started at 1500 to 2500 units of lipase/120 mL of formula or breast milk and may require division of capsule contents via visual estimation to obtain appropriate doses. Pancreatic enzymes cannot be placed in formula bottles due to inability to pass consistently through the nipple slit. Instead, enzyme microbeads are placed on a small dot of infant applesauce (or moistened infant rice cereal) and administered via infant spoon with subsequent nursing or bottle-feeding to facilitate swallowing. The oral mucosa must be examined afterward to ensure that all enzymes are swallowed because remnant microbeads can cause oral erosions (ulcers).

Table 16–4

Common Pancreatic Enzyme Replacement Products

Trade Name	Lipase (Units)	Amylase (Units)	Protease (Units)
CREON 3000	3000	15,000	9500
CREON 6000	6000	30,000	19,000

Zenpep 25,000	25,000	136,000	85,500
Zenpep 40,000	40,000	168,000	126,000

[a]The number after a trade name refers to the approximate number of thousands of units of lipase contained per dosage form.

[b]Nonenteric coated enzyme. Must be given with a gastric acid suppressant. Often administered via feeding tube.

KEY CONCEPT Titration of pancreatic enzyme doses is based on control of steatorrhea, stool output, and abdominal symptoms. Infants should have no more than three to four stools per day, whereas older patients should have no more than two to three (children) or one to two (adolescents/adults) well-formed stools per day. Doses are titrated at 2- to 3-week intervals in increments of 150 to 250 units of lipase/kg/meal (or the next easily administered capsule or half-capsule) up to 2500 units/kg/meal. Maximum infant doses are typically 4000 units of lipase/120 mL of formula. Higher doses should be used cautiously due to risk of fibrosing colonopathy observed with doses above 6000 units of lipase/kg/meal for more than 6 months.[1,11] Patients receiving enteral formulas via feeding tubes (either at nighttime or continuously) may receive intermittent doses of oral enzymes. They may also receive enzymes that are administered directly through the feeding tube using a vehicle such as an applesauce bolus, or they may receive crushed enzymes that are given as either intermittent doses via the feeding tube or added to the enteral formula bags in the actual feedings. An *ex vivo* cartridge device containing immobilized lipase (RELiZORB) may also be used with some enteral formulas to predigest fat within the tube feeding apparatus prior to the formula reaching the patient.

Patients responding poorly to maximal doses of one product may benefit from changing to another product and/or addition of a histamine H_2-receptor antagonist or proton pump inhibitor. Acid suppression may boost the effective enzyme dose, if duodenal pH is not alkaline enough to neutralize residual gastric acid and dissolve enteric coating.[11] Acid suppression also treats concomitant gastroesophageal reflux disease, which is common in CF.[8,20]

Fat-Soluble Vitamin Supplementation This is usually required in pancreatic insufficiency. Specially formulated products for CF patients (AquADEKs, DEKAs, MVW Complete, Choiceful) are usually sufficient to attain normal serum vitamin levels at a dose of 1 mL daily for infants, one tablet daily for younger children, and one tablet/capsule twice daily for teenagers and adults taken with food and pancreatic enzymes. Additional supplementation may be needed in uncontrolled malabsorption or for replacement of severe vitamin deficiency based on serum vitamin levels.[1,11] Appetite stimulants such as cyproheptadine, dronabinol, mirtazapine, or megestrol may be an option for promoting nutrition and weight gain, but must be balanced with potential side effects which can range in severity from drowsiness (cyproheptadine, dronabinol, mirtazapine) to adrenal suppression (megestrol).[11]

Liver Disease Ursodiol at 20 mg/kg/day in two divided doses may slow progression of liver disease. It improves bile flow and may displace toxic bile acids that accumulate in a cholestatic liver, stimulate bicarbonate secretion into the bile, offer a cytoprotective effect, and reduce elevated liver enzymes.[1,9]

Intestinal Obstruction Treatment of DIOS consists of enteral administration of polyethylene glycol (PEG) electrolyte solutions. Severe presentations may require surgical resection. Enemas may also be used to facilitate stool clearance. IV fluids are often required to correct dehydration due to vomiting or decreased oral intake. Reevaluation of enzyme adherence and dosing is essential to prevent recurrence, and some patients may require daily PEG administration (MiraLAX).[1,11]

▶ *CF-Related Diabetes*

Patients with mild CFRD may be managed with carbohydrate modification if nutritional status is optimal. However, most patients present with poor nutrition and weight loss and require more aggressive treatment. KEY CONCEPT Because CFRD results from insulin insufficiency, exogenous insulin replacement is usually required. Many patients can be successfully managed by meal coverage with short- or rapid-acting insulin (regular, lispro, or aspart) dosed per carbohydrate counting. Patients with fasting hyperglycemia or patients receiving nighttime tube feedings typically also require longer-acting basal insulin. Regular home glucose monitoring is essential to appropriate therapy. Oral antidiabetic agents have not been studied adequately in CFRD, and routine use is not recommended.[10]

▶ *Bone Disease and Arthritis*

CF patients with low bone mineral density and low serum vitamin D levels may improve bone health through supplemental vitamin D analogs beyond those found in standard CF vitamins. The CF Foundation recommends 25-hydroxyvitamin D levels of at least 30 ng/mL (75 nmol/L) for all patients. For cholecalciferol (or ergocalciferol), a minimum of 400 to 500 IU and 800 to 1000 IU should be taken daily by infants and patients 1 to 10 years of age, respectively. Patients older than 10 years should take 800 to 2000 IU daily. Vitamin D concentrations should be measured annually in the winter for evaluation of dosing.[14] Total weekly or biweekly doses of 12,000 IU for children younger than 5 years of age and 50,000 IU for patients 5 years of age and older may be required to achieve target vitamin D concentrations. Supplemental calcium should be provided if 1300 to 1500 mg of elemental calcium intake cannot be achieved through diet.[13]

Antiresorptive agents (oral or IV bisphosphonates) may be used to treat adult CF patients with osteoporosis. Remaining upright daily for 30 minutes after dosing may be difficult for patients needing to perform airway clearance therapy, so products offering less frequent dosing should be considered. Pamidronate 30 mg IV every 3 months or zoledronic acid 5 mg IV once yearly may be considered in adult CF patients.[7,13] Androgen replacement may benefit bone health in some male CF patients with documented hypogonadism.[7]

▶ *Precision Therapy*

Since the discovery of the CF gene and the CFTR protein defect, research has focused on gene mutation-specific pharmacologic therapy to correct or modulate dysfunctional CFTR protein. Ivacaftor (Kalydeco, VX-770) is a CFTR potentiator that activates defective CFTR at the cell surface and improves CFTR function in patients with gating mutations. Ivacaftor is indicated for treatment of CF patients 2 years and older who have at least

Patient Encounter Part 2

The parents received education about CF and met with the multidisciplinary CF team. Additional laboratory testing was sent to confirm the CF genotype. The team would like to initiate first-line CF therapies because the baby displays symptoms of pancreatic insufficiency (see Part 1). The neonate weighs 3.25 kg and is 54 cm long.

Given this information, what is your assessment of the infant's nutritional status?

What are the treatment goals for this patient?

What nonpharmacologic therapy should be initiated?

What pharmacologic therapy should be initiated?

one mutation in the *CFTR* gene that is responsive to ivacaftor potentiation based on clinical and/or in vitro assay data. Ivacaftor treatment (added to standard CF care) is associated with improved lung function (approximately 10% increase in FEV_1), decreased pulmonary exacerbations, weight gain, and increased quality of life.[19,35] Ivacaftor given alone is not effective for patients homozygous for *Phe508del*. Ivacaftor should not be recommended, prescribed, or dispensed without first verifying that the patient has an appropriate *CFTR* gene mutation that has been identified to be responsive to ivacaftor.

The ivacaftor dose is 150 mg orally every 12 hours with food containing at least 20 g of fat for patients age 6 years and older. Patients 2 to 5 years of age should receive 50 mg (< 14 kg) or 75 mg (> 14 kg) orally every 12 hours. Dosage must be reduced in moderate to severe hepatic impairment (Child-Pugh Class B or C) and when coadministered with moderate or strong CYP3A inhibitors (eg, azole antifungals, clarithromycin, erythromycin). Use with strong CYP3A inducers (eg, rifampin, rifabutin, phenytoin, phenobarbital, carbamazepine) is contraindicated. Ivacaftor therapy is generally well tolerated, although elevated liver enzymes have been reported; hepatic enzymes should be monitored quarterly in the first year of therapy.

LO 5

Another precision therapy contains a combination of lumacaftor and ivacaftor (Orkambi, VX-809/VX-770) to treat CF in patients 6 years and older who are homozygous for *Phe508del* and has been shown to reduce pulmonary exacerbations.[35] Lumacaftor stabilizes the CFTR protein so more reaches the cell surface, whereas ivacaftor potentiates ion transport. Lumacaftor/ivacaftor should not be recommended, prescribed, or dispensed without first verifying that the patient has two copies of the *Phe508del* gene mutation. Dosing is lumacaftor 400 mg/ivacaftor 250 mg orally every 12 hours for patients age 12 years and older, and lumacaftor 200 mg/ivacaftor 250 mg orally every 12 hours for patients 6 to 11 years of age. Dosage must be reduced in moderate to severe hepatic impairment (Child-Pugh Class B or C). Dose titration may be needed when imitated in patients already on strong CYP3A inhibitors, and use with strong CYP3A inducers is contraindicated. Lumacaftor is also a strong inducer of several CYP enzymes, and interactions with many medications may require dose adjustment or alternative therapy. Careful review of drug interactions is essential.

In February 2018, a third precision therapy consisting of tezacaftor and ivacaftor (Symdeko, VX-661/VX-770) was approved for CF patients 12 years and older who are homozygous for *Phe508del* or who have at least one gene responsive to therapy. Dosing is tezacaftor 100 mg/ivacaftor 150 mg in the morning and ivacaftor 150 mg in the evening. Dosage must be reduced in moderate to severe hepatic impairment (Child-Pugh Class B or C) and when coadministered with moderate or strong CYP3A inhibitors. Use with strong CYP3A inducers is contraindicated. Quarterly monitoring of hepatic enzymes is also recommended. Triple combination therapies are also currently being investigated.[35]

OUTCOME EVALUATION

Pulmonary Function

- Monitor for changes in pulmonary symptoms (cough, sputum production, respiratory rate, and oxygen saturation). Symptoms should improve with antibiotics and aggressive airway clearance therapy. PFTs should be markedly increased after 1 week and trend back to pre-exacerbation levels after 2 weeks of therapy. If improvement lags, 3 weeks of therapy may be needed.

Patient Encounter Part 3

The infant is now 11 months old (weight: 9 kg) and is brought to a routine CF clinic appointment. Her parents report that she has had a runny nose, cough productive of yellow sputum for the past week, and an intermittent fever of up to 101.3°F (38.5°C) at home. Also, the baby has had some post-tussive emesis, reduced oral intake, and has been sleeping more. Vital signs are as follows: BP 82/44 mm Hg, HR 130 beats/min, RR 44/min, 100.8°F (38.2°C), oxygen saturation 94% (0.94). Review of throat cultures since diagnosis reveals the following organisms:

- *S. aureus*: sensitive to nafcillin, trimethoprim–sulfamethoxazole, minocycline, linezolid, and vancomycin; resistant to clindamycin and erythromycin
- *P. aeruginosa*: sensitive to ceftazidime, cefepime, piperacillin/tazobactam, aztreonam, meropenem, ciprofloxacin, and tobramycin; resistant to levofloxacin, amikacin, and gentamicin
- *A. xylosoxidans*: sensitive to trimethoprim–sulfamethoxazole, minocycline, and piperacillin/tazobactam; resistant to ceftazidime, meropenem, and ciprofloxacin

The infant has no known drug allergies.

Based on the information available, design an antibiotic regimen for outpatient therapy of this first pulmonary exacerbation.

What antibiotic(s) and dose(s) would you recommend for inpatient therapy?

Develop a monitoring plan to assess antibiotic response.

- For IV antimicrobial therapy, obtain serum drug levels for aminoglycosides and/or vancomycin and perform pharmacokinetic analysis. Adjust the dose, if needed, according to the targets in Table 16–3. Obtain follow-up trough levels and serum creatinine at least weekly or more frequently if renal function is unstable.

Gastrointestinal Function

- Monitor short- and long-term nutritional status through evaluation of height, weight, and BMI. Ideally, parameters should be near the normals (50th percentile) for non-CF patients.
- Evaluate the patient's stool patterns. Steatorrhea indicates suboptimal enzyme replacement or noncompliance. Infants should have two to three well-formed stools daily, whereas older children and adults may have one or two stools daily.
- Monitor efficacy of vitamin supplementation through yearly serum vitamin levels. Obtain levels more frequently if treating a deficiency.

CF-Related Diabetes

- Monitor morning fasting and 2-hour postprandial blood glucose in patients with CFRD or those taking systemic corticosteroids. Follow A1C levels on an outpatient basis to assess long-term glucose control. Levels may be falsely low in CF due to a shorter red blood cell half-life.

Patient Care Process

Collect Information:

- Conduct a history of prescription, nonprescription, and alternative medications. Review drug allergies and intolerances, especially antibiotics.
- Review the medical history and physical assessment findings with a focus on frequency and quality of cough, sputum production, dyspnea, respiratory rate, oxygen saturations, temperature, and PFT trends. Review the patient's airway clearance methods and order of inhaled therapies.
- Speak with the patient and/or caregivers and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Evaluate for signs and symptoms of pulmonary exacerbation. If present, determine if antibiotics are indicated.
- Review culture and sensitivity tests over the last 1 to 2 years. Review pharmacokinetic history. What antibiotics were used previously? Was response better to a particular regimen?
- Review other available laboratory tests (renal and hepatic function, complete blood count, vitamin levels, IgE level, blood glucose, A1C, bone density). Identify presence of CF comorbidities (eg, diabetes, liver disease, bone disease).
- Determine nutritional status, weight, height, and BMI trends. Assess GI symptoms: quantity and quality of bowel movements, gastroesophageal reflux, bloating, flatulence, or abdominal pain. Are oral supplements or tube feedings being used?
- Evaluate medications for effectiveness, drug interactions, and adverse reactions. Are all appropriate maintenance medications prescribed and dosed appropriately for weight and age?
- Assess adherence, including timing of inhaled medications with respect to airway clearance therapies and timing of enzymes and insulin with regard to meals.

Develop a Care Plan:

- Devise an appropriate IV or oral/inhaled antibiotic regimen for a pulmonary exacerbation. Optimize doses based on pharmacokinetic and pharmacodynamic parameters.
- Optimize maintenance therapies, doses, and schedules that promote efficacy and ease care burden.

Implement the Care Plan:

- Educate the patient and family about any changes in drug therapy, medication administration requirements, and potential side effects. Emphasize importance of therapy adherence.
- Review the patient's practices and technique for self-administration or caregiver-administration of therapies.
- Determine if the patient has insurance coverage, if there are any specialty pharmacy medication access restrictions, and if recommended agents are included on the institution's formulary. Determine if the patient qualifies for any patient assistance programs.

Follow-up: Monitor and Evaluate:

- For antibiotic regimens, evaluate pulmonary symptoms daily if inpatient or every 1 to 2 weeks if outpatient.
- For IV antibiotic regimens, obtain drug levels and perform pharmacokinetic dose adjustments as necessary. Monitor renal function at least weekly. Evaluate fluid intake and urine output daily.
- Review physical examination, lab tests, and results of other diagnostic tests to assess changes in clinical status. Assess effectiveness and safety of maintenance therapies at least quarterly.
- Assess medication adherence and access at least quarterly.

Abbreviations Introduced in This Chapter

ABPA	Allergic bronchopulmonary aspergillosis
CF	Cystic fibrosis
CFRD	Cystic fibrosis-related diabetes
CFTR	Cystic fibrosis transmembrane regulator
CPT	Chest physiotherapy
DIOS	Distal intestinal obstruction syndrome
FEV_1	Forced expiratory volume in 1 second
FVC	Forced vital capacity
HFCC	High-frequency chest compression
IPV	Intrapulmonary percussive ventilation
MIC	Minimum inhibitory concentration
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-sensitive *Staphylococcus aureus*
OPEP	Oscillating positive expiratory pressure
PEG	Polyethylene glycol
PFT	Pulmonary function test
PMN	Polymorphonuclear
PT	Prothrombin time
RDA	Recommended daily allowance

17 Gastroesophageal Reflux Disease

Jeremy J. Prunty and Leesa M. Prunty

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying causes of gastroesophageal reflux disease (GERD).
2. Understand the difference between typical, atypical, and alarm symptoms.
3. Determine when diagnostic tests should be recommended based on the clinical presentation.
4. Identify the desired therapeutic outcomes for patients with GERD.
5. Recommend appropriate nonpharmacologic and pharmacologic interventions for patients with GERD.
6. Educate patients on appropriate lifestyle modifications and drug therapy issues including adherence, adverse effects, and drug interactions.
7. Formulate a monitoring plan to assess the effectiveness and safety of pharmacotherapy for GERD.

INTRODUCTION

Gastroesophageal reflux is the retrograde, effortless movement of stomach contents into the esophagus. When troublesome symptoms or mucosal damage occurs as a result of this process, this is defined as gastroesophageal reflux disease (GERD).[1,2] Treatment is usually initiated based on symptom presentation rather than laboratory tests or invasive monitoring and consists of various lifestyle interventions and pharmacotherapy. Lack of response to empiric therapies may require further evaluation to identify potential underlying complicating conditions.[1,3]

EPIDEMIOLOGY AND ETIOLOGY

GERD is one of the most common gastrointestinal conditions. Up to 40% of Americans report intermittent GERD symptoms, with 10% to 20% of the US population reporting at least weekly symptoms.[1] GERD symptoms can result in morbidity and decreased work productivity. The incidence of **erosive esophagitis** and **Barrett esophagus** increases with age, especially in Caucasian men over 50 years of age with symptoms for more than 10 years.[3,4]

The precise etiology of GERD is difficult to determine in most patients. Increased intraabdominal pressure or decreased **lower esophageal sphincter (LES)** tone may allow gastric refluxate to enter the esophagus causing GERD symptoms in some patients. These processes can be transient and are often due to physical activity, food, or medications.

PATHOPHYSIOLOGY

LO 1

Retrograde movement of gastric contents into the esophagus, oral cavity, or lungs is the origin of symptoms or complications that define GERD. Reflux is normally prevented through muscle tone of the LES. Reduction in LES function or tone may allow reflux of gastric contents into the esophagus. Other physiologic and mucosal defense mechanisms may also become compromised and affect the refluxate composition and development of GERD. Such mechanisms include slowed esophageal clearance, decreased salivary buffering, impaired mucosal resistance, delayed gastric emptying, and increased intraabdominal pressure.

Lower Esophageal Sphincter Pressure

In the normal state, the LES maintains a tonic pressure that separates gastric contents from the esophagus, relaxing during swallowing to allow esophageal contents to pass into the stomach. Decreased LES pressure can occur via spontaneous relaxation, increased intraabdominal pressure, and an atonic LES. Spontaneous relaxation of the LES occurs during vomiting, belching, retching, and esophageal distention. Transient increases in intraabdominal pressure may occur during straining, exercise, bending over, or **Valsalva maneuver**. An atonic LES allows unopposed passage of refluxate from stomach into the esophagus. A **hiatal hernia** may cause or worsen GERD symptoms by increasing intragastric pressure and decreasing LES tone. Some foods and medications may worsen LES dysfunction, whereas others can directly irritate the esophageal mucosa (**Table 17–1**).

Esophageal and Mucosal Protection

Several normal processes protect the esophageal tissue and mucosal barrier from irritants such as refluxed gastric fluid. Swallowing enhances esophageal clearance by increasing salivary flow, which contains bicarbonate that buffers the acidic gastric contents. This usually maintains a neutral esophageal pH; however, salivary production decreases during sleep and in older persons, which may contribute to GERD symptoms. Mucus-secreting glands in the esophageal mucosa and submucosa also help neutralize acidic refluxate by releasing bicarbonate. Most patients with GERD do not produce abnormally large amounts

Table 17–1

Foods and Medications That May Worsen GERD Symptoms

Decreased LES Pressure	
Foods	
Fatty meal/fried foods	Coffee, caffeinated drinks
Carminatives (eg, peppermint)	Garlic
Chocolate	Onions
	Chili peppers
Medications	
Anticholinergics	Ethanol
Barbiturates	Isoproterenol
Benzodiazepines	Nicotine
Caffeine	Nitrates
Dihydropyridine calcium channel blockers	Opioids (eg, morphine)
	Phentolamine
Dopamine	Progesterone
Estrogen	Theophylline
Direct Irritants to the Esophageal Mucosa	
Foods	
Carbonated beverages	Orange juice
Citrus fruits	Spicy foods
Coffee	Tomatoes
Medications	
Aspirin	Iron
Bisphosphonates	NSAIDs
Dabigatran	Quinidine
Doxycycline	Potassium chloride

GERD, gastroesophageal reflux disease; LES, lower esophageal sphincter; NSAIDs, nonsteroidal anti-inflammatory drugs.

Adapted from May DB, Thiman M, Rao S. Gastroesophageal reflux disease. In: DiPiro JT, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill, 2017:437, with permission.

of acid, but slowed esophageal clearance of gastric contents increases contact time of refluxate with esophageal mucosa, possibly leading to symptoms or erosion. Refluxate contains gastric acid, pepsin, bile acids, and pancreatic enzymes that promote mucosal erosion and GERD symptoms.

Gastric Emptying and Increased Abdominal Pressure

Gastric fluid volume depends on the rate of gastric acid secretion, stomach emptying time, and the amount of gastric fluid that refluxes from the duodenum into the stomach. Prolonged stomach emptying time increases the volume of fluid in the stomach, thereby increasing intragastric pressure. Increased gastric volume can increase the amount and frequency of fluid being refluxed, which may cause or worsen GERD symptoms. Factors that increase gastric volume and/or decrease gastric emptying, such as smoking and high-fat meals, are often associated with reflux.

Obesity is a risk factor for developing GERD symptoms and complications. Obesity has been linked to GERD due to increased abdominal pressure. Even weight gain in patients with a normal body mass index may cause new-onset GERD symptoms.[3] Morbidly obese patients may also have more transient LES relaxations, incompetent LES function, and impaired esophageal motility.[5]

Patient Encounter 1, Part 1

A 53-year-old African-American man complains of constant heartburn and regurgitation. He reports no recent weight loss or dyspepsia. He has been self-medicating with over-the-counter calcium carbonate tablets for the last month with no improvement. His weight is 200 kg and his height is 5'11" (180 cm). He has no known drug allergies.

Are this patient's symptoms consistent with GERD?

Would the patient's symptoms be described as typical, atypical, or alarm?

What risk factors does he have that may worsen GERD symptoms?

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

KEY CONCEPT Patients with GERD may have symptoms classified as: (a) typical, (b) atypical, or (c) alarm (see accompanying box Clinical Presentation of GERD).[3]

Diagnosis of GERD

LO 3

Diagnosis of GERD is assumed with typical patient symptoms and a positive response to a trial of acid-suppressing therapy. Diagnostic testing should be reserved for patients with atypical or alarm symptoms. **Endoscopy** is preferred for assessing mucosal injury and to identify complications such as **esophageal strictures** (which can cause difficulty swallowing) and erosive esophagitis due to repeated and prolonged exposure to gastric refluxate. A mucosal biopsy should be taken to identify Barrett esophagus, which is associated with an increased risk of developing esophageal cancer. Endoscopy may also be performed in patients not responding to an adequate trial of a twice-daily proton pump inhibitor (PPI).[1,3] **Ambulatory esophageal reflux monitoring** identifies excessive esophageal acid exposure and the frequency of reflux episodes. **Esophageal manometry** may be beneficial for patients who have failed twice-daily PPIs and have

Clinical Presentation of GERD

Symptoms

- *Typical symptoms* (may be aggravated by activities that worsen gastroesophageal reflux such as recumbent position, bending over, or eating a high-fat meal): Heartburn, often described as a substernal sensation of warmth or burning rising up from the abdomen that may radiate to the neck and may be waxing and waning in character; hypersalivation; regurgitation; belching
- *Atypical symptoms* (associated with GERD, but causality should only be considered if typical symptoms are also present): Chronic cough, laryngitis, hoarseness, wheezing, noncardiac chest pain, asthma (~50% with asthma have GERD)
- *Alarm symptoms* (may indicate GERD complications such as Barrett esophagus, esophageal strictures, or esophageal adenocarcinoma and require further diagnostic evaluation): Dysphagia, odynophagia, weight loss, bleeding

normal endoscopic findings or those contemplating antireflux surgery. These tests help to determine whether symptoms are acid related and may also be useful in patients not responding to acid suppression therapy or prior to antireflux surgery.

GERD and **dyspepsia** (often occurring with peptic ulcer disease) commonly overlap in presentation. Dyspepsia is characterized predominantly by epigastric pain but can also be associated with other upper GI symptoms including heartburn.[6] Care should be taken when evaluating patient symptom history to differentiate GERD from dyspepsia due to differing treatment strategies. Patients reporting epigastric pain for at least 1 month should be evaluated for dyspepsia. Although *Helicobacter pylori*-positive patients frequently present with gastritis, symptomatic reflux does not correlate well with an active *H. pylori* infection. Routine screening for *H. pylori* in patients with GERD is controversial and not currently recommended.[3,7,8]

TREATMENT

Desired Outcomes

LO 4

KEY CONCEPT The goals of GERD treatment are to alleviate symptoms, decrease the frequency of recurrent disease, promote healing of mucosal injury, and prevent complications.

General Approach to Treatment

KEY CONCEPT Treatment for GERD involves one or more of the following modalities: (a) patient-specific lifestyle changes, (b) pharmacologic intervention primarily with acid-suppressing therapy, or (c) antireflux surgery (Table 17–2).[3,9] The best initial therapeutic option depends on the frequency and severity of symptoms, degree of esophagitis, and presence of complications (Figure 17–1).[1,3,10]

Nonpharmacologic Therapy

▶ *Lifestyle Modifications*

Although most patients do not respond to lifestyle changes alone, it is helpful to maintain these changes throughout therapy to potentially reduce the need for long-term pharmacologic therapies. The most beneficial lifestyle changes include: (a) losing weight if overweight or obese, and (b) elevating the head of the bed with a foam wedge if symptoms are worse when recumbent. Elevating the head of the bed decreases the contact time of gastric acid with the esophageal mucosa at night. A reduction in body mass index in obese patients, particularly those who reduce waist circumference, may improve GERD symptoms.[11]

Table 17–2

Therapeutic Approach to GERD in Adults

Recommended Regimen	Brand Name	Oral Dose	Comments
INTERMITTENT, MILD HEARTBURN (individualized lifestyle modifications + patient-directed therapy with antacids and/or nonprescription H_2RA *or* PPI)			
Individualized lifestyle modifications			Lifestyle modifications should be individualized for each patient
Patient-directed therapy with antacids (≥ 12 years old)			
Magnesium hydroxide/aluminum hydroxide with simethicone	Maalox®	10–20 mL as needed or after meals and at bedtime	If symptoms are unrelieved with lifestyle modifications and nonprescription medications after 2 weeks, patient should seek medical attention; do not exceed 16 teaspoonfuls per 24 hours
Antacid/alginic acid	Gaviscon®	2–4 tablets or 10–20 mL after meals and at bedtime	Note: Content of alginic acid varies greatly among products; the higher the alginic acid, the better
Calcium carbonate	Tums®	500 mg, 2–4 tablets as needed	
Patient-directed therapy with nonprescription H_2RA (up to twice daily) (≥ 12 years old)			
Cimetidine	Tagamet HB®	200 mg	If symptoms are unrelieved with lifestyle modifications and nonprescription H_2RA after 2 weeks, patient should seek medical attention
Famotidine	Pepcid AC®	10–20 mg	
Nizatidine	Axid AR®	75 mg	
Ranitidine	Zantac®	75–150 mg	
Patient-directed therapy (> 18 years old) with nonprescription PPI (taken once daily)			
Esomeprazole	Nexium® 24HR	20 mg	If symptoms are unrelieved with lifestyle modifications and nonprescription PPI after 2 weeks, patient should seek medical attention
Lansoprazole	Prevacid® 24HR	15 mg	
Omeprazole	Prilosec OTC®	20 mg	
Omeprazole/sodium bicarbonate	Zegerid OTC®	20 mg/1100 mg	

(*Continued*)

Table 17–2

Therapeutic Approach to GERD in Adults (*Continued*)

Recommended Regimen	Brand Name	Oral Dose	Comments
SYMPTOMATIC RELIEF OF GERD (individualized lifestyle modifications + prescription-strength H_2RA *or* PPI)			
Individualized lifestyle modifications			Lifestyle modifications should be individualized for each patient
Prescription-strength H_2RA (for 6–12 weeks)			
Cimetidine (off-label use)	Tagamet®	400 mg four times daily or 800 mg twice daily	• For typical symptoms, treat empirically with prescription-strength acid suppression therapy • If symptoms recur, consider maintenance therapy. Note: Most patients require standard doses for maintenance therapy
Famotidine	Pepcid®	20 mg twice daily	
Nizatidine	Axid®	150 mg twice daily	
Ranitidine	Zantac®	150 mg twice daily	
Prescription-strength PPI (for 4–8 weeks)			
Dexlansoprazole	Dexilant®	30 mg once daily for 4 weeks	• For typical symptoms, treat empirically with prescription-strength acid suppression therapy • Patients with moderate to severe symptoms should receive a PPI as initial therapy • If symptoms recur, consider maintenance therapy
Esomeprazole	Nexium®	20–40 mg once daily	
Lansoprazole	Prevacid®	15 mg once daily	
Omeprazole	Prilosec®	20 mg once daily	
Omeprazole/sodium bicarbonate	Zegerid®	20 mg once daily	
Pantoprazole (Off-label use)	Protonix®	40 mg once daily	
Rabeprazole	Aciphex®	20 mg once daily	
HEALING OF EROSIVE ESOPHAGITIS OR TREATMENT OF MODERATE TO SEVERE SYMPTOMS OR COMPLICATIONS (individualized lifestyle modifications + high-dose H_2RA *or* PPI *or* antireflux surgery)			
Individualized lifestyle modifications			Lifestyle modifications should be individualized for each patient.
PPI (up to twice daily for up to 8 weeks)			
Dexlansoprazole	Dexilant®	60 mg daily	• For atypical or alarm symptoms, obtain endoscopy with biopsy to evaluate mucosa • If symptoms are relieved, consider maintenance therapy. PPIs are the most effective maintenance therapy for patients with atypical symptoms, complications, and erosive disease. Start with twice-daily PPI therapy if reflux chest syndrome present • Patients not responding to pharmacologic therapy should be evaluated via manometry and/or ambulatory reflux monitoring • Twice daily dosing of PPIs is considered off-label use
Esomeprazole	Nexium®	20–40 mg daily	
Lansoprazole	Prevacid®	30 mg once or twice daily	
Omeprazole	Prilosec®	20 mg once or twice daily	
Rabeprazole	Aciphex®	20 mg once or twice daily	
Pantoprazole	Protonix®	40 mg once or twice daily	
High-dose H_2RA (for 8–12 weeks)			
Cimetidine	Tagamet®	400 mg four times daily or 800 mg twice daily	Note: If high-dose H_2RA needed, may consider using PPI to lower cost, increase convenience, and increase tolerability Note: Four times daily use is considered off-label for nizatidine
Famotidine	Pepcid®	20–40 mg twice daily	
Nizatidine	Aciphex®	150 mg two–four times daily	
Ranitidine	Zantac®	150 mg four times daily	
Interventional therapy			
Antireflux surgery			

GERD, gastroesophageal reflux disease; H_2RA, histamine-2 receptor antagonist; PPI, proton pump inhibitor.

From May DB, Thiman M, Rao S. Gastroesophageal reflux disease. In: DiPiro JT, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill, 2017:442–443, with permission.

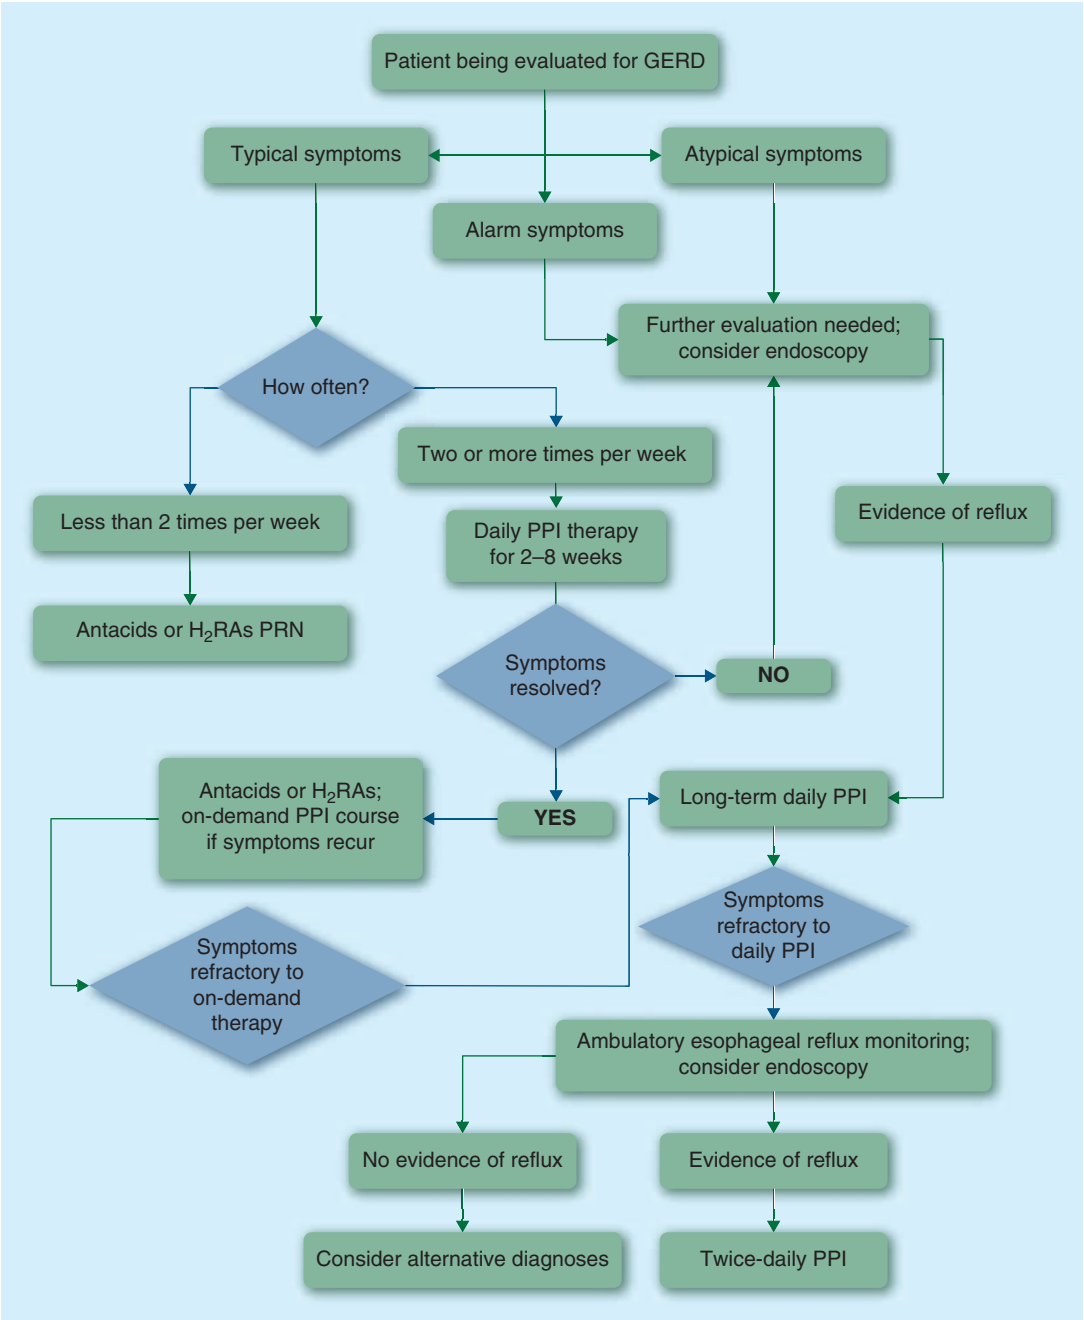

FIGURE 17–1. GERD treatment algorithm for adults. (GERD, gastroesophageal reflux disease; H_2RA, histamine-2 receptor antagonist; PPI, proton pump inhibitor, PRN, as needed.)

Other lifestyle modifications should be considered based on patient circumstances. These might include: (a) eating smaller meals and avoiding meals 3 hours before sleeping, (b) avoiding foods or medications that exacerbate GERD, (c) smoking cessation, and (d) avoiding alcohol. The patient's medication and food histories should be evaluated to identify potential factors that may exacerbate GERD symptoms (Table 17–1).

▶ *Surgical Treatment*

Antireflux surgical options may be considered when pharmacologic management is undesirable due to side effects or adherence challenges in patients with well-documented GERD.[7] Fundoplication increases LES pressures by wrapping the fundus of the stomach around the distal esophagus; the wrap may include the total esophageal circumference (Nissen fundoplication), only the posterior circumference (Toupet), or only the anterior circumference (Dor). The LINX procedure consists of placing a band of interlinked titanium beads with magnetic cords around the LES to aid in maintaining LES pressure. LES stimulators are surgically inserted to modulate LES pressures and reduce refluxate from the stomach.[12]

The goal of surgery is to reestablish the antireflux barrier, position the LES within the abdomen where it is under positive (intraabdominal) pressure, and close any associated hiatal defect. Antireflux surgery provided more symptom control than omeprazole in patients with esophagitis in a 7-year follow-up study.[13]

The evidence for surgery is not as strong in patients who do not respond to PPI therapy.[3,7] Roux-en-Y gastric bypass has been shown to reduce symptoms of GERD in obese patients; however, not all forms of bariatric surgery, such as vertical banded gastroplasty, have been shown to improve GERD symptoms.[3,14]

Surgical options may be considered at any time during therapy; however, surgery is not recommended for patients who respond to adequate PPI therapy. Surgical therapies have significant inherent risks including risk of mortality; therefore, surgery may be an appropriate option if a patient has a strong desire to discontinue medication therapy, the presence of a large hiatal hernia, or refractory GERD symptoms.[3]

Pharmacologic Therapy

Pharmacologic therapy for GERD involves increasing the pH of gastric contents through either direct gastric acid neutralization or reducing acid production through inhibition of stimulation pathways, thereby reducing GERD symptoms and tissue damage. Pharmacologic options can be stratified by effectiveness: antacids are inferior to histamine-2 receptor antagonists (H_2RAs) due to brief neutralization of gastric acid and lack of acid-suppressive properties. H_2RAs decrease acid secretion to a lesser extent than PPIs because PPIs block the rate-limiting step in acid secretion from gastric parietal cells, thereby blocking all pathways for gastric acid secretion.[3]

▶ *Antacids*

Antacids are useful for intermittent treatment of GERD symptoms and can be used for patients with infrequent typical reflux symptoms. They are effective for immediate, symptomatic relief but require frequent dosing (Table 17–2). Aluminum or magnesium-containing antacids may result in electrolyte abnormalities, particularly in patients with renal impairment. Antacids are usually well tolerated, but potential side effects include constipation or diarrhea depending on the formulation being used. Antacids may also chelate with medications such as fluoroquinolones, tetracyclines, iron products, and thyroid hormones; therefore, doses should be separated by several hours to avoid decreased efficacy.

▶ *Histamine-2 Receptor Antagonists*

The H_2RAs (cimetidine, famotidine, nizatidine, ranitidine) decrease acid secretion by blocking histamine$_2$-receptors in gastric parietal cells. H_2RAs provide relief from typical acute GERD symptoms and can also be administered prophylactically. H_2RAs are more effective than antacids at controlling chronic GERD symptoms but less effective than PPIs. H_2RAs may be dosed intermittently or on a scheduled basis depending on the degree of symptom control (Table 17–2). LO 5

H_2RAs are generally well tolerated; side effects are mild and most commonly include headache and nausea. Cimetidine is a weak inhibitor of the cytochrome P-450 system with many common drug interactions; other H_2RAs have limited drug interactions. Cimetidine also has unique adverse effects such as gynecomastia and vitamin B_{12} deficiency, which limits patient tolerance in chronic therapy.[15] Most H_2RAs are renally eliminated and may require dose adjustment in kidney dysfunction.

▶ *Proton Pump Inhibitors*

KEY CONCEPT PPIs (eg, omeprazole, lansoprazole) block gastric acid secretion by inhibiting gastric H^+/K^+-adenosine triphosphatase in gastric parietal cells, producing a profound, long-lasting antisecretory effect capable of maintaining the gastric pH above 4, even during acid surges occurring postprandially. LO 5 Primary uses of PPIs are treating frequent reflux symptoms and healing of gastric or esophageal ulcerations. KEY CONCEPT PPIs provide significant reduction in gastric acid and the greatest relief of symptoms, especially in patients with moderate to severe GERD, with high rates of healing erosive disease. PPIs are available as both prescription and nonprescription products with various formulations available (Table 17–2).

Because PPIs degrade in acidic environments, they are typically formulated in delayed-release capsules or tablets. For patients unable to swallow intact capsules (including children) or those with nasogastric tubes, the capsule contents can be mixed in applesauce or orange juice.[16] The acidic juices help maintain the integrity of the enteric-coated pellets until they reach the small intestine.[16] Esomeprazole pellets can be mixed with water prior to delivery through a nasogastric tube.[16]

Most patients should be instructed to take their PPI in the morning, 30 to 60 minutes before breakfast to maximize efficacy, because these agents inhibit only actively secreting proton pumps. Due to their slow onset of action, PPIs are most effective when taken on a scheduled basis. Patients with nighttime symptoms may benefit from taking the PPI prior to the evening meal. If a second daily dose is needed, it should be taken before the evening meal and not at bedtime. Dexlansoprazole and the combination product omeprazole–sodium bicarbonate may be taken without regard to food.[9] All PPIs can decrease the absorption of medications that require an acidic environment to be absorbed (eg, dabigatran, encapsulated itraconazole, dipyridamole) and are all metabolized by the cytochrome P-450 system to some extent.[17,18]

LO 6 PPIs are generally well tolerated; the most common side effects are headache and GI effects such as diarrhea and nausea. Several concerns have been raised about consequences of long-term PPI use. Renal complications (acute kidney injury and chronic kidney disease), bone fractures, and dementia have been reported from retrospective observational studies and case reports; however, prospective data are limited and additional study is needed to determine causality.[19] LO 6 Reduced absorption of micronutrients such as calcium, magnesium, and vitamin B_{12} with long-term use has also been reported in observational studies.[10] However, routine screening and supplementation of these vitamins and minerals based solely on chronic PPI use is not warranted.[3,7,10] In patients with documented hypocalcemia, it is reasonable to replete calcium with the citrate rather than the carbonate salt due to improved absorption in a less acidic environment.[20]

LO 6 Concerns for drug interactions with clopidogrel and PPIs that inhibit CYP 2C19 were initially raised by pharmacodynamic studies showing possible attenuation of clopidogel's antiplatelet function. Clopidogrel is a prodrug requiring a two-step activation via CYP2C19, which may be competitively depleted due to metabolism of PPIs via the same enzyme.[21,22] However, the 2010 COGENT study found no meaningful interaction or increase in the incidence of myocardial infarction in patients who used omeprazole with aspirin and clopidogrel.[23] Although the COGENT study had limitations, the interaction between clopidogrel and PPIs is not considered to be clinically significant, and use of PPIs may decrease GI-related events such as upper GI bleed when used with dual antiplatelet agents. Use of a PPI with clopidogrel should be considered based on the individual patient's cardiovascular and bleeding risk. If patients or providers wish to avoid the combination, alternatives include switching to a P2Y12 inhibitor not activated by CYP2C19, switching to a PPI with less CYP2C19 metabolism (omeprazole is most affected), or substituting an H_2RA for a PPI.[24]

Infectious complications attributed to chronic PPI use include spontaneous bacterial peritonitis, small intestinal bacterial overgrowth, *Clostridium difficile* infection, and pneumonia.[25] Studies have been mostly small observational trials attributing a low to moderate overall increased infection risk with PPI treatment. PPIs have been postulated to increase the risk of gastrointestinal malignancies by facilitating *H. Pylori* proliferation and by causing hypergastrinemia as a result of profound gastric acid suppression. Although no clinical studies have found an association with PPIs and increased cancer risk, hypergastrinemia does have a trophic effect in colonic cells in mice and in vitro human colorectal cancers.[19,26] Further monitoring of this possible complication will be necessary due to the slow growth of some colonic tumors.[19] The potential risks of chronic PPI use must be evaluated on an individual basis, and judicious use should guide clinical decisions.

▶ *Prokinetic Agents*

Metoclopramide, a central dopamine antagonist, accelerates gastric emptying and can increase LES pressure. Metoclopramide has been studied for GERD symptom relief in conjunction with a PPI; however, potential side effects can be significant and include extrapyramidal effects and tardive dyskinesia.[3] Domperidone is a peripherally acting dopamine antagonist that does not have central nervous system toxicities; however, it is not approved for use in the United States and requires monitoring for QT prolongation. In patients without gastroparesis, there is no clear role for the use of prokinetic agents for treatment of GERD.[3]

▶ *Alternative Pharmacologic Agents*

Baclofen, a gamma-aminobutyric acid (GABA) agonist, has been shown to provide some benefit in reducing GERD symptoms by increasing gastric pH. Due to limited efficacy data and potential side effects including dizziness, somnolence, and constipation, baclofen is not recommended for treatment of GERD without diagnostic evaluation.[3]

Sucralfate, a nonabsorbable aluminum salt of sucrose octasulfate, has limited value in the treatment of GERD. Sucralfate is suboptimal compared with PPI therapy and has no role in nonpregnant patients with GERD.[3]

Initial Therapy of GERD

LO 7

On presentation to a health care provider, patients may have already attempted an over-the-counter (OTC) trial of self-directed therapy with all three of the major pharmacologic agents. After confirmation of the diagnosis of GERD, a trial of a scheduled PPI for 8 weeks is typically recommended, monitoring for symptomatic improvement. Most patients with nonerosive GERD respond positively to a PPI trial and therefore should be evaluated for an appropriate long-term maintenance therapy. Adherence and appropriate administration should be monitored throughout therapy. For patients with refractory nocturnal symptoms or symptoms not controlled with daily therapy, a trial of twice daily PPIs may provide benefit.[10]

Patients with erosive esophagitis on endoscopy should be treated with at least 8 weeks of twice-daily PPI therapy. PPIs are superior to H_2RAs for healing erosive lesions.[3] Maintenance therapy in these patients should be individualized after the initial treatment period; if PPIs are continued, they should be used at the lowest effective dose and schedule.[3]

Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Dyslipidemia, hypertension, and depression

FH: Mother had breast cancer, father has hypertension and depression

SH: Recently went on disability; lives at home with wife and teenage daughter. Smokes 2½ packs of cigarettes per day and drinks 1–2 large caffeinated energy drinks daily. Reports drinking about 6 alcoholic beverages per week

Meds: Hydrochlorothiazide 12.5 mg once daily, amlodipine 10 mg once daily, atorvastatin 20 mg at bedtime, citalopram 10 mg once daily

ROS: (+) Heartburn, regurgitation; (–) chest pain, nausea, vomiting, diarrhea, weight loss, change in appetite, shortness of breath or cough

PE:

VS: BP 125/72 mm Hg, P 82 beats/min, RR 16 breaths/min, T 37°C (98.6°F)

CV: RRR, normal S_1, S_2; no murmurs, rubs, or gallops

Abd: Soft, nontender, nondistended; (+) bowel sounds, (–) hepatosplenomegaly, heme (–) stool

Given this additional information, what factors could be contributing to the patient's GERD symptoms?

Does this patient require further diagnostic evaluation based on his clinical presentation? If so, which procedure would you recommend?

What nonpharmacologic and pharmacologic changes would you recommend for his GERD therapy?

Maintenance GERD Therapy

KEY CONCEPT Maintenance therapy may be necessary in patients with refractory symptoms while on maximal acid suppression (Table 17–2).[3,7,10] KEY CONCEPT Adding an H_2RA to a PPI regimen may provide initial benefit for refractory symptoms but may result in tachyphylaxis with continued use. While maintenance daily PPI therapy may be necessary in some patients, on-demand PPI dosing may also be effective. On-demand therapy consists of stopping PPI therapy upon resolution of GERD symptoms, with reinitiation of therapy for 2 to 4 weeks if symptoms occur two or more times within 7 days while off therapy.[10] In a large prospective study of GERD patients (most of whom had erosive esophagitis) who used on-demand therapy, 70% had 0 or 1 relapse and only 30% changed to chronic daily PPI therapy after almost one year of follow-up.[27] Other studies found that on-demand therapy can decrease PPI exposure by 60% to 80%, with more than 80% of patients being willing to continue the dosing strategy when given the option.[28]

KEY CONCEPT Patients who wish to stop long-term PPI therapy should be slowly titrated off using a stepwise or prolonged taper due to the potential for rebound gastric acid hypersecretion with sudden withdrawal. Rebound hypersecretion can occur with continual PPI use for at least 2 months. For these reasons, the PPI dose and frequency should be tapered slowly, using H_2RAs for breakthrough symptoms. The duration of the taper must be individualized; rebound hypersecretion symptoms can last 3 months or longer after PPI discontinuation.[29]

Special Populations

▶ *Children with GERD*

Generally, reflux is a common physiologic process in children that occurs several times per day with no clinical consequence; however, as with adults, GERD is present when symptoms become troublesome or if complications are present.[30,31] Regurgitation is common in children and may occur daily in as many as 50% of infants younger than 3 months.[30] Most babies who "spit up" are "happy spitters"; they are comfortable, gaining weight, and have no breathing problems caused by vomiting. More troublesome symptoms may include vomiting, apnea, poor weight gain, sleep disturbances, and refusing to eat.[31]

Reflux episodes are common during transient LES relaxations not related to swallowing because of developmental immaturity of the LES.[30] Other causes include impaired luminal clearance of gastric acid and infant diet. Formula-fed infants are more likely than breastfed infants to exhibit GERD symptoms.[32] Children with neurologic impairment and impaired swallowing, obesity, repaired congenital abnormalities of the esophagus, cystic fibrosis, or hiatal hernia are at a higher risk for developing GERD.[30]

Lifestyle modifications are emphasized in pediatric patients with uncomplicated GERD. Symptoms usually resolve by 12 to 18 months of life and respond to supportive therapy, including dietary adjustments such as smaller meals, more frequent feedings, switching to an extensively hydrolyzed protein or amino acid-based formula, or thickening infant formula with rice cereal. However, excessive thickening of infant formula is discouraged, particularly in preterm infants due to concerns of increased risk for necrotizing enterocolitis.[31] Postural management (ie, positioning the infant in an upright position, especially after meals) may be helpful. Changes in maternal diet such as restricting eggs and milk may be useful in breast-fed infants with GERD symptoms because milk protein allergy in infants can mimic the presentation of GERD.[31]

If lifestyle modifications are not effective, medical therapy may be indicated. Acid suppression with either an H_2RA or PPI is the mainstay of pharmacologic therapy for pediatric GERD.[30] Chronic use of antacids or routine use of prokinetics or sucralfate is not recommended. Monotherapy with an H_2RA is commonly used; however, chronic use may lead to tachyphylaxis, as with adults.

Increased use of PPIs in children has led to concerns because long-term safety is unknown. Therefore, clinicians must carefully weigh potential risks versus benefits along with appropriate indications for therapy and duration of treatment.[30]

▶ *GERD During Pregnancy*

GERD is common during pregnancy, and 30% to 50% of pregnant women report heartburn symptoms. Lifestyle modifications such as eating smaller meals can reduce heartburn and regurgitation. Mild to moderate GERD symptoms can be treated with antacids that have limited systemic absorption, such as calcium carbonate. Pregnant patients with severe, frequent heartburn can be started on a PPI. A large retrospective cohort of over 5000 patients found no increase in the number of birth defects in infants exposed to PPIs in utero.[33]

OUTCOME EVALUATION

- Monitor for symptom relief and the presence of symptoms.
- Record the frequency and severity of symptoms by interviewing the patient after 4 to 8 weeks of acid-suppressing

Patient Care Process

Collect Information:

- Perform a medication history to determine use of prescription, nonprescription, and dietary supplements.
- Identify patient allergies and intolerances that may affect current or planned pharmacotherapy.
- Review the patient's medical and surgical history for issues that may be related to GERD.

Assess the Information:

- Determine whether the patient is taking medications or eating foods that may worsen GERD symptoms (Table 17–1).
- Document severity, characteristics, and frequency of GERD symptoms (eg, typical or alarm symptoms).
- Assess the efficacy, safety, and patient adherence of current therapies and identify any significant adverse effects or interactions.

Develop a Care Plan:

- Implement lifestyle modifications that the patient is willing to do in order to reduce GERD symptoms.
- Decide if self-treatment is an option or if the patient should be referred to a physician.
- Choose medications and doses that are appropriate considering symptoms, drug or food interactions, and the patient's ability to obtain the chosen therapies that will likely improve quality of life.

Implement the Care Plan:

- Educate the patient about the chosen drug therapy including medication administration, potential adverse effects, and follow-up parameters.
- Educate the patient about symptoms that suggest the presence of complications requiring immediate medical attention, such as dysphagia or odynophagia.
- Discuss the importance of weight loss and dietary changes (if appropriate) for reducing GERD symptoms.
- Address any patient concerns about the GERD management plan.

Follow-up: Monitor and Evaluate:

- Instruct the patient on the proper time for reassessment if symptoms have not resolved.
- Review medication adherence and timing of doses.
- Monitor for adverse drug effects and determine a plan if symptoms recur.
- Refer patients with atypical or alarm symptoms to their physician for further diagnostic evaluation.
- Determine if long-term maintenance therapy is necessary after completion of the initial course of therapy.

Patient Encounter 2

A 63-year-old, 110-kg woman with a history of hypertension, diabetes, glaucoma, and GERD presents for her annual appointment after 2 years of daily PPI therapy, with symptoms well controlled. She reports concern about her PPI therapy after reading a news article about adverse health risks of long-term PPI use.

What is your response to the patient's concerns about risks of long-term PPI therapy?

What alternative treatment options are available for the patient?

Create a pharmacotherapy plan for this patient.

What counseling points should be discussed with the patient regarding the regimen change?

How would you monitor for effectiveness of the treatment plan?

therapy. Continued symptoms may indicate the need for long-term maintenance therapy.

- KEY CONCEPT Review the patient profile for drugs that may aggravate GERD.
- Monitor for adverse drug reactions, drug–drug interactions, and adherence.
- Reassess the need for continued PPI therapy at the completion of the recommended treatment regimen (Table 17–2).

Abbreviations Introduced in This Chapter

GABA	Gamma-aminobutyric acid
GERD	Gastroesophageal reflux disease
H$_2$RA	Histamine-2 receptor antagonist
LES	Lower esophageal sphincter
PPI	Proton pump inhibitor

18 Peptic Ulcer Disease

Catherine Bourg Rebitch and
Michael L. Thiman

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Recognize differences between ulcers induced by *Helicobacter pylori*, nonsteroidal anti-inflammatory drugs (NSAIDs), and stress-related mucosal damage (SRMD) in terms of risk factors, pathogenesis, signs and symptoms, clinical course, and prognosis.
2. Identify desired therapeutic outcomes for patients with *H. pylori*–associated ulcers and NSAID-induced ulcers.
3. Identify factors that guide selection of an *H. pylori* eradication regimen and improve adherence with these regimens.
4. Determine the appropriate management for a patient taking a nonselective NSAID who is at high risk for ulcer-related gastrointestinal (GI) complications (eg, GI bleed) or who develops an ulcer.
5. Employ an algorithm for evaluation and treatment of a patient with signs and symptoms suggestive of an *H. pylori*–associated or NSAID-induced ulcer.
6. Given patient-specific information and the prescribed treatment regimen, formulate a monitoring plan for drug therapy either to eradicate *H. pylori* or to treat an active NSAID-induced ulcer or GI complication.

INTRODUCTION

Peptic ulcer disease (PUD) refers to a defect in the gastric or duodenal mucosal wall that extends through the **muscularis mucosa** into the deeper layers of the submucosa.[1] PUD is a significant cause of morbidity and is associated with substantial health care costs.[2,3] Although there are many etiologies of PUD, the three most common are (a) *H. pylori* infection, (b) use of nonsteroidal anti-inflammatory drugs (NSAIDs), and (c) stress-related mucosal damage (SRMD).

Complications of PUD include gastrointestinal (GI) bleeding, perforation, and obstruction. Complications of untreated or undiagnosed *H. pylori* infection include gastric cancer and PUD. This chapter focuses mainly on pharmacotherapy of PUD related to *H. pylori* infection or NSAID use. Prophylaxis of SRMD in hospitalized patients is also discussed briefly.

EPIDEMIOLOGY AND ETIOLOGY

PUD affects approximately 10% of women and 12% of men in the United States, resulting in 4 million cases annually.[4] The mean direct medical cost (including pharmacy, inpatient, and outpatient costs) was $23,819 per patient per year in one study evaluating workplace absences, short-term medical disability, worker's compensation, and medical and pharmacy claims for six large US employers.[5]

The prevalence of *H. pylori* infection in the United States and Canada is about 30%, whereas the global prevalence is greater than 50%. Factors that influence the incidence and prevalence of *H. pylori* infection include age, ethnicity, sex, geography, and socioeconomic status.

Helicobacter Pylori

LO 1

H. pylori is usually contracted in the first few years of life and tends to persist indefinitely unless treated. The infection normally resides in the stomach and is transmitted through ingestion of fecal-contaminated water or food. The organism causes **gastritis** in all infected individuals, but fewer than 10% actually develop symptomatic PUD.

Nonsteroidal Anti-Inflammatory Drugs

Chronic NSAID ingestion causes nausea and dyspepsia in nearly half of patients. Peptic ulceration occurs in up to 30% of chronic NSAID (including aspirin) users, with GI bleeding or perforation occurring in 1.5% of patients who develop an ulcer.[2] Ulcer-related complications result in 100,000 hospitalizations and more than 20,000 deaths in the United States each year.[2]

Risk factors for NSAID-induced PUD and complications are presented in Table 18–1. Risk factors are generally additive. Corticosteroid therapy is not an independent risk factor for ulceration but increases PUD risk substantially when combined with NSAID therapy.[6] Whether *H. pylori* infection is a risk factor for NSAID-induced ulcers remains controversial; however, *H. pylori* and NSAIDs act independently to increase ulcer risk and ulcer-related bleeding and also appear to have synergistic effects.[7,8]

Stress-Related Mucosal Damage

SRMD occurs most frequently in critically ill patients due to mucosal defects caused by gastric mucosal ischemia and intraluminal acid.[9] The ulcers are usually superficial, but SRMD may also penetrate into the submucosa and cause significant GI bleeding. Physiologically stressful situations that lead to SRMD include sepsis, organ failure, prolonged mechanical ventilation, thermal injury, and surgery. Critical care patients with the specific characteristics listed above are at highest risk.[10]

Table 18–1

Risk Factors for Ulcers and GI Complications Related to NSAID Use

- Age older than 65 years
- Concomitant anticoagulant use
- Preexisting coagulopathy (elevated INR or thrombocytopenia)
- Concomitant corticosteroid therapy
- Previous PUD or PUD complications (bleeding/perforation)
- Cardiovascular disease and other comorbid conditions
- Multiple NSAID use (eg, low-dose aspirin plus another NSAID)
- Longer duration of NSAID use
- High-dose NSAID use

GI, gastrointestinal; INR, international normalized ratio; NSAID, nonsteroidal anti-inflammatory drug; PUD, peptic ulcer disease.

From Lanza FL, Chan FKL, Quigley EMM, et al. Guidelines for prevention of NSAID-related ulcer complications. Am J Gastroenterol. 2009;104:728–738.

Zollinger–Ellison Syndrome

Zollinger–Ellison syndrome (ZES) is caused by a gastrin-producing tumor called a gastrinoma. The resulting gastric acid hypersecretion causes diarrhea and malabsorption. Ulcers tend to be numerous and have a high risk of perforation and bleeding.[11] Treatments include surgical resection when feasible and high-dose oral proton pump inhibitor (PPI) therapy.

Other Causative Factors

Cigarette smoking is associated with a higher prevalence of ulcers in *H. pylori*-infected patients.[2] The detrimental effects of smoking on the gastric mucosa may involve increased pepsin secretion, duodenogastric reflux of bile salts, elevated levels of free radicals, and reduced prostaglandin-2 (PG_2) production, resulting in decreased mucus and bicarbonate secretion.[12]

Although psychosocial factors such as life stress, personality patterns, and depression may influence PUD prevalence, a clear causal relationship has not been demonstrated.[2]

Dietary factors such as coffee, tea, cola, alcohol, and spicy foods may cause dyspepsia but have not been shown to independently increase PUD risk.

PATHOPHYSIOLOGY

LO 1

Ulcers related to *H. pylori* infection more commonly affect the duodenum (duodenal ulcers [DUs]), whereas NSAID-related ulcers more frequently affect the stomach (gastric ulcers [GUs]) (Figure 18–1). However, ulcers may be found in either location from either cause.[11]

Ulcer formation in the GI tract results from disrupted homeostasis between factors that break down food (eg, gastric acid and pepsin) and those that promote mucosal defense and repair (eg, bicarbonate, mucus secretion, and PGs).

Gastric Acid and Pepsin

Hydrochloric acid and pepsin are the primary substances that cause gastric mucosal damage in PUD. Three different stimuli (eg, histamine, acetylcholine, and gastrin) cause acid secretion through interactions with the histaminic, cholinergic, and gastrin receptors on the surface of parietal cells. Gastric acid output occurs in two stages: (a) basal acid output during fasting, and (b) maximal acid output in response to meals. Basal acid secretion follows a circadian cycle and is modulated by the effects of acetylcholine and histamine on parietal cells.[13]

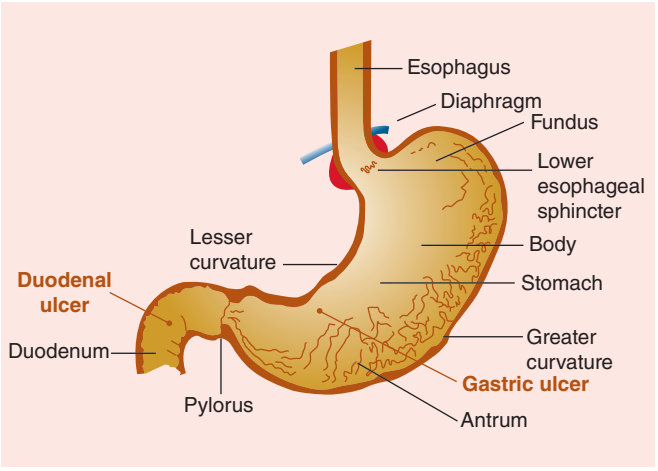

FIGURE 18–1. Anatomic structure of the stomach and duodenum and most common locations of gastric and duodenal ulcers. (From Love B, Thoma MN. Peptic ulcer disease. In: DiPiro JT, Talbert RA, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014 with permission. www.accesspharmacy.com.)

Food increases gastric acid secretion in two ways: (1) vagus nerve stimulation in response to sight, smell, or taste; and (2) stomach distention during the gastric and intestinal phases of acid secretion.

After stimulation by histamine, acetylcholine, and gastrin, acid is secreted by the H^+-K^+-ATPase$^+$ (proton) pump, located on the luminal side of parietal cells. Acid secretion in PUD is usually normal or only slightly elevated. NSAID ingestion does not usually affect acid secretion, whereas *H. pylori* infection often slightly increases acid output.[13]

Pepsinogen released from chief cells in the body of the stomach is converted to pepsin in an acidic environment; pepsin initiates protein digestion and collagen proteolysis and serves as a signal for the release of other digestive enzymes such as gastrin and cholecystokinin.[14] The proteolytic activity of pepsin appears to influence ulcer formation.

Mucosal Defense and Repair

Several normal processes prevent mucosal damage and subsequent ulcer formation. The buffering action of the mucus/phospholipid and bicarbonate barrier shields the gastric epithelial surface from gastric acid.[2] This allows an acidic environment in the gastric lumen but a near neutral pH on the epithelial lining.

PGs inhibit gastric acid secretion and protect gastric mucosa by stimulating mucus, bicarbonate, and phospholipid production. PGs also increase mucosal blood flow and stimulate epithelial cell regeneration.[2] Damage to the mucosal defense system is the primary method by which *H. pylori* and NSAIDs cause peptic ulcers.

▶ *Helicobacter pylori*

H. pylori, a gram-negative rod, is found on the surface of the gastric epithelium. Flagella provide motility that allows the organism to penetrate the mucous gel barrier and infect epithelial cells.[15] Cellular invasion by *H. pylori* is necessary for an active infection. The organism survives in the acidic milieu of the stomach by producing urease, an enzyme that hydrolyzes urea in gastric juice into carbon dioxide and ammonia.[15]

H. pylori may cause gastroduodenal mucosal injury through (a) direct mucosal damage, (b) alterations in host inflammatory responses, and (c) hypergastrinemia and elevated acid secretion.

Nonsteroidal Anti-Inflammatory Drugs

NSAIDs can cause gastric mucosal damage by two mechanisms: (1) direct irritation of the gastric epithelium, and (2) systemic inhibition of endogenous mucosal PG synthesis. Direct irritation occurs because NSAIDs are weak acids. Less acidic agents, such as nonacetylated salicylates, may confer decreased GI toxicity.[16] Direct irritant effects contribute to NSAID-induced gastritis but play a minor role in the development of NSAID-induced PUD.

Systemic inhibition of PG synthesis is the primary means by which NSAIDs cause PUD. NSAID inhibition of PG production by blocking the cyclooxygenase-2 (COX-2) enzyme produces beneficial analgesic and anti-inflammatory effects. However, NSAIDs may also block the COX-1 enzyme, which produces PGs that provide gastroprotection. NSAIDs given parenterally (eg, ketorolac) and rectally (eg, indomethacin) have an incidence of PUD similar to oral NSAIDs. Topical NSAIDs (eg, diclofenac) are unlikely to cause PUD because very low serum concentrations are achieved. The antiplatelet effects of NSAIDs may worsen bleeding complications associated with PUD.

CLINICAL PRESENTATION AND DIAGNOSIS

Clinical Presentation

See text box for the clinical presentation of PUD. Dyspepsia (upper abdominal discomfort) is found in 10% to 40% of the general population. PUD is found in 5% to 15% of patients with dyspepsia.

PUD can be classified as uncomplicated or complicated. Uncomplicated disease is typically characterized by mild epigastric pain, whereas complicated disease involves acute upper GI complications such as GI bleeding, obstruction, or perforation. Bleeding may be occult or may present as **melena** or **hematemesis**. Up to 20% of patients who develop a PUD-related hemorrhage do not have prior symptoms. Gastric outlet obstruction is usually caused by ulcer-related inflammation or scar formation. Patients typically present with early satiety after meals, nausea, vomiting, abdominal pain, and weight loss. Perforation requires emergent surgical intervention, and these patients should not undergo endoscopy.

Diagnosis

Radiologic and/or endoscopic procedures are usually required to document the presence of ulcers. Because endoscopic testing is invasive and expensive, it is only indicated in patients 60 years of age or older with new-onset dyspepsia.[17] Patients with dyspepsia who are younger than 60 years may forego endoscopy but should be tested for *H. pylori* using noninvasive testing and treated if positive.[17] Those who test negative for *H. pylori* should be offered a trial (4–8 weeks) of acid suppression therapy or proceed to endoscopy. Persistent dyspepsia despite a trial of acid suppressive therapy warrants upper endoscopy evaluation.[1]

Testing for *H. pylori* infection is indicated in patients with active PUD, history of documented PUD, low-grade gastric mucosa-associated lymphoid tissue (MALT) lymphoma, or history of endoscopic resection of early gastric cancer.[18] Diagnostic tests to detect *H. pylori* presence can be either endoscopic or nonendoscopic.[15,18] Endoscopic diagnosis involves extraction of gastric tissue samples that are subsequently tested for *H. pylori*.[18] Histology is the standard identification method, but culture, polymerase chain reaction (PCR), and the rapid urease test can also identify *H. pylori* in tissue samples.[19]

Nonendoscopic testing methods for *H. pylori* include the urea breath test, serologic testing, and stool antigen assay.[15,18] These tests are less invasive and less expensive than endoscopy. The urea breath test is usually first line because of its high sensitivity and specificity and short turnaround time.[19] Concomitant acid-suppressive or antibiotic therapy may give false-negative results.[19] The urea breath test can also be used to confirm eradication of *H. pylori* infection.[19]

Serologic testing provides a quick (within 15 minutes) office-based assessment of exposure to *H. pylori*, but it cannot differentiate active infection from previously treated infection; patients can remain **seropositive** for years after eradication. Serologic testing is also less sensitive and specific than the urea breath test.[15] Serologic testing is recommended in patients with recent or current antibiotic or acid-suppressive therapy.[19]

Stool antigen assays can be useful for initial diagnosis or to confirm *H. pylori* eradication. They have high sensitivity and specificity and are affected less by concomitant medication use.[15] Use of antimicrobial agents within 4 weeks, PPIs within 2 weeks, and histamine-2 receptor antagonists (H_2RAs) within 24 hours of testing can suppress the infection and reduce the sensitivity of testing.[15]

TREATMENT

The treatment selected for PUD depends on the etiology of the ulcer, whether the ulcer is new or recurrent, and whether complications have occurred. **Figure 18–2** shows an algorithm for evaluation and treatment of a patient with signs and symptoms suggestive of an *H. pylori*–associated or NSAID-induced ulcer.

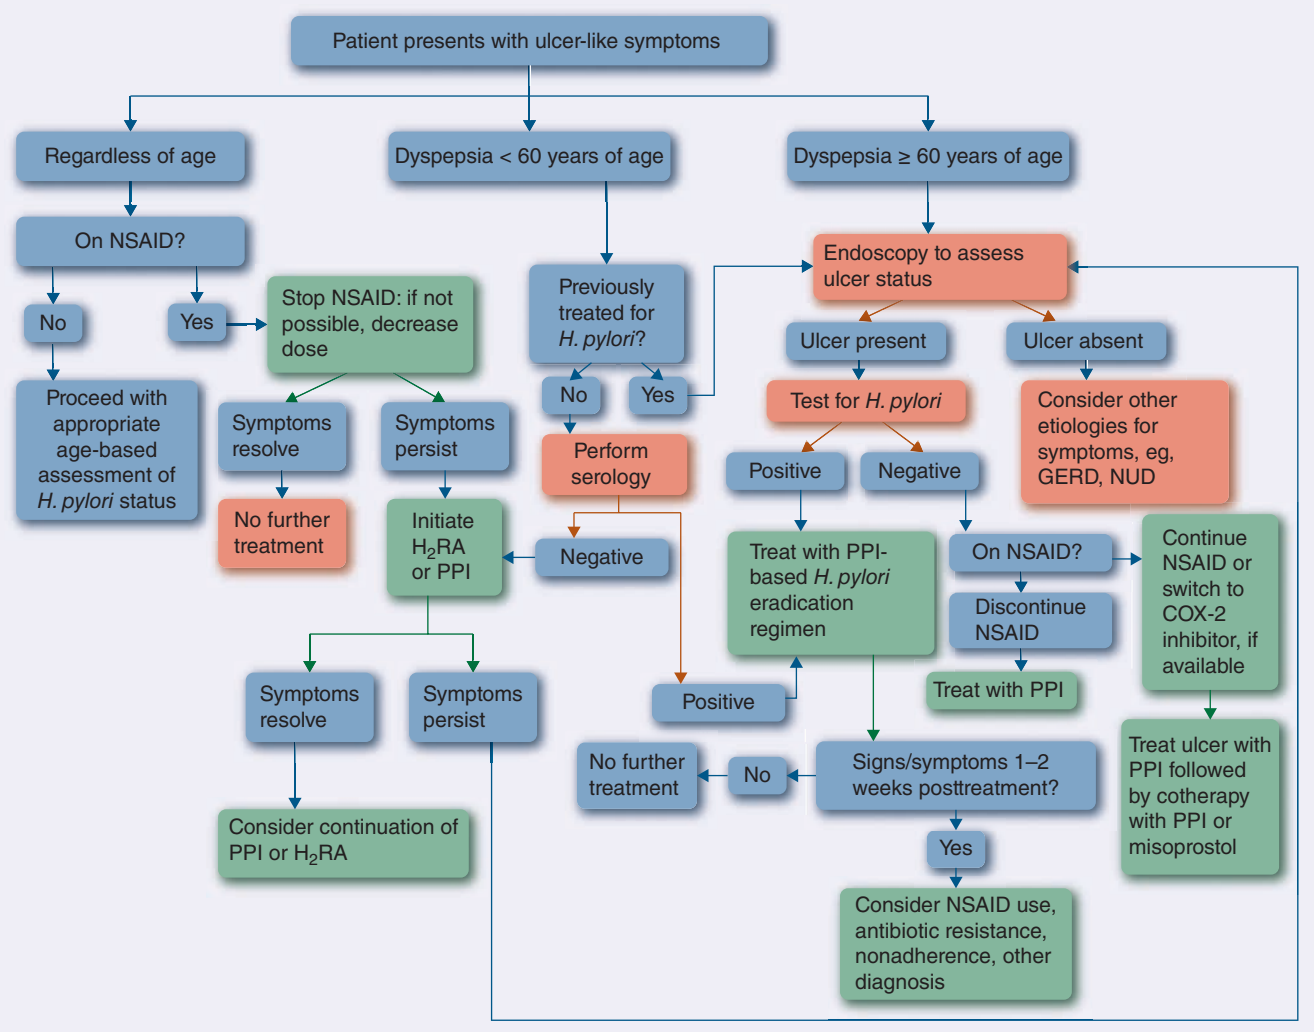
Clinical Presentation of PUD

Symptoms

- Dyspepsia and mild epigastric pain that may be described as burning, gnawing, or aching in character.
- Epigastric pain with DUs typically occurs 1 to 3 hours after meals or at night and is often relieved by food.
- Pain with GUs is often aggravated by food.
- Abdominal pain may be described as burning or a feeling of discomfort.
- Pain severity often fluctuates and the character can vary from dull to sharp.
- Patients may also complain of heartburn, belching, bloating, nausea, or vomiting.

Signs

- Weight loss may be associated with nausea and vomiting.
- Complications such as bleeding, perforation, or obstruction may occur.
- Alarm findings include family history of upper GI malignancy, unintentional weight loss, overt GI bleeding, iron deficiency anemia, progressive dysphagia or odynophagia, early satiety, persistent vomiting, palpable mass, or lymphadenopathy.



LO 5 **FIGURE 18–2.** Guidelines for the evaluation and management of a patient who presents with dyspeptic or ulcer-like symptoms. (COX-2, cyclooxygenase-2; GERD, gastroesophageal reflux disease; H_2RA, H_2-receptor antagonist; NSAID, nonsteroidal anti-inflammatory drug; NUD, nonulcer dyspepsia; PPI, proton pump inhibitor.) (Adapted from Love BL, Mohorn PL. Peptic ulcer disease. In: DiPiro JT, Talbert RA, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017, with permission. www.accesspharmacy.com.)

LO 2

Desired Outcomes

The goals of PUD therapy are to resolve symptoms, reduce acid secretion, promote epithelial healing, prevent ulcer-related complications, and prevent ulcer recurrence. For *H. pylori*–related PUD, eradication of *H. pylori* is an additional outcome.

Nonpharmacologic Therapy

▶ *Risk Factor Avoidance*

KEY CONCEPT Patients with PUD should avoid exposure to factors known to worsen the disease, exacerbate symptoms, or lead to ulcer recurrence. Patients should be advised to reduce psychological stress and avoid cigarette smoking, alcohol consumption, and NSAID or aspirin use if possible. Patients who require chronic NSAID therapy (eg, for rheumatoid arthritis) may be given prophylaxis with misoprostol or a PPI (see Prevention of NSAID-Induced Ulcers section).

▶ *Surgery*

The high success rates of medical therapies have reduced the need for surgical procedures. Elective surgeries performed for PUD have decreased by more than 70% since the 1980s mainly due to *H. pylori* eradication.[20] Surgical interventions are generally reserved for complicated or refractory PUD.

For patients with acute GI bleeding, endoscopic hemostasis can be achieved using contact thermal therapy, mechanical therapy using clips, or epinephrine injection followed by either thermal or mechanical therapy.[21] Angiography with embolization of bleeding lesions can be used if the bleeding cannot be stopped endoscopically and the patient is either high risk for surgery or not a surgical candidate.[22]

Pharmacologic Therapy

▶ *Treatment of* H. pylori*–Associated Ulcers*

The goal of *H. pylori* therapy is to eradicate the organism using an effective antibiotic-containing regimen. KEY CONCEPT Reliance on conventional acid-suppressive drug therapy alone as an alternative to H. pylori eradication is inappropriate because it is associated with a higher incidence of ulcer recurrence and ulcer-related complications. Reinfection rates are generally low after the initial course of therapy as long as the patient was

adherent. In addition to proven efficacy, the optimal treatment regimen should cause minimal adverse events, have low risk for development of bacterial resistance, and be cost-effective.[15,18]

LO 3

H. pylori treatment regimens are presented in Table 18–2. KEY CONCEPT Eradication therapy should be pursued in all patients who test positive for *H. pylori* infection. Several regimens are recommended as first-line eradication therapy. Different antibiotics should be used if a second course of *H. pylori* eradication therapy is required. The cure rates of *H. pylori* with H_2RAs in combination with antibiotics are lower than with PPIs.[18]

Important considerations in selecting first-line treatment regimens include presence of a penicillin allergy and previous exposure to macrolide antibiotics. Acceptable first-line regimens that carry strong recommendations include bismuth quadruple therapy as well as concomitant therapy. Other acceptable regimens for first-line treatment with weak recommendations include: (1) clarithromycin triple therapy in regions with clarithromycin resistance less than 15% when a patient has no previous macrolide exposure, (2) sequential therapy, (3) hybrid therapy, (4) levofloxacin triple therapy, and (5) fluoroquinolone sequential therapy. Substitution of one PPI for another is acceptable and does not affect eradication rates. Alcohol consumption must be considered prior to selecting a metronidazole containing treatment regimen.[18]

The duration of therapy for *H. pylori* eradication is controversial; US guidelines recommend either 10 or 14 days.[18] Compared with 7 days of triple therapy, a 10-day duration increases eradication rates by 4% and 14 days increases eradication rates by 5% to 12%.[26] Longer treatment courses may decrease adherence and increase drug costs; ultimately, the most effective eradication regimens still fail in 10% to 20% of patients.[11]

Bismuth-based four-drug regimens have clinical cure rates similar to three-drug PPI-based regimens.[25] Bismuth salts promote ulcer healing through antibacterial and mucosal protective effects. Disadvantages of bismuth-based regimens include frequency of administration (four times a day), risk for salicylate toxicity in renal impairment, and bothersome side effects (eg, stool and tongue discoloration, constipation, nausea, vomiting).[11]

Pylera™ and PrevPac® are proprietary products designed to improve regimen adherence (Table 18–2). Pylera™ is a combination product, whereas PrevPac® is a conveniently packaged eradication regimen. Both products are substantially more expensive than their individual generic and nonprescription components.

Recent literature has indicated a potential role for probiotics in first-line treatment of *H. pylori*. These data associated probiotic therapy with increased cure rates and reduced side effects compared to conventional eradication regimens. However, further study is needed due to limitations of the available evidence. Current guidelines reinforce several areas for additional research regarding optimal dosing of probiotic therapy.[18]

Patients may remain infected with *H. pylori* after the initial treatment course because of reinfection, nonadherence, or antimicrobial resistance. Factors associated with decreased adherence include polypharmacy, need for frequent drug administration or long treatment duration, and use of drugs that may cause intolerable side effects. Potential adverse drug effects include taste disturbances (clarithromycin and metronidazole), nausea, vomiting, abdominal pain, and diarrhea. Superinfections with oral thrush or vaginal candidiasis can occur. Alcohol should be avoided during treatment with metronidazole or tinidazole due to the potential for a disulfiram-like reaction.

Resistance data for *H. pylori* in the United States are limited. Recent data from a Veterans Affairs Medical Center demonstrated

Table 18–2

Drug Regimens to Eradicate *Helicobacter pylori*

Treatment Regimen	Medications	Duration
Clarithromycin triple therapy	Clarithromycin 500 mg BID + amoxicillin 1 g BID OR metronidazole 500 mg TID + PPI BID	14 days
Bismuth quadruple therapy[a]	Bismuth subsalicylate 300 mg QID + metronidazole 250–500 mg QID + tetracycline 500 mg QID + PPI BID	10–14 days
Concomitant[a] therapy	Clarithromycin 500 mg BID + amoxicillin 1 g BID + nitroimidazole[c] 500 mg BID + PPI BID	10–14 days
Sequential therapy	Amoxicillin 1 g BID + PPI BID followed by clarithromycin 500 mg BID + nitroimidazole[c] 500 mg BID + PPI BID	5–7 days 5–7 days
Hybrid therapy	Amoxicillin 1 g BID + PPI BID followed by amoxicillin 1 g BID + clarithromycin 500 mg BID + nitroimidazole[c] 500 mg BID + PPI BID	7 days 7 days
Levofloxacin triple therapy	Levofloxacin 500 mg daily + amoxicillin 1 g BID + PPI BID	10–14 days
Levofloxacin sequential therapy	Amoxicillin 1 g BID + PPI BID followed by amoxicillin 1 g BID + levofloxacin 500 mg daily + nitroimidazole[c] 500 mg BID + PPI BID	5–7 days 5–7 days
Rifabutin triple therapy[b]	Rifabutin 300 mg daily + amoxicillin 1 g (BID or TID)[d] + PPI BID	10 days
High-dose dual therapy	Amoxicillin (1 g TID or 750 mg QID) + PPI (TID or QID)	14 days
Combination Therapies		
PREVPAC®	Clarithromycin 500 mg BID + amoxicillin 1 g BID + lansoprazole 30 mg BID (contained in blister pack cards)	10–14 days
Pylera™	(Bismuth subcitrate potassium 140 mg + metronidazole 125 mg + tetracycline 125 mg) three capsules QID + omeprazole 20 mg BID	10 days

[a]Regimens with strong recommendation based on current guidelines.

[b]Salvage regimen only.

[c]Metronidazole or tinidazole.

[d]Dosing varied in clinical trials.

BID, twice daily; H_2RA, histamine-2 receptor antagonist; PPI, proton pump inhibitor; QID, four times daily; TID, three times daily.

From Chey WD, Leontiadis GI, Howden CW, et al. ACG Clinical Guideline: treatment of Helicobacter pylori infection. Am J Gastroenterol. 2017;112:212–238.

Patient Encounter 1

A 62-year-old man presents with abdominal pain and heartburn that occur two to three times per week. He also reports a 10-pound (4.5-kg) weight loss in the last 6 weeks, despite not dieting or increasing physical activity. He does not report any recent antibiotic use.

PMH: Hypertension × 5 years

FH: Mother alive at 84 with hypertension, type 2 diabetes; father deceased at 68 following MI

SH: Smokes half pack per day; no alcohol or illicit drug use

Allergies: Penicillin

Meds: Lisinopril/hydrochlorothiazide 20/25 mg daily, acetaminophen 500 mg as needed for headache

Based on this patient's clinical presentation, what is the most appropriate course of action to establish a diagnosis?

The patient receives a diagnosis of H. pylori *infection based on the diagnostic method recommended. What eradication therapy would you recommend?*

The patient completed the course of eradication therapy recommended; however, he returns with similar symptoms 3 months later. What regimen would you recommend for eradication therapy?

Patient Encounter 2

A 52-year-old man presents with persistent epigastric pain and heartburn. His chief complaint today is, "I think my ulcer is back again!"

PMH: Hypertension × 2 years

FH: Mother deceased at age 70, cancer; father alive with hypertension, dyslipidemia

SH: Nonsmoker, 1 to 2 alcoholic beverages three times weekly, no illicit drug use

Allergies: NKDA

Meds: Hydrochlorothiazide 25 mg daily, amlodipine 5 mg daily

The patient previously completed the following courses for *H. pylori* eradication:

- Clarithromycin 500 mg + amoxicillin 1 g + lansoprazole 30 mg, each given twice daily
- Pylera + omeprazole 20 mg twice daily for 10 days

H. pylori recurrence is confirmed with a urea breath test.

Discuss possible reasons for treatment failure in this patient.

What regimen would you recommend for salvage eradication therapy?

clarithromycin resistance rates exceeding the threshold for use in current guidelines. A threshold of 15% to 20% is recommended to differentiate between regions of high and low clarithromycin resistance. In the setting of resistance, efficacy of a three-drug regimen containing clarithromycin can decrease to 10% to 30%. Culture and sensitivity tests are not routinely performed with *H. pylori* infection unless a patient has already failed two different treatment regimens; these tests are also not widely available in the United States.[18,26]

Initiation of a second *H. pylori* treatment regimen after failure of initial treatment is usually associated with a lower success rate. Reasons for failure are often the same as failure of the initial regimen. Selection of a salvage treatment regimen should be based on the initial treatment the patient received, history of quinolone exposure, and penicillin allergy status.

- If clarithromycin triple therapy was used as the initial treatment regimen and the patient is not penicillin allergic, recommended salvage therapies include: (1) bismuth quadruple therapy, (2) levofloxacin triple therapy, (3) rifabutin triple therapy, or (4) high-dose dual therapy. For patients who received initial clarithromycin triple therapy and are penicillin allergic, bismuth quadruple therapy is recommended.
- When bismuth quadruple therapy was the initial treatment regimen and the patient is not penicillin allergic, recommended salvage regimens include: (1) levofloxacin triple therapy, (2) concomitant therapy, (3) rifabutin triple therapy, or (4) high-dose dual therapy. Levofloxacin triple therapy should be avoided in patients with previous quinolone exposure. Salvage regimens are less well defined for patients who received bismuth quadruple therapy as initial treatment and are penicillin allergic. There is no standard third-line therapy for *H. pylori* treatment.[18]

LO 6 Confirmation of *H. pylori* infection eradication is recommended in all treated patients.[18] Testing should occur at least 4 weeks after completion of the eradication regimen and 1 to 2 weeks after discontinuation of PPI.[18] Eradication may be confirmed by either the urea breath test or stool antigen testing. Eradication may also be confirmed by endoscopy, but this should only be done when endoscopy is required because it is more expensive and invasive.[15]

► Treatment of NSAID-Induced Ulcers

LO 4

Treatment recommendations to heal NSAID-induced ulcers or provide maintenance therapy in patients receiving NSAIDs are shown in Table 18–3. Choice of regimen depends on whether NSAID use is to be continued. NSAIDs should be discontinued and replaced with alternatives (eg, acetaminophen), when possible. For patients who cannot discontinue NSAID therapy, PPIs, H_2RAs, or sucralfate are effective for ulcer healing and to prevent further recurrences.[11] PPIs are usually preferred because they provide more rapid relief of symptoms, have the strongest acid suppression, and heal ulcers more quickly than H_2RAs or sucralfate.[11] Standard doses of H_2RAs effectively heal DUs but are minimally effective in GUs. A PPI provides equivalent efficacy with treatment duration of only 4 weeks. PPI therapy should only be continued for longer than 4 weeks if an ulcer is confirmed to still be present or if the patient develops severe complications from PUD.

► Prevention of NSAID-Induced Ulcers

Prophylactic regimens against PUD are often required in patients receiving long-term NSAID or aspirin therapy for osteoarthritis, rheumatoid arthritis, or cardioprotection.[27] Misoprostol, H_2RAs, PPIs, and COX-2 selective inhibitors have been evaluated in controlled trials to reduce the risk of NSAID-induced PUD. KEY CONCEPT In patients at risk for NSAID-induced ulcers, PPIs at standard doses reduce the risk of both gastric and DUs as effectively as misoprostol and more effectively than H_2RAs. In addition, PPIs are generally better tolerated than misoprostol.

Table 18–3

Oral Drug Regimens to Heal Peptic Ulcers or Maintain Ulcer Healing in the Absence of Antibiotic Therapy

Drug	DU or GU Healing (mg/day)	Maintenance of DU or GU Healing (mg/day)
Mucosal Protectant		
Sucralfate	1 g four times a day 2 g two times a day	1 g four times a day 1–2 g two times a day
H_2-Receptor Antagonists		
Cimetidine	300 mg four times a day 400 mg two times a day 800 mg at bedtime	400–800 mg daily
Famotidine	20 mg two times a day 40 mg at bedtime	20–40 mg daily
Nizatidine	150 mg two times a day 300 mg at bedtime	150–300 mg daily
Ranitidine	150 mg two times a day 300 mg at bedtime	150–300 mg daily
Proton Pump Inhibitors		
Dexlansoprazole	30–60 mg daily	30–60 mg daily
Esomeprazole	20–40 mg daily	20–40 mg daily
Lansoprazole	15–30 mg daily	15–30 mg daily
Omeprazole	20–40 mg daily	20–40 mg daily
Pantoprazole	40 mg daily	40 mg daily
Rabeprazole	20 mg daily	20 mg daily

DU, duodenal ulcer; GU, gastric ulcer.

Misoprostol A synthetic prostaglandin E1 (PGE_1) analog that exogenously replaces PG stores, misoprostol is indicated for reducing the risk of NSAID-induced GUs in patients at high risk of complications from ulcers (eg, the elderly and patients with concomitant debilitating disease), as well as patients at high risk of developing gastric ulceration, such as patients with a history of ulcers. Misoprostol 200 mcg four times a day reduces ulcer complications by inhibiting acid secretion and promoting mucosal defense. It is superior to H_2RAs for prevention of NSAID-induced ulcers.[28] Misoprostol use is limited by a high frequency of bothersome GI effects such as abdominal pain, flatulence, and diarrhea, and it is contraindicated in pregnancy due to potential abortifacient effects. Arthrotec is a combination product that contains diclofenac (either 50 or 75 mg) and misoprostol 200 mcg in a single tablet.

H_2-Receptor Antagonists The efficacy of H_2RAs (eg, famotidine 40 mg daily) in preventing NSAID-related ulcers varies. DUs appear to respond better than GUs (the most frequent type of ulcer associated with NSAIDs). Higher doses of H_2RAs (eg, famotidine 40 mg twice daily) may reduce the risk of NSAID-induced gastric and DUs, but results from clinical trials are variable.

Duexis™, a prescription combination product containing ibuprofen 800 mg and famotidine 26.6 mg, is indicated for relief of signs and symptoms of rheumatoid arthritis and osteoarthritis and to decrease the risk of developing upper GI ulcers. The recommended dosage is one tablet orally three times daily. Clinical trials evaluating this agent are 6 months or less in duration and primarily evaluated patients younger than 65 years with no ulcer history.

Proton Pump Inhibitors PPI therapy is more effective than H_2RAs in reducing the risk of nonselective NSAID-related gastric and DUs.[28] PPIs are as effective as misoprostol but better tolerated. All PPIs are effective when used in standard doses. In patients who experience a PUD-related bleeding event while taking aspirin but who require continued aspirin therapy, the addition of a PPI reduces the incidence of recurrent GI bleeding.[29] Prevacid NapraPAC™ provides naproxen (either 250, 375, or 500 mg) and lansoprazole 15 mg in individual blister packages. Vimovo™ provides naproxen (either 375 or 500 mg) and esomeprazole 20 mg in each tablet.

COX-2 Selective Inhibitors NSAIDs with COX-2 selectivity were developed in an attempt to reduce the incidence of PUD and its complications. KEY CONCEPT However, selective COX-2 inhibitors are no more effective than the combination of a PPI and a nonselective NSAID in reducing the incidence of ulcers. Celecoxib is the only agent in this class available in the United States. There was no difference in cardiovascular outcomes when celecoxib was compared to ibuprofen and naproxen.[30,31]

Sucralfate This drug is a negatively charged, nonabsorbable agent that forms a complex by binding with positively charged proteins in exudates, forming a viscous, paste-like adhesive substance that protects the ulcerated area of the gastric mucosa against gastric acid, pepsin, and bile salts.[16] Limitations of sucralfate include the need for multiple daily dosing, large tablet size, and interaction with a number of other medications (eg, digoxin and fluoroquinolones).

Adverse effects of sucralfate include constipation, nausea, metallic taste, and the possibility for aluminum toxicity in patients with renal failure. Sucralfate is effective in the treatment of NSAID-related ulcers when the NSAID will be stopped, but it is not recommended for NSAID-related ulcer prophylaxis.

▶ *Prevention of Stress-Related Mucosal Damage*

Prevention of stress ulcers involves maintaining hemodynamic stability to maximize mesenteric perfusion and pharmacologic suppression of gastric acid production. Stress ulcer prophylaxis (SUP) is only indicated in intensive care unit (ICU) patients with certain risk factors (see Table 18–4).[9,32] The clinician must weigh the risks and benefits of using acid suppression, especially PPIs, in low-risk patients. PPIs and H_2RAs are the drugs of choice for SUP; however, antacids and sucralfate may be acceptable options in some patients.

▶ *Long-Term Maintenance of Ulcer Healing*

KEY CONCEPT Low-dose maintenance therapy with a PPI or H_2RA is only indicated in patients with severe complications secondary to PUD such as gastric outlet obstruction or patients who need to be on long-term NSAIDs or high-dose corticosteroids and are at high risk for bleeding. Drug regimens and doses for PUD treatment and maintenance are presented in Table 18–3.

▶ *Treatment of GI Bleeding*

The immediate priorities in treating patients with a bleeding peptic ulcer are to achieve IV access, correct fluid losses, and restore hemodynamic stability. Insertion of a nasogastric tube is helpful in initial patient assessment, but the absence of bloody or coffee-ground material does not definitively rule out ongoing or recurrent bleeding; about 15% of patients without bloody nasogastric tube output have a high-risk lesion at endoscopy.[21]

Patients should be started on IV PPI therapy because optimal platelet aggregation, partially inhibited fibrinolysis, and better

Table 18–4

Appropriate Indications for Stress Ulcer Prophylaxis in Intensive Care Unit Patients

- Mechanical ventilation for longer than 48 hours
- Coagulopathy or hepatic failure (platelet count < 50 × 10^3/mm^3 [50 × 10^9/L], INR > 1.5, or aPTT > two times control)
- History of GI ulceration or bleeding within 1 year of admission
- Head trauma or Glasgow Coma Score of 10 or less (or inability to obey simple commands)
- Thermal injuries to more than 35% of body surface area
- Multiple traumas (injury severity score of 16 or greater)
- Partial hepatectomy
- Transplant patients in the ICU perioperatively
- Spinal cord injuries
- Two of the following risk factors: sepsis, ICU stay for more than 1 week, occult bleeding lasting 6 or more days, and use of high-dose corticosteroids (> 250 mg/day of hydrocortisone or equivalent)

GI, gastrointestinal; ICU, intensive care unit; INR, international normalized ratio; aPTT, activated partial thromboplastin time.

Data from Quenot JP, Thiery N, Barbar S. When should stress ulcer prophylaxis be used in the ICU? Curr Opin Crit Care. 2009;15:139–143 and Nissen SE, Yeomans ND, Solomon DH. Cardiovascular safety of celecoxib, naproxen, or ibuprofen for arthritis. N Engl J Med. 2016;375:2519–2529.

clot stabilization on the ulcer are achieved when the gastric pH is greater than 6.[33] IV PPI therapy should be continued for 72 hours (because most rebleeding occurs during this time) followed by oral PPI therapy. Three-day PPI infusion therapy has been shown to be as effective as twice-daily IV PPI therapy.[33]

▶ *Treatment of Refractory Ulcers*

Refractory ulcers are defined as ulcers that fail to heal despite 8 to 12 weeks of acid suppressive therapy.[1] The presence of refractory ulcers requires a thorough assessment, including evaluation of medication adherence, extensive counseling and questioning regarding recent over-the-counter and prescription medication use, and testing for *H. pylori* using a different method than previously done if testing was negative. Changing from H_2RA therapy to a PPI should be considered.[16] Other considerations include esophagogastroduodenoscopy (EGD) with biopsy of the ulcer to exclude malignancy, *H. pylori* testing (if not done initially), serum gastrin measurement to exclude ZES, and gastric acid studies.

OUTCOME EVALUATION

- Obtain a baseline complete blood count (CBC). Recheck the CBC if the patient exhibits alarm signs or symptoms.
- Obtain a baseline serum creatinine measurement. Calculate the estimated creatinine clearance and adjust the dose of H_2RAs and sucralfate if needed.
- Obtain a history of symptoms from the patient. Monitor for improvements in pain symptoms (eg, epigastric or abdominal pain) daily.
- Monitor the patient for the development of any alarm signs and symptoms.
- Recommend a follow-up visit if signs and symptoms worsen at any time or do not improve within the defined treatment period.
- Assess for potential drug interactions whenever there is a change in the patient's medications.

Patient Encounter 3

A 68-year-old woman presents with reports of dark, tarry stools for 3 days. She denies coffee-ground emesis or recent weight loss but reports occasional abdominal pain.

PMH: Hypertension × 10 years, type 2 diabetes × 5 years, dyslipidemia × 5 years, osteoarthritis × 3 years

FH: Parents deceased; mother with stroke at age 82, father with MI at age 74; one sister alive at 74 with hypertension, type 2 diabetes, and dyslipidemia

SH: Smokes one pack per day, denies alcohol or illicit drug use

Allergies: NKDA

Meds: Lisinopril 40 mg daily, amlodipine 5 mg daily, metformin 1000 mg twice daily, glipizide 10 mg twice daily, simvastatin 40 mg daily, ibuprofen 800 mg three times daily, aspirin 81 mg daily, Tums™ Extra Strength as needed for dyspeptic symptoms

Other: An endoscopy reveals a duodenal ulcer that is negative for *H. pylori*

What risk factors does this patient have for GI complications related to NSAID use?

Make a recommendation for treatment of this patient's ulcer.

Discuss the use of prophylactic therapy in this patient after the treatment course is completed.

Patient Encounter 4

A 55-year-old man is brought to the surgical ICU after emergency surgery following a motor vehicle accident. The physician would like him to remain NPO (nothing by mouth except for medications) for at least several days until he improves clinically and can sit up in bed.

PMH: Type 2 diabetes × 5 years, dyslipidemia × 5 years, hypothyroidism × 2 years

FH: Father with type 2 diabetes

SH: Nonsmoker; 1 drink 1–2 times weekly; no illicit drug use

Allergies: NKDA

Meds: Atorvastatin 20 mg daily, metformin 500 mg twice daily, levothyroxine 75 mcg daily, aspirin 81 mg daily, ibuprofen 800 mg alternating with oxycodone 5 mg/acetaminophen 325 mg two tablets every 8 hours for surgical site pain

Based on this patient's clinical presentation, is he a candidate for stress ulcer prophylaxis?

What pharmacologic therapy would you recommend for this patient?

Two days later, the patient is transferred to a general medicine floor and begins a regular diet that is well tolerated. Ibuprofen has been discontinued, and he is alternating between oxycodone/acetaminophen and acetaminophen alone to relieve incision site pain. He is sitting up in bed and feeling much better. Is this patient still a candidate for stress ulcer prophylaxis?

Patient Care Process: Peptic Ulcer Disease

Collect Information:

- Obtain a history of prescription and over-the-counter medications and dietary supplements.
- Verify patient allergies and intolerances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Based on review of signs and symptoms and assessment of risk factors (Table 18–1), determine whether the patient is experiencing signs or symptoms of PUD.
- Review available diagnostic tests (eg, serologic testing, urea breath test, stool antigen assay, endoscopy) to determine etiology of peptic ulcer.
- If patient is already receiving pharmacotherapy, assess its efficacy, safety, and patient adherence.

Assess the potential for drug interactions, particularly in patients taking regimens containing metronidazole, clarithromycin, or cimetidine.

Develop a Care Plan:

- If patient has been diagnosed with a peptic ulcer, determine which course of therapy is indicated.
- Recommend an appropriate regimen (Tables 18–2 and 18–3) that will eradicate *H. pylori* and/or heal the peptic ulcer.
- Avoid drug classes to which the patient is allergic.
- If the patient has been treated for *H. pylori* previously, recommend different antibiotics if this episode is a result of treatment failure.
- Evaluate patient accessibility to medication (eg, formulary status, insurance coverage).

Implement the Care Plan:

- Inform patient about potential adverse drug effects and drug interactions.
- Educate the patient on the importance of adherence to eradication and ulcer-healing therapy.
- Identify appropriate lifestyle modifications.

Follow-up: Monitor and Evaluate:

- Assess patient adherence and progress toward efficacy and safety goals.
- Monitor annually for signs and symptoms of complications such as unintentional weight loss or bleeding.
- Evaluate the need for a prophylactic acid suppressive regimen in patients requiring chronic NSAID therapy.

- Educate the patient on the importance of adhering to the *H. pylori* eradication regimen.
- Monitor the patient for complications related to antibiotic therapy (eg, diarrhea or oral thrush) during and after completion of *H. pylori* eradication therapy.
- Recommend follow-up care if the patient's signs and symptoms do not improve after completion of *H. pylori* eradication therapy.

Abbreviations Introduced in This Chapter

COX	Cyclooxygenase
DU	Duodenal ulcer
EGD	Esophagogastroduodenoscopy
GI	Gastrointestinal
GU	Gastric ulcer
H_2RA	Histamine-2 receptor antagonist
INR	International normalized ratio
MALT	Mucosa-associated lymphoid tissue
NSAID	Nonsteroidal anti-inflammatory drug
NUD	Nonulcer dyspepsia
PG	Prostaglandin
PGE_1	Prostaglandin E1
PPI	Proton pump inhibitor
PUD	Peptic ulcer disease
SRMD	Stress-related mucosal damage
SUP	Stress ulcer prophylaxis
ZES	Zollinger–Ellison syndrome

19 Inflammatory Bowel Disease

Brian A. Hemstreet

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Characterize the pathophysiologic mechanisms underlying inflammatory bowel disease (IBD).
2. Recognize the signs and symptoms of IBD, including major differences between ulcerative colitis (UC) and Crohn disease (CD).
3. Identify appropriate therapeutic outcomes for patients with IBD.
4. Describe pharmacologic treatment options for patients with acute or chronic symptoms of UC and CD.
5. Create a patient-specific drug treatment plan based on symptoms, severity, and location of UC or CD.
6. Recommend appropriate monitoring parameters and patient education for drug treatments for IBD.

INTRODUCTION

KEY CONCEPT The term inflammatory bowel disease (IBD) encompasses ulcerative colitis (UC) and Crohn disease (CD). Both disorders are associated with acute and chronic inflammation of the gastrointestinal (GI) tract. Differences exist between UC and CD with regard to regions of the GI tract that may be affected and the distribution and depth of intestinal inflammation. Patients with IBD may also develop inflammation involving organs other than the GI tract, known as extraintestinal manifestations. Symptoms of IBD are associated with significant morbidity, reduction in quality of life, and costs to the health care system.[1–6]

EPIDEMIOLOGY AND ETIOLOGY

IBD is most common in Western countries such as the United States and Northern Europe. The age of initial presentation is bimodal, with patients typically diagnosed between the ages of 20 and 40 or 60 and 80 years. Approximately 1.6 million Americans have UC or CD. Up to 70,000 new cases of IBD are diagnosed in the United States each year.[3]

Men and women are approximately equally affected by IBD in Western countries.[6] In general, whites are affected more often than blacks, and persons of Jewish descent are also at higher risk. The incidence of IBD is 10 to 40 times greater in individuals with a first-degree relative who has IBD compared with the general population.[4,5,7] A positive family history may be more of a contributing factor for development of CD than UC.[7–9]

The cause of IBD is not fully understood. Dysregulation of the inflammatory response within the GI tract in response to environmental or microbiologic factors is thought to be the prevailing mechanism.[3,4] The fact that a positive family history is a strong predictor of IBD supports the theory that genetic predisposition is involved in many cases. Many potential candidate genes have been identified.

An alteration in the inflammatory response regulated by intestinal epithelial cells may also contribute to development of IBD. This may involve inappropriate processing of antigens presented to the GI epithelial cells.[3-5,10,11] The inflammatory response in IBD may be directed at bacteria that normally colonize the GI tract. Products derived from these bacteria may translocate across the mucosal layer of the GI tract and interact with various cells involved in immunologic recognition. The result is T-cell stimulation, excess production of proinflammatory cytokines, and persistent inflammation within the GI tract. Drugs such as nonsteroidal anti-inflammatory drugs (NSAIDs) that disrupt the integrity of the GI mucosa may facilitate mucosal entry of intestinal antigens and lead to IBD flares.[12]

Use of oral contraceptives has been associated with increased development of CD in white patients in some cohort studies, but a strong causal relationship has not been proven.[5] Use of antibiotics in childhood and low levels of vitamin D have also been reported to increase risk of UC and CD.[5]

Smoking has protective effects in UC, leading to reductions in disease severity.[5] The opposite is true in CD because smoking may lead to increases in symptoms or worsening of the disease in Caucasian and Middle Eastern migrants.[5] Tea or coffee consumption is protective in Asian patients.[5]

PATHOPHYSIOLOGY

Ulcerative Colitis

LO 1

The inflammatory response in UC is propagated by atypical type 2 helper T cells that produce proinflammatory cytokines such as interleukin (IL)-1, IL-6, and tumor necrosis factor-α (TNF-α).[3,4,9] The potential role of environmental factors in development of UC implies that the immune response is directed against an unknown antigen. The findings that development and severity of UC are reduced in patients who smoke, those who have had appendectomies, and patients who were breastfed may support the theory that these factors may somehow modify either the genetic component or phenotypic response to immunologic stimuli.[3,4,5]

The inflammatory process within the GI tract is limited to the colon and rectum in patients with UC (Figure 19–1). Most

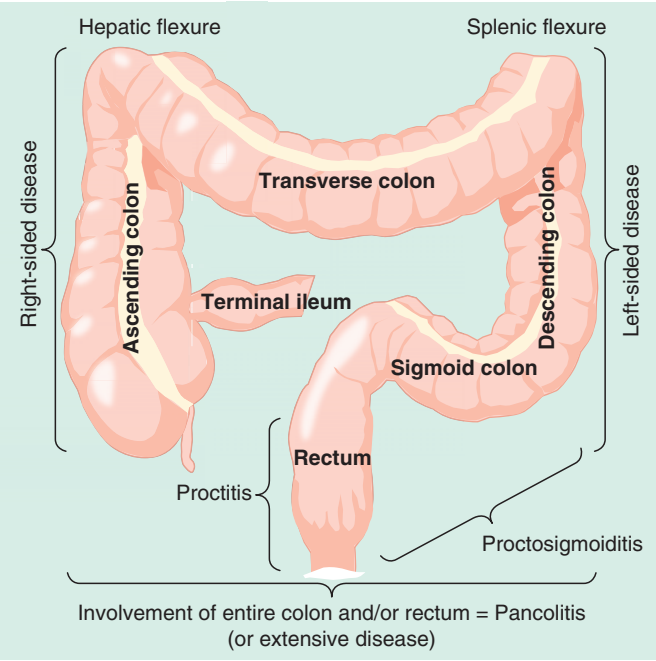

FIGURE 19–1. Major GI landmarks and disease distribution in inflammatory bowel disease.

patients with UC have involvement of the rectum (**proctitis**) or both the rectum and the sigmoid colon (**proctosigmoiditis**). Inflammation involving the entire colon is referred to as extensive disease or **pancolitis**. Left-sided (distal) disease, defined as inflammation extending from the rectum to the splenic flexure, occurs in 30% to 40% of patients.[12] A small number of cases of UC involve mild inflammation of the terminal ileum, referred to as "backwash ileitis."

The pattern of inflammation in UC is continuous and confluent throughout the affected areas of the GI tract. The inflammation is superficial and does not typically extend below the submucosal layer of the GI tract (Figure 19–2). Ulceration or erosion of the GI mucosa may be present and varies with disease severity. Formation of **crypt abscesses** within the mucosal layers of the GI tract is characteristic of UC and may help to distinguish it from CD. Severe inflammation may also result in areas of hypertrophied GI mucosa, which may manifest as **pseudopolyps** within the colon.[13] The inflammatory response may progress in severity, leading to mucosal friability and significant GI bleeding.

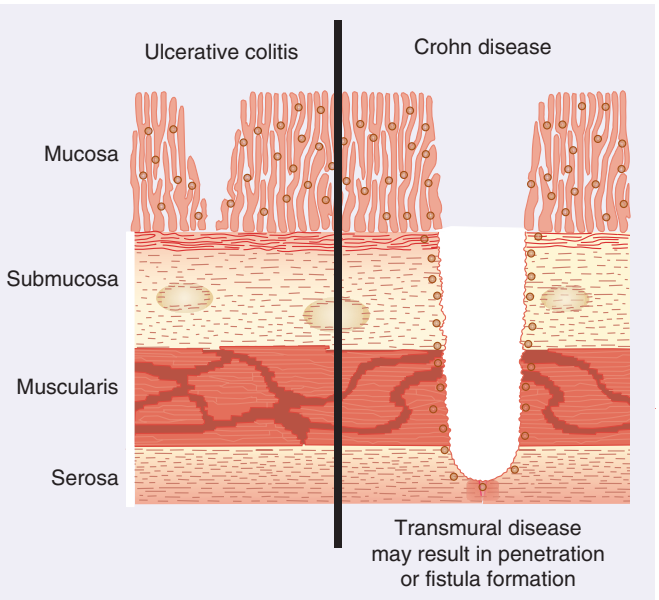

FIGURE 19–2. Depth of disease penetration in ulcerative colitis and Crohn disease.

Crohn Disease

LO 1

As with UC, the immune activation seen in CD involves the release of many proinflammatory cytokines. Cytokines thought to play major roles in CD are derived from T-helper type 1 cells and include interferon-γ, transforming growth factor-β, TNF-α, and IL-1, IL-6, IL-8, IL-12, and IL-23. TNF-α, IL-12, and IL-23 are major contributors to the inflammatory process and development of fibrosis in CD.[3-5,11,15] TNF-α effects include activation of macrophages, procoagulant effects in the vascular endothelium, and increased production of matrix metalloproteinases in mucosal cells.[10–15] TNF-α is also thought to induce production of nuclear factor κβ, which stimulates further production of TNF-α and other proinflammatory cytokines.[3,11,15] Alterations in Paneth cell function may also dictate the phenotypes of CD that are observed.[10] IL-12 and IL-23 are involved in T-cell and lymphocyte differentiation and expansion as part of the inflammatory process.

In contrast to UC, the inflammation in CD may affect any part of the entire GI tract from the mouth to the anus. The small intestine is most commonly involved, and the terminal ileum and cecum are almost always affected. Approximately 20% of patients have isolated colonic involvement, whereas inflammation proximal to the small intestine is almost never seen without the presence of small or large intestinal disease.[13]

The pattern of inflammation in CD is discontinuous; areas of inflammation are intermixed with areas of normal GI mucosa, resulting in characteristic "skip lesions." Superficial **aphthous ulcers** may also develop in the GI mucosa. These ulcers may coalesce into larger linear ulcers, resulting in fissure formation as they increase in depth, giving rise to the characteristic "cobblestone" pattern observed upon examination of the mucosa.

The inflammation may be **transmural**, penetrating to the muscularis or serosal layers of the GI tract (Figure 19–2). This propensity for transmural involvement may lead to serious complications such as **strictures**, **fistulae**, abscesses, and perforation.[13] Although rectal inflammation is typically less common in CD than UC, several types of perianal lesions may be observed including skin tags, hemorrhoids, fissures, anal ulcers, abscesses, and fistulae.[14]

CLINICAL PRESENTATION AND DIAGNOSIS

KEY CONCEPT Differentiation between UC and CD is based on signs and symptoms as well as characteristic endoscopic findings, including the extent, pattern, and depth of inflammation. See accompanying box for the clinical presentation of IBD.

Extraintestinal Manifestations and Complications of IBD

KEY CONCEPT Patients may manifest signs and symptoms of disease in areas outside the GI tract (extraintestinal manifestations).[13] Painful joint complications associated with IBD include sacroiliitis and ankylosing spondylitis. Ocular involvement with episcleritis, uveitis, or iritis may manifest as blurred vision, eye pain, and photophobia. Associated skin findings include pyoderma

Clinical Presentation of IBD

LO 2

General

- Patients with UC or CD may present with similar symptoms.
- The onset may be insidious and subacute.
- Some patients present with extraintestinal manifestations before GI symptoms occur.
- It may be impossible to distinguish between UC and CD in approximately 10% of cases. These patients are described as having "indeterminate colitis."

Symptoms

- *Ulcerative colitis*: Diarrhea (bloody, watery, or mucopurulent), rectal bleeding, abdominal pain/cramping, weight loss and malnutrition, tenesmus, constipation (with proctitis)
- *Crohn disease*: Diarrhea (less bloody than UC), rectal bleeding (less than UC), abdominal pain/cramping, weight loss and malnutrition (more common than UC), fatigue/malaise

Signs

- *Ulcerative colitis*: Fever, tachycardia (with severe disease), dehydration, arthritis, hemorrhoids, anal fissures, perirectal abscesses
- *Crohn disease*: Fever, tachycardia (with severe disease), dehydration, arthritis, abdominal mass and tenderness, perianal fissure or fistula

Laboratory Tests

- *Ulcerative colitis*: Leukocytosis, decreased hematocrit/hemoglobin, elevated erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP), positive test for fecal occult blood, (+) perinuclear antineutrophil cytoplasmic antibodies (pANCA; up to 70% of patients), and elevated fecal calprotectin
- *Crohn disease*: Leukocytosis, decreased hematocrit/hemoglobin, elevated ESR or CRP, positive test for fecal occult blood, (+) anti–*Saccharomyces cerevisiae* antibodies (up to 50% of patients), hypoalbuminemia with severe disease, and elevated fecal calprotectin

gangrenosum (papules and vesicles that develop into painful ulcerations) and erythema nodosum (red nodules of varying size typically found on the lower extremities). Nephrolithiasis may also develop at a higher rate in patients with IBD. Oxalate stones are more common in CD, and uric acid-containing stones are more common in UC.[13]

Liver and biliary manifestations of IBD include increased incidence of gallstone formation in patients with CD and development of sclerosing cholangitis or cholangiocarcinoma in patients with UC. Patients with UC are at increased risk for developing colorectal cancer and should undergo periodic cancer screening. Ongoing inflammation due to active IBD may induce a hypercoagulable state, resulting in higher rates of both arterial and venous thromboembolism, including deep vein thrombosis and pulmonary embolism. Likewise, inflammation and recurrent blood loss may result in chronic anemia. Patients with IBD also have higher rates of osteopenia, osteoporosis, and fractures, which are most strongly associated with use of corticosteroids.[16]

A serious complication of UC is toxic megacolon, defined as dilation of the transverse colon greater than 6 cm (2.4 in). Patients with toxic megacolon typically manifest systemic signs of severe inflammation such as fever, tachycardia, and abdominal distention.[3,9,13] Surgical intervention, including colonic resection, may be necessary to acutely manage toxic megacolon.

Patients with CD may develop significant weight loss or nutritional deficiencies secondary to malabsorption of nutrients in the small intestine, or as a consequence of multiple small- or large-bowel resections. Common nutritional deficiencies in IBD include vitamin B_{12}, fat-soluble vitamins, zinc, folate, and iron. Malabsorption in children with CD may contribute to significant reductions in growth and development.

Diagnosis

Because patients often present with nonspecific GI symptoms, initial diagnostic evaluation includes methods to characterize the disease and rule out other potential etiologies. This may include stool cultures to examine for infectious causes of diarrhea.[9] Use of fecal calprotectin, a protein found in neutrophil granulocytes and released during leukocyte trafficking, is measured in the stool and may help to differentiate IBD from nonorganic disease (intestinal damage due to external causes such as drugs or mechanical intervention).[9] Levels greater than 120 mcg/g are considered abnormal.

Endoscopic approaches are typically used and may include colonoscopy, proctosigmoidoscopy, or possibly upper GI endoscopy in patients with suspected CD. Endoscopy is useful for determining the disease distribution, pattern and depth of inflammation, and to obtain mucosal biopsy specimens. Supplemental information from imaging procedures, such as computed tomography, abdominal x-ray, abdominal ultrasound, or intestinal barium studies may provide evidence of complications such as obstruction, abscess, perforation, or colonic dilation.[9]

The information derived from diagnostic testing and the patient's medical history and symptoms are used to gauge disease severity. Traditionally, the severity of active IBD is classified as mild, moderate, severe, or fulminant.[1,2] These categories are determined using a mix of signs, symptoms, and laboratory markers such as daily stool count, hydration status, presence of tachycardia, and elevated ESR or CRP.

A clinical care pathway developed by the American Gastroenterological Association (AGA) provides guidance on assessing severity of UC based on risk for colectomy.[35] After a diagnosis is made, inflammatory status (based on signs/symptoms, lab markers, and endoscopic findings), comorbidities, and therapy-related complications (if the patient is already receiving treatment) are assessed. Patients are then stratified according to low risk for colectomy (limited anatomic extent and mild endoscopic disease) or high risk for colectomy (extensive colitis, age less than 40 years, deep ulcers, high ESR/CRP, steroid dependence, history of hospitalization, and *Clostridium difficile* or cytomegalovirus infection).

The AGA also developed a similar clinical decision support tool for managing CD.[39] Initially, the patient's inflammatory status, comorbidities, and disease and therapy-related complications are assessed. Categorization is slightly different from UC, and patients considered low risk (age at initial

diagnosis over 30 years, limited anatomic involvement, no perianal and/or severe rectal disease, superficial ulcers, no prior surgical resection, and no stricturing and/or penetrating disease) or moderate–high risk (age at initial diagnosis less than 30 years, extensive anatomic involvement, perianal and/or severe rectal disease, deep ulcers, prior surgical resection, stricturing and/or penetrating disease).

TREATMENT

Desired Outcomes

LO 3

Treatment goals for IBD involve both management of active disease and prevention of disease relapse. KEY CONCEPT Major treatment goals include alleviation of signs and symptoms and suppression of inflammation during acute episodes and maintenance of remission thereafter. Addressing active IBD in a timely and appropriate manner may prevent major complications and reduce the need for hospitalization or surgical intervention.

Once control of active disease is obtained, treatment regimens are designed to achieve these long-term goals: (a) maintain remission and prevent disease relapse, (b) improve the patient's quality of life, (c) prevent the need for surgical intervention or hospitalization, (d) manage extraintestinal manifestations, (e) prevent malnutrition, and (f) prevent treatment-associated adverse effects.

General Approach to Treatment

Pharmacologic interventions for IBD are designed to target the underlying inflammatory response. KEY CONCEPT When designing a drug regimen for treatment of IBD, several factors should be considered, including the patient's symptoms; medical history; current medication use; drug allergies; and extent, location, and severity of disease. The history may also help identify a family history of IBD or potential exacerbating factors, such as tobacco or NSAID use.

Nonpharmacologic Therapy

No specific dietary restrictions are recommended for patients with IBD, but avoidance of high-residue foods in patients with strictures may help prevent obstruction. Avoidance of excess dietary fat and foods containing emulsifying agents (eg, mayonnaise, salad dressing, ice cream) may also be preferred.[8] Nutritional strategies in patients with longstanding IBD may include vitamin and mineral supplementation and intake of soluble fiber.[8] Administration of vitamin B_{12}, folic acid, fat-soluble vitamins, and iron may be needed to prevent or treat deficiencies. In severe cases, enteral or parenteral nutrition may be needed to achieve adequate caloric intake.[8]

Patients with IBD, particularly those with CD, are also at risk for bone loss. This may be a function of malabsorption of vitamin D or repeated courses of corticosteroids.[16] Risk factors for osteoporosis should be determined, and baseline bone density measurement may be considered.[16] Vitamin D and calcium supplementation should be used in all patients receiving long-term corticosteroids. Oral bisphosphonate therapy may also be considered in patients receiving prolonged courses of corticosteroids or in those with osteopenia or osteoporosis.

Surgical intervention is an option in patients with complications such as fistulae or abscesses, or in patients with medically refractory disease. UC is curable with performance of a total colectomy; patients with UC may opt to have a colectomy to reduce the chance of developing colorectal cancer. Patients with CD may have affected areas of intestine resected. Unfortunately, CD may recur following surgical resection. Repeated surgeries in CD may lead to significant malabsorption of nutrients and drugs consistent with development of short-bowel syndrome.

Pharmacologic Therapy

Several pharmacologic classes are available for acute treatment and maintenance therapy of IBD. Selection of an initial agent for patients with active IBD should be designed to deliver maximum efficacy while minimizing toxicity. Response rates to individual classes of medications for both UC and CD are discussed within the specific treatment section for each disease.

▶ *Symptomatic Interventions*

LO 4

Patients with active IBD often have severe abdominal pain and diarrhea. Medications used to manage these symptoms may have adverse consequences. KEY CONCEPT Antidiarrheal medications that reduce GI motility such as loperamide, diphenoxylate/atropine, and codeine should be avoided in patients with active IBD due to the risk of precipitating acute colonic dilation (toxic megacolon).[13] Drugs with anticholinergic properties, such as hyoscyamine and dicyclomine, are often used to treat intestinal spasm and pain, but these drugs may also reduce GI motility and should generally be avoided in active IBD.

Patients who have had multiple intestinal resections due to CD may have diarrhea related to the inability to reabsorb bile salts. Cholestyramine may improve diarrheal symptoms in this population.[14] NSAIDs should be avoided for pain management because they can worsen IBD symptoms. Opioid analgesics should be used with caution because they may significantly reduce GI motility.

▶ *Aminosalicylates*

LO 4

The aminosalicylates are among the most commonly used drugs for inducing and maintaining remission in patients with mild to moderate IBD (Table 19–1). These drugs are designed to deliver 5-aminosalicylate (5-ASA, mesalamine) to areas of inflammation within the GI tract. The mechanism of mesalamine is not fully understood, but it appears to have favorable anti-inflammatory effects. The delivery of mesalamine to the affected sites is

Patient Encounter 1

A 28-year-old man presents to the clinic for initial treatment of UC. A colonoscopy revealed extensive disease in the colon and rectum. He reports two to three loose stools per day 5 to 6 days per week with intermittent blood and abdominal pain. This has caused a significant impact on his daily activities and quality of life. His medical history is significant for gastroesophageal reflux disease, and he takes nonprescription ranitidine as needed. He reports no tobacco use and social intake of alcohol. He has an allergy to peanuts (hives). His medical provider has determined this episode to be of moderate severity and would like to initiate adalimumab.

How does adalimumab differ from infliximab with regard to chemical structure and route of administration?

How would you educate this patient on the appropriate storage of adalimumab?

Table 19–1

Aminosalicylates for Treatment of IBD

Drug	Trade Names	Formulation	Strengths	Daily Dosage Range (g)	Site of Action
Sulfasalazine	Azulfidine	Immediate-release or enteric-coated tablets	500 mg	1.6–4.8	Distal ileum and colon
	Azulfidine En-tabs	Suspension	250 mg/5 mL		
Mesalamine	Rowasa	Enema	4 g/60 mL	4	Distal left colon and rectum
Mesalamine	Asacol Asacol-HD	Delayed-release resin tablet	400 mg, 800 mg	1.6–4.8	Distal ileum and colon
	Delzicol	Delayed-release capsule	400 mg	1.6–4.8	Distal ileum and colon
	Canasa	Rectal suppository	1000 mg	1	Rectum
	Pentasa	Delayed-release capsule	250 mg 500 mg	2–4	Small bowel and colon
	Lialda	MMX formulated pH-dependent polymer film coated tablet	1.2 g	1.2–4.8	Terminal ileum and colon
	Apriso	Enteric-coated granules in polymer matrix	375 mg	1.5	Colon
Olsalazine	Dipentum	Delayed-release capsule	250 mg	1–3	Colon
Balsalazide	Colazal	Delayed-release capsule	750 mg	2–6.75	Colon
	Giazo	Tablet	1.1 g	2.2–6.6	Colon

accomplished by either linking mesalamine to a carrier molecule or altering the formulation to release drug in response to changes in intestinal pH. Topical suppositories and enemas are designed to deliver mesalamine directly to the distal colon and rectum.[7,17–20]

The prototypical aminosalicylate is sulfasalazine, which chemically is mesalamine linked by a diazo bond to the carrier molecule sulfapyridine. This linkage prevents premature absorption of mesalamine in the small intestine. Once sulfasalazine is delivered to the colon, bacterial degradation of the diazo bond frees mesalamine from sulfapyridine. Sulfapyridine is then absorbed and excreted renally while mesalamine acts locally within the GI tract.

Newer mesalamine products utilize nonsulfapyridine methods for drug delivery. Olsalazine consists of two mesalamine molecules linked together, whereas balsalazide uses the inert carrier molecule 4-aminobenzoyl-β-alanine. Both drugs use a diazo bond similar to sulfasalazine. Lialda is a proprietary multimatrix (MMX) mesalamine formulation with a pH-sensitive coat that releases in the terminal ileum, allowing for once-daily dosing.[17,18] Apriso contains enteric-coated mesalamine granules also with a polymer matrix for extended release that can be given once daily.

Sulfasalazine is associated with various adverse effects, most of which are thought to be due to the sulfapyridine component. Common dose-related adverse effects include headache, dyspepsia, nausea, vomiting, and fatigue.[20–22] Idiosyncratic effects include bone marrow suppression, reduction in sperm counts in males, hepatitis, and pulmonitis. Hypersensitivity reactions may occur in patients allergic to sulfonamide-containing medications.

Nonsulfapyridine-based aminosalicylates are better tolerated than sulfasalazine. Although the types of adverse effects are similar, they occur much less frequently. However, olsalazine is associated with a higher incidence of secretory diarrhea than other aminosalicylates. These agents can be used safely in patients with a reported sulfonamide allergy, but they are more expensive than generic sulfasalazine.

▶ *Corticosteroids*

LO 4

Corticosteroids have potent anti-inflammatory properties and are used in active IBD to suppress inflammation rapidly. They may be administered systemically or delivered locally to the site of action (Table 19–2). Corticosteroids usually improve symptoms and disease severity rapidly, but use should be restricted to short-term management of active disease. Long-term systemic corticosteroid use is associated with significant adverse effects, including cataracts, skin atrophy, hypertension, hyperglycemia, adrenal suppression, osteoporosis, increased risk of infection, and delayed growth in children, among others.[20–22]

Table 19–2

Corticosteroids for Treatment of IBD

Drug	Trade Names	Daily Dose
Prednisone	Generic	20–60 mg orally
Prednisolone	Generic	20–60 mg orally
Methylprednisolone	Medrol (orally) Solu-Medrol (IV)	15–60 mg orally or IV
Hydrocortisone	Solu-Cortef	300 mg IV in three divided doses
	Cortenema	100 mg rectally at bedtime
	Cortifoam	90 mg rectally once or twice daily
	Anusol-HC	25–50 mg rectally twice daily
	Proctocort	30 mg rectally twice daily
Budesonide	Uceris 9-mg tablet	9 mg orally once daily
	Entocort 3-mg capsule	9 mg orally once daily
	Uceris rectal foam	2 mg twice daily, then once daily

Budesonide is a high-potency glucocorticoid used in IBD that has low systemic bioavailability when administered orally or rectally.[23,24] Oral formulations may release in either the terminal ileum or colon. Rectal foam formulations reach up to 40 cm from the anal verge. Compared to traditional corticosteroids, budesonide may reduce long-term adverse effects and can be used for induction therapy.[21–23]

▶ *Immunomodulators and Immunosuppressants*

LO 4 Agents targeting the immune response or cytokines involved in IBD are potential treatment options (Table 19–3). Azathioprine and 6-mercaptopurine (6-MP) are immunomodulators that inhibit purine biosynthesis and reduce IBD-associated GI inflammation. They are most useful for maintaining remission of IBD or reducing the need for long-term use of corticosteroids.[22,2,25–27] Use in active disease is limited by their slow onset of action, which may be as long as 3 to 12 months. Azathioprine is metabolized to 6-MP, which is further metabolized to the active 6-thioguanine (6-TGN) nucleotide, which functions as a purine antagonist. Evaluation of 6-TGN concentrations can be performed in patients who may not be responding to therapy or may be experiencing toxicity. Adverse effects associated with azathioprine and 6-MP include hypersensitivity reactions resulting in pancreatitis, fever, rash, hepatitis, and leukopenia.[21,22,25,26] Patients should be tested for activity of thiopurine methyltransferase (TPMT), the major enzyme responsible for metabolism of azathioprine prior to use. Deficiency or reduced activity of TPMT may result in toxicity from azathioprine and 6-MP and may require dose reductions.

LO 4 Methotrexate, also an immunomodulator, is a folate antagonist used primarily for maintaining remission of CD. It may be administered orally, subcutaneously, or IV and may have a steroid-sparing effect in patients with steroid-dependent disease.[6,25,26] Long-term methotrexate use may result in serious adverse effects, including hepatotoxicity, pulmonary fibrosis, and bone marrow suppression.

LO 4 Cyclosporine is a cyclic polypeptide immunosuppressant typically used to prevent organ rejection in transplant patients. Its use in IBD is restricted to patients with fulminant or refractory symptoms in patients with active disease. Significant toxicities associated with cyclosporine are nephrotoxicity, risk of infection, seizures, hypertension, and liver function test abnormalities.[1,20]

▶ *Biologic Agents*

LO 4 Several biologic agents targeting TNF-α are used for treatment of IBD (Table 19–3). Reduction in TNF-α activity is associated with improvement in the underlying inflammatory process. Infliximab is a chimeric anti-TNF-α agent (ie, 75% human, 25% mouse), certolizumab is a pegylated antibody fragment, and both adalimumab and golimumab are humanized anti-TNF-α antibodies.

"Biosimilars" are highly similar to an FDA-approved biologic agent (called the reference product) and have been shown to have no clinically meaningful differences in efficacy or adverse effects from the reference product. They are not identical in structure or considered generically equivalent to the originator compound because of molecular complexity and production using recombinant DNA techniques in living organ systems. However, some biosimilars may be considered to be interchangeable with the reference product. The FDA will approve a biosimilar product only if it has the same mechanism of action, route of administration, dosage form, and strength as the reference product. Also, a biosimilar can only be approved for the indications that were previously approved for the reference product. Biosimilars have a nonproprietary name plus an FDA-designated suffix consisting of four lowercase letters that have no intended meaning. Five biosimilar agents are now approved for use in UC and CD: Infliximab-dyyb, infliximab-abda, infliximab-qbtx, adalimumab-adbm, and adalimumab-atto.

Disadvantages of anti-TNF biologic therapy include the need for parenteral administration, significant drug cost, and the

Table 19–3

Immunodulators and Biologic Agents for Treatment of IBD

Drug	Trade Name(s)	Dose
Azathioprine	Imuran, Azasan	1.5–2.5 mg/kg/day orally
Mercaptopurine	Purinethol, Purixan	1.5–2.5 mg/kg/day orally
Methotrexate	Trexall	15–25 mg weekly (IM/SC/orally)
Cyclosporine	Sandimmune	4 mg/kg/day IV continuous infusion
Infliximab	Remicade	Induction: 5 mg/kg IV at 0, 2, and 6 weeks; 10 mg/kg per dose IV for nonresponders Maintenance: 5 mg/kg IV every 8 weeks
Infliximab-dyyb	Inflectra	
Infliximab-abda	Renflexis	
Inflixmab-qbtx	IXIFI	
Adalimumab	Humira	Induction: 160 mg SC day 1 (given as four 40-mg injections in 1 day or as two 40-mg injections per day for 2 consecutive days), then 80 mg SC 2 weeks later (day 15) Maintenance: 40 mg SC every other week, starting on day 29 of therapy
Adalimumab-atto	Amjevita	
Adalimumab-adbm	Cyltezo	
Certolizumab	Cimzia	Induction: 400 mg SC initially, then 400 mg SC at 2 and 4 weeks Maintenance: 400 mg SC every 4 weeks if initial response
Golimumab	Simponi	200 mg SC at week 0 and 2; then every 4 weeks
Natalizumab	Tysabri	Induction/maintenance: 300 mg IV every 4 weeks; discontinue by 12 weeks if no response or if unable to withdraw steroids within 6 months
Vedolizumab	Entyvio	300 mg IV at weeks 0, 2, and 6; then every 8 weeks; discontinue if no response at 14 weeks
Ustekinumab	Stelara	Weight-based initial IV dose < 55 kg (260 mg), 55–85 kg (390 mg), > 85 kg (520 mg); then 90 mg SC every 8 weeks

IM, intramuscular; IV, intravenously; SC, subcutaneously.

potential for serious adverse effects. Adalimumab, golimumab, and certolizumab are administered subcutaneously, whereas infliximab requires intravenous (IV) infusion. Adverse effects of IV infliximab may include infusion-related reactions such as fever, chest pain, hypotension, and dyspnea. Antibodies may develop to infliximab over time that may reduce its efficacy and predispose patients to development of infusion-related adverse effects.

All TNF-α inhibitors have been associated with reactivation of serious infections, particularly intracellular pathogens such as tuberculosis, as well as hepatitis B.[15,20,25,26] Biologic agents should not be used in patients with existing infections, and patients should be screened for latent tuberculosis and viral hepatitis prior to initiating therapy. Exacerbation of heart failure is also a potential adverse effect, so these agents should be avoided in patients with advanced or decompensated heart failure.[15,20] Anti-TNF-α agents also carry a risk of developing lymphoma, including a rare form known as hepatosplenic T-cell lymphoma. The risk appears to be highest in younger male patients and those using concomitant azathioprine or 6-MP.[20,23-28]

LO 4 Natalizumab and vedolizumab are humanized monoclonal antibodies that antagonize integrin heterodimers, prevent α_4-mediated leukocyte adhesion to adhesion molecules, and prevent migration across the endothelium.[28-31] Natalizumab is associated with development of progressive multifocal leukoencephalopathy (PML). Vedolizumab carries a theoretical risk of PML, but this has not been reported to date. Use of natalizumab is restricted to patients who have failed all other therapies, including anti TNF-α agents. Vedolizumab can be used as alternative to anti-TNF therapy or reserved for patients who fail these agents.[30]

LO 4 Ustekinumab is a biologic therapy that blocks IL-21 and IL-23 action by binding to the p40 protein subunit used by these cytokines.[31] It is approved for use in moderate to severe CD in patients who failed immunomodulators or corticosteroids but have not received anti-TNF therapy. It can also be used for patients who have failed anti-TNF therapy.

► *Other Agents*

Antibiotics have been used in IBD based on the rationale that they may interrupt the inflammatory response directed against endogenous bacterial flora. Metronidazole and ciprofloxacin have been the two most widely studied agents.[1,2,32] Metronidazole LO 4 may benefit some patients with pouchitis (inflammation of surgically created intestinal pouches) and patients with CD who have had ileal resection or have perianal fistulas. Ciprofloxacin has shown some efficacy in refractory active CD and may be used in combination with metronidazole. Long-term metronidazole use is associated with development of peripheral neuropathy.

Because smoking is associated with reduced UC symptoms, transdermal nicotine has been studied as a potential treatment option. Improvement in mild to moderate UC symptoms may be seen and may be more evident in patients who are ex-smokers.[1,33] Daily doses between 15 and 25 mg appear to be most effective.

Probiotics such as *Lactobacillus acidophilus* or *Bifidobacterium* have been used with the rationale that modification of host flora may alter the inflammatory response. There are minimal data to support use of probiotics in CD.[2] In patients with UC, the probiotic preparation VSL#3 demonstrated efficacy in reducing recurrence of pouchitis in patients with ileal pouch anal anastomosis and may prevent relapse in mild to moderate disease.[1,34]

Treatment of UC

LO 4 As described previously, patients may be stratified for treatment based on risk level for colectomy. See Table 19–4 for the AGA recommendations for induction and maintenance therapy of UC based on risk level.

Table 19–4

Ulcerative Colitis Initial Inductive and Maintenance Therapy Based on Colectomy Risk

Risk Level	Inductive Therapy	Maintenance Therapy (Remission)
Low risk	• Oral mesalamine and/or • Rectal mesalamine and/or • Oral budesonide or prednisone and/or • Rectal corticosteroids	• Oral and/or rectal mesalamine • Taper oral corticosteroids over 60 days
High-risk outpatients	1. Short course of systemic corticosteroids (eg, prednisone) with initiation of thiopurine	1. Options: • Thiopurine and taper corticosteroids over 60 days • Anti-TNF agent, with or without thiopurine • Vedolizumab, with or without thiopurine or methotrexate
	2. Anti-TNF agent with or without thiopurine	2. Continue anti-TNF agent, with or without thiopurine
	3. Vedolizumab, with or without thiopurine or methotrexate	3. Continue vedolizumab, with or without thiopurine or methotrexate
High-risk inpatients	1. IV corticosteroids	1. Options: • Thiopurine • Anti-TNF agent with or without thiopurine • Vedolizumab with or without thiopurine or methotrexate
	2. Infliximab	2. Infliximab with or without thiopurine
	3. IV cyclosporine	3. Options: • Start thiopurine • Anti-TNF agent with or without thiopurine • Vedolizumab with or without thiopurine or methotrexate

Thiopurine = azathioprine or mercaptopurine.

Anti-TNF agent = adalimumab, certolizumab, golimumab, infliximab.

▶ Low-Risk Active UC in Outpatients

LOS KEY CONCEPT Treatment of acute episodes of UC is dictated by the severity and extent of disease. First-line therapy of mild to moderate disease or low-risk patients involves oral or topical aminosalicylate derivatives, oral or topical budesonide, or oral prednisone and/or rectal steroids. Topical mesalamine is superior to both topical corticosteroids and oral aminosalicylates for inducing remission in active mild to moderate UC.[1,35–37] Enemas are appropriate for patients with left-sided disease because the medication will reach the splenic flexure. Suppositories deliver mesalamine up to approximately 20 cm and are most appropriate for treating proctitis.[6,7,35] Oral and topical mesalamine preparations may be used together for maximal effect. Oral mesalamine may also be used for patients who are unwilling or unable to use topical preparations.[35–37]

Topical corticosteroids are usually reserved for patients who do not respond to topical mesalamine.[1,22] Patients should be properly educated regarding appropriate use of topical products, including proper administration and adequate retention in order to maximize efficacy. Oral or rectal budesonide may be used as either an alternative first-line therapy or as add-on to aminosalicylates in patients with active UC.[2,23,24] Oral prednisone is also an option; however, its effects are systemic, and oral formations targeting specific areas of the colon are not available. Patients requiring corticosteroids should have them tapered over 60 days.

For patients with disease extending proximal to the splenic flexure, oral sulfasalazine, any oral mesalamine product, or oral budesonide are considered first-line therapy.[1,6,23,24] Doses should provide 4 to 6 g of sulfasalazine or 2.4 g of mesalamine or equivalent.[6,17-19] Use of once-daily formulations may improve patient adherence.[17-19] Induction of remission may require 4 to 8 weeks of therapy at appropriate treatment doses.

▶ High-Risk Active UC in Outpatients

LOS In moderate to severe UC or high-risk outpatients, oral corticosteroids may be used for short-term treatment of patients who are unresponsive to sulfasalazine or mesalamine. Prednisone doses of 40 to 60 mg/day (or equivalent) are recommended.[1,22] Azathioprine or 6-MP should be started when corticosteroids are initiated and can be continued with an anti-TNF agent as maintenance therapy.[35,37] Infliximab, adalimumab, and golimumab are effective for patients with moderate disease who are unresponsive to oral therapies.[38] Vedolizumab is an alternative to anti-TNF therapy or can be reserved for patients who fail oral therapies and anti-TNF-α agents.[30] Vedolizumab can also be combined with an immunomodulator and continued as maintenance therapy once remission is achieved.

Patient Encounter 2, Part 1

A 21-year-old African-American woman presents to the gastroenterology clinic because of a 1-month history of crampy abdominal pain and two to three loose stools 3 to 4 days per week. She denies vomiting, fever, or chills, and has missed several days of school and work in the past 2 weeks.

What other pertinent information from the history would be beneficial to help determine the cause of her symptoms?

What additional information would you obtain prior to recommending drug therapy?

▶ High-Risk UC in Inpatients

LOS Patients with severe or high-risk UC symptoms generally require hospitalization. If the patient is unresponsive to mesalamine and oral corticosteroids, a course of IV corticosteroids should be initiated.[1] Hydrocortisone 300 mg/day IV given in three divided doses or methylprednisolone 60 mg IV once daily for 7 to 10 days are recommended.[1,22,35] Infliximab is also an option for severe UC in high-risk inpatients. If remission with steroids is achieved, then a thiopurine with or without an anti-TNF agent, or vedodlizumab with or without an immunomodulator are maintenance options. Cyclosporine 2 to 4 mg/kg/day given as a continuous IV infusion can be used as inductive therapy but is often reserved for patients unresponsive to 7 to 10 days of IV corticosteroid therapy.

▶ Maintenance of Remission in UC

Unfortunately, up to 50% of patients receiving oral therapies and up to 70% of untreated patients relapse within 1 year after achieving remission.[37] For this reason, patients may require maintenance drug therapy indefinitely to preserve remission.

LOS KEY CONCEPT Maintenance of remission of UC may be achieved with oral or topical aminosalicylates. In low-risk patients with proctitis, mesalamine suppositories 1 g daily may prevent relapse in up to 90% of patients.[1,7,35] Mesalamine enemas are appropriate for left-sided disease and may often be dosed two to three times weekly. Oral mesalamine at lower doses (eg, 1.2–1.6 g/day) may be combined with topical therapies to maintain remission.

Oral sulfasalazine or mesalamine is effective in maintaining remission in low-risk patients with more extensive disease.[1,6] Lower daily doses (eg, 2–4 g sulfasalazine or 2–2.4 g mesalamine) may be used for disease maintenance. Oral or topical corticosteroids are not effective for maintaining remission and should be avoided due to the high incidence of adverse effects. Systemic corticosteroids and budesonide should be tapered over 60 days in low-risk patients achieving remission.[37]

LOS KEY CONCEPT Immunomodulators (eg, azathioprine, 6-MP), anti-TNF agents (eg, infliximab, adalimumab, golimumab), or vedolizumab can be used to maintain UC remission in unresponsive patients or those who develop corticosteroid dependency. Intermittent anti-TNF agent dosing may be used to maintain remission and reduce the need for corticosteroids in patients with moderate to severe UC. Combining a thiopurine and anti-TNF agent may be more effective initially, and patients may be able to be transitioned to azathioprine monotherapy. Vedolizumab may be used as an alternate maintenance option if patients had a favorable response to induction therapy and may be combined with azathioprine or methotrexate.[30,35] Colectomy is an option for patients with progressive disease who cannot be maintained on drug therapy alone.

▶ Treatment of CD

LOS See Table 19–5 for a summary of the AGA treatment recommendations for CD based on risk level.

▶ Low-Risk Active CD

LOS KEY CONCEPT Induction of remission in low-risk patients with mild to moderate active CD may be accomplished with oral budesonide, with or without azathioprine, in patients with ileal and/or proximal colonic involvement and no to minimal systemic symptoms, or a tapering course of prednisone with or without azathioprine in patients with diffuse or left colonic involvement. Budesonide 9 mg orally once daily for up to 8 weeks

Table 19–5

Crohn Disease Initial Inductive and Maintenance Therapy Based on Risk

Risk Level	Inductive Therapy	Maintenance Therapy (Remission)
Low risk	1. Ileum and/or proximal colon with none to minimal systemic symptoms. Options: • Oral budesonide 9 mg/day without or without azathioprine • Tapering course of prednisone with or without azathioprine 2. Diffuse or left colon with none to minimal systemic symptoms. Options: • Tapering course of prednisone with or without azathioprine	Options: • Stop therapy and observe (high chance of relapse over 1 year) • Oral budesonide 6 mg/day (prolongs median time to relapse by about 114 days, but no difference in remission rates vs. placebo at 1 year) • Immunosuppressive therapy (azathioprine, mercaptopurine, and methotrexate are effective in maintaining prednisone- or prednisolone-induced remissions but are associated with rare risk of infection and lymphoma)
Moderate to high risk	Moderately severe Crohn disease. Options: • Systemic corticosteroids • Use anti-TNF monotherapy over no therapy or thiopurine monotherapy • Use anti-TNF agent plus thiopurine over monotherapy with either thiopurine or anti-TNF agent • Use methotrexate for patients who do not tolerate thiopurine plus anti-TNF agent	Options: • Steroid-induced remission: Use thiopurine or methotrexate over no immunomodulator; **or** use anti-TNF agent with or without thiopurine over no anti-TNF agent • Anti-TNF alone or anti-TNF plus thiopurine-induced remission: Use anti-TNF agent with or without thiopurine over no anti-TNF agent

Thiopurine = azathioprine or mercaptopurine.

Anti-TNF agent = adalimumab, certolizumab, golimumab, infliximab.

Adapted from: Sandborn WJ. Crohn's disease evaluation and treatment: clinical decision tool. Gastroenterology. 2014;147:702–705.

is effective for low-risk, active CD in patients with involvement of the terminal ileum or ascending colon, with success expected in 50% to 69% of patients.[3,22,37,39] Because the formulation releases budesonide in the terminal ileum, it is not effective in reaching sites distal to the ascending colon.[39] Conventional oral corticosteroids (eg, prednisone, methylprednisolone) may also be used with or without an immunomodulator and are preferred if there is diffuse or left-sided disease.[39] However, other oral corticosteroids carry a higher risk of adverse effects than budesonide.[6]

Sulfasalazine or mesalamine products have demonstrated minimal efficacy in patients with ileal, ileocolonic, or colonic CD due to their more favorable adverse effect profile when compared to corticosteroids.[2,3,40]

Metronidazole or ciprofloxacin can be used in patients who do not respond to budesonide or oral aminosalicylates. Response rates of up to 50% are reported, but data are conflicting, and these agents should generally not be considered first-line therapy.[2,3,32,39]

▶ *Moderate- to High-Risk Active CD*

LO 5

Patients with moderate- to high-risk CD may be treated with oral corticosteroids (eg, prednisone 40–60 mg daily). Per the AGA recommendations (Table 19–5), moderately severe patients can be treated with anti-TNF monotherapy or anti-TNF therapy combined with a thiopurine. Methotrexate can be used in patients who do not tolerate purine therapy.

For patients with perianal fistulae, antibiotics (metronidazole or ciprofloxacin), infliximab, adalimumab, and certolizumab are appropriate treatment options. Complex perianal fistulae may require surgical intervention but may also be amenable to treatment with antibiotics, azathioprine, 6-MP, or anti-TNF-α agents.[15,22,26,27]

Many patients with severe CD require hospitalization for appropriate treatment. Patients should be assessed for possible surgical intervention if abdominal distention, masses, abscess, or obstruction are present. Daily IV doses of corticosteroids equivalent to prednisone 40 to 60 mg may be tried as initial therapy to rapidly suppress severe inflammation.

LO 5

Anti-TNF agents or vedolizumab may be used in severe active CD. Anti-TNF therapy can be combined with a thiopurine for increased effectiveness. Patients failing to respond should have drug trough concentrations and anti-drug antibodies assessed if anti-TNF agents are being used. Depending on the outcome this may necessitate a dose increase or a switch to another drug within the class. Ustekinumab is generally reserved for outpatients with severe disease who have failed other traditional therapies.

Adjunctive therapy with fluid and electrolyte replacement should be initiated. Nutritional support with enteral or parenteral nutrition may be indicated for patients unable to eat for more than 5 to 7 days.[2] Limited evidence indicates that cyclosporine, or possibly tacrolimus, may be effective as salvage therapy for patients who fail IV corticosteroid therapy.[2,3,26] Surgical intervention may ultimately be necessary for medically refractory disease.

▶ *Maintenance of Remission in CD*

Patients with CD are at high risk for disease relapse after induction of remission. Within 2 years, up to 80% of patients experience a relapse; therefore, many patients require indefinite maintenance therapy. KEY CONCEPT Maintenance of remission of CD may be achieved with immunosuppressants (azathioprine, 6-MP, or methotrexate), biologic agents (infliximab, adalimumab, certolizumab pegol, or vedolizumab), and less frequently with oral or topical aminosalicylate derivatives.

LO 5

In contrast to their use in UC, sulfasalazine and the newer aminosalicylates are marginally effective in preventing CD relapse in patients with medically induced remission, with success rates of only 10% to 20% at 1 year.[3,37,39,40] Despite not being

recommended as first-line therapy, aminosalicylates are routinely used to attempt maintenance of remission of CD.

The anti-TNF agents are effective in maintaining remission in CD.[26,27] Azathioprine and 6-MP in oral doses up to 2.5 mg/kg/day have been shown to maintain remission in 45% of patients for up to 5 years.[22,25–27] The immunomodulators azathioprine and 6-MP may be preferred for maintenance following a steroid-induced remission. There is evidence to support use of combination therapy with an anti-TNF agent plus azathioprine or methotrexate to maintain remission in CD in patients achieving steroid-induced remission.[26,27,39] Anti-TNF agents are preferred for patients with surgically induced remission and may also be combined with azathioprine in this situation.[42] Vedolizumab or ustekinumab may be used for maintenance in patients unresponsive to anti-TNF-α agents.[29–31]

Patients not responding to anti-TNF agents should have drug trough levels obtained and be assessed for presence of antibodies.[43] Dose escalation or switching to another anti-TNF agent may be required. Similarly, evaluation of azathioprine metabolites, particularly 6-thioguanine, should be performed to evaluate the need for dose escalation if there is lack of response or in the setting of potential thiopurine toxicity.[35,44]

Systemic or topical corticosteroids should not be used for maintaining remission in patients with CD. Unfortunately, up to 50% of patients treated acutely with corticosteroids become dependent on them to prevent symptoms.[2] Budesonide 6 mg (2 × 3-mg Entocort capsules) orally once daily may be used in place of conventional corticosteroids for up to 3 months after remission induction in mild to moderate CD or in patients dependent on corticosteroids.[3,22,23]

Treatment of IBD in Special Populations (Table 19–6)

▶ *Older Persons*

Approximately 10% to 30% of patients with IBD initially develop symptoms after age 60.[45] In general, IBD presents similarly in older patients and younger individuals. Elderly patients may have more comorbid diseases, some of which may make the diagnosis of IBD more difficult. Such conditions include ischemic colitis, diverticular disease, and microscopic colitis. Increased age is also associated with a higher incidence of adenomatous polyps, but the onset of IBD at an advanced age does not appear to increase the risk of developing colorectal cancer. Older patients may also use more medications, particularly NSAIDs, which may induce or exacerbate colitis. Adherence may be more challenging for older patients, especially for injectable products, and costs of some agents may be problematic depending on the patient's financial or insurance situation.

LOS

Treatment of older patients with IBD is similar to that for younger patients, but special consideration should be given to some of the medications used. Corticosteroids may worsen diabetes, hypertension, heart failure, or osteoporosis. The TNF-α inhibitors should be used cautiously in patients with heart failure and should be avoided in New York Heart Association class III or IV disease. Older patients requiring major surgical interventions

Patient Encounter 2, Part 2: Medical History and Physical Examination

PMH: Migraine headaches, UTI

FH: Both parents alive; father has a history of hypertension; mother has a history of migraines

SH: College student (majoring in elementary education); social alcohol use; no tobacco use

Allergies: Sulfa (rash)

Meds: Sumatriptan subcutaneous as needed, ibuprofen as needed

ROS: (+) Diarrhea, abdominal pain

PE:

VS: BP 121/72 mm Hg, P 101 beats/min, RR 17/min, T 37.7°C (99.8°F)

CV: Tachycardia with normal rhythm. No murmurs, rubs, or gallops

HEENT: Slightly dry mucous membranes

Skin: No evidence of tenting

Abd: Soft, nondistended, mild diffuse tenderness, (+) bowel sounds, (–) hepatosplenomegaly, (–) masses, heme (+) stool

MS: 5/5 strength in upper and lower extremities; normal ROM

Labs:

Sodium 135 mEq/L (mmol/L)
Potassium 3.3 mEq/L (mmol/L)
Chloride 98 mEq/L (mmol/L)
AST 22 IU/L (0.36 µkat/L)
ALT 22 IU/L (0.36 µkat/L)
Albumin 4.0 g/dL (40 g/L)
Bicarbonate 26 mEq/L (mmol/L)
BUN 15 mg/dL (5.4 mmol/L)
Serum creatinine 1 mg/dL (88 µmol/L)
Glucose 100 mg/dL (5.6 mmol/L)
Hemoglobin 10 g/dL (100 g/L; 6.21 mmol/L)
Hematocrit 34% (0.34)
WBC 18.0 × 10^3/mm^3 (10^9/L)
Platelets 490 × 10^3/mm^3 (10^9/L)
CRP 3.5 mg/dL (35 mg/L)
A1C 5% (0.05; 31 mmol/mol Hb)
ESR 115 mm/hour

Abdominal x-ray: (–) obstruction, free-air, or colonic dilation

Colonoscopy: Patchy inflammation involving the terminal ileum with evidence of recent bleeding, (–) polyps or strictures, biopsy taken

Pathology: Evidence of granuloma and PMN infiltration

How is this additional information helpful in determining disease extent and location?

What factors should you consider in choosing appropriate therapy for this patient?

What treatment options would you consider at this time?

What are some important educational points you would provide to this patient regarding appropriate use of her medication?

Table 19–6

Dosing Considerations of IBD Therapies in Special Populations

Therapy	Pediatric Patients	Elderly Patients	Pregnancy[44–46]
Sulfasalazine	Age > 2 years: 40–60 mg/kg/day in 3–6 divided doses; 30 mg/kg/day in 3–6 divided doses for maintenance	No specific changes	Category B[a] Administer folic acid 2 mg daily during prenatal period and pregnancy
Mesalamine	No specific changes; Balsalazide indicated for age > 5 years	No specific changes	Category B (Olsalazine Category C) Generally considered safe and effective
Corticosteroids	No specific changes	No specific changes Elderly patients at high risk for osteoporosis	Older agents not rated Budesonide category C Generally considered safe and effective
TNF-α inhibitors	Infliximab indicated for pediatric patients: 5 mg/kg at 0, 2, and 6 weeks, then every 8 weeks Adalimumab indicated for patients age ≥ 6 or greater: 80 mg (< 40 kg), 40 mg week 2, then 20 mg every other week or 160 mg (> 40 kg) initial followed by 80 mg week 2, then 40 mg every other week	Avoid in patients with heart failure Elderly patients at higher risk for infections	Category B Pregnancy registry for adalimumab via manufacturer
Natalizumab	Dose of 3 mg/kg IV at 0, 4, and 8 weeks reported; data are lacking in children	No specific changes	Category C Report pregnancy to manufacturer's pregnancy registry
Vedolizumab	Not indicated	No specific changes	Category B Manufacturer pregnancy exposure registry
Ustekinumab	Not indicated	No specific changes	Manufacturer pregnancy exposure registry
Azathioprine 6-Mercaptopurine	1.5–2 mg/kg/day to start	No specific changes	Category D Accepted as safe Avoid initiating during pregnancy, but continue if patient is already receiving when pregnant
Methotrexate	17 mg/m^2 orally/SC/IM	No specific changes	Category X Contraindicated
Cyclosporine	No specific changes	No specific changes	Category C Use only in refractory patients
Metronidazole	30–50 mg/kg/day divided every 6 hours	No specific changes	Category B Use short courses if possible
Ciprofloxacin	Avoid use	Adjust dose for CrCl < 50 mL/min (0.83 mL/s)	Category C Consider other alternatives

[a]In 2015, the FDA recommended that the pregnancy categories be replaced with narrative recommendations to better inform clinical decision making. Drugs submitted for approval after June 30, 2015 will use this new designation immediately, whereas those approved after June 30, 2001 will be gradually phased in (https://www.drugs.com/pregnancy-categories.html).

CrCl, creatinine clearance; IM, intramuscular; SC, subcutaneously.

may be at higher risk for surgical complications or may not meet eligibility criteria for surgery because of comorbid conditions, age-related organ dysfunction, or reduced functional status.[45]

► *Children and Adolescents*

Approximately 50,000 individuals younger than 20 years of age in the United States have IBD, which represents 5% of all IBD patients. CD occurs twice as frequently as UC in children.[46,47] A major issue in children with IBD is the risk of growth failure secondary to inadequate nutritional intake and corticosteroid therapy. Failure to thrive may be an initial presentation of IBD in this population. Aggressive nutritional interventions may be required to facilitate adequate caloric intake. Chronic corticosteroid therapy may also be associated with reductions in growth and bone demineralization. Using lower doses in patients who are corticosteroid dependent may reduce altered height velocity.[46] Guidelines for management of acute severe UC in children favor methylprednisolone as first-line therapy, with calcineurin inhibitors or infliximab used for unresponsive patients.[47]

LO 5

The aminosalicylates, azathioprine, 6-MP, and infliximab are all viable options for treatment and maintenance of IBD in pediatric patients. Infliximab is approved for use in the United States for patients 6 to 17 years of age with moderate to severe active CD. Use of immunosuppressive therapy or infliximab may help reduce overall corticosteroid exposure. Adalimumab is also approved for use in patients 6 years of age or older with CD. Certolizumab, natalizumab, vedolizumab, and ustekinumab are only FDA approved for use in adults with IBD; data in children are limited.[49]

► *Pregnant Women*

Inducing and maintaining remission of IBD prior to conception is the optimal approach in women planning to become

pregnant. Pregnant women with IBD are at higher risk of spontaneous abortion, preterm birth, low birth weight infants, and complications of delivery such as preeclampsia and liver and platelet disorders.[48,49] Given these implications, preconception counseling should be provided, and good communication among medical providers is necessary. Vaccination schedules should be updated and disease severity assessed.

LO 5 Patients do not need to discontinue drug therapy for IBD once they become pregnant. Maintenance medications may generally be continued, but certain adjustments may be required.[4] The aminosalicylates are considered safe in pregnancy, but sulfasalazine is associated with folate malabsorption. Because pregnancy results in a higher folate requirement, pregnant patients treated with sulfasalazine should be supplemented with folic acid 1 mg orally twice daily. Asacol-HD contains dibutyl phthalate, which has been implicated in fetal defects; therefore, this product should be switched to an alternate mesalamine formulation.[48] Methotrexate is a known abortifacient and should be discontinued prior to patients becoming pregnant and an alternate medication initiated.

As pregnancy progresses, there is a potential risk of increased placental transfer of biologic drugs. Recommendations are to modify the dosing schedule in the third trimester to allow for the last dose to be given as far in advance of delivery as possible to reduce placental transfer.[48] This may require evaluation of trough concentrations of the anti-TNF agents.[44] Metronidazole carries a theoretical risk of mutagenicity in humans, but short courses are safe during pregnancy. Prolonged use of metronidazole should be avoided in pregnant patients due to lack of safety data supporting its use. Ciprofloxacin should be avoided in pregnant women. Lastly, the safety of continuing current therapies for IBD should be evaluated if the patient is considering breastfeeding to assess potential risk if the drugs are transferred into breastmilk.

OUTCOME EVALUATION

LO 6

- Monitor for improvement of symptoms in patients with active IBD, such as reduction in the number of daily stools, abdominal pain, fever, and heart rate.
- For patients in remission, assure that proper maintenance doses are used and inform the patient to seek medical attention if symptoms recur or worsen.
- Evaluate patients receiving systemic corticosteroid therapy for improvement in symptoms and opportunities to taper or discontinue therapy. For patients using more than 5 mg daily of prednisone for more than 2 months or for steroid-dependent patients consider the following:
  - Central bone mineral density testing to evaluate need for calcium, vitamin D, or bisphosphonate therapy
  - Periodic monitoring of blood glucose, lipids, and blood pressure
  - Evaluation for evidence of Cushingoid features or signs or symptoms of infection
- When considering treatment with azathioprine or 6-MP, obtain baseline complete blood count (CBC), liver function tests, and TPMT activity. These tests, except TPMT, should be monitored closely (every 2–4 weeks) at the start of therapy and then approximately every 3 months during maintenance therapy.

Patient Care Process

Collect the Information:

- Evaluate the medical record to determine the extent and location of IBD.
- Assess for evidence of extraintestinal manifestations or GI complications related to IBD.
- Interview the patient to evaluate the impact on quality of life and to identify psychosocial problems related to the presence of IBD.

Assess the Information:

- Assess inflammatory status, severity, and classify as high vs. low risk for colectomy.
- Determine if the patient is treatment-naive or if they are currently receiving pharmacotherapy.
- Evaluate the patient's current medication doses and adherence to therapy. Identify potential barriers to adherence, such as cost or inability to properly use certain drug formulations.
- Identify adverse effects related to current therapy.

Develop a Care Plan:

- Based on the current therapy and disease severity and location, choose appropriate drug(s) and formulations to target the regions of intestinal inflammation.
- Process any prior authorizations for insurance providers that require this.

Implement the Care Plan:

- Remove or switch medications that may be exacerbating IBD symptoms.
- Educate the patient on proper use of drug therapy, including when to expect symptom improvement after initiation of treatment and which signs or symptoms to report that might be adverse drug effects.
- Provide a detailed description of the tapering schedule for corticosteroids if applicable.
- Refer patients to available support groups or IBD organizational resources if they are having difficulty coping with their disease.

Follow-up: Monitor and Evaluate:

- Depending on disease severity, follow up in 2 to 4 weeks. Earlier telephone follow-up may be required to determine whether the patient is achieving some relief of symptoms.
- Assess adherence to therapy and determine if drug concentrations should be evaluated if lack of response is present.
- Assess patient quality of life and impact of treatment on ability to perform daily activities.

- With azathioprine and 6-MP, monitor for hypersensitivity reactions including severe skin rashes and pancreatitis. Educate the patient regarding signs and symptoms of pancreatitis (nausea, vomiting, and abdominal pain).
- Prior to initiating methotrexate therapy, obtain CBC, serum creatinine, liver function tests, chest x-ray, and pregnancy test (if female). Monitor blood counts weekly for 1 month, then monthly thereafter.
- Prior to initiating anti-TNF therapy, ustekinumab, or vedolizimab, obtain a tuberculin skin test to rule out latent tuberculosis, monitor for signs and symptoms of tuberculosis, and measure viral hepatitis serologies. Also monitor patients with a prior history of hepatitis B virus infection for signs of liver disease, such as jaundice. Assure that patients do not have a clinically significant systemic infection or New York Heart Association class III or IV heart failure.
- In patients receiving infliximab, monitor for infusion-related reactions such as hypotension, dyspnea, fever, chills, or chest pain when administering IV doses.
- Recommended trough concentrations for anti-TNF biologic agents are infliximab ≥ 5 mcg/mL (mg/L), adalimumab ≥ 7.5 mcg/mL (mg/L), and certolizumab ≥ 20 mcg/mL (mg/L).[44]
- In patients with fistulae, monitor at every anti-TNF therapy dosing interval for evidence of fistula closure and overall reduction in the number of fistulae.
- If receiving natalizumab or vedolizumab therapy, monitor for signs of PML such as mental status changes, signs of liver disease (eg, jaundice), and hypersensitivity reactions following administration.

Abbreviations Introduced in This Chapter

5-ASA	5-Aminosalicylate
6-MP	6-Mercaptopurine
CD	Crohn disease
CRP	C-reactive protein
ESR	Erythrocyte sedimentation rate
HLA	Human leukocyte antigen
IBD	Inflammatory bowel disease
IL	Interleukin
NSAID	Nonsteroidal anti-inflammatory drug
pANCA	Perinuclear antineutrophil cytoplasmic antibodies
PR	Per rectum
TNF-α	Tumor necrosis factor-α
TPMT	Thiopurine methyltransferase
UC	Ulcerative colitis

20 Nausea and Vomiting

Sheila Wilhelm and Melissa Lipari

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify common causes of nausea and vomiting.
2. Describe the pathophysiologic mechanisms of nausea and vomiting.
3. Distinguish between simple and complex nausea and vomiting.
4. Create goals for treating nausea and vomiting.
5. Describe attributes of available antiemetic therapies.
6. Recommend treatment regimens for nausea and vomiting associated with cancer chemotherapy, surgery, pregnancy, or motion sickness.
7. Outline a monitoring plan to evaluate treatment outcomes for nausea and vomiting.

INTRODUCTION

Nausea and vomiting result from complex interactions of the gastrointestinal (GI) system, the vestibular system, and the brain and have a variety of causes. Preventing and treating nausea and vomiting requires pharmacologic and nonpharmacologic measures tailored to individual patients and situations.

EPIDEMIOLOGY AND ETIOLOGY

LO 1

KEY CONCEPT Nausea and vomiting are symptoms that can be due to many different causes such as GI, cardiac, neurologic, and endocrine disorders and various medications (Table 20–1).[1,2] Cancer chemotherapy agents are rated according to their emetogenic potential, and antiemetic therapy is prescribed based on these ratings. Radiation therapy can induce nausea and vomiting, especially when it is used to treat abdominal malignancies.[3]

Oral contraceptives, hormone therapy, and opioids can cause nausea and vomiting.[1] Some medications, such as digoxin, cause nausea and vomiting in a dose-related fashion, which may indicate excessive drug concentrations. Ethanol and other toxins also cause nausea and vomiting.

Postoperative nausea and vomiting (PONV) occurs in 30% of surgical patients overall and in up to 70% of high-risk patients.[4] Risk factors for PONV include female sex, history of motion sickness or PONV, nonsmoking status, and use of opioids postoperatively.[5] The choice of anesthetic agents and duration of surgery may also contribute to PONV.[4,5]

Nausea and vomiting of pregnancy (NVP) affects 70% to 85% of pregnant women, especially early in pregnancy.[6] In 0.3% to 3% of pregnancies, this can lead to **hyperemesis gravidarum**, a potentially life-threatening condition of prolonged nausea, vomiting, and resultant malnutrition.[6]

PATHOPHYSIOLOGY

Nausea is the unpleasant subjective feeling of the need to vomit.[1,2] Autonomic symptoms of pallor, tachycardia, diaphoresis, and salivation often accompany nausea. Vomiting (or emesis) is a forceful oral expulsion of upper GI contents due to sustained contractions in the abdominal and thoracic musculature.[1]

LO 2

Specific areas in the central nervous system (CNS) and GI tract are stimulated when the body is exposed to noxious stimuli or GI irritants: the **chemoreceptor trigger zone (CTZ)** in the area postrema of the fourth ventricle of the brain, the vestibular apparatus, visceral afferents from the GI tract, and the cerebral cortex.[1] These in turn stimulate regions of the reticular areas of the medulla within the brainstem. This area is the central vomiting center, which coordinates the impulses sent to the salivation and respiratory centers, and the pharyngeal, GI, and abdominal muscles that lead to vomiting (Figure 20–1).[7]

The CTZ, located outside the blood–brain barrier, is exposed to cerebrospinal fluid and blood.[1] Therefore, it is easily stimulated by uremia, acidosis, and circulating toxins such as chemotherapeutic agents. The CTZ has many 5-hydroxytryptamine (serotonin) type 3 (5-HT_3), neurokinin-1 (NK_1), and dopamine (D_2) receptors.[8] Visceral vagal nerve fibers are rich in 5-HT_3 receptors. They respond to GI distention, mucosal irritation, and infection.

Motion sickness is caused by stimulation of the vestibular system, rich in histaminic (H_1) and muscarinic cholinergic receptors.[9] The cerebral cortex is affected by sensory input such as sights, smells, or emotions that can lead to vomiting. This area is involved in anticipatory nausea and vomiting associated with chemotherapy.

LO 3

Nausea and vomiting can be classified as either simple or complex.[10] Simple nausea and vomiting occurs occasionally and is either self-limiting or relieved by minimal therapy. It does not detrimentally affect hydration status, electrolyte balance, or weight. Alternatively, complex nausea and vomiting requires more aggressive therapy because electrolyte imbalances, dehydration, and weight loss may occur.

CLINICAL PRESENTATION AND DIAGNOSIS

Refer to the accompanying box for the clinical presentation and diagnosis of nausea and vomiting.

Table 20–1

Causes of Nausea and Vomiting

GI or Intraperitoneal	Cardiac	Neurologic	Therapy or Toxin Induced	Endocrine/Metabolic
Mechanical obstruction	Cardiomyopathy	Vestibular disease	Antibiotics	Pregnancy (NVP or hyperemesis gravidarum)
Achalasia	Myocardial infarction	Motion sickness	Antiarrhythmics	Uremia
Enteric infections	Heart failure	Labyrinthitis	Aspirin	Diabetic ketoacidosis
Pancreatitis		Migraine headache	Cancer chemotherapy	Hyperthyroidism
Inflammatory bowel disease		Increased intracranial pressure	Digoxin	Parathyroid disease
Irritable bowel syndrome		Intracranial hemorrhage	Iron	Addison disease
Cholecystitis		Meningitis	Lead	
Hepatitis		Hydrocephalus	Marijuana	
Gastroparesis		Psychogenic causes	Oral antidiabetics	
Gastroesophageal reflux		Eating disorders	Oral contraceptives	
Peptic ulcer disease		Depression	Opioids	
Peritonitis		Anxiety disorders	Anticonvulsants	
			Radiation therapy	
			Ethanol	

TREATMENT

Desired Outcomes

LO 4

The primary goals of treatment are to relieve the symptoms of nausea and vomiting, increase quality of life, and prevent complications such as dehydration or malnutrition. Drug therapy for nausea and vomiting should be safe, effective, and economical.

General Approach to Treatment

KEY CONCEPT To treat nausea and vomiting most effectively, it is important to first identify and treat the underlying cause. Profuse or prolonged vomiting can lead to complications of dehydration and metabolic abnormalities. Patients must have adequate hydration and electrolyte replacement orally (if tolerated) or IV to prevent and correct these problems. Some pharmacologic treatments work locally in the GI tract, whereas others work in the CNS.[1]

Nonpharmacologic Therapy

KEY CONCEPT Nonpharmacologic approaches to nausea and vomiting include dietary, physical, and psychological measures. Dietary management is important when treating NVP due to concern for teratogenic effects with drug therapies.[11] Recommendations include eating frequent, small meals; avoiding spicy or fatty foods; eating high-protein snacks; avoiding iron-containing pills; and eating bland or dry foods the first thing in the morning.[6,11] The dietary supplement ginger (500–1000 mg daily given in three to four divided doses) was effective in NVP in some studies and is recommended in treatment guidelines.[6,11]

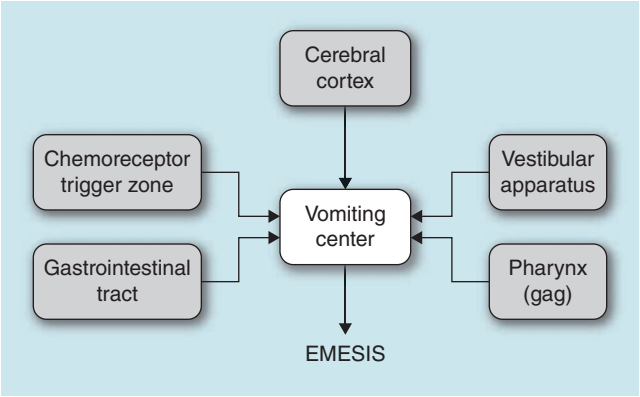

FIGURE 20–1. Primary afferent components to the vomiting center. (Reproduced, with permission, from Toy EC, Loose DS, Tischkau SA, Pillai AS, eds. Case Files: Pharmacology. 3rd ed. New York, NY: McGraw-Hill; 2014.)

Clinical Presentation and Diagnosis of Nausea and Vomiting

Symptoms

- Patients with nausea often complain of autonomic symptoms such as diaphoresis, disinterest in surroundings, pallor, faintness, and salivation.

Signs

- With complex and prolonged nausea and vomiting, patients may show signs of malnourishment, weight loss, and dehydration (dry mucous membranes, skin tenting, tachycardia, and lack of axillary moisture).

Laboratory Tests

- Dehydration, electrolyte imbalances, and acid–base disturbances may be evident in complex and prolonged nausea and vomiting.
- Dehydration is suggested by elevated blood urea nitrogen (BUN), serum creatinine (SCr), and BUN-to-SCr ratio (20:1 or greater using traditional units of measurement [100:1 or greater using SI units of mmol/L]).
- Calculated fractional excretion of sodium (FeNa) less than 1% (0.01) indicates dehydration and reduced renal perfusion.
- Low serum chloride and elevated serum bicarbonate levels indicate metabolic alkalosis.
- Hypokalemia may occur from GI potassium losses and intracellular potassium shifts to compensate for alkalosis.

Acupressure and electroacupoint stimulation of the P6 (Neiguan) point on the inside of the wrist seem safe and cost-effective; however, efficacy data for treatment of NVP, PONV, and motion sickness are conflicting.[6,12,13] Hypnosis and psychotherapy are also safe during pregnancy and in situations where adverse drug effects and interactions are a concern.

Pharmacologic Therapy

LO 5

Table 20–2 contains the names, usual dosages, and common adverse effects of the pharmacologic treatments for nausea and vomiting.[1,4,10,14]

▶ *Anticholinergics (Scopolamine)*

Scopolamine blocks muscarinic receptors in the vestibular system, thereby halting signaling to the CNS. It is effective for preventing and treating motion sickness and has some efficacy in preventing PONV.[15] Scopolamine is available as an adhesive transdermal patch that is effective for up to 72 hours after application. This may be beneficial for patients unable to tolerate oral medications or those requiring continuous prevention of motion sickness (eg, passengers on cruise ships). Transdermal scopolamine should be applied 4 hours prior to motion sickness triggers and the evening before surgery if used to prevent PONV. Scopolamine is associated with adverse anticholinergic effects such as sedation, visual disturbances, dry mouth, and dizziness. These adverse effects are worsened when a patient is taking concurrent anticholinergic agents, and these agents should be used with caution in older adults.

▶ *Antihistamines*

Antihistamines are used to prevent and treat nausea and vomiting due to motion sickness, vertigo, or migraine headache.[1,9,16] Their efficacy is presumably due to the high concentration of H_1 and muscarinic cholinergic receptors within the vestibular system. First-generation antihistamines cause undesired effects including drowsiness, blurred vision, and urinary retention. Although first-generation antihistamines are effective, the second-generation antihistamines cetirizine and fexofenadine were found to be ineffective for treating motion sickness, perhaps because they lack CNS depressant properties.[17]

Some first-generation antihistamines such as diphenhydramine, dimenhydrinate, doxylamine, and meclizine are available without a prescription, making self-treatment convenient. The combination of doxylamine and vitamin B6 (pyridoxine) has efficacy in NVP. Antihistamines are available in a variety of dosage forms, including oral capsules, tablets, and liquids. Liquid formulations are convenient for children or adults who are unable to swallow solid dosage forms.

▶ *Dopamine Antagonists*

Stimulation of D_2 receptors in the CTZ leads to nausea and vomiting (Figure 20–1). There are three main groups of dopamine antagonists: phenothiazines, butyrophenones, and prokinetic agents. Phenothiazine antiemetics act primarily via a central antidopaminergic mechanism in the CTZ.[1] Phenothiazines used to treat nausea and vomiting include promethazine, prochlorperazine, and chlorpromazine. Availability in multiple dosage forms (ie, oral, parenteral, rectal) permits use in a variety of settings including severe motion sickness or vertigo, gastritis or gastroenteritis, NVP, PONV, and chemotherapy-induced nausea and vomiting (CINV).[18,19]

Phenothiazines may cause sedation, orthostatic hypotension, and **extrapyramidal symptoms (EPS)** such as dystonia (involuntary muscle contractions), tardive dyskinesia (irreversible and permanent involuntary movements), and akathisia (motor restlessness or anxiety).[1,20] Chronic phenothiazine use has been associated with EPS, but single doses have also caused these effects.[21] Promethazine intravenous injection should not be administered in an undiluted bolus because this may lead to tissue necrosis requiring limb amputation.[20] The highest risk for this adverse event is when the medication is administered intraarterially.

Droperidol, a butyrophenone, is another centrally acting antidopaminergic agent effective for preventing PONV.[1,4] It may also be used for treating CINV for patients who are intolerant to serotonin receptor antagonists and corticosteroids.[14] Its adverse effects include sedation, agitation, and restlessness. Droperidol carries a US FDA black box warning regarding the potential for QT interval prolongation and cardiac arrhythmias that may result in torsades de pointes and sudden cardiac death.[22] Droperidol should not be used in patients with a prolonged QT interval or in those who are at risk for developing a prolonged QT interval (eg, heart failure, electrolyte abnormalities, or taking other medications concurrently that may prolong the QT interval).[22] A 12-lead electrocardiogram (ECG) is recommended prior to treatment with droperidol.

Haloperidol is another butyrophenone with some antiemetic effects at low doses (0.5–2 mg).[23] It has been explored as an alternative to droperidol.[24]

Metoclopramide and domperidone (not available in the United States) act as D_2-receptor antagonists centrally in the CTZ and peripherally in the GI tract.[1] They also display cholinergic activity, which increases lower esophageal sphincter tone and promotes gastric motility. Their antiemetic and prokinetic effects are useful in PONV, CINV, gastroparesis, and gastroesophageal reflux disease (GERD).[1,4,14] Metoclopramide is available in injectable, oral solid, and oral liquid dosage forms, allowing for its use in both hospitalized and ambulatory patients.

Metoclopramide crosses the blood–brain barrier and has centrally mediated adverse effects. Young children and the elderly are especially susceptible to these effects, which include somnolence, reduced mental acuity, anxiety, depression, and EPS and occur in 10% to 20% of patients.[1,25]

Domperidone minimally crosses the blood–brain barrier and is less likely to cause centrally mediated adverse effects.[1,25] It should not be used for patients with underlying long QT interval or for those taking medications that prolong the QT interval. Both metoclopramide and domperidone can cause hyperprolactinemia, galactorrhea, and gynecomastia.

▶ *Corticosteroids*

Oral or IV corticosteroids, especially dexamethasone and methylprednisolone, are used alone or in combination with other antiemetics for preventing and treating PONV, CINV, or radiation-induced nausea and vomiting.[3,8,14,23] Efficacy is thought to be due to release of 5-HT, reduced permeability of the blood–brain barrier, and decreased inflammation.[26] Common adverse effects with short-term use include GI upset, anxiety, insomnia, and hyperglycemia.[14] Adverse effects associated with long-term use (eg, decreased bone mineral density, diabetes, cataracts) are not usually seen when corticosteroids are used for acute nausea and vomiting.

▶ *Cannabinoids*

Cannabinoids have antiemetic and appetite stimulant activity when used alone or in combination with other antiemetics.[27]

Table 20–2

Antiemetic Agents: Usual Doses for Adults and Children and Adverse Effects

Drug	Adult Dosing	Pediatric Dosing	Adverse Effects[a]
Anticholinergics			
Scopolamine	TD: 1.5 mg patch applied 1 or more hours before the procedure, 4 hours prior to motion sickness triggers, repeated every 72 hours as needed	N/A	Most common: Dry mouth, drowsiness, blurred vision Rare: Disorientation, dizziness, hallucinations
Antihistamines			
Cyclizine	Oral: 50 mg every 4–6 hours as needed	Oral: 6–11 years: 25 mg every 6–8 hours as needed (max: 3 tablets per day)	Most common: Sedation, dry mouth, constipation Less common: Confusion, blurred vision, urinary retention
Dimenhydrinate	Oral: 50–100 mg every 4–6 hours as needed	Oral: 2–6 years, 12.5–25 mg every 6–8 hours not to exceed 75 mg in 24 hours; 6–12 years, 25–50 mg every 6–8 hours, not to exceed 150 mg in 24 hours	
Diphenhydramine	Oral: 25–50 mg every 4–6 hours IV/IM: 10–50 mg every 2–4 hours as needed	Oral/IV/IM: 2–6 years, 6.25 mg every 4–6 hours	
Doxylamine	Oral: 20–40 mg daily	N/A	
Hydroxyzine	Oral/IV/IM: 25–100 mg every 4–6 hours as needed	Oral: 0.6 mg/kg IM: 0.5–1 mg/kg	
Meclizine	Oral: 12.5–25 mg every 12–24 hours as needed	Oral: ≥ 12 years: use adult dose	
Phenothiazines			
Chlorpromazine	Oral: 10–25 mg every 4–6 hours as needed IV/IM: 25–50 mg every 4–6 hours as needed	Oral: ≥ 6 months, 0.5 mg/kg every 4–6 hours as needed IV/IM: ≥ 6 months, 0.5–1 mg/kg every 6–8 hours	Most common: Sedation, lethargy, skin sensitization Less common: Cardiovascular effects, EPS, cholestatic jaundice, hyperprolactinemia
Prochlorperazine	Oral: 5–10 mg three to four times a day as needed Supp: 25 mg twice daily as needed IV/IM: 2.5–10 mg every 3–4 hours as needed	Oral: > 2 years and > 9 kg: 0.4 mg/kg/day or 10 mg/m^2 daily in two to three divided doses Supp: See oral dosing IM: > 2 years and > 9 kg: 0.13 mg/kg	Avoid using in pediatric patients if possible due to sensitivity to adverse effects. If use is considered necessary, employ the lowest effective dose
Promethazine	Oral/IM/IV/Supp: 12.5–25 mg every 4–6 hours as needed	Oral/IM/IV/Supp: ≥ 2 years, 0.25–0.5 mg/kg or 7.5–15 mg/m^2 four to six times daily	
Butyrophenones			
Droperidol	IM/IV: 0.625–2.5 mg every 4–6 hours as needed	IM/IV: 2–12 years: 0.05–0.1 mg/kg (max 2.5 mg) every 4–6 hours as needed	Most common: Sedation, hypotension, tachycardia Less common: EPS, dizziness, increased blood pressure, chills, hallucinations, QT prolongation
Haloperidol	Oral, IM/IV: 0.5–5 mg every 12 hours as needed	N/A	
Benzamides			
Domperidone	Oral: 10–20 mg every 4–8 hours as needed Supp: 30–60 mg every 4–8 hours as needed	Oral: 0.2–0.4 mg/kg every 4–8 hours as needed for CINV prophylaxis Supp: Max daily dose based on weight	Most common: Sedation, restlessness, diarrhea (metoclopramide), agitation, CNS depression Less common: EPS, hypotension, neuroleptic syndrome, supraventricular tachycardia (with IV), QT prolongation, serotonin syndrome (when used with serotonergic agents)
Metoclopramide	PONV: 10–20 mg oral/IV/IM 10 min prior to anesthesia CINV Prophylaxis: 1–2 mg/kg oral/IV every 2–4 hours	N/A	
Trimethobenzamide	IM: 200 mg two to four times a day as needed	Not recommended	

(*Continued*)

Table 20–2

Antiemetic Agents: Usual Doses for Adults and Children and Adverse Effects (*Continued*)

Drug	Adult Dosing	Pediatric Dosing	Adverse Effects[a]
Corticosteroids			
Dexamethasone	*CINV*: 12–20 mg oral/IV day 1, then 8–12 mg oral/IV daily *PONV*: 4–5 mg oral/IV at induction of anesthesia	*CINV*: 10 mg/m^2 prior to chemotherapy then 5 mg/m^2	Most common: GI upset, anxiety, insomnia Less common: Hyperglycemia, facial flushing, euphoria, perineal itching or burning (with dexamethasone)
Methylprednisolone	125–500 mg oral/IV every 6 hours for total of four doses	N/A	
Cannabinoids			
Dronabinol	Oral: 5–15 mg/m^2 every 2–4 hours as needed	Use adult dose with caution and adjust based on response	Most common: Drowsiness, euphoria, somnolence, vasodilation, vision changes, dysphoria Less common: Diarrhea, flushing, tremor, myalgia
Nabilone	Oral: 1–2 mg two to three times a day as needed	N/A	
Benzodiazepines			
Lorazepam	Oral/IV: 0.5–2 mg prior to chemotherapy	Oral/IV: 2–15 years old: 0.05 mg/kg (up to 2 mg) prior to chemotherapy	Most common: Sedation, amnesia Rare: Respiratory depression, ataxia, blurred vision, hallucinations
Alprazolam	Oral: 0.5–2 mg three times a day prior to chemotherapy	N/A	
Serotonin Antagonists			
Dolasetron	*CINV*: Contraindicated due to dose-dependent QTc prolongation *PONV*: 12.5 mg IV 15 min before end of anesthesia or at onset of N/V or 100 mg PO within 2 hours before surgery	*CINV*: Contraindicated due to dose-dependent QTc prolongation *PONV*: 0.35 mg/kg IV (max 12.5 mg) or 1.2 mg/kg PO (max 100 mg) within 2 hours before surgery	Most common: Headache, QT prolongation Less common: Constipation, asthenia, somnolence, diarrhea, fever, tremor or twitching, ataxia, lightheadedness, dizziness, nervousness, thirst, muscle pain, warm or flushing sensation on IV administration, serotonin syndrome (with ondansetron when used with serotonergic agents) Rare: Transient elevations in hepatic transaminases Granisetron may be degraded by light. Cover patch application site (eg, with clothing) if risk of exposure to sunlight or sunlamps during use and for 10 days after removal
Granisetron	*CINV*: 10 mcg/kg IV prior to chemotherapy; or 1 mg orally 1 hour before chemotherapy and 1 mg 12 hours after first dose, or 2 mg 1 hour before chemotherapy *PONV*: 1 mg IV before induction of anesthesia or immediately before reversal of anesthesia, or at onset of N/V	*CINV*: 2–16 years: Use adult dosing IV or PO regimen *PONV*: Not recommended for pediatric patients	
Granisetron	*CINV*: 1 patch 24–48 hours before chemotherapy; may wear for up to 7 days	N/A	
Ondansetron	*CINV*: Oral: 24 mg single dose prior to chemotherapy, or 8 mg prior to chemotherapy, repeat every 12 hours IV: 0.15 mg/kg, not to exceed 16 mg per dose, for three doses. Give the first dose 30 min prior to chemotherapy. Repeat dose 4 and 8 hours after the first dose *PONV*: 4 mg IV/IM before anesthesia induction or at onset of N/V; 16 mg orally once given 1 hour before anesthesia induction	*CINV*: Oral: 4–11 years, 4 mg 30 min prior to chemotherapy, repeat at 4 and 8 hours and every 8 hours for 1–2 days after chemotherapy completion IV: 6 months to 18 years: 0.15 mg/kg, not to exceed 16 mg per dose, for three doses. Give the first dose 30 min prior to chemotherapy. Repeat dose 4 and 8 hours after the first dose *PONV*: 1 month–12 years: 4 mg IV/IM before anesthesia induction for over 40 kg and 0.1 mg/kg IV for under 40 kg Oral recommendations not available	.
Palonosetron	*CINV*: 0.25 mg IV 30 min before chemotherapy; 0.5 mg orally 1 hour before chemotherapy *PONV*: 0.075 mg IV before anesthesia induction	*CINV*: 20 mcg/kg (maximum 1.5 mg) IV 30 min before chemotherapy	

(*Continued*)

Table 20–2

Antiemetic Agents: Usual Doses for Adults and Children and Adverse Effects (*Continued*)

Drug	Adult Dosing	Pediatric Dosing	Adverse Effects[a]
Neurokinin-1 Antagonist			
Aprepitant	*CINV*: 150 mg IV (fosaprepitant) 30 min before chemotherapy on first day of chemotherapy only; or 125 mg orally on day 1, 1 hour prior to chemotherapy followed by 80 mg on days 2 and 3 *PONV*: 40 mg orally 3 hours prior to anesthesia induction	*CINV*: 12 years and older: 125 mg PO on day 1, 1 hour prior to chemotherapy followed by 80 mg on days 2 and 3 6 months to 12 years: 3 mg/kg (max 125 mg) day 1, then 2 mg/kg (max 80 mg) day 2 and 3	Most common: Fatigue, hiccups Less common: Dizziness, headache, insomnia Rare: Transient elevations in hepatic transaminases
Rolapitant	*CINV*: 180 mg PO on day 1, 1–2 hours prior to chemotherapy	N/A	
Netupitant	*CINV*: Netupitant 300 mg plus palonosetron 0.5 mg combination product on day 1, 1 hour prior to chemotherapy	N/A	
Other			
Doxylamine/ pyridoxine	Oral: 10 mg/10 mg tablets, 2 tablets PO at bedtime, titrate to a maximum of 4 tablets daily for persistent symptoms	N/A	See adverse effects for antihistamines above.
Olanzapine	*CINV*: 10 mg PO daily, days 1–4 of highly emetogenic chemotherapy	N/A	Sedation

[a]Most common, greater than 10%; less common, 1% to 10%; rare, less than 1%. Based on US FDA-approved labeling and generalized to drug class.

CINV, chemotherapy-induced nausea and vomiting; EPS, extrapyramidal symptoms; IM, intramuscularly; Inj, injectable dosage form for IV or IM use; N/A, not available; PO, orally; PONV, postoperative nausea and vomiting; TD, transdermal; Supp, rectal suppository.

Oral dronabinol and nabilone are used for preventing and treating refractory CINV.[14,27] Cannabinoids are thought to exert their antiemetic effect centrally, although the exact mechanism of action is unknown.[27] Sedation, euphoria, hypotension, ataxia, dizziness, and vision difficulties can occur. Medical marijuana is an area of increased interest, but current evidence is insufficient to recommend its use for this indication.[3]

▶ *Benzodiazepines*

Benzodiazepines, especially lorazepam, are used to prevent and treat CINV.[8,14] Lorazepam is used as an adjunct to antiemetic agents.[14] Sedation and amnesia are common side effects. Respiratory depression can occur with high doses or when other central depressants such as alcohol are used concomitantly.

▶ *Serotonin Antagonists*

Serotonin is a neurotransmitter synthesized in neurons in the CNS and in enterochromaffin cells of the GI tract. Chemotherapeutic agents release 5-HT, which is a predominant mediator in nausea and vomiting.[28] This increase in 5-HT concentrations stimulates the visceral vagal nerve fibers and CTZ, thereby triggering nausea and vomiting. Selective 5-HT_3 receptor antagonists (ondansetron, granisetron, dolasetron, and palonosetron) prevent and treat nausea and vomiting due to stimulation of these receptors, especially for CINV and PONV.[4,29] These agents are well tolerated; the most common adverse effects are headache, somnolence, diarrhea, and constipation.[14] Dose-related QT changes (including torsades de pointes) have been reported, and ECG monitoring is recommended for patients with risk factors for QT prolongation who will receive ondansetron or dolasetron.[29] Although the labeling for granisetron and palonosetron does not include a recommendation for ECG monitoring, patients may still be at risk for QT changes.

Palonosetron is the first 5-HT_3 antagonist to be approved for preventing both acute and delayed CINV.[14] Compared to other 5-HT_3 antagonists, palonosetron has a longer serum half-life (40 hours compared to 4–9 hours) and a higher receptor-binding affinity, which may contribute to its efficacy in preventing delayed CINV.[30]

▶ *Neurokinin-1 Receptor Antagonists*

Substance P is a neurokinin neurotransmitter that binds to neurokinin-1 (NK_1) receptors in the GI tract and the brain and is believed to mediate both acute and delayed nausea and vomiting.[31] Aprepitant was the first NK_1 receptor antagonist antiemetic and is effective for preventing acute and delayed CINV when used with a 5-HT_3 antagonist and a corticosteroid.[31,32] It is also effective for preventing PONV.[4,33] Aprepitant has numerous drug interactions because it is an inhibitor and substrate of the CYP 3A4 metabolic pathway.[33]

Netupitant is the second NK_1 receptor antagonist; it is available only as a combination product with palonosetron (Akynzeo) for preventing acute and delayed CINV following moderately or highly emetogenic chemotherapy.[3] Rolapitant is the third NK_1 receptor antagonist.[34] It is available as an oral formulation that may be used in place of aprepitant or netupitant and is given as a single dose due to its long elimination half-life and does

not have the same concerns for drug interactions associated with aprepitant and netupitant. None of the NK_1 antagonists are renally eliminated.

▶ *Olanzapine*

Olanzapine is an antipsychotic agent that has effects at dopamine D_2, 5-HT_{2c}, and 5-HT_3 receptors, among others. Current guidelines recommend the addition of olanzapine to combination therapy for prevention of CINV in patients receiving highly emetogenic chemotherapy.[3] When used for short-term treatment in this way, olanzapine is well tolerated with sedation on day 2 of chemotherapy the only reported significant adverse effect.

Chemotherapy-Induced Nausea and Vomiting

CINV is classified as: (a) acute (within 24 hours after chemotherapy); (b) delayed (more than 24 hours after chemotherapy); or (c) anticipatory (prior to chemotherapy when acute or delayed nausea and vomiting occurred with previous courses).[3,8,14] Risk factors for CINV include poor emetic control with prior chemotherapy, female sex, low chronic alcohol intake, and younger age.[35]

Chemotherapeutic agents are classified according to their emetogenic potential, which aids in predicting CINV.[3,8] Cisplatin, high-dose cyclophosphamide (1.5 gm/m^2 or more), or cyclophosphamide combined with an anthracycline are examples of highly emetogenic chemotherapeutic regimens. Lower doses of cyclophosphamide, ifosfamide, and carboplatin are examples of moderately emetogenic agents. Risk factors for anticipatory nausea and vomiting include poor prior control of CINV and a history of motion sickness or NVP.[3,14]

LO 6

KEY CONCEPT A combination of antiemetics with different mechanisms of action is recommended to prevent acute CINV for patients receiving moderately or highly emetogenic chemotherapy (Table 20–3).[3,8,14] Patients receiving chemotherapeutic agents with low emetogenic potential should receive a single dose of a 5-HT_3 antagonist or an 8-mg dose of dexamethasone as CINV prophylaxis, and those receiving chemotherapy with minimal emetogenic risk do not require prophylaxis.

Delayed nausea and vomiting is more difficult to prevent and treat. It occurs most often with cisplatin- and cyclophosphamide-based regimens, especially if delayed nausea and vomiting occurred with previous chemotherapy courses.[8] Patients who had poorly controlled acute CINV in the past are at greatest risk for delayed CINV.[3,8,35]

Oral and IV antiemetics can be equally effective for CINV, depending on patient characteristics such as ability to take oral medications, dosage form availability, and cost.[3,14] Patients undergoing chemotherapy should have antiemetics available to treat breakthrough nausea and vomiting even if prophylactic antiemetics were given.[3,14] A variety of antiemetics may be used, including lorazepam, dexamethasone, methylprednisolone, prochlorperazine, promethazine, metoclopramide, 5-HT_3 antagonists, dronabinol, and olanzapine. If breakthrough CINV occurs despite prophylaxis, treatment with an antiemetic with a different mechanism of action is recommended.

The best strategy for preventing anticipatory nausea and vomiting is to prevent acute and delayed CINV by using the most effective antiemetic regimens based on the emetogenic potential of the chemotherapy and patient factors. CINV should be aggressively prevented with the first cycle of therapy. If anticipatory nausea and vomiting occurs, benzodiazepines and behavioral therapy such as relaxation techniques may be tried.[8,14]

Table 20–3

Recommended Drug Regimens for Prevention of CINV Based on Emetogenic Risk[3]

Emetogenic Risk	Acute CINV (Day 1)	Delayed CINV (Days 2–4)
Minimal	None	None
Low	Dexamethasone OR 5-HT_3 antagonist	None
Moderate[a,b]	5-HT_3 antagonist + dexamethasone	Dexamethasone (days 2 and 3) for agents with known risk for delayed nausea and vomiting
High (includes AC regimens)	NK_1 receptor antagonist + 5-HT_3 antagonist + dexamethasone[b] + olanzapine	If aprepitant[c] is used, continue days 2 and 3 Continue dexamethasone days 2–4 for non-AC highly emetogenic regimens Olanzapine (days 2–4)

[a]Add NK_1 receptor antagonist if using carboplatin and area under the curve is ≥ 4 mg/mL per minute.

[b]If rolapitant is the NK_1 receptor used, use full dose (20 mg) dexamethasone on day 1. If aprepitant, fosaprepitant, or netupitant are used, dose-adjust dexamethasone (12 mg) on day 1.

[c]If fosaprepitant, netupitant/palonosetron combination or rolapitant are used as the NK_1 receptor antagonist on day 1, no subsequent doses required.

AC, anthracycline (daunorubicin, doxorubicin, epirubicin, or idarubicin) plus cyclophosphamide; CINV, chemotherapy-induced nausea and vomiting.

Postoperative Nausea and Vomiting

PONV is a common complication of surgery that can lead to delayed discharge and unanticipated hospitalization.[4] The overall incidence of PONV is 25% to 30%, but it can occur in 70% to 80% of high-risk patients.[4,5] Risk factors for PONV include patient factors (female sex, nonsmoking status, and history of PONV or motion sickness), anesthetic factors (volatile anesthetics, nitrous oxide, or intraoperative or postoperative opioids), and surgical factors (duration and type of surgery).[4,5]

The first step in preventing PONV is reducing baseline risk factors when appropriate.[4,5] For example, the incidence of PONV may be less with regional anesthesia than general anesthesia, and nonsteroidal anti-inflammatory drugs may cause less PONV than opioid analgesics.

LO 6

KEY CONCEPT Some agents should be administered prior to induction of anesthesia (aprepitant, palonosetron, dexamethasone), whereas others are more effective when administered at the end of surgery (droperidol, 5-HT_3 receptor antagonists). Scopolamine should be administered the evening prior to surgery or 2 hours prior to surgery.[1,4] Aprepitant prevents PONV, but it is not more effective than other agents and is costly.[4,23] Combinations of antiemetics are recommended to prevent PONV for high-risk patients.[23] A 5-HT_3 antagonist plus droperidol or dexamethasone, or dexamethasone plus droperidol are effective combinations.[4,23]

Patient Encounter 1

A 37-year-old woman is having surgery today to remove her gallbladder.

PMH: GERD, hyperemesis gravidarum 5 years ago, and hypotension

SH: Negative for tobacco, occasional alcohol, negative for illicit drugs

FH: Hypertension, dyslipidemia

Current meds: Pantoprazole 40 mg once daily, OTC "motion sickness" medicine when she travels

VS: BP 98/62 mm Hg, HR 95 beats/min, RR 18 breaths/min, T 98.6°F (37.0°C)

Labs: All within normal limits

EKG shows normal sinus rhythm and a QTc of 410 msec

General analgesia is planned for surgery and includes thiopental 4.5 mg/kg, atracurium 0.5 mg/kg, and fentanyl 0.05 mg followed by tracheal intubation, 70% nitrous oxide, and 0.5% to 2% isoflurane in oxygen. Postoperative orders include opioid analgesics for pain control.

What risk factors does this patient have for developing PONV?

What pharmacologic or nonpharmacologic PONV prevention or treatment options are recommended for this patient?

What treatment options would be recommended if she experiences PONV despite receiving prophylactic antiemetic agents?

If PONV occurs despite appropriate prophylaxis, it should be treated with an antiemetic from a pharmacologic class not already administered.[23] If no prophylaxis was used, a low-dose 5-HT_3 antagonist should be used.[23]

Nausea and Vomiting of Pregnancy

LO 6

KEY CONCEPT Nausea and vomiting affect the majority of pregnant women; the teratogenic potential of the therapy is the primary consideration in drug selection, followed by severity of the nausea and vomiting.[6] Risks and benefits of any therapy must be weighed by the health care professional and the patient.

Pyridoxine (vitamin B_6) 10 to 25 mg four times daily alone or in combination with an antihistamine such as doxylamine is first-line pharmacotherapy for NVP.[6,11] A combination product is available (Diclegis) with a recommended dose of two 10 mg/10 mg delayed-release tablets at bedtime. Pyridoxine is well tolerated, but doxylamine and other antihistamines may cause drowsiness.

Ondansetron (pregnancy category B) has been used to treat severe NVP; animal data do not indicate a safety concern in pregnancy, but safety and efficacy data in humans for NVP are sparse. Although the safety of anticholinergics and metoclopramide have been established, data demonstrating efficacy are lacking.[6]

In rare instances (0.3%–3% of pregnancies), NVP progresses to hyperemesis gravidarum.[6] Enteral or parenteral nutrition might be used if oral liquids cannot be tolerated or if dehydration occurs. A corticosteroid such as methylprednisolone may be considered. Because methylprednisolone is associated with oral clefts in the fetus when used during the first trimester, corticosteroids should be reserved as a last resort and should be avoided during the first 10 weeks of gestation.[6,11]

Patient Encounter 2

A 30-year-old woman who is 11 weeks pregnant with NVP seeks your advice. She complains of constant nausea, frequent vomiting, increased thirst, decreased urine output, and weight loss. She has been unable to tolerate oral liquids. Her medications are doxylamine 10 mg-pyridoxine 10 mg delayed release, 2 tablets at bedtime. In addition, she has been taking prenatal vitamins since before her pregnancy and has tried avoiding provoking stimuli, eating frequent small meals, and avoiding spicy and fatty foods.

What type of nausea and vomiting is this patient experiencing?

What nonpharmacologic and pharmacologic treatment options may help prevent and treat this patient's nausea and vomiting?

Should this patient seek additional medical attention for her symptoms?

Motion Sickness and Vestibular Disturbances

Nausea and vomiting can be caused by disturbances of the vestibular system in the inner ear because of infection, trauma, neoplasm, or motion.[16] Patients may experience dizziness and vertigo in addition to nausea and vomiting. If a patient is susceptible to motion sickness, preventive measures include minimizing exposure to movement, restricting visual activity, ensuring adequate ventilation, reducing the magnitude of movement, and taking part in distracting activities.[16]

LO 6

KEY CONCEPT Because the vestibular system is replete with muscarinic type cholinergic and histaminic (H_1) receptors, anticholinergics and antihistamines are the most commonly used agents to prevent and treat motion sickness. Oral medications should be taken prior to motion exposure to allow time for adequate absorption. Once nausea and vomiting due to motion sickness occur, oral medication absorption may be unreliable, making the therapies ineffective. Transdermal scopolamine

Patient Encounter 3

A 70-year-old woman who presents to your practice is planning a 10-day Mediterranean cruise. She has a past medical history significant for overactive bladder and hypertension for which she takes oxybutynin 10 mg XR once daily and lisinopril 10 mg once daily. She has experienced nausea and vomiting during boat rides in the past and states that a friend recommended she purchase "a patch" at her local pharmacy to prevent nausea and vomiting.

What recommendations for nonpharmacologic interventions would you give this patient to help prevent motion sickness?

What are the pharmacologic options for this patient to prevent or treat nausea and vomiting?

What potential adverse effects would you counsel this patient about?

may be considered as a first-line option for patients who cannot tolerate oral medications or who require treatment for a prolonged period.[16] Drowsiness and reduced mental acuity are the most bothersome side effects of antihistamines and anticholinergics. Visual disturbances, dry mouth, and urinary retention can also occur.

Pharmacist's Patient Care Process

Collect Information:

- Obtain a thorough patient history including the prescription, nonprescription, and herbal medications being used. Identify any substances that may be causing or worsening nausea and vomiting.

Assess the Information:

- Assess the patient to determine whether the nausea and vomiting is simple or complex and whether patient-directed therapy is appropriate.
- Determine which treatments for nausea and vomiting have been used in the past and their degree of efficacy.

Develop a Care Plan:

- Eliminate the underlying cause of nausea and vomiting if possible.
- Develop a treatment plan with the patient and other health care professionals if appropriate.
- Choose treatments based on the underlying cause of nausea and vomiting, duration and severity of symptoms, comorbid conditions, medication allergies, presence of contraindications, risk of drug–drug interactions, and adverse-effect profiles.
- Use the oral route for mild nausea with minimal or no vomiting. Seek an alternative route (eg, transdermal, rectal, parenteral) if the patient is unable to retain oral medications due to vomiting.

Implement the Care Plan:

- Counsel the patient to avoid known triggers.
- Provide patient education regarding causes of nausea and vomiting, avoidance of triggers, potential complications, treatment options, medication adverse effects, and when to seek medical attention.
- Educate the patient about nonpharmacologic measures such as stimulus avoidance, dietary changes, acupressure or acupuncture, and psychotherapy.

Follow-up: Monitor and Evaluate:

- To assess efficacy, ask the patient whether nausea or vomiting is resolving with therapy. Assess whether treatment failure is due to inappropriate medication use or the need for additional or different treatments and proceed accordingly.
- Assess adverse effects by asking the patient what he or she has experienced. Patient observation or examination is also useful for diagnosing adverse effects such as EPS.

OUTCOME EVALUATION

LO 7

- The symptoms of simple nausea and vomiting are self-limited or relieved with minimal treatment. Monitor patients for adequate oral intake and alleviation of nausea and vomiting.
- Patients with complex nausea and vomiting may have malnourishment, dehydration, and electrolyte abnormalities.
- If the patient has weight loss, assess whether enteral or parenteral nutrition is needed.
- Assess for dry mucous membranes, skin tenting, tachycardia, and lack of axillary moisture to determine if dehydration is present.
- Obtain blood urea nitrogen (BUN), serum creatinine (SCr), calculated fractional excretion of sodium (FeNa), serum electrolytes, and arterial blood gases.
- Ask patients to rate the severity of nausea.
- Monitor the number and volume of vomiting episodes.
- Ask patients about adverse effects to the antiemetics used. Use this information to assess efficacy and tailor the patient's antiemetic regimen.

Abbreviations Introduced in This Chapter

CINV	Chemotherapy-induced nausea and vomiting
CTZ	Chemoreceptor trigger zone
D_2	Dopamine type 2 receptor
EPS	Extrapyramidal symptoms
FeNa	Fractional excretion of sodium
GERD	Gastroesophageal reflux disease
H_1	Histamine type 1 receptor
$5\text{-}HT_3$	5-Hydroxytryptamine (serotonin) type 3 receptors
NK_1	Neurokinin type 1 receptors
NVP	Nausea and vomiting of pregnancy
PONV	Postoperative nausea and vomiting

21 Constipation, Diarrhea, and Irritable Bowel Syndrome

Beverly C. Mims

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify the causes of constipation.
2. Compare the features of constipation with those of irritable bowel syndrome with constipation (IBS-C).
3. Recommend lifestyle modifications and pharmacotherapy for treatment of constipation.
4. Distinguish between acute and chronic diarrhea.
5. Compare diarrhea caused by different infectious agents.
6. Explain how medication use can cause diarrhea.
7. Discuss nonpharmacologic strategies for treating diarrhea.
8. Identify the signs and symptoms of IBS.
9. Contrast IBS with diarrhea (IBS-D) and IBS-C.
10. Establish treatment goals for IBS.
11. Evaluate the effectiveness of pharmacotherapy for IBS.

INTRODUCTION

Constipation and diarrhea are common gastrointestinal (GI) complaints that have various etiologies. Thorough patient assessment is important to accurately identify the underlying cause and implement safe and effective treatment. Functional gastrointestinal disorders (FGIDs) have received increasing attention in recent years.[1] FGIDs are characterized by persistent and recurring GI symptoms due to abnormal GI tract function but without structural or biochemical abnormalities. As a result, many diagnostic tests (eg, x-rays, endoscopic examinations) are often negative. The most common FGID is irritable bowel syndrome (IBS). This chapter will focus on the evaluation and management of constipation, diarrhea, and IBS.

CONSTIPATION

KEY CONCEPT Constipation, when not associated with symptoms of IBS, is a syndrome characterized by infrequent bowel movements (< 3 stools per week) or difficult passage of stools, hard stools, or a feeling of incomplete evacuation. Occasional constipation usually does not require medical evaluation or treatment.

EPIDEMIOLOGY AND ETIOLOGY

Constipation affects people of all ages and occurs in approximately 16% of all adults and in one-third of adults age 60 and older. Although it is rarely life threatening, constipation results in over 8 million physician visits, 1.1 million hospitalizations, and 5.3 million prescriptions annually. In 2016, US sales of nonprescription laxative products totaled more than $1.3 billion.[2]

LO 1

Constipation can be due to primary and secondary causes (Table 21–1). Functional constipation is defined as constantly problematic, infrequent, or seemingly incomplete defecation that does not meet criteria for diagnosis of IBS. Opioid-induced constipation (OIC) is defined as a change from baseline bowel habits and patterns of defecation after initiating opioid therapy that is characterized by reduced bowel movement frequency, development or worsening of straining to pass bowel movements, a sense of incomplete bowel evacuation, or the patient's perception of stress related to bowel habits.[3] OIC is an opioid-induced adverse effect that can overlap with and worsen functional constipation.[4] OIC constipation is associated with significant economic burden. In cancer patients taking opioids for pain the incidence of OIC constipation approached 94%.[5] Constipation is associated with significant socioeconomic costs and considerable quality-of-life ramifications.[5,6] Physiological, environmental, and demographic factors may play roles in the development of constipation. Some diseases and many medications are associated with constipation.[7,8]

PATHOPHYSIOLOGY

Primary or idiopathic constipation is categorized as normal-transit constipation (NTC), slow-transit constipation (STC), or defecatory or rectal evacuation disorders. In NTC, colonic motility is unchanged, and patients experience hard stools despite normal movements. In STC, motility is decreased or caloric intake is inadequate, resulting in infrequent, harder, drier stools. Dyssynergic defecatory or rectal evacuation disorders involve prolonged rectal storage of fecal residue or disorders of evacuation with normal or delayed colonic transit resulting in incomplete expulsion of feces from the rectum. Underlying causes may include inadequate relaxation of muscles or paradoxical

Table 21–1

Some Causes of Constipation

Primary Causes
Normal-transit constipation
Slow-transit constipation (disturbances of neurogastroentero- and brain-gut interactions, inadequate caloric intake)
Defecatory or colonic/rectal evacuation disorders

Secondary Causes (Selected)
Endocrine/metabolic conditions (diabetes mellitus, hypercalcemia, hypokalemia, hypomagnesemia, hypothyroidism, uremia)
Myopathies (amyloidosis, scleroderma)
Neurogenic conditions (brain trauma, stroke, Parkinson disease, multiple sclerosis, spinal cord injury or tumor)
Mechanical obstruction (colon cancer, lesion compression, stricture, rectocele)
Medications (analgesics, anticholinergics, antidiarrheals, antihistamines, some antipsychotics and antidepressants, aluminum-containing products, calcium channel blockers, calcium-containing products, clonidine, diuretics, iron-containing supplements, ondansetron, phenothiazines)
Other (autonomic neuropathy, cardiac disease, cognitive impairment, diet, volume depletion, immobility, laxative abuse, postponing urge to defecate, deliberate suppression of defecation, psychological distress, perceptions about bowel frequency)

contractions of the pelvic diaphragm, perineal membrane and deep perineal pouch (the pelvic floor), and the external anal sphincter during defecation.[7-9] Chronic constipation without an identifiable cause is often referred to as chronic idiopathic constipation (CIC).

Physiologic changes associated with OIC occur when opioids activate GI tract G-protein–coupled opioid μ, κ, and δ receptors. Activation of these receptors reduces acetylcholine release, which contributes to physiologic changes such as decreased propulsive activity; increased nonpropulsive contractions; decreased pancreatic, biliary and gastric secretions; and increased anal tone. All of these changes may contribute to constipation.[10]

CLINICAL PRESENTATION AND DIAGNOSIS

A medical history is important to ascertain the frequency and character of bowel movements and the duration of symptoms (see accompanying box for the clinical presentation of constipation). It is important to understand the symptoms that the patient considers to constitute constipation. Dietary, hydration, and physical activity habits should also be determined to identify potential contributing factors. Family history should be assessed for the presence of inflammatory bowel disease and colon cancer. A complete record of prescription medications, over-the-counter products, and dietary supplements is mandatory to identify drug-related causes.

KEY CONCEPT The diagnosis of constipation is based on clinical history, physical examination, minimal laboratory tests, colonoscopy or other procedures, and specific tests to evaluate underlying pathophysiology.

Endoscopy is required in patients with weight loss greater than 10 pounds in 3 months, rectal bleeding, or anemia to exclude cancer or strictures, especially in patients older than 50 years. Anorectal examination, manometry, radiography, colonoscopy, and other procedures may be useful in certain circumstances.

Clinical Presentation and Diagnosis of Constipation

Symptoms of Constipation

- Infrequent bowel movements (fewer than three per week); straining; lumpy or hard stools; painful or difficult defecation; abdominal pain or distention; bloating; sensation of incomplete evacuation, anorectal obstruction, or blockage; and need for manual maneuvers to facilitate defecations.
- Alarm (or "red flag") findings include worsening of constipation, sudden change in bowel habits after age 50, rectal bleeding in the absence of documented hemorrhoids or anal fissures, unintentional weight loss (> 10% within 3 months), family history of colon cancer or family polyposis syndromes, anemia, or recent constipation onset without explanation. These findings require prompt medical evaluation and appropriate intervention.

Physical Examination

- Presence of central nervous system (CNS) or spinal cord lesions may suggest an underlying cause.
- Abdominal examination findings may include distention, hard stool in a palpable colon, or abdominal mass.
- Rectal examination may indicate fecal impaction, anal stricture, or rectal mass.

Laboratory Tests (to Identify Secondary Causes)

- Thyroid-stimulating hormone (hypothyroidism)
- Serum calcium (may be increased or decreased)
- Glucose (diabetes mellitus)
- Serum electrolytes (dehydration, volume depletion)
- Urinalysis (dehydration)
- Complete blood count (anemia)

Other Tests

- Screening colonoscopy and other specialized tests may be conducted based on presenting signs and symptoms.

LO 2

In most cases, the physical examination is normal, and no underlying cause of constipation is identified. However, evaluation may reveal one or more of the following conditions: (a) IBS with constipation (IBS-C); (b) STC with normal pelvic floor function and evidence of slow transit; (c) a defecatory disorder; (d) a combination of IBS-C and STC; (e) organic constipation (mechanical obstruction or adverse drug effect); and (f) secondary constipation (metabolic disorder).[7,8]

TREATMENT

Desired Outcomes

The primary goals of treatment are to: (a) educate the patient, (b) identify underlying causes, (c) treat or remove secondary causes, (d) relieve symptoms, and (e) restore normal bowel function.[1,7,8] The treatment of constipation depends on the characteristics, severity, and cause of symptoms.

Nonpharmacologic Therapy

KEY CONCEPT In many cases nonpharmacologic treatment including lifestyle and dietary modifications should be employed prior to recommending pharmacotherapy. The patient should be

educated about possible causes of constipation and appropriate use of nonpharmacologic measures described below. Medication use should be evaluated to identify possible contributing factors. Patients should be encouraged to schedule routine bathroom time after the morning or evening meal. It may be helpful to elevate the feet with a stool during defecation.

LO 3 Increased dietary fiber intake or fiber supplementation (total 20–30 g/day) can improve NTC, whereas patients with STC or drug-induced constipation are unlikely to respond to increased fiber. High-fiber foods include beans, whole grains, bran cereals, fresh fruits, and vegetables such as asparagus, brussels sprouts, cabbage, and carrots.

There are two types of fiber: soluble and insoluble. Soluble fiber is dissolved by water and forms a gel that slows digestion. Some sources of soluble fiber include lentils, apples, nuts, flaxseed, and psyllium. Insoluble fiber does not dissolve in water and remains mostly intact as it decreases the time at which food and feces traverse the intestines. Insoluble fiber adds bulk to the diet and helps prevent constipation. Some sources of insoluble fiber include whole wheat, corn bran, couscous, dark leafy green vegetables, and root vegetable skins.

LO 3 Adequate fluid intake is important, especially in patients with evidence of volume depletion. Adult men aged 19 years and over should ingest 3.7 L and women aged 19 and over should ingest 2.7 L of water daily. The thirst mechanism changes with age; keeping a daily intake diary may assist patients who need to be reminded to drink fluids. Increased exercise may improve symptoms of constipation.[1,3] Some trials have indicated that ingestion of **probiotics** may improve stool consistency and stool frequency in patients with constipation.[3]

LO 3 Biofeedback-aided pelvic floor training may be useful for treatment of defecatory disorders. Patients are guided to demonstrate the ability to coordinate abdominal and pelvic floor motion during evacuation.[3]

LO 3 Surgery may be considered after all other approaches have failed and activities of daily living are compromised. Colectomy and ileorectal anastomosis may be considered in select patients with slow-transit constipation.[3]

Pharmacologic Therapy

LO 3 KEY CONCEPT Oral laxatives are the primary pharmacologic intervention for relief of most forms of constipation, including OIC; several different drug classes are available (Table 21–2). Additional treatment options for OIC include a calcium-channel activator and peripherally acting μ-opioid receptor antagonists.[11]

▶ *Bulk Producers*

These agents are either naturally derived (psyllium), semisynthetic (polycarbophil), or synthetic (methylcellulose) fiber supplements. They act by swelling in intestinal fluid, forming a gel that aids in fecal elimination and promoting peristalsis. They may cause flatulence (less commonly with methylcellulose), bloating, distention, and abdominal cramping. Fiber supplements may result in less improvement in patients with delayed colon transit constipation and/or obstruction. Bulk-forming or fiber laxatives must be taken with sufficient water (240 mL/dose) to avoid becoming lodged in the esophagus and producing obstruction or worsening constipation. Hypersensitivity reactions may occur and rarely may be manifested as an anaphylactic reaction.

▶ *Osmotics*

Lactulose, sorbitol, and glycerin are osmolar sugars. These products cause water to enter the lumen of the colon and may

Table 21–2

Dosage Recommendations for Treatment of Constipation

Agent	Adults and Children Ages 12 and Over	Children Ages 6–11 Years
OTC Agents That Cause Softening of Feces in 1–3 Days		
Bulk-forming agents/osmotic laxatives		
Methylcellulose	4–6 g/day PO	0.45–1.5 g PO per dose up to 3 g/day
Polycarbophil	4–6 g PO daily	On advice of practitioner
Psyllium	Varies with product	On advice of practitioner
Emollients		
Docusate sodium	50–360 mg PO daily	50–100 mg PO daily
Docusate calcium	50–360 mg PO daily	On advice of practitioner
Docusate potassium	100–300 mg PO daily	100 mg PO daily
Lactulose	15–30 mL PO daily	7.5 mL (5 g) PO daily
Sorbitol	30–50 g/day PO daily	2 mL/kg (as 70% solution) PO daily
Mineral oil	15–30 mL PO daily	5–15 mL PO daily
OTC Agents That Result in Soft or Semifluid Stool in 6–12 Hours		
Bisacodyl (oral)	5–15 mg PO	5–10 mg (0.3 mg/kg) PO
Senna	Dose varies with formulation	6–25 mg PO once or twice daily
OTC Agents That Cause Watery Evacuation in 1–6 Hours or Less		
Magnesium citrate	120–300 mL PO	100–150 mL PO
Magnesium hydroxide[a]	30–60 mL PO (15–30 mL of concentrate PO)	2.5–5 mL PO up to four times
Magnesium sulfate[a]	10–30 g PO	5–10 g PO
Bisacodyl (suppository)	10 mg rectally	5 mg rectally (1/2 suppository)
Polyethylene glycol–electrolyte preparations	Up to 4 L PO	Safety and efficacy not established
Miscellaneous Agents		
Linaclotide	145 mcg PO once daily	Safety and efficacy not established in patients under age 18; contraindicated in children < 6 years old
Plecanatide	3 mg PO once daily with or without food	Safety and efficacy not established in age <18 years; contraindicated in < 6 years of age; avoid use in ages 6–18 years. Watch for diarrhea and dehydration in all ages

[a]Magnesium can accumulate in renal dysfunction.

stimulate peristalsis. Lactulose acidifies colonic contents, increases water content of the gut, and softens the stool. Glycerin causes local irritation and possesses hyperosmotic action. Glycerin may be administered rectally and can cause rectal discomfort. Sorbitol can cause intestinal irritation and may affect blood glucose levels in diabetic patients. Osmotic agents may cause flatulence, abdominal cramping, and bloating. Polyethylene glycol (PEG) 3350 (MiraLAX) is used to treat occasional constipation and is expected to produce a bowel movement within 1 to 3 days. In patients with kidney disease this over-the-counter product should be used only on the advice and supervision of a physician.

Ingestion of PEG 3350 with electrolytes, a prescription product (eg, GoLYTELY, Colyte), is used for acute complete bowel evacuation prior to GI examination. PEG can cause distention and diarrhea.

▶ *Lubricants*

Lubricant laxatives coat the stool, allowing it to be expelled more easily. The oily film covering the stool also keeps the stool from losing its water to intestinal reabsorption processes. Oral mineral oil (liquid petrolatum) is a nonprescription heavy oil that should be used with caution, if at all, because it can be aspirated into the lungs and cause lipoid pneumonia. This is of particular concern in the young and elderly. It may also inhibit absorption of fat-soluble vitamins.

▶ *Stimulant Laxatives*

Diphenylmethane derivatives (eg, bisacodyl) and anthraquinones (eg, senna) have a selective action on the nerve plexus of intestinal smooth muscle leading to enhanced motility. Enteric-coated bisacodyl tablets should be swallowed whole to avoid gastric irritation and vomiting. Ingestion should be avoided within 1 to 2 hours of antacids, H_2-receptor antagonists, proton pump inhibitors, and milk. Bisacodyl oral tablets, rectal suppository, and enema products are available. The onset of effect is more rapid with rectal administration. The effects can be harsh (cramping), depending on the dose taken. Castor oil is used less frequently; it is pregnancy category X and is associated with uterine contractions and rupture. Use of castor oil in breastfeeding is considered "possibly unsafe."

▶ *Emollients*

Also known as surfactants and stool softeners, emollients (eg, salts of docusate) act by increasing the surface-wetting action on the stool leading to a softening effect. They reduce friction and make the stool easier to pass. The onset of action of stool softeners is longer than with most stimulants and may take up to 72 hours. These agents tend to be less effective in treating constipation of long duration.

▶ *Saline Agents*

Salts of sodium, magnesium, and phosphate pull water into the lumen of the intestines resulting in increased enteral pressure. Magnesium and phosphate may accumulate in patients with renal dysfunction. Principal concerns with sodium phosphate derivatives include dehydration, hypernatremia, hyperphosphatemia, acidosis, hypocalcemia, and worsening renal function. Elderly individuals and patients with heart failure and renal dysfunction should be advised to avoid saline agents. Nonprescription oral sodium phosphate solutions are no longer available because of the risk of acute phosphate nephropathy, a form of acute kidney injury. Prescription oral sodium phosphate products (eg, Visicol, OsmoPrep) used to cleanse the bowel prior to colonoscopy or other medical procedures contain a black box warning about this complication in high-risk patients.

Table 21–3

Medications for Treatment of Opioid-Induced Constipation[a]

Agent	Adults and Children Ages 12 and Over
Lubiprostone	24 mcg PO twice daily with food and water
Methylnaltrexone bromide	Given subcutaneously every other day based on body weight: 12 mg if 62–114 kg; 8 mg if 38–61 kg; other doses based on weight if outside these parameters
Naloxegol	25 mg PO once daily in the morning on an empty stomach or if not tolerated 12.5 mg PO daily
Naldemedine	0.2 mg PO once daily with or without food

[a]Safety and efficacy have not been established in children younger than age 12.

▶ *Intestinal Secretagogues*

Lubiprostone (Amitiza) This oral agent is derived from prostaglandin E_1 and acts locally on intestinal chloride channels to increase intestinal fluid secretion, resulting in increased intestinal motility and passage of stool.[11] It is approved for treatment of CIC and OIC in adults with chronic noncancer pain (Table 21–3). Efficacy and safety have not been established for constipation due to methadone (a diphenylheptane opioid derivative) or in children. Adverse effects of lubiprostone include dyspnea, nausea, diarrhea, abdominal distention and pain, flatulence, vomiting, and loose stools. Nausea may be minimized by taking lubiprostone with food. The capsule should be swallowed whole; it should not be chewed or broken apart. Lubiprostone is classified as pregnancy category C.[11-14]

Linaclotide (Linzess) The parent compound and its active metabolite activate guanylate cyclase-C (GC-C) act locally by increasing intracellular and extracellular concentrations of cyclic guanosine monophosphate (GMP). Cyclic GMP stimulates secretion of chloride and bicarbonate into the intestinal lumen, resulting in increased interstitial fluid and intestinal transit. Linaclotide is indicated for treatment of IBS-C and CIC in adults only.[15]

The linaclotide dose for CIC is 145 mcg is administered once daily on an empty stomach at least 30 minutes before the first meal of the day; 72 mcg once daily can be used based on patient presentation and tolerability (Table 21–3). The capsule should be swallowed whole and not be broken or chewed.

Adverse effects of linaclotide include diarrhea, headache, fatigue, dehydration, abdominal pain, flatulence, and abdominal distention. Loose stools and greater stool frequency may occur after administration with a high-fat breakfast. Patients should be monitored for fluid and electrolyte loss. Linaclotide is classified as pregnancy category C.

Plecanatide (Trulance) This medication functions as a guanylate cyclase-C (GC-C) agonist. It is indicated for treatment of CIC in adults. The efficacy and safety of plecanatide have not been established in children less than 18 years of age, and it should be avoided in persons ages 6 to 18 years. It is contraindicated in children under the age of 6 years because increased fluid secretion may lead to serious dehydration.[16]

It is also contraindicated in patients with known or suspected mechanical GI obstruction.

The recommended adult dose of plecanatide is 3 mg orally once daily. The tablet can be given with or without food and should be swallowed whole. For adults with swallowing difficulties, the tablets can be crushed and administered orally either in applesauce or with water or given with water via a nasogastric or gastric feeding tube.

The major adverse effect associated with plecanatide is diarrhea, which may lead to discontinuation in some patients. Less common adverse effects include sinusitis, upper respiratory tract infection, abdominal distention, flatulence, abdominal tenderness, and increased hepatic enzymes. Although there is insufficient data on potential harm in pregnancy, plecanatide and its active metabolite are absorbed negligibly, and maternal use is not expected to result in fetal drug exposure.[16] No human lactation studies have yet been conducted.

▶ *Peripherally Acting μ-Opioid Receptor Antagonists (PAMORAs)*

There are currently three antagonists of opioid binding at the mu-opioid receptor that have negligible ability to cross the blood–brain barrier: methylnaltrexone bromide, naloxegol, and naldemedine (Table 21–3). They function as peripherally acting μ-opioid receptor antagonists (PAMORAs) in tissues such as the GI tract, thereby decreasing the constipating effects of opioids without diminishing the opioid analgesic effects in the CNS. They are indicated for treatment of OIC in adults with chronic pain that is not caused by active cancer (including chronic pain related to prior cancer or its treatment) who do not require frequent (eg, weekly) opioid dosage escalation.[17-19] The opioid analgesic regimen does not need to be altered before starting a PAMORA. Patients should be near toilet facilities after a PAMORA is administered. Patients receiving opioids for less than 4 weeks may be less responsive to these agents. All maintenance laxative therapy should be discontinued before starting a PAMORA; laxatives may be resumed if there is suboptimal response to the PAMORA after 3 days. Concomitant PAMORA use with other opioid antagonists can result in additive adverse effects and should be avoided. PAMORA treatment should be stopped if opioid therapy is discontinued.

The most common PAMORA adverse effects are abdominal pain, nausea, diarrhea, flatulence, and vomiting. GI perforation has been reported in patients with other conditions that reduce the structural integrity of the GI tract wall (eg, peptic ulcer disease, Crohn disease); the PAMORA should be discontinued if severe, persistent, or worsening abdominal pain occurs. Symptoms of opioid withdrawal may occur (sweating, chills, diarrhea, abdominal pain, anxiety, yawning) in patients physically dependent on opioids.

Methylnaltrexone Bromide (Relistor) is a quaternary amine derivative of naltrexone. The recommended oral dose is 450 mg (3 × 150-mg tablets) once daily with water on an empty stomach at least 30 minutes before the first meal of the day; there is a subcutaneous (SC) product that can also be used for treating OIC in adults with chronic noncancer pain; the dose is 12 mg SC once daily. The SC injection is also indicated for treatment of OIC in adults with advanced illness or pain caused by active cancer who require opioid dosage escalation for palliative care.[20] The SC injection is usually given every-other-day as needed; the dose is weight-based for this indication (refer to product labeling). The oral or SC methylnaltrexone dose must be reduced in patients with moderate to severe renal or hepatic dysfunction.

Naloxegol (Movantik) is a pegylated derivative of naloxone. The recommended dose is 25 mg orally once daily on an empty stomach at least 1 hour prior to the first meal of the day or 2 hours after the meal. The dose may be reduced to 12.5 mg daily if the larger dose is not tolerated. The starting dose should also be reduced to 12.5 mg daily in patients with moderate to severe renal impairment. If a patient cannot swallow the tablet whole, it may be crushed to a powder, mixed with 4 oz (120 mL) of water, and administered immediately; the glass should then be refilled with 4 oz water, stirred, and the contents drunk.[21] Patients should avoid consumption of grapefruit and grapefruit juice because these foods may increase plasma naloxegol concentrations.

Naloxegol is contraindicated in patients receiving strong CYP3A4 inhibitors (eg, clarithromycin, ketoconazole) and should be avoided if possible in patients taking moderate CYP3A4 inhibitors (eg, diltiazem, erythromycin, verapamil) due to increased naloxegol concentration that may increase the risk of adverse reactions.

Naldemedine (Symproic) is a derivative of naltrexone that contains an added side chain that increases molecular weight and reduces its ability to cross the blood–brain barrier. It has binding affinities for μ-, δ-, κ-opioid receptors. The recommended dose is 0.2 mg orally once daily with or without food.[22]

Concomitant use of strong CYP3A inducers such as rifampin should be avoided because decreased naldemedine concentrations can occur. On the other hand, increased naldemedine concentrations can occur when moderate (eg, fluconazole) or strong (eg, itraconazole) CYP3A4 inhibitors are used concomitantly; patients should be monitored for adverse reactions. Naldemedine is also a substrate of the P-glycoprotein (P-gp) efflux transporter; patients taking P-gp inhibitors (eg, amiodarone, captopril, cyclosporine, verapamil) should be monitored for adverse effects due to increased naldemedine concentrations.

Treatment Recommendations

LO 3

The conventional effective, safe, and inexpensive modalities (fluid intake; dietary and supplemental fiber; stool softeners; and saline, stimulant, or osmotic laxatives) should be attempted before agents such as secretagogues are prescribed. The μ-receptor antagonists are indicated only for treatment of OIC.

Patients who are not constipated but need to avoid straining (eg, patients with hemorrhoids, hernia, or myocardial infarction) may benefit from stool softeners or mild laxatives such as PEG 3350.

Pregnant women should be advised to eat regular meals that are balanced among fruits, vegetables, and whole grains and maintain adequate water intake to avoid constipation. Bulk producers and stool softeners are probably safe during pregnancy because they are poorly absorbed. Lactulose and magnesium products are pregnancy category B. Magnesium-based antacids have minimal absorption and are considered low risk in pregnant women. Long-term use of magnesium citrate should be avoided (pregnancy category B). Laxatives may provide relief for constipation occurring during the postpartum period when the mother is not breastfeeding.

Children younger than 6 years old should be evaluated by a healthcare provider before being given a laxative because they may not be able to describe their symptoms well. Evaluation of patients' ability to recognize and self-report constipation symptoms should be considered. Treating secondary causes may resolve constipation without use of laxatives. As in adults, children benefit from a balanced diet and adequate water intake.

Patient Encounter 1

An 89-year-old man with chronic constipation was admitted to the hospital after a fall. He lives with his daughter and her family. Review of his medication profile revealed the following: amlodipine 10 mg orally daily, calcium carbonate 650 mg plus vitamin D 4000 IU twice daily. The patient stated that he fell at about 10:30 AM as he was leaving the bathroom. The medical team determined that he suffered no serious injury and had no cognitive impairment. All laboratory tests were within the reference ranges, and the patient was discharged to home.

What general approach to this patient should be employed?

What are the possible contributing causes of his constipation?

What nonpharmacologic and pharmacologic therapies would be appropriate for his condition?

Because many older persons experience constipation, laxative use is sometimes viewed as a normal part of daily life. However, oral ingestion of mineral oil can present a particular hazard to bedridden individuals because inhalation of oil droplets can lead to pneumonia. Lactulose may be a better choice in this situation. Regular use of any laxative that affects fluid and electrolytes may result in significant adverse effects.

Patients with the following conditions should use laxatives only under the supervision of a health care provider: (a) colostomy; (b) diabetes mellitus (some laxatives contain sugars such as dextrose, galactose, and/or sucrose); (c) heart disease (some products contain sodium); (d) kidney disease; and (e) swallowing difficulty (bulk-formers may produce esophageal obstruction). Saline laxatives containing magnesium, potassium, or phosphates should be used cautiously in persons with reduced kidney function. Monitor appropriate serum electrolyte concentrations in patients with unstable renal function evidenced by changing serum creatinine or creatinine clearance.

OUTCOME EVALUATION

- Ask the patient about symptom improvement to determine effectiveness of laxative therapy. Patients should have an increase in stool frequency to three or more well-formed stools per week. Patients should report reduced defecation time or absence of excessive straining.
- When acute overuse or chronic misuse of saline or stimulant laxatives is suspected, electrolyte disturbances should be evaluated (eg, hypokalemia, hypernatremia, hyperphosphatemia, hypocalcemia).
- Some laxatives (eg, bulk producers) contain significant amounts of sodium or sugar and may be unsuitable for salt-restricted or diabetic patients. Monitoring of fluid retention (edema) and blood pressure changes is indicated in patients on sodium-restricted diets. Glucose monitoring may be required in diabetic patients with chronic use. Use of low-sodium or sugar-free products may be indicated.
- All laxatives are contraindicated in patients with undiagnosed abdominal pain, nausea, or vomiting. Patients should consult their health care providers if changes in bowel habits persist for more than 14 days or if laxative use for 7 or more days results in no effect.

Patient Care Process for Constipation

Collect Information:

- Ask about symptoms to determine if patient-directed therapy is appropriate or if the patient should be evaluated by a physician. Determine type, frequency, and duration of symptoms; presence or absence of abdominal pain; and exclude the presence of alarm symptoms.
- Review available information to determine potential causes and type of constipation. List factors that seem to make it better or worse. Assess dietary habits, fluid intake, and level of physical activity. Use of bowel and medication diary may help identify patterns. Use of the Bristol Stool Form Scale may be considered (see https://en.wikipedia.org/wiki/Bristol_stool_scale).

Assess the Information:

- Obtain a thorough history of prescription medication, nonprescription product, and dietary supplement use. Determine what treatments have been helpful in the past, whether the patient is taking any medications that may contribute to constipation, usual diet, and fluid intake. Assess for the presence of adverse drug reactions, drug allergies, and drug interactions.
- Assess the presence of pain to help differentiate functional constipation condition from possible IBS-C.

Develop a Care Plan:

- Recommend administration of soluble dietary fiber such as psyllium, then an osmotic agent such as PEG, then a magnesium-based or stimulant/stool softener-based product.
- Provide patient education about constipation, dietary modifications, and drug therapy. Consider asking, "Do you take the time to have a bowel movement?"

Implement the Care Plan:

- Educate the patient about causes of constipation and recommend ways to avoid it.
- Counsel the patient about appropriate laxative use, when to expect onset of relief, need for adequate fluid intake, and to seek medical attention if there is no improvement with laxative use in 3 or more days or if symptoms worsen.
- Advise the patient to seek medical attention if alarm symptoms occur.

Follow-up: Monitor and Evaluate:

- Develop a plan to assess the effectiveness of laxative use.

DIARRHEA

The definition of diarrhea is based on two characteristics of stool: frequency and consistency.[23] Diarrhea can be defined as increased frequency of passing abnormally liquid or unformed stools. Functional diarrhea is defined as the presence of loose or watery stools, without predominant abdominal pain or bothersome bloating, occurring in more than 25% of stools. The symptoms must be present for the last 3 months with symptom onset at least 6 months before the diagnosis is made. Patients

LO 4 meeting the criteria for IBS-D should be excluded. Diarrhea is defined as acute if it lasts less than 2 weeks, persistent if it lasts from 2 to 4 weeks, and chronic if it lasts longer than 4 weeks.[23] The World Health Organization (WHO) describes three levels of severity: (1) mild (diarrhea three or more times a day with occasional abdominal discomfort); (2) moderate (diarrhea three or more times a day with painful abdominal cramps and thirst); and (3) severe (diarrhea three or more times a day with severe abdominal cramps, thirst, nausea, and tiredness).[24] Diarrhea can also be classified based on the appearance of the stool: fatty, inflammatory (associated with blood in the stool), or watery.[24]

EPIDEMIOLOGY AND ETIOLOGY

The WHO reported that in 2015 diarrhea was the eighth-leading cause of death globally (more than 1.3 million deaths), the second most common cause of death in low-income economies (> 57.2 million deaths) and the sixth most common cause of death in lower-middle income economies (over 30.9 million deaths).[25]

Acute Diarrhea

Acute diarrhea generally involves the sudden onset of three or more loose or liquid stools above baseline in a 24-hour period. More than 90% of cases of acute diarrhea are caused by infectious agents. Acute diarrheal infection is also referred to as gastroenteritis. Most infectious diarrheas are acquired by fecal–oral transmission or via ingestion of food or water contaminated with human or animal fecal pathogens. Many of these cases are accompanied by abdominal pain and cramps, bloating, flatulence, passage of bloody stools, tenesmus, fecal urgency, fever, and vomiting. Some acute GI infections may cause vomiting as a predominant symptom with little to no diarrhea.[25] The remaining 10% of acute diarrhea cases are caused by medications, toxic ingestions, ischemia, food intake, and other conditions. Acute diarrhea is a leading cause of outpatient visits and hospitalizations and has a direct negative impact on quality of life.[24]

LO 5

Viruses cause a large proportion of acute diarrhea cases. Common culprits include Rotavirus, Norwalk, and adenovirus. Bacterial causes include *Escherichia coli*, *Salmonella* species, *Shigella* species, *Vibrio cholerae*, and *Clostridium difficile* (especially if antibiotics had been administered). The term *dysentery* describes some of these bacterial infections when associated with serious occurrences of bloody diarrhea.[26]

Acute or persistent diarrheal conditions can also result from parasites and protozoa such as *Entamoeba histolytica*, *Microsporidium*, *Giardia lamblia*, and *Cryptosporidium parvum*. Most of these infectious agents can cause **traveler's diarrhea**, a common condition that can afflict travelers worldwide. It usually occurs during or just after travel following ingestion of food or water that is contaminated with feces. It has an abrupt onset but usually subsides within 2 to 3 days (see Chapter 76, Gastrointestinal Infections, for more detailed information on traveler's diarrhea).

Brainerd diarrhea may be associated with subtle distal small intestine or proximal colonic inflammatory changes and is believed to be caused by an infectious origin. It is described as an abrupt-onset diarrhea that persists for 4 weeks and may last 1 to 3 years. It is named after Brainerd, Minnesota, the community where the first outbreak occurred in 1983.

Noninfectious causes of acute diarrhea include drugs and toxins, laxative abuse, food intolerance, IBS, inflammatory bowel disease, ischemic bowel disease, lactase deficiency, vitamin B_{12} deficiency anemia, diabetes mellitus, malabsorption, fecal impaction, diverticulosis, and celiac sprue.

Lactose intolerance is responsible for many cases of acute diarrhea, especially in persons of African descent, Asians, and Native Americans. Possible food-related causes include fat substitutes, dairy products, and products containing nonabsorbable carbohydrates.

The diarrhea of IBS is sudden, perhaps watery but likely loose, usually accompanied by urgency, bloating, and abdominal pain often in the morning or immediately following a meal. Inflammatory bowel disease is typically associated with the sudden onset of bloody diarrhea accompanied by urgency, crampy abdominal pain, and fever. Patients who experience bowel ischemia may develop bloody diarrhea, particularly if they progress to shock.

In the United States, high-risk groups for acquiring acute diarrhea include travelers, consumers of certain foods, immunodeficient persons, daycare attendees and their family members, and institutionalized persons.

Chronic Diarrhea

Chronic diarrhea is much less likely to be infectious and usually results from functional or inflammatory bowel disorders, endocrine disorders, malabsorption syndromes, and drugs (including laxative abuse). Daily watery stools may not occur with chronic diarrhea. Diarrhea may be either intermittent or continual.[27]

PATHOPHYSIOLOGY

Approximately 9 L (2.4 gallons) of fluid normally traverse the GI tract daily. Of this amount, 2 L represent gastric juice, 1 L is saliva, 1 L is bile, 2 L are pancreatic juice, 1 L is intestinal secretions, and 2 L are ingested. Of the 9 L of fluid presented to the intestine, only about 150 to 200 mL remain in the stool after reabsorptive processes occur.

Any event that increases the amount of fluid retained in the stool may result in diarrhea. Large-stool diarrhea often signifies small intestinal involvement, whereas small-stool diarrhea usually originates in the colon. Diarrhea may be classified according to pathophysiologic mechanisms, including osmotic, secretory, inflammatory, and altered motility.

Osmotic diarrhea results from the intake of nonabsorbable, water-soluble solutes in the intestinal lumen leading to water retention. Common causes include lactose intolerance and ingestion of magnesium-containing antacids.

Secretory diarrhea results from increased movement (secretion) of ions into the intestinal lumen, leading to increased intraluminal fluid. Medications, hormones, and toxins may be responsible for secretory activity.

Inflammatory (or exudative) diarrhea results from changes to the intestinal mucosa that damage absorption processes leading to increased proteins and other products in the intestinal lumen with fluid retention. The presence of blood or fecal leukocytes in the stool indicates an inflammatory process. The diarrhea of inflammatory bowel disease fits this classification.

Increased motility results in decreased contact time of ingested food and drink with the intestinal mucosa, leading to reduced reabsorption and increased fluid in the stool. Diarrhea resulting from altered motility is often established after other mechanisms have been excluded. IBS-related diarrhea is due to altered motility.

Diarrhea may be attributed to a single or to multiple overlapping mechanisms. For example, malabsorption syndromes and traveler's diarrhea are associated with both secretory and osmotic mechanisms.

Table 21–4

Selected Drugs and Substances That May Cause Acute Diarrhea

Drugs			
Antibiotics	Hydralazine	Metformin	Sorbitol
Colchicine	Laxatives	Misoprostol	Theophylline
Digitalis	Mannitol	Quinidine	Thyroid products
Dietary Supplements			
St. John's wort	Echinacea	Ginseng	Aloe vera
Poisons			
Arsenic	Cadmium	Mercury	Monosodium glutamate

LO 6

Drugs are a common cause of diarrhea (Table 21–4). Drug-induced diarrhea can occur by several mechanisms. First, water can be drawn into the intestinal lumen osmotically (eg, saline laxatives). Second, the intestinal bacterial ecosystem can be upset leading to emergence of invasive pathologic organisms triggering secretory and inflammatory processes (eg, antibiotic use). Third, some drugs increase intestinal motility. Other drugs produce diarrhea through undetermined mechanisms (eg, procainamide, colchicine). Discontinuation of the offending drug may be the only measure needed to ameliorate diarrhea.

CLINICAL PRESENTATION AND DIAGNOSIS

Patients with diarrhea should be questioned about the onset of symptoms, recent travel, diet, source of water, and medication use; see accompanying box for the clinical presentation of diarrhea. Other important considerations include duration and severity of the diarrhea and the presence of abdominal pain or vomiting; blood in the stool; stool consistency, appearance, and frequency; and weight loss. Although most cases of diarrhea are self-limited, infants, children, elderly persons, and immunocompromised patients are at risk for increased morbidity.

Findings on physical examination can assist in determining hydration status and disease severity. The presence of blood in the stool suggests an invasive organism, an inflammatory process, or perhaps a neoplasm. Large-volume stools suggest a small-intestinal disorder, whereas small-volume stools suggest a colon or rectal disorder. Further investigation should be performed in patients who present with diarrhea in the presence of alarm symptoms such as unintentional weight loss, diarrhea awakening the patient, recent antibiotic use, hematochezia (in the absence of documented bleeding hemorrhoids or anal fissures), very frequent bowel movement (> 6–10 daily), high volume diarrhea (> 250 mL of feces daily), evidence of malnutrition, family history of new or abnormal growth of colorectal tissue, celiac disease, or inflammatory bowel disease (IBS). Patients with prolonged or severe symptoms may require colonoscopic evaluation to identify the underlying cause.

TREATMENT

Acute diarrhea is generally self-limited, lasting 3 to 4 days even without treatment. Most healthy adults with diarrhea do not develop significant dehydration or other complications and can self-medicate symptomatically if necessary. KEY CONCEPT Dehydration can occur when diarrhea is severe and oral intake is limited, particularly in older persons and infants. Other complications of diarrhea resulting from fluid loss include electrolyte disturbances, metabolic acidosis, and cardiovascular collapse.

Children are more susceptible to dehydration (particularly when vomiting occurs) and may require medical attention early in the course, especially if younger than 3 years. Physician intervention is also necessary for elderly patients who are sensitive to fluid loss and electrolyte changes due to concurrent chronic illness.

Patients should undergo medical evaluation in the following circumstances: (a) moderate to severe abdominal tenderness, distention, or cramping; (b) bloody stools; (c) evidence of dehydration (eg, thirst, dry mouth, fatigue, dark-colored urine, infrequent urination, reduced urine, dry skin, reduced skin elasticity, rapid pulse, rapid breathing, muscle cramps, muscle

Clinical Presentation of Diarrhea

Signs and Symptoms of Acute Diarrhea

- Acute diarrhea presents abruptly as loose, watery, or semi-formed stools.
- Abdominal cramps and tenderness, rectal urgency, nausea, bloating, and fever may be present.
- Patients infected with invasive organisms may have bloody stools and severe abdominal pain.

Laboratory Tests in Acute Diarrhea

- Stool cultures can help identify infectious causes. Methods using real-time polymerase chain reaction shorten the reporting time.
- Stool may be analyzed for mucus, fat, osmolality, fecal leukocytes, and pH. Mucus fragments suggest colonic involvement; fat in the stool suggests malabsorption. Fecal leukocytes are present in inflammatory diarrheas including bacterial infections. Stool pH (normally > 6) is decreased by bacterial fermentation processes.
- Assessment of stool volume and electrolytes in large-volume watery stools may identify osmotic or secretory diarrhea.
- CBC and blood chemistries to determine extent of vitamin and electrolyte deficiencies may be helpful when symptoms persist. Findings of anemia, leukocytosis, or neutropenia offer further clues to the underlying cause.

Signs and Symptoms of Chronic Diarrhea

- Presenting symptoms may be severe or mild. Weight loss can be demonstrated, and weakness may be present.
- Dehydration may manifest as decreased urination, dark-colored urine, dry mucous membranes, increased thirst, and tachycardia.

Laboratory Tests in Chronic Diarrhea

- Tests described for acute diarrhea are also useful to diagnose chronic diarrhea; the differential diagnosis is more complicated. Results can help categorize the diarrhea as watery, inflammatory, or fatty, narrowing the focus on a primary disorder.
- Colonoscopy allows visualization, and biopsy of the colon and is preferred when there is blood in the stool or if the patient has acquired immune-deficiency syndrome.

weakness, sunken eyes, or lightheadedness); (d) high fever (38.3°C or 101°F or higher); (e) evidence of weight loss greater than 5% of total body weight; and (f) diarrhea that lasts longer than 48 hours.

Desired Outcomes

The goals of treatment for diarrhea are to relieve symptoms, maintain hydration, treat the underlying cause(s), and maintain nutrition. KEY CONCEPT The primary treatment of acute diarrhea includes fluid and electrolyte replacement, dietary modifications, and drug therapy.

Nonpharmacologic Therapy

▶ *Fluid and Electrolytes*

LO 7

Fluid replacement is not a treatment to relieve diarrhea but rather an attempt to restore fluid balance. In many parts of the world where diarrheal states are frequent and severe, fluid replacement is accomplished using oral rehydration solution (ORS), a measured mixture of water, salts, and glucose. The solution recognized by the WHO consists of 75 mEq/L (mmol/L) sodium, 75 mmol/L glucose, 65 mEq/L (mmol/L) chloride, 20 mEq/L (mmol/L) potassium, and 10 mEq/L (3.3 mmol/L) citrate, having a total osmolarity of 245 mOsm/L (mmol/L). A simple solution can be prepared from 1 L water mixed with eight teaspoonfuls of sugar and one teaspoonful of table salt. Some commercial products include Pedialyte, Rehydralyte, and CeraLyte.

Consistent intake of water (perhaps by slowly sipping), along with eating as tolerated, should restore lost fluids and salt for typical diarrhea sufferers. Patients may also replace lost fluid by drinking flat soft drinks such as ginger ale, tea, fruit juice, broth, or soup. Although sports drinks may be used to treat dehydration, caution should be exercised so they are not viewed as a casual panacea. Severe diarrhea may require use of parenteral solutions, and parenteral products should be used if patients are vomiting or unconscious.[23,24]

▶ *Dietary Modifications*

During an acute diarrheal episode, patients typically eat less as they focus on the diarrhea. Both children and adults should attempt to maintain nutrition because food helps replete lost nutrients and fluid volume. However, food-related fluid may not be sufficient to compensate for diarrheal losses. Some foods may be inappropriate if they irritate the GI tract or if they are implicated as the cause of the diarrhea. Patients with chronic diarrhea may find that increasing bulk in the diet may help (eg, rice, bananas, whole wheat, and bran).

Pharmacologic Therapy

The goal of drug therapy is to control symptoms, enabling the patient to continue with as normal a routine as possible while avoiding complications (Table 21–5). Most infectious diarrheas are self-limited or curable with anti-infective agents.

▶ *Adsorbents and Bulk Agents*

Attapulgite adsorbs excess fluid in the stool with few adverse effects. Formulations of attapulgite are available in Canada but not within the United States. Calcium polycarbophil is a hydrophilic polyacrylic resin (widely available in the United States) that also works as an adsorbent, binding about 60 times its weight in water and leading to formation of a gel that enhances stool formation. Neither attapulgite nor polycarbophil is systemically absorbed. Calcium polycarbophil is effective in reducing fluid in the stool. However, caution must be exercised because it can also adsorb nutrients and other medications, thereby reducing their benefits. Its administration should be separated from other oral medications by 2 to 3 hours. Psyllium and methylcellulose products may also be used to reduce fluid in the stool and relieve chronic diarrhea.

Table 21–5

Pharmacotherapy for Diarrhea

Drug	Usual Oral Dose	Type of Diarrhea
Calcium polycarbophil (OTC)	Adults: 1000 mg four times daily PO or after each loose stool, not to exceed 12 tablets per day Children 6–12 years: 500 mg PO three times daily Children 3–6 years: 500 mg twice daily	Chronic
Loperamide (OTC, RX)	Adults: 4 mg initially, then 2 mg PO after each subsequent loose stool. Maximum: 8 mg in 24 hours (OTC), 16 mg in 24 hours (RX) Children maximum daily doses: Age 2–5: 3 mg Age 6–8: 4 mg Age 8–12: 6 mg	Acute and chronic
Diphenoxylate/atropine (RX)	Adults: Two tablets (5 mg) initially, then one tablet PO every 3–4 hours, not to exceed 20 mg in 24 hours Children 2–12 years: Oral solution (avoid tablets) 0.3–0.4 mg/kg/day in divided doses. Do not administer to children younger than 2 years	Acute and chronic
Bismuth subsalicylate (OTC) (Kaopectate, PeptoBismol)	Adults and children 12 years and over: 524 mg/30 mL PO every 30–60 minutes as needed; Do not exceed 8 doses (240 mL or 16 tablets) per day Children: Consumers should speak with a physician before giving to children under 12 years of age	Traveler's and nonspecific acute diarrhea

OTC, over the counter; PO, by mouth; RX, prescription only.

▶ *Antiperistaltic (Antimotility) Agents*

Antiperistaltic drugs prolong intestinal transit time, thereby reducing the number of stools and the amount of fluid lost in the stool. The two drugs in this category are loperamide HCl (available over-the-counter as Imodium A–D and generically) and diphenoxylate HCl with atropine sulfate (available by prescription as Lomotil and generically). The atropine is included only as an abuse deterrent; when taken in large doses, the unpleasant anticholinergic effects of atropine negate the euphoric effect of diphenoxylate. Both loperamide and diphenoxylate are effective in relieving symptoms of acute noninfectious diarrhea and are

safe for most patients experiencing chronic diarrhea. These products should be discontinued in patients whose diarrhea worsens despite therapy.

Loperamide is considered safe when used in recommended doses. When excessive doses are ingested, severe problems such as cardiac arrhythmias and death can occur. Loperamide misuse and abuse has been reported. Coadministration of potent CYP450 3A4 inhibitors (eg, azole antifungals, clarithromycin, conivaptan, delavirdine, erythromycin, nefazodone, protease inhibitors, telithromycin) and 2C8 inhibitors (eg, gemfibrozil, clopidogrel) with loperamide may increase plasma loperamide concentrations and adverse effects. Patients who have ingested large doses of loperamide alone or with medications that can enhance loperamide effect may experience dizziness, lightheadedness, fainting, palpitations, irregular heart rhythm, shortness of breath, or syncope and should be advised to discontinue loperamide and seek medical attention.[28-31]

▶ *Antisecretory Agents*

Bismuth subsalicylate (BSS) is thought to have antisecretory and antimicrobial effects and is used to treat acute diarrhea. Although it passes largely unchanged through the GI tract, the salicylate portion is absorbed in the stomach and small intestine. For this reason, BSS should not be given to people who are allergic to salicylates, including aspirin. Caution should be exercised with regard to the total dose given to patients taking salicylates for other reasons to avoid **salicylism**. Patients taking BSS should be informed that their stool will turn black.

Octreotide is an antisecretory agent used for severe secretory diarrhea associated with cancer chemotherapy, human immunodeficiency virus, diabetes, gastric resection, and GI tumors. It is administered as a subcutaneous or IV bolus injection in an initial dose of 50 mcg three times daily to assess the patient's tolerance to GI adverse effects. Possible adverse effects include nausea, bloating, pain at the injection site, and gallstones (with prolonged therapy).

▶ *Probiotics, Prebiotics, and Synbiotics*

Probiotics are dietary supplements containing bacteria (*Lactobacillus* species, *Bifidobacterium* species, and others) that may promote health by enhancing the normal microflora of the GI tract while resisting colonization by potential pathogens. Probiotics can stimulate the immune response and suppress the inflammatory response. Probiotics can be taken in tablets, gummies, capsules, powders, and liquids. The type of product is not as important as the viability and number of organisms present.

Yogurt may provide relief from diarrhea due to lactose intolerance. The *Lactobacillus acidophilus* in yogurt, cottage cheese, and acidophilus milk improve digestion of lactose and may prevent or relieve diarrhea related to lactose deficiency and milk intake. Although lactase is not a probiotic, lactase tablets may also be used to prevent diarrhea in susceptible patients.

Patient Encounter 2

A 22-year-old female first-grade school teacher visited the urgent care clinic 3 weeks after the fall school year began complaining of fatigue, nausea, vomiting, episodes of mild abdominal pain, and frequent watery stools. She stated that she has increased thirst and her saliva has been thick and sticky. She also stated that her heart was racing after her evening walks the past few nights. She was excited to begin her teaching career but hasn't felt well for the past 3 days. Her temperature at home last night was 100°F (37.8°C). She is healthy and reports no known allergies; she recently began taking vitamin C to "improve resistance to infections."

Assess the likelihood that her diarrhea is due to an invasive microorganism.

Identify which of her symptoms suggest the presence of dehydration.

Discuss potential treatment measures for this woman.

Patient Care Process for Diarrhea

Collect Information:

- Determine symptoms, severity, frequency, and exacerbating factors.
- Review hydration status.
- Determine if patient-directed therapy is appropriate or a referral is needed.
- Inquire about recent foreign travel.
- Obtain history of prescription, nonprescription, and dietary supplement use.

Assess the Information:

- Review current therapy as potential cause(s) of diarrhea.
- Determine if any diarrhea treatments have been attempted, including home remedies.
- Assess need for medical evaluation if patient is pregnant, breastfeeding, younger than 3 years or older than 70 years, or has multiple medical conditions.

Develop a Care Plan:

- If home care is recommended, provide clear instructions about how to proceed if symptoms do not improve or new symptoms emerge.
- Discuss the importance of maintaining nutrition by diet modification.
- Educate the patient about: (a) acute and chronic diarrhea causes, (b) possible complications, (c) treatment goals, (d) the medication used to manage diarrhea, and (e) if appropriate, the circumstances when antibiotics are necessary.

Implement the Care Plan:

- Educate the patient about diarrhea and its likely causes.
- Advise the patient to seek medical attention if diarrhea does not resolve.

Follow-up: Monitor and Evaluate:

- Although most diarrheal episodes resolve with minimal intervention, individuals with a protracted course should be followed until symptoms have abated or are under control. Pay special attention to the very young, the aged, and those who are medically compromised.
- Refer the patient for medical attention if needed.

Prebiotics are nondigestible food ingredients that are fermentable in the colon and stimulate potentially health-promoting bacteria such as bifidobacteria and lactobacilli. Synbiotics are formed when prebiotics and postbiotics are joined. The use of fecal microbiota as biological agents in the treatment of diarrhea is being studied.

OUTCOME EVALUATION

- Monitor the patient with diarrhea from the point of first contact until symptoms resolve, keeping in mind that most episodes are self-limiting.
- Question the patient to determine whether symptom resolution occurs within 48 to 72 hours in acute diarrhea.
- Monitor for the maintenance of hydration, particularly when symptoms continue for more than 48 hours. Ask about increased thirst, decreased urination, dark-colored urine, dry mucous membranes, and rapid heartbeat, which suggest dehydration especially when nausea and vomiting are present.
- Monitor for symptom control in patients with chronic diarrhea.
- When antibiotics are used, monitor for completion of the course of therapy.

IRRITABLE BOWEL SYNDROME

KEY CONCEPT IBS is a functional bowel disorder (FBD) in which recurrent abdominal pain is associated with defecation or a change in bowel habits. In the absence of alarm symptoms such as rectal bleeding, family history of colon cancer, or unintentional weight loss, disordered bowel habits such as constipation, diarrhea, or a mix of constipation and diarrhea and symptoms of abdominal bloating/distention are usually present. IBS is classified into one of four types: (1) constipation predominant (IBS-C), (2) diarrhea predominant (IBS-D), (3) mixed with both constipation and diarrhea (IBS-M), or (4) unsubtyped (IBS-U; hard or lumpy stools < 25% of the time and loose or watery stools < 25% of the time). IBS is associated with frequent fluctuation in symptoms, loss of productivity, and decreased quality of life.[32]

LO 9

EPIDEMIOLOGY AND ETIOLOGY

The incidence and prevalence of IBS are unknown in many countries; therefore, global epidemiological features are difficult to determine. Furthermore, the current definition of IBS according to Rome IV criteria and consideration for cultural perspectives may affect the epidemiology of IBS.[1,32] IBS is one of the most common disorders seen in primary care and the most common reason for referral to gastroenterologists. Although between 15% and 20% of Americans suffer from IBS, only about one-quarter of those affected seek medical attention. The associated costs to society are estimated to be billions of dollars, and the recurrent nature of IBS contributes to these costs through missed workdays, inattention on the job, and high consumption of health care services.

In the United States, IBS affects women about twice as often as men. However, this may simply reflect a greater tendency to seek medical care. IBS can occur at any age but is most common between 20 and 50 years; onset beyond age 60 is rare.

IBS is associated with psychiatric distress, sleep disturbance, affective vulnerability, and difficulty adjusting behavior to environmental demands. Alcohol consumption and smoking have not been shown to be risk factors for developing IBS. However, alcohol may worsen symptoms in affected persons.

Some people show first evidence of IBS after contracting gastroenteritis (sometimes referred to as postinfectious IBS). This has led to speculation about whether infection heightens GI tract susceptibility. Menstrual periods may trigger symptoms in some women.[32]

PATHOPHYSIOLOGY

Enteric nerves control intestinal smooth muscle action and are connected to the brain by the autonomic nervous system. IBS is thought to result from dysregulation of this "brain–gut axis." The enteric nervous system is composed of two ganglionated plexuses that control gut innervation: the submucous plexus (Meissner plexus) and the myenteric plexus (Auerbach plexus). The enteric nervous system and the CNS are interconnected and interdependent. A number of neurochemicals mediate their function, including serotonin (5-hydroxytryptamine or 5-HT), acetylcholine, substance P, and nitric oxide, among others.[33]

Serotonin is particularly important because the GI tract contains the largest amounts in the body. Two 5-HT receptor subtypes, 5-HT_3 and 5-HT_4, are involved in gut motility, visceral sensitivity, and gut secretion. The 5-HT_3 receptors slow colonic transit and increase fluid absorption, whereas 5-HT_4 receptor stimulation accelerates colonic transit.

Although no single pathologic defect accounts for the pattern of exacerbation and remission in IBS, CNS abnormalities, dysmotility, visceral hypersensitivity, and other factors have been implicated.[33]

The passage of fluids into and out of the colon is regulated by epithelial cells. In IBS, the colonic lining (epithelium) appears to function properly. However, increased movement of the contents in the colon can overwhelm its absorptive capacity. Disturbed intestinal motility appears to be a central feature of IBS, which leads to altered stool consistency. Studies suggest that the colon of IBS sufferers is abnormally sensitive to normal stimuli. Enhanced visceral sensitivity manifests as pain, especially related to gut distention.

Some IBS patients demonstrate sensitivity to common foods such as wheat, beef, pork, soy, and eggs. Evidence suggests that an immune component may be involved in IBS patients who experience bloating and dysmotility-like dyspepsia and that gender specificity exists.

CLINICAL PRESENTATION AND DIAGNOSIS

Refer to the accompanying box for the clinical presentation of IBS. KEY CONCEPT The diagnosis of IBS is made by symptom-based criteria, the absence of alarm symptoms, and the exclusion of organic disease. Patient diagnosis is categorized by the predominant disorder (IBS-C, -D, -M, or -U).

IBS is diagnosed by obtaining a thorough history to distinguish the characteristic symptoms of IBS from other conditions having similar symptoms, physical examination including anorectal examination, limited diagnostic tests, and careful follow-up. Patients should be questioned about the frequency, consistency, color, and size of stools. Because of the functional nature of IBS, a patient may present with symptoms of upper GI problems such as gastroesophageal reflux disease or with excessive flatulence. Patients should also be questioned about diet to establish any symptom relationship to meals or specifically after consumption of certain foods.

Barium enema, **sigmoidoscopy**, or **colonoscopy** may be indicated in the presence of red flag symptoms (fever, weight loss, bleeding, anemia, and persistent severe pain), which often point to a potentially serious non-IBS problem. A barium enema may identify polyps, diverticulosis, tumors, or other abnormalities that might be responsible for the symptoms. Furthermore, barium enema may detect exaggerated haustral contractions, which can impede stool movement and contribute to constipation. Flexible sigmoidoscopy can identify obstructions in the rectum and lower colon, whereas colonoscopy can evaluate the entire colon for organic disease.

The Rome IV diagnostic criteria for IBS include symptoms of recurrent abdominal pain occurring on average at least 1 day per week in the last 3 months, associated with two or more of the following: (1) related to defecation, (2) associated with a change in frequency of stool, or (3) associated with a change in form (appearance of stool). These findings should exist for the last 3 months with symptom onset at least 6 months prior to diagnosis.[1]

TREATMENT

Desired Outcomes

LO 10

KEY CONCEPT The principal goal of IBS treatment is to reduce or control symptoms. The treatment strategy is based on: (a) the prevailing symptoms and their severity, (b) the degree of functional impairment, and (c) the presence of psychological components. A standard treatment regimen is not possible because of the heterogeneous nature of the IBS patient population. Patients suffering from IBS can benefit from clinician support and reassurance.

Nonpharmacologic Therapy

▶ *Diet and Other General Modifications*

Dietary modification is a standard therapeutic modality. Food hypersensitivities and adverse effects have been associated with IBS, especially IBS-D. Elimination diets are the most commonly used strategy, usually focusing on milk and dairy products,

Clinical Presentation of IBS

LO 8

Symptoms

- Patients report a history of abdominal pain or discomfort that is relieved with defecation. Symptom onset is associated with change in frequency or appearance of stool. Some persons experience hard, dry stools; others have loose or watery stools. Stools may be small and pellet-like or narrow and pencil-like in appearance.
- KEY CONCEPT Symptoms can typically be categorized as either IBS-D or IBS-C. Patients with IBS-D usually report more than three loose or watery stools daily. Those with IBS-C usually have fewer than three bowel movements per week; stools are typically hard and lumpy and accompanied by straining. However, stool frequency may be normal in many cases.
- IBS-C can often be distinguished from functional constipation by the presence of abdominal pain and discomfort. Although pain and discomfort may be present in some patients with functional constipation, it is an expected feature of IBS.
- Some patients report alternating episodes of diarrhea and constipation (IBS-M).
- Patients with IBS-U report hard or lumpy stools less than 25% of the time and loose or watery stools less than 25% of the time.
- Other common symptoms include: (a) feelings of incomplete evacuation, (b) abdominal fullness, (c) bloating, (d) flatulence, (e) passage of clear or white mucus with stool, and (f) occasional fecal incontinence.
- Periods of normal stools and bowel function are punctuated by episodes of sudden symptoms.
- Symptoms are often exacerbated by stress.
- Left lower quadrant abdominal pain is often brought on or made worse by eating. Passage of stool or flatus may provide some relief.
- Patients with IBS may experience comorbidities outside the GI tract such as fibromyalgia, sleep disturbances, headaches, dyspareunia, and temporomandibular joint syndrome.

Signs

- The physical examination is often normal in IBS.
- The patient may appear to be anxious.
- Palpation of the abdomen may reveal left lower quadrant tenderness, which may indicate a tender sigmoid colon.
- Abdominal distention may be present in some cases.
- The following "red flag" or alarm features are *not* associated with IBS and may indicate inflammatory bowel disease, cancer, or other disorders: fever, weight loss, bleeding, anemia, and persistent severe pain.

Laboratory Tests

- In most cases, laboratory testing reveals no abnormalities, but certain tests can help identify other causes for the patient's symptoms:
  - CBC may identify anemia, which may suggest blood loss and an organic source for GI symptoms.
  - Serum electrolytes and chemistries may indicate metabolic causes of symptoms.
  - Thyroid-stimulating hormone (TSH) should be ordered when thyroid dysfunction is suspected. Hypothyroidism may be responsible for constipation and related symptoms.
  - Stool testing for ova and parasites may identify *C. difficile* and amoebae as possible causes of diarrhea rather than IBS.
  - Fecal leukocytes can be found in inflammatory diarrhea, especially when due to invasive microorganisms.
  - A positive stool guaiac test indicating blood in the GI tract does not support a diagnosis of IBS.
  - An elevated erythrocyte sedimentation rate is consistent with a systemic inflammatory process such as inflammatory bowel disease rather than IBS.
  - Testing for lactase deficiency can confirm the presence of lactose intolerance, which may explain the symptoms.

Patient Encounter 3, Part 1

A recently widowed 38-year-old woman presents to the clinic complaining of headaches, sleep disturbances, cramping abdominal pain, bloating, excessive flatulence, and small amounts of hard, dry stools. When asked to show where her abdomen hurts, she points to both her lower left and lower right abdomen. She indicates that the pain seems to lessen after a bowel movement. Further, she states that the symptoms have become worse over the last month with dry stools that make it difficult to defecate. During some weeks, she can go a few days without a single bowel movement. She was diagnosed with fibromyalgia 7 months ago and was started on pregabalin. She states that the pregabalin has helped somewhat.

Identify symptoms characteristic of IBS in this patient.

Discuss how this patient fits within the typical epidemiologic profile of patients with IBS.

fructose and sorbitol, wheat, and beef. Flatulence may be controlled by reducing gas-causing foods (beans, celery, onions, prunes, bananas, carrots, and raisins). Response to elimination diets varies widely, but they may be useful in individual patients. Care should be taken to avoid nutritional deficits while attempting to eliminate offending foods.

The low FODMAP diet is said to control IBS symptoms in some patients. FODMAPs are carbohydrates (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) that are poorly absorbed and quickly fermented by bacterial action in the gut. The gas byproduct of the bacterial action is thought to contribute to IBS symptoms.[34]

Probiotics may also be an option for some patients with IBS. *Bifidobacterium infantis* is one product used for its effect in constipation, diarrhea, gaseousness, bloating, and abdominal discomfort. It has not been associated with significant untoward effects. The usual dose is one 4-mg capsule daily.

▶ *Psychological Treatments*

Psychotherapy focused on reducing the influence of the CNS on the gut has been studied. Cognitive behavioral therapy (CBT), dynamic psychotherapy, relaxation therapy, and hypnotherapy have been effective in some patients. However, psychological approaches are not considered replacements for usual care.

Pharmacologic Therapy

▶ *Agents for Pain and Bloating*

Botanicals Peppermint oil is widely advocated; it acts as an antispasmodic agent due to its ability to relax GI smooth muscle. However, it also relaxes the lower esophageal sphincter, which could allow reflux of gastric contents into the esophagus. The usual dose is one to two enteric-coated capsules containing 0.2 mL of peppermint oil two to three times daily. *Matricaria recutita*, known as German chamomile, is also purported to have antispasmodic properties. It is taken most often as a tea up to four times a day. Benzodiazepine, alcohol, and warfarin users should be cautioned against taking this product because it can cause drowsiness, and it contains coumarin derivatives. Primrose oil is used by some patients, but evidence of effectiveness is lacking.

Patient Encounter 3, Part 2

Upon further questioning, the patient recalls experiencing similar symptoms about 15 years ago when she thought she would have to leave school because of dwindling finances. She did not seek medical attention then because she couldn't afford it. She is a full-time pharmacy technician and recently started studying for the PCAT. Her diet consists mostly of fast food.

PMH: Insomnia, headaches, fibromyalgia

FH: None

SH: Has a glass of wine occasionally with dinner

Meds: Pregabalin 150 mg two times daily for fibromyalgia; melatonin 3 mg one tablet 1 to 2 hours before bedtime as needed for insomnia; ibuprofen 600 mg every 6 hours as needed for headache; loperamide 2 mg as needed for diarrhea; docusate sodium 100 mg as needed for constipation

Allergies: Penicillin (rash, hives, and difficulty breathing after taking amoxicillin at the age of 9)

PE:

General: Well nourished; somewhat anxious and nervous when speaking

VS: BP 135/87 mm Hg; Pulse 86 beats/min; RR 18 breaths/min; T 97.4°F (36.3°C); Ht. 5'5" (165 cm); Wt. 148 lbs. (67.1 kg)

Integ: Nails are chewed up; skin appears dry and scaly

HEENT: PERRLA, EOMI

Ext: Normal, no swelling

Chest: Clear to A and P bilaterally

CV: RRR

Abd: (+) BS, tender LLQ and LRQ

Rectal: No abnormalities, negative stool guaiac test

Which of this patient's findings are indicative of IBS?

Propose a comprehensive treatment approach to IBS in this patient. Where appropriate, consider the presence and influence of comorbidities.

▶ *Agents for Constipation Predominance (IBS-C)*

LO 11 **Bulk Producers** These agents may improve stool passage in IBS-C but are unlikely to have a favorable effect on pain or global IBS symptoms. Psyllium may increase flatulence, which can worsen discomfort in some patients. Methylcellulose products are less likely than psyllium to increase gas production. Although fiber-based supplement use is common in IBS-C, methylcellulose may be dose-adjusted in diarrhea to increase stool consistency.

LO 11 **Osmotic Laxatives** More studies are needed to determine the evidence of benefit on quality of life, number of stools, symptom improvement, and ability to continue therapy in patients with IBS-C with use of polyethylene glycol 3350 (PEG) or PEG 3350 with electrolytes.

Linaclotide (Linzess) This drug is a guanylate cyclase-C (GC-C) agonist indicated for treatment of IBS-C in adults. In IBS-C the recommended linaclotide dose is 290 mcg orally once daily. Linaclotide relieves the abdominal pain, bloating and constipation associated with IBS-C while exhibiting a low

tendency for systemic side effects. However, diarrhea may lead to discontinuation in some patients. Clinical trials have demonstrated symptom relief and improved quality of life in treated patients. Studies of linaclotide had high overall quality of evidence across all critical outcomes such as abdominal pain response, spontaneous complete bowel movement response, improvement in quality of life, and improvement in stool consistency and urgency.[35]

LO 11

Lubiprostone (Amitiza) This agent is also FDA approved for treatment of IBS-C, but only in women age 18 years and older. Lubiprostone is generally well tolerated in such patients. It is typically given in smaller doses than those used in CIC. However, as with treatment for constipation, nausea may limit its use. Diarrhea leading to treatment discontinuation may occur. Recent evidence indicated a moderate degree of symptom relief and improvement in quality of life with lubiprostone use.[35] No clinical studies currently exist that compare the beneficial effects or harm associated with the use of linaclotide versus lubiprostone.

LO 11

Plecanatide (Trulance) This guanylate cyclase-C agonist is indicated for treatment IBS-C.[36] Plecanatide and its active metabolite act locally on the luminal surface of the intestinal epithelium to increase availability of intra- and extracellular cyclic GMP. In animal models increased availability of cyclic GMP has been associated with decreased activity of pain-sensing nerves of visceral pain, and stimulation of secretion of chloride and bicarbonate via activation of the cystic fibrosis transmembrane conductance regulator (CFTR) ion channel into the intestinal lumen, resulting in increased intestinal fluid and accelerated transit. Due to risk of serious dehydration, plecanatide is contraindicated in patients less than 6 years of age, and its use should be avoided in patients aged 6 to 18 years of age. The safety and efficacy of plecanatide in patients less than 18 years of age has not been established. The recommended adult dosage for treating IBS-C is one 3-mg tablet orally once daily.[37] The tablet should be swallowed whole and can be taken with or without food. Upon receipt of the medication the patient should be instructed to read the accompanying medication guide. Diarrhea leading to discontinuation is the most common adverse reaction associated with plecanatide. Most cases of diarrhea occurred within the first 4 weeks of therapy, but severe diarrhea has been reported within the first day of treatment. Less commonly reported adverse effects included nausea, nasopharyngitis, upper respiratory tract infection, urinary tract infection, and dizziness. Increased liver alanine aminotransferase (AST) levels have been reported.

Tegaserod maleate (Zelnorm) is indicated for men and women with IBS-C and women under the age of 55 with CIC. It enhances intestinal secretion and motility through its partial 5-hydroxytryptamine (5-HT_4) receptor partial agonist activity. The availability and use of tegaserod maleate is restricted because of an increased risk of heart attack, stroke, and unstable angina. When no other satisfactory alternative therapy is available, physicians may obtain tegaserod maleate under the FDA Expanded Access Program for a single patient emergency use by submitting a Single Patient IND application to the FDA. Medical conditions that are cause for denial of use include prior history of heart attack or stroke, unstable angina, hypertension, hyperlipidemia, diabetes, age greater than 55 years, smoking obesity, depression anxiety, and suicidal ideation.[38]

▶ *Agents for Diarrhea Predominance (IBS-D)*

Loperamide This antidiarrheal inhibits peristalsis and fluid secretion, thereby improving stool consistency and reducing the number of stools. Consequently, it is most useful in patients who have diarrhea as a prominent symptom. However, it does not lessen abdominal pain and can occasionally aggravate pain. Recent evidence indicates that the level of symptom relief and improvement in quality of life with loperamide is very low.[35] As described in the Diarrhea section, excessive dosing can result in serious cardiovascular adverse effects; patients should be instructed not to exceed the maximum recommended dose of 8 mg (OTC) or 16 mg (prescription) daily.

LO 11

Antispasmodics Dicyclomine and hyoscyamine have been among the most frequently used medications for treating abdominal pain in patients with IBS (Table 21–6). They have shown improvement in global symptoms and abdominal pain associated with IBS. Nevertheless, the overall quality of evidence across all critical outcomes for antispasmodics is low.

LO 11

Side effects include dry mouth, dizziness, blurred vision, constipation, urinary retention, and (rarely) psychosis. Although their effectiveness remains unconfirmed, these drugs may deserve a trial in patients with intermittent postprandial pain.[35]

Antidepressants Tricyclic antidepressants (TCAs) (eg, amitriptyline, desipramine, trimipramine, doxepin) may help patients with IBS who predominantly experience abdominal pain. They modulate pain principally through effects on neurotransmitter reuptake, especially norepinephrine and serotonin. Their effectiveness in functional GI disorders seems independent of mood-altering effects normally associated with these agents. Continued TCA therapy may be limited by adverse effects. The overall effect of TCAs on quality of life, symptom relief, and presence of adverse events leading to treatment discontinuation is reported as low.[35]

LO 11

The selective serotonin-reuptake inhibitors (SSRIs) paroxetine, fluoxetine, and citalopram are potentially useful due to the significant effect of serotonin in the gut. SSRIs principally act on 5-HT_1 or 5-HT_2 receptors, but they can also have some effect on gut-predominant 5-HT_3 and 5-HT_4 receptors, perhaps reducing visceral hypersensitivity. They may be beneficial for patients with IBS-C or when the patient presents with IBS complicated by a mood disorder. IBS patients receiving SSRIs may report improved well-being, mood, and GI symptoms. Serotonin–norepinephrine reuptake inhibitors (SNRIs) do not offer significant improvement of global symptoms or abdominal pain. Recent evidence indicates that use of SSRIs in IBS patients in relationship to the overall quality of evidence across all critical outcomes was rated as low.[35]

LO 11

Rifaximin (Xifaxan) This semisynthetic antibacterial agent is structurally similar to rifampin. It has very low systemic absorption and is FDA approved for treatment of IBS-D in adults. Research suggests bacterial overgrowth plays a role in producing bloating experienced by some IBS patients. Rifaximin is not to be used in patients with diarrhea accompanied by fever or blood in the stool or diarrhea due to pathogens other than *E. coli*. It should be used with caution in patients with severe (Child-Pugh Class C) hepatic impairment. Rifaximin has proven to be better than placebo in relieving bloating, and its lack of absorption reduces the likelihood of adverse effects. The overall quality of evidence across outcomes such as pain relief, stool consistency, and return of complete spontaneous bowel movements is considered to be moderate.[35]

LO 11

For treatment of IBS-D, rifaximin 550 mg tablets are administered orally 3 times daily for 14 days. The same regimen can be repeated up to 2 times in patients who experience recurrence. Potential adverse reactions include nausea, increased alanine aminotransferase (ALT) and creatine kinase (CK) enzymes, *C. difficile*-associated colitis, myalgia, and hypersensitivity reactions including exfoliative dermatitis, rash, swelling of the

Table 21–6

Pharmacologic Treatments for IBS

Generic Name	Dose
Antispasmodics	
Dicyclomine	10–20 mg PO every 4–6 hours as needed
Hyoscyamine	0.125–0.25 PO mg or sublingually every 4 hours as needed
Propantheline bromide	15 mg PO three times a day (before meals) and 30 mg at bedtime
Clidinium bromide plus chlordiazepoxide HCl	5–10 mg PO three to four times a day
Hyoscyamine, scopolamine, atropine, phenobarbital	One to two tablets PO three to four times daily
Tricyclic Antidepressants	**In IBS with Diarrhea:**
Amitriptyline	50–150 mg PO daily
Doxepin	10–150 mg PO daily
Selective Serotonin-Reuptake Inhibitors	**In IBS with Constipation:**
Paroxetine (others can be used)	10–40 mg PO daily
Bulk-Forming Laxatives	
Psyllium	2.5–4 g PO daily
Methylcellulose	4–6 g PO daily
Antimotility Agents	
Loperamide	4 mg PO; then 2 mg PO after each loose stool; daily maximum: 8 mg (OTC) or 16 mg (RX)
5-HT$_3$ Receptor Antagonist	
Alosetron[a]	0.5 mg PO two times a day for 4 weeks; then assess appropriate dose
5-HT$_4$ Receptor Agonist	
Tegaserod maleate[a]	6 mg PO twice daily
Guanylate Cyclase-C (GC-C) Agonist	
Linaclotide	290 mcg PO once daily
Plecanatide	3 mg PO once daily
Nonabsorbable antibiotic	
Rifaximin	550 mg PO three times daily for 14 days; patients who experience symptom recurrence can be retreated up to two times with the same dosage regimen
Mu-Opioid Receptor Agonist	
Eluxadoline	100 mg PO twice daily with food; 75 mg PO twice daily is recommended for select patients (eg, hepatic impairment)
Chloride Channel Activator	
Lubiprostone	8 mcg PO twice daily with food and water

[a]Withdrawn from general use; available only as emergency treatment.

face and tongue and difficulty swallowing. Hypersensitivity reactions can occur within 15 minutes of rifaximin ingestion. Rifaximin use for treatment of IBS-D has not been studied in pregnant women or children under the age of 18. Caution should be used in patients with liver dysfunction.[39]

Alosetron (Lotronex) Stimulation of 5-HT$_3$ receptors triggers hypersensitivity and hyperactivity of the large intestine. Alosetron, a selective 5-HT$_3$ antagonist, blocks these receptors and is indicated only for women with severe IBS-D who have: (1) chronic IBS symptoms (6 months or longer); (2) no anatomic or biochemical abnormalities of the GI tract; and (3) not responded adequately to conventional therapy. Recent evidence found moderate improvement in symptoms and quality of life with alosetron.[35] The recommended starting dose is 0.5 mg twice daily, increasing to 1 mg twice a day after 4 weeks if the starting dosage is well tolerated but does not adequately control IBS symptoms. The most common adverse effects are constipation, abdominal discomfort and pain, nausea, and GI discomfort and pain. Alosetron labeling contains a black box warning related to serious GI adverse reactions, including ischemic colitis and serious complications of constipation that have resulted in hospitalization and, rarely, blood transfusion, surgery, and death.

LO 11

Eluxadoline (Viberzi) This μ-opioid receptor agonist reduces bowel contractions and is FDA approved for treatment of adults with IBS-D.[40,41] The recommended dose is 100 mg orally twice daily taken with food. The dose can be reduced to 75 mg twice daily with food in patients who cannot tolerate the 100-mg dose and in patients with mild or moderate hepatic impairment. The most common adverse effects are constipation, nausea, and abdominal pain. It is contraindicated in persons who drink more than three alcoholic beverage per day because these patients are at increased risk for acute pancreatitis.[41] Eluxadoline should not be used in patients without a gallbladder because these patients are at increased risk of developing pancreatitis and/or sphincter of Oddi spasm. Eluxadoline is a Schedule IV controlled substance.

OUTCOME EVALUATION

- Monitor for adequate symptom relief. Patients whose pain does not respond to drug therapy may have a psychological comorbid condition requiring psychiatric intervention.
- Monitor for relief of pain if initially present. Monitor IBS-C or IBS-D patients for stool frequency, appearance, and size relative to normal characteristics. As stools normalize, associated symptoms such as bloating and abdominal distention should resolve.
- For IBS-C and IBS-M patients taking bulk producers, monitor for relief of constipation. Hard stools should soften within 72 hours.
- Monitor antidepressant and antispasmodic therapy for relief of abdominal pain and potential adverse effects.
- Assess 5-HT$_4$ receptor agonists for relief of crampy abdominal pain and bloating.
- Monitor linaclotide for treatment-limiting diarrhea in IBS-C.
- Evaluate 5-HT$_3$ receptor antagonists (alosetron) for relief of abdominal pain and fecal incontinence. Monitor for constipation.
- Expect antimotility agents to reduce stool frequency and control diarrhea within 18 to 36 hours unless severe.
- Monitor CBC, serum electrolytes and chemistries, stool guaiac, and erythrocyte sedimentation rate yearly for changes that might signal an overlapping organic problem.
- Refer for medical evaluation any patient presenting with red flag signs (eg, fever, weight loss, bleeding, anemia, persistent severe pain).

Patient Care Process for IBS

Collect Information:

- Determine the type, severity, and frequency of symptoms and possible exacerbating factors.
- Obtain a thorough current history of prescription, nonprescription, and dietary supplement use.

Assess the Information:

- Determine if any IBS treatments have been attempted and their effectiveness.
- Establish whether self-care is appropriate or a medical referral is needed.

Develop a Care Plan:

- Determine whether the patient has received prior education about IBS, lifestyle modifications, drug therapy for IBS, and symptom prevention measures. If necessary:
  - Explain medication use relative to symptom intensity
  - Describe potential adverse effects
  - List drugs that may interact with the therapy

Implement the Care Plan:

- Provide patient education about IBS and the treatment selected.

Follow-up: Monitor and Evaluate:

- Encourage patients to report every professional interaction since their last encounter to remain current with all treatment recommendations.
- Be vigilant for the occurrence of red flag symptoms.

Abbreviations Introduced in This Chapter

BSS	Bismuth subsalicylate
CBT	Cognitive behavioral therapy
CIC	Chronic idiopathic constipation
FBD	Functional bowel disorder
FGID	Functional gastrointestinal disorder
GMP	Guanosine monophosphate
IBS	Irritable bowel syndrome
IBS-C	Irritable bowel syndrome with constipation
IBS-D	Irritable bowel syndrome with diarrhea
IBS-M	Irritable bowel syndrome with constipation and diarrhea (mixed)
NTC	Normal-transit constipation
OIC	Opioid-induced constipation
ORS	Oral rehydration solution
STC	Slow-transit constipation
PAMORA	Peripherally acting μ-opioid receptor antagonist
TCA	Tricyclic antidepressant
TD	Traveler's diarrhea

22 Portal Hypertension and Cirrhosis

Laurajo Ryan

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Explain the pathophysiology of cirrhosis and portal hypertension.
2. Identify signs and symptoms of cirrhosis.
3. Identify laboratory abnormalities that result from liver disease and describe the associated pathophysiology.
4. Describe the consequences associated with decreased hepatic function.
5. Identify treatment goals for a patient with complications of cirrhosis.
6. Recommend a specific treatment regimen for a patient with cirrhosis that includes lifestyle changes, nonpharmacologic measures, and pharmacologic therapy.

INTRODUCTION

Cirrhosis involves replacement of normal hepatic architecture with fibrous scar tissue. Scarring is accompanied by loss of viable hepatocytes, which are the functional cells of the liver. Cirrhosis is characterized by progressive damage and deterioration of liver function, but even with extensive scarring some patients remain asymptomatic. KEY CONCEPT Advanced cirrhosis is irreversible and leads to portal hypertension, which in turn is responsible for the complications that define decompensated cirrhosis. Complications of cirrhosis include ascites, spontaneous bacterial peritonitis (SBP), hepatic encephalopathy (HE), hepatorenal syndrome (HRS), and variceal bleeding.[1] These complications all carry high mortality rates and are signs of disease progression.

EPIDEMIOLOGY AND ETIOLOGY

Cirrhosis is the 12th leading cause of death in the United States. It places an enormous economic and social burden on society from hospitalizations, lost wages, decreased productivity, and emotional strain of the disease on both patients and their families.

Cirrhosis is the result of long-term insult to the liver, and damage usually doesn't become clinically evident until the fourth decade of life. Infection with one or more strains of viral hepatitis causes acute, potentially reversible hepatic inflammation, whereas chronic infection with hepatitis B (HBV) or C (HCV) can lead to cirrhosis. Alcohol ingestion and HCV are the most common causes of cirrhosis in the United States, whereas HBV accounts for the majority of cases worldwide.[2] HCV therapies that provide sustained virologic response (SVR) essentially cure the disease, and are expected to dramatically decrease new cases of cirrhosis. Even patients who have already developed HCV cirrhosis can benefit from antiviral therapy, and recent guidelines recommend treatment for nearly all patients (see Chapter 24, Viral Hepatitis, for more details).[3]

Alcoholic cirrhosis usually develops only after decades of heavy drinking. It develops more quickly in women than men, even after taking body weight into account. Estimates vary, but alcoholic cirrhosis can develop after as few as two to three daily drinks in women and three to four drinks in men, although five to eight daily drinks is more typical.[4] Differences in metabolism may account for the gender disparity; women metabolize less alcohol in the gastrointestinal (GI) tract, allowing delivery of more ethanol (which is directly hepatotoxic) to the liver.[5] Genetic factors also play a role in disease progression; some patients develop cirrhosis with much less cumulative alcohol intake than is typical (either fewer drinks per day or faster disease onset), while others with much greater intake never develop cirrhosis.

Alcoholic Liver Disease

Alcoholic liver disease progresses through several distinct phases—from fatty liver to alcoholic hepatitis and finally to cirrhosis. Changes in metabolism account for the fatty liver, hypertriglyceridemia, and acidemia observed in alcoholic liver disease. Fatty liver and alcoholic hepatitis are often reversible with cessation of alcohol intake, and even though the scarring of cirrhosis is usually permanent, stopping drinking can decrease complications and slow progression to end-stage liver disease.[6]

Ethanol metabolism begins prior to absorption; alcohol dehydrogenase in the gastric mucosa oxidizes a portion of alcohol to acetaldehyde. The remaining alcohol is rapidly absorbed from the GI tract and readily enters body tissues because it is highly lipid soluble. KEY CONCEPT Alcohol dehydrogenase oxidizes ethanol to acetaldehyde primarily in the liver, which causes inflammation and fibrosis.[7] Acetaldehyde exerts direct toxic effects on the liver by damaging hepatocytes, inducing fibrosis, and directly coupling to proteins, interfering with their intended function. High ethanol levels saturate the alcohol dehydrogenase enzyme system. Once it is overwhelmed, the microsomal ethanol oxidizing system takes over the detoxification process. This is an inducible cytochrome P-450 (CYP450) enzyme system; it participates in

phase 1 metabolism, and like alcohol dehydrogenase, produces acetaldehyde as its end product.[8]

Less Common Causes of Cirrhosis

Genetics and metabolic risk factors mediate other less common causes of cirrhosis. These diseases vary widely in prevalence, disease progression, and treatment options.

Primary biliary cirrhosis is characterized by progressive inflammatory destruction of the bile ducts. This immune-mediated inflammation of the intrahepatic bile ducts causes remodeling and scarring, resulting in retention of bile in the liver, hepatocellular damage, and cirrhosis. The prevalence of primary biliary cirrhosis is difficult to estimate because it is often asymptomatic and patients are frequently diagnosed incidentally during routine health care visits.

Nonalcoholic fatty liver disease (NAFLD) begins with asymptomatic fatty liver but can progress to cirrhosis. NAFLD is a diagnosis of exclusion; viral, genetic, or environmental causes must be ruled out prior to making this diagnosis. NAFLD is directly related to several metabolic abnormalities—diabetes mellitus, dyslipidemia, obesity, insulin resistance, and other conditions associated with increased hepatic fat.[9]

Hereditary hemochromatosis is an autosomal recessive disease that causes increased intestinal iron absorption and subsequent deposition in hepatic, cardiac, and pancreatic tissue. Hepatic iron overload results in fibrosis, hepatic scarring, cirrhosis, and hepatocellular carcinoma. Repeated blood transfusions can also cause hemochromatosis, but this mechanism rarely leads to cirrhosis.

In Wilson disease (also an autosomal recessive disease), the protein responsible for facilitating copper excretion in the bile is faulty, so copper accumulates in hepatic tissue. High copper levels are toxic to hepatocytes, and fibrosis leading to cirrhosis can develop in untreated patients. Patients with Wilson disease usually present with symptoms of liver and/or neurologic disease while still in their teens.

A third autosomal recessive genetic disease is α_1-antitrypsin deficiency (AATD). Abnormalities in the α_1-antitrypsin protein cause it to deposit in the liver. AATD causes cirrhosis in children as well as adults; adults usually have concomitant pulmonary disease.

PATHOPHYSIOLOGY

Portal Hypertension and Cirrhosis

The portal vein is the primary vessel leading into the liver; it receives deoxygenated venous blood from the splanchnic bed (intestines, stomach, pancreas, and spleen) at a rate of 1 to 1.5 L/min (Figure 22–1). Portal flow accounts for approximately 75% of blood delivered to the liver; the hepatic artery provides the remaining 25% in the form of oxygenated blood from the abdominal aorta. Normal portal vein pressure is 5 to 10 mm Hg. Portal hypertension, defined as portal pressure greater than 10 to 12 mm Hg, is a consequence of increased resistance to hepatic blood flow.[10]

LO 1

The obstruction to flow that causes portal hypertension can develop from prehepatic, intrahepatic (sinusoidal), or posthepatic damage. Hepatic sinusoids are porous vessels within the liver that surround radiating rows of hepatocytes (Figure 22–2). Sinusoids transport systemic blood that contains ingested substances (eg, food, drugs, toxins) to the hepatocytes. The liver processes the nutrients (carbohydrates, proteins, lipids, vitamins, and minerals) for either immediate use or storage, while drugs and toxins are processed through a variety of metabolic steps.

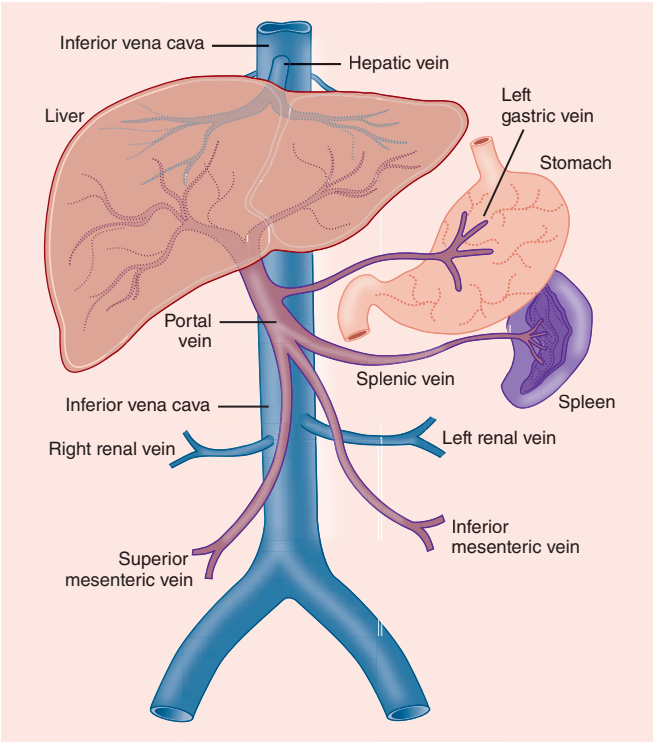

FIGURE 22–1. The portal venous system. (From Sease JM, Clements JN. Portal hypertension and cirrhosis. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill, 2017. www.accesspharmacy.com, with permission.)

Progressive destruction of hepatocytes combined with an increase in fibroblasts and connective tissue culminates in cirrhosis. Fibrosis scar tissue nodules modify the basic architecture of the liver, disrupting hepatic blood flow and liver function.

Reduced hepatic blood flow significantly alters normal metabolic processes and decreases protein synthesis. Hepatic drug metabolism is reduced, which can result in higher systemic drug concentrations and toxicity by extending half-life of drugs normally eliminated by the liver (especially those with high first-pass metabolism). Decreased hepatic metabolism can also reduce or delay prodrug activation and cause therapeutic failure.

LO 1 LO 2

The liver processes metabolic waste products for excretion; in cirrhosis, bilirubin (from the enzymatic breakdown of heme) can accumulate, causing jaundice (yellowing of the skin), scleral icterus (yellowing of the sclera), and tea-colored urine (urinary bilirubin excreted as urobilinogen).

Changes in steroid hormone production, conversion, and handling are prominent features of cirrhosis. These changes manifest as decreased libido, gynecomastia (development of breast tissue in men), testicular atrophy, and feminization in men. Another effect of changes in sex hormone metabolism is development of palmar erythema and spider angiomata (nevi). Spider angiomata are vascular lesions found mainly on the trunk that have a central arteriole (body) surrounded by radiating "legs." When blanched, the lesions fill from the center body outward toward the legs. They are not specific to cirrhosis, but the number and size do correlate with disease severity, and their presence relates to risk of variceal hemorrhage.[10]

Increased intrahepatic resistance to portal blood flow increases pressure on the entire splanchnic bed; an enlarged spleen

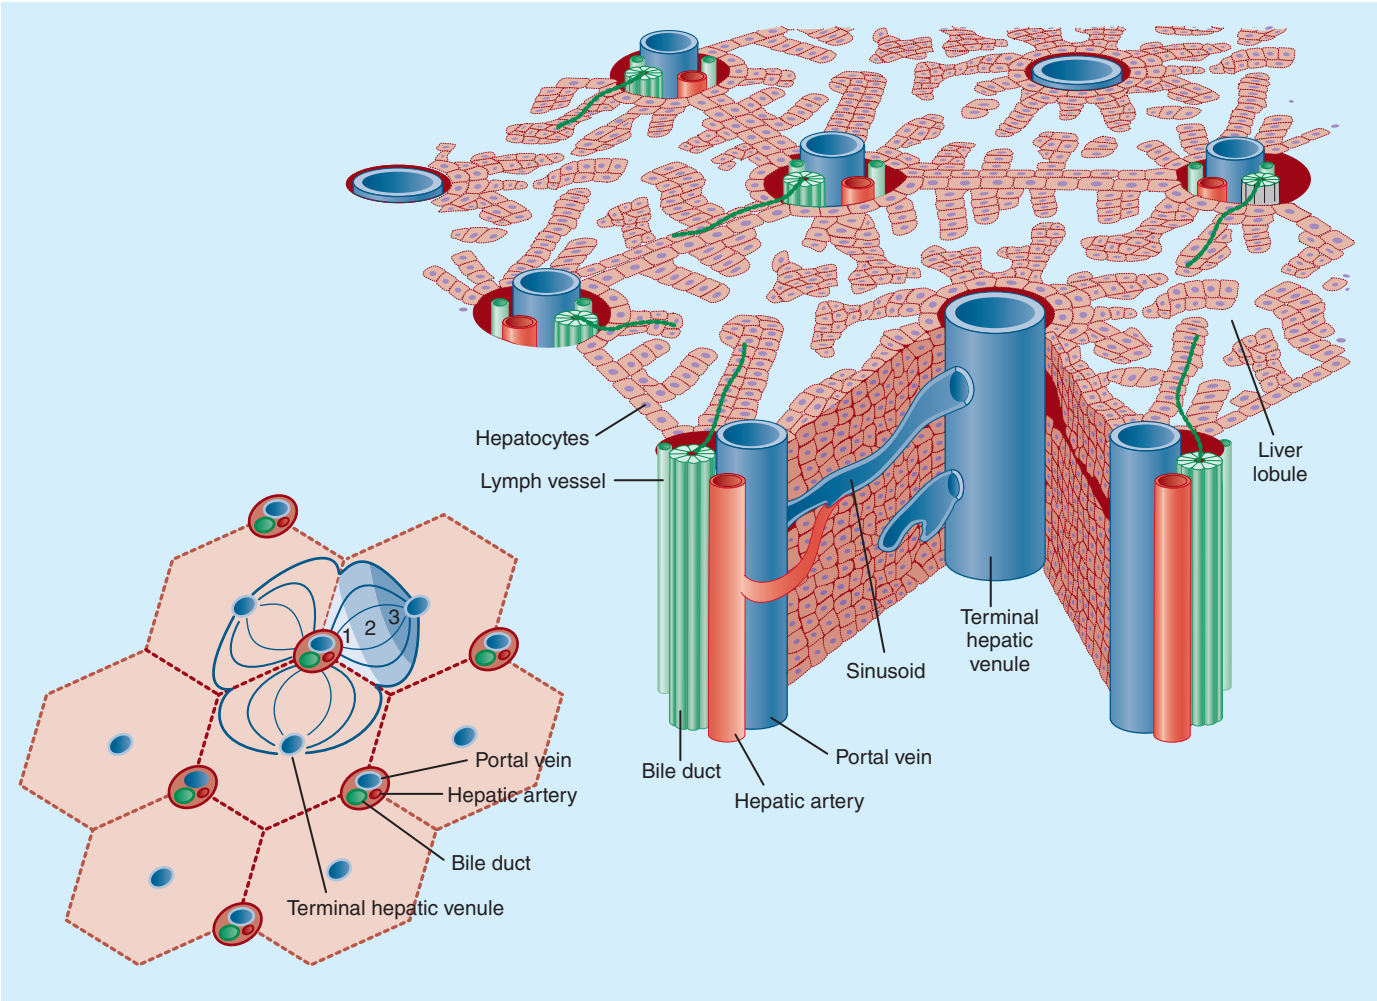

FIGURE 22–2. Relationship of sinusoids to hepatocytes and the venous system. (From Sease JM, Clements JN. Portal hypertension and cirrhosis. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill, 2017. www.accesspharmacy.com, with permission.)

(splenomegaly) is a common finding in cirrhotic patients. Splenic platelet sequestration secondary to splenomegaly is one of the causes of thrombocytopenia in cirrhotic patients.

LO 1 Portal hypertension mediates systemic and splanchnic arterial vasodilation by increasing production of nitric oxide and other vasodilators in an attempt to counteract the increased pressure gradient. Nitric oxide causes a fall in systemic arterial pressure; this drop in pressure activates the renin–angiotensin–aldosterone system (RAAS) and sympathetic nervous system, and increases antidiuretic hormone (ADH, vasopressin) production.[11] These systems are activated in an attempt to maintain arterial blood pressure and renal blood flow by increasing sodium and water retention. The excess sodium and water puts increased pressure on the vascular system. As a result, the umbilical vein, which LO 2 is usually eradicated in infancy, may become patent and cause prominent dilated veins that are visible on the surface of the abdomen. This phenomenon is called caput medusae because it resembles the head of the mythical Gorgon Medusa.

Ascites

LO 4 Ascites is the accumulation of fluid in the peritoneal space. It is the most common condition associated with decompensated cirrhosis and indicates a poor prognosis.[6]

The pathophysiology of ascites, portal hypertension, and cirrhosis are interrelated (Figure 22–3). Cirrhotic changes and subsequent decreases in synthetic function lead to decreased albumin production (hypoalbuminemia). Because albumin is the primary intravascular protein responsible for maintaining vascular oncotic pressure, low serum albumin levels, elevated hydrostatic pressure, and increased capillary permeability allow fluid to leak from the vascular space into body tissues. This results in ascites, peripheral edema, and fluid in the pulmonary system. Obstruction of hepatic sinusoids and hepatic lymph nodes also allows fluid to seep into the peritoneal cavity, further contributing to ascitic fluid formation.

The decrease in effective intravascular volume decreases renal perfusion; this activates the RAAS, increasing plasma renin activity, aldosterone production, and sodium retention. The subsequent increase in intravascular volume furthers the imbalance of intravascular oncotic pressure, allowing even more fluid to escape to the extravascular spaces, increasing ascites and peripheral edema. Unchecked, these combined effects enable the cycle of portal pressure and ascites to continue, creating a self-perpetuating loop of ascites formation.

Patients with ascites avidly retain sodium and water, not only through elevated aldosterone concentrations (from increased production and decreased clearance), but also through increases

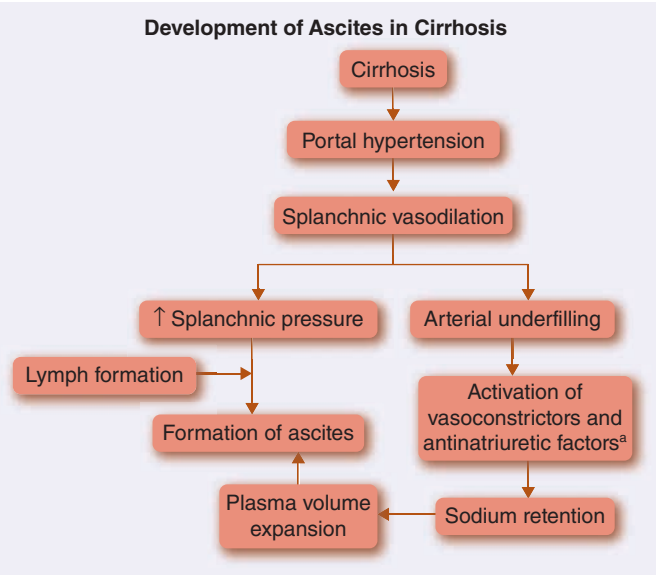

FIGURE 22–3. Development of ascites in cirrhosis. This flow diagram illustrates the importance of portal hypertension with splanchnic vasodilation in the development of ascites. [a]Antinatriuretic factors include the renin-angiotensin-aldosterone system and the sympathetic nervous system. (From Bacon BR. Cirrhosis and its complications. In: Kasper DL, Hauser SL, Jameson JL, et al., eds. Harrison's Principles of Internal Medicine, 19th ed. New York, NY: McGraw-Hill, 2015. www.accesspharmacy.com, with permission.)

in ADH and sympathetic nervous system activation. Patients become hyponatremic because of decreased free water excretion. This is not the result of too little sodium; it is a dilutional effect. Untreated, this combination of factors can lead to a decrease in renal function and HRS.[4,11]

Hepatorenal Syndrome

LO 4 HRS is a decline in renal function not caused by intrinsic renal disease in the setting of cirrhosis. Type 1 HRS is characterized by rapid deterioration of renal function (acute kidney injury [AKI]) that is not reversible with volume repletion. Untreated, it is rapidly fatal with a 50% mortality rate at 14 days. Renal artery vasoconstriction (stimulated by the sympathetic nervous system and RAAS) and decreased mean arterial pressure (mediated by nitric oxide) decrease renal perfusion and precipitate renal failure. Production of renin stimulates a cascade that causes fluid retention and peripheral vasoconstriction in an attempt to increase arterial pressure. Prostaglandin E_2 and prostacyclin production increase to stimulate renal vasodilation and maintain renal blood flow. HRS develops when these mechanisms are overwhelmed and renal perfusion drops acutely. SBP is a common trigger for HRS, as are nonsteroidal anti-inflammatory drugs (NSAIDs), which precipitate HRS by inhibiting prostaglandin production. Type 2 HRS has similar pathophysiology to type 1 HRS but is characterized by a less acute decline in renal function.

LO 3 The traditional laboratory parameters used to monitor renal function (serum creatinine, blood urea nitrogen [BUN]) tend to be deceptively low in cirrhotic patients because of reduced muscle mass and decreased hepatic urea production, respectively. Because of this, even minor changes in these laboratory values should be monitored closely; small changes can represent significant changes in renal function.

Varices

LO 4 The splanchnic system drains venous blood from the GI tract to the liver. Because portal hypertension increases resistance to drainage from the originating organ, collateral vessels (varices) develop in the esophagus, stomach, and rectum to compensate for the increase in pressure and blood volume. Varices divert blood meant for hepatic circulation back to the systemic circulation. This diversion decreases clearance of drugs and potential toxins through loss of first-pass (presystemic) metabolism. Varices are weak superficial vessels; any additional increase in pressure can cause them to rupture and bleed.[12]

Spontaneous Bacterial Peritonitis (SBP)

LO 4 SBP is an acute bacterial infection of peritoneal (ascitic) fluid in the absence of intraabdominal infection or intestinal perforation; up to 30% of patients with ascites develop SBP.[13] The peritoneal cavity is usually a sterile space. One proposed mechanism of bacterial contamination is translocation of intestinal bacteria to mesenteric lymph nodes, which then seed the ascitic fluid.[14] Bacterial translocation correlates with the delay in intestinal transit time and increased intestinal wall permeability observed in cirrhotic patients. Another possible mechanism of SBP is the hematogenous spread of bacteria into the peritoneal space.[15] Low protein ascites (< 1 g/dL [10 g/L]) is associated with increased rates of SBP; low protein is presumably correlated to low antibacterial activity.

Enteric gram-negative aerobes (*Escherichia coli*, *Klebsiella pneumoniae*) are the most common bacteria isolated from patients with SBP. *Streptococcus pneumoniae* is the most common gram-positive pathogen.[6]

Hepatic Encephalopathy

LO 4 Numerous factors, many of them poorly understood, are involved in the development of hepatic encephalopathy (HE). In severe hepatic disease, systemic circulation bypasses the liver; substances that are normally metabolized by the liver accumulate in the systemic circulation. These byproducts, especially nitrogenous waste, are neurotoxic.[16]

Ammonia (NH_3) is just one of the toxins implicated in HE. It is a metabolic byproduct of protein catabolism and is also generated by gut bacteria. In a normally functioning liver, hepatocytes degrade ammonia to form urea, which is renally excreted; in cirrhosis, conversion to urea is reduced and ammonia accumulates, causing encephalopathy. Patients with HE commonly have elevated serum ammonia concentrations, but ammonia levels do not correlate with the degree of CNS impairment.[16]

High levels of "false neurotransmitters" (aromatic amino acids, γ-aminobutyric acid, endogenous benzodiazepines) have also been implicated in HE. These substances bind to both the γ-aminobutyric acid and benzodiazepine receptors and act as agonists at the active receptor sites.[16]

HE is a clinical diagnosis; decreased cognition, confusion, and changes in behavior combined with physical signs such as asterixis (characteristic flapping of hands upon extension of arms with wrist flexion) indicate HE. A precipitating event associated with increased production and/or decreased elimination of toxins can often be identified in patients with previously stable cirrhosis who develop acute encephalopathy. Infections, variceal hemorrhage, renal insufficiency, electrolyte abnormalities, and increased dietary protein have all been associated with acute HE. Acute HE is often readily reversible, but changes of a more chronic, insidious nature are more difficult to treat; patients rarely recover fully from chronic HE.

Bleeding Diathesis and Synthetic Failure

LO 4

Coagulopathies signal end-stage liver disease. The liver manufactures both procoagulant and anticoagulant factors essential for blood clotting and maintenance of blood homeostasis. In advanced disease, the liver is unable to synthesize these proteins, resulting in extended clotting times (eg, prothrombin time) and bleeding irregularities.[17] These patients were previously thought to be "auto-anticoagulated," but better understanding of the spectrum of coagulation abnormalities has led to the understanding that these patients are at increased risk of venous thromboembolisms in addition to having extended clotting times.[18]

Thrombocytopenia is common in advanced liver disease as a result of both decreased hepatic thrombopoietin stimulation in the bone marrow and splenic sequestration of formed platelets.

CLINICAL PRESENTATION AND DIAGNOSIS

Refer to accompanying clinical presentation box for symptoms, signs, and laboratory abnormalities associated with cirrhosis.

Diagnosis of Cirrhosis

Cirrhosis may be diagnosed incidentally before the patient develops symptoms or acute complications, but many patients have decompensated disease (eg, ascites, SBP, variceal bleeding, HE) at initial presentation. Patients may have some, all, or none of the laboratory abnormalities and/or signs and symptoms of cirrhosis.[19]

Liver biopsy can definitively diagnose cirrhosis but is usually deferred in lieu of a presumptive diagnosis using noninvasive techniques such as ultrasound or computed tomography. A nodular liver with increased echogenicity is consistent with cirrhosis. The Model for End-Stage Liver Disease (MELD) score predicts 3-month mortality; it is used to classify disease severity and prioritize patients awaiting deceased-donor liver transplantation. The calculator is available at the Organ Procurement and Transplantation Network website (https://optn.transplant.hrsa.gov/resources/allocation-calculators/meld-calculator/).

Patients with ascites or known varices are presumed to have portal hypertension, but direct measurement is typically deferred because it requires invasive testing and increases the risk of bleeding.

Diagnosis of Ascites

Analysis of ascitic fluid obtained during **paracentesis** provides diagnostic clues to the etiology of fluid accumulation. Evaluation includes cell count with differential, albumin, total protein, Gram stain, and bacterial cultures. In patients without an established diagnosis of liver disease, the serum ascites–albumin gradient (SAAG) is used to determine the cause of ascites.[6] SAAG compares serum albumin concentration to ascitic fluid albumin concentration:

$$Alb_{serum} - Alb_{ascites} = SAAG$$

A value of 1.1 g/dL (11 g/L) or greater identifies portal hypertension as the cause of the ascites with 97% sensitivity.[6] In portal hypertension, low albumin in the peritoneal space balances the oncotic pressure gradient with the hydrostatic pressure gradient of portal hypertension. The differential diagnosis for SAAG values less than 1.1 g/dL (11 g/L) includes peritoneal carcinoma, peritoneal infection (tuberculosis, fungal, cytomegalovirus), and nephrotic syndrome. Serum albumin should be measured at the time of paracentesis for an accurate comparison.[6]

Clinical Presentation of Cirrhosis and Complications of Portal Hypertension

LO 2

General

- Signs and symptoms are specific to the complication the patient is experiencing at presentation.

Symptoms

- Patients with cirrhosis may be asymptomatic until acute complications develop.
- Nonspecific symptoms include anorexia, fatigue, weakness, changes in libido, and disturbances in sleep patterns. Patients may also bruise easily or bleed from minor injuries.
- Patients with ascites describe feelings of abdominal fullness and pain, nausea, shortness of breath, and early satiety.
- Hemorrhage from esophageal or gastric varices often presents as nausea, vomiting, and **hematemesis** and may be associated with melena, pallor, fatigue, and weakness from blood loss. Bleeding from rectal varices may present as **hematochezia**.
- In patients with bleeding varices, digestion of swallowed blood can cause nausea and precipitate symptoms of HE.
- Neurologic changes from HE can be overwhelming or so subtle that they are not apparent except during a targeted clinical evaluation.
- Patients with HE may complain of disruption of sleep patterns and day-to-night inversion; patients have delayed bedtime and wake times, which may progress to complete inversion of the normal diurnal cycle.
- SBP should be suspected in patients with symptoms of infection such as fever, chills, abdominal pain, and mental status changes.

Signs

- Nonspecific signs of liver disease include jaundice, scleral icterus, tea-colored urine, bruising, hepatomegaly, splenomegaly, spider angiomata, caput medusae, palmar erythema, gynecomastia, and testicular atrophy.
- Ascites can be detected by increased abdominal girth accompanied by shifting dullness and a fluid wave.
- Signs of variceal bleeding depend on the degree of blood loss and abruptness of onset. Rapid and massive blood loss is more likely to result in hemodynamic instability than slow, steady bleeding.
- Signs of acute bleeding may include pallor, hypotension, tachycardia, mental status changes, and hematemesis.
- Markers of hepatic encephalopathy (HE) include decreased cognition, confusion, changes in behavior, and asterixis.

(*Continued*)

Clinical Presentation of Cirrhosis and Complications of Portal Hypertension (Continued)

- Patients with SBP may present with fever, painful tympanic abdomen, and changes in mental status.
- Decreases in clotting factors may manifest as abnormal bruising and bleeding.
- Dupuytren's contracture is a contraction of the palmar fascia that usually affects the fourth and fifth digits. It is not specific to cirrhosis and can also be seen in repetitive use injuries.

Laboratory Abnormalities

LO 3

- Hepatocellular damage manifests as elevated alanine aminotransferase (ALT) and aspartate aminotransferase (AST). The degree of elevation does not correlate with remaining functional metabolic capacity of the liver. An AST level twofold higher than ALT suggests alcoholic liver damage.
- Elevated alkaline phosphatase is nonspecific and may correlate with liver or bone disease; it tends to be elevated in biliary tract disease; γ-glutamyl transferase (GGT) is specific to the bile ducts, and in conjunction with an elevated alkaline phosphatase, suggests hepatic disease. Extremely elevated GGT levels further indicate obstructive biliary disease.
- Increased total, direct, and indirect bilirubin concentrations indicate defects in transport, conjugation, or excretion of bilirubin.
- Lactate dehydrogenase (LDH) is a nonspecific marker of hepatocyte damage; a disproportionate elevation of LDH indicates ischemic injury.
- Thrombocytopenia may occur because of decreased platelet production and splenic sequestration of platelets.
- Anemia (decreased hemoglobin and hematocrit) occurs as a result of variceal bleeding, decreased erythrocyte production, alcohol use, and hypersplenism.
- Loss of hepatic synthetic function can manifest as elevated prothrombin time (PT) and international normalized ratio (INR).
- Decreased serum albumin and total protein occur in chronic liver damage due to loss of synthetic capacity within the liver.
- Portal hypertension causes serum albumin-to-ascites gradient of 1.1 g/dL (11 g/L) or greater.
- Increased blood ammonia concentration is characteristic of HE, but levels do not correlate to degree of impairment.
- Increased serum creatinine and blood urea nitrogen (BUN) signal a decline in renal function and may indicate hepatorenal syndrome.
- Signs and symptoms of infection (eg, mental status change, fever, abdominal pain) should prompt a diagnostic paracentesis in a patient with ascites (Figure 22–4). In SBP, there is decreased total serum protein, elevated white blood cell count (with left shift), and the ascitic fluid contains at least 250 cells/mm^3 (250 × 10^6/L) neutrophils. Bacterial culture of ascitic fluid may be positive, but lack of growth does not exclude the diagnosis.

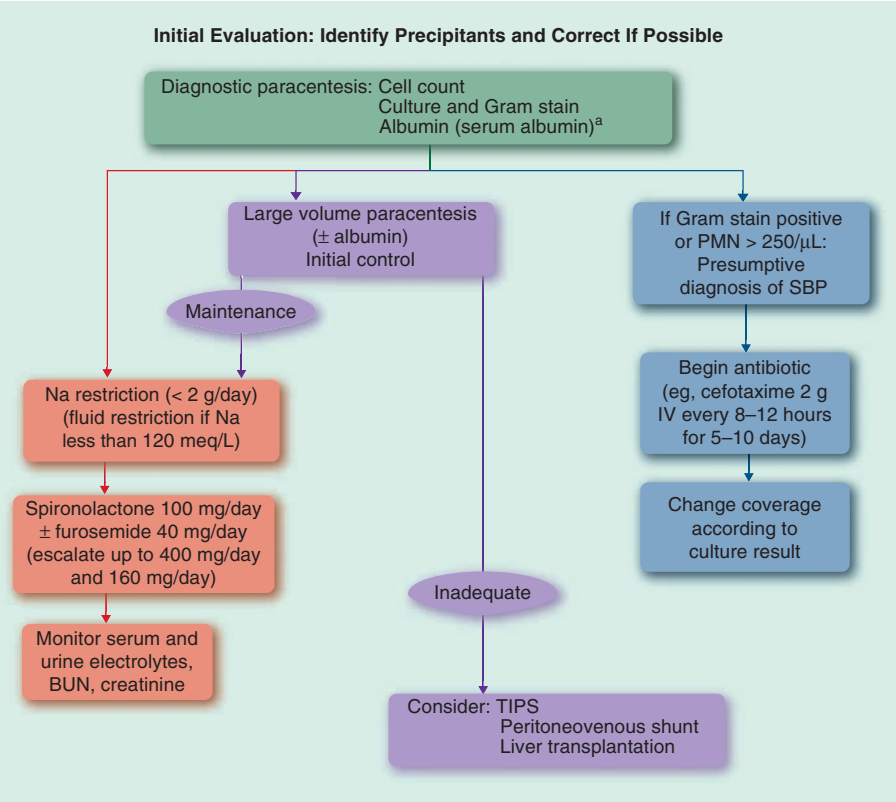

FIGURE 22–4. Approach to the patient with ascites and spontaneous bacterial peritonitis (SBP). [a]If PMN is greater than 250/μL (250 × 10^6/L) but culture is negative (culture-negative neutrocytic ascites), begin empiric antibiotics and retap after 48 hours. If culture is positive but PMN less than 250/μL (250 × 10^6/L), treat as if PMN greater than 250/μL (250 × 10^6/L) (presumed SBP). If polymicrobial infection exists, exclude SBP. (BUN, blood urea nitrogen; Na, sodium; PMN, polymorphonuclear leukocyte; TIPS, transjugular intrahepatic portosystemic shunt.) (Adapted from Chung RT, Podolsky DK. Cirrhosis and its complications. In: Kasper DL, Braunwald E, Fauci AS, et al., eds. Harrison's Principles of Internal Medicine, 17th ed. New York, NY: McGraw-Hill, 2005:1858–1869, with permission.)

TREATMENT OF PORTAL HYPERTENSION, CIRRHOSIS, AND COMPLICATIONS

Desired Outcomes

Recognizing and treating the underlying cause of cirrhosis is paramount. KEY CONCEPT Until recently, cirrhosis was considered irreversible, but treating the underlying cause in its early stages may reverse the damage. Eradication of HCV decreases mortality even with advanced disease. In patients without a reversible cause, cirrhosis treatment is directed at limiting disease progression and minimizing complications.[20] Immediate treatment goals are to stabilize acute complications such as variceal bleeding and prevent SBP. Once life-threatening conditions have stabilized, the focus shifts to preventing complications and further liver damage. The sections that follow concentrate on therapy to prevent and treat cirrhotic complications.

LO 5

Nonpharmacologic Therapy

Avoiding additional hepatic insult is critical for successful cirrhosis management. Lifestyle modifications can limit disease complications and slow further liver damage. The only proven treatment for alcoholic liver disease is immediate cessation of alcohol use, and because alcohol is hepatotoxic, all cirrhotic patients should abstain from alcohol to prevent further liver damage.

LO 6

Patients with ascites require dietary sodium restriction. Intake should be limited to less than 800 mg sodium (2 g sodium chloride) per day. More stringent restriction may cause faster mobilization of ascitic fluid, but adherence to such strict limits is very difficult. Ascites usually responds well to sodium restriction accompanied by diuretic therapy.[6]

Medications must be monitored carefully for potential adverse effects; hepatically metabolized drugs can accumulate in patients with liver disease. Unfortunately, little guidance is available on drug dosing in hepatic impairment because these patients have historically been excluded from drug trials. Daily acetaminophen use should not exceed 2 g. Dietary supplements, herbal remedies, and nutraceuticals have not been well studied in hepatic impairment and cannot be recommended.

LO 6

In patients with variceal bleeding, nasogastric (NG) suction reduces the risk of aspirating stomach contents; aspiration pneumonia is a major cause of death in patients with variceal bleeding. Because blood in the GI tract is very nauseating, NG suction during variceal bleeding can decrease vomiting by removing blood from the GI tract.

Endoscopic band ligation (EBL) involves application of a stricture around the varix to stop acutely bleeding varices. EBL is the preferred endoscopic treatment and is effective in up to 90% of patients.[21] It is also the standard of care for secondary prophylaxis of repeat bleeding in patients with a history of either esophageal or gastric variceal bleeding. Band ligation is best used in conjunction with pharmacologic treatment.[22,23]

During episodes of acute HE, temporary protein restriction to decrease ammonia production can be a useful adjuvant to pharmacologic therapy, but long-term protein restriction in cirrhotic patients is not recommended. Cirrhotic patients are already in a nutritionally deficient state, and prolonged protein restriction will exacerbate the problem.[16]

Hepatitis A and B vaccination is recommended in patients with cirrhosis to prevent additional liver damage from an acute viral infection.[24] Pneumococcal and influenza vaccination may also be appropriate and can reduce hospitalizations.

LO 6

Shunts are long-term solutions to decrease elevated portal pressure. Shunts divert blood flow through or around the diseased liver, depending on the location and type of shunt employed. Transjugular intrahepatic portosystemic shunts (TIPS) create a communication pathway between the intrahepatic portal

Patient Encounter Part 1

A 53-year-old woman was admitted to your unit overnight from the emergency department. She is a very poor historian and seems somewhat confused.

Chief Complaint: Abdominal pain and fullness; patient states, "I feel like I'm going to explode."

HPI: Increasing abdominal girth over the past 2 weeks; abdominal pain and intense tightness started yesterday afternoon

PMH: DVT "long time ago," and "bleeding ulcer" 2 years ago

Drug Allergies: NKDA

PSH: Cesarean section × 3

SH: Marital status unclear, at intake she stated she was not married, but later said her husband lives in Oklahoma. She works as a clerk at an elementary school. Denies tobacco, states she uses marijuana and alcohol on a "recreational" basis only. Cannot quantify intake.

FH: Mother with osteoporosis and hyperthyroidism; father with hypertension

Meds (Outpatient): OTC NSAIDs (ibuprofen, naproxen), antacids occasionally

ROS: Abdominal pain with nausea and early satiety

PE:

VS: BP 84/58 mm Hg, P 110 beats/min, T 101.7°F (38.7°C), RR 20 breaths/min, oxygen saturation 99% (0.99) on room air, Ht 67" (170 cm), Wt 56 kg, BMI 19.3 kg/m^2

General: Somnolent, ill-looking woman who appears older than stated age

HEENT: PERRL, EOMI, (+) scleral icterus, jaundiced skin with mild temporal wasting

CV: Tachycardic, no murmurs, rubs, or gallops

Chest: CTA bilaterally

Abd: Distended tense abdomen that is tender to palpation, hypoactive bowel sounds, hepatosplenomegaly, large ascites

Ext: 3+ pedal pulses, 2+ pitting edema

What signs and symptoms does she have that are consistent with cirrhosis?

Based on the current information, what is the most likely cause of her abdominal pain?

What risk factors does she have for cirrhosis?

Is there anything in her history that could indicate previous complications from cirrhosis?

Should this patient receive pharmacologic DVT prophylaxis?

vein and the hepatic vein. TIPS procedures may be preferred over surgically inserted shunts because they are placed through the vascular system rather than through more invasive surgical procedures, but they still carry a risk of bleeding and infection. TIPS placement can improve HRS but is associated with an increased incidence of HE.[16] The increased risk of HE results from decreased detoxification of nitrogenous waste products because the shunt allows blood to evade metabolic processing.

Hemodialysis is usually used only as a bridge for HRS patients awaiting liver transplantation. It can contribute to hemodynamic instability and does not correct the underlying liver disease.

Pharmacologic Therapy

Drug therapy directed at reducing portal hypertension can alleviate symptoms and prevent complications but cannot reverse cirrhosis.

▶ *Portal Hypertension*

LO 6 KEY CONCEPT Nonselective β-blockers (NSBB) such as propranolol and nadolol are first-line treatments for portal hypertension. They reduce bleeding and decrease mortality in patients with known varices.

Only nonselective β-blockers (those that block both β_1 and β_2 receptors) reduce bleeding complications in patients with known varices. Blockade of β_1 receptors reduces cardiac output and splanchnic blood flow, while β_2-adrenergic blockade prevents β_2-receptor–mediated splanchnic vasodilation while allowing unopposed α-adrenergic effects; this enhances vasoconstriction of the systemic and splanchnic vascular beds. The combination of β_1 and β_2 blockade makes the NSBB preferable to cardioselective (β_1 selective) agents in treating portal hypertension.[1,22,25] Although cardioselective β-blockers do lose β_1 selectivity at higher doses, most patients with cirrhosis cannot tolerate the high doses.

Because β-blockers decrease blood pressure and heart rate, they should be started at low doses to increase tolerability; cirrhotic patients often already have low blood pressure and heart rate. Propranolol is hepatically metabolized, so initial drug concentration, half-life, and pharmacologic effects are all increased in cirrhosis. A reasonable starting dose of propranolol is 10 to 20 mg once or twice daily.

LO 5 Doses should be titrated as tolerated with the goal of decreasing heart rate by 25% or to approximately 55 to 60 beats/min.[26] Heart rate reduction is not an accurate predictor of portal pressure reduction but is associated with maximally tolerated effect.

Carvedilol is a unique NSBB that also blocks α_1 receptors. The α_1 blockade induces intrahepatic vasodilation for a more potent decrease in portal pressure compared to other NSBB, but it also mediates greater decreases in mean arterial pressure.

The role of NSBB was called into question after observational trials suggested increased mortality in patients with a history of refractory ascites or SBP.[27,28] Later publications identified a complex dose–response relationship for NSBB in these patients; high doses (propranolol doses above 160 mg/day) are associated with increased mortality risk, while lower doses are associated with improved survival.[29,30] NSBB use should be carefully monitored in cirrhotic patients with tenuous blood pressure or other evidence of circulatory dysfunction, and discontinued in patients with acute decompensation (eg, variceal bleed, SBP, HRS). Carvedilol should be avoided in patients with refractory ascites to avoid additional vasodilation.[26]

Nitrates (eg, isosorbide mononitrate) have been shown in clinical trials to reduce portal pressure when used alone or in combination with β-blockers. However, they cause systemic vasodilation and increase mortality when used alone, and because patients treated with combination therapy have significantly more adverse events compared to β-blocker monotherapy, nitrates are seldom used in cirrhotic patients.[26]

▶ *Ascites*

LO 6 KEY CONCEPT The goals of treating ascites are to minimize acute discomfort, reequilibrate ascitic fluid, and prevent SBP. Treatment should modify underlying disease pathology; without directed therapy, fluid rapidly reaccumulates.

LO 6 Acute discomfort from ascites may be ameliorated by therapeutic paracentesis. Often removing just 1 to 2 L of ascitic fluid provides relief from pain and fullness. Volume resuscitation should be provided for large volume paracentesis; 6 to 8 g of IV albumin should be given per liter of fluid removed. Albumin 25% should be used because it has one-fifth the volume of the 5% product. Large-volume paracentesis without albumin administration can precipitate HRS through decreased perfusion. Albumin has not been shown to be beneficial in hemodynamically stable patients if less than 5 L of fluid is removed.[6]

LO 6 **Diuretics** Diuretics are usually required in addition to sodium restriction (see Nonpharmacologic Therapy). KEY CONCEPT Spironolactone (an aldosterone antagonist) with or without furosemide forms the basis of pharmacologic therapy for ascites. Cirrhosis is a high aldosterone state; spironolactone counteracts the effects of RAAS activation. Not only is aldosterone production increased, but decreased hepatic metabolism prolongs aldosterone half-life.

LO 6 A loop diuretic is typically added to spironolactone for more potent diuresis. A ratio of 40 mg furosemide (the most common loop diuretic) to 100 mg spironolactone usually maintains serum potassium within the normal range.

Doses should be titrated upward every 3 to 5 days. Because spironolactone is used for its antialdosterone effects, high doses (up to 400 mg/day) are used. If intolerable side effects such as painful gynecomastia occur with spironolactone, other potassium-sparing diuretics may be used, but clinical trials have not shown equivalent efficacy.[6]

Patient Encounter Part 2

Laboratory results for the patient showed the following:

Sodium 126 mEq/L (mmol/L)	Albumin 2.1 g/dL (21 g/L)
Potassium 3.2 mEq/L (mmol/L)	Total bilirubin 4.3 mg/dL (73.5 μmol/L)
Chloride 97 mEq/L (mmol/L)	Alk phos 174 IU/L (2.9 μkat/L)
Bicarbonate 19 mEq/L (mmol/L)	AST 68 IU/L (1.13 μkat/L)
BUN 6 mg/dL (2.1 mmol/L)	ALT 39 IU/L (0.65 μkat/L)
SCr 0.5 mg/dL (44 μmol/L)	INR 1.4
Glucose 89 mg/dL (4.9 mmol/L)	PT 17 seconds
Hemoglobin 8.4 g/dL (84 g/L; 5.21 mmol/L)	GGT 163 IU/L (2.72 μkat/L)
Hematocrit 28% (0.28)	LDH 187 IU/L (3.12 μkat/L)
WBC 11.3 × 10^3/mm^3 (10^9/L)	Serum NH_3 91 mcg/dL (53 μmol/L)
Platelets 63 × 10^3/mm^3 (10^9/L)	

Which laboratory values support a diagnosis of cirrhosis?

What test(s), if any, should be done to further investigate the source of abdominal pain?

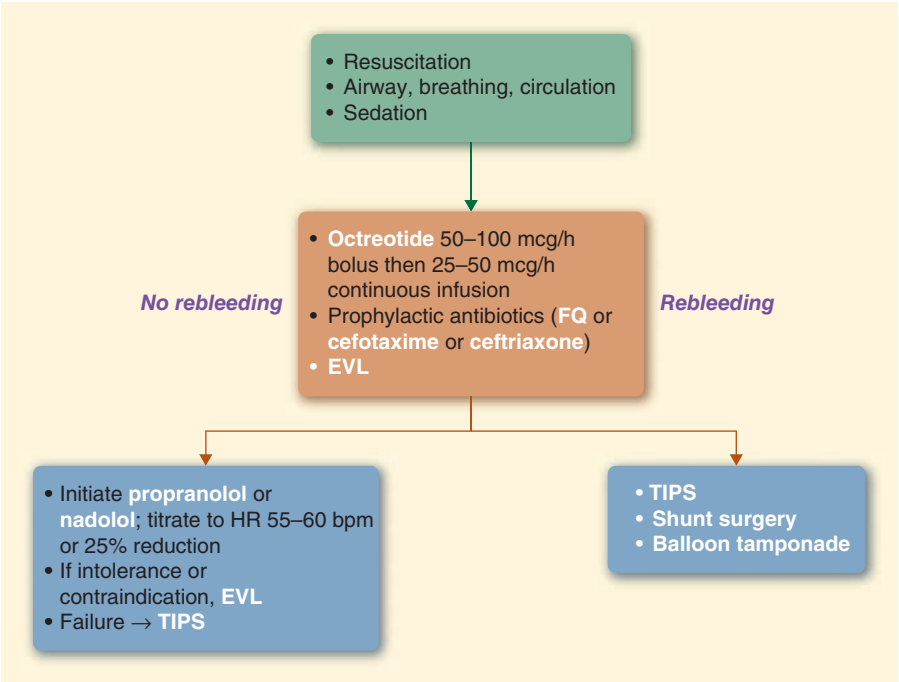

FIGURE 22–5. Treatment of acute variceal bleeding. (EVL, endoscopic variceal ligation; (FQ, fluoroquinolone; HR, heart rate; TIPS, transjugular intrahepatic portosystemic shunt.) (From Ryan L, Attridge RL, Moote R, Miller ML. Chapter 9. Portal Hypertension and Cirrhosis. In: Attridge RL, Miller ML, Moote R, Ryan L, eds. Internal Medicine: A Guide to Clinical Therapeutics, New York, NY: McGraw-Hill; 2013, with permission.)

Because ascites equilibrates with vascular fluid at a much slower rate than does peripheral edema, aggressive diuresis is associated with intravascular volume depletion rather than depletion of peritoneal fluid. The maximum amount of ascitic fluid that can be removed through diuresis is approximately 0.5 L/day.[6] Aggressive diuresis should be avoided unless patients have concomitant peripheral edema. These patients may require increasing furosemide doses until they are euvolemic; IV diuretics are often necessary. Diuretic therapy is typically lifelong.

▶ *Varices*

LO 5 Variceal bleeding is common in cirrhotic patients. KEY CONCEPT During acute variceal hemorrhage, it is crucial to control bleeding, prevent rebleeding, and avoid complications such as SBP. Mortality at 6 weeks is 15% to 25%.[26] A treatment algorithm for acute variceal bleeding is depicted in Figure 22–5.

LO 6 Octreotide (a synthetic somatostatin analog) causes selective vasoconstriction of the splanchnic bed, decreasing portal venous pressure with few serious side effects. The most common octreotide dose is a 50-mcg IV loading dose followed by a 50 mcg/hour continuous IV infusion. Therapy should continue for at least 24 to 72 hours after bleeding has stopped, but the optimal treatment duration has not been defined. Some clinicians continue octreotide for a full 5 days because this is the time frame with highest risk of rebleeding. Octreotide combined with endoscopic therapy results in decreased rebleeding rates and transfusion needs when compared with endoscopic treatment alone.[26] These patients are at high risk of developing SBP, and LO 6 prophylactic antibiotics provide both a morbidity and mortality benefit in this situation. Choice of specific agent should be based on local susceptibility data, but ceftriaxone (1 g IV every 24 hours) for 5 to 7 days has been proven effective.[26]

▶ *Spontaneous Bacterial Peritonitis*

LO 6 Prophylactic antibiotic therapy is recommended during acute variceal bleeding to prevent SBP; this is typically initiated with a third-generation cephalosporin. Prophylactic antibiotic therapy reduces in-hospital infections and mortality in patients hospitalized for variceal bleeding.[26]

LO 6 If SBP is suspected, empiric antibiotic therapy should be initiated with a broad-spectrum anti-infective agent after ascitic fluid collection, pending cultures, and susceptibilities (Figure 22–4). In the setting of presumed infection, delaying treatment while awaiting laboratory confirmation is inappropriate and may result in death. The preferred initial antibiotic should be an IV third-generation cephalosporin (eg, cefotaxime 2 g every 8 hours, ceftriaxone 1 g every 24 hours).[6,26] These agents cover the most common organisms implicated in SBP, but local resistance patterns must be taken into account when choosing empiric antibiotic therapy. Once a bacterial pathogen is identified, coverage should be narrowed to an agent that is highly active against that particular organism. SBP is rarely polymicrobial.

SBP is the primary cause of HRS. The risk of renal failure can be reduced with albumin therapy, 1.5 g/kg initially, followed by 1 g/kg on day 3 of SBP therapy for high-risk patients with SCr greater than 1 mg/dL (88 µmol/L), BUN above 30 mg/dL (10.7 mmol/L), or bilirubin higher than 4 mg/dL (68.4 µmol/L).[31]

LO 6 KEY CONCEPT Long-term SBP prophylaxis decreases mortality and is recommended in a select group of patients—those with a history of SBP, and those with low-protein ascites (ascitic fluid albumin less than 1.5 g/dL [15 g/L]) plus one of the following: SCr 1.2 mg/dL (106 µmol/L) or greater, BUN 25 mg/dL (8.9 mmol/L) or greater, serum sodium 130 mEq/L (mmol/L) or less, or Child–Pugh score of at least 9 (Child–Pugh classification estimates mortality from cirrhosis), with bilirubin of at least 3 mg/dL (51.3 µmol/L). Oral options are one trimethoprim–sulfamethoxazole double-strength daily or ciprofloxacin 500 mg daily.[6]

▶ *Hepatorenal Syndrome*

HRS is a life-threatening complication of cirrhosis. Targeted treatment increases central venous system volume. Peripheral vasoconstriction redistributes fluid from the periphery to the venous system; fluid is retained in the vascular space LO 5 by administering albumin (to increase oncotic pressure). The ultimate goal is to increase renal perfusion.

LO 6 A common regimen involves giving albumin 1 g/kg on day of diagnosis (day 1), followed by 20 to 40 g on subsequent treatment days. This regimen is used in combination with midodrine (an α-agonist) and octreotide. The initial midodrine dose is 7.5 mg orally three times daily; octreotide is usually administered subcutaneously (as opposed to IV during variceal bleeding) 100 mcg three times daily. Both drugs can be titrated as tolerated to achieve increases in mean arterial pressure of at least 15 mm Hg.

Terlipressin, a vasopressin analog available in Europe, has been used with success in patients with HRS, but it is not currently available in the United States.

▶ *Encephalopathy*

LO 6 **Lactulose** KEY CONCEPT Lactulose is the foundation of pharmacologic therapy to prevent and treat HE. It is a nondigestible synthetic disaccharide laxative; it is hydrolyzed in the gut to an osmotically active compound that draws water into the colon and stimulates defecation. Lactulose lowers colonic pH, which favors the conversion of ammonia (NH_3) to ammonium (NH_4^+), which cannot cross back from the gut into the systemic circulation because it is ionic. Lactulose is usually initiated at 15 to 30 mL two to three times per day and titrated to a therapeutic goal of two to three soft bowel movements daily.[16]

Antibiotic Therapy Rifaximin is a nonabsorbable antibiotic that decreases urease-producing gut bacteria, decreasing ammonia production. It is used extensively in Europe as first-line therapy for HE. Although rifaximin is both effective and well tolerated, its expense may prohibit long-term use. In the United States, it is reserved for use as add-on therapy after lactulose failure. The rifaximin dose is 550 mg twice daily to prevent HE recurrences and 400 mg three times a day for treatment.

LO 6

Metronidazole and neomycin have also been used to treat hepatic encephalopathy but are not generally recommended because of toxicity; prolonged metronidazole use is associated with peripheral neuropathy, and although neomycin is classified as a nonabsorbable aminoglycoside antibiotic, patients with cirrhosis do have detectable plasma concentrations. This is thought to be a result of decreased intestinal mucosa integrity, and it may lead to nephrotoxicity. Neomycin should not be used if other options exist.[16]

LO 6

Patient Encounter Part 3

An ultrasound-guided paracentesis was performed, and 7 L of fluid was removed. The analysis reveals clear yellowish fluid, total protein 0.8 g/dL (8 g/L), PMNs 255 cells/mm^3 (255 × 10^6/L), Gram stain was negative, sample sent for culture.

Should the patient receive fluids (crystalloid or colloid) after the paracentesis?

If so, what specific therapy would you initiate and why?

Because the Gram stain was negative, should you wait for the culture results to avoid potentially inappropriate antibiotic use?

If antibiotics are initiated, what is the most appropriate regimen?

Should any other therapy be considered at this time?

What are potential sources of her confusion?

How should her confusion be treated?

Patient Encounter Part 4

The next day, the patient's mental status has improved, she is less somnolent, and she states that her pain is much better, but feels like she has more fluid in her belly than immediately after the paracentesis. On physical examination, her abdomen is less tense than on admission, and she has decreased tenderness to palpation.

What pharmacologic and nonpharmacologic treatments are appropriate to reduce reaccumulation of ascitic fluid?

Does she require long-term prophylaxis to prevent recurrent SBP?

What is the best option for long-term SBP prophylaxis?

Flumazenil Evidence for false transmitters as the cause of encephalopathy has been demonstrated by functional improvement after administering flumazenil (a benzodiazepine antagonist). Unfortunately, long-term benefit has not been demonstrated, and because flumazenil can only be administered parenterally, it is not an appropriate choice for clinical use; flumazenil use is limited to the research setting.

▶ *Coagulation Abnormalities*

Vitamin K is essential for hepatic synthesis of coagulation factors. The elevated clotting time that results from decreased protein synthesis is indistinguishable from coagulopathy that is a result of malnutrition or poor intestinal absorption. When given subcutaneously (10 mg for 3 days), vitamin K_1 (phytonadione) can replete stores and establish if coagulation abnormalities are due to malabsorption alone. It is unusual to completely reverse clotting abnormalities, but INR decreases in most patients, conferring a decreased risk of bleeding. Because cirrhotic patients may have decreased bile production resulting in decreased absorption of fat-soluble vitamins, phytonadione should be given subcutaneously instead of orally to ensure absorption.

OUTCOME EVALUATION

- Reevaluate the pharmacotherapy regimen at each visit to assess adherence, effectiveness, adverse events, and need for drug titration.
- Determine adherence to lifestyle changes such as cessation of ethanol intake and avoidance of over-the-counter medications (particularly NSAIDs and acetaminophen) and dietary supplements that may exacerbate complications of cirrhosis.
- Assess dietary sodium intake by patient food recall. Measure dietary sodium adherence using spot urine sodium-to-potassium ratio to assess appropriate sodium excretion.
- Ask the patient specific, directed questions regarding adherence and adverse effects of β-blockers; inquire about symptoms of orthostatic hypotension (eg, lightheadedness, dizziness, or fainting).
- Evaluate effectiveness of diuretic therapy with regard to ascitic fluid accumulation and development of peripheral edema. Ask the patient directed questions regarding abdominal girth, fullness, tenderness, and pain. Weigh the patient at each visit, and ask the patient to keep a weight diary. Assess for peripheral edema at each visit.

Patient Care Process

Collect Information:

- Perform a medication history at each visit, and ask specifically about prescription, nonprescription, herbal products, and nutraceuticals as well as illicit substances. Be especially mindful of NSAID pain relievers and herbal remedies that can be hepatotoxic or affect renal function. Ask the patient how each medication is taken; this can provide insight into adherence.
- Ask about dietary compliance with sodium restriction; a 24-hour diet recall can help identify high-sodium intake.
- Complete a comprehensive review of systems and physical examination to identify subtle changes. Pay particular attention to fluid status and any GI complaints.

Assess the Information:

- Determine if the patient is taking any drugs that could adversely affect their liver disease or renal function.
- Identify drugs that can precipitate altered mental status or cause confusion.
- Identify medications that may have better alternatives, or are not crucial to continue.
- Identify any changes in health status that could signal decompensation: (1) changes in fluid status (peripheral edema or new or worsening ascites); (2) changes in GI habits that could signal hematochezia, melena, or hematemesis; and (3) changes in mentation such as confusion, changes in sleep patterns, or increased forgetfulness that could signal hepatic encephalopathy.
- Examine laboratory results for signs of worsening hepatic synthetic function or decompensation.

Develop a Care Plan:

- Identify methods to achieve and maintain lifestyle changes including avoiding alcohol and illicit drugs, and achieving a low-sodium diet.
- Choose drug therapies that do not worsen hepatic or renal function, and avoid drugs that may impair cognition or balance. A good resource for those (although targeted at the geriatric population) is the BEERS criteria medication list; a printable pocket card is available on the Internet.

Implement the Care Plan:

- Educate patient (and family as applicable) about lifestyle changes and pharmacotherapy regimens; make sure they understand the purpose of each.
- Select medications that are expected to be well tolerated as well as affordable, and choose the least burdensome dosing regimen.
- Educate the patient on potential adverse effects of drug therapy, how to identify and potentially mitigate those affects, and when to seek medical care.

Follow-up: Monitor and Evaluate:

- Follow up at regular intervals to assess both drug therapy and disease progression.
- Review adherence to lifestyle changes and medication regimens.
- Complete review of systems, physical and laboratory examinations as appropriate to assess changes in patient status.

- Obtain complete blood count (CBC) and PT/INR to assess for anemia, thrombocytopenia, or coagulopathy. Ask about bruising, bleeding, hematemesis, hematochezia, and melena to assess for bleeding.
- Review biopsy reports and laboratory data. Hepatic transaminases and blood ammonia levels do not correlate well with disease progression, but increased coagulation times are markers of loss of synthetic function.
- Evaluate for signs and symptoms of HE. Mental status changes may be subtle; questioning family members or caregivers about confusion or personality changes may reveal mild HE even if the patient is unaware of deficits. In patients taking lactulose therapy, titrate the dose to achieve two to four soft bowel movements daily.

Abbreviations Introduced in This Chapter

ADH	Antidiuretic hormone
ALT	Alanine aminotransferase
AST	Aspartate aminotransferase
BUN	Blood urea nitrogen
CBC	Complete blood count
CYP450	Cytochrome P-450 isoenzyme
GGT	γ-Glutamyl transferase
GI	Gastrointestinal
HE	Hepatic encephalopathy
HRS	Hepatorenal syndrome
INR	International normalized ratio
LDH	Lactate dehydrogenase
MELD	Model for End-Stage Liver Disease
NAFLD	Nonalcoholic fatty liver disease
NG	Nasogastric
NH_3	Ammonia
NH_4^+	Ammonium
NSAID	Nonsteroidal anti-inflammatory drug
PT	Prothrombin time
RAAS	Renin-angiotensin-aldosterone system
SAAG	Serum ascites–albumin gradient
SBP	Spontaneous bacterial peritonitis
TIPS	Transjugular intrahepatic portosystemic shunt

23 Pancreatitis

Janine E. Then and Heather M. Teufel

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the pathophysiology of acute pancreatitis and chronic pancreatitis.
2. Differentiate acute pancreatitis from chronic pancreatitis.
3. Formulate care plans for managing acute and chronic pancreatitis.
4. Choose appropriate pancreatic enzyme supplementation for patients with chronic pancreatitis.

INTRODUCTION

The pancreas is a gland in the abdomen lying in the curvature of the stomach as it empties into the duodenum. It functions primarily as an exocrine gland but also has endocrine function. The exocrine cells of the pancreas are called **acinar cells** that produce and store digestive enzymes that mix with a bicarbonate-rich solution released from duct cells to produce pancreatic juice. This juice is released through the **ampulla of Vater** into the duodenum to aid in digestion and buffer acidic fluid released from the stomach (Figure 23–1).[1]

Pancreatic enzymes are produced and stored as inactive proenzymes within **zymogen** granules to prevent autolysis and digestion of the pancreas. Amylase and lipase are released from the zymogen granules in the active form, whereas the proteolytic enzymes are activated in the duodenum by enterokinase. Enterokinase triggers the conversion of trypsinogen to the active protease **trypsin**, which then activates the other proenzymes to their active enzymes. The pancreas contains a trypsin inhibitor to prevent autolysis.

ACUTE PANCREATITIS

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT In the Western Hemisphere, acute pancreatitis (AP) is caused mainly by ethanol use/abuse and gallstones (**cholelithiasis**). Ethanol use accounts for about 30% of AP cases and gallstones about 30% to 40% of cases. Other common causes include hypertriglyceridemia, endoscopic retrograde cholangiopancreatography (ERCP), pregnancy, and autodigestion due to early activation of pancreatic enzymes. Numerous medications have been implicated as causes of AP, but other causes should be ruled out before discontinuing a medication indefinitely (Table 23–1).[2]

PATHOPHYSIOLOGY

LO 1

Ethanol abuse may cause precipitation of pancreatic enzymes in pancreatic ducts, leading to chronic inflammation and fibrosis resulting in loss of exocrine function. Ethanol may be directly toxic to the pancreatic cells and may lead to an upregulation of enzymes that produce toxic metabolites leading to further damage.[3] Gallstones can obstruct the ampulla of Vater causing pancreatic enzymes or bile to move in a retrograde fashion into the pancreas. This retrograde movement may be responsible for pancreatic autolysis.[1]

Autolysis of the pancreas can occur when zymogens are activated in the pancreas before being released into the duodenum. AP can result from the initial injury to the zymogen-producing cells, which is followed by neutrophil, lymphocyte, and macrophage invasion of the pancreas and further activation of enzymes within the pancreas.

LO 2

AP can progress to peripancreatic fluid collections in or around the pancreas; they usually require no intervention and resolve spontaneously.[4,5] **Pancreatic pseudocysts** are walled-off fluid collections that form 4 weeks or longer after the onset of AP. Many pseudocysts resolve spontaneously, but some require surgical or percutaneous drainage. Rupture of a pancreatic pseudocyst is a serious complication and can lead to peritonitis and gastrointestinal (GI) bleeding.[4]

Pancreatic enzyme damage may lead to pancreatic necrosis, which is diffuse inflammation of the pancreas containing both necrotic tissue and fluid. KEY CONCEPT Pancreatic necrosis occurs within the first 2 weeks of AP and affects 10% to 20% of patients. Infected necrotic fluid collections occur in 16% to 47% of patients, usually due to bacteria normally present in the GI tract (*Escherichia coli*, Enterobacteriaceae, Enterococcal species, viridans group streptococci, and anaerobes). Disseminated infection may result from pancreatic necrosis.[4,6] Pancreatic abscess is pancreatic necrosis that is walled-off by granulation tissue and occurs weeks after AP.

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

Patients with AP may develop severe local and systemic complications. Multiorgan failure is a poor prognostic indicator. Disease severity can be predicted using the Ranson criteria, Glasgow severity scoring system, Acute Physiology and Chronic Health Evaluation II (APACHE II), and sequential organ failure assessment (SOFA). Awareness of risk factors for severe disease, including age greater than 55 years, comorbid conditions, laboratory findings, and presence of **systemic inflammatory response syndrome** (SIRS), may be more beneficial than scoring systems.[7]

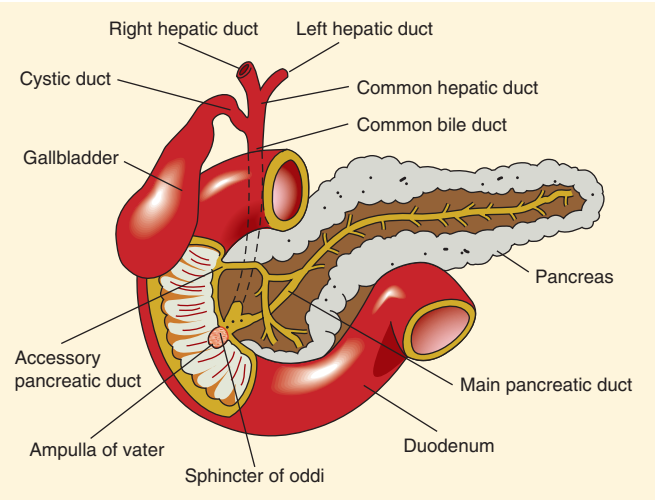

FIGURE 23–1. Anatomical structure of the pancreas and biliary tract. (From Bolesta S, Montgomery PA. Pancreatitis. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017; Figure 39–1, with permission. www.accesspharmacy.com.)

DIAGNOSIS

Diagnosis of AP is based on patient history, signs and symptoms, and laboratory values. The history can identify risk factors, such as alcohol abuse and medications. A serum lipase greater than three times the normal limit supports the diagnosis. The serum lipase has greater sensitivity and specificity for AP than does the serum amylase due to its duration of elevation.[2,8] Elevated hepatic enzymes may indicate gallstone pancreatitis, and triglycerides should be checked to rule out hypertriglyceridemia as the cause.[2,7]

Abdominal ultrasound can identify gallstones and sludge in the common bile duct but has limited sensitivity. Computed tomography (CT) may be more useful in staging pancreatitis or identifying complications. ERCP should be used early when patients have concurrent acute cholangitis. Magnetic resonance imaging (MRI) and magnetic resonance cholangiopancreatography (MRCP) are more costly options that can be used to evaluate severity and pancreatic abnormalities.[2,7]

Table 23–1

Selected Medications Associated with Acute Pancreatitis

Cardiovascular: Enalapril, lisinopril, ramipril, losartan, furosemide, hydrochlorothiazide, amiodarone, statins
Anti-infectives: Metronidazole, sulfonamides, tetracycline, tigecycline, pentamidine, isoniazid, lamivudine, didanosine, nelfinavir, interferon/ribavirin
Gastrointestinal: Omeprazole, mesalamine
Neurologic: Valproic acid, clozapine
Hormonal: Conjugated estrogens, tamoxifen
Oncologic: Ifosfamide, cytarabine
Analgesics: Sulindac, salicylates
Other: Propofol, mercaptopurine, azathioprine, corticosteroids, marijuana

Clinical Presentation of Acute Pancreatitis

Signs and Symptoms

- Sudden upper abdominal pain is the most common symptom.
- Pain may radiate to the back, and ecchymosis may be present in the flank and periumbilical areas.
- Nausea and vomiting are other common symptoms.
- Tachycardia, hypotension, fever, and abdominal distention may be present.

Laboratory Tests

- The serum amylase may be elevated to more than three times the upper limit of normal within the first 12 hours of the onset of AP. The degree of elevation does not correlate with disease severity, and levels may return to normal before the patient presents for care.
- Serum lipase rises within 4 to 8 hours of onset, peaks at 24 hours, and returns to normal within 8 to 14 days.
- Other laboratory abnormalities may include elevated white blood cell (WBC) count, hyperglycemia, hypocalcemia, hyperbilirubinemia, elevated serum lactate dehydrogenase (LDH), and hypertriglyceridemia.

TREATMENT

Desired Outcomes

The goals of treatment for AP include: (a) resolution of nausea, vomiting, abdominal pain, and fever; (b) ability to tolerate oral intake; (c) normalization of serum amylase, lipase, and WBC count; and (d) resolution of abscess, pseudocyst, or fluid collection as measured by CT scan.

Nonpharmacologic Therapy

KEY CONCEPT Therapy of AP is primarily supportive unless a specific etiology is identified (Figure 23–2). Supportive therapy involves fluid repletion, nutrition support, and analgesia. Patients are administered IV fluids to maintain hydration and blood pressure. Lactated Ringer's solution at a rate of 250 to 500 mL/hour should be used to provide aggressive hydration.[9] The total amount of fluids administered should be based on vital signs and urine output. Fluid requirements should be assessed carefully, especially in patients with concomitant cardiac, renal, and liver disease. Electrolytes such as potassium and magnesium may be added to the infusions if necessary. Hyperglycemia can be managed with insulin-containing IV infusions.[7]

LO 3

While it is common to discontinue oral feedings during AP, this does not prevent further damage because secretion of trypsin is already reduced.[6] In mild to moderate AP, diet should be advanced based on resolution of nausea, vomiting, and pain. In severe AP enteral nutrition should be started as early as possible and may include nasogastric or nasojejunal feedings. Early use of enteral nutrition (within 48 hours)[10] has been shown to decrease surgical interventions and infectious complications. Enteral nutrition is preferred, but if a patient is not meeting caloric goals, it may be supplemented with total parenteral nutrition.[6,7,10]

LO 3

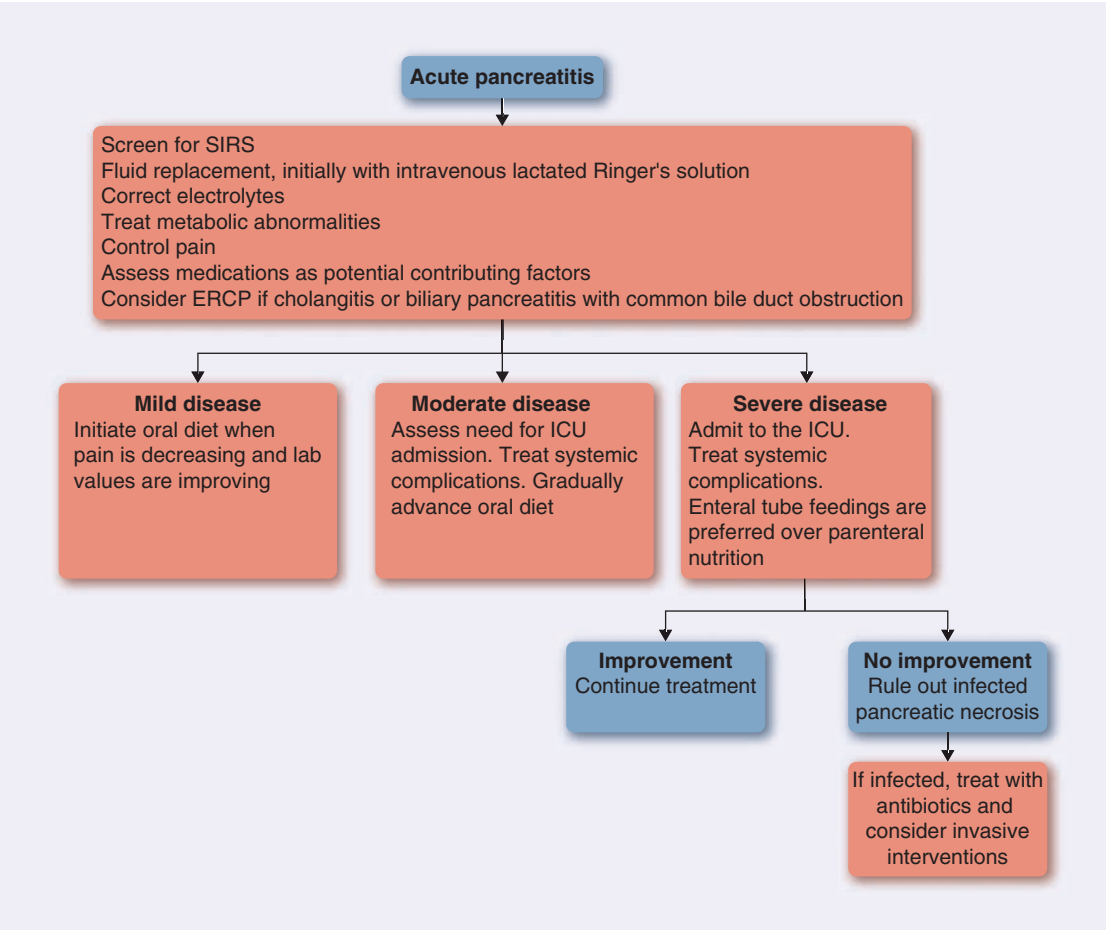

FIGURE 23–2. Algorithm for evaluation and treatment of acute pancreatitis. (ERCP, endoscopic retrograde cholangiopancreatography; ICU, intensive care unit; SIRS, systemic inflammatory response syndrome.) (From Bolesta S, Montgomery PA. Pancreatitis. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill; 2017; Figure 39–3, with permission. www.accesspharmacy.com.)

If pancreatic necrosis or abscesses are present, surgical or interventional procedures may be necessary.

Pharmacologic Therapy

▶ *Analgesics*

No single opioid analgesic has proven to be superior to other opioids in treating pain associated with pancreatitis. Opioids should be titrated to the lowest effective dose. Consideration should also be given to nonopioid analgesic therapy based on current perioperative pain management strategies.[10] (See Chapter 34, Pain Management.)

Patient Encounter 1, Part 1

A 23-year-old man presents to the emergency department with a 2-day history of nausea and vomiting. He also complains of abdominal pain that is unrelieved and persistent. He has not eaten in the past 2 days because food exacerbates the pain. Upon examination, his abdomen is found to be distended.

What information about the patient presentation is consistent with acute pancreatitis?

What tests may be helpful in diagnosing acute pancreatitis?

▶ *Antibiotics*

Antibiotics do not prevent formation of pancreatic abscess or necrosis when given early in the course of AP.[2,7] Empiric antibiotics are not indicated if the patient has mild disease or a known noninfectious cause. In necrotizing pancreatitis, antibiotics may be appropriate for patients who fail to improve after 1 week, or deteriorate. The decision to use antibiotics should be guided by fine needle aspiration whenever possible. Stable patients with infected necrosis should be treated with antibiotics; surgical, radiologic, and/or endoscopic drainage would ideally be delayed by 4 weeks to allow for the area of necrosis to become walled off.[6,7,10] Consideration should be given to discontinuing antibiotics if no source of infection is confirmed.

Infections are usually polymicrobial, so broad-spectrum antibiotics with activity against enteric gram-negative bacilli are appropriate (Table 23–2). Patients may receive long courses of broad-spectrum antibiotics and may develop superinfections with resistant bacteria. Routine use of antifungal agents (eg, fluconazole) is not recommended but may be considered if peritonitis or GI perforation develops due to the presence of fungi such as *Candida albicans* in the GI tract.[1,7]

Patient Encounter 1, Part 2

PMH: None

Allergies: Amoxicillin (hives)

FH: Father—MI at 48 years of age, CHF, COPD; mother—osteoporosis, breast cancer, gallstones

SH: History of heavy drinking; tobacco 1 ppd; no recreational drugs

Meds: Bactrim DS twice daily for a skin lesion (started last week), naproxen 500 mg twice daily as needed for pain

ROS: Positive for sharp right upper quadrant (RUQ) abdominal pain that radiates to the right shoulder and back, nausea, vomiting; negative for substernal chest pain

PE:

VS: BP 105/60 mm Hg seated, 90/50 mm Hg standing, P 120 beats/min, RR 22 breaths/min, T 37.9°C (100.2°F), pain score 9/10, Wt 91 kg (200 lb), Ht 6′1″ (185 cm)

CV: Regular rate and rhythm, no murmurs

Abd: Distended, (+) rebound tenderness, (+) bowel sounds, (+) guarding

Labs:

WBC 15.8 × 10^3/mm^3 (10^9/L)	Amylase 90 IU/L (1.50 µkat/L)
Hgb 10.9 g/dL (109 g/L, 6.77 mmol/L)	Lipase 1250 IU/L (20.8 µkat/L)
Hct 30% (0.30)	AST 520 IU/L (8.67 µkat/L)
Platelets 250 × 10^3/mm^3 (10^9/L)	ALT 480 IU/L (8.0 µkat/L)
BUN 19 mg/dL (6.8 mmol/L)	Total bilirubin 2.7 mg/dL (46.2 µmol/L)
SCr 1.2 mg/dL (106 µmol/L)	
Glucose 220 mg/dL (12.2 mmol/L)	LDH 1050 IU/L (17.5 µkat/L)

Abdominal x-ray and ultrasound: Pending

What clinical signs are consistent with acute pancreatitis?

What additional information is needed at this point?

What treatment(s) would you initiate?

▶ *Ineffective Therapies*

KEY CONCEPT Therapies with no proven benefit on morbidity and mortality include reducing pancreatic secretion by administering somatostatin analogues or atropine, reducing gastric acidity and pancreatic secretion with histamine$_2$-receptor antagonists, probiotics, and immunomodulation.[11]

OUTCOME EVALUATION

- Monitor hydration and nutrition status closely; replace electrolytes as necessary.
- Provide analgesia and monitor pain severity using validated scales.
- Monitor patients with moderate to severe AP in an intensive care setting with frequent monitoring of vital signs.
- Continually assess patients for signs of infection, including fever, leukocytosis, and other signs of sepsis.

Table 23–2

Selected IV Antimicrobial Regimens for Pancreatic Necrosis

Drug	Usual Dose[a]	Notes
Meropenem	1 g every 8 hours	Risk of superinfection
Piperacillin/tazobactam	3.375–4.5 g every 6–8 hours	Avoid if allergic to penicillin
Cefepime + metronidazole	2 g every 12 hours + 500 mg every 8–12 hours	Will not cover enterococci
Aztreonam + vancomycin + metronidazole	1 g every 8 hours + 15 mg/kg every 8–12 hours + 500 mg every 6 hours	Option for penicillin-allergic patients

[a]Doses must be adjusted for the degree of renal impairment.

CHRONIC PANCREATITIS

EPIDEMIOLOGY AND ETIOLOGY

The incidence of chronic pancreatitis (CP) ranges from 5 to 12 per 100,000 persons, and is higher in men than women.[12] KEY CONCEPT The most common cause of CP in adults in Western countries is ethanol abuse. Other causes include genetic

Patient Care Process for Acute Pancreatitis

Collect Information:

- Assess fluid and nutritional status and abdominal pain severity using a pain scale.
- Review laboratory data: lipase and/or amylase; triglycerides.
- Review imaging results to determine potential causes (eg, obstruction) and extent of pancreatic damage.

Assess the Information:

- Review laboratory data, imaging and medication history for potential risk factors for pancreatitis (Table 23–1).

Develop a Care Plan:

- Determine the level of monitoring required based on the patient's location (eg, ICU, medical floor)
- Determine how to assess ongoing pain

Implement the Care Plan:

- Provide fluid resuscitation until the patient shows signs of adequate perfusion (monitor blood pressure and urine output).
- Provide analgesia using multimodal therapy.
- Initiate enteral nutrition early; consider parenteral nutrition if enteral nutrition is not tolerated within 1 week.

Follow-up: Monitor and Evaluate:

- Assess vital signs and pain frequently.
- Provide ongoing monitoring for potential infection.

predisposition, obstructive disease (secondary to ductal strictures or pseudocysts), autoimmune pancreatitis, abnormal cystic fibrosis transmembrane conductance regulator (CFTR) function as seen in cystic fibrosis (CF) patients, tropical pancreatitis, and idiopathic pancreatitis.[3,13] Cigarette smoking is an independent risk factor for CP.[14]

PATHOPHYSIOLOGY

LO 1

CP is an inflammatory process that occurs over time leading to impaired endocrine and exocrine function secondary to diffuse scarring and fibrosis. The pathogenesis of CP is not completely understood and varies depending on etiology. One theory is that protein-rich plugs form leading to ductal obstruction and inflammation, ultimately causing parenchymal fibrosis and ischemic injury to the acinar cells.[15]

KEY CONCEPT Long-term sequelae of CP include dietary malabsorption, impaired glucose tolerance, cholangitis, and potential addiction to opioid analgesics. As pancreatic exocrine function diminishes, patients have decreased ability to absorb lipids and protein with normal dietary intake, leading to weight loss and malnutrition. Fat- or protein-containing stools are common; carbohydrate absorption is usually unaffected.[13] Patients with CP are at risk and should be screened for deficiencies of vitamin B_{12} and fat-soluble vitamins (A, D, E, and K).[16,17]

LO 3

CLINICAL PRESENTATION AND DIAGNOSIS

The symptoms, signs, and laboratory abnormalities associated with CP are shown in the accompanying box. Several genetic mutations have been associated with CP (*PRSS1*, *SPINK1*, and *CFTR* genes) and may be useful in the diagnostic workup of CP.[15] Pancreatic biopsy with histologic examination is the gold standard for diagnosis of CP, but it is rarely performed. In the absence of histology, abdominal ultrasound, CT, MRCP, or ERCP can assist in the diagnosis.[3,13] Malabsorption and steatorrhea can be diagnosed using quantitative estimations of stool fat, including a 72-hour stool collection or the less cumbersome fecal elastase test.[18]

Patient Encounter 1, Part 3

The patient was discharged and presents again to the hospital 3 weeks later with similar pain and feeding intolerance. On this admission, his WBC count is elevated at $21.2 \times 10^3/mm^3$ ($10^9/L$), and he has a temperature of 38.7°C (101.6°F). He is hypotensive with a mean arterial pressure (MAP) of 60 mm Hg, and his HR is 115 beats/min. His RR is 28 breaths/min and SCr is 2.0 mg/dL (177 µmol/L).
A CT scan demonstrates pancreatic necrosis, and a fine needle aspiration is performed. His APACHE II score is calculated to be 13.

Should this patient be admitted to the ICU or general floor unit?

Does this patient meet criteria for antibiotics? If so, what agents should be considered?

Besides antibiotics, what other pharmacologic treatments may need to be optimized?

Clinical Presentation of Chronic Pancreatitis

General

- Presentation of CP can be similar to that of AP.

Symptoms

- Pain is the most common symptom, and it typically starts in the epigastrium and may radiate to the back or scapula. Pain can be sharp or dull, is not relieved by antacids, and can be provoked by ethanol ingestion or a fatty meal. Pain can be episodic with pain-free intervals, or prolonged and requiring hospitalization.
- Pain may be associated with nausea and vomiting, causing patients to avoid food.
- Weight loss can result from chronic fat and protein malabsorption.

Signs

- Steatorrhea (due to fat malabsorption), malnutrition, and glucose intolerance are often present in advanced CP.
- Chronic obstruction of the common bile duct by the inflamed pancreas can cause icterus (jaundice), cholangitis, and biliary cirrhosis.

Laboratory Tests

- Serum amylase and lipase concentrations may be normal to slightly elevated in CP and are not particularly useful in the diagnosis.
- Glucose intolerance may occur because of chronic destruction of pancreatic endocrine function.
- The serum bilirubin or alkaline phosphatase may be elevated due to inflammation near the common bile duct.
- Erythrocyte sedimentation rate (ESR), IgG4, rheumatoid factor, antinuclear antibody (ANA), and anti-smooth muscle antibody titer may be elevated in autoimmune pancreatitis.

TREATMENT

Desired Outcomes

Goals of pharmacotherapy for CP include: (a) relief of acute and chronic abdominal pain, (b) correction of dietary malabsorption with exogenous pancreatic enzymes, and (c) treatment of endocrine insufficiency and associated diabetes.

▶ *Nonpharmacologic Therapy*

LO 3

KEY CONCEPT Avoidance of ethanol, cigarette smoking, and fatty meals can decrease the pain of CP. Alcohol and cigarette abstainers may have slower disease progression and better response to pain therapy than nonabstainers.[3,13,14] Patients should consume a diet consisting of frequent small low-fat meals (< 20 g fat/day) or one with medium-chain triglycerides where absorption requires only minimal amounts of pancreatic enzymes.[3,19] Surgical procedures for CP include drainage procedures, partial pancreatic resection, and total pancreatectomy. Indications for surgery include poorly controlled pain, ductal obstruction, and symptomatic pseudocysts.[15] Most surgical procedures to reduce inflammation or remove strictures have not been studied in clinical trials and carry a high risk of morbidity and mortality.[3,13]

Pharmacologic Therapy

▶ *Analgesics*

LO 2 LO 3

KEY CONCEPT Pain management is an important component of therapy and similar to that of AP. Nonopioid analgesics (eg, acetaminophen, nonsteroidal anti-inflammatory drugs [NSAIDs]) are preferred, but the severe and persistent nature of the pain often requires opioid therapy. Patients can require chronic doses of opioid analgesics, with resulting risk of addiction.[3,20] Patients should also be assessed for neuropathic pain and treated accordingly (eg, tricyclic antidepressants, pregabalin).[20-22] Refer to Chapter 34 (Pain Management) for guidance in selecting an analgesic dose.

LO 3

▶ *Pancreatic Enzymes*

Pancreatic enzyme supplements (PES) are indicated in symptomatic patients with steatorrhea. The goal is to deliver exogenous enzyme to the duodenum without causing further GI side effects, risking noncompliance due to the large number of dosage units required, or causing undue medication expense.

LO 4

KEY CONCEPT Supplementation with pancreatic enzymes may reduce the pain and fatty diarrhea associated with CP. Common PES contain lipase, protease, and amylase in varying proportions. The half-life of endogenous lipase is based on the presence of its substrates (ie, triglycerides), and therefore dietary fat restriction should be reconsidered when pancreatic enzyme replacement is used.[18,19]

PES products approved by the US Food and Drug Administration are shown in Table 23–3.[23] Enteric-coated products are designed to release enzymes in the alkaline environment (pH > 5.5) of the duodenum, thus minimizing enzyme destruction in the stomach. However, in patients with delayed gastric emptying, the efficacy of the enteric-coated PES may be decreased due to early activation of the lipase enzymes. Addition of an H_2-blocker or proton pump inhibitor will decrease stomach acidity, thereby enhancing delivery of the PES to the site of action. The nonenteric-coated PES are deactivated immediately in an acidic

Table 23–3

FDA-Approved Pancreatic Enzyme Supplements

	Enzyme Content (Units)[a]		
Product	**Lipase**	**Protease**	**Amylase**
Creon 3000	3000	9500	15,000
Creon 6000	6000	19,000	30,000

Zenpep 40,000	40,000	126,000	168,000

[a]All products are porcine derived.

[b]Bicarbonate-buffered enteric-coated microspheres.

[c]Nonenteric-coated tablets; must be administered with a proton pump inhibitor.

Patient Encounter 2

A 68-year-old man presents to the emergency department complaining of a chronic dull pain with a burning/tingling sensation in his abdomen for several months that is no longer relieved with over-the-counter analgesics. He has also had light-colored liquid stools for the past month and has lost 10 pounds (4.5 kg) because of decreased appetite and worsening abdominal pain with meals.

PMH: Hypertension, coronary artery disease, hypothyroidism, depression, recurrent acute pancreatitis, GERD

SH: Consumes a six-pack of beer per day and has a 35 pack–year history of cigarette smoking

Meds: Aspirin 81 mg once daily, enalapril 20 mg once daily, hydrochlorothiazide 25 mg once daily, metoprolol 25 mg twice daily, levothyroxine 150 mcg every morning, sertraline 100 mg once daily, omeprazole 20 mg once daily, and recent use of ibuprofen 400 mg every 4 to 6 hours without pain relief

ROS: (+) for RUQ abdominal pain that radiates to his back, decreased appetite, 10-lb (4.5-kg) weight loss and diarrhea for the past month. (–) for chest pain or shortness of breath

PE:

VS: BP 148/86 mm Hg, HR 75 beats/min, RR 15 breaths/min, T 37.1°C (98.8°F), Wt 77.3 kg (170 lb), Ht 5′10″ (178 cm)

Pain Assessment: Ranges from 6–8 out of 10 (numerical rating scale); currently 8/10 pain. Describes as dull aching pain and tingling, needle-like pain

CV: Regular rate and rhythm, no murmurs

Abd: Distended, (+) rebound tenderness, (+) bowel sounds

Labs:

Amylase 50 IU/L (0.83 µkat/L)	BUN 19 mg/dL (6.8 mmol/L)
Lipase 100 IU/L (1.7 µkat/L)	SCr 0.75 mg/dL (66 µmol/L)
AST 32 IU/L (0.53 µkat/L)	Glucose 248 mg/dL (13.8 mmol/L)
ALT 29 IU/L (0.48 µkat/L)	Triglycerides 180 mg/dL (2.03 mmol/L)

CT Scan Abdomen: Diffuse pancreatic scarring and calcifications

What signs and symptoms are consistent with chronic pancreatitis?

Why are the serum amylase and lipase normal?

What lifestyle modifications would you recommend for this patient?

What, if any, treatment regimens would you initiate, and how would you monitor their effects?

Patient Care Process for Chronic Pancreatitis

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Review the medical history and physical assessment findings to identify signs/symptoms of abdominal pain, steatorrhea, decreased appetite secondary to abdominal pain, and/or signs of glucose intolerance.
- Speak with the patient and review lifestyle and dietary habits, specifically any significant alcohol or smoking history.
- Ask the patient to rate the pain, if any, and relate factors that exacerbate and relieve the pain.

Assess Information:

- Determine whether the patient is receiving any medication(s) that may cause or exacerbate pancreatitis.
- Using validated pain scales, determine whether the pain is currently controlled.
- Review relevant laboratory tests (eg, amylase, lipase, basic metabolic panel, liver panel, complete blood count, lipid panel, fasting glucose, fat-soluble vitamin levels) and imaging (eg, ultrasound, CT, MRI, MRCP).
- If the patient is already receiving pharmacotherapy, assess efficacy, safety, and patient adherence.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- If the patient has signs of malnutrition or nutritional deficiencies, determine if PES or supplemental vitamins are indicated.
- If the patient has elevated fasting blood glucose or A1C, consider starting insulin therapy (see Chapter 43, Diabetes Mellitus).
- Develop an analgesic plan to control and prevent pain (see Chapter 34, Pain Management).

Implement the Care Plan:

- Provide resources for alcohol and smoking abstinence, if applicable.
- Address any patient concerns about pancreatitis and its management.
- Initiate PES in patients with steatorrhea.
- Discuss importance of diet, medication adherence, and lifestyle modifications to reduce complications of AP and/or CP.

Follow-up: Monitor and Evaluate:

- Adjust PES dosage based on nutritional status and pain with meals on a monthly basis until adequate control is achieved. Once stable doses of PES and analgesia are established, monitor the patient once or twice yearly.
- Evaluate the patient's Vitamin A, D, E, K, and B_{12} levels, fasting blood glucose, and A1C at least annually.
- Reassess analgesia and adjust medication and dosages as indicated.

environment and therefore must be administered with a proton pump inhibitor.[18,19]

PES should be taken immediately prior to or portioned throughout meals and snacks to aid in the absorption and digestion of food. KEY CONCEPT Dosing is initiated on body weight and adjusted based on clinical symptoms and stool fat content. The usual starting dose is 500 units/kg/meal of lipase with half of the mealtime dose administered with snacks. Doses of lipase more than 10,000 units/kg/day should be used with caution because they may be associated with colonic stricture and fibrosis.[18,19] LO 4

► *Endocrine*

Patients with CP can develop glucose intolerance, but it usually does not progress to overt diabetes mellitus until late in the disease. Fasting blood glucose should be monitored annually, and ensuing diabetes should be treated with insulin. Patients with CP are at increased risk of hypoglycemia due to dysfunction of the pancreatic alpha cells, which are responsible for glucagon secretion.[3,13,24] LO 2 LO 3

► *Other Therapies*

In patients with autoimmune pancreatitis, prednisolone 30 to 40 mg/day tapered over a 3-month period may provide rapid relief of symptoms.[25] Antioxidants such as methionine, ascorbic acid, and selenium may reduce the number of painful days per month in patients with CP.[3,26,27] LO 3

OUTCOME EVALUATION

- Monitor pain control and adjust analgesics accordingly.
- Encourage lifestyle modifications such as abstinence from ethanol and cigarettes.
- Counsel patients to monitor for weight gain or loss and fatty stool output as markers of malabsorption.
- Educate patients that adherence with PES is key to improved outcomes.

Abbreviations Introduced in This Chapter

ANA	Antinuclear antibody
AP	Acute pancreatitis
APACHE II	Acute Physiology and Chronic Health Evaluation II
CF	Cystic fibrosis
CFTR	Cystic fibrosis transmembrane conductance regulator
CP	Chronic pancreatitis
CT	Computed tomography
ERCP	Endoscopic retrograde cholangiopancreatography
ESR	Erythrocyte sedimentation rate
GI	Gastrointestinal
LDH	Lactate dehydrogenase

MAP	Mean arterial pressure
MRCP	Magnetic resonance cholangiopancreatography
MRI	Magnetic resonance imaging
PES	Pancreatic enzyme supplements
RUQ	Right upper quadrant
SIRS	Systemic inflammatory response syndrome
SOFA	Sequential organ failure assessment
WBC	White blood cell

24 Viral Hepatitis

Juliana Chan

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Differentiate the five types of viral hepatitis by epidemiology, etiology, pathophysiology, clinical presentation, and natural history.
2. Identify modes of transmission and risk factors among the major types of viral hepatitis.
3. Evaluate hepatic serologies to understand how the type of hepatitis is diagnosed.
4. Create treatment goals for a patient infected with viral hepatitis.
5. Recommend appropriate pharmacotherapy for prevention of viral hepatitis.
6. Develop a care plan for treatment of chronic viral hepatitis.
7. Formulate a monitoring plan to assess adverse effects of pharmacotherapy for viral hepatitis.

INTRODUCTION

The most common types of viral hepatitis include hepatitis A (HAV), B (HBV), C (HCV), D (HDV), and E (HEV). Acute hepatitis may be associated with all five types of hepatitis and rarely exceeds 6 months in duration. Chronic hepatitis (disease lasting longer than 6 months) is usually associated with hepatitis B, C, and D. KEY CONCEPT Chronic viral hepatitis may lead to the development of **cirrhosis** and may result in **end-stage liver disease** (ESLD) and **hepatocellular carcinoma** (HCC). Complications of ESLD include **ascites**, edema, **hepatic encephalopathy**, infections (eg, spontaneous bacterial peritonitis), hepatorenal syndrome, and **esophageal varices**. *Therefore, prevention and treatment of viral hepatitis may prevent ESLD and HCC.*

Viral hepatitis may occur at any age and is one of the most common causes of liver disease in the world. The true prevalence and incidence may be underreported because most patients are asymptomatic. The epidemiology, etiology, and pathogenesis vary depending on the type of hepatitis and are considered separately below.

EPIDEMIOLOGY AND ETIOLOGY

Hepatitis A (HAV)

LO 1 HAV affects 1.4 million people yearly worldwide.[1] The prevalence is highest in economically challenged and underdeveloped countries, including Central and South America, Africa, the Middle East, Asia, and the Western Pacific.[2] The numbers of acute HAV infections and hospitalizations have decreased since the introduction of the HAV vaccine in 1995.[3] However, outbreaks may still occur, as observed in 292 confirmed HAV cases in Hawaii in 2016 that was linked to scallops.[4]

LO 2 HAV is primarily detected in contaminated feces and infects people via the fecal–oral route.[1,2] Outbreaks occur in areas of poor sanitation.[2] About 45% of the cases reported have no identifiable risk factors; individuals at greatest risk of acquiring HAV are listed in Table 24–1.[2]

There are no documented cases of chronic hepatitis A.[2] Death from HAV is rare and mostly associated with fulminant hepatitis; approximately 100 people in the United States die each year from HAV-related causes.[2]

Hepatitis B (HBV)

LO 1 Approximately 2 billion people worldwide have evidence of past or present HBV infection, and more than 240 million people have chronic hepatitis B (CHB).[5] Globally, more than 680,000 deaths are associated with HBV annually.[5] Despite having an effective vaccine against HBV since 1982, it is estimated that there were 21,900 new HBV infections in 2015 in the United States.[3] Fewer than 1% of individuals in North America and Western Europe are chronically infected, compared with greater than 5% in developing areas in parts of Africa, South America, East Asia, and Pacific Islands.[5]

LO 2 The primary modes of transmission of HBV are by blood and body fluids through perinatal, sexual, or percutaneous exposure (Table 24–1).[5,6] Infants born to mothers who are infected with actively replicating HBV have a 90% risk of becoming infected.[6]

Hepatitis C (HCV)

LO 1 Up to 3.9 million Americans and 80 million people worldwide have chronic HCV.[5,7] The prevalence is highest in injection drug users, who account for 60% of newly diagnosed acute HCV infections.[8] HCV is categorized by genotypes, which are geographically specific. There are seven genotypes (numbered 1–7) and 67 subtypes (eg, genotypes 1a, 1b, 2a, 3b), with the newest genotype recently identified, genotype 7.[9] Genotype 1 is the most common in the United States, whereas genotype 4 is most common in the Middle East and North Africa.[10] Approximately 75% of patients with HCV in the United States have genotype 1, and about 15% and 9% have genotypes 2 and 3, respectively.[11] Genotype does not indicate disease severity but is used to determine the duration of therapy and the likelihood of therapeutic response.[12]

Table 24–1

Risk Factors for Acquiring Viral Hepatitis

Hepatitis A
International travelers to endemic areas (eg, Africa, Asia, and parts of South America)
Sexual contact with infected persons (eg, men having sex with other men)
Day care centers or household contacts with people infected with HAV
IV drug users using unsterilized needles
Workers involved with nonhuman primates
Patients with clotting factor disorders

Hepatitis B and D
Infants born to infected mothers
International travelers to endemic areas
Men having sex with other men
Individuals with multiple heterosexual partners
IV drug users using unsterilized needles
Recipients of blood products
Household contacts with acute hepatitis B
Health care providers and public safety workers in contact with infected blood
Residents and staff of facilities for developmentally disabled persons
Patients undergoing dialysis

Hepatitis C
Current or former injection drug users
Recipients of blood products (clotting factor concentrates made before 1987, blood transfusions or solid organ transplants before July 1992)
Health care providers in contact with infected needles
Chronic hemodialysis
Individuals having multiple sexual partners
HIV infection
Perinatal transmission (< 5%)
Unprofessional body piercing and tattooing
Person born from 1945 through 1965

Hepatitis E
International travelers to endemic areas (eg, parts of Asia, Africa, and Mexico)
Ingestion of foods and drinks contaminated with bodily waste

LO2 Contaminated needles and syringes with or without paraphernalia (eg, containers, filters) used by intravenous drug users (IVDU) are the primary source of HCV transmission.[8] As many as 70% to 90% of IVDUs have HCV infection.[12] The risk of HCV transmission via blood transfusion is very low (0.001% per unit transfused).[13] Approximately 10% of individuals with HCV have no identifiable risk factors[13] (Table 24–1).

Hepatitis D (HDV)

LO1 Hepatitis D affects up to 20 million people worldwide.[14] Areas with the highest prevalence include the Middle East, parts of Africa and Central Asia, and parts of South America.[15]

LO2 HDV infection is unique because it can only occur in people who are also infected with the HBV.[14,15] The most likely modes of transmitting HDV are similar to those of HBV (Table 24–1).[15]

Hepatitis E (HEV)

LO1 An estimated 20 million individuals worldwide are infected annually with HEV, and the disease was associated with about 44,000 deaths in 2015.[16] The highest prevalence is found in East and South Asia.[16] HEV infection primarily occurs in underdeveloped countries with poor sanitation. The HEV is transmitted mainly by the fecal–oral route (eg, contaminated drinking water).[16]

LO2

PATHOPHYSIOLOGY

Hepatitis A

Hepatitis A is a nonenveloped single-stranded RNA virus classified as the *Hepatovirus* genus under the Picornaviridae family.[2] The primary host for the HAV is humans, with hepatic cells as the main site for viral replication. As part of the viral degradation process, the HAV is released into the biliary system causing elevated HAV concentrations in the feces. Hepatitis A infections are usually self-limiting and do not lead to chronic disease; rarely it may result in fulminant hepatitis.[1,2]

LO1

Hepatitis B

The HBV belongs to the Hepadnaviridae family.[6] It is a partially double-stranded DNA virus with a phospholipid layer containing hepatitis B surface antigen (HBsAg) that surrounds the nucleocapsid. The nucleocapsid contains the core protein that produces hepatitis B core antigen (HBcAg), which is undetectable in the serum. Hepatocellular injury from HBV is thought to be due to a cytotoxic immune reaction that occurs when HBcAg is expressed on the surface of hepatic cells. Fortunately, antibodies against hepatitis B core antigen (anti-HBc) are measurable in the blood, where anti-HBc to immunoglobulin M (IgM) indicates active infection, and anti-HBc to IgG indicates either chronic infection or possible immunity against HBV.

LO1

Viral replication usually occurs when the hepatitis B envelope antigen (HBeAg) is present and circulating in the blood. The serum HBV DNA concentration is a measure of viral infectivity and quantifies viral replication. Once the HBV infection resolves, antibodies against the hepatitis B envelope (anti-HBe) and antibodies against hepatitis B surface antigen (anti-HBs) develop, and HBV DNA levels become undetectable. However, if these antibodies do not develop, the likelihood of developing CHB increases. This depends primarily on the host's immune system at the time of infection. In immunocompetent individuals, the disease resolves spontaneously and does not lead to further complications. In immunocompromised persons, the HBV is less likely to be eradicated, thus causing persistent infection leading to hepatic cell damage and inflammation.[5,6]

Approximately 90% of adults infected with the HBV develop anti-HBs, which results in lifelong immunity. Unfortunately, about 90% of infants born to mothers with active HBV infection will go on to develop CHB.[5] About 50% of adults with acute HBV infections are asymptomatic, and those with symptoms may experience jaundice or fatigue.[6]

Hepatitis C

Hepatitis C, first known as non-A, non-B hepatitis, is a bloodborne infection caused by a single-stranded RNA virus belonging to the Flaviviridae family and the *Hepacivirus* genus.[17]

Antibodies against HCV (anti-HCV) in the blood indicate infection. If the infection persists for more than 6 months and viral replication is confirmed by HCV RNA levels, the person has chronic hepatitis C, which occurs in 55% to 85% of cases.[5,7]

About 15% of patients have acute hepatitis C that resolves without further complications.[7] Chronic disease may be due to an ineffective host immune system, with cytotoxic T lymphocytes unable to eradicate the HCV, thereby allowing persistent damage to hepatic cells. The most common risk factors for developing

LO1

Patient Encounter Part 1

A 53-year-old white woman presents to the doctor's office for a yearly check-up. Her complaints include fatigue and itching for past few years. Over the past week she had eaten store-bought fish that gave her an upset stomach.

PMH: Diet-controlled hypertension, osteoporosis, arthritis, hemodialysis on Tuesday, Thursday, and Saturday

PSH: None

FH: Father with HTN; mother with NASH; married with a 24-year-old daughter

SH: Never smoked tobacco. One time use of IV cocaine at age 16. Drinks alcohol socially (drank heavily in her 20s when she was in college). Professor in business administration at a local university

Meds: Multivitamin daily, acetaminophen as needed, calcium and vitamin D

ROS: Complains of fatigue and itching; no nausea, vomiting, diarrhea, abdominal pain, or anorexia; never experienced an episode of jaundice, pale stools, or tea-colored urine

PE:

VS: BP 130/85 mm Hg, P 82 beats/min, RR 20/minute, T 37.0°C (98.6°F), Wt 76 kg (167 lb), Ht 5'10" (178 cm)

Abd: Soft, nontender, normal liver span; no hepatosplenomegaly, no ascites

The remainder of the examination was within normal limits.

Labs:

Sodium 141 mEq/L (mmol/L)
Potassium 5.1 mEq/L (mmol/L)
Chloride 99 mEq/L (mmol/L)
CO_2 21 mEq/L (mmol/L)
BUN 20 mg/dL (7.1 mmol/L)
SCr 4.1 mg/dL (362 µmol/L)
Glucose 122 mg/dL (6.8 mmol/L)
Hgb 10.1 g/dL (101g/L; 6.26 mmol/L)
Hct 30.1% (0.301)
Plt 119 × 10^3/mm^3 (119 × 10^9/L)
WBC 5.1 × 10^3/mm^3 (5.1 × 10^9/L)

AST 40 IU/L (0.67 µkat/L)
ALT 42 IU/L (0.70 µkat/L)

Alk phos 164 IU/L (2.73 µkat/L)
Albumin 3.1 g/dL (31 g/L)
Anti-HAV IgM (–)
Anti-HAV IgG (–)
Anti-HCV (+), genotype 1b
HCV RNA 3,188,750 IU/mL (kIU/L)
TSH 1.3 µIU/mL (mIU/L)

FibroScan: Moderate fibrosis, F3

What information is suggestive of viral hepatitis?

What risk factors does she have for viral hepatitis?

What additional information do you need before creating a treatment plan for this patient?

hepatic fibrosis include obesity, diabetes, heavy alcohol use, male sex, and coinfections with HIV or HBV.[8]

From 55% to 85% of chronic cases progress to mild, moderate, or severe hepatitis. Cirrhosis and its complications may take several decades to develop in 15% to 30% of patients infected with HCV. Once cirrhosis is confirmed, the risk of developing HCC is 2% to 4% per year.[5]

Hepatitis D

LO 1

The HDV belongs to the genus *Delta virus* of the Deltaviridae family. The HDV is a defective single-stranded circular RNA virus that requires the presence of HBV for HDV viral replication, causing either coinfection (both hepatitis B and D infection occurring simultaneously) or superinfection (acquiring HDV after having long-standing HBV disease).[14] This occurs because the HDV antigen (HDVAg) is coated by the HBsAg.[14]

Hepatitis E

LO 1

Hepatitis E is a nonenveloped single-stranded messenger RNA virus of the Hepeviridae family, with at least 4 different genotypes; genotypes 1 and 2 are found in humans, and genotypes 3 and 4 occur in animals.[16,18] The HEV is similar to HAV in that the virus is found in contaminated feces, thus infecting people via the fecal–oral route. HEV infections are usually self-limiting and rarely result in hepatic complications. Chronic infections occur rarely but may lead to cirrhosis; they are more common in immunocompromised individuals (eg, HIV infection) and organ transplant recipients.[18]

CLINICAL PRESENTATION AND DIAGNOSIS

See box for the clinical presentation of viral hepatitis.

Diagnosis of Viral Hepatitis

Diagnosing viral hepatitis may be difficult because most infected individuals are asymptomatic.[2,5,15,18] Because symptoms alone cannot identify the specific type of hepatitis, laboratory serologies

Clinical Presentation of Viral Hepatitis

Symptoms

- Most patients infected with any type of viral hepatitis have no symptoms.
- Symptomatic patients may experience a flu-like syndrome, fevers, fatigue/malaise, anorexia, nausea, vomiting, diarrhea, dark urine, pale-appearing stools, pruritus, and abdominal pain.

Signs

Jaundice may be evident in the whites of the eyes (scleral icterus) or skin.

- An enlarged liver (hepatomegaly) and spleen (splenomegaly) may be present.
- In fulminant hepatitis with hepatic encephalopathy, patients may have asterixis and coma.
- In rare instances, extrahepatic symptoms may develop (arthritis, postcervical lymphadenopathy, palmar erythema, cryoglobulinemia, and vasculitis).

Laboratory Tests

- See Table 24–2.

LO 3

Table 24–2

Interpretation of Viral Hepatitis Serology Panels

Type	Laboratory Test	Result	Interpretation of Panel
Hepatitis A	IgM anti-HAV IgG anti-HAV	Negative Negative	Susceptible to infection
	IgM anti-HAV IgG anti-HAV	Positive Positive	Acutely infected Immune due to either natural infection or HAV vaccine
Hepatitis B[a]	HBsAg anti-HBc anti-HBs	Negative Negative Negative	Susceptible to infection
	HBsAg anti-HBc anti-HBs	Negative Positive Positive	Immune due to natural infection
	HBsAg anti-HBc anti-HBs	Negative Negative Positive	Immune due to hepatitis B vaccination
	HBsAg anti-HBc IgM anti-HBc anti-HBs	Positive Positive Positive Negative	Acutely infected
	HBsAg anti-HBc IgM anti-HBc anti-HBs	Positive Positive Negative Negative	Chronically infected
	HBsAg anti-HBc Anti-HBs	Negative Positive Negative	Four interpretations possible: (a) Resolved infection (most common); (b) false-positive anti-HBc, thus susceptible; (c) low-level chronic infection; (d) resolving acute infection
Hepatitis C	anti-HCV	Negative	Susceptible to infection
	anti-HCV	Positive	Acutely or chronically infected
Hepatitis D[b]	IgM anti-HDV HDVAg HBsAg HBeAg anti-HBc	Positive Positive Positive Positive Positive	Acute HBV-HDV coinfection
Hepatitis E	IgM anti-HEV IgG anti-HEV	Negative Negative	Susceptible to infection
	IgM anti-HEV	Positive	Acutely infected
	IgG anti-HEV	Positive	Immune due to natural infection

[a]Centers for Disease Control and Prevention. Hepatology [Internet]. http://www.cdc.gov/hepatitis/HBV/PDFs/SerologicChartv8.pdf.

[b]Hepatitis D should be suspected in those who have HBsAg positivity. Hepatitis D may present as either coinfection where both HDV and HBV serologies appear simultaneously, whereas for superinfection, HBV has been present for some time and later HDV develops.

anti-HAV, hepatitis A antibody; anti-HBc, hepatitis B core antibody; anti-HBs, hepatitis B surface antibody; HBsAg, hepatitis B surface antigen; anti-HCV, hepatitis C antibody; anti-HDV, hepatitis D antibody; anti-HEV, hepatitis E antibody; HAV, hepatitis A virus; HBV, hepatitis B virus; HDV, hepatitis D virus; HDVAg, hepatitis D antigen; IgG, immunoglobulin G; IgM, immunoglobulin M.

must be obtained (Table 24–2). A liver biopsy may be obtained to determine the severity of the liver disease, but this is an invasive test that may be associated with complications such as severe pain, bleeding, and death.[19] Therefore, several patented blood tests (FibroTest®, HepaScore®) have been developed that use a panel of serum biomarkers (eg, ALT, AST, platelet count) along with the age and sex of the patient to determine the degree of hepatic fibrosis. A noninvasive imaging test that uses ultrasound vibration-controlled transient elastography (VCTE) is now recommended to assess the severity of liver disease.[19] These invasive and noninvasive tests are imperfect and are usually only able to identify mild and severe disease. Therefore, it is important to monitor laboratory values over time to assess the severity of liver fibrosis (eg, AST, ALT, serum albumin, platelet counts, prothrombin time/INR).

► *Hepatitis A*

LO 3

Hepatitis A is diagnosed by detecting immunoglobulin antibodies to the capsid proteins of the HAV. Detectability of IgM anti-HAV in the serum indicates acute infection. IgM appears approximately 3 weeks after exposure and becomes undetectable within 6 months. In contrast, IgG anti-HAV appears in the serum at approximately the same time that IgM anti-HAV develops but indicates protection and lifelong immunity against hepatitis A.[2]

► *Hepatitis B*

LO 3

Hepatitis B is diagnosed when HBsAg is detectable in the serum, but it does not distinguish between acute and chronic HBV. The presence of IgM antibodies to HBcAg indicates active infection.

IgG anti-HBc indicates either chronic infection or possible immunity against HBV.[6]

In most cases, detectable HBeAg indicates active viral replication. Measurement of HBV DNA determines viral infectivity and quantifies viral replication. Once HBV viral replication ceases, anti-HBe is detectable in the serum. However, a minority of patients may develop anti-HBe and still have elevated HBV DNA levels because of a mutation in the HBV.[20] Therefore, CHB infections may be differentiated as either HBeAg-positive or HBeAg-negative.[20,21] Hepatitis B serologies are evaluated to assess HBV treatment response and determine whether to vaccinate.

▶ *Hepatitis C*

LO 3

Hepatitis C is diagnosed by testing for anti-HCV in the serum and confirmed by the presence of HCV RNA. HCV RNA levels quantify viral replication and are used to determine if antiviral treatment for HCV is effective. Undetectable HCV RNA levels indicate past infection or that the infection is resolved. An HCV genotype should be obtained to determine the likelihood of response to anti-HCV therapy and the duration of treatment required.[8]

▶ *Hepatitis D*

LO 3

Hepatitis D infection requires the presence of HBV for HDV viral replication. Measuring HDV RNA levels confirms hepatitis D infection and is the most accurate diagnostic test. The presence of IgM anti-HD indicates active disease, and IgG anti-HD also becomes detectable if the infection does not resolve spontaneously. HDV antibodies do not confer immunity.[15]

▶ *Hepatitis E*

LO 3

Diagnosis of acute hepatitis E is based on the presence of IgM anti-HEV. IgG anti-HEV emerges when the HEV infection resolves.[16] HEV RNA levels can be obtained from either blood or stool and are usually tested if chronic HEV infection is suspected.[16]

PREVENTION AND TREATMENT OF VIRAL HEPATITIS

Desired Outcomes

LO 4

Treatment outcomes for viral hepatitis are to (a) prevent the spread of infection, (b) prevent and treat symptoms, (c) suppress viral replication, (d) normalize hepatic aminotransferases, (e) improve liver histology, and (f) decrease morbidity and mortality by preventing cirrhosis, HCC, and ESLD.

For hepatitis B, additional treatment goals include seroconversion or loss of HBsAg, and seroconversion or loss of HBeAg.[20] The primary goal of treating chronic HCV is to achieve undetectable HCV RNA for at least 12 weeks after completing hepatitis C therapy, known as achieving a sustained virologic response (SVR).[8]

General Approach

LO 5

Managing viral hepatitis involves both prevention and treatment. Prevention of hepatitis A and B (and indirectly for hepatitis D) can be achieved with immune globulin (IG) or vaccines. KEY CONCEPT Acute viral hepatitis is primarily managed with supportive care. Mild to moderate symptoms rarely require hospitalization, but hospital admission is recommended in individuals experiencing significant nausea, vomiting, diarrhea, and encephalopathy. Liver transplantation may be required rarely if fulminant hepatitis develops. Treatment is available for chronic HBV, HCV, and HDV.

Hepatitis A Prevention

LO 5

KEY CONCEPT Good personal hygiene and proper disposal of sanitary waste are required to prevent HAV fecal–oral transmission.[1,2] This includes frequent hand washing with soap and water after using the bathroom and prior to eating meals. Drinking bottled water and avoiding fruits, vegetables, and raw shellfish harvested from sewage-contaminated water may minimize the risk of becoming infected with the HAV. Individuals at risk of acquiring HAV (Table 24–1) should receive serum IG and/or the hepatitis A vaccine.[2, 22]

▶ *Immune Globulin*

IG is a solution containing antibodies from sterilized pooled human plasma that provides passive immunization against HAV.[2] IG is available as an IV (IGIV) or intramuscular (IGIM) formulation, but only IGIM is used for prevention of HAV. IGIM does not confer lifelong immunity but is effective in providing pre- and postexposure prophylaxis against HAV.[2]

IGIM should be injected into a deltoid or gluteal muscle. It does not affect the immune response of inactivated or live-virus vaccines; however, administrating live vaccines concomitantly with IGIM may decrease the immune response significantly.[2]

Preexposure Prophylaxis IGIM administration is indicated for individuals at high risk of acquiring the HAV who (a) are younger than 12 months, (b) elect not to receive the hepatitis A vaccine, or (c) cannot receive the hepatitis A vaccine (eg, because of allergic reaction). Because active immunity takes several weeks to develop, travelers who are older than 40 years, immunocompromised, or have chronic liver disease or other chronic medical conditions who plan to depart for endemic areas within 2 weeks *and* have not received the hepatitis A vaccine should receive IGIM. If the duration of travel is 1 month or less, the dose of IGIM should be 0.1 mL/kg. However, if travel will be 2 months or longer, then a dose of 0.2 mL/kg should be administered and repeated every 2 months during the stay.[2,24]

Postexposure Prophylaxis Individuals in contact with people infected with acute HAV (Table 24–1) may be candidates for postexposure prophylaxis. IGIM is recommended for individuals younger than 12 months or older than 40 years of age, immunocompromised, diagnosed with chronic liver disease, or have contraindications to the hepatitis A vaccine.[2,22]

The risk of infection may be decreased by 90% if IGIM 0.02 mL/kg is given within 2 weeks of exposure to the HAV. IGIM may still be beneficial if given more than 2 weeks after exposure to a known case of HAV.[22]

▶ *Hepatitis A Vaccine*

Persons at risk of acquiring HAV should receive the hepatitis A vaccine to provide pre- and postexposure prophylaxis. Two inactivated hepatitis A vaccines are available in the United States: HAVRIX and VAQTA. The recommended regimen is to administer two injections 6 months apart (at months 0 and 6).[2,22] These vaccines are considered interchangeable, and doses depend on age (Table 24–3).[2]

Efficacy is defined by measuring antibody response. Protective levels are greater than 20 mIU/mL (IU/L) for HAVRIX and greater than 10 mIU/mL (IU/L) for VAQTA.[23] Within 4 weeks

Table 24–3

Recommended Intramuscular Doses of Hepatitis A Vaccines

Product	Recipient Age (years)	Dose (Units)	Volume (mL)	No. of Doses	Schedule (months)
VAQTA	1–18	25	0.5	2	0, 6–18
	19 or more	50	1	2	0, 6–18
HAVRIX	1–18	720 ELISA	0.5	2	0, 6–12
	19 or more	1440 ELISA	1	2	0, 6–12

ELISA, enzyme-linked immunosorbent assay.

From: Centers for Disease Control and Prevention. Hepatitis A FAQs for Health Professionals [Internet]. http://www.cdc.gov/hepatitis/HAV/HAVfaq.htm#vaccine.

of administering the first vaccine dose, more than 95% of adults and 97% of children and adolescents develop protective antibody concentrations. All recipients receiving the second dose in clinical trials had 100% antibody coverage; therefore, postvaccination measurement of antibody response is not required.[2]

For preexposure prophylaxis, the hepatitis A vaccine is recommended for travelers to endemic hepatitis A countries. It should be administered to healthy travelers 40 years of age and younger regardless of the scheduled dates for departure. Adults who are older than age 40 or are immunocompromised should receive both the hepatitis A vaccine and IGIM (0.02 mL/kg) if travel will occur in less than 2 weeks.[22]

For postexposure prophylaxis, the hepatitis A vaccine is effective in preventing clinical infection in healthy individuals between 12 months and 40 years of age when administered within 14 days after exposure.[22] Individuals outside these age ranges or with significant comorbid conditions should receive IGIM rather than the hepatitis A vaccine because this population has not been studied.[22]

The hepatitis A vaccine may provide immunity for about 25 years in adults and 14 to 20 years in children.[24] The most common and often self-limiting adverse effects in adults include injection site reactions (eg, tenderness, pain, and warmth), headaches, fatigue and flu-like symptoms. Infants and children may have feeding disturbances. Local reactions may be minimized by using an age-appropriate needle length and injecting into the deltoid muscle. Hepatitis A vaccine given during pregnancy has not been evaluated; however, the risk of fetal complications should be minimal because both vaccines are made from inactivated HAV.[2,24]

Hepatitis B Prevention

LO 5

KEY CONCEPT The risk of acquiring the HBV may be minimized by avoiding contaminated blood products and high-risk behavior (Table 24–1) and by receiving the hepatitis B vaccine.[6] Screening pregnant women for HBV and providing universal hepatitis B vaccinations to all newborns is effective in preventing hepatitis B infections.[25,26] In some cases, postexposure prophylaxis with hepatitis B immune globulin (HBIG) may be recommended to prevent the development of acute infection and complications associated with HBV.

▶ *Hepatitis B Immune Globulin (HBIG)*

HBIG is a sterile solution containing antibodies prepared from pooled human plasma that has a high concentration of anti-HBs. A single dose intramuscular of HBIG 0.06 mL/kg provides passive immunization to prevent CHB infections.[25]

The most common side effects of HBIG include erythema at the injection site, headaches, myalgia, fatigue, urticaria, nausea, and vomiting. Serious adverse effects are rare and may include abnormal liver function tests, arthralgias, and anaphylactic reactions. HBIG should be used with caution in individuals who have experienced hypersensitivity reactions to IG or have immunoglobulin A deficiency. Concomitant administration of HBIG and live vaccines should be avoided because the efficacy of the immunization may decrease significantly.

▶ *Hepatitis B Vaccine*

Two single-antigen hepatitis B vaccines are available in the United States: Recombivax HB and Engerix-B. KEY CONCEPT Persons at high risk of acquiring the HBV (Table 24–1) should be vaccinated at months 0, 1, and 6. The vaccine dose depends on the person's age. A third HBV vaccine, Heplisav-B, has a unique adjuvant that stimulates direct immune response to the HBsAg. This product requires only two doses versus three doses for Recombivax HB and Engerix-B (Table 24–4).

The hepatitis B vaccine is also indicated for postexposure prophylaxis to prevent CHB. Individuals exposed to HBV should receive the hepatitis B vaccine with or without HBIG, preferably within 24 hours of exposure based on the source of exposure and the vaccination status of the exposed person (Table 24–5).[6] Postexposure prophylaxis for perinatal exposure depends on several factors, including maternal HBsAg status and the newborn's weight (Table 24–6).[6]

For optimal response, the hepatitis B vaccine should be administered intramuscularly (the anterolateral thigh in neonates and infants and the deltoid region in older children and adults) and not IV or intradermally. Intragluteal IM injections should be avoided because they may result in lower rates of immunity.[25]

The hepatitis B vaccine is effective when antibody concentrations are greater than 10 mIU/mL (IU/L), but postvaccination antibody testing is not routinely recommended because most people completing the vaccination series obtain adequate antibody levels. It may be advisable to determine if immunity has been achieved in infants born to HBsAg-positive mothers and immunocompromised persons.[6]

Effective immunity may last for more than 20 years in healthy individuals. However, patients with poor immune systems may have an anamnestic response that requires titers to be checked periodically with booster doses given.[6]

The most frequent adverse effects are local injection site reactions, flu-like symptoms, dizziness, and irritability.[6] Anaphylaxis, serum sickness-like hypersensitivity syndrome, chronic fatigue syndrome, Guillain-Barré syndrome, and neurologic diseases (leukoencephalitis, optic neuritis, and transverse myelitis) have been reported rarely.[6] Hepatitis B vaccine is not contraindicated during pregnancy and should be safe to the fetus because it is an inactivated vaccine.[6,25]

Table 24–4

Recommended Intramuscular Dosing Regimens for Hepatitis B Vaccines

Product	Patient Categories	Dose (mcg)	Volume (mL)	No. of Doses	Schedule (months)
Recombivax HB	0–19 years of age	5	0.5	3	0, 1, 6
	11–15 years of age[a]	10	1	2	1, 4–6
	≥ 20 years of age	10	1	3	0, 1, 6
	Hemodialysis[b] < 20 years of age	5	0.5	3	0, 1, 6
	Hemodialysis ≥ 20 years of age	40	1	3	0, 1, 6
Engerix-B	0–19 years of age	10	0.5	3	0, 1, 6
	≥ 20 years of age	20	1	3	0, 1, 6
	Hemodialysis[b] < 20 years of age	10	0.5	3	0, 1, 6
	Hemodialysis ≥ 20 years of age	40[c]	2	4	0, 1, 2, 6
Heplisav-B	≥ 18 years of age	20 mcg HBsAg and 3000 mcg CpG 1018 adjuvant	0.5	2	0, 1

[a]Adolescents 11 through 15 years of age may receive either the 5-mcg three-dose pediatric formulation or a 10-mcg two-dose regimen using the adult formulation.

[b]Higher doses might be more immunogenic, but no specific recommendations have been made.

[c]Two 1.0-mL doses administered at one site.

▶ *Hepatitis A and B Combination Vaccine*

KEY CONCEPT Twinrix combines both inactivated HAV and HBV and is approved for individuals older than 18 years who are at risk for HAV and HBV infections.[6] A 1-mL dose of Twinrix may be administered at either months 0, 1, and 6 or in an accelerated schedule on days 0, 7, between 21 and 30, and with a fourth dose at month 12.[6] The accelerated schedule is intended for patients who start the vaccination series but are unable to complete the standard three-dose schedule in time to develop adequate immunity before embarking on travel that will put them at risk of exposure to hepatitis A and B.[27] The side-effect profile of Twinrix is similar to giving each vaccine separately.

Chronic Hepatitis B Treatment

The American Association for the Study of Liver Diseases (AASLD) recommends treatment for CHB patients with persistently elevated ALT (more than two times the upper limit of normal) or significant histological disease and elevated HBV DNA levels greater than 20,000 IU/mL (kIU/L) to delay progression to cirrhosis and prevent the development of ESLD.[20] Similar treatment criteria apply to patients infected with HBeAg-negative CHB except that therapy should be initiated when HBV DNA levels exceed 2000 IU/mL (kIU/L).[20]

The primary treatment endpoint is to suppress HBV replication to achieve undetectable serum levels. The ideal treatment should induce a biochemical response (normalize ALT levels), histological response (decrease liver inflammation documented by liver biopsy scores), and serological conversion (loss of HBeAg and HBsAg and detectable antiHBe).[20]

LO 6

KEY CONCEPT The drug of choice for CHB depends on the patient's past medical history, ALT, HBV DNA level, HBeAg status, severity of liver disease, and history of previous HBV therapy. There were eight approved HBV agents: two formulations of interferon (IFN) alfa and six nucleoside/nucleotide analogs. Telbivudine as an oral agent is no longer available in the United States as of December 2016, but it may still be available in other parts of the world.[20,28] All HBV therapies are effective with no agent showing superiority to others in reducing the risk of developing HBV complications.[20]

Entecavir, tenofovir, and pegylated (peg) IFN-α_{2a} are recommended first-line therapies due to profound HBV DNA suppression; the latter agent should be considered in patients with compensated liver disease because of its finite treatment duration and lack of drug resistance.[20]

Adefovir, lamivudine, and telbivudine are not recommended due to high rates of resistance.[20,21] Patients who are responding should continue therapy, but adding or switching to a more potent HBV agent should be considered if there is inadequate virologic response or drug resistance develops.

For all oral HBV agents, patients should be monitored for lactic acidosis and severe hepatomegaly because some cases have been fatal. Hepatic function tests should be monitored if treatment is to be discontinued, because severe acute hepatitis exacerbations have been reported. Dosage adjustments are required in patients with renal dysfunction for all oral HBV regimens. With all oral HBV agents, HIV resistance may develop if given as monotherapy; therefore, test for HIV prior to starting a single anti-HBV agent. Patients coinfected with HIV and HBV should receive concomitant highly active antiretroviral therapy (HAART) with an HBV agent. Each HBV agent is described briefly in the sections that follow.

▶ *Interferon and Pegylated Interferon*

IFN-α_{2b} and pegIFN-α_{2a} are the only IFN therapies approved for HBV. PegIFN is IFN attached to a polyethylene glycol molecule that increases the drug's half-life, thereby allowing once-weekly dosing rather than thrice-weekly administration of unmodified IFN. IFN is effective in suppressing, and in some cases ceasing, viral replication without inducing resistance.[20]

Approximately one-third of HBeAg-positive patients achieve HBeAg seroconversion after 48 weeks of pegIFN therapy.[28] HBeAg-negative hepatitis B may require more than 48 weeks of therapy to attain undetectable HBV DNA levels.[28] Factors associated with a greater chance of HBeAg seroconversion include low baseline HBV DNA concentrations and high pretreatment ALT levels.[30]

PegIFN-α_{2a} (Pegasys) 180 mcg subcutaneously once weekly for 48 weeks is well tolerated and recommended for compensated CHB.[20,29,30] The same dose is recommended for HBeAg-negative CHB; however, the treatment duration may exceed 48 weeks to increase sustained virological response rates.[20,30]

Although pegIFN has lack of resistance and possible HBsAg loss or seroconversion (development of anti-HBs), its disadvantages include the need for subcutaneous injections and a pronounced adverse-effect profile that may require dosage reductions or treatment discontinuation (see Table 24–7). PegIFN is contraindicated with telbivudine due to potential neuropathy.[29]

▶ *Entecavir*

Entecavir (Baraclude) is a guanosine nucleoside analog approved for patients over 2 years of age with either HBeAg-positive

Table 24–7

Adverse Effects of Pegylated Interferon and Ribavirin

Adverse Effect	Therapeutic Intervention
Pegylated interferon	
Flu-like symptoms (eg, fevers, chills, rigors, myalgias)	Premedicate with acetaminophen or nonsteroidal anti-inflammatory drugs. Administer at bedtime.
Psychiatric abnormalities (eg, irritability, depression, and rarely, suicidal, or homicidal ideations)	Seek mental health specialist, antidepressants, anxiolytics. If symptoms are severe, discontinue treatment.
Neutropenia	Obtain a complete blood count with differential and monitor ANC. If less than 1.0×10^9/L, consider reducing dose.
Thrombocytopenia	Obtain a complete blood count and monitor platelet count. Consider reducing dose if platelet count is significantly low.
Elevated ALTs	Obtain LFTs and monitor. Only use pegylated interferon in patients with compensated liver disease.
Ribavirin	
Dermatological (rash, itching, dry skin)	Recommend creams, lotions, oral antihistamines
Hemolytic anemia	Monitor hemoglobin, shortness of breath, chest pain. Reduce dose if hemoglobin less than 10 g/dL (100 g/L; 6.21 mmol/L) or significant symptoms

or HBeAg-negative CHB.[20] Resistance rates are low (1%–2%) in lamivudine-naive patients treated with entecavir for up to 5 years.[29,30] For patients previously treated with lamivudine and switched to entecavir, the resistance rate is approximately 28% at 1 year and up to 51% at 5 years.[31]

The dose of entecavir is 0.5 mg orally once daily for patients 16 years or older with compensated liver disease and naïve to lamivudine therapy. Entecavir 1 mg once daily is recommended for lamivudine or telbivudine resistance or decompensated liver disease. Entecavir should be given on an empty stomach (at least 2 hours before or after a meal). The side-effect profile of entecavir is similar to lamivudine and adefovir dipivoxil.

▶ *Tenofovir Disoproxil Fumarate and Tenofovir Alafenamide*

Tenofovir disoproxil fumarate (TDF; Viread) is an acyclic adenine nucleotide reverse transcriptase inhibitor similar in structure to adefovir dipivoxil that inhibits HIV and HBV replication. It is indicated for HBV patients older than 12 years of age with either HBeAg-positive or HBeAg-negative CHB and/or HIV when prescribed with other HAART therapies.

TDF 300 mg orally once daily (taken on an empty stomach) has high efficacy with almost no development of resistance and is generally well tolerated. However, rare but significant adverse effects include nephrotoxicity and Fanconi syndrome, decreased bone mineral density, and osteomalacia.[20,29,32] TDF is a prodrug that is converted to tenofovir in the plasma and is then phosphorylated to tenofovir diphosphate. High concentrations of the diphosphate compound in cells increase risk of kidney and bone toxicity. Creatinine clearance (CrCl), serum phosphate, liver function tests, and bone mineral density should be monitored prior to initiating treatment and during therapy. The TDF dose must be reduced with CrCl less than 50 mL/min (0.84 mL/s).

Tenofovir alafenamide (TAF; Vemlidy) was subsequently approved for compensated CHB. The recommended TAF dose is 25 mg orally once daily taken with food. TAF offers antiviral activity similar to TDF but with a safer side-effect profile. TAF delivers the prodrug tenofovir directly to hepatic cells intracellularly, resulting in lower concentrations in the kidneys and bone.[32] TAF may be administered at full doses until the CrCl is less than 15 mL/min (0.25 mL/s).

▶ *Adefovir Dipivoxil*

Adefovir dipivoxil (Hepsera) is a prodrug of adefovir, an adenosine nucleotide analog that inhibits DNA polymerase; it is indicated for CHB in patients older than 12 years. Resistance to adefovir is minimal for the first few years of treatment but increases to approximately 30% after 5 years of therapy.[29]

The dose of adefovir is 10 mg orally once daily taken with or without food. The most common side effects include asthenia, abdominal pain, diarrhea, dyspepsia, headaches, nausea, and flatulence. Adefovir is associated with nephrotoxicity at higher doses (30 mg/day). Renal function should be monitored during treatment in all patients, especially those with preexisting or risk factors for renal impairment.

▶ *Lamivudine*

Lamivudine (Epivir-HBV) is an oral synthetic cytosine nucleoside analog with antiviral effects against HIV and HBV. Lamivudine is effective in suppressing HBV replication, normalizing ALT levels, and improving liver histology. Patients may have a similar or a superior response in achieving these endpoints when compared with pegIFN. Prolonged lamivudine therapy (up to 5 years) may be needed to sustain seroconversion, but this leads to lamivudine resistance rates as high as 70% at 5 years.[29] Due to the high rate of resistance, lamivudine is no longer recommended as first-line therapy for CHB.[20,29]

The adult dose of lamivudine is 100 mg orally once daily for CHB without HIV coinfection. Lamivudine 3 mg/kg once daily up to a maximum dose of 100 mg is approved for pediatric patients (2–17 years of age). It may be taken with or without food. Adverse effects are minimal and include fatigue, diarrhea, nausea, vomiting, and headaches. ALT levels should be monitored during therapy because a two- to threefold increase may be observed; levels should also be monitored when therapy is discontinued because increased levels may indicate a disease flare leading to liver failure.

▶ *Telbivudine*

Telbivudine (Tyzeka) is an L-nucleoside analog that inhibits HBV replication. It was commercially available in the United States until December 2016 for patients 16 years or older with HBeAg-positive or HBeAg-negative CHB. Telbivudine offers a slightly more effective reduction in HBV DNA levels and normalization of aminotransferases than lamivudine. Telbivudine resistance is lower than lamivudine, but rates are significant with continued treatment. Also, there is a higher rate of telbivudine treatment failure in patients who have lamivudine resistance.[23] Telbivudine is not highly recommended but may be considered if adefovir or tenofovir resistance is present.

Where commercially available in the world, the dose of telbivudine is 600 mg orally once daily with or without food. Adverse effects are similar to other HBV oral agents. Patients should also be monitored for myopathy characterized by elevated creatine kinase levels and muscle weakness.[20] Peripheral neuropathy has also occurred when used together with pegIFN, so the combination is contraindicated.[20,29] Elevated LFTs occur at rates similar to lamivudine.

Hepatitis C Prevention

Avoiding high-risk behaviors such as sharing needles among IV drug users is the primary means of avoiding infection with the HCV. The risk of acquiring HCV through a blood transfusion is 1 in 2 million since 1992, when widespread screening of blood products and universal precautions took effect. More than 75% of individual infected with the HCV were born during the "baby boomer" generation. Although the reasons for these high infection rates are not completely understood, HCV had not yet been identified and there was no method for detecting it in blood products. The CDC recommends that everyone born between 1945 and 1965 be tested at least once in their lifetime for HCV. There are currently no vaccines to prevent HCV, but several are under development.[33] Therefore, high-risk individuals (Table 24–1) should be tested for HCV because most people are asymptomatic and unaware they are infected.[5]

LO 6 Chronic Hepatitis C Treatment

Treatment for HCV has been revolutionized over the past decade, with efficacy rates above 90% compared to 50% to 80% before 2011. The primary goal of HCV treatment is to achieve an SVR, also known as a "virological cure," defined as undetectable HCV RNA levels at 12 weeks or longer after treatment completion.

Patient Encounter Part 2: Creating a Care Plan

Based on the information presented, create a care plan for this patient's hepatitis. Your plan should include:

(a) a statement of the drug-related needs and/or problems;

(b) the goals of therapy;

(c) a patient-specific detailed therapeutic plan;

(d) a follow-up plan to determine whether the goals have been achieved; and

(e) a follow-up plan to identify potential adverse effects of therapy.

Normalization of liver function tests and improvement of histology are additional treatment outcomes, but the primary goal is to prevent progression and development of cirrhosis, HCC, and ESLD.[8] Patients who achieve SVR do not cure the existing liver disease; those with advanced disease and cirrhosis continue to have liver disease progression; thus, cirrhotic surveillance must be performed (eg, ultrasound to evaluate for HCC). Initiating HCV treatment early before development of advanced liver disease may minimize the risk of developing cirrhosis and the complications associated with ESLD.

KEY CONCEPT Treatment for chronic hepatitis C depends on the patient's past medical history, previous HCV treatment history, severity of liver disease, and HCV genotype.[8]

▶ *Interferon/Pegylated Interferon and Ribavirin*

IFN and pegIFN are no longer recommended for chronic HCV because SVR rates are suboptimal, only 10% to 40% with genotype 1 and 30% with genotype 2 or 3. PegIFN-α_{2a} (Pegasys) and pegIFN-α_{2b} (PEG-Intron) have extended half-lives allowing for once-weekly administration compared to thrice-weekly with unpegylated IFN. The SVR rates with pegIFN can be increased to 50% to 80% by adding ribavirin, a synthetic guanosine analog that inhibits viral polymerase. From 2002 to 2011, pegIFN plus ribavirin was considered standard-of-care for HCV.[8]
