Linezolid	Myelosuppression: Monitor CBC once weekly. MAO inhibitors; evaluate for potential drug–drug interactions. Linezolid should not be used concomitantly or within 2 weeks of medications that inhibit monoamine oxidases A or B. Serotonin syndrome; evaluate for potential drug–drug and drug–food interactions. Patients taking serotonergic antidepressants should receive linezolid only if no other therapies are available. Discontinue serotonergic antidepressants and monitor patients for signs and symptoms of both serotonin syndrome and antidepressant discontinuation. Peripheral and/or optic neuropathy has been reported with long-term therapy; perform routine neurologic and ophthalmic evaluations in these patients. Elevation of blood pressure in certain patients (eg, uncontrolled hypertension): monitor blood pressure. Hypoglycemia in patients with diabetes mellitus receiving insulin or oral hypoglycemic agents: monitor glucose.
Vancomycin	Targeted steady state trough is 15–20 mcg/mL (15–20 mg/L; 10–14 µmol/L) for serious infections such as osteomyelitis. Renal dysfunction: monitor weekly renal function (BUN/SCr) and troughs in stable patients; more often in nonstable patients. Potential for additive renal toxicity if being coadministered with a nephrotoxic agent (eg, aminoglycoside, piperacillin-tazobactam).

BUN, blood urea nitrogen; CBC, complete blood count; CPK, creatine phosphokinase; MAO, monoamine oxidase; SCr, serum creatinine.

Data from Refs. 1, 7, 11, 19, and 21–26.

Patient Encounter Part 4

Culture from the bone aspirate grows *S. aureus* (sensitive to daptomycin, linezolid, rifampin, trimethoprim-sulfamethoxazole, and vancomycin but resistant to clindamycin, erythromycin, and oxacillin). The patient received 2 weeks of empiric IV antimicrobial therapy following debridement. The patient has shown clinical and laboratory improvement. The multidisciplinary medical team plans to complete therapy with an oral antibiotic(s).

What oral antimicrobial therapy would you recommend for this patient?

Evaluate the patient's medication profile for drug–drug interactions.

Counsel the patient regarding this drug therapy.

Patient Care Process

Collect Information:

- Review the medical history for osteomyelitis risk factors.
- Based on physical examination and review of systems, determine whether the patient is experiencing signs or symptoms of osteomyelitis.
- Review available imaging studies and laboratory tests, especially WBC, ESR, and CRP.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.

Assess the Information:

- Review culture data for antimicrobial drug selection and stewardship.
- Evaluate drug allergies or intolerance, as well as drug–drug interactions that would impact antimicrobial selection.
- Assess available imaging studies and laboratory data to differentiate acute versus chronic disease.

Develop a Care Plan:

- Select an appropriate antimicrobial regimen, including drug, dose, and duration, given patient-specific information.
- Identify criteria for possible de-escalation to oral therapy during treatment course.
- Establish monitoring parameters based on the antimicrobial regimen selected.

Implement the Care Plan:

- Provide patient education with regard to disease state and drug therapy. Stress the importance of adherence to the therapeutic regimen.

Follow-up: Monitor and Evaluate:

- Determine whether the antibiotic dosage regimen is optimal based on patient-specific factors and site of infection.
- Patients should be monitored for clinical and laboratory response, development of adverse drug reactions, and potential drug–drug interactions. Patients should also be closely monitored for adherence in the outpatient setting.

all laboratory tests have returned to normal following 4 to 8 weeks of appropriate treatment. Due to high rates of relapse, patients should have medical follow-up for at least 1 year following resolution of symptoms.[4] Patients should be evaluated at predefined follow-up intervals (3- to 6- to 12-months) for any clinical manifestations of recurring infection and continued normalization of laboratory tests.[8,11] Follow-up imaging studies at 1 to 2 years may be useful in some patients to confirm therapeutic success.

Abbreviations Introduced in This Chapter

ALT	Alanine aminotransferase
AST	Aspartate aminotransferase
BUN	Blood urea nitrogen
CBC	Complete blood count
CRP	C-reactive protein
CPK	Creatine phosphokinase
CT	Computed tomography
ESR	Erythrocyte sedimentation rate
IDSA	Infectious Diseases Society of America
IV	Intravenous
MAO	Monoamine oxidase
MRI	Magnetic resonance imaging
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-sensitive *Staphylococcus aureus*
Scr	Serum creatinine
WBC	White blood cell

82 Sepsis and Septic Shock

Trisha N. Branan, Susan E. Smith, Christopher M. Bland, and S. Scott Sutton

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Compare and contrast the definitions of syndromes related to sepsis.
2. Identify the pathogens associated with sepsis.
3. Discuss the pathophysiology of sepsis as it relates to pro- and anti-inflammatory mediators.
4. Identify patient symptoms as early or late sepsis and evaluate diagnostic and laboratory tests for patient treatment and monitoring.
5. Assess complications of sepsis and discuss their impact on patient outcomes.
6. Design desired treatment outcomes for septic patients.
7. Formulate a treatment and monitoring plan (pharmacologic and nonpharmacologic) for septic patients.
8. Evaluate patient response and devise alternative treatment regimens for nonresponding septic patients.

INTRODUCTION

KEY CONCEPT Sepsis occurs across a continuum of physiologic stages in response to infection which manifests as systemic inflammation, coagulation, and tissue hypoperfusion, potentially leading to organ dysfunction.[1] The Third International Consensus Definitions for Sepsis and Septic Shock were published in 2016 and included updated nomenclature to standardize sepsis terminology. Previous definitions focused largely on inflammatory changes that may not necessarily be associated with organ dysfunction. Currently, sepsis is defined as life-threatening organ dysfunction caused by a dysregulated host response represented by an increase of at least 2 points in the Sequential [Sepsis-related] Organ Failure Assessment (SOFA) (Table 82–1). Septic shock is defined as a subset of patients with further increases in mortality resulting from underlying circulatory, cellular, and/or metabolic abnormalities. These patients require the use of vasopressor support in addition to adequate volume resuscitation to maintain a mean arterial pressure of at least 65 mm Hg and have an elevated serum lactate level greater than 2 mmol/L. Adult patients with suspected sepsis may be screened using a bedside clinical scoring system known as the quickSOFA (qSOFA) to rapidly identify patients who may need further diagnostic workup and intervention (Table 82–2).[2,3]

LO 1

EPIDEMIOLOGY AND ETIOLOGY

Sepsis is the leading cause of morbidity and mortality for critically ill patients and the tenth leading cause of death overall.[4,5] Mortality rates remain high for patients with sepsis and septic shock with septic shock and multiorgan failure as the most common causes of death.[1] There are approximately 750,000 cases of sepsis diagnosed every year in the United States which continues to increase.[1]

Risk factors for developing sepsis include increased age, cancer, immunodeficiency, chronic organ failure, genetic factors (male gender and nonwhite ethnic origin in North America), and the presence of bacteremia.[5–9] Pulmonary infections cause approximately half of all sepsis cases, followed by intraabdominal and genitourinary infections.[2] In approximately one-third of sepsis cases, a pathogen is not identified making de-escalation from broad spectrum to a more narrowed antimicrobial regimen difficult.[2]

KEY CONCEPT Gram-positive and gram-negative bacteria, fungal species, and viruses may cause sepsis (Table 82–3). Gram-positive infections account for 30% to 50% of sepsis and septic shock cases.[5–7] The percentages of gram-negative, polymicrobial, and viral sepsis cases are 25%, 25%, and 4%, respectively.[5–7,10] A multinational study of 14,000 critically ill patients showed an increase in gram-negative bacterial causes of sepsis compared to gram-positive bacterial and fungal causes.[2] Multidrug-resistant (MDR) bacteria are responsible for approximately 25% of sepsis cases, are difficult to treat due to fewer antimicrobial options, and increase mortality.[6,7] The rate of fungal infections has significantly increased with *Candida albicans* as the most common fungal species identified; however, nonalbicans species (*C. glabrata, C. krusei,* and *C. tropicalis*) have increased from 24% to 46%.[5,10,11] Other fungi identified as causes of sepsis include species of *Cryptococcus, Coccidioides, Fusarium*, and *Aspergillus*.

LO 2

PATHOPHYSIOLOGY

The development of sepsis is complex and multifactorial. The normal host response to infection is designed to localize and control microbial invasion and initiate repair of injured tissue through phagocytic cells and inflammatory mediators.[4] KEY CONCEPT Sepsis results when the interplay between the host's immune, inflammatory, and coagulant responses becomes exaggerated, extending to normal tissue distant from the initial tissue site.

Table 82–1

The SOFA Score

SOFA Score	1	2	3	4
Respiration				
PaO_2/FiO_2, mm Hg	< 400	< 300	< 200 ——with respiratory support——	< 100
Coagulation				
Platelets x $10^3/mm^3$	< 150	< 100	< 50	< 20
Liver				
Bilirubin, mg/dL (μmol/L)	1.2–1.9 (20–32)	2.0–5.9 (33–101)	6.0–11.9 (102–204)	≥ 12.0 (> 204)
Cardiovascular				
Hypotension	MAP < 70 mm Hg	Dopamine ≤ 5 or dobutamine (any dose)[a]	Dopamine > 5.1–15 or epinephrine ≤ 0.1 or norepinephrine ≤ 0.1	Dopamine > 15 or epinephrine > 0.1 or norepinephrine > 0.1
Central nervous system				
Glasgow Coma Score	13–14	10–12	6–9	< 6
Renal				
Creatinine, mg/dL (μmol/L) or urine output	1.2–1.9 (110–170)	2.0–3.4 (171–299)	3.5–4.9 (300–400) or < 500 mL/day	≥ 5.0 (> 440) or < 200 mL/day

[a]Adrenergic agents administered for at least 1 h (doses given are in μg/kg/min).

Pro- and Anti-inflammatory Mediators

LO 3

The key factor in the development of sepsis is inflammation, which is intended to be a local and contained response to infection or injury. Infection or injury is controlled through proinflammatory and anti-inflammatory mediators. Proinflammatory mediators facilitate clearance of the injuring stimulus, promote resolution of injury, and are involved in processing of damaged tissue.[4,14–17] To control the intensity and duration of the inflammatory response, anti-inflammatory mediators are released that act to regulate proinflammatory mediators.[16,17] The balance between pro- and anti-inflammatory mediators localizes infection/injury of host tissue.[14–17] However, systemic responses ensue when equilibrium in the inflammatory process is lost.

The inflammatory process in sepsis is linked to the coagulation system. Proinflammatory mediators may have procoagulant and antifibrinolytic effects, whereas anti-inflammatory mediators may have **fibrinolytic** effects. A key factor in the inflammation of sepsis is activated protein C, which enhances fibrinolysis and inhibits inflammation. Protein C levels are decreased in many septic patients.

CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of sepsis varies, and the rate of development of clinical manifestations may differ from patient to patient.

Table 82–2

Quick SOFA (qSOFA) Criteria

- Respiratory rate ≥ 22 breaths/min
- Altered mentation
- Systolic blood pressure ≤ 100 mm Hg

Positive qSOFA score indicated by meeting ≥ 2 criteria

A physical examination should be performed rapidly and efficiently when sepsis is suspected, with efforts directed toward uncovering the most likely cause of sepsis. The patient may not provide any medical history; therefore, historical data may

Table 82–3

Pathogens in Sepsis

Organism	Frequency (%)
Gram-positive bacteria	30–50
Methicillin-susceptible *Staphylococcus aureus*	14–24
Methicillin-resistant *Staphylococcus aureus*	5–11
Other *Staphylococcus* species	1–3
Streptococcus pneumoniae	9–12
Other *Streptococcus* species	6–11
Enterococcus species	3–13
Anaerobes	1–2
Other gram-positive bacteria	1–5
Gram-negative bacteria	25–30
Escherichia coli	9–27
Pseudomonas aeruginosa	8–15
Klebsiella pneumoniae	2–7
Enterobacter species	6–16
Haemophilus influenzae	2–10
Anaerobes	3–7
Other gram-negative bacteria	3–12
Fungi	
Candida albicans	1–3
Other *Candida* species	1–2
Parasites	1–3
Viruses	2–4

Data from Refs. 5, 12, and 13.

Possible Physical Examination Results in Sepsis

HEENT: Scleral icterus, dry mucous membranes, pinpoint pupils, dilated and fixed pupils, nystagmus

Neck: Jugular venous distention, carotid bruits

Lungs: Crackles (rales), consolidation, egophony, absent breath sounds

CV: Irregular rhythm, S_3 gallop, murmurs

Abd: Tense, distended, tender, rebound, guarding, hepatosplenomegaly

Rectal: Decreased tone, bright red blood

Exts: Swollen calf, disparity of blood pressure between upper extremities

Neurologic: Agitation, confusion, delirium, obtundation, coma

Skin: Cold, clammy, or warm; hyperemic skin; rashes

be obtained from medical records and/or family. The patient's medical condition, recent illnesses, infections, or activities may provide valuable information about the cause of sepsis.

Diagnostic and Laboratory Tests

LO 4

Microbiologic cultures should be obtained before antimicrobial therapy is initiated as long as this does not significantly delay the start of therapy. However, cultures take 6 to 72 hours for results to be completed and often are negative (no growth of bacterial organisms). Negative cultures do not rule out the presence of infection. Administering antimicrobials before obtaining cultures may lead to a false-negative culture. Rapid diagnostics of blood cultures allows for identification of specific pathogens within as little as 20 minutes to 3 hours after initial growth is identified. However, not all health care systems have this technology available.

At least two sets of blood cultures should be obtained to rule out contamination, with at least one set drawn percutaneously and one set drawn through each vascular access device present for greater than 48 hours.

Cultures of urine (with urinalysis), respiratory secretions, cerebrospinal fluid, and wounds should be obtained if the clinical presentation suggests infection of these specific fluids, tissues, or organs. Laboratory tests should be performed to evaluate infection or complications of sepsis, including complete blood count (CBC) with differential, coagulation parameters, comprehensive metabolic panel (CMP), serum lactate concentration, arterial blood gas (ABG), and appropriate diagnostic radiographic imaging studies.

The use of biomarkers of sepsis, such as endotoxin and procalcitonin, has been controversial. Measurement of endotoxin, procalcitonin, or other markers in blood or serum is not routinely recommended. Concentrations of procalcitonin in serum are usually increased in sepsis, but fail to differentiate between infection and inflammation. However, procalcitonin has a high negative predictive value and may allow for the discontinuation of antibiotics. It is important to note that the measurement of any biomarker, including procalcitonin, should be used in conjunction with the patient's overall clinical assessment and should never be used as the sole indicator for altering microbial therapy.

Complications of Sepsis

KEY CONCEPT Recognition and treatment of sepsis complications, particularly organ failure, is essential to improve outcomes. The cumulative burden of sepsis complications is the leading factor

Clinical Presentation and Diagnosis of Sepsis

LO 4

The signs and symptoms of septic patients are referred to as early and late sepsis.

Signs and Symptoms

The initial clinical signs and symptoms represent early sepsis, and they include fever, chills, and change in mental status. Other signs and symptoms include:

- Tachycardia
- Tachypnea
- Nausea and vomiting
- Hyperglycemia
- Myalgias
- Lethargy and malaise
- Proteinuria
- Leukocytosis
- Hypoxia
- Hyperbilirubinemia

Septic patients may have an elevated, low, or normal temperature. The absence of fever is common in neonates and elderly patients. Hypothermia is associated with a poor prognosis. Hyperventilation may occur before fever and chills and may lead to respiratory alkalosis. Disorientation and confusion may develop early in septic patients, particularly in the elderly and patients with preexisting neurologic impairment. Disorientation and confusion may be related to the infection or due to sepsis signs and symptoms (eg, hypoxia).

Late sepsis represents a slow process that develops over several hours of hypoperfusion. Signs and symptoms of late sepsis include:

- Lactic acidosis
- Oliguria
- Leukopenia
- Thrombocytopenia
- Myocardial depression
- Pulmonary edema
- Hypotension
- Hypoglycemia
- Gastrointestinal hemorrhage

Oliguria often follows hypotension because of decreased renal perfusion. Metabolic acidosis ensues because of diminished clearance of lactate by the kidneys and liver.

Patient Encounter Part 1

A 64-year-old woman with history of hypertension, diabetes, and end-stage renal disease presents to the emergency department with complaints of fever and chills during hemodialysis. The patient is becoming increasingly lethargic and is unable to answer simple questions, such as her name and the year.

What information is suggestive of infection and/or sepsis?

What information do we need in order to confirm or diagnose sepsis in this patient?

of mortality. The risk of death increases 20% with failure of each additional organ. The most common complications are respiratory and cardiovascular compromise, usually seen as **acute respiratory distress syndrome** (ARDS), hemodynamic compromise, and elevated serum lactate levels. Other complications include altered mentation, acute kidney injury (AKI) which may require renal replacement therapy, paralytic ileus, **disseminated intravascular coagulation** (DIC), and adrenal insufficiency.[2]

LO 5

TREATMENT AND OUTCOME EVALUATION

Desired Outcomes

KEY CONCEPT The primary treatment goal of sepsis is to prevent morbidity and mortality through rapid recognition and intervention. Treatment is aimed at early implementation of therapies, such as fluid resuscitation and antimicrobials, reducing or eliminating organ dysfunction, eliminating the source of infection, avoiding adverse reactions of treatment, and providing cost-effective therapy.[18–24]

LO 6

General Approach to Treatment

Similar to the emphasis placed on the expedited treatment of patients with acute myocardial infarction and cerebrovascular accidents, rapid intervention with appropriate therapies, once a diagnosis of sepsis has been made, is crucial to decrease morbidity and mortality.[18,20]

LO 7

Pertinent approaches in the management of septic patients are as follows (**Figure 82–1**)[24]:

1. Prompt recognition of the septic patient and early implementation of therapies.
2. Fluid therapy, using crystalloids initially, to restore intravascular volume depletion.
3. Early administration of broad-spectrum antimicrobial therapy.
4. Vasopressor therapy, using norepinephrine initially, to maintain hemodynamic stability (on average a mean arterial pressure of 65 mm Hg [8.6 kPa]) in patients with septic shock refractory to fluid resuscitation.
5. Intravenous (IV) hydrocortisone may be considered for patients who remain hemodynamically unstable despite adequate fluid resuscitation and vasopressor support.
6. Glycemic control via infusion of regular insulin to maintain glucose levels between 140 and 180 mg/dL (7.8 and 10.0 mmol/L).
7. Adjunctive therapies: blood product administration, sedation, analgesia, neuromuscular blockade, renal replacement therapy, deep vein thrombosis (DVT) prophylaxis, stress ulcer prophylaxis, and nutrition.

Treatment for sepsis focuses on infection, inflammation, hypoperfusion, and widespread tissue injury. Septic patients may require multiple simultaneous treatment regimens to achieve desired outcomes of decreased morbidity and mortality.

Initial Resuscitation

A landmark study of early goal directed therapy (EGDT) using a standardized protocol that required the use of a special catheter for central venous oxygen saturation monitoring decreased 28-day mortality in septic patients by approximately 16%.[23] Three subsequent randomized controlled studies comparing EGDT to groups of patients receiving contemporary care (with or without the use of protocols) found no differences in mortality.[25–27] These results demonstrate that continued focus on early recognition and treatment of these patients may play a more important role than protocol-based therapy; however, the use of EGDT was not associated with harm.

Upon recognition of sepsis, resuscitation should begin immediately. Within the first 3 hours, at least 30 mL/kg of crystalloid fluid should be administered intravenously. Subsequent fluid administration should be guided by frequent reassessment of hemodynamic status and dynamic variables to predict fluid responsiveness. The use of static variables, such as central venous pressure (CVP), to assess the need for additional fluid administration should not be used alone. Rather, these variables in conjunction with other dynamic measures, such as the passive leg raise technique, fluid challenges, and pulse pressure variation, may be better predictors of fluid responsiveness.[20,23,24,28]

Emerging noninvasive techniques, such as the use of cardiac ultrasound, have recently shown reliability in assessing intravascular volume status through measuring inferior vena cava diameter changes and collapsibility.[29,30] Resuscitation should also target the normalization of blood lactate levels in patients with an initially elevated blood lactate as a marker of improved tissue perfusion.[20]

Fluid Therapy

Crystalloid fluids (such as 0.9% sodium chloride or lactated Ringer solutions) or colloids (albumin products) are used for resuscitation, and clinical studies comparing the fluids have found them to be equivalent.[28,31,32] Crystalloids require more fluid volume, which may lead to more edema (utilize caution in patients at risk for fluid overload, eg, congestive heart failure, renal failure, and ARDS); however, albumin is significantly more expensive. Hydroxyethyl starch (HES), another type of colloid, should not be used due to studies demonstrating increased morbidity and mortality.[33,34] A large, multicenter, randomized controlled trial comparing HES to Ringer's acetate in patients with severe sepsis showed an increased 90-day mortality rate and a higher need for renal replacement therapy in patients administered HES for fluid resuscitation.[33] For these reasons, crystalloids are preferred versus colloids for initial resuscitation, except in cases where large amounts of crystalloids are needed and hypervolemia may be harmful to the patient.[20]

After initial fluid administration, there remains clinical controversy surrounding the appropriate type of fluid for continued resuscitation. There are emerging data which suggest potential benefit of using balanced crystalloid solutions or a chloride-restrictive strategy. There are low-quality data that suggest the administration of large volumes of isotonic saline may be associated with increased incidences of AKI and renal replacement therapy secondary to hyperchloremic metabolic acidosis.[35,36]

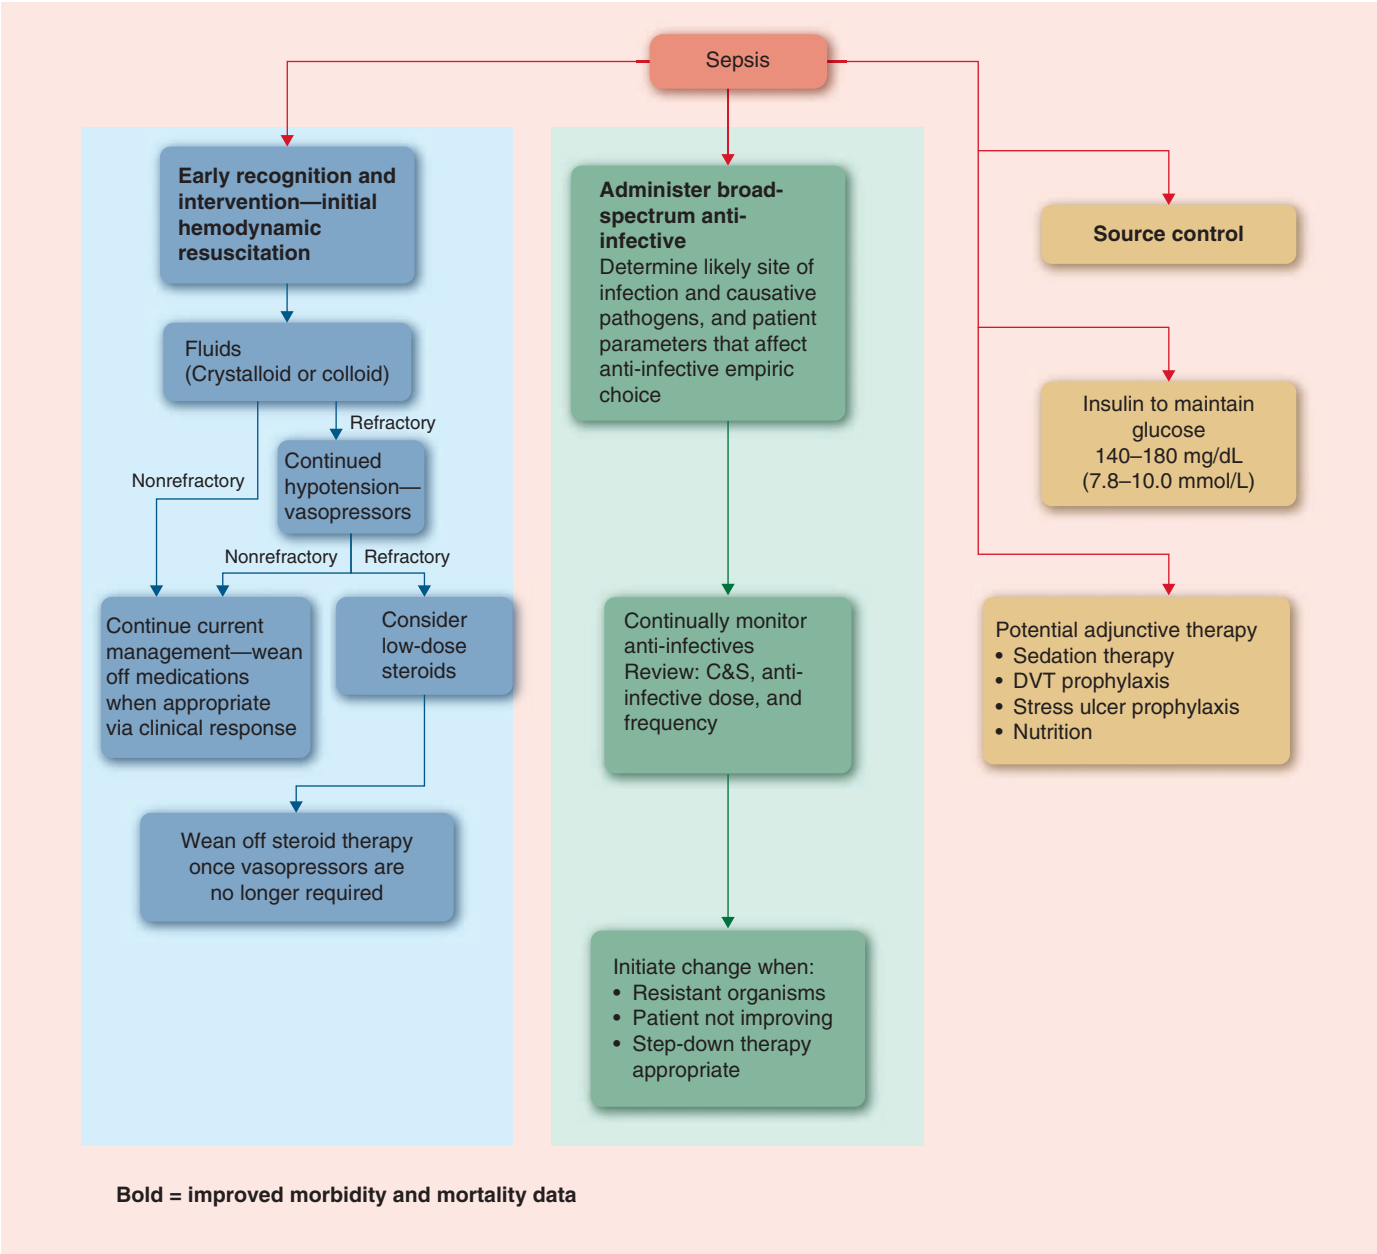

FIGURE 82–1. Therapeutic approach to sepsis. (C&S, cultures and susceptibilities.)

Anti-infective Therapy

KEY CONCEPT Appropriate empiric antimicrobial therapy decreases 28-day mortality compared with inappropriate empiric therapy (24% vs 39%).[18,19,37] Additionally, appropriate therapy administered within 1 hour of sepsis recognition also decreases complications and mortality.[18,19,37] Empiric antimicrobial therapy should include multiple agents for most cases, depending on the likely site of infection and causative pathogens. Anti-infective clinical trials in sepsis and septic shock patients are scarce and have not demonstrated differences among agents; therefore, factors that determine selection are:

- Site/source of infection.
- Causative pathogens.
- Community- or nosocomial-acquired infection.
- Immune status of patient.
- Antibiotic susceptibility and resistance profile for the institution and local community. Clinicians should be cognizant of growing prevalence of bacterial resistance in community and health care settings.
- Patient history (underlying disease, previous cultures or infections including any recent antibiotic therapy, and drug allergy/intolerance).
- Adverse reactions.
- Cost.

Anti-infective regimens should be broad-spectrum since delays in appropriate therapy result in increased mortality. In the subset of patients with septic shock, empiric therapy should include combination regimens with multiple antibiotics from different

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Hypertension, poorly controlled type 2 diabetes mellitus, end-stage renal disease on hemodialysis three times weekly

FH: Father died of heart attack at 71; mother has history of hypertension and diabetes mellitus

SH: Postal worker; previous smoker (10 pack-year history, quit at age 40); rare alcohol intake

Allergies: Penicillin (rash as child)

Meds: Lisinopril 20 mg by mouth once daily; insulin glargine 20 units subcutaneously at bedtime; insulin lispro 7 units subcutaneously before each meal and as needed per sliding scale; sevelamer 1600 mg by mouth three times daily with meals; Renal Caps (multivitamin) 1 tablet by mouth once daily

ROS: Unable to obtain; patient has become more confused

PE:

Within normal limits except as noted below

VS: BP 78/46 mm Hg, P 115 beats/min, RR 27 breaths/min, T 35.8°C (96.4°F)

Neurologic: Obtunded, oriented to person only

Skin: Cool, clammy

Labs: Serum creatinine 7.6 mg/dL (671.8 µmol/L); glucose 201 mg/dL (11.2 mmol/L); white blood cells: leukocytosis (18,300/mm^3 [18.3 × 10^9/L]) with left shift; lactic acid 7.2 mEq/L (7.2 mmol/L)

Cultures: Blood and urine cultures pending

Radiology: Chest x-ray unremarkable

According to the patient's parameters, what is her most likely diagnosis (ie, systemic inflammatory response syndrome, sepsis, or septic shock)?

What are the goals of treatment?

Formulate an initial plan for therapy.

mechanistic classes (eg, two anti-pseudomonal antimicrobials in patients with known risk factors to ensure appropriate coverage of multidrug resistant organisms or clindamycin with β-lactam antibiotics for streptococcal toxic shock to decrease toxin production).

Monitoring and Treatment Strategies to Maximize Efficacy and Minimize Toxicity for Antimicrobials

- Administer broad-spectrum antimicrobials for initial therapy as early as possible and within the first hour of recognition of sepsis.
- Appropriate cultures should be obtained before initiating antibiotic therapy, but should not prevent prompt administration.
- Administer antibiotics that concentrate at the site of infection.
- Monitor patient parameters to ensure adequate dosing.
- Abnormal renal and hepatic function will increase drug concentration and predispose the patient to toxicity.
- Ensure antibiotic dosing is changed to normal doses once renal dysfunction has resolved to limit the development of treatment failure, antimicrobial resistance, or both.
- Septic patients may have increased volume of distribution due to initial large volume resuscitation.

Patient Encounter Part 3: Treatment and Outcome Evaluation

The patient has been intubated due to altered mental status and concern for inability to protect her airway. She remains hypotensive despite previous intervention. Her serum creatinine remains elevated at 8.8 mg/dL (777.9 µmol/L) and her serum potassium has risen to 5.9 mEq/L (5.9 mmol/L).

What additional therapies will you consider adding to this patient?

- Reevaluate the initial dosing regimen daily to optimize activity, prevent development of resistance, reduce toxicity, and decrease costs.
- Initiate step-down therapy based on microbiologic cultures to prevent resistance, reduce toxicity, including *Clostridium difficile* infection, and minimize cost.
- Monotherapy is equivalent to combination therapy once a causative pathogen has been identified in the vast majority of cases.

Duration of Anti-infective Therapy

Average duration of antimicrobial therapy for septic patients is 7 to 10 days. However, durations vary depending on the site of infection and response to therapy. Step-down therapy from IV to oral antimicrobials is recommended in certain targeted patients who are hemodynamically stable, afebrile for 48 to 72 hours, have a normalized WBC, have an organism susceptible to oral therapies, and are able to take oral medications.

Source Control

Evaluate septic patients for the presence of a localized infection amenable to **source control** measures. Common source control measures include drainage and debridement, device removal, and prevention.[20-22] Implementation of source control methods should be instituted as soon as possible following initial fluid resuscitation. The selection of optimal source control methods must weigh benefits and risks of the intervention. Source control measures may cause complications (bleeding, fistulas, and organ injury); therefore, the method with the least risk should be employed.[20]

HEMODYNAMIC SUPPORT

Vasopressors and Inotropic Therapy

LO 8

KEY CONCEPT When fluid resuscitation does not provide adequate arterial pressure and organ perfusion, vasopressors and/or inotropic agents should be initiated. Vasopressors are recommended in patients with a systolic blood pressure less than 90 mm Hg or MAP lower than 60 to 65 mm Hg (8.0–8.6 kPa), after failed treatment with crystalloids.[20,23,24] Vasopressors and

inotropes are effective in treating life-threatening hypotension and improving cardiac index, but complications such as tachycardia and myocardial ischemia require slow titration of the adrenergic agents to restore MAP without impairing stroke volume. Vasopressor therapy may also be required transiently to sustain life and maintain perfusion in the face of life-threatening hypotension, even when fluid resuscitation is in progress and hypovolemia has not yet been corrected. Agents commonly considered for vasopressor or inotropic support include norepinephrine, epinephrine, dopamine, phenylephrine, vasopressin, and dobutamine. Norepinephrine is the first-line vasopressor to correct hypotension in septic shock.[20]

Norepinephrine is a potent α-adrenergic agent with less pronounced β-adrenergic activity. Doses of 0.01 to 3 mcg/kg/min can reliably increase blood pressure through vasoconstriction with small changes in heart rate or cardiac index. Norepinephrine is a more potent agent than dopamine in refractory septic shock.[20,23,24] Norepinephrine induces less arrhythmias compared with dopamine.[38]

Dopamine is an α- and β-adrenergic agent with dopaminergic activity. Low doses of dopamine (1–5 mcg/kg/min) maintain renal perfusion; higher doses (> 5 mcg/kg/min) exhibit α- and β-adrenergic activity and are frequently utilized to support blood pressure and to improve cardiac function, mainly through increasing stroke volume and heart rate. Because of the effects on heart rate, dopamine causes more tachycardia and thus increases potential for arrhythmias versus norepinephrine. Based on these data, dopamine should not be used routinely in the management of septic shock.[20,38] Low doses of dopamine should not be used for renal protection as part of the treatment of sepsis.[20,23,24]

Epinephrine is a nonspecific α- and β-adrenergic agonist that can increase cardiac index and produce significant peripheral vasoconstriction. Some human and animal studies suggest it can also increase lactate levels and impair blood flow to the splanchnic system; however, studies comparing norepinephrine to epinephrine show no difference in mortality rates. Epinephrine may be added to norepinephrine in patients with persistent hypotension.[20,23,24]

Phenylephrine is a fast-acting, short-acting pure α_1-agonist. Phenylephrine is the least likely vasopressor to cause tachycardia, but may decrease stroke volume. Phenylephrine should be reserved for use in patients with high cardiac output in whom tachycardia or ischemia limits the use of other vasopressors or as salvage therapy.[20,23,24]

Vasopressin levels are increased during hypotension to maintain blood pressure by vasoconstriction. However, there is a vasopressin deficiency in septic shock. Low, fixed doses of vasopressin increase MAP, leading to the discontinuation of vasopressors. However, routine use of vasopressin with norepinephrine is not recommended because of no difference in mortality compared with norepinephrine monotherapy.[39] Vasopressin is a direct vasoconstrictor without inotropic or chronotropic effects and may result in decreased cardiac output and hepatosplanchnic flow. The addition of vasopressin to other vasopressor agents may be considered in patients with refractory shock despite adequate fluid resuscitation and high-dose vasopressors.[20,23,24]

Dobutamine is recommended as the first-line inotropic agent. Dobutamine is a β-adrenergic inotropic agent that can be utilized for improvement of cardiac output and oxygen delivery. Doses of 2 to 20 mcg/kg/min increase cardiac index; however, heart rate increases significantly. Dobutamine should be considered in septic patients with adequate filling pressure and blood pressure, but low cardiac index. If used in hypotensive patients, dobutamine should be combined with vasopressor therapy.[20,23,24]

Patient Encounter Part 4

Three days later, the patient's blood pressure begins to respond to therapy with a MAP remaining greater than 65 mm Hg (8.6 kPa) on minimal vasopressor support.

What changes to the patient's medication regimen do you recommend?

Corticosteroids

LO 8

Stress-induced adrenal insufficiency complicates 9% to 24% of septic patients and is associated with increased mortality. The role of steroid use in septic shock remains unclear. Previous studies have demonstrated a mortality benefit or quicker reversal of shock in patients with sepsis-induced adrenal insufficiency treated with hydrocortisone.[40] However, a large, multicenter, randomized controlled trial (CORTICUS) showed no difference in mortality rates in septic shock patients treated with hydrocortisone.[41] KEY CONCEPT For these reasons, the use of IV hydrocortisone at a dose of 200 mg/day should be reserved for patients who remain hemodynamically unstable despite fluid and vasopressor therapy.[20] Patients should be weaned from steroid therapy when vasopressors are no longer required.

Glucose Control

The optimal blood glucose range in septic patients is unknown. Tight glycemic control (80–110 mg/dL [4.4–6.1 mmol/L]) improved survival in postoperative surgical patients, but did not show a benefit in medical critically ill patients.[42,43] More recent studies, including the large NICE-SUGAR trial, do not demonstrate a mortality benefit in favor of tight glycemic control, but actually a higher incidence of severe hypoglycemia and increased mortality rates.[44] KEY CONCEPT Following initial stabilization of septic patients, current guidelines recommend initiating insulin therapy when two consecutive blood glucose measurements are greater than 180 mg/dL (10.0 mmol/L) and then maintaining a blood glucose of less than or equal to 180 mg/dL (10.0 mmol/L). Blood glucose levels should be monitored frequently, every 1 to 2 hours, until glucose values and insulin infusion rates are stable, then every 4 hours thereafter.[20]

Adjunctive Therapies

▶ *Blood Product Administration*

There are no trials showing the optimal hemoglobin concentration in patients with sepsis. However, based on other studies which included subgroups of septic patients, with the exception of myocardial ischemia, severe hypoxemia, acute hemorrhage, or ischemic coronary artery disease, it is recommended to target a hemoglobin concentration of 7 to 9 g/dL (70–90 g/L; 4.34–5.59 mmol/L) and red blood cell transfusion should occur when the hemoglobin concentration is less than 7 g/dL (70 g/L; 4.34 mmol/L).[20,45] Erythropoietin-stimulating agents, fresh frozen plasma, and antithrombin should not be administered, unless other compelling indications exist, to treat sepsis-induced abnormalities.[20]

▶ *Sedation, Analgesia, and Neuromuscular Blockade*

It is common for sepsis patients to require mechanical ventilation during their course of therapy. These patients may require analgesic or sedative agents to facilitate mechanical ventilation. Historically, concerns for patient safety and posttraumatic stress

disorder emphasized the need for sedation in these patients. However, there continue to be ample data indicating that, while sedation may be necessary, limiting exposure to certain sedative medications, specifically benzodiazepines, may improve morbidity and mortality rates. When sedation is needed, a standardized protocol targeting specific endpoints should be utilized.[20,46]

Neuromuscular blockade usually is reserved for patients in whom sedation alone does not improve the effectiveness of mechanical ventilation. Neuromuscular blockers may lead to prolonged skeletal muscle weakness and should be avoided if possible especially if receiving concomitant corticosteroid therapy, which can increase the risk of critical illness polyneuropathy. Patients requiring neuromuscular blockade should be monitored, and intermittent bolus doses or continuous infusion should be utilized. Monitor depth of neuromuscular blockade with either train-of-four stimulation or other forms of clinical assessment when using continuous infusion. Patients with early, sepsis-induced ARDS with a PaO_2/FiO_2 less than 150 mm Hg (20.0 kPa) may benefit from a short course of a neuromuscular blocking agent not to exceed 48 hours.[20]

Renal Replacement Therapy

Patients who develop AKI as a manifestation of sepsis may require some type of renal replacement therapy. There are no data currently that suggest superiority for either continuous or intermittent modalities of hemodialysis as both have demonstrated similar mortality rates. In patients who are hemodynamically unstable, continuous renal replacement therapy may be more beneficial due to less overall hypotension during therapy.

Deep Vein Thrombosis Prophylaxis

Combination pharmacologic and mechanical prophylaxis against venous thromboembolism is recommended for septic patients when possible. Low-dose unfractionated heparin, low-molecular-weight heparin (eg, enoxaparin or dalteparin), or pentasaccharide therapy (eg, fondaparinux) may be utilized. Graduated compression stockings or an intermittent compression device is recommended for patients with a contraindication to heparin products (thrombocytopenia, severe coagulopathy, active bleeding, or recent intracerebral hemorrhage).[20]

Stress Ulcer Prophylaxis

Patients with severe sepsis are at increased risk for developing a stress ulcer bleeding event. Stress ulcer prophylaxis using either a histamine-receptor antagonist (H-2 blocker) or proton pump inhibitor (PPI) is recommended in septic patients. Patients at greatest risk for stress ulcers include those who are coagulopathic, mechanically ventilated (> 48 hours), or hypotensive. Histamine-2 receptor antagonists (eg, ranitidine)

Patient Care Process

LO 8

Collect Information:

- Retrieve available diagnostic and laboratory data, especially CBC with differential, CMP, ABG, and lactic acid.
- Measure vital signs, including temperature, heart rate, respiratory rate, and blood pressure.
- Speak with patient/family and review records to identify previous antimicrobial history, microbiologic cultures, and medication allergies.

Assess the Information:

- Based on physical examination and review of systems, determine whether the patient meets criteria for sepsis.
- Assess for a potential source of infection.
- Identify comorbidities, concomitant medications, and/or laboratory findings that may impact antimicrobial choices.
- Understand which parameters indicate effective/ineffective resuscitation. Plan for additional resuscitation therapy if the patient remains hypotensive.

Develop a Care Plan:

- Formulate an appropriate plan for antimicrobial therapy, which should include starting broad spectrum agents that cover the most likely pathogens within 1 hour of suspecting sepsis.
- Make recommendations to control the source of infection.
- Develop a strategy to optimize hemodynamics. Crystalloid fluids should be used first, followed by vasopressors and/or inotropes. Corticosteroids may be utilized in patients who remain hemodynamically unstable.
- Formulate appropriate dosing regimens for medications involved in therapy and revise as needed.
- Consider the need for adjunctive therapies such as analgesics, sedatives, insulin, neuromuscular blockers, blood product administration, renal replacement therapy, deep vein thrombosis prophylaxis, stress ulcer prophylaxis, and nutrition.

Implement the Care Plan:

- Patient parameters may change frequently, thus requiring modifications of therapy. Reassess vital signs and laboratory values often and adjust medications and dosing regimens as needed.
- Involve the patient and family members in each step of the care plan.

Follow-up: Monitor and Evaluate:

- Continually monitor patient parameters to ensure optimal therapy to minimize morbidity and mortality.
- Continue antimicrobial therapy on average for a total of 7 to 10 days, depending on the site of infection and response to therapy. Monitor for ongoing signs and symptoms of infection, including leukocytosis, fever, hypotension, and tachycardia.
- Step-down therapy from IV to oral antimicrobials when the patient is hemodynamically stable, afebrile, has a normalized WBC, has a pathogen susceptible to oral therapy, and is able to take oral medications.
- Escalate or de-escalate antimicrobial therapy based on culture and susceptibility results, which should be assessed daily.

are more efficacious than sucralfate. There is ongoing debate to determine if PPIs (eg, omeprazole) are more efficacious than H-2 blockers with low-quality data showing conflicting outcomes.[20,47] Both, however, demonstrate equivalence in the ability to increase gastric pH.[20] The benefit of prophylaxis must be weighed against the potential effect of increased stomach pH and development of infectious complications, such as hospital-acquired pneumonia and/or *Clostridium difficile* infection.

Nutrition

Meeting the nutritional needs of septic patients can be challenging, especially in patients who are hemodynamically unstable. When possible, early initiation of enteral nutrition should be considered to maintain gut mucosa and potentially decrease the risk of bacterial translocation leading to infection. Patients who are hemodynamically unstable may not tolerate enteral nutrition and are at risk for gut ischemia. Parenteral nutrition alone or in conjunction with enteral nutrition should not be initiated in the first 7 days as this has not been shown to improve outcomes.[20]

Prognosis

There are various factors that influence outcome. Gram-negative bacteria are more likely to produce septic shock than gram-positive bacteria (50% vs 25%) and have a higher mortality rate than other pathogens. This may be related to the severity of the underlying condition. Patients with rapidly fatal conditions, such as leukemia, aplastic anemia, and burns, have a worse prognosis than patients with nonfatal underlying conditions, such as diabetes mellitus or chronic renal insufficiency. Other factors that worsen the prognosis of septic patients include advanced age, malnutrition, resistant bacteria, utilization of medical devices, and immunosuppression. Data for long-term mortality are lacking (it is estimated that the mortality for sepsis survivors within the first year is 20%).[12] Patients may have prolonged physical disability related to muscle weakness and posttraumatic stress.

Abbreviations Introduced in This Chapter

ABG	Arterial blood gas
AKI	Acute kidney injury
ARDS	Acute respiratory distress syndrome
CBC	Complete blood count
CMP	Comprehensive metabolic panel
CVP	Central venous pressure
DIC	Disseminated intravascular coagulation
DVT	Deep vein thrombosis
EGDT	Early goal directed therapy
FiO_2	Fraction of inspired oxygen
HES	Hydroxyethyl starch
IV	Intravenous
MAP	Mean arterial pressure
MDR	Multidrug-resistant
PaO_2	Partial pressure of oxygen
PPI	Proton pump inhibitor
SOFA	Sequential [Sepsis-related] organ failure assessment

83 Superficial Fungal Infections

Kathryn A. Fuller and Lauren S. Schlesselman

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying pathophysiology of vulvovaginal candidiasis (VVC), oropharyngeal candidiasis (OPC), esophageal candidiasis, and fungal skin infections.
2. Identify symptoms of VVC, OPC, esophageal candidiasis, and fungal skin infections.
3. Identify the desired therapeutic outcomes for patients with uncomplicated and complicated VVC, OPC, esophageal candidiasis, and fungal skin infections.
4. Recommend appropriate lifestyle modifications and pharmacotherapy interventions for patients with VVC, OPC, esophageal candidiasis, and fungal skin infections.
5. Recognize when long-term suppressive therapy is indicated for a patient with VVC.
6. Recognize when topical versus oral treatment is indicated for a patient with OPC, esophageal candidiasis, VVC, and fungal skin infections.
7. Educate patients about the disease state, appropriate lifestyle modifications, and medication therapy required for effective treatment of VVC, OPC, esophageal candidiasis, and fungal skin infections.

INTRODUCTION

Superficial fungal infections, also referred to as mycoses, are common and treatable conditions seen in everyday practice. Treatment largely depends on the use of azole and allylamine antifungal agents, either topically or orally, depending on the site, severity, and immune status of the patient.

VULVOVAGINAL CANDIDIASIS

Vulvovaginal candidiasis (VVC), whether symptomatic or asymptomatic, refers to infections in women whose vaginal cultures are positive for *Candida* species.

EPIDEMIOLOGY AND ETIOLOGY

VVC, also known as moniliasis, is a common form of vaginitis, accounting for 20% to 25% of vaginitis cases. Although VVC is uncommon prior to **menarche**, an estimated 75% of women will have at least one occurrence of VVC.[1]

According to the treatment guidelines of the Centers for Disease Control and Prevention (CDC),[1] VVC can be classified as uncomplicated or complicated. Uncomplicated infections occur sporadically, cause mild to moderate symptoms, and occur in nonimmunocompromised women. Uncomplicated infections, most often caused by *Candida albicans*, often have no identifiable precipitating cause. Complicated infections, including recurrent, severe infections, and those in women with uncontrolled diabetes, debilitation, or immunosuppression, may be caused by nonalbicans or azole-resistant fungal organisms. Recurrent VVC, defined as four or more infections per year, occurs in less than 5% of women, and is distinguishable from a persistent infection by the presence of a symptom-free interval between infections.[1]

LO 1

KEY CONCEPT *C. albicans* is the primary pathogen responsible for VVC, accounting for 66% of cases.[2] Other cases are caused by nonalbicans species, including *Candida glabrata, Candida tropicalis, Candida krusei*, and *Candida parapsilosis*.[2]

PATHOPHYSIOLOGY

The normal vaginal environment protects women against vaginal infections. Under the influence of estrogen, vaginal epithelium cornifies to reduce the risk of infection. Vaginal discharge, composed of exfoliated cells, cervical mucus, and colonized bacteria, cleans the vagina. The normal pH of vaginal secretions, near 4.0, is toxic to many pathogens and is maintained by *Lactobacillus acidophilus*, diphtheroids, and *Staphylococcus epidermidis*. Alterations in the vaginal environment, including pH changes, allow for overgrowth of organisms that are normally suppressed, increasing the risk of vulvovaginitis.

RISK FACTORS

LO 2

KEY CONCEPT Although no risk factors are consistently associated with conversion to symptomatic infection, a variety of factors may increase the risk of developing symptomatic VVC in certain women (Table 83–1).

TREATMENT

The goals of treatment of VVC are as follows:

- Relief of symptoms
- Eradication of infection
- Reestablishment of normal vaginal flora
- Prevention of recurrent infections in complicated infections

Clinical Presentation and Diagnosis of VVC

Patients with VVC may present with vulvar and/or vaginal symptoms. Symptoms often develop the week before menses and resolve with the onset of menses.

Symptoms

- Vaginal itching
- Vaginal soreness
- Vaginal burning
- Irritation
- External dysuria
- Dyspareunia

Signs

- Nonodorous vaginal discharge (may vary from watery to curd-like)
- Yellow or yellowish green discharge
- Erythema and edema of the labia and vulva
- Fissures
- Pustulopapular lesions
- Normal cervix

Diagnostic Testing

- Microscopic investigation for the presence of blastospores or pseudohyphae; saline wet mount has a sensitivity of 40% to 50%, whereas a potassium hydroxide (KOH) preparation has a sensitivity of 50% to 70%.[7] Asymptomatic vaginal colonization of *C. albicans* is not diagnostic of VVC since 10% to 20% of women are asymptomatic carriers of *Candida* species. Asymptomatic vaginal colonization does not require treatment; therefore, the presence alone of *Candida* should not determine care.
- Vaginal pH less than or equal to 4.5; pH should remain normal in cases of fungal infection, whereas an elevated pH suggests bacterial infection.
- *Candida* cultures should be obtained only if signs and microscopy are inconclusive or in cases of recurrent VVC.

Table 83–1

Possible Risk Factors Associated with VVC

Risk Factor	Proposed Mechanism
Broad-spectrum antibiotic use	Altered vaginal flora allowing overgrowth of *Candida* organisms; risk increases with duration of antibiotic use
Systemic corticosteroid or immunosuppressant use	Reduced vaginal protection by immunoglobulins
Sexual activity	VVC is often associated with the onset of sexual activity; partners may have penile or oral colonization; use of vaginal irritants or devices, including diaphragms and intrauterine systems, can irritate vaginal mucosa
Tight-fitting and nonabsorbent clothing	Promotes warm, moist environment for fungus growth
Elevated estrogen levels, hormonal contraceptives, and pregnancy	Estrogen enhances *Candida* adherence to vaginal epithelial cells and yeast-mycelial transformation; this is supported by the fact that infection rates are lower before menarche and after menopause (except in women taking hormone replacement therapy), whereas rates are higher during pregnancy
Vaginal pH	Changes in glycogen and lactic acid levels
Gastrointestinal reservoir of *Candida* organisms	Transfer of organism from rectum to vagina; irritation of the vulvovaginal area during sexual intercourse may enhance invasion of organisms
Diabetes	Enhanced binding of *Candida* to epithelial cells due to hyperglycemia; asymptomatic colonization is more common in patients with diabetes; elevated sugar levels may cause conversion to symptomatic infection

VVC, vulvovaginal candidiasis.

Nonpharmacologic Treatments

In combination with pharmacologic treatment, the practitioner should recommend basic nonpharmacologic approaches to treatment and prevention of VVC:

- Keep the genital area clean and dry.
- Avoid prolonged use of hot tubs.
- Avoid constrictive clothing.
- Avoid vaginal douching.
- Wear underwear made of breathable materials, such as cotton.
- Avoid soaps and perfumes in the genital area.
- Although study results are conflicting, possibly due to the strain or concentration studied, the daily consumption of active *Lactobacillus* may reduce recurrence. Newer studies have found ingestion of *Lactobacillus rhamnosus* and *Lactobacillus reuteri* suppressed metabolic activity and killed *C. albicans*,[3] whereas older studies found no difference in infection rates in women who ingested yogurt.[4]

Patient Encounter 1

A 29-year-old woman presents to your clinic complaining of itching in her vaginal area and a white discharge. After questioning the woman, you determine that she has vaginal burning, soreness, and itching, accompanied by a curd-like discharge. Upon further questions, you determine that the woman is currently training for a marathon despite the summer heat. She reports having had a vaginal infection once before. The woman is concerned that she has either developed another vaginal infection or is allergic to her running shorts. On examination, she has erythema of the labia and a nonodorous discharge.

What information is suggestive of VVC?

What additional information do you need to know before creating a treatment plan for this patient?

Pharmacologic Treatment of Uncomplicated VVC

For most cases of uncomplicated VVC, the CDC guidelines recommend a short course of therapy (1–3 days) with an oral or vaginal antifungal agent, either prescription or nonprescription.[1] Nonprescription azole antifungal products are available as 1-night, 3-night, and 7-night regimens in a variety of formulations, including cream, suppository, and vaginal tablets (Table 83–2). Oral fluconazole offers the option of treatment with one dose administered without regard to time of day. Due to the risk of severe hepatotoxicity, the use of oral ketoconazole should be reserved for severe fungal infections resistant to other antifungal options.

Inability to resolve an infection may indicate a mixed infection, infection owing to a nonalbicans strain, an infection that is not fungal, or indicative of serious underlying conditions, such as diabetes or human immunodeficiency virus (HIV) infection. For these reasons, if infection does not resolve with a single antifungal course or if symptoms return within 2 months, practitioners should check cultures and further evaluate the patient's health status.

LO 3

KEY CONCEPT Due to the numerous treatment options available, a variety of factors can influence product selection, with patient preference playing a significant role. To improve adherence with therapy, the practitioner should discuss with the patient what options are available and what her preferences are.

Adherence rates are greater with oral treatment than with vaginal therapy, possibly due to ease of administration, short duration, and administration flexibility. Vaginal creams provide rapid relief of itching and burning, while symptom resolution may take 1 to 2 days with oral treatment. The practitioner may wish to recommend applying a vaginal cream externally to reduce itching and burning when using an oral agent, although this increases the cost of therapy. Most over-the-counter (OTC) products cost $10 to $20 per course of therapy. The cost of prescription products can vary based on insurance coverage. If the patient does not have prescription coverage, nonprescription products may prove less expensive than even one or two fluconazole tablets.

▶ *Risk of Adverse Effects and Interactions*

Systemic adverse effects associated with vaginally administered azoles are less frequent than with oral products. With topical products, local discomfort such as burning, itching, stinging, and redness may occur, particularly with the first application. In contrast, common adverse effects associated with fluconazole include headache, diarrhea, nausea, dizziness, abdominal pain, and taste alterations. Around 15% of patients experience gastrointestinal side effects with orally administered fluconazole.[5]

Oral azoles are associated with significant drug interactions, particularly due to potent inhibition of cytochrome P-450 (CYP) 2C9 and moderate inhibition of CYP 3A4. For patients receiving only one dose of oral fluconazole, these interactions may not pose a significant risk but may pose a risk with long-term suppressive therapy for recurrent infections.

TREATMENT OF RECURRENT VVC

The goal of treating recurrent VVC is control of the infection, rather than cure. First, any acute episodes are treated, followed by maintenance therapy. Although acute episodes of recurrent VVC will respond to azole therapy, some patients may require prolonged therapy to achieve remission. To achieve remission, 14 days of topical azole therapy or a second dose of oral fluconazole 150 mg repeated 3 days after the first dose can be used. The practitioner should consider that nonalbicans infections are more common in recurrent VVC; therefore, fluconazole and itraconazole resistance may make these agents less effective.

LO 4

KEY CONCEPT After achieving remission, recurrent VVC requires long-term suppressive therapy for 6 months (Table 83–3). Per CDC guidelines, oral fluconazole 100-, 150-, or 200-mg weekly for 6 months is first-line treatment.[1] Cessation of suppressive therapy is associated with resurgence of symptomatic infection in 30% to 50% of women.[1]

TREATMENT OF NONALBICANS INFECTIONS

Treatment response rates are lower for nonalbicans infections (eg, *C. glabrata* and *C. krusei*). Although an optimal regimen is unknown, use of nonfluconazole azole therapy for 7 to 14 days is recommended.[1] For second-line therapy, boric acid

Table 83–2

Treatment Options for Uncomplicated VVC

1-Day Therapies
Butoconazole 2% sustained-release cream, 5 g intravaginally as a single application
Fluconazole 150 mg, one tablet orally as a single dose
Tioconazole 6.5% ointment, 5 g intravaginally as a single application
3-Day Therapies
Butoconazole 2% cream, 5 g intravaginally for 3 nights
Clotrimazole 100-mg vaginal tablet, two tablets for 3 nights
Miconazole 200-mg vaginal suppository, one suppository for 3 nights
Terconazole 0.8% cream, 5 g intravaginally for 3 nights
Terconazole 80-mg vaginal suppository, one suppository for 3 nights
7- to 14-Day Therapies
Boric acid 600-mg vaginal suppository, one suppository intravaginally twice daily for 14 days
Clotrimazole 1% cream, 5 g intravaginally for 7–14 nights
Clotrimazole 100-mg vaginal tablet, one tablet for 7 nights
Miconazole 2% cream, 5 g intravaginally for 7 nights
Miconazole 100-mg vaginal suppository, one suppository for 7 nights
Nystatin 100,000-unit vaginal tablet, one tablet for 14 nights
Terconazole 0.4% cream, 5 g intravaginally for 7 nights

VVC, vulvovaginal candidiasis.

Table 83–3

Treatment Options for Maintenance Therapy

Daily
Boric acid 600 mg in gelatin capsule vaginally daily during menses (5 days)
Itraconazole 100 mg orally once daily
Ketoconazole 100 mg orally once daily
Weekly
Clotrimazole 500 mg vaginal suppository once weekly
Fluconazole 100 or 150 mg orally once weekly
Terconazole 0.8% cream 5 g vaginally once weekly
Monthly
Fluconazole 150 mg orally once monthly
Itraconazole 400 mg orally once monthly

600 mg in a gelatin capsule administered vaginally daily for 2 weeks is recommended.[1] This regimen provides mycologic cure rates of 40% to 100%,[6] although local irritation often limits its use. Oral itraconazole 200-mg twice daily 1 day per month for 6 months is also effective.[7] Other topical options include nystatin intravaginal suppositories, 100,000 units/day for 2 weeks. Topical 4% flucytosine is also effective, but use should be limited due to the potential for resistance.

VVC DURING PREGNANCY

During pregnancy, VVC may prove difficult to treat due to elevated estrogen levels, lower response rates, and frequent recurrences, accompanied by concern for the fetus. Vaginal antifungals remain the preferred treatment during pregnancy, although therapy should continue for 1 to 2 weeks to ensure effectiveness.[8] Most topical antifungals are classified as risk category C, whereas clotrimazole is classified as risk category B. Fluconazole's risk category classification for the single 150-mg dose is risk category C but category D for all other doses due to case studies of congenital limb deformities with doses of 400 to 800 mg daily during the first trimester.[9] Therefore, topical intravaginal application of clotrimazole or miconazole is generally preferred over oral antifungal therapy with fluconazole in pregnant patients.

Cultural Awareness During Treatment of VVC

As with all gynecologic issues, the practitioner is faced with cultural perceptions of female genitalia. In particular, practitioners are treating an increased number of patients who have undergone female genital mutilation. Female genital mutilation, formerly known as female circumcision, describes the intentional alteration or injury of female genitalia. More than 100 million women and girls, particularly in Africa and the Middle East, have undergone such procedures for cultural and religious reasons.[10] Some authorities suggest using the term "genital cutting" when dealing with patients to avoid appearing judgmental.[11] Women who have undergone this procedure suffer acute and chronic complications. Patients with female genital mutilation may suffer from recurrent VVC due to inadequate drainage of vaginal fluids. Regardless of the practitioner's opinion on female genital mutilation, the practitioner must be sensitive to the patient's feeling and cultural values.

OUTCOME EVALUATION

Whether using a topical or an oral agent, patients should notice relief of itching and discomfort within 1 to 2 days. The volume of discharge should also begin to decrease within a few days. The entire course of therapy should be continued even if symptoms have resolved. If the condition recurs within 4 weeks or more than four times per year, the patient should be further evaluated for possible non-*Candida* infections, resistant organism, or other complicating factors, along with assessment of need for long-term suppressive therapy.

OROPHARYNGEAL AND ESOPHAGEAL CANDIDIASIS

Oropharyngeal candidiasis (OPC) is a common fungal infection, often associated with immune suppression (ie, HIV infection, diabetes, and malignancies). If left untreated, it will progress to more serious oral disease, such as esophageal candidiasis.

Patient Care Process: VVC

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. If patient has experienced previous VVC, determine what medications were utilized and were effective previously.
- Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substances that could interact with prescribed medications.
- Based on the medical history and lifestyle factors, determine whether the patient has compelling risk factors for VVC.
- Based on physical examination, determine whether the patient's signs and symptoms are consistent with VVC or another vaginal infection, such as a sexually transmitted infection.
- Review relevant laboratory tests, if any available, such as A1C.
- Assess the efficacy, safety, and patient adherence of current and planned pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

Implement the Care Plan:

- Educate the patient about lifestyle modifications, medication therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about VVC and its management.
- Discuss importance of medication adherence and lifestyle modifications to cure VVC and prevent recurrence.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the formulary.

Follow-up: Monitor and Evaluate:

- No monitoring and evaluation is necessary unless unresolved.
- If unresolved, review medication and lifestyle modification adherence, review physical examination, and consider diagnostic laboratory to evaluate for other types of infection.

EPIDEMIOLOGY AND ETIOLOGY

LO 4

KEY CONCEPT The occurrence of oropharyngeal and esophageal candidiasis is an indicator of immune suppression, often developing in infants, the elderly, and the immunocompromised. One-third to one-half of geriatric inpatients develop OPC. Denture stomatitis is present in approximately 40% of denture wearers,[12] more commonly in women than men. Oral candidiasis is the most commonly reported adverse drug event reported by patients receiving inhaled corticosteroids,[13] with the prevalence of esophageal candidiasis reaching 37% among patients treated with inhaled corticosteroids.[14] The incidence of esophageal candidiasis is highest among patients receiving high doses of corticosteroids or with diabetes.

The prevalence of HIV infection plays a significant role in the incidence of oropharyngeal and esophageal candidiasis. In the 1980s, the incidence of OPC increased fivefold, in association with the spread of HIV infections.[15] Although HIV infection remains a risk factor for candidiasis, the introduction of highly active antiretroviral therapy precipitated a decline in the incidence of oral candidiasis to 45.9% to 79.1%, varying by geographic location, race, and therapy.[16]

OPC remains the most common opportunistic infection in patients with HIV. For the majority of patients, it is the first manifestation of HIV infection.[28] The incidence of oropharyngeal infection increases with decreasing CD4+ lymphocyte counts, and most often observed when CD4+ counts are less than 200 cells/mm^3 (350 × 106/L). An incidence of 59% is observed in patients with a CD4+ count less than 350 cells/mm^3 (350 × 106/L).[17]

Esophageal candidiasis usually occurs in patients with lower CD4+ counts than those that develop OPC.[21] Although esophageal candidiasis represents the first manifestation of HIV infection in less than 10% of cases, it is the most common acquired immunodeficiency syndrome (AIDS)–defining disease.[18] The CDC classifies esophageal candidiasis as a Stage 3-defining opportunistic infection in HIV.[19] As with OPC, the incidence of esophageal candidiasis increases with decreasing CD4+ counts, and therefore is a measure of declining CD4+ count or treatment failure.

C. albicans accounts for 80% of cases of OPC and esophageal candidiasis. Over the last 20 years, an increasing incidence of *C. albicans* resistance has been accompanied by an increased incidence of nonalbicans species infections, including *C. glabrata, C. tropicalis, C. krusei*, and *C. parapsilosis*. In patients with cancer and HIV, the prevalence of *C. glabrata* infections or mixed *C. albicans* and *C. glabrata* infection has been increasing.[20] Such infections tend to be more severe and require larger doses of antifungal agents for treatment.

PATHOPHYSIOLOGY

Similar to VVC, the development of OPC occurs when the normal environment is altered. *Candida* organisms frequently colonize the oropharynx and mucous membranes. These organisms do not become pathogenic until the environmental balance is disturbed. This occurs in the setting of broad-spectrum antibiotic use, tissue damage (due to chemotherapy, catheter tubing, trauma, or smoking), hyposalivation, or immune deficiency.

RISK FACTORS

Risk factors for OPC can be found in Table 83–4.

CLINICAL PRESENTATION AND DIAGNOSIS

See text boxes for clinical presentation and diagnosis of OPC and esophageal candidiasis.

Table 83–4

Risk Factors for Oropharyngeal and Esophageal Candidiasis

Factor	Proposed Mechanism
Extremes of age	Immature immunity in infants and reduced immunity in the elderly
Impaired mucosal integrity	Breaks in the protective barrier allows fungal invasion; often due to radiation, surgery, or mucositis
Dentures	Adherence of fungus to dentures, along with reduced salivary flow under dentures; ill-fitting dentures may impair mucosal integrity
Xerostomia	Reduced cleansing and defense factors of saliva
Use of antibiotics	Altered flora of mucosa allowing fungal overgrowth
Use of steroids	Suppression of immunity
Use of immunosuppressant	Suppression of immunity
HIV infection	Decreased CD4 T lymphocytes
Diabetes mellitus	Elevated glucose levels and defense factors in saliva
Nutritional deficiencies	Altered defense mechanisms, impaired mucosal integrity, or enhanced pathogenic potential of fungus

HIV, human immunodeficiency virus.

TREATMENT

Along with selecting an effective treatment, selection of an appropriate antifungal agent requires consideration of location and severity of infection, medication adherence, potential drug interactions, concomitant medical conditions, and presence of sucrose or dextrose. Topical agents require frequent dosing and prolonged contact time with oral mucosa. Rough surfaces of tablets and troches may irritate sensitive mucosa. Patients with xerostomia may have inadequate saliva to dissolve troches. Topical agents containing sucrose or dextrose may increase the risk of caries or cause elevated blood sugar in patients with diabetes. Along with being expensive, oral azoles exhibit an increased risk of toxicity and drug interactions due to inhibition of CYP-450.

Because oropharyngeal and esophageal candidiasis are signs of immunocompromise, the immune status of the patient should be considered in the therapeutic care plan. For HIV-infected patients, this should also include an evaluation of the patient's antiretroviral therapy because fungal infections may represent immune status deterioration.

LO 5

KEY CONCEPT For low-risk patients, topical agents are first-line therapy for OPC, although systemic agents may be used for severe or unresponsive cases. Infectious Disease Society of America (IDSA) guidelines recommend clotrimazole troches, 10 mg five times per day, or miconazole mucoadhesive buccal 50 mg tablet for 7 to 14 days for mild infections. Alternatives for mild infections include nystatin suspension or pastilles four times daily.[21] Once-daily oral fluconazole 100 to 200 mg for 7 to 14 days is reserved for moderate-to-severe cases.[21] Two weeks of oral itraconazole 200-mg or posaconazole 400-mg daily, voriconazole 200-mg twice daily, or amphotericin-B suspension four times daily are alternatives, typically reserved for refractory cases. For refractory cases additional therapy options include intravenous echinocandin or intravenous amphotericin-B deoxycholate but

Clinical Presentation and Diagnosis of Oropharyngeal Candidiasis

OPC is often a presumptive diagnosis based on signs and symptoms, along with the resolution of them after treatment with antifungal agents.

Symptoms

- Sore, painful mouth and tongue
- Burning tongue
- Dysphagia
- Metallic taste/loss of taste

Signs

Signs vary depending on the type of oropharyngeal candidiasis.

- Diffuse erythema on the surface of buccal mucosa, throat, tongue, and gums
- White patches on tongue, palate, gums, or buccal mucosa; removal of patches reveals erythematous and bloody tissue; ability to remove patches distinguishes OPC from oral hairy leukoplakia
- Angular cheilitis presents with small cracking lesions, erythema, and soreness at the corners of the mouth; associated with vitamin and iron deficiency
- Denture stomatitis presents with flat, red lesions on mucosa beneath dentures; signs of chronic erythema and edema on mucosa
- Hyperplastic OPC presents with discrete, transparent raised lesions on the inner mucosa of the cheek; typically found in men who smoke
- Pseudomembranous OPC presents with yellow-white plaques that may be small and discrete or confluent; most common form found in HIV patients

Diagnostic Testing

Diagnosis is primarily based on identification of characteristic lesions and confirmed by scraping of lesions to perform a gram-stain. Although rarely necessary, diagnostic testing is possible if a definitive diagnosis is required.

- Cytology, although presence of *Candida* is not diagnostic because colonization is common
- Culture to identify species of yeast or presence of resistance
- Biopsy

are considered second-line due to lack of concentration of drug at the site of infection.

For non–HIV-infected patients who have suppressed immune systems, the practitioner must consider the patient's risk of dissemination. Patients with cell-mediated immune deficiency but near-normal granulocyte function, such as patients with diabetes, solid organ transplant, or solid tumors, are at low risk for dissemination. The risk of dissemination is higher in patients who develop neutropenia, including patients with leukemia or bone marrow transplant. These patients should be treated aggressively to prevent invasive fungal infection.

For the treatment of OPC in HIV-infected individuals, initial episodes can be adequately controlled with topical agents, such as clotrimazole troches, so long as symptoms are not severe and no esophageal involvement is suspected.

LO 6

KEY CONCEPT Representing a severe extension of OPC, esophageal candidiasis requires systemic antifungal therapy. The significant morbidity associated with esophageal candidiasis warrants aggressive treatment.

Unlike OPC, which can be treated with topical agents, esophageal candidiasis requires systemic antifungal therapy for effective treatment.[18] The IDSA recommends oral fluconazole for 7–14 days in patients with esophageal candidiasis and moderate to severe disease, with an echinocandin or amphotericin-B as alternatives in patients unable to tolerate oral therapy, or with resistant or refractory disease.[21] Itraconazole 200-mg daily, posaconazole 400-mg twice daily, voriconazole 200-mg twice daily, and intravenous fluconazole are considered second-line therapy. If immunocompromised patients experience frequent or severe recurrences, particularly of esophageal candidiasis,

Clinical Presentation and Diagnosis of Esophageal Candidiasis

Symptoms

- Fever
- Odynophagia
- Dysphagia
- Retrosternal pain

Signs

- Fever
- Hyperemic or edematous white plaques
- Ulceration of esophagus
- Increased mucosal friability
- Narrowing of lumen

Diagnostic Testing

Unlike OPC, diagnosis of esophageal candidiasis is not based solely on clinical presentation, instead requiring endoscopic visualization of lesions and culture confirmation. Due to the invasive nature of these procedures, most practitioners opt to treat the infection presumptively, reserving endoscopic evaluation for patients who fail therapy.

- Cytology and culture to identify species of yeast or presence of resistance
- Barium esophagogram
- Endoscopy revealing whitish plaques with progression to superficial ulceration of the esophageal mucosa
- Mucosal biopsy

Patient Care Process: Oropharyngeal Candidiasis

Collect Information:

- Assess the patient's symptoms to determine whether symptoms are consistent with oropharyngeal or esophageal candidiasis.
- Review any available diagnostic data, including cultures.
- Evaluate for risk factors, such as immunocompromise.
- Review the medical history. Does the patient have compelling indications or contraindications for specific antifungal treatment?
- Review available laboratory tests, especially liver function.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications that may contribute to candidiasis? Is the patient taking any medications that may interfere with treatment?
- Determine if the patient has any allergies.

Assess the Information:

- If the patient has had oropharyngeal or esophageal candidiasis previously, determine what treatments were helpful to the patient in the past.
- If the patient has had oropharyngeal or esophageal candidiasis previously, determine whether the patient has risk factors for recurrent infection.
- Determine whether long-term suppressive therapy is necessary.
- Evaluate the patient for the potential of adverse drug reactions, drug allergies, or drug interactions.

Develop a Care Plan:

- Select antifungal therapy that is likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.
- Discuss warning signs to report, include recurrence or worsening symptoms.

Implement the Care Plan:

- Stress the importance of adherence with the antifungal regimen until complete.
- Provide patient education pertaining to oropharyngeal or esophageal candidiasis and antifungal therapy, including causes, risk factors, medication administration, potential adverse effects, and potential medication interactions.
- Discuss warning signs to report, include recurrence or worsening symptoms.

Follow-up: Monitor and Evaluate:

- Follow-up if symptoms do not resolve within 7 days or if symptoms worsen.
- Follow up on any identifiable precipitating cause, such as immunocompromise.

chronic maintenance therapy with fluconazole 100 to 200 mg daily should be considered.

OUTCOME EVALUATION

Patients should notice symptomatic relief within 2 to 3 days of initiating therapy. Complete resolution typically occurs within 7 to 10 days. The entire course of therapy should be continued even if symptoms have resolved. If the condition does not resolve or worsens, the patient should be referred to a specialist for aggressive therapy.

Patient Encounter 2, Part 1

A 40-year-old man presents to your clinic stating that he noticed "this funny white stuff" in his mouth, along with "burning and soreness in my mouth." He also mentions that he has a metallic taste in his mouth.

On initial examination, he has white patches on his tongue, gums, and buccal mucosa. These patches are easily removed, revealing erythematous tissue underneath.

Although he has visited the clinic before, his medical records are incomplete. He denies any current or recent medication use or being HIV-positive.

What additional information do you need to know before creating a treatment plan for this patient?

What underlying medical conditions might make him susceptible to fungal infections?

Short courses of oral azoles are associated with gastrointestinal upset, whereas courses lasting longer than 7 to 10 days are associated with increased risk of hepatotoxicity and CYP-450 drug interactions. In patients receiving prolonged therapy lasting more than 3 weeks, periodic monitoring of liver function tests should be considered.

Immunocompetent patients generally do not require reassessment after treatment. Patients with neutropenia exhibit an increased risk of dissemination of infection and therefore should be monitored for signs of systemic fungal infection. Due to an increased risk of recurrence, HIV-positive patients should routinely be evaluated for recurrence at each visit.

MYCOTIC INFECTIONS OF THE SKIN, HAIR, AND NAILS

Tinea infections are superficial fungal infections in which the pathogen remains within the keratinous layers of the skin or nails (Table 83–5). Typically these infections are named for the affected body part, such as tinea pedis (feet), tinea cruris (groin), and tinea

Patient Encounter 2, Part 2

How is the treatment care plan altered if the patient has a history of frequent and severe OPC? If the patient is HIV-positive? If the patient is neutropenic?

Table 83–5

Signs, Symptoms, and Risk Factors of Superficial Fungal Infections

Infection	Symptoms, Signs, and Risk Factors
Tinea pedis	• Involves plantar surface and interdigital spaces of foot • Interdigital infections produce itching; presents as fissures, scaling, or macerated skin; can occur between any toes but most often between fourth and fifth toes; may cause foul smell due to superinfection with *Pseudomonas* or diphtheroids • Hyperkeratotic infections present with slivery white scales on a thickened, red base; usually covers entire foot; occasionally may also affect hand • Vesiculobullous tinea pedis presents as pustules or vesicles on soles of feet; associated with maceration, itching, and thickening of sole; may cause lymphangitis and cellulitis; most common during summer months • Ulcerative tinea pedis presents as macerated, denuded, and weeping ulcers on soles; may produce extreme pain and erosion of interdigital spaces; typically complicated by opportunistic gram-negative infections • Risk factors include occlusive footwear, foot trauma, and use of public showers
Tinea manuum	• Infection of the interdigital and palmar surfaces • Presents as white scales in palmar folds; may also develop scales on remainder of palm; may present as singular plaque • More commonly affecting only one hand • Presents with hyperkeratotic skin
Tinea cruris	• Presents with follicular papules and pustules on the medial thigh and inguinal folds • Ringed lesions may extend from inguinal fold over adjacent inner thigh • Lesions usually spare the penis and scrotum, in contrast to candidiasis • Frequency increases during summer • Primarily develops in young men • Risk factors include tight-fitting clothing, excessive sweating, poor hygiene, increased humidity and temperatures • Commonly referred to as "jock itch"
Tinea corporis	• Presents with circular, scaly patch with enlarged border • Lesions may have red papules or plaque in center that clears, leaving hypopigmentation or hyperpigmentation • Itching may be present • Commonly referred to as ringworm of the body • Risk factors include animal to human contact
Tinea versicolor	• Characterized by skin depigmentation but can present as hyperpigmentation, particularly in dark-skinned patients • Typically occurs in areas with sebaceous glands, including neck, trunk, and arms • Depigmentation may persist for years • Primarily develops in young and middle-aged adults • Risk factors include application of oil, greasy skin, high ambient temperature, high relative humidity, tight-fitting clothing, immunodeficiency, malnutrition, hereditary predisposition
Tinea barbae	• Infection of beard area
Tinea capitis	• Infection of the head and scalp • May be asymptomatic initially, then progresses to inflammatory alopecia • "Black dot" alopecia may develop due to breakage of hair at the root • May form kerions (nodular swellings) • Scaling or favus may develop on scalp • Cervical lymphadenopathy is common • Primarily found in infants, children, and young adolescents, often in African American and Hispanic populations • Can be spread from person to person or animal to person
Onychomycosis (tinea unguium)	• Infection of nail plate and bed • Nail becomes opaque, thick, rough, yellow or brownish, and friable; nail may separate from bed • Toenails affected more frequently than fingernails • Prevalence increases with advanced age

corporis (body). Tinea infections are commonly referred to as ringworm due to the characteristic circular lesions. In actuality, tinea lesions can vary from rings to scales and single or multiple lesions.

EPIDEMIOLOGY AND ETIOLOGY

Tinea infections are second only to acne in frequency of reported skin disease. The common tinea infections are tinea pedis, tinea corporis, and tinea cruris. Tinea pedis, the most prevalent cutaneous fungal infection, afflicts more than 25 million people annually in the United States.

Fungal skin infections are primarily caused by **dermatophytes** such as *Trichophyton*, *Microsporum*, and *Epidermophyton*. *Trichophyton rubrum* accounts for more than 75% of all cases in the United States.[22] To a lesser extent, *Candida* and other fungal species cause skin infections. With tinea infections, the causative dermatophyte typically invades the stratum corneum without penetration into the living tissues, leading to a localized infection.

PATHOPHYSIOLOGY

The primary mode of transmission of tinea infections is direct contact with other persons or surface reservoirs. Upon contact, the dermatophytes attach to the keratinized cells, leading to thickening of the cells. Although infection remains localized, bacterial superinfections may develop.

Clinical Presentation and Diagnosis of Mycotic Infections

Symptoms and Signs

See Table 83–5.

Diagnostic Testing

- KOH prep
- Wood's ultraviolet lamp
- Microscopic examination
- Fungal cultures
- Periodic acid-Schiff (PAS) staining of nail

Treatment of Skin and Hair Infections

The goals of treatment include the following:

- Providing symptomatic relief
- Resolution of infection
- Preventing spread of infection

The pathophysiology of onychomycosis depends on the clinical type. With the most common form of onychomycosis, distal lateral subungual, the fungus spreads from the plantar skin. The fungus invades the underside of the nail through the distal lateral nail bed, leading to inflammation of the area. In cases of white superficial onychomycosis, the fungus invades the surface of the nail plate directly. With white superficial onychomycosis, the nail bed and hyponychium are infected secondarily. Proximal subungual onychomycosis infections begin in the cuticle and the proximal nail fold, then penetrate the dorsum of the nail plate.

RISK FACTORS

- Prolonged exposure to sweaty clothing
- Excessive skin folds
- Sedentary lifestyle
- Warm, humid climate
- Use of public pools
- Walking barefoot in public areas
- Skin trauma
- Poor nutrition
- Diabetes mellitus
- Immunocompromise
- Impaired circulation

TREATMENT

Nonpharmacologic Therapy

- Because fungi thrive in warm, moist environments, the practitioner should encourage patients to wear loose-fitting clothing and socks, preferably garments made of cotton or other fabrics that wick moisture away from the body. Avoid clothing made with synthetic fibers or wool.
- Sweaty or wet clothing should be removed as soon as possible.
- Clean the infected area daily with soap and water.
- The infected area should be dried completely prior to dressing, paying particular attention to skin folds.
- To allow circulation of air, the infected area should not be bandaged.
- For foot infections, cotton socks are recommended, although these should be changed two to three times a day to reduce moisture.
- To prevent spread, towels, clothing, and footwear should not be shared with other persons.
- Wear protective footwear in public showers and pool areas.

Pharmacologic Therapy of Tinea Infections

LO 7

KEY CONCEPT Since dermatophyte hyphae seldom penetrate into the living layers of the skin, instead remaining in the stratum corneum, most infections can be treated with topical antifungals. Infections covering large areas of the body, infections involving nails or hair, chronic infections, or infections not responding to topical therapy may require systemic therapy. Treatment is typically initiated based on symptoms, rather than on microscopic evaluation. For infections accompanied by inflammation, combination therapy with a topical steroid can be considered (Tables 83–6, 83–7, and 83–8).

Typically, tinea pedis requires treatment one to two times daily for 4 weeks, whereas tinea corporis and tinea cruris require topical treatment one to two times daily for 2 weeks. When applying treatment, the medication should be applied at least 1 inch beyond the affected area. Treatment of infection should continue at least 1 week after resolution of symptoms. Many practitioners opt to initiate therapy with nonprescription clotrimazole, tolnaftate, miconazole, or terbinafine, reserving prescription topical agents, such as naftifine, ciclopirox, and butenafine, for second-line therapy or refractory cases and systemic therapy for refractory cases.

When recommending topical therapy, the selection of vehicle is based on the type of lesion and location of the infection. Solutions and lotions are recommended for hairy areas and oozing lesions, whereas creams and ointments should be avoided in these areas. Creams are better for moderately scaling and nonoozing lesions. For hyperkeratotic lesions, ointments can be considered. The selected formulation should be applied to the affected area after it is cleaned and dried. The medication should be rubbed into the infected area for improved penetration. Because most patients do not rub in sprays and powders, penetration of the epidermis is minimal, making them less effective than other formulations. Sprays and powders should be considered as adjuvant therapy with a cream or lotion or as prophylactic therapy to prevent recurrence.[7] For OTC medications, in addition to formulation, it is important to identify the active ingredient desired. Even products with the same brand name may contain different active ingredients. Due to the severity of infection and inflammation, tinea capitis does not adequately respond to topical agents; therefore, oral agents for 6 to 8 weeks are recommended. Griseofulvin has long been considered the treatment of choice due to its ability to achieve high levels within the stratum corneum.[23] Terbinafine and itraconazole have also demonstrated effectiveness.[23] Due to its lipophilicity, itraconazole achieves high dermal concentrations that are maintained for 4 weeks after discontinuation of therapy.[24]

Table 83–6

Available Topical Antifungal Agents

Medication	Rx/OTC	Cream/Ointment	Gel	Lotion	Spray/Solution	Powder

Treatment of Onychomycosis

For onychomycosis, a chronic infection that rarely remits spontaneously, adequate treatment is essential to prevent spread to other sites, secondary bacterial infections, cellulitis, or gangrene. LO 8 KEY CONCEPT Due to the chronic nature and impenetrability of nails, topical agents have low efficacy rates for treating onychomycosis. Oral agents that can penetrate the nail matrix and nail base, such as itraconazole and terbinafine, are more effective than ciclopirox lacquer, efinaconazole solution, or tavaborole solution. Itraconazole (200 mg twice daily for 1 week per month or 200 mg daily for 12 weeks) and terbinafine (250 mg daily for 12 weeks) demonstrate mycological cure rates of 71% and 77%, respectively, whereas the cure rate range from 29% to 36% for ciclopirox, approximately 55% for efinaconazole, and 35% for tavaborole.[25] For patients with liver disease or who are unable to use oral agents, ciclopirox lacquer, efinaconazole solution, and tavaborole solution remain reasonable alternatives, despite requiring 48 weeks of therapy. Due to low efficacy, griseofulvin should only be considered as second-line therapy with therapy continued for 4 months for fingernail infections or 6 months for toenail infections.

There is a small but real risk of developing congestive heart failure with itraconazole therapy due to its negative inotropic effects.[26] Itraconazole should not be administered to patients with ventricular dysfunction such as congestive heart failure. The Food and Drug Administration (FDA) also released warnings that itraconazole and terbinafine are associated with serious hepatic toxicity, including liver failure and death. Liver failure associated with these medications has occurred in patients with no preexisting living disease or serious underlying medical conditions. Treatment with itraconazole or terbinafine for prolonged periods requires laboratory monitoring of liver function tests before initiation of therapy and at monthly intervals.

Table 83–7

Dosing of Topical Agents for Tinea Infections and Onychomycosis

Agents	Topical Dosing Frequency
Butenafine	Once daily
Ciclopirox	Twice daily; at bedtime (lacquer)
Clotrimazole	Twice daily
Econazole	Once daily
Efinaconazole	Once daily (nail solution)
Haloprogin	Twice daily
Ketoconazole	Once daily
Miconazole	Twice daily
Naftifine	Once daily (cream); twice daily (gel)
Oxiconazole	Twice daily
Sertaconazole	Twice daily
Sulconazole	Twice daily
Tavaborole	Once daily (nail solution)
Terbinafine	Twice daily
Tolnaftate	Two to three times daily

Cultural Awareness When Treating Mycotic Infections

Awareness of cultural beliefs related to feet and hands is essential when treating patients with fungal infections. In Arab countries, showing the bottom of the foot is a grave insult. The foot is considered the dirtiest part of the body. As such, patients from these countries may be hesitant to show their feet to the practitioner. In other countries, the open palm "high five" gesture is considered insulting. When treating patients with infections on the hand, the practitioner should refrain from making this gesture while discussing the patient's hand infection.

Table 83–8

Dosing of Systemic Therapy for Tinea Infections

Medication	Adult Dosing	Pediatric Dosing
Fluconazole	150 mg/week	6 mg/kg/week
Griseofulvin	0.5–1 g/day	10–20 mg/kg/day
Itraconazole	200 mg twice daily	Not studied
Ketoconazole	200–400 mg/day	3.3–6.6 mg/kg/day
Terbinafine	250 mg/day	< 25 kg: 125 mg/day; 25–35 kg: 187.5 mg/day; > 35 kg: 250 mg/day

Patient Care Process: Mycotic Infections—1

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. If patient has experienced previous tinea infections, determine the location of that infection and what medications were utilized and were effective previously.
- Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substances that could interact with prescribed medications.
- Based on the medical history and lifestyle factors, determine whether the patient has compelling risk factors for tinea infections.
- Based on physical examination of affected area, determine whether the patient's signs and symptoms are consistent with a superficial fungal infection.
- Review relevant laboratory tests, if any available.
- Assess the efficacy, safety, and patient adherence of current and planned pharmacotherapy.
- Identify any significant adverse drug effects or interactions.

Develop a Care Plan:

- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

Implement the Care Plan:

- Educate the patient about lifestyle modifications, medication therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about the tinea infection and its management.
- Discuss importance of medication adherence and lifestyle modifications to cure tinea pedis, cruris, or corporis and prevent fungal infection recurrence.
- Determine whether the patient has insurance coverage or whether recommended agents are included on the formulary.

Follow-up: Monitor and Evaluate:

- No monitoring and evaluation is necessary for short course therapy unless unresolved. For courses lasting longer than 6 weeks in children, baseline alanine aminotransferase (ALT) and aspartate aminotransferase (AST) measurements are recommended, along with complete blood count (CBC) at 6 weeks.
- If unresolved, review medication and lifestyle modification adherence, review physical examination, and consider diagnostic laboratory to evaluate for other types of infection.

OUTCOME EVALUATION

For infections of the skin, patients should notice relief of symptoms, including pruritus, scales, and inflammation, within 1 to 2 weeks. Therapy should be continued at least 1 week after complete resolution of symptoms. If the condition worsens on topical therapy, the patient should be treated with oral therapy.

For onychomycosis, relief of symptoms is slow. The infected nail will need months to grow out. The practitioner should advise the patient not to become frustrated by the slow resolution. Despite the slow progress, the antifungal agent is curing the infection. The practitioner should also advise the patient that even after the infection is cured, the nail may not look "normal."

Patient Care Process: Mycotic Infections—2

Collect Information:

- Assess the patient's symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate. Exclusions for self-treatment include infection of nails or hair, unsuccessful initial treatment, worsening condition, signs of secondary bacterial or systemic infection, large infected areas, or chronic medical conditions such as diabetes, immunosuppression, or impaired circulation.
- Review any available diagnostic data, including cultures and KOH preps.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.
- Any allergies?

Assess the Information:

- If the patient has had a mycotic infection previously, determine what treatments were helpful to the patient in the past.
- Determine whether long-term prophylactic therapy is necessary to prevent recurrence.
- Determine whether the patient has prescription coverage.

Develop a Care Plan:

- Evaluate the patient for the potential for adverse drug reactions, drug allergies, and drug interactions.
- Select lifestyle modifications and antifungal therapy that are likely to be effective and safe.
- Choose medications, doses, and dosage forms that are optimal for the patient.

(*Continued*)

Patient Care Process: Mycotic Infections—2 (*Continued*)

Implement the Care Plan:

- Educate the patient on lifestyle modifications that will prevent recurrence, including keeping the area dry, wearing shower shoes, washing clothing in hot water, using drying powders, avoiding sharing towels or clothing, and wearing loose-fitting clothing.
- Provide the patient education pertaining to mycotic infections and antifungal therapy, including causes, medication application or administration, length of therapy, how to avoid spread of infection or recurrence, and potential adverse effects.
- Discuss dietary modifications that are necessary with oral agents.
- Discuss medications that may interact with antifungal therapy, particularly with oral agents used for nail infections.
- Discuss warning signs to report such as recurrent or difficult-to-cure infections, infections with malodorous discharge or bleeding.
- Stress the importance of adherence with the antifungal regimen.

Follow-up: Monitor and Evaluate:

- Follow-up if unresolved or worsens with treatment.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
CDC	Centers for Disease Control and Prevention
HIV	Human immunodeficiency virus
KOH	Potassium hydroxide
OPC	Oropharyngeal candidiasis
OTC	Over-the-counter
PAS	Periodic acid-Schiff test
VVC	Vulvovaginal candidiasis

84 Invasive Fungal Disease

Russell E. Lewis and P. David Rogers

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Differentiate epidemiologic differences and host risk factors for acquisition of primary and opportunistic invasive fungal diseases.
2. Recommend appropriate empiric or targeted antifungal therapy for the treatment of invasive fungal diseases.
3. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for invasive fungal disease.
4. Evaluate the role of antifungal prophylaxis in the prevention of opportunistic fungal diseases.

INTRODUCTION

Invasive fungal disease or invasive mycoses are general terms for diseases caused by invasion of living tissue by fungi. In contrast to superficial mycoses (see Chapter 83), invasive fungal diseases are less common, but are of greater medical concern because of their disproportionately higher severity and mortality. Approximately 1.5 million people die each year from the 10 most common invasive fungal diseases, which is higher than World Health Organization mortality estimates for tuberculosis (1.4 million) or malaria (1.2 million).[1] However, these numbers likely underestimate the actual mortality burden of invasive fungal disease considering that the four most common infections (cryptococcosis, invasive candidiasis, invasive aspergillosis (IA), and *Pneumocystis jiroveci* pneumonia) are often underdiagnosed and not reportable diseases to public health agencies (Table 84–1).

Invasive fungal diseases are broadly categorized as either primary or opportunistic mycoses. KEY CONCEPT Primary invasive fungal diseases develop following exposure to fungal spores or conidia in the soil that, when disturbed, can become aerosolized and inhaled leading to infection, even in an immunocompetent patient exposed to a sufficient inoculum. Because these fungi are in specific soil types in select geographic areas, they are also referred to as endemic fungi. In the United States, three species (*Histoplasma capsulatum*, *Blastomyces dermatitidis*, and *Coccidioides immitis/Coccidioides posadasii*) account for most of these infections (see Table 84–1).

KEY CONCEPT In contrast, opportunistic fungal diseases are most frequently encountered in the setting of compromised host immune defenses, and are caused by a wider spectrum of less virulent fungal species that rarely cause infection in healthy patients (see Table 84–1). Hence, the spectrum, severity, and outcome of opportunistic fungal diseases are strongly influenced by the degree, type, and severity of host immunosuppression. As a rule, opportunistic fungal diseases are difficult to diagnose, but often fatal if not diagnosed early and treated aggressively.

Occasionally, opportunistic fungal diseases may be associated with outbreaks in non-immunocompromised patients if fungi are inadvertently inoculated into patients from contaminated drug solutions or medical devices. In 2012, an outbreak of fungal meningitis and joint infections (n = 751 cases) in 20 states was eventually traced by the Centers for Disease Control and state health departments to contaminated preservative-free methylprednisolone solution compounded by a pharmacy that was distributed to multiple doctors' offices. These contaminated steroid solutions were administered as epidural and **articular** injections in patients with chronic back or joint pain. The **dematiaceous** mold eventually linked to the fungal meningitis

Table 84–1

Invasive Mycoses

Primary (Endemic) Invasive Fungi
Histoplasma capsulatum[a]
Coccidioides immitis/Coccidioides posadasii[a]
Blastomyces dermatitidis[a]
Opportunistic Invasive Fungi
Yeast
Candida species (*C. albicans, C. glabrata, C. parapsilosis, C. tropicalis, C. krusei*, and others)[a]
Cryptococcus neoformans[a]
Trichosporon spp. and others
Mold
Hyalohyphomycoses (non-dematiaceous)
Aspergillus fumigatus, *Aspergillus terreus*, *Aspergillus flavus*, and other species[a]
Fusarium solani and *Fusarium oxysporum*
Mucorales (formally *zygomycosis*) (*Mucor, Absidia, Rhizopus, Cunninghamella*, and *Rhizomucor*)
Penicillium species
Phaeohyphomycoses (dematiaceous)
Pseudallescheria boydii (*Scedosporium* spp.)
Bipolaris
Alternaria
Exserohilum rostratum
Other
Pneumocystis jiroveci (formerly *P. carinii*)[a]

[a]Most common.

cases, *Exserohilum rostratum*, had rarely been described as a human pathogen prior to the outbreak.[2]

PRIMARY (ENDEMIC) MYCOSES

EPIDEMIOLOGY AND ETIOLOGY

Endemic mycoses are capable of infecting otherwise healthy individuals. In immunocompromised patients, endemic fungal infections present with more severe manifestations or can reactivate with life-threatening consequences. Because initial symptoms of an endemic fungal infection are nonspecific and produce symptoms indistinguishable from other slowly progressing infections (tuberculosis), a careful patient history concerning travel and activities that may have resulted in exposure to endemic fungi are essential for early diagnosis.

LO 1

Two of the most common endemic fungal infections (histoplasmosis and North American blastomycosis) are found in overlapping regions in the eastern and central river basins of the United States (Figure 84–1). *H. capsulatum* var. *capsulatum*, the causative fungus of histoplasmosis, grows heavily in soil contaminated with bird or bat excreta, which serve to enhance sporulation of the fungus.[3,4] Infections have been associated with activities that disturb soil contaminated with this excreta, including cave exploration (spelunking), working in or demolishing chicken coops or older buildings, or work in campsites in heavily wooded areas. For blastomycosis, decaying organic matter, warm humid conditions, and proximity to water or frequent rainfall support growth of this fungus. Outbreaks of blastomycosis have been most frequently associated with occupational or recreational activities around the major waterways such as the Great Lakes region, where soil concentrations of *B. dermatitidis* are elevated.[4]

Coccidioidomycosis differs from histoplasmosis and blastomycosis, as the fungus is associated with arid to semiarid climates, hot summers, low altitude, alkaline soil, and sparse flora. Hence the fungus is found in the Southwestern region of the United States stretching from Western Texas to Southern California (see Figure 84–1).[5] Epidemics of coccidioidomycosis have been reported in California following dust storms and earthquakes, including cycles of intense drought and rain, which favor the growth of the fungus and dispersal of its spores, called arthroconidia.

Patient Encounter 1, Part 1: Endemic Fungal Infection

A 42-year-old Filipino woman from Phoenix, Arizona presents with headache, fever, and new skin lesions 3 months following a liver transplant for autoimmune hepatitis. The patient has had persistent fever for 3 weeks despite a recent 2-week course of amoxicillin/clavulanate. The skin lesions were tender and warm to palpation but lacked erythema, pallor, or fluctuance. Lymphadenopathy was not appreciated on physical examination. Her medications included an immunosuppressant tacrolimus. Chest computed tomography (CT) found multiple pulmonary nodules.

What information is suggestive that this patient may have an endemic fungal infection?

What is the most likely endemic fungal pathogen based on this patient's area of residence?

PATHOPHYSIOLOGY

Endemic fungi share several characteristics that contribute to their pathogenicity in humans. All endemic fungi exhibit temperature-dependent dimorphism, meaning they can propagate as either

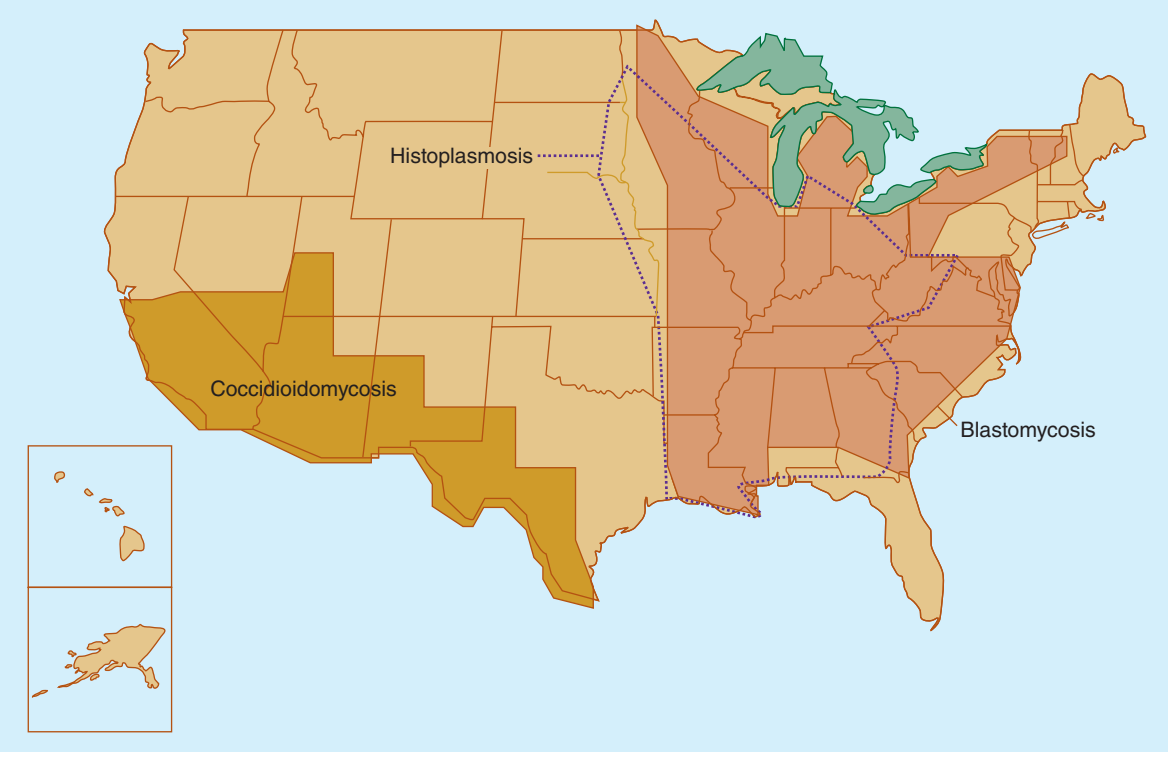

FIGURE 84–1. Geographic localization of primary (endemic) fungi in the United States.

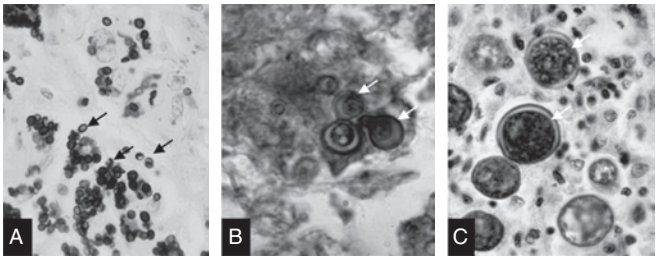

FIGURE 84–2. Histopathology of endemic mycoses in tissue. **(A)** Histoplasmosis (yeast). **(B)** Blastomycoses (broad-based budding yeast). **(C)** Coccidioidomycoses (spherules with endospores).

yeast (single cells that reproduce by budding into daughter cells) or molds (multicellular filamentous fungi that reproduce through production of conidia or spores). At environmental temperatures (25–30°C [77–86°F]), *H. capsulatum*, *B. dermatitidis*, and *C. immitis* grow in the mold form, producing 2- to 10-µm round- to oval-shaped (*Histoplasma* and *Blastomyces*) or barrel-shaped **conidia** (*Coccidioides*) that are dispersed throughout the environment and in air currents. At physiologic temperatures, the conidia germinate into yeast (*Histoplasma* and *Blastomyces*) or in specialized cell forms called spherules (*Coccidioides*) that are resistant to killing by alveolar macrophages and neutrophils in the lung.

Control of infection by the host requires the development of antigen-specific T-lymphocyte response that enhances macrophage fungicidal activity and formation of a **granuloma** to contain the fungus.[6] Not surprisingly, patients with T-cell–mediated immune deficiency (eg, acquired immunodeficiency syndrome [AIDS] patients and transplant recipients requiring immunosuppressive therapy) or suppressed cellular immunity due to drug therapy (eg, chemotherapy, high-dose corticosteroids, or tumor necrosis-α blockers such as infliximab) are at higher risk for reactivation of fungal disease.

The most common route of infection for endemic fungi is the respiratory tract, where conidia aerosolized from contaminated soil are inhaled into the lung. Once in the lung, conidia are phagocytosed but not destroyed by macrophages and neutrophils in the alveoli and bronchioles. Within 2 to 3 days, conidia germinate into yeast resistant to phagocytosis and killing by macrophages and neutrophils (**Figure 84–2A** and **B**). For *C. immitis*, germination of the arthroconidia results in the formation of a sac-like structure called a spherule filled with endospores (**Figure 84–2C**). Spherules then rupture to release large numbers of endospores, which are the propagating form of the infection. Control of infection in the lungs requires the formation of a granuloma to contain the fungus. However, in patients exposed to an overwhelming inoculum, or a lower-inoculum exposure in the setting of suppressed T-cell–mediated immunity can result in a potentially fatal infection that disseminates outside the lung to the skin and oral mucosa, adrenal glands, bone, spleen, thyroid, gastrointestinal (GI) tract, heart, and central nervous system (CNS).

CLINICAL PRESENTATION AND DIAGNOSIS

Histoplasmosis and coccidioidomycosis frequently present with mild self-limiting, influenza-like or mild lower-respiratory tractlike illness 1 to 3 weeks after inhalation of conidia. The clinical presentation of blastomycosis can range from asymptomatic infection, to acute or chronic pneumonia that develops weeks after exposure, to full-blown disseminated disease.

Severe endemic fungal disease often presents with a clinical history of persistent pneumonia despite multiple courses of antibiotic therapy that is accompanied by fever, chills, cough, arthralgia, night sweats, and weight loss. This clinical presentation is often indistinguishable from other chronic infections such as pulmonary tuberculosis. Therefore, the diagnosis of endemic fungal infection is often prompted by a patient history of prolonged infectious symptoms, travel or residence in an endemic area, and/or participation in activities that result in exposures to soil contaminated by endemic fungi.

LO 1

Radiological findings

- Chest radiographs often reveal either diffuse or nodular infiltrates in the lung, accompanied by enlargement of the hilar and/or mediastinal lymph nodes.
- Fulminant pneumonia may be seen with high inoculum exposures, resulting in diffuse lung infiltrates that progress to **acute respiratory distress syndrome** (ARDS) and respiratory failure.

Signs and Symptoms

- Rheumatologic symptoms such as severe arthritis, **pericarditis**, and **erythema nodosum** may be seen in 10% to 30% of patients with endemic fungi.[3–5]
- Dissemination outside the lung is common in patients with suppressed cellular immunity and frequently produces signs of progressing infection.
- Ulcerative oral and cutaneous lesions may also arise with any endemic fungal infection.
- Verrucose (wart-like) skin lesions on sun-exposed areas on the face are particularly suggestive of progressing blastomycosis and are frequently mistaken for skin cancer.
- Dissemination of the fungi to bone marrow may result in anemia or thrombocytopenia.
- Hepatomegaly, splenomegaly, and adrenal insufficiency can also occur with dissemination of the endemic fungi to these internal organs.
- Seizures, meningeal signs, and **hydrocephalus** may occur with dissemination of the infection to the CNS and signify a poor prognosis.

Definitive diagnosis of an endemic fungal infection requires growth of the fungus from body fluids or tissue, or evidence of cellular or tissue invasion in clinical samples by histopathology. However, cultures may only be positive in the setting of high inoculum exposures, pneumonia, or disseminated disease. Serologic detection of antibodies is helpful in the diagnosis and management of patients with histoplasmosis or coccidioidomycosis, but lacks specificity for diagnosis of *B. dermatitidis*.[4] In general, a fourfold rise in antibody or complement fixation titers of *Histoplasma* or *Coccidioides*, or any titer greater than 1:16, suggests active infection. However, many clinicians still consider titers as low as 1:8 as evidence of active disease because undetectable titers may be present in one-third of all active infections. Enzyme-linked immunosorbent assays (ELISAs) have been developed for direct detection of *Histoplasma* antigens in serum and urine. Serial antigen testing can also provide a means for assessing response of histoplasmosis to antifungal therapy and detection of relapsing disease.[3]

TREATMENT

LO 2

KEY CONCEPT The approach to antifungal therapy in patients with endemic fungal infections is determined by the severity of clinical presentation, the patient's underlying immunosuppression, and potential toxicities and drug interactions associated with antifungal treatment. Immunocompetent patients with mild disease following exposure to *H. capsulatum* or *C. immitis* often experience a benign course of infection that does not require antifungal therapy. Persons of Filipino or African descent have a higher risk for dissemination with *C. immitis*, and this may also be taken to consideration for more aggressive treatment.[5] Approximately 9% of patients exposed to coccidioidomycosis (defined by positive IgM or IgG serology) develop pneumonia requiring hospitalization, and 1% may develop infections of the CNS, which are difficult to treat if not incurable.[5]

Current guidelines suggest that patients with mild histoplasmosis or coccidioidomycosis may be initially followed in the outpatient setting with serial antigen or serologic studies to confirm resolving infection. Patients without clinical improvement within the first month can be treated with oral itraconazole for 6 to 12 weeks (Table 84–2).[3,5] Broader-spectrum triazoles such as voriconazole and posaconazole, and possibly isavuconazole, appear to have clinically useful activity against endemic fungi; but have limited data to recommend their routine first-line use. Fluconazole treatment (6–12 mg/kg/day; 400–800 mg/day) is associated with somewhat higher relapse rates than itraconazole but has fewer GI adverse effects and drug interactions compared to itraconazole. Echinocandins and flucytosine are not clinically useful agents for the treatment of endemic mycoses.

LO 2

Patients with symptoms persisting longer than 2 weeks, greater than 10% weight loss, extensive pneumonia, or serologic titers greater than 1:8 of histoplasmosis or coccidioidomycosis are candidates for immediate antifungal therapy. Any patient with underlying immunosuppression should also receive immediate antifungal therapy. The following signs and symptoms are indicators of severe disease that require

Table 84–2

Common Treatment Regimens for Endemic Fungal Infections

Mycosis	Recommended Treatment Regimens	Comments
Histoplasmosis		
Mild to moderate	Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 weeks. Fluconazole 12 mg/kg/day PO for 6–12 weeks adjusted for renal function.[a]	Fluconazole has a higher rate of relapse than itraconazole but is better tolerated by many patients than itraconazole. Echinocandins are not clinically effective against endemic mycoses.
Severe including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg/day IV or liposomal AMB. Amphotericin B 3–5 mg/kg/day for 12 weeks or until clinically stable.	Liposomal amphotericin B better tolerated than conventional formulations, especially for CNS disease. Patients initially treated with amphotericin B–based regimens are transitioned to itraconazole or fluconazole once they are clinically stable. Corticosteroid therapy should be considered in hypoxic patients with acute pulmonary infection. Itraconazole is less effective for CNS infections.
Blastomycosis		
Mild to moderate	Itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 months.	
Severe including CNS disease or immunocompromised host	Amphotericin B 0.7 mg/kg/day IV until patient is clinically stable, then itraconazole (non-CNS) or fluconazole 12 mg/kg/day orally adjusted for renal function.[a]	
Coccidioidomycosis		
Mild to moderate including non-complicated pneumonia	Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 3–6 months. OR Fluconazole 6–12 mg/kg/day (400–800 mg daily) daily adjusted for renal function[a] for 3–6 months.	Itraconazole demonstrated trend toward superiority over fluconazole in a randomized-controlled trial for progressive, nonmeningeal coccidioidomycosis; however, fluconazole is better tolerated than itraconazole.
Diffuse pneumonia or disseminated infection	Amphotericin B 1–1.5 mg/kg/day with dose and frequency decreased as improvement occurs. Patient then transitioned to triazole therapy. OR Liposomal amphotericin B formulation 3–5 mg/kg/day. Patient then transitioned to triazole therapy.	Fluconazole 800–1000 mg/day adjusted for renal function[a] is often recommended after initial AMB therapy for meningitis.

[a]CrCl > 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl < 10 mL/min (0.17 mL/s) 50%.
CNS, central nervous system; IV, intravenous; PO, oral.

hospitalization and initial treatment with systemic amphotericin B (see Table 84–2).

- Hypoxia indicated by a partial pressure of oxygen less than 80 mm Hg (10.6 kPa)
- Hypotension (systolic blood pressure < 90 mm Hg)
- Impaired mental status
- Anemia (hemoglobin < 10 g/dL [100 g/L or 6.2 mmol/L])
- Leukopenia (< $1 \times 10^3/mm^3$ [$1 \times 10^9/L$])
- Elevated hepatic transaminases (> 5 times upper limit of normal) or bilirubin (> 2.5 times upper limit of normal)
- Coagulopathy (impaired clotting ability)
- Evidence of dissemination, including cutaneous manifestations
- Meningitis

All patients with blastomycosis require antifungal treatment, even though patients with mild disease can be managed as outpatients with oral itraconazole.[7] Patients with evidence of severe pulmonary disease or dissemination require initial treatment in the hospital with amphotericin B–based regimens until they are clinically stable, whereupon they can complete a 6- to 12-month treatment course as outpatients with oral triazoles.[4] Methylprednisolone (0.5–1 mg/kg daily IV) may be administered during the first 1 to 2 weeks of antifungal therapy if the patient develops hypoxemia or significant respiratory distress.

OUTCOME EVALUATION

Response to antifungal therapy may be slow in patients with a prolonged history of infection or severe manifestations. However, gradual improvements in symptoms and reduction in fever are indicators of response to treatment. For histoplasmosis and coccidioidomycosis, decreasing antigen titers or serology are indicative of response to antifungal therapy.[3,5]

LO 3

Antifungals used for the treatment of endemic mycoses can be associated with many clinically significant drug interactions and toxicities, especially with the prolonged treatment courses required for endemic mycoses. Itraconazole is available as a capsule formulation that should be taken with food and as a cyclodextrin-solubilized solution taken without food. The liquid formulation of itraconazole has several advantages over the capsule: It has a better oral bioavailability and does not require the low gastric pH that is required for dissolution and absorption of the capsule. However, the oral solution is somewhat dilute, has an unpalatable aftertaste (an issue when taking months of therapy), and has a much higher rate of GI intolerance. Therefore, the capsule formulation is often preferred provided patients are not on acid-suppression therapy (ie, proton pump inhibitors, histamine antagonists, or antacids). Acidic beverages, such as orange or apple juice, or cola can improve the absorption of itraconazole capsules.

Fluconazole is available in both IV and oral formualtions that have good bioavailability. Posaconazole is formulated as a micronized suspension that is best absorbed when taken with high-fat meals and when taken in divided doses up to 800 mg/day. A delayed-release tablet formulation of posaconazole with improved bioavailability and fewer gastric pH-associated drug interactions is also available, and is probably the preferred oral treatment formulation of posaconazole in most patients unless the patient cannot swallow the tablet.[8] An IV formulation of posaconazole is also available for patients who cannot take oral formulations. Absorption of voriconazole is not affected by gastric pH, but is generally administered 1 hour prior to or 2 hours after eating. Isavuconazole is available in both an IV and oral pro-drug formulation that is not affected by gastric pH or food.[9]

Drug interactions are an important concern in patients taking long-term triazole therapy. Itraconazole, voriconazole, and isavuconazole are substrates of the cytochrome P450 (CYP) 3A4 enzyme. Coadministration of itraconazole, voriconazole, and to lesser extent fluconazole, posaconazole, and isavuconazole with inducers of this CYP 3A4 enzyme (eg, rifampin, phenytoin, and phenobarbital) increase drug clearance resulting in ineffective plasma and tissue concentrations of the drug.[10] In general, coadministration of the broader-spectrum triazoles (itraconazole, voriconazole, posaconazole, and isavuconazole) with these inducers should be avoided. Itraconazole, voriconazole, posaconazole, and, to a lesser extent, isavuconazole are also potent inhibitors of CYP 3A4, which predisposes these agents to a large number (estimated > 2000) of clinically significant pharmacokinetic drug–drug interactions.[10]

LO 3

All patients should have their medication profile carefully reviewed prior to initiating and stopping triazole antifungals, preferably with the aid of a computerized drug-interactions database. Even in the absence of drug interactions, serum drug levels of triazoles can be unpredictable.[11] Serum drug concentration monitoring or therapeutic drug monitoring (TDM) has been recommended in patients receiving itraconazole, voriconazole, and posaconazole suspension for documented infections, or when inadequate serum concentrations are suspected because of altered absorption, drug interactions.[11] Suspected toxicities, especially CNS adverse effects during voriconazole therapy,[12] may also be indicative of excessive drug levels that can be detected with TDM (Table 84–3).

LO 3

All azole antifungals carry the potential for rash, photosensitivity, and hepatotoxicity. In general, hepatotoxicity is mild and reversible, presenting as asymptomatic increases in liver transaminases, and less frequently increases in total bilirubin. Fulminant hepatic failure is less common and typically mediated by immunologic mechanisms. Therefore, serial monitoring of liver function is recommended in all patients receiving triazole antifungals. Long-term therapy with itraconazole has also been associated with reversible adrenal suppression and cardiomyopathy due to negative inotropic effects of the drug. Long-term therapy with voriconazole can be associated with severe phototoxic reactions and cutaneous erythema in sun-exposed skin, which may not be preventable with sunscreen alone. This phototoxic reaction has been linked to a high risk for developing squamous cell carcinoma or melanoma.[13] Patients should be instructed to avoid sun exposure while on voriconazole therapy and have frequent skin examinations by a dermatologist. Long-term voriconazole therapy may also predispose patients to perisotitis, or inflammation of tissue surrounding bone due to

Patient Encounter 1, Part 2: Endemic Fungal Infection

Patient Management

The patient's serum titer for coccidioidomycosis returns as greater than 1:8. Based on the information presented, select an appropriate treatment plan for the patient's infection.

Should the patient receive antifungal therapy now? What factors need to be considered?

Table 84–3

Recommendations for Antifungal Therapeutic Drug Monitoring

Drug	Indication for Monitoring	Time of First Measurement	Target Conc. for Efficacy (mcg/mL or mg/L)	Target Conc. for Safety (mcg/mL or mg/L)
Flucytosine	Routine during first week of therapy, renal insufficiency, or poor clinical response	3–5 days	Peak > 20 (155 µmol/L)	Peak < 50 (387 µmol/L) to reduce risk of marrow toxicity
Itraconazole	Routine during first week of therapy, GI dysfunction, suspected drug interactions	4–7 days	Prophylaxis > 0.5 (0.7 µmol/L); therapy trough > 1–2 (1.4–2.8 µmol/L)	Some evidence to suggest trough > 4 (5.7 µmol/L) increased adverse effects
Voriconazole	Lacking response, GI dysfunction, suspected drug interactions, pediatrics,[a] IV to oral switch, unexplained neurological changes	4–7 days	Prophylaxis trough > 0.5 (0.7 µmol/L); therapy trough 1–2 (2.9–5.7 µmol/L)	Trough < 6 (17.2 µmol/L) to reduce risk of CNS toxicities
Posaconazole	Lacking response, GI dysfunction, potent acid suppression therapy (ie, proton pump inhibitor) therapy, suspected drug interactions	4–7 days	Prophylaxis trough > 0.5 (0.7 µmol/L); therapy trough 0.5–1.5 (0.7–2.1 µmol/L)	Not established Delayed-release tablet formulation preferred for most patients because fewer pH drug interactions and improved bioavailability. IV formulation is available for patients who cannot take oral therapy
Isavuconazole	Lacking response, suspected drug interactions, mucormycosis	4–7 days	Not established, in clinical trials media trough concentration surpassed 2 (5.7 µmol/L)	Not established, in clinical trials the average trough concentration surpassed 2 (5.7 µmol/L)

[a]Pediatric patients display accelerated linear clearance of voriconazole. Therefore, higher daily voriconazole dosing (7 mg/kg every 12 hours) are recommended to achieve similar exposures to adults. Some children may require doses as high as 12 mg/kg every 12 hours to achieve similar serum drug exposures to adults. Therefore, therapeutic drug monitoring is recommended.

GI, gastrointestinal; IV, intravenous.

fluoride toxicity from chronic voriconazole exposure, (fluoride toxicity) that present with nonspecific joint, shoulder, and limb pain that can be diagnosed by x-ray and serum analysis of fluoride levels.[14] Alopecia, chapped lips and brittle nails, and cognitive difficulties have also been reported with longer-term voriconazole therapy, especially at higher doses.[15] Peripheral neuropathy may develop in 3% to 17% of patients on long-term triazole therapy, and is most frequently reported with itraconazole and voriconazole.[16]

Amphotericin B remains the mainstay of treatment of patients with severe endemic fungal infections. The conventional deoxycholate formulation of the drug can be associated with substantial infusion-related adverse effects (chills, fever, nausea, rigors, and in rare cases hypotension, flushing, respiratory difficulty, and arrhythmias). As-needed premedication with low doses of acetaminophen and diphenhydramine, and less frequently nonsteroidal anti-inflammatory agents hydrocortisone or meperidine (if rigors are present) are used to reduce acute infusion-related reactions. Venous irritation associated with the drug can also lead to thrombophlebitis; hence, central venous catheters are the preferred route of administration in patients receiving more than a week of therapy.

LO 3

The most severe adverse effect associated with amphotericin B therapy is nephrotoxicity, which occurs through direct effects on glomerular filtration (constriction of the afferent arterioles in the kidney tubule) and damage of the distal tubular membrane.[17] Generally, nephrotoxicity with amphotericin B is reversible provided the drug is stopped. However, treatment interruptions can be problematic in patients with severe infections. Precipitous decreases in glomerular filtration may occur in patients with marked dehydration or during aggressive diuresis. Infusion of normal saline before and after amphotericin B, a practice known as "sodium loading," can blunt precipitous decreases in renal perfusion pressure and slow the rate of decline in the glomerular filtration rate, but may not be tolerated in patients with poor cardiac function. Administration of amphotericin B by continuous infusion reduces the glomerular but not distal tubular toxicity, and is generally not advocated because of unproven efficacy. Amphotericin B–associated nephrotoxicity can be delayed by avoiding the use of other drugs with known tubular toxicity such as aminoglycosides, calcineurin inhibitors, cisplatin, or foscarnet. The initial manifestation of tubular toxicity manifests in patients with severe wasting of potassium and magnesium in the urine. Therefore, patient electrolytes must be carefully monitored and potassium and magnesium supplementation is always necessary. Hypokalemia and hypomagnesaemia frequently precede decreases in glomerular filtration (increased serum creatinine), especially in patients who are adequately hydrated.[17] Continued tubular damage eventually results in decreases in renal blood flow and glomerular filtration through tubuloglomerular feedback mechanisms that further constrict the afferent arteriole.

During the 1990s, amphotericin B was reformulated into three different lipid-based formulations (Abelcet, AmBisome, and Amphotec) that have reduced rates of nephrotoxicity compared with the conventional deoxycholate formulation (Fungizone). Two of the formulations that are currently available (Abelcet and AmBisome) have lower rates of infusion-related reactions. Although these lipid formulations are generally considered to be as effective as conventional amphotericin B deoxycholate, they are not dosed equivalently to the standard formulation (see Table 84–2).

PROPHYLAXIS

LO 4 Primary **prophylaxis**, before development of infection, is generally not recommended for endemic fungi. Antifungal prophylaxis is generally recommended in specific situations, including the following:

1. Patients with HIV infection [and with $CD4^+$ cell counts less than 150 cells/mm^3 (150×10^6/L) (histoplasmosis)] living in regions with high endemic case rates (> 10 cases per 100 patient-years), or in any patient with positive IgM or IgG antibodies. The recommended regimen is itraconazole 200 mg daily.
2. Secondary prophylaxis or suppressive therapy with itraconazole 200 mg daily is recommended to prevent recurrence of blastomycosis in immunosuppressed patients if immunosuppression cannot be reversed.[4]
3. In patients with prior CNS disease, fluconazole or voriconazole are preferred over itraconazole and posaconazole due to the lower penetration of itraconazole and posaconazole into the CNS.[5]

OPPORTUNISTIC MYCOSES

LO 1 KEY CONCEPT Commensal or environmental fungi that are typically harmless can become invasive mycoses when the host immune defenses are impaired. Host immune suppression and risk for opportunistic mycoses can be broadly classified into three categories:

1. A reduction in the number or quality of neutrophils
2. Deficits in **cell-mediated immunity**
3. Disruption of the skin, gut and/or microbiologic barriers

A reduction in the number of neutrophils (neutropenia) resulting from neoplastic diseases, cytotoxic chemotherapy, marrow transplantation, or bone marrow aplasia are among the most common risk factors for opportunistic mycoses. Functional neutrophil defects may be seen in certain disease states (eg, advanced diabetes mellitus and chronic granulomatous disease) or with high-dose corticosteroid therapy. Deficits in T-cell–mediated immunity associated with HIV infection, high-dose corticosteroid therapy, calcineurin inhibitors, or other immunosuppressive drugs, chemotherapy, transplantation, bone marrow failure, and other immunodeficiencies are increasingly prevalent with the prolonged survival of transplant patients or other chronically immunosuppressed populations.

Immune deficits arising from disruption of the skin GI/genitourinary barriers can also predispose patients to fungal diseases. The most common types of barrier disruptions include surgery or infections/perforation of the abdominal viscus, use of central venous and urinary catheters, parenteral nutrition, and mucositis associated with cytotoxic chemotherapy and antibiotic therapy. Broad-spectrum antibacterial therapy, which is common in high-risk hematology patients and the critically-ill patient in the ICU, disrupts the protective microbiologic flora of the gut allowing overgrowth of *Candida* species that can translocate to the bloodstream and invade internal organs.

In general, opportunistic mycoses are difficult to diagnose and are frequently treated empirically before diagnosis is proven.

LO 1 KEY CONCEPT Deciding when to initiate antifungal therapy and what opportunistic pathogens to cover is a decision governed largely by the immune deficits of the host, local epidemiology and experience, or clinical or diagnostic clues suggestive of incipient infection.

INVASIVE CANDIDIASIS

EPIDEMIOLOGY AND ETIOLOGY

Candida species are the most common opportunistic fungal pathogens encountered in hospitals, ranking as the third to fourth most common cause of nosocomial bloodstream infections in **ICU**s in the United States and the eighth most common cause of bloodstream infections overall.[18] The incidence of nosocomial candidiasis has increased steadily since the early 1980s, with the widespread use of central venous catheters, broad-spectrum antimicrobials, and other advancements in the supportive care of critically ill patients. In the 1980s, *C. albicans* accounted for more than 80% of all bloodstream yeast isolates cultured from patients. By the late 2000s, this relative frequency of *C. albicans* had decreased to less than 50% in national surveys of bloodstream infections with increasing proportion of infections caused by non-*albicans* species.[19] Because of the inherent resistance (eg, *C. glabrata, C. krusei*, and more recently *C. auris*) of many of the non-*albicans* species, the introduction of fluconazole in the early 1990s is often cited as the key element driving the shift in the microbiology of invasive candidiasis.

LO 1 KEY CONCEPT Familiarity with the local epidemiology and frequency of non-albicans *Candida* species in the institution or intensive care unit (ICU) is essential before selecting **empiric** antifungal therapy for invasive candidiasis, as fluconazole is not recommended for the treatment of *C. glabrata* and *C. krusei* infections, and echinocandin-resistance among *C. glabrata* is increasing in some centers. *C. auris* is an emerging, multidrug-resistant fungal pathogen for which therapeutic options are limited.

CLINICAL PRESENTATION AND DIAGNOSIS

Invasive candidiasis encompasses several infectious syndromes broadly categorized as candidemia or deep-seated infections, which most frequently affect the kidney, eye, or bones but may also affect heart valves, the CNS, and other organs including the spleen and liver.[20] A major difficulty in the diagnosis of invasive candidiasis in high-risk patients is dinstinguishing colonization from true infection. *Candida* frequently colonizes the urine, sputum, and skin and wounds, especially in patients receiving broad-spectrum antibacterial therapy. However, isolation of *Candida* from these sites frequently does not indicate true infection. For example, *Candida* in the urine can be an indication of renal candidiasis or an obstructing fungus ball; however, it must be distinguished from more common benign colonization of the urinary tract, especially in patients with chronic indwelling urinary catheters. Similarly, *Candida* species isolated for respiratory samples (sputum, bronchoalveolar lavage) are nearly always indicative of colonization and not true *Candida* pneumonia, which is a rare clinical entity.

Approximately one-third of all patients with true invasive candidiasis fall within three groups at the time of diagnosis: (1) patients with uncomplicated candidemia in the absence of deep-seated candidiasis, most frequently arising from an infected catheter; (2) candidemia associated with deep-seated candidiasis, most frequently arising from the GI tract or secondary seeding from a separate infection site; and (3) deep-seated candidiasis without candidemia.[21]

Invasive candidiasis is most frequently diagnosed by growth of yeast in blood culture, which detects infection in most patients with candidemia alone, fewer patients with mixed of deep-seated disease and intermittent candidemia, and virtually no patients who have infection limited to deep tissues at the time of culture. As a result, it is estimated that half of all episodes of invasive candidiasis

are not detected by blood cultures alone. Therefore, a positive blood for *Candida* is always considered strong evidence of infection but a negative blood culture cannot rule out the possibility of invasive candidiasis, especially in patients with multiple underlying risk factors. The development of new diagnostic tools that do not exclusively rely on microbiological isolation of *Candida* has become a major research focus for improving diagnosis of the infection, especially deep-seated disease.[20]

Serodiagnostic tests have been developed for the detection of *Candida* cell wall antigens, or nucleic acids of *Candida* species, in the hope of improving the detection of invasive disease missed by blood cultures. Currently, the most frequently used test is the Fungitell (1→3)-β-D-glucan test, Associates of Cape Cod Inc. False-positive results may occur, however, in patients with gram-negative bacteremia, certain gauze dressing or dialysis membranes, or patients heavily colonized with *Candida* species. More recently the development and Food and Drug Administration (FDA) approval of the T2 Magnetic Resonance–based T2Candida Panel has made possible the rapid, direct, and culture-independent detection of *Candida* species, although this test is not available in all institutions.[22]

Laboratory identification of *Candida* in clinical samples must be performed to the species level whenever possible, as *Candida* species differ considerably in their susceptibility to antifungal agents (Figure 84–3A). Rapid discrimination of *C. albicans* from common non-albicans *Candida* species can be accomplished by the germ-tube test, which presumptively identifies *C. albicans* by the early formation (< 4 hours) of a hyphae-like structure when the yeast is incubated in serum at 37°C (98.6°F). Definitive species identification, however, may require an additional 48 to 72 hours after the organism is isolated on agar, but can be accelerated with fluorescent in situ hybridization (FISH) of *Candida* species–specific DNA sequences. Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) and magnetic resonance–based technologies have shown some promise in the early identification of *Candida* species in whole blood specimens in as little as 3 hours, which could shorten the time to earlier diagnosis.

C. albicans remains the most common cause of invasive candidiasis and is the most virulent of *Candida* species, but is

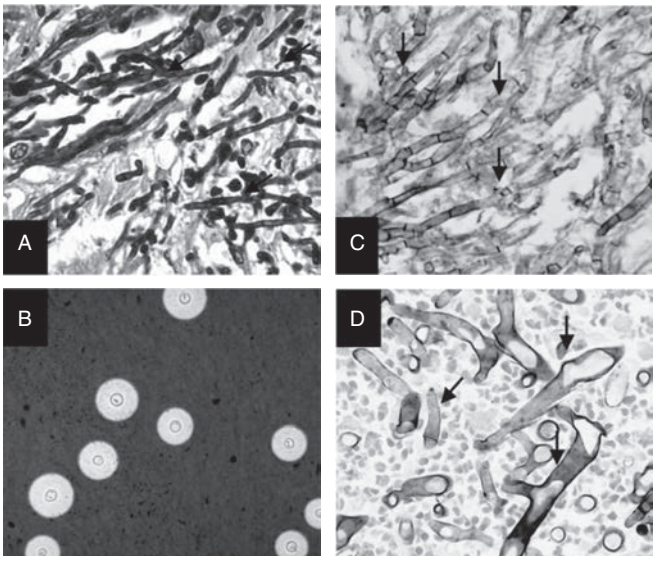

FIGURE 84–3. Opportunistic mycoses in clinical samples. **(A)** Candidiasis (tissue). **(B)** Cryptococcosis (India ink stain of CSF). **(C)** Aspergillosis (tissue). **(D)** Mucormycosis (tissue).

Patient Encounter 2, Part 1: Invasive Candidiasis

A 48-year-old man recovering in the surgical ICU following an abdominal gunshot wound and diffuse peritonitis develops fever while receiving broad-spectrum antibacterial therapy (meropenem 1 g every 8 hours and vancomycin 1 g every 12 hours). The patient has a central venous catheter and a Foley catheter. Blood cultures are negative at the time, but the patient has yeast growing in the sputum and urine. A serum (1→3)-β-D-glucan test is positive at 120 pg/mL (80 ng/L). Laboratory studies reveal a white blood cell count of 13,200 cells/mm^3 (13.2 × 10^9/L).

What are this patient's risk factors for developing an invasive fungal infection?

What evidence suggests this patient has an invasive fungal infection despite negative blood cultures?

If antifungal therapy is empirically started in this patient, what information should be considered?

the most susceptible to commonly used antifungals including fluconazole.[23] Like *C. albicans*, *C. tropicalis* is a relatively virulent species associated with the highest mortality rates, but has similar susceptibility profiles as *C. albicans*. *C. parapsilosis* is a less virulent species seen frequently in neonates and in adults with central venous catheters. However, many *C. parapsilosis* isolates form thick biofilms on prosthetic materials and catheters that make the organism difficult to eradicate. *C. parapsilosis* is generally susceptible to most antifungals, including fluconazole, although mean inhibitory concentrations (MICs) for echinocandins are higher than for other *Candida* species. *C. krusei* is uniformly resistant to fluconazole, although most isolates retain susceptibility to voriconazole and posaconazole. *C. auris* is an emerging highly virulent, multi-drug resistant pathogen that has been associated with infection outbreaks in hospitals and nursing homes.[24] A major problem with *C. auris* is frequent misidentification by automated systems used by many clinical microbiological laboratories, potentially resulting in the patient getting the wrong treatment. Therefore, specialized methods have been proposed for detection and identification of *C. auris* in health care facilities.[24]

C. glabrata may present as a breakthrough infection on fluconazole prophylaxis, and is becoming increasingly resistant to echinocandins.[18] Although *C. glabrata* is generally less virulent than other *C. albicans*, infections with this organism are typically seen in older patients with poor performance status, and therefore mortality remains high. The marginal susceptibility of *C. glabrata* to fluconazole and increasing echinocandin resistance[25,26] has fueled a growing clinical need for susceptibility testing of this species, as some isolates may demonstrate resistance to multiple antifungal classes. Generally, fluconazole-resistant strains of *C. glabrata* should be assumed to be cross-resistant to other triazoles.

TREATMENT

Seven antifungals (amphotericin B, fluconazole, voriconazole, isavuconazole, caspofungin, micafungin, and anidulafungin) have been studied as monotherapy in prospective, randomized comparative clinical trials for the treatment of invasive candidiasis. In a patient-level meta-analysis of several of these trials, increased patient age, elevated APACHE II score, use

of immunosuppressive therapy, and infection with *Candida tropicalis* were independent risk factors for mortality.[27] (See Table 84–4.) On the other hand, removal of central venous catheters in patients with candidemia and treatment with an echinocandin were variables associated with reduced patient mortality. It is also recommended that all patients with candidemia should undergo an eye examination to rule out *Candida* endophthalmitis, which can be sight threatening if not recognized early and may require direct installation of antifungal therapy for adequate treatment.[21] KEY CONCEPT Based on these findings and treatment guidelines endorsed by the Infectious Diseases Society of America, echinocandins are recommended as the preferred initial treatment for invasive bloodstream candidiasis, even less "critically-ill" patients.[21] Timely initiation of antifungal therapy for invasive candidiasis is critical, as any delay in the initiation of antifungal therapy once a patient has a positive blood culture increases the potential for metastatic seeding of organs and mortality. Clinically stable patients can

LO 2

Table 84–4

Therapeutic Approach to Opportunistic Invasive Fungal Infections

Mycoses	Recommended Treatment Regimens	Comments
Candidiasis		
Catheter-related and acute hematogenous	Fluconazole 12 mg/kg loading dose, then 6–12 mg/kg/day IV every 24 hours (400–800 mg/day) adjusted for renal function[a] OR Echinocandin[b] OR Voriconazole 6 mg/kg every 12 hours IV for 1 day, then 3 mg/kg every 12 hours IV *Second line:* Lipid amphotericin B formulation 3–5 mg/kg /day[c] OR Amphotericin B 0.7 mg/kg/day IV OR Amphotericin B + fluconazole	Treat for 14 days after the last positive blood culture and resolution of signs and symptoms; catheter should be removed whenever possible. Patients can be switched to oral fluconazole when clinically stable if isolate is susceptible. Echinocandins and amphotericin B are preferred agents for fluconazole-resistant species. Voriconazole appears to be effective against fluconazole-resistant *C. krusei*.
Empirical therapy in neutropenic patient	Fluconazole 6–12 mg/kg/day (low risk) adjusted for renal function[a] OR Liposomal amphotericin B 3 mg/kg every 24 hours OR Echinocandin OR Amphotericin B 0.7 mg/kg every 24 hours	Antifungals with coverage of *Aspergillus* spp. should be used in higher risk patients or prolonged neutropenia (ie, > 2 weeks).
Urinary candidiasis	Fluconazole 200 mg IV or orally for 7–14 days OR Amphotericin B 0.3 mg/kg/day IV for 1–7 days	Asymptomatic candiduria does not require therapy.
Cryptococcosis		
Pulmonary-Isolated	Fluconazole 6 mg/kg/day IV or PO for 6–12 months adjusted for renal function[a]	
Severe Pulmonary Infection and Meningitis	*Induction:* Amphotericin B 1 mg/kg/day + flucytosine 100 mg/kg/day orally divided every 6 hours for 2 weeks adjusted for renal function[c] *Consolidation:* Fluconazole 6–12 mg/kg/day for 10 weeks adjusted for renal function[a] *Second line:* Fluconazole + flucytosine for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a,c] OR Amphotericin + fluconazole for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a] OR Liposomal amphotericin B 5 mg/kg/day for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a]	Therapeutic drug monitoring is required for safe use of flucytosine, see Table 84–3. Echinocandins have no activity against cryptococci. Use of flucytosine-amphotericin B combination therapy was associated with faster CSF sterilization and improved survival. Similar benefits were not observed with combination fluconazole-amphotericin B regimens.

(*Continued*)

Table 84–4

Therapeutic Approach to Opportunistic Invasive Fungal Infections (*Continued*)

Mycoses	Recommended Treatment Regimens	Comments
Aspergillosis	Voriconazole 6 mg/kg IV every 12 hours × 2 doses, then 4 mg/kg IV every 12 hours Voriconazole 4 mg/kg oral every 12 hours OR Isavuconazole 300 mg (372 mg of isavuconazonium prodrug) every 8 hours for two days, then 300 (372 mg isavuconazonium prodrug) daily *ALTERNATIVES* Lipid formulations of amphotericin B OR Echinocandin[b] OR Posaconazole 300 mg every 12 hours IV day 1, then 300 mg IV daily Posaconazole delayed-release tablet 300 mg twice daily, day 1, then 300 mg daily Posaconazole suspension 200 mg by mouth four times daily for 14 days, then 400 mg PO twice daily OR Combination therapy, typically echinocandin plus triazole	Voriconazole can be administered as oral therapy in patients taking oral medications. However, patients with suspected aspergillosis should initially be stated on IV therapy. Therapeutic drug monitoring should be considered in patients receiving voriconazole (any formulation) or posaconazole suspension, see Table 84–3. Posaconazole tablets and IV formulations have less pharmacokinetic variability but some patients may still benefit from TDM. Combination therapy with triazole and echinocandin associated with improved survival in patients with galactomannan-diagnosed infection. *A. terreus* and *A. flavus* should be considered resistant to amphotericin B.

[a]Fluconazole renal dosing adjustments: CrCl > 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl < 10 mL/min (0.17 mL/s) 50%.

[b]Anidulafungin 200 mg loading dose day 1, then 100 mg daily, caspofungin 70 mg loading dose day 1, then 50 mg daily; or micafungin 100 mg daily.

[c]Flucytosine renal dosing adjustments: CrCl > 50–90 mL/min (0.83–1.50 mL/s), 25 mg/kg every 12 hours; CrCl 10–50 mL/min (0.17–0.83 mL/s), 25 mg/kg every 12–24 hours; CrCl < 10 mL/min (0.17 mL/s) 25 mg/kg every 24 hours. Therapeutic drug monitoring is required for safe use of flucytosine (see Table 84–3).

CSF, cerebrospinal fluid; IV, intravenous; PO, oral; TDM, therapeutic drug monitoring.

be transitioned to oral fluconazole or other triazoles once the infecting isolate has been identified and susceptibility is known.[28]

The efficacy of echinocandins for deep-tissue candidiasis is less well established compared to bloodstream infections, and higher failure rates were reported for infections located in anatomical sites where echinocandin penetration is limited (ie, meninges, endophthalmitis, urine).[29] For other forms of deep tissue candidiasis, triazoles or lipid amphotericin B formulation may be preferable as initial therapy until diagnosis and culture results are available, depending on the suspected organs involved and the clinical severity of illness.[21] Frequently patients are transitioned to oral triazole therapy once stable because of the long-treatment courses that are often required (4–6 weeks minimum) for deep-seated infections.

An important caveat for echinocandin treatment is that cryptococcosis, endemic fungi, or other rare yeast (eg, *Trichosporon* species) occasionally produce fungemia in lymphopenic patients that may initially be mistakenly assumed to be *Candida*. Therefore, initial treatment with a lipid amphotericin B formulation may be judicious in profoundly lymphopenic patients (ie, $CD4^+ < 250/mm^3$ [250×10^6/L]) with yeast in blood cultures until fungal identification is confirmed, as echinocandins have poor activity against non-*Candida* yeast.

LO 2

Echinocandins (ie, caspofungin, micafungin, or anidulafungin); voriconazole; or lipid amphotericin B formulation are often administered as empiric treatment for *Candida* spp. in patients with prolonged neutropenia (ie, absolute neutrophil count < 500 PMN/mm^3 [500×10^6/L] for > 7 days) with fever.[21] (See Table 84–4.) Fluconazole may be an acceptable option in patients expected to have short duration of neutropenia (< 2 weeks) not receiving systemic antifungal prophylaxis with a triazole. Lipid amphotericin B formulations, an echinocandin, or voriconazole are preferred if the patient has or is expected to have prolonged neutropenia (ie, > 2 weeks) because of the increased risk for mold infections. If patients are receiving fluconazole prophylaxis, breakthrough infections with *C. glabrata*, and less frequently *C. krusei*, are possible and should be initially treatable with an echinocandin or amphotericin B.

Urinary candidiasis is a term for group of syndromes that can range from benign colonization (candiduria) in the bladder to invasive disease of the renal parenchyma. Isolation of *Candida* in the urine from nonneutropenic patients does not require antifungal therapy, as transient clearance of *Candida* from the urine has no demonstrable clinical benefit.[21] Patients should receive 7 to 14 days of antifungal therapy for urinary candidiasis if they are (a) symptomatic, (b) have clinical or laboratory evidence of infection, (c) are neutropenic, (d) are low-birth-weight infants; (e) will undergo urologic manipulations, or (f) have renal allografts. Removal of urinary tract instruments, including Foley catheters and stents, is essential to prevent relapse. The preferred therapy is fluconazole 200 mg daily, although IV amphotericin B deoxycholate 0.3 to 1 mg/kg/day is

Patient Encounter 2, Part 2: Invasive Candidiasis

The patient was started on fluconazole 400 mg/d, but 4 days later has persistent fever and develops hypotension and decreased urine output. Blood cultures are now growing a germ tube–negative yeast. Laboratory studies revealed a white blood cell count of 14,200/mm^3 (14.2 × 10^9/L), aspartate aminotransferase 68 IU/L (1.13 µkat/L), alanine aminotransferase 75 IU/L (1.25 µkat/L), alkaline phosphatase 168 IU/L (2.80 µkat/L), and normal bilirubin. Serum creatinine has increased from 1.2 to 1.8 mg/dL (106–159 µmol/L) over the last 3 days.

What factors suggest empiric antifungal therapy should be changed in this patient?

What other procedures should be recommended in this patient to improve management and response to antifungal therapy?

also effective. Other antifungal agents (except for flucytosine) do not achieve appreciable concentrations in the urine and therefore should not be considered first-line treatments for urinary candidiasis.[29] Irrigation with amphotericin B is not effective for infections above the bladder and should not be used in higher-risk patients except for its use as a diagnostic tool for confirming a localized infection of the bladder. *Candida* infections of the renal parenchyma secondary to metastatic seeding from the bloodstream are treated in a similar fashion to candidemia.

Oral candidiasis (thrush) is not an invasive disease and can be treated with topical azoles (clotrimazole troches), oral fluconazole, or oral polyenes (such as nystatin or oral amphotericin B). Orally administered and absorbed azoles (fluconazole, voriconazole, or itraconazole solution), amphotericin B suspension, IV echinocandins, or IV amphotericin B are recommended for refractory or recurrent infections.

Although more severe than mucocutaneous candidiasis, esophageal candidiasis typically does not evolve into a life-threatening infection unless the esophagus is ruptured. However, topical therapy is ineffective. Triazole antifungals (fluconazole, itraconazole solution, or voriconazole), echinocandins, or IV amphotericin B (in cases of unresponsive infections because of antifungal resistance, most commonly to fluconzole) are effective treatment options. Parenteral therapy should be used in patients who are unable to take oral medications.

OUTCOME EVALUATION

The outcome of invasive candidiasis is influenced by the timely administration of appropriately dosed antifungal therapy appropriate for the *Candida* species isolated, as well as early source control (eg, removal of infected catheters) which reduces the risk of progression to sepsis. To ensure appropriate and cost-effective use of diagnostics and treatments for invasive candidiasis, some institutions have devised "*Candida* treatment bundles" to ensure logical evidence-based interventions in the management of invasive candidiasis and support antifungal stewardship. Examples of elements of treatment bundles for invasive candidiasis are highlighted at the end of the chapter (see Patient Care Process section).

PROPHYLAXIS

Prophylaxis for invasive candida infections has been evaluated in high-risk populations such as those with neutropenia, hematopoietic stem cell transplant, or non-neutropenic patients requiring hospitalization in an intensive care unit. Fluconazole (400 mg/day) has been studied as a prophylactic regimen to prevent invasive candidiasis in patients with prolonged (> 2 weeks) neutropenia.[21] Placebo-controlled, prospective randomized trials performed in the 1990s demonstrated that fluconazole was effective in reducing the frequency, morbidity, and, in some trials, mortality due to invasive candidiasis in neutropenic patients if administered until marrow recovery. However, the major limitation with fluconazole is its lack of mold coverage needed for high-risk patients with prolonged (ie, > 3 weeks) neutropenia. Itraconazole, voriconazole, posaconazole, and the echinocandin micafungin have demonstrated a benefit in reducing the incidence of invasive candidiasis when used for prophylaxis in hematopoietic cell transplant recipients until engraftment; however, all of the drugs have limitations with respect to prolonged administration in high-risk patients. Therefore, the approach toward antifungal prophylaxis is often institution-specific depending on the patient population, epidemiology of invasive fungal infections, and options for outpatient IV drug therapy.

LO 4

Use of antifungal prophylaxis for invasive candidiasis in non-neutropenic patients remains an area of controversy. Fluconazole prophylaxis has been shown to reduce the incidence but not necessarily mortality associated with invasive candidiasis in select high-risk transplant populations (eg, liver, pancreatic, or small-bowel transplantation) or subsets of ICU patients at high risk for infection (ie, neonatal intensive care).[21] Because prophylaxis can result in excessive antifungal use in lower-risk patients, many experts have advocated **preemptive** (ie, starting therapy based on biomarkers of infection such as serum β-glucan) or empirical (symptoms of infection) treatment approaches in this population instead of routine prophylaxis.

LO 2

A multiinstitutional prospective randomized trial of administering empirical fluconazole (800 mg/day versus placebo) in ICU patients with persistent fever failed to demonstrate significant benefits in reducing the incidence or mortality associated with invasive candidiasis.[30] Similarly, a recent multiinstitutional studies that focused on ICU patients identified as "high risk" for invasive candidiasis that administered either caspofungin[31] or micafungin[32] failed to demonstrate any mortality benefit. Therefore, many questions persist regarding the optimal approach for preventing or preemptive treating invasive candidiasis in non-neutropenic ICU patients.

CRYPTOCOCCOSIS

EPIDEMIOLOGY

Cryptococcus neoformans is an encapsulated yeast that can infect normal hosts but has historically been associated with severe infections in immunocompromised patients. *C. neoformans* is divided into two varieties based on serotype: *C. neoformans* var. *neoformans* (serotypes a and d) that is associated with infections in immunocompromised patients, and *C. neoformans* var. *gattii* (serotypes b and c) that is associated with infections in healthy hosts. *C. neoformans* var. *gattii* is found predominantly in tropical and subtropical climates with eucalyptus trees, and has been linked to infectious outbreaks around Vancouver Island and the US Pacific Northwest. *C. neoformans* var. *neoformans* is found

worldwide and is associated with pigeon droppings and other avian excreta. Before the AIDS pandemic, cryptococcosis was a relatively uncommon disease, but became a leading cause of meningitis among HIV-infected patients. Although the incidence of cryptococcal meningitis has declined in developed countries with the widespread use of highly active antiretroviral therapy (HAART), *C. neoformans* remains an important pathogen in the developing regions with high rates of AIDS and in immunocompromised patients, including transplant and cancer patients, who may present with initially indolent pulmonary forms of the infection.

LO 1

CLINICAL PRESENTATION AND DIAGNOSIS

C. neoformans is acquired primarily through inhalation of the desiccated yeast particles found in the environment. Inhaled cells reach distal alveolar spaces where they gradually rehydrate and form a polysaccharide capsule that is resistant to phagocytosis. Defects in cellular immunity allow reconstitution of the protective capsule and multiplication of yeast in the lungs. Although alveolar macrophages phagocytose the yeast, containment and killing require a coordinated response between innate and adaptive humoral (complement and anti-cryptococcal antibodies) and T-cell–mediated host responses.[6] Deficiencies in host cell-mediated immunity allow the yeast to survive as a **facultative** intracellular pathogen in macrophages as they migrate from the lung to draining lymph nodes, leading to dissemination via the bloodstream to the meninges.

Unlike most opportunistic fungi, true virulence factors have been identified for *C. neoformans*. The capsules, including the soluble polysaccharides released from the yeast cells during infection, impair phagocytosis and binding of anti-cryptococcal antibodies. Primary cryptococcal infection begins in the lung, presenting as a mildly symptomatic or asymptomatic infection that resolves spontaneously or undergoes encapsulation in noncalcified lung nodules. These isolated nodules may be detected on chest x-rays during routine workup and aspirated or removed because of concerns for lung cancer.

In the immunocompromised host, infection of the lung may present with more diffuse, bilateral, and interstitial disease that mimics the presentation of *P. jiroveci (carinii)* pneumonia (PCP). Dissemination to other organs, particularly the CNS, eye, and possibly the skin, is more likely to occur in patients with severe deficits in cell-mediated immunity. Fever, cough, dyspnea, and pleural pain are common at presentation, with accompanying hypoxemia that can rapidly evolve to acute respiratory failure. Because the features of diffuse pulmonary cryptococcosis overlap with other opportunistic pathogens, early diagnosis requires bronchoalveolar lavage or transbronchial biopsy, which can effectively diagnose 80% to 100% of cases.[33] The clinical course of diffuse cryptococcal pneumonia can be as severe as PCP, with mortality rates approaching 100% in untreated patients by 48 hours.

C. neoformans readily disseminates from the lung to the CNS, specifically the leptomeninges, and occasionally the parenchyma of the brain. The clinical characteristics of cryptococcal meningitis differ somewhat, however, between patients with and without underlying AIDS. In patients without AIDS, disease presentation is more insidious, and symptoms such as dizziness, irritability, decreased comprehension, and unstable gait may present many weeks to months before the diagnosis is established. Patients with AIDS generally present much later in the course of disease with severe meningoencephalitis.[33] The most common signs and symptoms on presentation are fever, headache, **meningismus**, photophobia, mental status changes, and seizures. CT or more tissue-sensitive imaging techniques such as magnetic resonance imaging (MRI) may reveal cerebral edema, multiple areas of enhanced nodules, or a single mass lesion (cryptococcoma). Examination of the cerebrospinal fluid (CSF) often reveals increased opening pressure upon lumbar puncture, but glucose, protein, and leukocyte levels can be normal.[33]

LABORATORY DIAGNOSIS

Clinical diagnosis is confirmed by cultures from the blood, CSF, or other clinically relevant fluids or tissue. *C. neoformans* can be directly visualized in the CSF when stained with India Ink, which is excluded by the yeast capsule (**Figure 84–3B**). However, infection is most frequently diagnosed by detection of cryptococcal antigen in either serum or CSF, which has high sensitivity and specificity (> 95%) and correlates with fungal burden.[33] A positive serum antigen test of greater than 1:4 strongly suggests cryptococcal infection, and greater than or equal to 1:8 is indicative of active disease. Antigen titers in serum are positive in 99% of patients with cryptococcal meningitis and often exceed 1:2048 in patients with AIDS.[33] However, the time course of cryptococcal antigen elimination is unknown, and a positive test result can persist for many years. Changes in the CSF cryptococcal antigen titers have limited value in the monitoring of drug therapy for cryptococcal meningitis, although it is expected that a decrease should be seen after 2 or more weeks of antifungal therapy.[33]

TREATMENT

Cryptococcal meningitis is fatal if left untreated. Because pneumonia frequently precedes dissemination of disease and subsequent meningitis, all patients with culture-, histopathology-, or serology-proven disease should receive antifungal therapy. In patients with isolated pulmonary cryptococcosis, fluconazole is generally considered to be the therapy of choice (see Table 84–2).[33] Alternatively, itraconazole, voriconazole, or combination therapy (fluconazole plus flucytosine) has also been used with some success, but these regimens are generally considered inferior to amphotericin B and are recommended only for persons unable to tolerate or unresponsive to standard treatment. Echinocandins do not have activity against *C. neoformans*.

Disseminated or CNS cryptococcosis requires a more aggressive treatment approach. Pretreatment predictors of a poor prognosis include:

- Progressive underlying disease or immune dysfunction
- Abnormal mental status at the time of presentation
- Increased opening pressure on lumbar puncture (> 260 mm H_2O [2.55 kPa])
- High fungal burden as reflected by a CSF antigen titer (in AIDS patients) of greater than 1:2048

LO 2

Clinical trials performed by the National Institute of Allergy and Infectious Diseases (NIAID) Mycoses Study Group defined the standard treatment regimen for cryptococcal meningitis consisting of 2 weeks of induction antifungal therapy with combination amphotericin B (0.7 mg/kg/day) plus flucytosine (100 mg/kg/day) for cryptococcal meningitis, followed by consolidation therapy with fluconazole (400 mg daily) for 8 weeks (see Table 84–2).[33] However, other combinations of either fluconazole plus flucytosine, or fluconazole plus amphotericin B were sometimes recommended due to difficulties in obtaining flucytosine (especially in developing countries) and toxicity (see Table 84–2).

KEY CONCEPT In a landmark study addressing which combination is best for cryptococcal meningitis, significantly fewer deaths were

observed in patients receiving amphotericin B plus flucytosine compared to patients receiving amphotericin B alone, or a combination of amphotericin B plus fluconazole.[34] Notably, the amphotericin B–flucytosine combination was associated with more rapid clearance of yeast from the CSF versus other regimens.

PROPHYLAXIS

LO 4

Fluconazole (200 mg/day) is recommended as maintenance therapy for life in patients with persistent underlying immune dysfunction to prevent recurrent cryptococcal meningitis.[33] Available data suggest it is safe to discontinue maintenance therapy in AIDS patients who have had a sustained immunologic response on effective antiretroviral therapy (ie, $CD4^+$ count greater than 100 cells/microliter [100×10^6/L] with undetectable or very low viral RNA) if they have received at least 12 months of antifungal therapy.[33] Occasionally, initiation of HAART can result in the reactivation of a subclinical, immunologic manifestation of cryptococcal infection (or other opportunistic infections). Manifestations of this **immune reconstitution inflammatory syndrome (IRIS)** may include exacerbations of meningitis or necrotizing pneumonia. Antifungal therapy plus a nonsteroidal anti-inflammatory agent or prednisone has been used successfully in patients with cryptococcal-associated IRIS.[35] However, there are few studies that have evaluated treatment options for control of IRIS.

INVASIVE ASPERGILLOSIS

EPIDEMIOLOGY

KEY CONCEPT Invasive molds, most frequently due to *Aspergillus* species but occasionally caused by *Fusarium* spp, or Mucorales may cause infection in patients undergoing intensive cancer chemotherapy required for hematologic malignancies, and prolonged immunosuppression following hematopoietic and solid organ transplantation.[36] The four most common *Aspergillus* species that cause invasive infection in humans are: *Aspergillus fumigatus*, *Aspergillus flavus*, *Aspergillus terreus*, and *Aspergillus niger*. Of these four species, *A. fumigatus* accounts for most infections. However, identification of *Aspergillus* mold in culture to the species level when cultures are available is still important because *Aspergillus terreus* and *Aspergillus flavus* display relatively higher MICs (resistance) to amphotericin B. Additionally, less common mold infections such as fusariosis and mucormycosis often present with similar clinical and radiographic features as aspergillosis, but require different treatment approaches due to their inherent resistance to many antifungal agents. Early and accurate diagnosis of IA improves the outcome of infection, reducing mortality rates by 30% to 50% with the timely administration of effective antifungal therapy.[36]

CLINICAL PRESENTATION AND DIAGNOSIS

The pathogenesis of IA is defined largely by the underlying immune dysfunction of the host. The most common route of acquisition for *Aspergillus* is through the respiratory tract. Conidia dispersed in air currents are continuously inhaled through the sinuses and mouth and penetrate down to distal alveolar spaces (see **Figure 84–4**). Most conidia are rapidly phagocytosed and removed by resident macrophages and neutrophils in the upper and lower respiratory tract.[6] However, macrophage function may be suppressed following transplantation, cytotoxic chemotherapy, or in patients who have received high-dose corticosteroid therapy. Conidia that escape phagocytosis begin to germinate into hyphal forms that invade blood vessels or contiguous tissues or bone (in sinuses), resulting in hemorrhage and/or infarction and coagulative

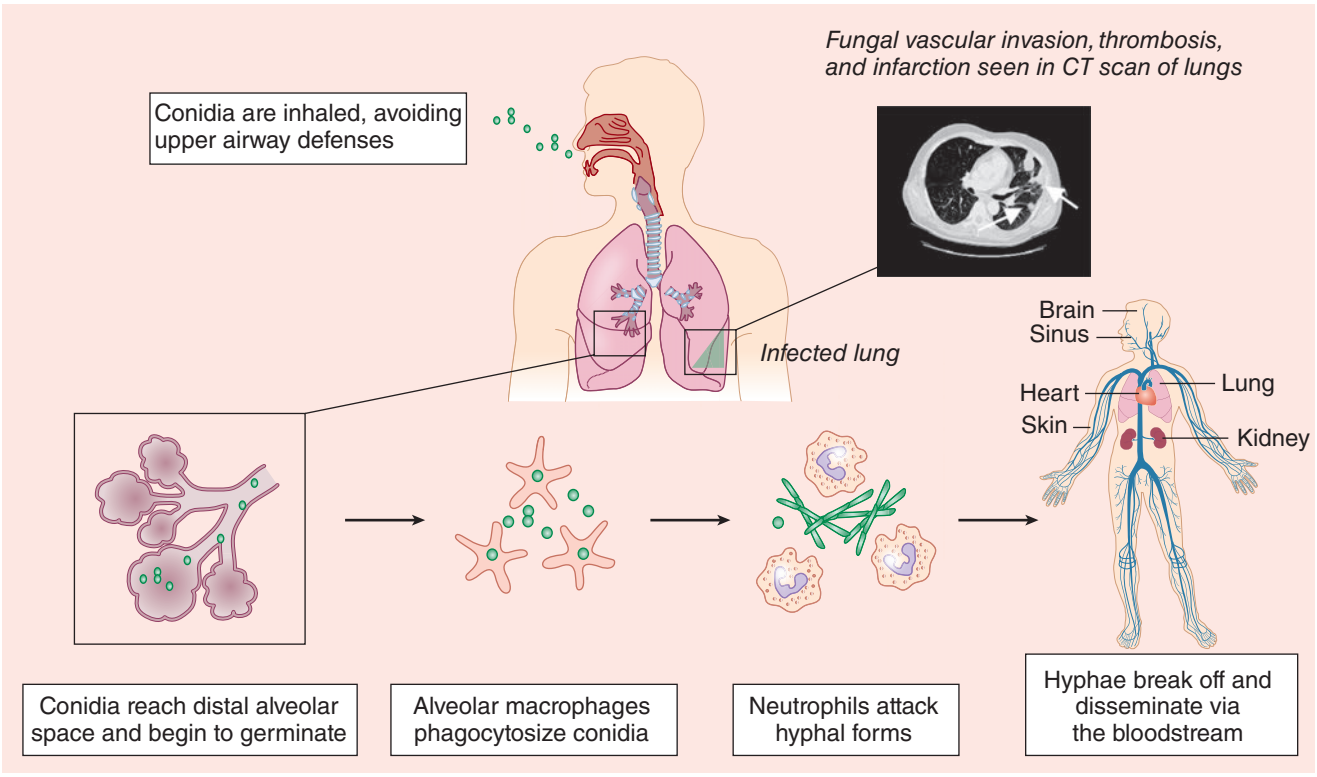

FIGURE 84–4. Pathogenesis of invasive aspergillosis (IA).

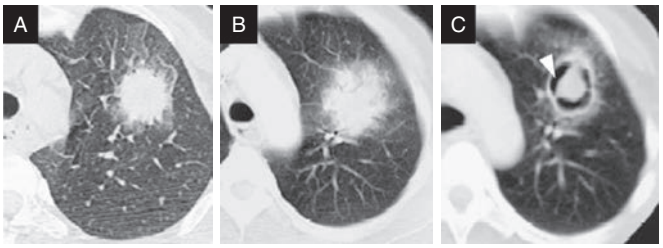

FIGURE 84–5. Radiographic evolution of invasive pulmonary aspergillosis in a neutropenic patient. **(A)** Early halo sign of ground glass opacity surrounding nodular lesions. **(B)** Nonspecific infiltrate of increased diameter. **(C)** Air crescent sign observed with neutrophil recovery, cavitation of infected lung in walled off cavity with air (*arrowhead*).

necrosis. Once in the bloodstream, viable hyphal fragments can break off and disseminate to distal organs including the brain. Control of the infection at this stage requires development of an adaptive T-helper cell type 1 (TH1) or type 17 (TH17) response to enhance the fungicidal activity of neutrophils against hyphal elements.[6] Patients with dysregulated, suppressed T-cell–mediated immunity, or prolonged neutropenia are unable to control fungal growth and are at high risk for dissemination of the infection to other organs including the brain. Without early diagnosis and antifungal therapy, IA in persistently immunosuppressed patients is uniformly fatal.

Signs and symptoms of IA are often subtle in the immunocompromised host. Fever is common but nonspecific for infection and may be accompanied by pleuritic chest pain, cough, hemoptysis, and/or friction rub.[36] Neurologic signs, including seizures, hemiparesis, and stupor, may be present in patients with dissemination to the brain. Cutaneous plaques or papules characterized by a central necrotic ulcer or eschar occur in up to 10% of patients with disseminated disease; however, concomitant blood cultures are often negative. Chest radiographs cannot detect early forms of disease and may remain negative in up to 10% of patients within 1 week of death. Nodular lesions detected by high-resolution computed tomography (HRCT), along with fever, are often the first indication of invasive pulmonary aspergillosis in severely immunocompromised patients. CT images of the lung often reveal wedge-shaped or nodular lesions, surrounded by intermediate attenuation called the "halo sign" (Figure 84–5). These early lesions on CT scans represent hemorrhage and edema surrounding an infarcted blood vessel. Despite "effective" antifungal therapy, lesions on CT scan may continue to increase in size in neutropenic patients until neutrophil counts recover, at which time they begin to cavitate, forming the "air-crescent sign" on chest radiographs, indicative of resolving infection. Immunocompromised patients on fluconazole with progressive sinus or pulmonary disease by radiography should be considered to have a possible mold infection and receive antifungal therapy directed (at minimum) against *Aspergillus* species.

LABORATORY DIAGNOSIS

Like other invasive mycoses, definitive diagnosis of aspergillosis requires histopathologic evidence of hyphal invasion in tissue (see Figure 84–3C and D). However, procedures needed to establish a definitive diagnosis by sampling of suspicious lesions (eg, fine-needle aspiration or open-lung thoracoscopic biopsy) are not feasible in many patients with underlying thrombocytopenia secondary to hematologic malignancies or chemotherapy. Even if **hyphae** are observed in tissue, histopathology alone cannot distinguish *Aspergillus* from other angioinvasive septate molds, such as *Fusarium*, which have different patterns of antifungal susceptibility (see Table 84–1). Therefore, respiratory and/or wound cultures (if cutaneous or sinus/hard palate lesions are present) are important factors in the modification of empiric antifungal therapy.

Respiratory cultures, including sputum, bronchial washings, or bronchoalveolar lavage, have a low sensitivity for diagnosis of IA but a higher positive predictive value in severely immunocompromised patients. Therefore, a negative bronchoalveolar lavage culture does not rule out invasive pulmonary aspergillosis, but a positive culture in a high-risk patient (eg, allogeneic hematopoietic cell transplant patients) indicates pulmonary aspergillosis in at least 60% to 80% of such patients. Blood cultures have little diagnostic value for IA, but may reflect true disease with *A. terreus.* Patients with limited lung involvement or on prophylactic or empiric antifungal therapy may continue to be culture-negative for *Aspergillus* species, despite the appearance of progressing disease. Therefore, negative cultures are never the sole indication for stopping antifungal therapy in patients with suspected or proven aspergillosis.

In the past, antifungal susceptibility testing was not routinely recommended for *Aspergillus* spp. in treatment guidelines because of limited data to support the recommendation. *Aspergillus terreus* and *A. flavus* were the major concerns because of their intrinsic resistance to amphotericin B. However, more recently multi-triazole-resistant *Aspergillus fumigatus* spp. have been reported in China, Canada, the United States, and several European countries, with especially high levels in the Netherlands and

Patient Encounter 3: Invasive Aspergillosis

A 52-year-old man with acute myeloid leukemia who received a matched-allogeneic donor hematopoietic stem-cell transplantation presents to the clinic 70 days after transplant with complaints of fever. On laboratory examination, he is noted to have an alanine aminotransferase of 119 IU/L (1.98 µkat/L), aspartate aminotransferase 107 IU/L (1.78 µkat/L), and total bilirubin of 1.8 mg/dL (31 µmol/L). The patient has an absolute neutrophil count of 970 (970×10^6/L). His current medications include tacrolimus 5 mg twice daily (most recent level: 9 ng/mL [9 mcg/L; 11 nmol/L]), prednisone 10 mg daily, levofloxacin 500 mg daily, fluconazole 200 mg/d, valacyclovir 500 mg twice daily. A CT scan of the chest reveals a single dense pleural-based lung nodule in the left lung. A serum galactomannan test is reported to be negative (index 0.4, positive when > 0.5). The primary service wishes to start voriconazole.

What are the patient's risk factors and signs that suggest he has an invasive fungal infection?

What problems need to be anticipated in this patient if voriconazole is started?

If the patient's infection appears to resolve and he continues to take voriconazole for months while tapering immunosuppression, what are some of the toxicities potentially associated with prolonged voriconazole therapy?

United Kingdom.[37] These trends suggest that MIC testing (when isolates can be grown from patient) may be increasingly necessary to confirm susceptibility to first-line antifungal treatments.

Considerable effort has been focused in the last decade to develop non–culture-based laboratory methods (antigen detection, polymerase chain reaction [PCR]) for the diagnosis of IA. The hope is that these surrogate tests could detect early evidence of *Aspergillus* infection before significant target organ damage eventually detected by CT scans occurs. Currently, most centers use an ELISA-based assay for the detection of a polysaccharide component of the *Aspergillus* cell wall called galactomannan. Although several large prospective studies have found that the sensitivity and specificity of the assay approaches 90% in neutropenic patients with hematologic malignancies, the median time span between galactomannan detection and clinical signs and symptoms of IA averages less than 6 days. The sensitivity of the galactomannan may be enhanced if the test is performed on bronchial lavage fluid collected during bronchoscopy. Other factors such as patient immune status (higher sensitivity in neutropenic vs. non-neutropenic patients) antibacterial therapy, antifungal prophylaxis, and diet may affect the sensitivity and specificity of the galactomannan test.[36] For example, false-positive results are reported more frequently in pediatrics, following the ingestion of certain cereals, pastas, nutritional supplements, or soy sauce. Piperacillin-tazobactam therapy was also associated with false-positive galactomannan tests in the past, but more recent studies have suggested that galactomannan-contamination of the antibiotic is now uncommon.[38]

Increasing galactomannan levels are a harbinger of breakthrough infection, and declining galactomannan concentrations are an early indicator of response to treatment. However, antifungal therapy is rarely stopped in patients once the serum galactomannan becomes negative, especially in persistently immunosuppressed patients. Hence, the galactomannan test and other non–culture-based strategies, such as serum β-glucan, which can also be detected during *Aspergillus* infection, serve as complementary methods to confirm results from microbiologic, histopathologic, and radiographic investigations directed toward diagnosing IA.[39]

TREATMENT

LO 2

Four comparative randomized controlled clinical trials have evaluated antifungal therapies for the treatment of diagnosis-proven IA. Voriconazole or isavuconazole are considered in consensus treatment guidelines to be the first-line antifungal for IA (see Table 84–2).[35] However, patients who are intolerant to triazoles, have ongoing hepatotoxicity issues, or have received voriconazole or posaconazole prophylaxis in the recent past may initially be treated with a liposomal amphotericin B formulation. Lipid amphotericin B formulations are recommended over echinocandins because of their better coverage of Mucorales molds which sometimes breakthrough on *Aspergillus*-active therapy because of their intrinsically higher resistance to voriconazole and other antifungals. Echinocandins are not typically recommended as a frontline monotherapy regimen for invasive aspergillosis due to poorer responses rates in nonrandomized trials compared to triazoles.[40] Once the infection has stabilized and diagnosis is clarified, patients can be transitioned back to an intravenous or oral triazole for the completion of therapy.

Isavuconazole is a newer triazole unique from other agents because it is administered as a prodrug, isavuconazonium, which is rapidly cleaved in vivo to the active drug (isavuconazole) and an inactive prodrug cleavage product (BAL8728). In a phase 3 trial, patients with proven or probable aspergillosis treated with isavuconazole achieved similar clinical response rates as a standard voriconazole regimen, but with significantly fewer hepatic, skin, and visual adverse effects.[9] Isavuconazole has also been reported to be as effective and amphotericin B–based treatment for mucormycosis. Therefore, isavuconazole appears to be a promising alternative to voriconazole for the treatment of IA.

Multiple studies in vitro and in animal models, as well as small clinical studies have suggested that administration of an echinocandin with a triazole such as voriconazole may be synergistic and improve survival in IA over monotherapy, but prospective clinical studies, until recently, have been lacking. A multicenter, randomized clinical trial comparing voriconazole-anidulafungin combination therapy to voriconazole monotherapy for proven or probable aspergillosis reported a trend in improved 6-week survival for patients randomized to combination therapy, that was significant among a post-hoc analyzed group of patients whose disease was diagnosed with galactomannan antigen but not culture (reflecting patients with earlier-diagnosed disease).[38] Nevertheless, the failure of the study to meet its primary endpoint objective raises lingering questions about the efficacy of combination therapy, and many clinicians reserve the use of combination regimens for patients with extensive disease (ie, multifocal or bilateral pneumonia, disseminated infection) or in cases of suspected breakthrough infection.

PROPHYLAXIS

LO 4

Primary antifungal prophylaxis against *Aspergillus* is recommended in guidelines for some groups of patients with baseline risk of IA that approaches or exceeds 10%. These subgroups typically include patients with acute myeloid leukemia undergoing remission induction chemotherapy, or allogeneic hematopoietic stem cell transplants with graft versus host disease. Depending on the institution and local epidemiology, other groups of patients may also be considered candidates for prophylaxis. KEY CONCEPT Posaconazole was shown in two prospective randomized trials to reduce Aspergillus-associated death in patients with acute high-risk leukemia and reduce mold infections in patients with graft-versus-host disease following hematopoietic stem cell transplantation. Similar data are available for voriconazole, for HSCT, but no significant advantage was observed compared to standard fluconazole prophylaxis plus intensive galactomannan monitoring in the hematopoietic stem cell transplant patients.[41]

OUTCOME EVALUATION

LO 3

Response to antifungal therapy in invasive molds is slow and difficult to judge by clinical signs alone. Resolution of fever and eventual clearing of CT scans (in the case of lung infections) are indications of response to antifungal therapy. Toxicity associated with antifungal therapy is similar in these patients as in those described earlier. Patients who develop breakthrough infections on voriconazole should also undergo a careful clinical workup for other invasive mold pathogens such as mucormycosis (see Table 84–1), which are not susceptible to voriconazole. In most cases, antifungal therapy may be continued until immunosuppression has resolved.

Patient Care Process

Collect Information:

- Review the medical history, physical assessment findings, and recent laboratory results of the patient to assess current immunological status and organ function.
- Perform a medication history for use of prescription and nonprescription medications. Identify allergies to medications and other substances.

Assess the Information:

- Analyze patient's medication profile for potential drug interactions with triazole antifungals using an updated computerized drug interaction database.
- Confirm prescribed antifungal therapy is the appropriate spectrum for likely fungal pathogen(s).
- Review whether modifiable risk factors affecting treatment outcome (eg, timely administration of antifungal therapy, catheter removal in patients with invasive candidiasis) have been addressed.
- Ensure prescribed antifungal dose is appropriate for patient age, weight, renal, and/or hepatic function.

Develop a Care Plan:

- Confirm prescribed antifungal therapy is the appropriate spectrum for likely fungal pathogen(s).
- Ensure prescribed antifungal dose is appropriate for patient age, weight, renal, and/or hepatic function.
- Prepare a strategy for therapeutic drug monitoring (TDM) for antifungals with unpredictable pharmacokinetics (eg, itraconazole, voriconazole, and posaconazole suspension).
- Anticipate how antifungal therapy can be modified when culture results become available, intolerance to the drug of first choice, or if there is consideration of switching from IV to oral therapy.

Implement the Care Plan:

- Educate the patient about potential for medication adverse effects, importance of taking medications correctly, and potential for drug interactions.
- Review TDM results, microbiology and susceptibility information if available, and treatment response parameters to ensure patient is on correct antifungal at the best dose.
- Streamline antifungal therapy if possible and/or switch to oral therapy if patient is clinically stable.

Follow-up: Monitor and Evaluate:

- Monitor patient clinical, laboratory, and radiographic parameters to assess effectiveness and safety of therapy.
- Reevaluate potential for serious drug interactions.
- Consider TDM if patient has changes to medication profile, change in clinical status, or new-onset toxicity.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ARDS	Acute respiratory distress syndrome
CNS	Central nervous system
CrCl	Estimated creatinine clearance
CSF	Cerebrospinal fluid
CT	Computed tomography
CYP	Cytochrome P-450 isoenzyme
ELISA	Enzyme-linked immunosorbent assay
FISH	Fluorescent in situ hybridization
HAART	Highly active antiretroviral therapy
HRCT	High-resolution computed tomography
IA	Invasive aspergillosis
ICU	Intensive care unit
IRIS	Immune reconstitution inflammatory syndrome
IV	Intravenous
MALDI-TOF	Matrix-assisted laser desorption/ionization time of flight
MIC	Minimum inhibitory concentration
NIAID	National Institute of Allergy and Infectious Diseases
PCP	*Pneumocystis jiroveci (carinii)* pneumonia
PCR	Polymerase chain reaction
PMN	Polymorphonuclear cell
TDM	Therapeutic drug monitoring

85 Antimicrobial Prophylaxis in Surgery

Mary A. Ullman and John C. Rotschafer

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the impact of surgical site infections (SSIs) on patient outcomes and health care costs.
2. Name and differentiate the four different types of wound classifications.
3. Recognize at least three risk factors for postoperative SSIs.
4. Identify likely pathogens associated with different surgical operations.
5. Compare and contrast antimicrobials used for surgical prophylaxis and identify potential advantages and disadvantages for each antimicrobial.
6. Discuss the importance of β-lactam allergy screening and how this could impact resistance and health care costs.
7. Identify nonantimicrobial methods that can reduce the risk of postoperative infection.
8. Discuss the importance of antimicrobial timing, duration, and redosing in relation to antimicrobial prophylaxis in surgery.
9. Recommend appropriate prophylactic antimicrobial(s) given in a surgical operation.

INTRODUCTION

KEY CONCEPT

Surgical site infections (SSIs) are a significant cause of morbidity and mortality. Data from the National Healthcare Safety Network (NHSN) showed an SSI rate of 1.9% for surgical procedures performed in the United States.[1–3] Rates may be higher than this percentage as half of SSIs are diagnosed after discharge.[1–3]

SSIs negatively affect patient outcomes and increase health care costs. Patients who develop SSIs are five times more likely to be readmitted to the hospital and have twice the mortality of patients who do not develop an SSI.[2] A patient with an SSI is also 60% more likely to be admitted to an ICU.[2] SSIs lengthen hospital stays and increase costs.[1,2,4,5] Deep SSIs, involving organs or spaces, result in longer durations of hospital stay and higher costs compared with incisional SSIs.[6] Additionally, since 2008, Medicare and Medicaid Services no longer reimburse hospitals for any cost incurred from treating certain hospital-acquired infections, including SSIs.[7]

LO 1

SSIs are defined and reported according to Centers for Disease Control and Prevention (CDC) criteria.[8] SSIs are classified as either incisional or organ/space. Incisional SSIs are further divided into superficial incisional SSI (skin or subcutaneous tissue) and deep incisional SSI (deeper soft tissues of the incision). Organ/space SSIs involve any anatomic site other than the incised areas (eg, meningitis after brain tumor removal). An infection is considered an SSI if any of the above criteria is met and the infection occurs within 30 days or 90 days depending on the site of operation and type of infection.[8]

LO 2

EPIDEMIOLOGY AND ETIOLOGY

LO 3

Risk factors for SSIs can be divided into two categories: patient and operative characteristics.[6,9,10] Patient risk factors for SSI include age, comorbid disease states (especially chronic lung disease and diabetes), malnutrition, immunosuppression, nicotine or steroid use, and colonization of the nares with *Staphylococcus aureus*. Modifying risk factors prior to planned operations may decrease the threat of SSI.

Operative characteristics are based on the actions of both the patient and the operating staff. Shaving of the surgical site prior to operating can produce microscopic lacerations and increase the chance of SSI and is, therefore, not accepted as a method of hair removal.[6] Maintaining aseptic technique and proper sterilization of medical equipment is effective in preventing SSI. Surgical staff should wash their hands thoroughly. In clean operations, most bacterial inoculums introduced postoperatively are generally small. However, subsequent patient contact between contaminated areas (such as the nares or rectum) and the surgical site can lead to SSI. Finally, the appropriate use of antimicrobial prophylaxis can have a significant impact on decreasing SSIs.

PATHOPHYSIOLOGY

Prophylaxis Versus Treatment

Antimicrobial prophylaxis begins with the premise that no infection exists but that during the operation there can be a low-level inoculum of bacteria introduced into the body. However, if sufficient antimicrobial concentrations are present, bacteria can be controlled without infection developing. This is the case when surgery is done

under controlled conditions, there are no major breaks in sterile technique or spillage of gastrointestinal (GI) contents, and perforation or damage to the surgical site is absent. An example would be an elective hysterectomy done with optimal surgical technique.

If an infection is already present, or presumed to be present, then antimicrobial use is for treatment, not prophylaxis, and the goal is to resolve the infection. This is the case when there is spillage of GI contents, gross damage or perforation is already present, or the tissue being operated on is actively infected (pus is present and cultures are positive). An example would be a patient undergoing surgery for a ruptured appendix with diffuse peritonitis.

KEY CONCEPT The distinction between prophylaxis and treatment influences the choice of antimicrobial and duration of therapy. Appropriate antimicrobial selection, dosing, and duration of therapy differ significantly between these two situations. Prophylatic antimicrobials are chosen based on the most common bacteria encountered in the area of the surgical site; treatment regimens should be narrowed based on culture data from the infected site. A regimen for antimicrobial prophylaxis ideally involves one agent and lasts less than 24 hours. Treatment regimens can involve multiple antimicrobials with durations lasting weeks to months depending on desired antimicrobial coverage and the surgical site.

Types of Surgical Operations

KEY CONCEPT Surgical operations are classified at the time of operation as clean, clean-contaminated, contaminated, or dirty. Antimicrobial prophylaxis is appropriate for clean, clean-contaminated, and contaminated operations. Dirty operations take place in situations of existing infection and antimicrobials are used for treatment, not prophylaxis (Table 85–1).

Microbiology

LO 4

KEY CONCEPT Appropriate prophylactic antimicrobial selection relies on anticipating which organisms will be encountered during the operation. SSIs associated with **extraabdominal** operations are the result of skin flora organisms in nearly all cases. These organisms include gram-positive cocci, with *S. aureus* and *Staphylococcus epidermidis* being among the most frequently isolated SSI pathogens[6,7,11] (Table 85–2). *Streptococcus* spp. may also be implicated.

Table 85–2

Major Pathogens in Surgical Wound Infections[11]

Pathogen	Percentage of Infections
Staphylococcus aureus	30.4
Coagulase-negative Staphylococci	11.7
Escherichia coli	9.4
Enterococcus faecalis	5.9
Pseudomonas aeruginosa	5.5
Streptococcus spp.	4.9
Enterobacter spp.	4
Klebsiella (pneumonia/oxytoca)	4
Enterococcus spp.	3.2
Proteus spp.	3.2
Enterococcus faecium	2.5
Serratia spp.	1.8
Candida albicans	1.3
Acinetobacter baumannii	0.6

Intraabdominal operations involve a diverse flora with the potential for polymicrobial SSIs. *Escherichia coli* make up a large portion of bowel flora and are frequently isolated as pathogens.[6,7] Other enteric gram-negative bacteria, as well as anaerobes (especially *Bacteroides* spp.), may be encountered during intra-abdominal operations.

Candida albicans continues to be an increasing cause of SSIs.[7] Increased use of broad-spectrum antimicrobials and rising prevalence of immunocompromised and human immunodeficiency virus-infected individuals are factors in fungal SSIs. Despite this increase, antifungal prophylaxis for surgery is not currently recommended.

Choosing an Antibiotic

LO 5

Ideal criteria for an antimicrobial in surgical prophylaxis include the following:

- Spectrum that covers expected pathogens
- Inexpensive

Table 85–1

National Red Cross Wound Classification, Risk of SSI, and Antimicrobial Indication

Classification	Description	SSI Risk	Antimicrobial Prophylaxis
Clean	No acute inflammation or transection of GI, oropharyngeal, GU, biliary, or respiratory tracts; elective case, no technique break	Low	Indicated
Clean-contaminated	Controlled opening of aforementioned tracts with minimal spillage or minor technique break; clean procedures performed emergently or with major technique breaks	Medium	Indicated
Contaminated	Acute, nonpurulent inflammation present; major spillage or technique break during clean-contaminated procedures	High	Indicated
Dirty	Obvious preexisting infection present (abscess, pus, or necrotic tissue present)	—	Not indicated; antimicrobials used for treatment

GI, gastrointestinal; GU, genitourinary.

Data from Refs. 9 and 13.

- Parenteral
- Easy to use
- Minimal adverse-event potential
- Longer half-life to minimize need for redosing during procedure

Operations can be separated into two basic categories: extraabdominal and intraabdominal. SSIs resulting from extraabdominal operations are frequently caused by gram-positive aerobes. Cefazolin, an antimicrobial with strong gram-positive coverage that fits the above criteria, is a mainstay for surgical prophylaxis of extraabdominal procedures. For patients with a **β-lactam allergy**, clindamycin or vancomycin can be used as an alternative.

Intraabdominal operations necessitate broad-spectrum coverage of gram-negative organisms and anaerobes. Antianaerobic cephalosporins, cefoxitin, and cefotetan are widely used. Fluoroquinolones or aminoglycosides, paired with clindamycin or metronidazole, should provide adequate coverage for intraabdominal operations; these regimens are recommended as appropriate regimens for use in patients with β-lactam allergies.

Guidelines do not recommend routine use of vancomycin for surgical procedures.[12,13] Vancomycin should be considered when a cluster of methicillin-resistant *S. aureus* (MRSA) or coagulase-negative staphylococci have been identified. Additionally, vancomycin is appropriate to use in patients with known MRSA colonization or at high risk for MRSA colonization. Vancomycin use in institutions where MRSA rates are "high" may not translate into a lower incidence of SSI. The incidence of SSI for patients on cefazolin or vancomycin did not differ despite a high MRSA rate at the study institution.[14] However, patients who received cefazolin were more likely to develop an SSI due to MRSA.[13]

Newer antimicrobials may be alternative agents for surgical prophylaxis, especially as drug shortages limit availability of routinely used antimicrobials. Ertapenem was superior to standard cefotetan in the prevention of SSIs after elective colorectal surgery.[15] However, the ertapenem treatment group had a larger proportion of *Clostridium difficile* infections than those in the cefotetan treatment group. Ertapenem has been included as an approved antimicrobial for colon surgery.[12] Routine use of newer antimicrobials for surgical prophylaxis is inappropriate; overuse of these antimicrobials may contribute to **collateral damage** and the development of bacterial resistance.

Guideline recommendations for antimicrobials are based on national trends of antimicrobial susceptibilities available at the time of publication. Local antibiogram data may be helpful in evaluating which agents recommended in the guidelines may not be as effective in a specific institution due to significant resistance. Responsibility for determining appropriate use of antimicrobial prophylaxis falls on each institution and interpretation of institutional resistance data.

β-Lactam Allergy

LO 6

Allergy to β-lactam antimicrobials such as penicillin is one of the most common reported drug allergies. Concerns over cross-reactivity between antimicrobials may limit the use of β-lactams for surgical prophylaxis. KEY CONCEPT A thorough drug allergy history should be taken to discern true allergy (eg, anaphylaxis) from medication intolerance (eg, upset stomach). Allergy testing may be helpful in confirming penicillin allergy and could spare vancomycin. Despite lack of commercial availability of minor determinants of penicillin allergy, skin testing with commercial major determinants provides greater than or equal to 95% accuracy for lack of penicillin allergy; addition of an oral challenge dose improves accuracy to near 100%.[16] Penicillin skin testing may be useful in outpatient and planned surgical procedures but may be difficult to perform in urgent/emergent surgical indications. Multiple studies have demonstrated a low incidence, ie, less than 1%, for cross-reactivity between penicillins and cephalosporins.[17–19] However, in the case of severe penicillin allergy (anaphylaxis), cephalosporins should be avoided.

Alternative Methods to Decrease SSI

LO 7

Several nonantimicrobial methods have been studied for reducing the risk of SSI.[20–34] Perioperative glucose levels of less than 200 mg/dL should be maintained in all patients, regardless of a diabetes comorbidity.[1] More intensive glucose control in the setting of surgical procedures have not been critically evaluated by randomized controlled trials. Current guidelines recommend maintenance of normotheria.[1] Studies have demonstrated a significant difference in SSI in patients who received supplemental oxygenation compared to normal controls.[19] However, despite these findings, there are insufficient data to make definitive recommendations on the use of these approaches.

Alternative topical routes of antimicrobial prophylaxis such as antimicrobial-impregnated bone cement, implantable antimicrobial collage sponges, antimicrobial irrigations, and topical administration of antimicrobial powders have not been well studied. Studies demonstrating an advantage often lack rigorous design and only show superiority when compared to placebo.[12,21,22] Irrigation with detergent solutions, rather than antimicrobials, appears to provide the same results but with less wound-healing problems encountered with antimicrobial irrigation.[25] Confounding this issue is the lack of standards for topical administration routes. An array of drugs, from aminoglycosides to macrolides, is used in these preparations. Some bone cements are produced commercially, whereas others are made in the operating room. The long-term durability of impregnated cements is also unknown, as the addition of antimicrobials may reduce the tensile strength of bone cement. Irrigation solutions may be compounded in the surgical suites and result in variable concentrations. High concentrations can result in local irritation, systemic absorption, and toxicity. Alternatively, low concentrations can contribute to the development of resistant organisms may occur. Further study is required before topical administration is recommended for use in surgical prophylaxis.

Increased importance has been placed on screening for *S. aureus*, especially MRSA and **decolonization**. Surgical patients with nasal colonization of *S. aureus* have a higher risk of an SSI due to *S. aureus*, and decolonization leads to a lower incidence of SSIs.[25–27] Guidelines endorse the use of mupirocin for *S. aureus* decolonization, especially in cardiac and orthopedic surgery. The most studied approach to eradication of methicillin-sensitive *S. aureus* (MSSA) and/or MRSA has been mupirocin applied to the anterior nares for 5 days prior to surgery.[12,30] Additionally, skin decolonization with 4% chlorhexidine for 5 days prior to surgery has also been recommended. Although decolonization of the anterior nares is the most common and most studied, some controversy exists because patients may be colonized elsewhere (rectum, throat, vagina, etc) and often do not receive complete decolonization.[30] Furthermore, decolonization usually does not lead to lifelong eradication. Other drugs, both topical and systemic, have been studied for decolonization/eradication of MRSA, but a review of randomized controlled trials for the eradication of MRSA found insufficient evidence for the use of any

agent for eradication of MRSA.[31] A significantly lower incidence of infections was demonstrated in surgical patients who were nasal colonized with *S. aureus* and completed a 5-day treatment of intranasal mupirocin twice daily and chlorhexidine wash daily. Although no MRSA infections were noted in the patients included in this study, the authors suggest that this treatment strategy would be beneficial in MRSA-colonized patients as long as those strains were susceptible to mupirocin. Although MRSA screening has gained more acceptance, less than 10% of centers screen for mupirocin and/or chlorhexidine resistance.[12,33] Mupirocin resistance rates have varied from 1.9% to 5.6% of *S. aureus* isolates.[34] Further studies are needed to elucidate this area of surgical prophylaxis, including cost-effectiveness.

Principles of Antimicrobial Prophylaxis

▶ Route of Administration

Intravenous (IV) antimicrobial administration is the most common delivery method for surgical prophylaxis. IV administration ensures complete bioavailability while minimizing the impact of patient-specific variables. Oral administration is also used in some bowel operations. Nonabsorbable compounds such as erythromycin base and neomycin are given during the 24 hours prior to surgery to reduce microbial concentrations in the bowel. Note that oral agents are used adjunctively and do not replace IV agents.

▶ Timing of First Dose

KEY CONCEPT For prevention of SSIs, correct timing of antimicrobial administration is imperative so as to allow the persistence of therapeutic concentrations in the blood and wound tissues during the entire course of the operation. The National Surgical Infection Prevention Project recommends infusing antimicrobials for surgical prophylaxis within 60 minutes of the first incision. Exceptions to this rule are fluoroquinolones and vancomycin, which can be infused 120 minutes prior to avoid infusion-related reactions.[2,12] No consensus has been reached on whether the infusion should be complete prior to the first incision.

Administration of the IV antimicrobial should begin as close to the first incision as possible. This is important for antimicrobials with short half-lives so that therapeutic concentrations are maintained during the operation and reduce the need for redosing. Beginning the antimicrobial infusion after the first incision is of little value in preventing SSI. Administration of the antimicrobial after the first incision had SSI rates similar to patients who did not receive prophylaxis.[35]

▶ Dosing and Redosing

LO 8

KEY CONCEPT The goal of antimicrobial dosing for surgical prophylaxis is to optimize the pharmacodynamic parameter of the selected agent against the suspected organism for the duration of the operation. Dosing recommendations can vary between institutions and guidelines. Clinical judgment should be exercised regarding dose modifications for renal function, age, and especially weight. Obese patients often require higher antimicrobial doses than do nonobese patients.[36] The newest guidelines available regarding specific antimicrobial dosing recommended higher doses of cefazolin based on population pharmacokinetic/pharmacodynamics data: 2 g for all patients less than 120 kg; 3 g for patients more than or equal to 120 kg.[12] Clindamycin should be given as a 900-mg preoperative IV dose.[11]

If an operation exceeds two half-lives of the selected antimicrobial, then another dose should be administered.[2,12] Repeat dosing reduces rates of SSI. For example, cefazolin has a half-life of about 2 hours, thus another dose should be given if the operation exceeds 4 hours. The clinician should have extra doses of antimicrobial ready in case an operation lasts longer than planned.

▶ Duration

KEY CONCEPT The duration of antimicrobial prophylaxis should not exceed 24 hours (48 hours for cardiac surgery); additional doses of antimicrobial past this time point do not demonstrate added benefits.[2,12] In clean and clean-contaminated procedures, antimicrobials are not needed after the surgical incision is closed.[1] Antimicrobial prophylaxis does not need to be continued until all drains and catheters have been removed.

PROPHYLAXIS REGIMENS

Antimicrobial Prophylaxis in Specific Surgical Procedures

LO 9

Table 85–3 lists the recommended regimens for antimicrobial prophylaxis of specific surgical procedures.

▶ Gynecologic and Obstetric

- Possible pathogens: enteric gram-negative bacilli, anaerobes, group B streptococci, enterococci
- Prophylaxis for hysterectomy: cefazolin, cefotetan, cefoxitin, ampicillin-sulbactam
  - Alternatives for β-lactam allergy: clindamycin or vancomycin combined with aminoglycoside, aztreonam, or fluoroquinolone; metronidazole combined with aminoglycoside or fluoroquinolone
- Prophylaxis for cesarean section: cefazolin
  - Alternatives for β-lactam allergy: clindamycin and aminoglycoside

Cesarean sections are stratified into low- and high-risk groups. Patients who undergo emergency operations or have cesarean sections after the rupture of membranes and/or onset of labor are considered high risk. Prophylactic antimicrobials are most beneficial for high-risk patients but are used in both groups. Antimicrobials should not be administered until after the first incision and the umbilical cord has been clamped. This practice prevents potentially harmful antimicrobial concentrations from reaching the newborn.

▶ Orthopedic Surgery

- Possible pathogens: gram-positive cocci, mostly staphylococci
- Prophylaxis for total joint arthroplasty (hip or knee): cefazolin
  - Alternatives for β-lactam allergy: clindamycin, vancomycin

Antimicrobial-impregnated bone cement can be useful in lowering infection rates in orthopedic surgery but has not been approved for prophylaxis.

▶ Cardiothoracic and Vascular Surgery

- Possible pathogens: gram-positive cocci, mostly staphylococci
- Prophylaxis for cardiac surgeries: cefazolin, cefuroxime
- Prophylaxis for noncardiac thoracic surgeries: cefazolin, ampicillin-sulbactam
- Prophylaxis for vascular surgeries: cefazolin
- For all cardiothoracic and vascular surgeries alternatives for β-lactam allergy: clindamycin, vancomycin

Table 85–3

Recommended Regimens for Antimicrobial Prophylaxis of Specific Surgical Procedures[a]

Type of Operation	Recommended Prophylaxis Regimen *(Duration is for a total of 24 hours unless specified)*[b]	Alternative Regimen for β-Lactam Allergy *(Duration is for a total of 24 hours unless specified)*
Vascular	Cefazolin 2–3 g[c] IV every 8 hours	Clindamycin 900 mg IV every 6–8 hours *or* vancomycin 15 mg/kg every 8–12 hours
Neurosurgery	Cefazolin 2–3 g[c] IV every 8 hours	Clindamycin 900 mg IV every 6–8 hours *or* vancomycin 15 mg/kg IV every 8–12 hours
Head and neck (clean with prosthesis placement excluding tympanostomy tubes)	Cefazolin 2–3 g[c] IV every 8 hours *or* cefuroxime 1.5 g every 8 hours	Clindamycin 900 mg IV every 6–8 hours
Head and neck (clean-contaminated)	(Cefuroxime 1.5 g every 8 hours AND metronidazole 500 mg every 8 hours) *or* amipicillin-sulbactam 3 g every 6 hours	Clindamycin 900 mg IV every 6–8 hours
Urologic (clean)	Cefazolin 2–3 g[c] IV × 1	Clindamycin 900 mg IV × 1 *or* vancomycin 15 mg/kg × 1
Urologic (lower tract instrumentation with risk factors for infection, transrectal prostate biopsy)	Ciprofloxacin 400 mg IV × 1 *or* levofloxacin 500 mg IV × 1 *or* trimethoprim-sulfamethoxazole *or* cefazolin 2–3 g[c] × 1	Gentamicin 5 mg/kg × 1 with or without clindamycin 900 mg × 1
Cesarean section	Cefazolin 2–3 g[c] IV × 1	See hysterectomy
Hysterectomy	Cefazolin 2–3 g[c] IV × 1 *or* cefotetan 2 g × 1 *or* cefoxitin 2 g × 1 *or* ampicillin-sulbactam 3 g × 1	(Clindamycin 900 mg × 1 or vancomycin 15 mg/kg × 1) AND (gentamicin 5 mg/kg × 1 or aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg)
Gastroduodenal (high-risk only: obstruction, acid suppression, morbid obesity, hemorrhage, malignancy)	Cefazolin 2–3 g[c] IV × 1	(Clindamycin 900 mg × 1 *or* vancomycin 15 mg/kg × 1) AND (gentamicin 5 mg/kg × 1 *or* aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg)
Biliary tract (open procedure or high-risk laparoscopic only: age > 70 years, acute cholecystitis, obstructive jaundice, duct stones, nonfunctioning gallbladder)	Cefazolin 2–3 g[c] IV × 1 *or* cefotetan 2 g × 1 *or* cefoxitin 2 g × 1 *or* ceftriaxone 2 g × 1 *or* ampicillin-sulbactam 3 g × 1	(Clindamycin 900 mg × 1 *or* vancomycin 15 mg/kg × 1) AND (gentamicin 5 mg/kg × 1 *or* aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg) or (metronidazole 500 mg × 1) AND (gentamicin 5 mg/kg × 1 *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg)
Colorectal	[d]Oral: neomycin 1 g plus erythromycin base 1 g (give 19, 18, and 9 hours prior to procedure)	
	IV: (Cefazolin 2–3 g[c] × 1 and metronidazole 500 mg × 1) *or* cefoxitin 2 g × 1 *or* cefotetan 2 g × 1 *or* ampicillin-sulbactam 3 g × 1 *or* (ceftriaxone 2 g × 1 AND metronidazole 500 mg × 1) *or* ertapenem 1 g × 1	See biliary tract
Appendectomy	Cefoxitin 2 g IV × 1; cefotetan 2 g IV × 1; cefazolin 2–3g[c] × 1 AND metronidazole 500 mg × 1	Metronidazole 0.5–1 g IV AND gentamicin 1.5 mg/kg IV × 1
Orthopedic	Cefazolin 2–3 g[c] IV every 8 hours	Vancomycin 15 mg/kg every 8–12 hours *or* clindamycin 900 mg every 6–8 hours
Cardiothoracic	Cefazolin 2–3 g[c] IV every 8 hours for a total of 48 hours *or* cefuroxime 1.5 g IV every 12 hours for a maximum of 48 hours	Vancomycin 15 mg/kg every 8–12 hours for a total of 48 hours *or* clindamycin 900 mg every 6–8 hours for a maximum of 48 hours

[a]Dosing recommendations are based on common clinical doses for adult patients with normal renal function; dosing for individual patients and institutions may vary.

[b]In clean and clean-contaminated procedures, additional antimicrobials after incision is closed are not necessary.

[c]3 g dose for weight ≥ 120 kg.

[d]Oral regimens should be used in conjunction with IV prophylaxis.

Data from Refs. 8, 12, 13, and 17.

Debate exists on the duration of antimicrobial prophylaxis for cardiothoracic operations. SSIs are rare after cardiothoracic operations, but the potentially devastating consequences lead some clinicians to support longer periods of prophylaxis. The National Surgical Infection Prevention Project cites data that extending prophylaxis beyond 24 hours does not decrease SSI rates and may increase bacterial resistance.[2,12] However, the Society of Thoracic Surgeons issued practice guidelines in 2006 which recommended a duration of up to 48 hours following cardiac surgeries.[37] Duration of therapy should be based on patient factors and risk of development of an SSI.

▶ *Colorectal Surgery*

- Possible pathogens: gram-positive, gram-negative, and anaerobic organisms
- Parenteral prophylaxis: cefazolin and metronidazole; cefoxitin; cefotetan; ampicillin-sulbactam; ceftriaxone and metronidazole; ertapenem
  - Alternatives for β-lactam allergy: clindamycin combined with aminoglycoside, aztreonam, or fluoroquinolone; metronidazole combined with aminoglycoside or fluoroquinolone

Oral routes for prophylaxis include the combination of neomycin with either erythromycin or metronidazole and are administered at 19, 18, and 9 hours prior to surgery. These oral routes should be given with mechanical bowel preparation. For most patients, this oral regimen should be combined with a parenteral regimen.

Appendectomy is one of the most common intraabdominal operations. Antimicrobial prophylaxis used for appendectomy is similar to that used for colorectal regimens. In the case of ruptured appendix, antimicrobials are used for treatment, not prophylaxis.

Patient Encounter Part 1

WL is a 55-year-old man with no significant past medical history who presented to the clinic with ongoing right knee pain. His knee pain continued to worsen despite oral analgesics and intraarticular steroid injections. WL chooses to undergo an elective right knee total joint replacement. He states that he was told as a child that he had a "bad reaction" to amoxicillin.

VS: BP 110/65 mm Hg, HR 75 beats/min, RR 20 breaths/min, T 97.9°F (36.6°C), Ht 72 inches (182.88 cm), Wt 272 lbs (123 kg)

Labs: WBC 4.2 × 10^3/mm^3 (4.2 × 10^9/L), serum creatinine 1.2 mg/dL (106.1 mmol/L), glucose 110 mg/dL (6 mmol/L)

What organisms are likely to be encountered for this operation and why?

What agents need to be avoided in this patient?

The patient shares that he has taken cephalexin before for a skin rash and tolerated it well. What drug and dose would you recommend for this patient?

Patient Encounter Part 2

In preparation for his surgery today, WL is given a chlorhexidine bath. His vitals and glucose are taken prior to surgery.

VS: BP 110/65 mm Hg, HR 75 beats/min, RR 20 breaths/min, T 99.0°F (37.2°C), Ht 72 inches (182.88 cm), Wt 267 lbs (121.1 kg)

Labs: glucose 225 mg/dL (12.5mmol/L)

What additional steps should be taken to reduce WL's risk of developing a surgical site infection?

The surgeon is behind schedule and WL's surgery is delayed. The incision on his surgery was initially scheduled to start in 45 minutes but has been delayed for at least 2 hours. When should his prophylactic antimicrobials be administered?

OUTCOME EVALUATION

The clinician should consistently follow up postoperative patients and screen for any sign of SSI. KEY CONCEPT According to CDC criteria, SSIs may appear up to 30 or 90 days after an operation depending on the type and site of operation.[6] This period often extends beyond hospitalization, so educate patients on warning signs of SSI and be encouraged to contact a clinician immediately if necessary. The presence of fever or leukocytosis in the immediate postoperative period does not constitute SSI and should resolve with proper patient care. Distal infections, such as pneumonia, are not considered SSIs even if these infections occur in the 30-day period. Check the appearance of the surgical site regularly and document any changes (eg, erythema, drainage, or pus). The presence of pus or other signs suggestive of SSI must be treated accordingly. Any wound requiring incision and drainage is considered an SSI regardless of appearance. Collect prompt cultures and initiate appropriate antimicrobial therapy to reduce any chance of morbidity and mortality.

Patient Encounter Part 3

WL is seen in the orthopedic office 3 months after his procedure. His chief complaint is increased redness on the right knee, which has been present for the past few days. Further radiologic investigation shows the presence of fluid collection near the prosthetic implant.

VS: BP 99/55 mm Hg, HR 85 beats/min, RR 20 breaths/min, T 99.5°F (37.5°C), Ht 72 inches (182.88 cm), Wt 250 lbs (113.4 kg)

Labs: WBC 12.9 x 10^3/mm^3 (12.9 × 10^9/L)

Based on the available data, does WL have an SSI?

What further steps should be taken in regard to this possible SSI?

Patient Care Process

Collect Information:

- Conduct thorough medication history.
- Obtain serum creatinine and weight.
- Document allergies and the type of reaction.
- Document type of operation that patient is to receive.

Assess the Information:

- Consider penicillin allergy testing in patients with unclear documentation of penicillin allergy.

Develop a Care Plan:

- Determine appropriate antibiotics based on the type of operation and medication allergies.
- Determine appropriate dosing based on weight and renal function.

Implement the Care Plan:

- Start antimicrobials within 1 hour of surgical incision (2 hours for vancomycin, fluoroquinolones).
- Monitor patient for signs of allergic reaction.
- Document any major breaks in surgical technique and adjust length of antimicrobial therapy if surgical classification changes.

Follow-up: Monitor and Evaluate:

- Monitor for signs and symptoms of postoperative infection (30 or 90 days postoperation, based on operation).
- Draw cultures to further guide therapy if SSI is suspected.

Abbreviations Introduced in This Chapter

CDC	Centers for Disease Control
MRSA	Methicillin-resistant *Staphylococcus aureus*
MSSA	Methicillin-sensitive *Staphylococcus aureus*
NHSN	National Healthcare Safety Network
SSI	Surgical site infection

86 Vaccines and Toxoids

Marianne Billeter

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Define vaccination and immunization.
2. Discuss the impact individual vaccines have on public health.
3. Recommend an immunization schedule for a child, including immunocompromised children.
4. Recommend an immunization schedule for an adult based on comorbid conditions and lifestyle choices.
5. Evaluate an adverse reaction and its probable association with a vaccine.

INTRODUCTION

The development and widespread use of vaccines is one of the greatest public health achievements of the 20th century. Other than safe drinking water, no other modality has had a greater impact on reducing mortality from infectious diseases.[1] The first accounts of deliberate inoculation to prevent disease date back as far as the 10th century. However, it wasn't until 1798 that Edward Jenner published his work on inoculation of natural cowpox as a means to prevent smallpox infection that documented the first scientific attempt at prevention by inoculation. Since 1900, the widespread use of vaccines has resulted in the eradication of smallpox worldwide and wild-type poliovirus from the Western hemisphere. There have also been dramatic declines in the incidence of diphtheria, pertussis, tetanus, measles, mumps, rubella, and *Haemophilus influenzae* type b infections.[2] In the United States, there are immunization recommendations against 17-vaccine preventable diseases affecting all age groups.

KEY CONCEPT Vaccines have traditionally been preparations of killed or attenuated microorganisms that provide active immunity against a variety of viral and bacterial infections. Most vaccines are designed to prevent acute infections that can be rapidly controlled and cleared by the immune system. Successful immunization involves activation of antigen-presenting cells with processing of the antigen by lysosomal or cytoplasmic pathways. T and B lymphocytes will be activated to replicate and differentiate to form large pools of memory cells for protection against subsequent exposure to the antigen.[2]

Vaccines against viral infections may be **attenuated** live viruses or inactivated viral particles. Attenuation may be accomplished by several methods to decrease the viruses' virulence while retaining their **immunogenicity**. Bacterial vaccines utilize antigenic particles of the outer membrane to elicit an immune response. KEY CONCEPT Outer membrane polysaccharides are poorly immunogenic in children younger than 2 years unless conjugated with a carrier protein. Also, bacterial toxins may undergo chemical treatment to render them nontoxic to form **toxoids** against infectious agents.

LO 1

Often the terms *vaccination* and *immunization* are used interchangeably even though they are distinct concepts. Vaccination refers to the act of administering a vaccine, whereas immunization refers to the development of immunity to a pathogen. The delivery of a vaccine does not imply that the individual mounted an adequate immune response to the vaccine to elicit protection. However, immunization implies that the act of vaccination resulted in the development of protective immunity.

LO 2

Herd immunity refers to high levels of immunization in one population, resulting in protection of another unvaccinated population. For example, concentrated vaccination of children with the pneumococcal conjugate vaccine resulted in decreased invasive *Streptococcus pneumoniae* infection not only in the vaccinated children, but also in elderly persons within the same community.[3]

Cocoon immunization is a strategy used to immunize all persons surrounding another high-risk individual, such as vaccinating parents, siblings, and grandparents of a new infant who is too young to be vaccinated. This strategy is used to protect individuals who are not able to be vaccinated themselves.

VACCINE ADMINISTRATION SCHEDULES

LO 3 LO 4

Most vaccines are administered in two- to four-shot series in order to elicit the best protection. KEY CONCEPT Childhood and adult immunization schedules are revised frequently and published annually by the Centers for Disease Control and Prevention (CDC) Advisory Committee on Immunization Practices (ACIP). Current immunization schedules can be found at www.cdc.gov/vaccines/. Recommendations will be published throughout the year in the *Morbidity and Mortality Weekly Report* (*MMWR*) as new vaccines are licensed or new information necessitates a change in previous recommendations.[4] See **Table 86–1** for vaccine dosing.

The childhood immunization schedule is complex and requires a large number of injections. In small infants, the number of injections can be intolerable to the infant, parent, and health care provider. Limiting the number of injections at each visit can lead

Table 86–1

Vaccine Dosing

Vaccine	Common Abbreviation	Dose	Route	Cautions and Adverse Effects
Diphtheria and tetanus toxoid	DT	0.5 mL	Intramuscular	History of arthus-type hypersensitivity reaction
Diphtheria, tetanus, acellular pertussis	DTaP	0.5 mL	Intramuscular	Systemic neurologic reaction from previous vaccine History of arthus-type hypersensitivity reaction Temperature > 40.6°C (105°F)
Haemophilus influenzae type b	HIB	0.5 mL	Intramuscular	
Hepatitis A	HepA	C: 0.5 mL A: 1 mL	Intramuscular	
Hepatitis B	HepB	C: 0.5 mL A: 1 mL	Intramuscular	
Human papillomavirus	HPV9	0.5 mL	Intramuscular	Pregnant women
Inactivated influenza	IIV3, IIV4	0.5 mL 0.1 mL	Intramuscular Intradermal	Severe egg allergy History of Guillain-Barré syndrome
Inactivated influenza, recombinant	RIV	0.5 mL	Intramuscular	History of Guillain-Barré syndrome
Measles, mumps, rubella	MMR	0.5 mL	Subcutaneous	Pregnant women Immunocompromised host
Meningococcal conjugate	MenACWY	0.5 mL	Intramuscular	
Meningococcal, serogroup B	MenB	0.5 mL	Intramuscular	
Pneumococcal 13-valent conjugate	PCV13	0.5 mL	Intramuscular	
Pneumococcal polysaccharide	PPSV23	0.5 mL	Intramuscular route preferred; subcutaneous	Children < 2 years
Poliovirus, inactivated	IPV	0.5 mL	Intramuscular, subcutaneous	Pregnancy
Rotavirus vaccine	RV (RV1, RV5)	1 or 2 mL	Oral	Immunocompromised host
Tetanus and diphtheria toxoid	Td	0.5 mL	Intramuscular	History of arthus-type hypersensitivity reaction
Tetanus, reduced diphtheria, acellular pertussis	Tdap	0.5 mL	Intramuscular	Systemic neurologic reaction from previous vaccine History of arthus-type hypersensitivity reaction
Varicella	VAR	0.5 mL	Subcutaneous	Pregnant women Immunocompromised host
Zoster, live	ZVL	0.65 mL	Subcutaneous	Immunocompromised host
Zoster, recombinant	RZV	0.5 mL	Intramuscular	

A, adult; C, children.

to missed vaccinations and increased expense for return visits. KEY CONCEPT Use of combination vaccines decreases the number of injections and increases the likelihood that the immunization schedule will be completed. Using combination vaccine does not adversely affect the immunity or increase adverse effects. Vaccine administration should not be delayed for mild to moderate respiratory tract illnesses or fevers.[4]

THE ROUTINE VACCINES

Diphtheria, Tetanus, and Pertussis Vaccines

Diphtheria is a contagious bacterial respiratory infection characterized by membranous pharyngitis. The impact of diphtheria is not from the causative bacteria, *Corynebacterium diphtheriae*, but rather from complications attributed to its exotoxin, such as myocarditis and peripheral neuritis. Diphtheria is rarely reported in the United States since the introduction of vaccination with diphtheria toxoid; however, diphtheria continues to be a major problem in developing countries.

The tetanus vaccine differs from others in that it does not protect against a contagious disease such as diphtheria, but rather against an environmental pathogen. *Clostridium tetani*, the causative pathogen, is widely found in the environment, especially in dirt and soils. Tetanus is rarely seen in developed countries.[5]

Pertussis is a highly contagious respiratory tract infection caused by the bacteria *Bordetella pertussis*. Pertussis is characterized by a protracted severe cough with or without posttussive vomiting, whoop, difficulty breathing, difficulty sleeping, and rib fractures. It is often referred to as "whooping cough" or the 100-day cough.[6]

▶ *Use of Diphtheria, Tetanus, and Acellular Pertussis Vaccine*

Diphtheria and tetanus toxoids and acellular pertussis vaccine should be administered in a five-shot series to all children beginning at 2 months of age. The shots are given at 2, 4, 6, and 15 to 18 months, and 4 to 6 years. Immunity to diphtheria, tetanus, and pertussis is achieved after the third vaccination.

▶ *Use of Tetanus and Diphtheria Toxiod Vaccine*

Immunity to tetanus and diphtheria wanes with increasing age necessitating the need for booster doses every 10 years. The preferred agent to use in adults is tetanus and diphtheria toxoid in order to also give a booster for diphtheria. Tetanus immunization status should be assessed in the management of moderate and severe wounds or contaminated wounds in individuals seeking medical care. A tetanus booster should be administered if necessary.

▶ *Use of Tetanus Toxiod, Reduced Diphtheria, and Acellular Pertussis Vaccine*

Pertussis continues to be reported in adolescents and adults of all ages indicating a waning immunity following primary immunization. Additionally, adults with pertussis may infect young infants who have not received the first three doses of primary vaccination resulting in hospitalizations and death. A tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is recommended for use in adolescents and adults.

Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine should be administered to adolescents 11 through 18 years as a single booster. Ideally it should be given at 11 to 12 years of age. Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is also recommended for adults 19 years and older as a single booster dose in individuals who have not already received it. This may be given as a routine vaccination or for wound management.[7]

Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is also used as part of cocoon immunization strategy to protect young infants. The vaccine should be administered to pregnant women during the third trimester (27–36 weeks preferred) of each pregnancy in order for transfer of maternal antibodies to the newborn infant. Additionally, individuals with close contact to infants less than 12 months of age, such as fathers, grandparents, health care workers, and child care workers, should also be vaccinated. Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine may be given at any interval following a tetanus vaccine.[8]

Haemophilus Influenzae Type b Vaccine

H. influenzae is a bacterial respiratory pathogen that causes a wide spectrum of disease ranging from upper respiratory infections to bacterial meningitis. Approximately two-thirds of the cases of *H. influenzae* type b meningitis resulted in a high degree of hearing loss or neurologic deficits among survivors.[9] Since the introduction of the vaccine, invasive disease due to *H. influenzae* type b has been nearly eliminated.

The *H. influenzae* type b vaccine is a protein conjugate that elicits an enhanced immune response in younger children including infants. *H. influenzae* type b conjugate vaccine is a recommended routine childhood vaccination beginning at 2 months of age. There are currently three licensed monovalent *H. influenzae* type b conjugate vaccines and three combination vaccines containing *H. influenzae* type b conjugate. The vaccines have different dosing schedules and use 2 or 3 doses for the primary series. Vaccine providers need to be aware of the brand being used and related dosing schedule. The immune response to *H. influenzae* type b is similar among the different vaccines. The different brands are interchangeable without affecting the primary immune response or booster response.[9] A booster dose of *H. influenzae* type b vaccine is also recommended in adolescents and adults at high risk for becoming infected with *H. influenzae*.

H. influenzae type b and influenza vaccines have the potential for confusion and medication errors because of the similarity of the names. Care should be taken when ordering, dispensing, and administering these vaccines.

Hepatitis A Vaccine

Hepatitis A virus continues to be a frequent cause of illness despite the availability of a highly effective vaccine. Frequently, children younger than 6 years are asymptomatic with primary infection and play a pivotal role in spreading disease to adults. The economic burden of hepatitis A is greater than $300 million annually in combined direct and indirect costs. Widespread use of the hepatitis A vaccine significantly decreases the disease burden caused by hepatitis A infection.[10]

Hepatitis A vaccine was licensed in the United States in 1995. It is an inactivated whole virus vaccine that is administered in a two-dose series. More than 94% of children, adolescents, and adults will have protective antibodies 1 month after receiving the first dose and 100% following the second dose. The hepatitis A vaccine is recommended for all children following the first birthday, with the second dose administered 6 months later. Adults who are at high risk for hepatitis A should receive two doses at least 6 months apart. High-risk adults include persons with clotting disorders or chronic liver disease, men who have sex with men, illicit drug users, and international travelers going to areas with high to intermediate endemicity of hepatitis A, persons with anticipated close contact with an international adoptee, or any other person who wishes to become immune.[10]

Hepatitis B Vaccine

Hepatitis B virus is transmitted following exposure to infected blood and body fluids. Individuals with chronic hepatitis B infection are at risk for cirrhosis, liver cancer, liver failure, and death. Vaccination with hepatitis B vaccine is the most effective way to prevent hepatitis B infection.[11]

Hepatitis B vaccine is manufactured using recombinant DNA technology to express hepatitis B surface antigen (HBsAg) in yeast. Hepatitis B vaccine is available as a single component or in combination vaccines.

Hepatitis B vaccine is recommended for routine use in infants and children in a three-dose series. The first dose should be given 12 to 24 hours following birth. The remaining two doses should be administered with other routine infant vaccinations during

Patient Encounter 1

A mother brings her infant girl to the pediatrician for her 6th-month check-up and vaccinations. The mother is apprehensive about more vaccines because her baby had a fever and cried uncontrollably following the 4th-month vaccinations. You note that the infant was born at 32 weeks gestation and spent 4 weeks in the neonatal intensive care unit (NICU) prior to discharge from the hospital.

What routine vaccines should this infant receive at this visit?

The infant has already received three hepatitis B vaccinations. Should the infant receive another at this visit?

What advise could be given to the mother to lessen her anxiety regarding her infant receiving vaccines at this visit?

the first 6 months of life. The dosing schedule will depend on the use of single component or combination vaccines. Adolescents should receive the three-dose series if not previously vaccinated.[11]

Hepatitis B vaccine is recommended for adults at high risk for hepatitis B infection, including health care workers, and those requesting protection from hepatitis B. The vaccine is administered in a three-dose series over 4 to 6 months.[11] Frequently, individuals do not follow through with the complete three-dose series and questions arise about restarting the series. Hepatitis B vaccine produces an amnesic response; therefore, the series may be continued at any time in order to complete the three doses.

Following vaccination with hepatitis B vaccine, hepatitis B virus serologic markers will remain negative, with the exception of antibody to hepatitis B surface antigen (anti-HBs), which will be positive indicating immunity. Persons with anti-HBs concentration greater than 10 mIU/mL (10 IU/L) after vaccination will have complete protection against acute and chronic infection.[11] There is no need for booster doses in immunocompetent individuals when anti-HBs concentrations fall below 10 mIU/mL (10 IU/L), since a good memory response will occur following exposure to hepatitis B virus. However, a booster dose may be warranted in immunocompromised individuals.

Human Papillomavirus Vaccine

Human papillomavirus (HPV) is the most common sexually transmitted virus and is associated with a wide range of diseases, including cervical cancer and genital warts. More than 150 HPVs have been identified and classified on their ability to cause malignant disease. HPV 16 and 18 are highly associated with causing cervical cancer, as well as anal, oropharyngeal, penile, vaginal, and vulval cancers. HPV 6 and 11 are associated with 90% of genital warts.[12]

The Food and Drug Administration (FDA) has approved three HPV vaccines, but only the 9-valent (9vHPV) is available in the United States. 9vHPV protects against HPV 6, 11, 16, 18, 31, 33, 45, 52, and 58. The HPV vaccine is unique in that preventing infection by HPV will translate into prevention of cancer. Areas with high uptake of HPV vaccine have started to see declines in HPV infections and related diseases such as genital warts and high-grade cervical disease.[13]

HPV vaccination is recommended for all adolescents at age 11 or 12 years. It is also recommended for females through 26 years and males through 21 years if not previously vaccinated. HPV vaccine is given in a 2-dose series prior to the 15th birthday or a 3-dose series if started after the 15th birthday.[13]

The overall rate of HPV vaccination continues to increase, but remains below other recommended adolescent vaccines. The main reason cited for not vaccinating teens is related to knowledge gaps among clinicians and parents regarding recommendations for use and safety concerns. The adverse event profile is similar to other vaccines administered to adolescents.[9]

Influenza Vaccine

Influenza is a contagious viral respiratory infection that usually occurs during the winter months in the Northern Hemisphere and Southern Hemisphere, and year round in the tropics. All age groups are affected by influenza; however, children have the highest rate of infection. Serious illness and death due to influenza usually occurs in extremes of age, those older than 65 years or younger than 2 years.

Influenza A and B viruses are responsible for causing human disease. Both influenza A and B undergo frequent antigenic drift, creating new influenza variants. Immunity to the surface antigens decreases the likelihood of infection. Unfortunately, antibody to one influenza subgroup does not give complete protection against other influenza subtypes.

The best way to protect against seasonal influenza is through vaccination. The current trivalent influenza vaccine contains two A strains, 1 A(H1N1), 1 A(H3N2), and one B strain. The quadrivalent influenza vaccine contains the same components of the trivalent and an additional B strain. Inactivated influenza vaccine is available in both trivalent and quadrivalent presentations.[14]

All individuals 6 months of age and older should receive yearly seasonal influenza vaccination. There is no preference for vaccine presentation when multiple types are available within an approved age range. In persons 65 years and older, the high-dose trivalent-inactivated influenza vaccine produced increased immunity and protection against confirmed influenza when compared to regular dose influenza vaccine.[15] The adjuvanted trivalent vaccine also showed improved protection against influenza when compared to unadjuvanted vaccine. These two vaccines should be considered for use in older adults.

Recommendations for influenza vaccination are update yearly, and should be consulted for information on use of specific products.

Measles, Mumps, and Rubella Vaccine

Measles, mumps, and rubella are acute viral infections that can cause serious disease and complications. Aggressive vaccination programs have made these infections uncommon in the United States. Measles and rubella have been eliminated from the United States. Recent outbreaks have been caused from importation of infected persons from other parts of the world where measles are still circulating. Some outbreaks also occur in communities with high levels of unvaccinated individuals.

Measles, mumps, and rubella vaccine is a live attenuated vaccine that causes a mild subclinical infection producing long-term immunity. Measles, mumps, and rubella vaccine is recommended for routine vaccination after the first birthday and a second dose administered at 4 through 6 years of age. Measles, mumps, and rubella vaccine is available in combination with varicella vaccine. This vaccine is not recommended for the first dose due to the increased risk of febrile seizures when compared to giving measles, mumps, and rubella and varicella separately at the same visit.[16] Measles, mumps, and rubella vaccine should also be given to adults older than 18 years who are found to be nonimmune.

Measles, mumps, and rubella vaccine should be avoided in immunocompromised persons because of the risk of acquiring measles from the vaccine. However, HIV-infected persons, who are not severely immunocompromised, including those on antiretroviral therapy, can be vaccinated if not immune.[16]

Measles, mumps, and rubella vaccine is a safe vaccine and rarely associated with severe reactions. The most common reaction is fever which usually occurs more than a week after vaccination. Children with a personal or family history of febrile seizures or epilepsy are at increased risk for measles, mumps, and rubella vaccine–associated febrile seizures.[16]

Meningococcal Vaccines

Neisseria meningitidis is a significant cause of meningitis and bacteremia. Invasive meningococcal disease is associated with a high morbidity and mortality rate. Morbidity in survivors is substantial, with approximately 20% having loss of limb

or neurologic sequelae. The highest rates of meningococcal disease are among young children. Thirteen meningococcal serogroups have been identified; however, five serogroups, A, B, C, Y, and W-135, are responsible for epidemic and endemic disease worldwide. Despite the availability of highly active antibacterial agents against *N. meningitidis*, there has been little impact on decreasing the morbidity and mortality due to invasive meningococcal disease.[17]

The quadrivalent meningococcal vaccine (A,C,Y,W-135) is recommended for routine vaccination of adolescents. The first dose should be administered at 11 to 12 years with a booster dose at age 16 years. Meningococcal vaccine is also recommended for high-risk individuals older than 2 months.[14] Serogroup B meningococcal (MenB) vaccine is recommended for individuals aged 16 to 23 years. There are two serogroup B meningococcal vaccines available, with no preference given between them. However, the vaccines are not interchangeable so the series should be completed with the same vaccine.[18]

Pneumococcal Vaccines

S. pneumoniae causes approximately 3000 cases of meningitis, 50,000 cases of bacteremia, 500,000 cases of pneumonia, and more than 1 million cases of otitis media each year.[19] The increasing prevalence of drug-resistant *S. pneumoniae* has emphasized the need for vaccination. Pneumococcal vaccines are highly effective in preventing disease from the common *S. pneumoniae* serotypes that cause human disease.

The 13-valent pneumococcal conjugate vaccine contains the serotypes that most commonly cause disease in children. The 23-valent pneumococcal polysaccharide vaccine contains 23 serotypes that are responsible for causing more than 80% of invasive *S. pneumoniae* infections in adults. The pneumococcal vaccines have demonstrated good immunogenicity and prevention of invasive pneumococcal disease.

The 13-valent pneumococcal vaccine is part of the routine childhood immunization schedule beginning at 2 months of age. Children older than 6 years who are at high risk of invasive pneumococcal disease should receive a single 23-valent pneumococcal polysaccharide vaccine, with a booster dose given in 5 years.[19]

Both the 13-valent pneumococcal conjugate and 23-valent pneumococcal polysaccharide vaccines are recommended for routine use in all adults 65 years of age or older. The 13-valent vaccine should be administered first followed by the 23-valent vaccine 1-year later. If an individual has already received the 23-valent pneumococcal vaccine, the 13-valent vaccine should be administered at least 12 months after the 23-valent vaccine. Adults 19 through 64 years who are at increased risk for invasive pneumococcal disease are recommended to receive a single vaccination with the 13-valent pneumococcal conjugate vaccine. This is followed in 8 weeks with a 23-valent pneumococcal polysaccharide vaccine, and a booster dose in 5 years.[20]

Revaccination with the 23-valent pneumococcal polysaccharide vaccine is recommended for adults older than 65 years if the first dose was administered when they were younger than 65 years and at least 5 years have passed. A dose of the 13-valent pneumococcal vaccine should be administered prior to receiving the 23-valent vaccine.[20]

Poliovirus Vaccine

Poliomyelitis is a highly contagious disease that is often asymptomatic; however, approximately 1 in every 100 to 1000 cases will develop a rapidly progressive paralytic disease. Since the introduction of the first poliovirus vaccine, there has been a significant reduction in the number of polio cases. Today, polio caused by wild-type poliovirus has been eradicated from the Western hemisphere with the goal of eradicating it from the world.[21]

The last reported case of indigenous wild-type poliovirus in the United States was in 1979; subsequent cases were all vaccine associated attributed to the oral poliovirus vaccine. In 1997, a transition period to the inactivated poliovirus vaccine was begun to reduce the risk of vaccine-associated paralytic poliomyelitis. By January 2000, the oral vaccine was no longer recommended for routine use. Currently, the inactivated poliovirus vaccine is recommended for routine use in the United States. It is available as a single component or in combination vaccines. A booster dose should be given after age 4 years; no matter how many doses were given in the infant vaccination series.[22]

Rotavirus Vaccine

Rotavirus is the most common cause of severe diarrheal disease in children younger than 5 years. It is a major cause of diarrhea hospitalizations for dehydration worldwide. Rotavirus G1 is the most prevalent strain found in the United States. However, in any given year, other strains (G2, G3, G4, and G9) may predominate.

There are two rotavirus vaccines available for use. They are a pentavalent human-bovine reassortant vaccine that contains outer capsid proteins for G1, G2, G3, G4, and P1, and a monovalent, G1 vaccine. The exact mechanism by which these vaccines produce an immune response is unknown; however, these live virus vaccines replicate in the small intestine and induce immunity.

The rotavirus vaccine is administered in either a two-dose or a three-dose series that is orally administered. The first dose is given to infants between 6 and 12 weeks of age. The impact of the rotavirus vaccine has been dramatic with a significant decrease in rotavirus hospitalizations and all-cause diarrhea hospitalizations in children younger than 5 years. The vaccine has also offered protection to children too old to receive the vaccine and young adults.[23] The most severe adverse events associated with rotavirus vaccine is **intussusception**, a telescoping of the intestines on to itself. Postlicensure monitoring has shown a minimal risk of the vaccine with 1 to 5 excess cases of intussusception per 100,000 vaccinated children.

Varicella Vaccine

Varicella zoster virus is a highly contagious herpes virus. Primary infection with varicella zoster causes chickenpox and was one of the most common childhood diseases in the prevaccine era. Following primary infection, varicella becomes latent in cranial nerve, dorsal roots, and autonomic ganglia where it may reactivate to cause shingles (Zoster) in older adults. Since the introduction of the varicella virus vaccine in 1995, there has been a 90% reduction in varicella infections and hospitalization in all age groups.[24]

The varicella vaccine is a live attenuated vaccine. Children younger than 12 years will have a 97% seroconversion rate following a single vaccination. Adolescents and adults older than 13 years will only have 78% seroconversion after a single inoculation, but will have 99% conversion following a second dose. Therefore, varicella vaccine is recommended to be administered in a two-dose series. The first dose should be administered after 12 months of age and a second dose at 4 years of age. Adolescents and adults without evidence of immunity to varicella zoster should receive two doses of varicella vaccine

Patient Encounter 2

A mother brings her son to the family physician for his 1-year-old visit. It is late September and the child has been suffering from poorly controlled asthma and has numerous food allergies. The mother has research childhood vaccines on the Internet and is reluctant to have any vaccines administered because of the risks of seizures and autism. The mother also feels they are unnecessary as these diseases no longer occur.

What routine vaccines should this child receive?

Does the child's asthma and food allergies impact the vaccines that should be administered?

How should the mother's concerns regarding autism be addressed?

How should the mother's concerns regarding the necessity of vaccines be addressed?

given 4 to 8 weeks apart. Antibody titers appear to persist for at least 20 years following immunization.

Varicella vaccine is well tolerated with tenderness at the injection site and mild rash the most common adverse events. Rashes due to the vaccine strain typically occur more than 20 days following vaccination. A few cases of secondary transmission to household contacts have been reported.[21]

Zoster Vaccine

Later in life, approximately 15% of the population will develop herpes zoster (shingles). Zoster is the reactivation of latent varicella zoster virus in the sensory ganglia. Zoster most frequently occurs in the elderly and immunocompromised individuals who have decreased circulating antibodies to varicella zoster virus.

There are two available Zoster vaccines: Zoster vaccine live and Zoster vaccine recombinant. Both vaccines are FDA-approved for use in individuals 50 years and older. However, ACIP recommends use of Zoster vaccine live in individuals 60 years and older.[25]

Zoster vaccine recombinant has been shown to have higher and longer lasting efficacy compared to Zoster vaccine live. Therefore, ACIP recommends the preferred use of Zoster vaccine recombinant over Zoster vaccine live. Zoster vaccine recombinant

Patient Encounter 3

An 18-year-old girl is receiving a physical prior to going to college. It is noted that the patient needs to be caught up on some of the routine adolescent vaccines.

What vaccines should this girl be evaluated for and receive if necessary?

The mother is reluctant to have the HPV series administered because her daughter is not sexually active. How should these concerns be addressed?

What precautions should be taken with this patient when administering vaccines?

Patient Encounter 4

A 65-year-old patient presents to the pharmacy to pick up his prescriptions. While there, he shows you the pictures of his new granddaughter. The pharmacist reviews the patient's vaccine history and offers to vaccinate the gentleman; he accepts all recommended vaccines.

What routine vaccines should this man receive?

What is the rationale for offering Tdap to this man?

What warnings should be given to the patient?

is administered in a two-dose series for immunocompetent individuals 50 years and older. If an individual has previously received Zoster vaccine live, it is recommended they also receive vaccination with Zoster vaccine recombinant.[26] Use of the zoster vaccines has shown a reduction in the incidence of zoster and postherpetic neuralgia.

VACCINE SAFETY

Vaccination is one of the most powerful tools used to prevent disease. As with all drugs, most vaccines have been reported to cause adverse reactions. The reactions are either acute or are related to the risk of developing another disease. Health care professionals should discuss the risks versus benefits of vaccines with individuals or caregivers prior to vaccination. Vaccine information sheets (VIS) provide written information about each vaccine and are required to be given to individuals prior to vaccination.[4]

LOS

Vaccine safety is monitored by the FDA and CDC through a passive reporting system that allows anyone, health professionals or lay public, to report any event through the Vaccine Adverse Event Reporting System (VAERS). KEY CONCEPT Health care professionals are mandated to report certain events through VAERS. Additionally, any serious, life-threatening, or unusual reactions should also be reported.

The VAERS database is continually monitored to determine whether the prevalence of reactions is changing and to identify previously unreported reactions to a particular vaccine. Large epidemiologic safety studies are conducted through the Vaccine Safety Datalink; a partnership between the CDC and nine large health care organizations.

Pain at the injection site is one of the most commonly reported adverse effects of vaccination. The reaction is usually mild, with complaints of pain and tenderness at the injection site that may or may not be accompanied by erythema. Local reactions tend to be more frequent with repeated doses or booster doses of vaccine.[4] Tetanus-containing vaccines are well known for causing localized reactions.

Fever is the most frequently reported adverse effect in children. Elevated temperature is usually self-limiting and resolves in a few days. Rarely febrile seizures may occur following vaccination with measles, mumps, and rubella vaccine.

Reports of syncope following vaccination have been increasing since the approval of HPV and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines. Syncope most commonly occurs in adolescent girls and young adults. Health care professionals should implement measures to mitigate secondary injuries when vaccinating this age group.[4]

Autism

Thimerosal is a preservative used in vaccines that has been purported to cause autism in children. The assumption is that thimerosal, also known as ethyl mercury, causes similar effects as methyl mercury, which has neurotoxic and nephrotoxic effects at high doses. Numerous epidemiologic studies have not shown a higher rate of autism among children receiving thimerosal-containing vaccines when compared with the normal background rate of autism. Despite lack of linkage to autism and other serious adverse effects, the United States created thimerosal-free versions of all childhood vaccines beginning in 2001. Additionally, the mercury exposure with vaccination is much lower than through many other environmental exposures.[27]

Guillain-Barré Syndrome

Guillain-Barré syndrome is a transient neurologic disorder causing flaccid paralysis. It is thought to be caused from the development of autoimmune antibodies that cause damage to the peripheral nerves. Guillain-Barré syndrome has been temporally associated with several bacterial and viral infections as well as vaccinations.

The association with vaccination and Guillain-Barré syndrome was first recognized with the Swine flu vaccine of 1976. Since that time a clear association of influenza vaccination and Guillain-Barré syndrome has not been clearly established. Caution is still recommended with influenza vaccines since the influenza strains contained in the vaccine has the potential to change each year.[28]

Several large epidemiologic studies have sought to establish a temporal association of Guillain-Barré syndrome and other routine vaccines. The evidence is inconclusive in determining a cause-and-effect relationship. Overall the risk of Guillain-Barré syndrome following vaccination is minimal with 1 to 2 cases per 100,000 vaccines administered. The benefits of vaccination far outweigh the risk of Guillain-Barré syndrome.[28]

SPECIAL POPULATIONS

Immunocompromised Host

The number of immunocompromised persons is continually increasing as advances are made in medicine. The life expectancy for persons with cancer, HIV infection, and solid organ or bone marrow transplantation is increasing. Vaccination provides one tool to prevent infection in the immunocompromised host. However, the individual's immunosuppressed state will alter the response to the vaccine. In general, all vaccinations should be updated prior to the person becoming immunosuppressed. KEY CONCEPT Once a person becomes significantly immunosuppressed, live virus vaccines should be avoided.

Infants, children, and adults with HIV should receive all routine vaccinations according to the recommended immunization schedule as long as T-lymphocyte CD4 count is more than 200 cells/mm^3 (200 × 10^6/L). Live vaccines should be used with caution when T-lymphocyte CD4 counts are less than 200 cells/mm^3 (200 × 10^6/L). All HIV-infected persons should receive yearly inactivated influenza vaccination.[29]

Following hematopoietic stem-cell transplantation, the patient will need most routine vaccines to be administered 6 to 12 months following transplantation. Diphtheria, tetanus, acellular pertussis, *H. influenzae* type b, hepatitis B, meningococcal, pneumococcal, and inactivated poliovirus should be given. Inactivated influenza vaccine is given yearly, starting 6 months after transplant. Measles, mumps, and rubella can be given 2 years after transplant and varicella and zoster vaccines are contraindicated.[29]

Solid organ transplant recipients have a blunted immune response to vaccines because the immunosuppressive regimens used to prevent organ rejection inhibit both T- and B-cell proliferation. Prior to transplant, children should complete primary immunization schedules if possible. Otherwise primary immunization schedule with inactivated vaccines may continue 2 months following transplantation. Adults should have all vaccinations updated prior to transplantation. Yearly inactivated influenza vaccination may be given 6 months following transplantation.[29]

Household contacts of immunocompromised persons should have all routine vaccines as scheduled, including yearly influenza vaccination. Children in the household may receive live virus vaccines without special precautions; however, if a rash develops following varicella vaccination, contact should be avoided with the immunocompromised host until the rash resolves.

Pregnancy

Vaccination during pregnancy can protect not only the mother but also the newborn infant. A fully immunized mother is less likely to infect their infant with critical diseases such as influenza, tetanus, and pertussis. Mothers who are vaccinated in the second half of the pregnancy will have maternal transfer of antibodies through the placenta giving protection to the newborn infant. Pregnant women should be vaccinated with inactivated influenza and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines during each pregnancy. Ideally the vaccines should be administered after 20-week gestation, but can be administered at any time during the pregnancy.[30] Household members (eg, fathers, grandparents, siblings) of newborns should also be current in their vaccinations to prevent transmission to the infant.

Live virus vaccines should be avoided during pregnancy due to the theoretical concern of the virus being transported across the placenta and infecting the fetus. Women found to be nonimmune to rubella or varicella may be vaccinated soon after delivery, but not during the pregnancy.[30]

Health Care Professionals

Health care professionals are in a unique position to protect themselves and their patients by receiving immunizations against vaccine preventable diseases. Health care professionals should have documented immunity to measles, mumps, rubella, and varicella. The vaccine series should be administered if found nonimmune. Health care professionals with direct patient contact should also receive the hepatitis B vaccine series and have proven immunity following the series. As concerns regarding the rise of pertussis among adults, it is now recommended that all health care professionals receive at least one dose of tetanus, reduced diphtheria, and acellular pertussis vaccine to protect against pertussis. This dose may be administered at any interval following a tetanus booster.[31]

The CDC recommends all health care professionals receive yearly influenza vaccination. Many health care facilities are now mandating that employees receive yearly influenza vaccination or wear masks during influenza season.[31]

OUTCOME MEASURES

KEY CONCEPT Vaccines are a cost-effective means for disease prevention. From a societal perspective, for every dollar spent on routine childhood vaccines, there will be a $10 savings in direct and indirect costs.[32] The rates of vaccination for young children are 90% or more for most recommended vaccines. This has been

attributed to the requirements for proof of vaccination by States for enrollment into daycare centers and school. For vaccines not required by schools, the rate of vaccination is lower.

Adolescents present a unique challenge for vaccinating because they do not have as many encounters with health care professionals as young children do. However, the constantly changing immunization schedule makes this population vulnerable to missing newly approved vaccines and catch-up doses of vaccines that were not recommended when they were younger. Every encounter with a health care establishment should be viewed as an opportunity to evaluate and vaccinate if necessary. Adolescents may also have incomplete medical records due to changes in health care providers. Therefore, it is important for health professionals to regularly utilize universal State immunization databases that document pediatric and adult vaccinations. This eliminates the problems of lost immunization records if a child changes health care providers.[4]

The vaccination rate in adults is much lower than that in children. Only 50% to 60% of adults who meet criteria have received pneumococcal vaccination, and less than 40% have received seasonal influenza vaccine. Comprehensive initiatives need to be implemented to increase the adult vaccination rate. Some proven concepts are providing reminders to patients that vaccines are due and implementation of standing orders for vaccines. This latter concept allows nurses and pharmacists to screen patients to determine whether pneumococcal, influenza, or other vaccines are needed and to vaccinate without a direct physician's order.

Patient Care Process

Collect information:

- Perform a complete vaccine history. Ask the patient, parent, or caregiver which vaccines the patient has received and when they were administered.
- Review the patient's medical record for vaccinations.
- Review the State immunization database.

Assess the Information:

- Compare the patient's vaccine history to published immunization schedules.

Develop a Care Plan:

- Determine if any immunizations need to be administered at this visit.
- Inform the patient, parent, or caregiver that immunizations are needed.

Implement the Care Plan:

- Provide Vaccine Information Sheets (VIS) to the patient, parent, or caregiver. Answer any questions that they may have.
- Vaccinate the patient with the needed vaccines.

Follow-up: Monitor and Evaluate:

- Observe the patient for 15 minutes for signs of immediate reactions.
- Document administration of vaccines in the patient's medical record and State immunization database.
- Provide the patient with vaccine administration card.

Abbreviations Introduced in This Chapter

ACIP	Advisory Committee on Immunization Practices
anti-HBs	Antibody to hepatitis B surface antigen
CDC	Centers for Disease Control and Prevention
HBsAg	Hepatitis B surface antigen
VAERS	Vaccine Adverse Event Reporting System
VIS	Vaccine information sheets

87 Human Immunodeficiency Virus Infection

Emily L. Heil, Mary F. Banoub, and Amanda H. Corbett

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the routes of transmission for human immunodeficiency virus (HIV) and its natural disease progression.
2. Identify typical and atypical signs and symptoms of acute and chronic HIV infection.
3. Identify the desired therapeutic outcomes for patients living with HIV.
4. Recommend appropriate first-line pharmacotherapy interventions for patients with HIV infection.
5. Recommend appropriate second-line pharmacotherapy interventions for patients with HIV infection.
6. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for HIV infection.
7. Educate patients about the disease state, appropriate lifestyle modifications, and drug therapy required for effective treatment.

INTRODUCTION

Human immunodeficiency virus (HIV) is the cause of acquired immunodeficiency syndrome (AIDS). HIV primarily targets $CD4^+$ T-lymphocytes, which are critical to proper immune system function. If left untreated, patients experience a prolonged asymptomatic period followed by rapid, progressive immunodeficiency. Therefore, most complications experienced by patients with AIDS involve opportunistic infections and cancers. AIDS occurs when a patient with HIV has a CD4+ cell count below 200 cells/mm^3 (200×10^6/L), a CD4+ cell percentage of total T-lymphocytes less than 14% (0.14), or one of the Centers for Disease Control and Prevention (CDC) AIDS defining conditions.[1]

EPIDEMIOLOGY

Although the global incidence of HIV has fallen 39% since 2000, HIV prevalence has increased, largely due to life-extending antiretroviral therapy. Combination antiretroviral therapy (cART) has increased both the length and quality of life for HIV-infected patients; however, to date, there are no treatments that eradicate HIV from the body.[2]

As of 2016, approximately 36.7 million people are infected with HIV worldwide. Approximately 70% of these cases are in Sub-Saharan Africa, with a prevalence of approximately 4%. In 2016 alone, approximately 1 million people worldwide died from HIV-related illnesses and 1.8 million people were newly infected with HIV. Most of these infections were acquired through heterosexual transmission. As of 2016, women accounted for 48.5% of all people living with HIV worldwide.[2]

In the United States, at the end of 2014, an estimated 1.1 million persons (aged 13 years or older) were living with HIV/AIDS. Approximately 15% of these are undiagnosed and unaware of their HIV infection and could be unknowingly transmitting the virus to others.[3]

In 2015, 45% of HIV diagnoses were in African Americans although this population comprises only 12% of the US population. Although HIV/AIDS rates in African American women dropped by 42% from 2005 to 2014, incidence in this population is three times the rate for Caucasian females and four times the rate for Hispanic females.[3]

PATHOPHYSIOLOGY AND ETIOLOGY

HIV-1 is a retrovirus and member of the genus *Lentivirus*. There are two molecularly and serologically distinct but related types of HIV: HIV-1 and HIV-2. These viruses have a prolonged latency period. HIV-2 is a less common cause of the epidemic and is found primarily in West Africa. HIV-1 is categorized by phylogenetic lineages into three groups (M [main or major], N [new], and O [outlier]). HIV-1 group M can be further categorized into nine subtypes: A through D, F through H, and J and K. HIV-1 subtype B is primarily responsible for the North American and Western European epidemic.

LO 1

HIV is primarily transmitted by sexual contact, by contact with blood or blood products, and from mother to child during gestation, delivery, or breast-feeding. HIV is transmitted through certain body fluids—blood, semen, preseminal fluid, rectal fluids, vaginal fluids, and breast milk—which must come into contact with a mucous membrane, damaged tissue, or be directly injected into the bloodstream. Risk factors for HIV/AIDS infection include men who have sex with men (MSM), history of or current IV drug use (needle or equipment sharing), unprotected sexual intercourse with high-risk individuals, the presence of other sexually transmitted infections (STIs) (eg, *Chlamydia trachomatis* or *Neisseria gonorrhoeae*), persons with coagulation/hemophilia disorders, and previous blood product recipients.

The most common method for transmission for HIV is receptive anal and vaginal intercourse, with the probability of transmission highest with receptive anal intercourse

(138 infections per 10,000 exposures).[4] The probability of transmission increases when the infected partner has a high level of viral replication (which occurs at the beginning of infection or late in disease) and subsequent high viral load or when the uninfected partner has ulcerative disease, compromised mucosal surfaces, or (in the case of men) has not been circumcised.

Parenteral transmission of HIV primarily occurs through injection drug use by sharing contaminated needles or injection-related supplies. Less than 1% of all cases of HIV infection occur as a result of transfusions of contaminated blood, blood products, or infected transplant organs.[3] Health care workers have a 0.23% estimated risk of acquiring HIV infection through percutaneous needlestick injury.[5]

Perinatal infection (also known as vertical transmission or mother-to-child transmission [MTCT]) can occur during gestation, at or near delivery, and during breast-feeding. In the absence of specific intervention including medications, the risk of MTCT up to and including delivery is approximately 25%. The risk of transmission during breast-feeding is approximately 15% to 20% within the first 6 months of life.[6] Because a high rate of HIV replication in the blood is a significant risk factor for transmission of HIV, it is important to treat women living with HIV during pregnancy regardless of the clinical stage of disease or CD4 count. After delivery, mothers are strongly recommended not to breast-feed if safe alternatives are available. Due to widespread availability of formula feeding options in the United States, breastfeeding should be avoided.

Understanding the life cycle of the virus is important to recognize how antiretroviral drugs are combined for optimal therapy (Figure 87–1). Once HIV enters the body, an outer glycoprotein (gp120) binds to CD4 receptors found on the surface of dendritic cells, T-lymphocytes, monocytes, and macrophages. This allows further binding to other chemokine receptors on the cell surface (CCR5 and/or CXCR4). Greater than 95% of newly infected patients have viruses that preferentially use CCR5 to enter the cell, and most patients with advanced disease have viruses that preferentially use CXCR4 to enter the cell.

After the virus has attached to CD4 and chemokine receptors, another viral glycoprotein (gp41) assists with viral fusion to the cell and internalization of the viral contents. The viral contents include single-stranded ribonucleic acid (RNA), an RNA-dependent deoxyribonucleic acid (DNA) polymerase (also known as **reverse transcriptase**), and other enzymes. Using the single-stranded viral RNA as a template, reverse transcriptase synthesizes a complementary strand of DNA. The single-stranded viral RNA is removed from the newly formed DNA strand by ribonuclease H, and reverse transcriptase completes the synthesis of double-stranded DNA. The viral reverse transcriptase enzyme is highly error-prone, and many mutations occur in the conversion of RNA to DNA. This inefficient reverse transcription activity is responsible for the ability of HIV to rapidly mutate and develop drug resistance.

A chronic infection is established when the double-stranded DNA migrates to the host cell nucleus and is integrated into the host cell chromosome by the HIV enzyme integrase. Once the cell becomes activated by antigens or cytokines, HIV replication starts. Host DNA polymerase transcribes viral DNA into messenger RNA, and messenger RNA is translated into viral

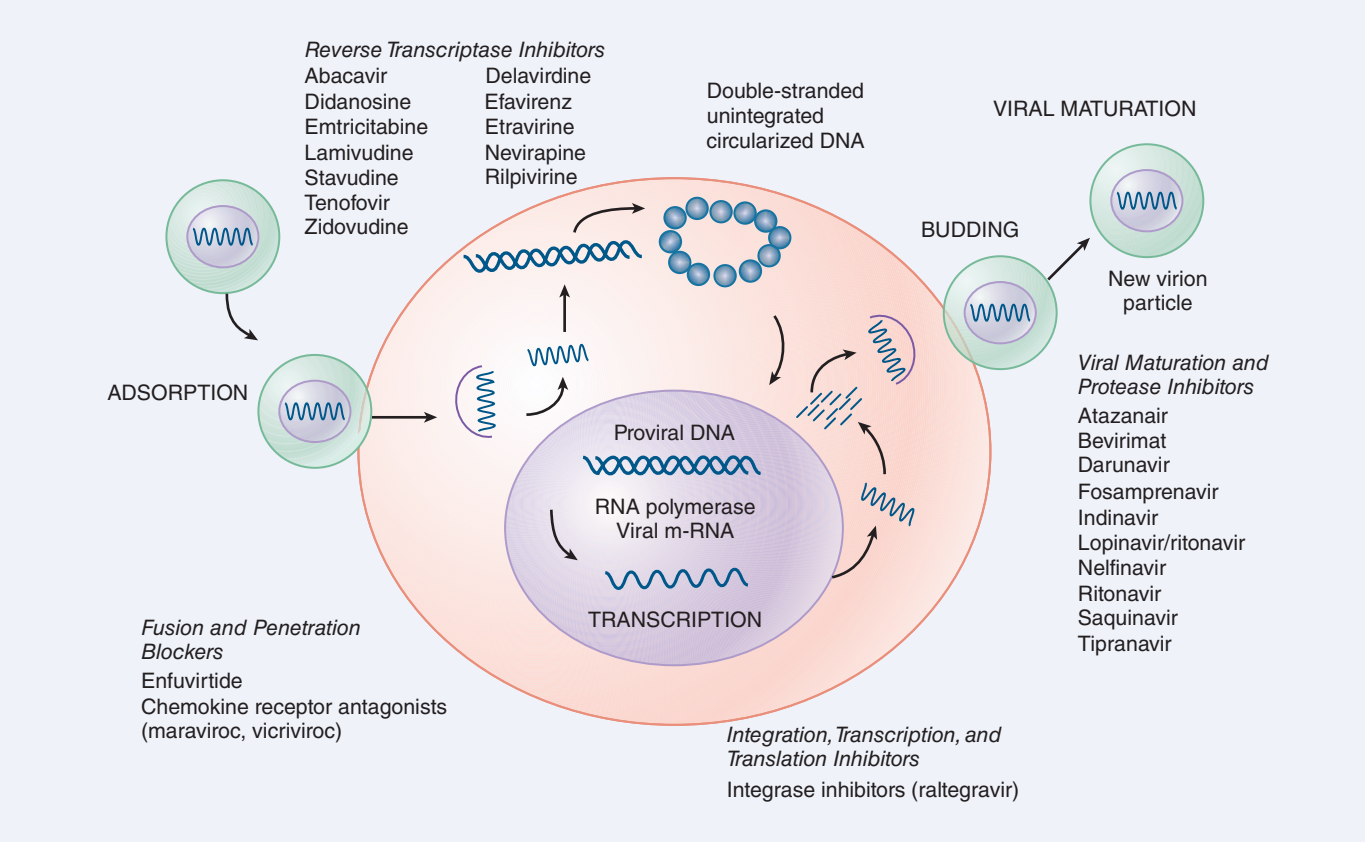

FIGURE 87–1. Life cycle of HIV and targets for antiretroviral drugs. (From Anderson PL, Kakuda TN, Fletcher CV. Human immunodeficiency virus infection. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill; 2014; with permission.)

proteins. These proteins assemble beneath the bilayer of the host cell, a nucleocapsid forms containing these proteins, and the virus buds from the cell. After budding, the virus matures when an HIV **protease** enzyme cleaves large polypeptides into smaller functional proteins. Without this process, the virus is unable to infect other cells.

During the early stages of infection, approximately 10 billion virions can be produced each day. Most of the cells containing these viruses will be lysed as a result of budding virions, cytotoxic T-lymphocytes, or apoptosis. However, HIV will be protected within some cells (macrophages, T cells in lymph nodes), which can stay dormant for years.

The initial immune response against HIV is relatively effective; however, it is unable to completely clear the infection, and the patient enters a latent, asymptomatic, or mildly symptomatic stage lasting 5 to 15 years. During this time, a high rate of viral replication can be seen in the lymph nodes. Eventually immune deficiency occurs when the body is no longer able to replenish helper T cells at a rate equal to that at which HIV is destroying them.

KEY CONCEPT The goal of therapy is to maximally and durably suppress HIV replication to restore and preserve immune system function and minimize morbidity and mortality. Because HIV replication has been found in all areas of the body, it is important to use potent combination drug therapy that can achieve adequate concentrations in all tissues, including protected sites such as the brain and genital tract.

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

Patients who are acutely infected with HIV may be asymptomatic or present with signs and symptoms associated with any viral infection, such as fever, myalgias, lymphadenopathy, pharyngitis, or rash. Taken together, these are the "acute retroviral syndrome," and 40% to 90% of acutely infected individuals will have symptoms.[8] Providers should consider the possibility of HIV infection in any patient with these findings and inquire about recent high-risk sexual encounters or other modes of high-risk exposures. In the United States, 1 in 6 patients living with HIV are not aware of their status, thus identifying acutely infected patients and providing referral into HIV care is critical for preventing HIV transmission.[3] In acute infection, HIV RNA concentrations in blood and the genital tract are very high, increasing the risk of transmission to others. These patients will generally have plasma HIV RNA concentrations greater than 10^6 copies/mL (10^9 copies/L). Increased infectiousness coupled with undiagnosed HIV infection in these patients may account for a substantial proportion of sexual HIV transmission.

If patients are not identified during acute infection, they may later present with nonspecific symptoms such as myalgias, fatigue, weight loss, thrush, or symptoms associated with opportunistic infections. The US CDC recommends that patients aged 13 to 64 years in all health care settings undergo opt-out HIV testing, meaning that a separate consent form for testing is not needed after the patient has been informed that testing will be completed. For those patients in the high-risk groups mentioned above, HIV testing should be performed on an annual basis, and pregnant women should be tested with each pregnancy.[7]

Diagnosis of HIV begins with a 4th generation combination immunoassay that detects HIV-1 and HIV-2 antibodies and HIV-1 p-24 antigen. No further testing is required for specimens that are nonreactive. Specimens that are reactive on the initial immunoassay should be tested with an antibody immunoassay that differentiates

Clinical Presentation and Diagnosis of HIV

LO 2

Patients with acute HIV infection may display symptoms described as acute retroviral syndrome. Patients with chronic HIV infection may present with these same nonspecific symptoms and/or opportunistic infections.

Acute Retroviral Syndrome

The majority of patients may present with fever, lymphadenopathy, pharyngitis, and/or rash.
Other symptoms include the following:

- Myalgia or arthralgia
- Diarrhea
- Headache
- Nausea and vomiting
- Hepatosplenomegaly
- Weight loss
- Thrush
- Neurologic symptoms (meningoencephalitis, aseptic meningitis, peripheral neuropathy, facial palsy, or cognitive impairment or psychosis)

Opportunistic Infections

Depending on the severity of immunosuppression (the CD4 count), patients may present with the following opportunistic infections (grouped by CD4 count):

- *Any CD4 count*
  - *Mycobacterium tuberculosis* disease
  - Bacterial pneumonia (commonly *Streptococcus pneumoniae, Haemophilus influenzae, Pseudomonas aeruginosa*, and *Staphylococcus aureus*)
  - Herpes simplex virus disease
  - Varicella zoster virus disease
  - Bacterial enteric disease (most commonly *Salmonella, Campylobacter*, and *Shigella*)
  - Syphilis
  - Bartonellosis
- *Less than 200 cells/mm^3 (200 × 10^6/L)*
  - Coccidioidomycosis
  - *Pneumocystis jiroveci* (formerly *carinii*) pneumonia (PCP or PJP)
  - Oropharyngeal and esophageal candidiasis
  - Kaposi sarcoma or human herpesvirus-8 disease
- *Less than 150 cells/mm^3 (150 × 10^6/L)*
  - Disseminated histoplasmosis
- *Less than 100 cells/mm^3 (100 × 10^6/L)*
  - *Toxoplasma gondii* encephalitis
  - Cryptosporidiosis
  - Microsporidiosis
- *Less than 50 cells/mm^3 (50 × 10^6/L)*
  - Disseminated *Mycobacterium avium* complex disease
  - Cytomegalovirus disease (CMV)
  - Cryptococcosis
  - Aspergillosis

HIV-1 from HIV-2 antibodies. Nonreactive or indeterminate specimens on the HIV-1/HIV-2 antibody differentiation immunoassay should be tested with an HIV-1 nucleic acid test (NAT). Positive results from this test indicate the need for HIV medical care that includes additional testing such as HIV-1 viral load and CD4 count to stage the disease. At-home HIV-1 test kits (eg, Home Access Systems, OraQuick) allow patients to self-collect blood or oral swab samples and obtain confidential results in the privacy of their home. Positive results require confirmation.

KEY CONCEPT HIV treatment response and disease progression is determined by following: (a) the CD4 T-lymphocyte count (CD4 count) and percentage, and (b) plasma HIV RNA (viral load). The CD4 percentage is followed because the absolute count may fluctuate and does not necessarily indicate a change in the patient's condition.

TREATMENT

LO 3

KEY CONCEPT The goals of treatment are to maximally and durably suppress viral replication, avoid the development of drug resistance, restore and preserve immune function, prevent opportunistic infections, minimize drug adverse effects, and prevent disease transmission. Elimination or cure of HIV is not possible with currently available therapies. Instead, maximal suppression of viral replication (defined as plasma HIV RNA concentrations undetectable by the most sensitive assay available) is desired. After the initiation of antiretroviral therapy, a rapid decline to undetectable plasma HIV RNA in 12 to 24 weeks is a predictor of improved clinical outcomes.[8]

KEY CONCEPT Degree of immune function preservation is also correlated with decreased viral replication and is measured by CD4 T-cell counts. CD4 measures are the best predictor of progression to AIDS and help clinicians determine when to initiate opportunistic infection prophylaxis. At CD4 T-cell counts of 200 cells/mm^3 (200 × 10^6/L) and lower, patients require drug prophylaxis for opportunistic infections. Table 87–1 details the monitoring points of HIV treatment for plasma HIV RNA and CD4 T-cell counts. In addition to these parameters, basic blood chemistry tests, liver function tests (LFT), complete blood counts, and lipid profiles should be monitored every 3 to 6 months in patients receiving antiretroviral therapy.[8]

Six classes of drugs are available to treat HIV infection: nucleoside (NRTI)/nucleotide (NtRTI) **reverse transcriptase** inhibitor, protease inhibitor (PI), nonnucleoside reverse transcriptase inhibitor (NNRTI), fusion inhibitors, CCR5 inhibitors, and integrase strand transfer inhibitors (INSTI). KEY CONCEPT Currently, combination antiretroviral drug therapy with three or more active drugs is the standard of care, at any CD4 count, which increases the durability of viral suppression and decreases the potential for the development of resistance. Two nucleoside (nucleotide) reverse transcriptase inhibitors AND an INSTI OR a PI with a pharmacokinetic enhancer OR an NNRTI are the recommended initial regimens of combination therapy. Combination regimens decrease plasma HIV RNA to less than 40 copies/mL (40 × 10^3 copies/L) in 80% to 90% of patients in clinical trials.[8] Therefore, monotherapy with any agent or the use of NRTIs without another drug class are not recommended treatment options. Fusion inhibitors are only Food and Drug Administration (FDA)-approved for use in treatment experienced patients with drug

Table 87–1

Monitoring End Points for CD4 T-Cell Counts and HIV RNA

CD4$^+$ T Cell Counts			HIV RNA Concentration		
When to Monitor?	**Why?**	**Goal**	**When to Monitor?**	**Why?**	**Goal**
Initial diagnosis	Assess immune function		Initial diagnosis/ evaluation	Establish baseline	
	Assess need for OI prophylaxis	Start prophylaxis when counts < 200 cells/ mm^3 (200 × 10^6/L)	2–8 weeks after starting or changing cART[a]	Early assessment of regimen efficacy	Undetectable concentrations
Every 3–6 months	Receiving cART: monitor success of treatment[b]	Average increase of 100–150 cells/mm^3/ year (100 × 10^6–150 × 10^6/L/year)	Every 3–6 months	Receiving cART: assess success and durability of virologic suppression and adherence with current regimen	Steadily decreasing and/ or consistently undetectable concentrations
	Not receiving cART: assess urgency to begin therapy	Start cART in appropriate patients	Every 3–6 months	Not receiving cART: Optional[c]	Start therapy in appropriate patients
	Assess need for OI chemoprophylaxis	Start prophylaxis when counts < 200 cells/ mm^3 (200 × 10^6/L)			

[a]If viral load is detectable, repeat every 4 to 8 weeks until less than 200 copies/mL (200 × 10^3/L), then resume every 3- to 6-month schedule.

[b]In clinically stable patients with viral loads less than 50 copies/mL (50 × 10^3/L) for more than 2 years, monitoring can be extended to every 12 months for CD4 count 300–500 cells/mm^3 or optionally for CD4 count > 500 cells/mm^3.

[c]For patients who choose to delay therapy, repeat viral load testing while not on therapy is optional. HIV RNA concentration should be determined prior to initiating therapy.

cART, combination antiretroviral therapy; HIV, human immunodeficiency virus; OI, opportunistic infection; RNA, ribonucleic acid.

Department of Health and Human Services. July 14, 2016. [cited 2017 Aug 16]. http://www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf.

resistance to NRTIs, NNRTIs, and/or PIs. Figure 87–1 details the mechanisms of action of the drug classes within the life cycle of HIV.

Nonpharmacologic Interventions

LO 7

KEY CONCEPT Patient adherence is a key component in treatment success. Drug therapy is required indefinitely, as the virus begins to replicate at high levels when medications are stopped.

Patient Encounter 1, Part 1: Treatment Initiation

A 42-year-old white man presents to your clinic with complaints of thrush, weight loss, myalgias, and general fatigue. During a detailed social history, you learn that for the past 10 years, he has occasionally had unprotected sexual intercourse with women and also uses IV heroin. His last HIV test was over 12 years ago and was negative. Based on his presentation and risk factors today, you decide to perform general STD as well as HIV testing.

PMH: Type II diabetes, atrial fibrillation, asthma

FH: Mother—breast cancer, osteoporosis; Father—HTN, seizure disorder, type II diabetes

SH: Retail store clerk; sexual history as above with no condom use. He reports moderate (4–5 times weekly) IV heroin use.

Meds: Metformin 1000 mg BID, rivaroxaban 20 mg daily, albuterol 2 inhalations every 4 to 6 hours as needed

All: Latex (rash)

ROS: Positive for weight loss, decreased appetite; Negative for shortness of breath, cough, chest pain, nausea, vomiting, diarrhea

PE:

Within normal limits

VS: BP 110/69 mm Hg, P 85 beats/min, RR 20 breaths/min, T 37.5°C

HEENT: Thrush, lymph nodes (+) lymphadenopathy

CV: RRR, normal S1, S2; no murmurs, rubs, gallops

Abd: Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly

Rectal: Deferred

Labs: Sodium 142 mEq/L (142 mmol/L), potassium 4.3 mEq/L (4.3 mmol/L), chloride 102 mEq/L (102 mmol/L), bicarbonate 25 mEq/L (25 mmol/L), blood urea nitrogen 10 mg/dL (3.57 mmol/L), creatinine 1.2 mg/dL (106 µmol/L), WBC 4 × 10^3/mm^3 (4 × 10^9/L), hemoglobin 11.4 g/dL (114 g/L or 7.07 mmol/L), hematocrit 32% (0.32), platelets 79 × 10^3/mm^3 (79 × 10^9/L), neutrophils 45% (0.45), bands 9% (0.09), lymphocytes 20% (0.20), monocytes 1% (0.01), eosinophils 1% (0.01), basophils 0% (0.00)

What information is suggestive of HIV?

What are the risk factors present for having HIV?

What is the likely time frame of this patient's HIV infection?

How can the diagnosis of HIV be made in this patient?

What additional laboratory measurements would be useful?

Combination therapy used in the past for HIV was exceedingly complicated for patients, with multiple daily doses, varying food restrictions, and large pill burdens. Advances in delivery and formulations now make possible once- or twice-daily dosing with fewer pills per day. Currently, three combination tablets are available that provide one pill, once daily NNRTI-containing regimens: tenofovir disoproxil fumarate (TDF) + emtricitabine + efavirenz (Atripla); tenofovir disoproxil fumarate + emtricitabine + rilpivirine (Complera); and tenofovir alafenamide + emtricitabine + rilpivirine (Odefsey). Additionally, three one pill, once daily INSTI-containing combination tablets are available: elvitegravir + cobicistat + tenofovir disoproxil fumarate + emtricitabine (Stribild); elvitegravir + cobicistat + tenofovir alafenamide + emtricitabine (Genvoya); and dolutegravir + abacavir + lamivudine (Triumeq). The use of low-dose ritonavir or cobicistat to enhance the concentrations of other PIs or elvitegravir, respectively (known as pharmacokinetic enhancement, or "boosting" agents), allows for significantly fewer daily doses and lower pill burdens. Cobicistat, unlike ritonavir, does not exert antiviral activity. Atazanavir or darunavir with ritonavir boosting are potent, once-daily PI options; once-daily lopinavir/ritonavir may be used in selected treatment-naïve patients. These advances, however, do not replace the need for patient counseling by a trained pharmacist and a multidisciplinary approach to promoting adherence.

LO 7

All patients should be counseled initially and repeatedly on ways to prevent viral transmission. Patients receiving antiretroviral therapy can still transmit virus to sexual partners, although the risk is extremely low when the patient is virally suppressed, and to those with whom they share needles or other drug equipment. Where both partners are living with HIV, safe sex and needle practices reduce the risk of superinfection with differing strains of HIV and the transmission of other sexually transmitted diseases. General guidelines for preventing viral transmission include using condoms with a water-based lubricant for vaginal or anal intercourse, using condoms without lubricant or dental dams for oral sex, and not sharing equipment used to prepare, inject, or inhale drugs. Treating other STIs, particularly genital herpes, in patients living with HIV may help to prevent HIV transmission. The presence of STIs increases genital tract HIV viral load and, correspondingly, the risk of HIV transmission to sexual partners.

KEY CONCEPT Nutrition and dietary counseling should also be included in the care of the HIV patient, as poor nutrition leads to poorer outcomes and complicates treatment. Antiretroviral therapy itself introduces a host of nutritional issues, including drug–food interactions, gastrointestinal (GI) adverse effects that may affect appetite and limit dietary intake, lipid abnormalities, and fat redistribution. The American Dietetics Association currently recommends assessing HIV-infected patients for their level of nutritional risk and involving a registered dietician as part of the clinical team for optimal nutrition care.[9]

Pharmacologic Therapy for Antiretroviral-Naïve Patients

Two expert panels publish guidelines for the treatment of HIV-infected individuals. Although the recommendations are quite similar, slight differences do exist between the Department of Health and Human Services (DHHS) Guidelines[8] and the International Antiviral Society–USA (IAS-USA) Panel Recommendations.[10] The DHHS Guidelines are updated frequently, and current and archived versions are available online at www.aidsinfo.nih.gov.

Due to the intense research and constant modifications to therapeutic approaches in the treatment of HIV, the majority of the treatment algorithms and recommendations presented herein follow the most up-to-date information found in the October 2017 DHHS recommendations.

KEY CONCEPT Initiating highly active antiretroviral therapy is recommended in all patients living with HIV willing to adhere to lifelong therapy to prevent HIV transmission and reduce the morbidity and mortality associated with HIV infection. Other factors to consider include the patient's viral load, decline in $CD4^+$ counts over time, hepatitis B and hepatitis C status, risk for cardiovascular disease, risk of transmission to sex partners, and willingness to begin therapy and maintain medication adherence. The DHHS Guidelines recommend initiating antiretroviral therapy in all HIV-infected individuals to reduce the risk of disease progression regardless of CD4 count. Once the decision is made to initiate treatment, the regimen is selected based on patient-specific factors. KEY CONCEPT All recommended regimens for initial treatment contain two NRTIs (tenofovir [disoproxil fumarate or alafenamide] + emtricitabine OR abacavir + lamivudine) with an INSTI, a PI with a pharmacokinetic enhancer, or an NNRTI. The recommended agents are shown in Table 87–2.

LO 4

Drug resistance testing should be performed at diagnosis and again prior to initiating treatment if treatment is deferred (see Pharmacologic Therapy for Antiretroviral-Experienced Patients for further discussion of drug resistance testing). The results of resistance testing may dictate which drug class is preferred; a minimum of 10% to 17% of newly diagnosed patients will have drug-resistant virus.[11] This initial resistance pattern often involves the NNRTIs, but may involve other drug classes. INSTI-based regimens have the advantage of avoiding many complex drug–drug interactions and toxicities seen with NNRTIs and PIs. However, elvitegravir must be coadministered with cobicistat which is associated with many cytochrome (CYP)-450-mediated drug interactions and should not be initiated in patients with a creatinine clearance (CrCl) less than 70 mL/min (1.17 mL/s) when using the co-formulation with TDF. If transmitted INSTI resistance is a concern, integrase resistance testing must be ordered separately from standard HIV genotyping, which only includes the protease and reverse transcriptase genes.

If abacavir is included in a regimen, patients should undergo human leukocyte antigen (HLA)-B*5701 testing prior to initiation to assess the risk of abacavir hypersensitivity. Patients who test positive for the allele are at high risk (approximately 50%–67%) of developing this reaction and should not be given abacavir.[8] An abacavir allergy should also be documented in the patient's medical record to prevent future administration. Those patients with a negative test may receive abacavir, but should still be counseled and monitored for the development of hypersensitivity. Tenofovir alafenamide is a new formulation of tenofovir that is associated with less nephrotoxicity and impact on bone mineral density than its predecessor tenofovir disproxil fumarate, and may be preferable from a toxicity standpoint.

In patients who cannot tolerate the recommended initial regimens for most patients living with HIV, or have a compelling reason to choose a different agent, the following alternative regimens are recommended (Table 87–3).[8]

PI-based regimens may be preferable in patients in whom adherence is a concern or drug resistance results are pending given the high threshold of this class resistance. NNRTI-based regimens have low pill burdens and may have decreased incidence of long-term adverse effects (eg, dyslipidemia) in comparison with some PI-based regimens. However, this class also has a low threshold for drug resistance (the K103N mutation causes high level cross-class resistance), and patient adherence is a critical consideration. Regimens with demonstrated efficacy but limited by other factors such as toxicities or pull burden are also provided in the guidelines. One of these regimens should only be selected if a first-line or alternate regimen is intolerable or the patient has a compelling reason to avoid drugs in a first-line or alternate regimen.

The guidelines include a list of therapies *not recommended* for initial treatment due to poor potency or significant toxicity. Other therapies that should not be used include darunavir without a pharmacokinetic enhancer ("unboosted"), and ritonavir used without another PI. Drugs that should *not be combined* due to overlapping toxicities include atazanavir plus indinavir (due to enhanced hyperbilirubinemia), two NNRTIs, and didanosine plus stavudine. Emtricitabine and lamivudine should not be combined because of their similar chemical structures, and antagonism can result when stavudine is combined with zidovudine.

Table 87–2

Recommended Initial ART Regimen Options for Most Patients Living with HIV, Regardless of Pre-ART Viral Load or CD4 Cell Count[8]

INSTI-Based Regimen:

Dolutegravir/abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative)*

Dolutegravir + tenofovir disoproxil fumarate/emtricitabine OR tenofovir alafenamide/emtricitabine

Elvitegravir/cobicistat/tenofovir alafenamide/emtricitabine *(Only for patients with pre-ART CrCL ≥ 30 mL/min [1.17 mL/s])*

Elvitegravir/cobicistat/tenofovir disoproxil fumarate/emtricitabine *(Only for patients with pre-ART CrCL > 70 mL/min [1.17 mL/s])*

Raltegravir + tenofovir disoproxil fumarate/emtricitabine OR tenofovir alafenamide/emtricitabine

ART, Antiretroviral therapy; HIV, human immunodeficiency virus.

Table 87–3

Recommended Initial cART Regimen Options in Certain Clinical Situations

PI-Based Regimens:

Darunavir/cobicistat OR Darunavir/ritonavir + tenofovir disoproxil fumarate/emtricitabine OR tenofovir alafenamide/emtricitabine

Atazanavir/cobicistat OR atazanavir/ritonavir + tenofovir disoproxil fumarate/emtricitabine OR tenofovir alafenamide/emtricitabine

Darunavir/cobicistat OR Darunavir/ritonavir + abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative)*

Atazanavir/cobicistat OR atazanavir/ritonavir + abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative and HIV RNA < 100,000 copies/mL)*

NRTI-Based Regimens:

Efavirenz + tenofovir disoproxil fumarate/emtricitabine OR tenofovir alafenamide/emtricitabine

Rilpivirine/tenofovir disoproxil fumarate/emtricitabine OR rilpivirine/tenofovir alafenamide/emtricitabine (If HIV RNA < 100,000 copies/mL and CD4 > 200 cells/mm^3)

INSTI-Based Regimen:

Raltegravir + abacavir/lamivudine *(Only for patients who are HLA-B*5701 negative and HIV RNA < 100,000 copies/mL)*

cART, combination antiretroviral therapy; HIV, human immunodeficiency virus; RNA, ribonucleic acid.

Patient Encounter 1, Part 2

After receiving the diagnosis of HIV and assessing his laboratory values and willingness to initiate therapy, the patient from Part 1 and his medical team decide to start antiretroviral therapy.

What is the guidance for when to start therapy in a treatment-naïve patient?

What are the recommended regimens according to the DHHS Guidelines?

What is the potential for drug interactions with each of the recommended regimens?

Which concomitant medication complicates initiating therapy in this patient and what are possible ways to manage such drug interactions?

What adverse effects does the patient need to be counseled on with each of the recommended regimens?

Pharmacologic Therapy for Antiretroviral-Experienced Patients

KEY CONCEPT Ongoing viral replication, whether at low levels (plasma HIV RNA < 200 copies/mL) in the face of adequate drug concentrations or at higher levels due to inconsistent systemic concentrations (or low concentrations in sanctuary sites, eg, male and female genital fluids, cerebrospinal fluid, or lymph nodes), will eventually lead to resistance to the prescribed medications. To avoid further progression of resistant mutations, drug-resistance testing should be performed and then a failing regimen should be discontinued as soon as possible.[8] The goal of therapy for patients with antiretroviral resistance is to reestablish virologic suppression or plasma HIV RNA lower than the limit of detection of the assay (typically < 40 *copies/mL* [40 × 10^3 copies/L]).

LOS Treatment considerations for antiretroviral-experienced patients are much more complex than for patients who are naïve to therapy. Prior to changing therapy, the reasons for treatment failure should be identified. A comprehensive review should be performed of the patient's severity of disease, antiretroviral treatment history, adherence to therapy, intolerance or toxicity, concomitant drug therapies, comorbidities, and results of current and past HIV resistance testing. If patients fail therapy due to poor adherence, the underlying reasons must be determined and addressed prior to initiation of a new regimen. Reasons for poor adherence may include problems with medication access, active substance abuse, depression and/or denial of the disease, and a lack of education on the importance of 100% adherence to therapy. Medication intolerance or toxicity can be remedied with therapy for the adverse event, exchanging the drug causing the toxicity with another in the same class, or changing the entire regimen. Pharmacokinetics or systemic drug exposure can be optimized by ensuring maximal drug absorption (taking the drug with or without food can alter exposure by up to 30%) and avoiding interactions with concomitant prescription or nonprescription medications and dietary supplements.

Drug interactions between different antiretroviral agents and between antiretrovirals and concomitant medications should be evaluated for each patient to avoid under- and/or overexposure of either therapy. KEY CONCEPT NNRTIs, PIs, certain INSTIs, and maraviroc are metabolized by CYP-450 enzymes. In addition, NNRTIs, PIs, and cobisistat are inhibitors and/or inducers of this enzyme system. Some of the antiretrovirals are substrates, inhibitors, and/or inducers of transporters such as P-glycoprotein (P-gp) and therefore may lead to drug interactions. Information provided in Table 87–4 describes the drug interaction potential of each antiretroviral. Due to ever-changing drug interactions, the regularly updated DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1–Infected Adults and Adolescents are a recommended source of specific drug interactions.[8]

The goals of therapy differ for antiretroviral-experienced patients who have limited drug exposure (ie, developing resistance to their first antiretroviral regimen) versus those with extensive exposure (ie, developing resistance to their third or fourth antiretroviral regimen). It is reasonable to expect maximal viral suppression in those with limited drug exposure. However, this may not be feasible for patients with prior exposure to multiple medications. In antiretroviral-experienced patients, a reasonable goal is to preserve immune function and prevent clinical progression.

Several issues need to be considered in choosing a salvage regimen for HIV infection. Knowing prior medication exposure can assist in identifying which drugs to avoid. However, direct HIV resistance testing can better identify the resistance and susceptibility patterns of the major viral strains. Two types of HIV resistance testing are available, an HIV **genotype** and an HIV **phenotype**. Genotyping involves detecting mutations by genetically sequencing the virus, whereas phenotyping determines the ability of the virus to replicate in the presence of varying antiretroviral concentrations. Phenotyping involves exposing a sample of a patient's HIV to antiretroviral drugs and directly measuring the ability of HIV to grow in the presence of these drugs to determine which drugs will have activity. Genotyping is more rapid and less costly than phenotyping, but results in a list of mutations that may be more difficult to interpret than phenotyping. An HIV virtual phenotype report may also be obtained when genotypes are ordered.[8] This compares the patient's viral sequence to a database of matched genotypes and drug susceptibilities to estimate the patient's phenotype (the likely susceptibility of the patient's virus to different antiretrovirals). Web-based tools are available to assist with interpretation of resistance mutations (eg, Stanford University's HIV Drug Resistance Database; http://hivdb.stanford.edu/index.html). However, interpretation of genotype and phenotype reports is recommended in conjunction with practitioners with advanced infectious diseases training.

Because HIV may be susceptible to certain components of the failing antiretroviral regimen, these drugs can be recycled into future regimens. Resistance testing should be obtained when all patients enter into care, in patients with virologic failure on an antiretroviral regimen, or with suboptimal suppression after initiation of antiretroviral therapy. Testing is generally preferred for antiretroviral naïve patients. For resistance testing to be useful, the patient should have a plasma HIV RNA of at least 1000 copies/mL (1 × 10^6 copies/L) and should be currently taking their antiretroviral medications (or be within 4 weeks of discontinuing antiretroviral therapy). Generally, this viral concentration is necessary to yield reliable amplification of the virus, and the antiretroviral medications are needed because the dominant viral species reverts to **wild-type** within 4 to 6 weeks after medications are stopped.

LOS Management of antiretroviral-experienced patients is complex, and expert opinion is advised before selecting therapy. KEY CONCEPT As with antiretrovial-naïve patients, three or more active drugs should be prescribed.[8] Since considerable cross-resistance can occur between medications within an antiretroviral class, using drugs to which the patient has not been exposed may be insufficient. Complete

Table 87–4

Summary of Currently Available, Commonly Used Antiretroviral Agents[a]

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Nucleoside (Tide) Reverse Transcriptase Inhibitors						
Abacavir (Ziagen)	300 mg tablet; 20 mg/mL oral solution	300 mg twice daily or 600 mg once daily	Child Pugh Class A: 200 mg twice daily Child Pugh Class B or C: contraindicated	None (alcohol increases abacavir conc. by 41%)	Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)—HLA B*5701 test before treatment	Alcohol dehydrogenase and glucuronyl transferase, 82% renal excretion of metabolites
Emtricitabine (Emtriva)	200 mg capsule; 10 mg/mL oral solution	200 mg daily; 240 mg oral solution daily	CrCl (mL/min [mL/s]): / Capsule: / Solution: 30–49 [0.50–0.82] / 200 mg every 48 hours / 120 mg every 24 hours 15–29 [0.25–0.49] / 200 mg every 72 hours / 80 mg every 24 hours < 15/HD [0.25/HD] / 200 mg every 96 hours / 60 mg every 24 hours Dose after dialysis on dialysis days	None	Minimal	Renal excretion; minimal drug interaction potential
Lamivudine (Epivir)	150 mg and 300 mg tablets, 10 mg/mL oral solution	150 mg twice daily or 300 mg once daily	CrCl (mL/min [mL/s]): / Dose: 30–49 [0.50–0.82] / 150 mg every day 15–29 [0.25–0.49] / 150 mg, then 100 mg every day 5–14 [0.08–0.24] / 150 mg, then 50 mg every day < 5/HD [0.08/HD] / 50 mg, then 25 mg every day	None	Minimal	Renal excretion
Tenofovir disoproxil fumarate (Viread)	150-, 200-, 250-, 300-mg tablet; 40 mg per 1g powder	300 mg once daily	CrCl (mL/min [mL/s]): / Dose: 30–49 [0.50–0.82] / 300 mg every 48 hours 10–29 [0.17–0.49] / 300 mg twice weekly ESRD/HD / 300 mg every 7 days	Powder taken with food	Asthenia, headache, diarrhea, renal insufficiency, decreased bone mineral density	Renal excretion
Tenofovir alafenamide (Vemlidy) *Of note, only FDA labelled for HBV infection, not HIV*	25 mg tablet	25 mg once daily	Do not use with CrCL < 15 mL/min (0.25 mL/s)	With food	Headache	32% excreted in feces and < 1% in urine

Zidovudine (Retrovir)	100-mg capsule, 300-mg tablet, 10 mg/mL IV solution, 10 mg/mL oral solution	300 mg twice daily	100 mg three times daily or 300 mg once daily in severe renal impairment (CrCl < 15 mL/min [0.25 mL/s]) or HD	None	Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia	Glucuonyl transferase and renal
Zidovudine + lamivudine (Combivir)	Zidovudine 300 mg + lamivudine 150 mg tablet	One tablet twice daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	See adverse events for zidovudine and lamivudine	See zidovudine and lamivudine
Abacavir + lamivudine + zidovudine (Trizivir)	Abacavir 300 mg + lamivudine 150 mg + zidovudine 300 mg tablet	One tablet twice daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	See adverse events for zidovudine, lamivudine, and abacavir	See zidovudine, lamivudine, and abacavir
Abacavir + lamivudine (Epzicom)	Abacavir 600 mg + lamivudine 300 mg tablet	One tablet daily	Do not use with CrCl < 50 mL/min (0.83 mL/s)	None	See adverse events for abacavir and lamivudine	See abacavir and lamivudine
Tenofovir disoproxil fumarate + emtricitabine (Truvada)	Tenofovir disoproxil fumarate 300 mg + emtrcitabine 200 mg	One tablet daily	**CrCl (mL/min [mL/s]):** / **Dose:** 30–49 [0.50–0.82] / One tablet every 48 hours 10–29 [0.17–0.49], ESRD/HD / Not recommended	None	See adverse events for tenofovir disoproxil fumarate and emtricitabine	See tenofovir disoproxil fumarate and emtricitabine
Tenofovir alafenamide + emtricitabine (Descovy)	Tenofovir alafenamide 25 mg + emtricitabine 200 mg	One tablet daily	Do not use with CrCl < 30 mL/min (0.5 mL/s)	None	See adverse events for tenofovir alafenamide and emtricitabine	See tenofovir alafenamide and emtricitabine
Nonnucleoside Reverse Transcriptase Inhibitors						
Efavirenz (Sustiva)	50-, 200-mg capsules or 600-mg tablet	600 mg daily at or before bedtime	Use with caution in patients with hepatic impairment	Take on an empty stomach high-fat/calorie meals increases C_{max} of capsule 39% and C_{max} of tablet 79%	Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys	Metabolized by CYP2B6 and CYP3A (3A mixed inducer/inhibitor); 14%–34% excreted in urine (glucuronidated metabolites, < 1% unchanged); 16%–61% in feces
Etravirine (Intelence)	25-, 100-, 200-mg tablets	200 mg twice daily following a meal	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C.	Take following a meal. Fasting decreases systemic exposure by 50%.	Rash, nausea	Metabolized by CYP3A, 2C9, and 2C19; induces 3A4 and inhibits 2C9 and 2C19

Table 87–4

Summary of Currently Available, Commonly Used Antiretroviral Agents[a] (*Continued*)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Nevirapine (Viramune, Viramune XR)	200-mg tablet, 100 and 400-mg XR tablet or 50 mg/5 mL oral suspension	200 mg once daily for 14 days; then 200 mg twice daily. For XR tablet, lead-in with 200 mg once daily of IR tablet followed by 400 mg daily XR tab not recommended for initiation in the following groups unless benefit outweighs the risk: 1) adult females with CD4 cell counts > 250 cells/mm^3 2) adult males with CD4 cell counts > 400 cells/mm^3	Use with caution in patients with hepatic impairment; avoid use with moderate to severe hepatic impairment	No food restrictions	Rash including Stevens-Johnson syndrome; symptomatic hepatitis, including fatal hepatic necrosis	Metabolized by CYP2B6 and CYP3A (3A inducer); 80% excreted in urine (glucuronidated metabolites; < 5% unchanged); 10% in feces
Rilpivirine (Edurant)	25-mg tablet	25 mg daily	No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C; use with caution in severe or end-stage renal impairment	Take with food (a normal- to high-calorie meal) Absorption dependent on gastric pH-special considerations needed when coadministered with antacids	Rash; depressive disorders	Metabolized by CYP3A4
Tenofovir disoproxil fumarate + emtricitabine + efavirenz (Atripla)	Tenofovir disoproxil fumarate 300 mg Emtricitabine 200 mg Efavirenz 600 mg	One tablet daily	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s)	High-fat/high-caloric meals increase peak plasma concentrations of efavirenz capsules by 39% and efavirenz tablets by 79%; take on empty stomach	See adverse events of tenofovir, emtricitabine, and efavirenz	See tenofovir, emtricitabine, and efavirenz
Tenofovir disoproxil fumarate+ emtricitabine + rilpivirine (Complera)	Tenofovir disoproxil fumarate 300 mg Emtricitabine 200 mg Rilpivirine 25mg	One tablet daily with a meal	Do not use in patients with CrCl < 50 mL/min (0.83 mL/s)	Take with food (preferably high fat meal), avoid acid suppression	See adverse events of tenofovir disoproxil fumarate, emtricitabine, and rilpivirine	See tenofovir disoproxil fumarate, emtricitabine, and rilpivirine

Tenofovir alafenamide+ emtricitabine + rilpivirine (Odefsey)	Tenofovir alafenamide 300 mg Emtricitabine 200 mg Rilpivirine 25mg	One tablet daily with a meal	Do not use in patients with CrCl < 30 mL/min (0.5 mL/s)	Take with food (preferably high fat meal), avoid acid suppression	See adverse events of tenofovir alafenamide, emtricitabine, and rilpivirine	See tenofovir alafenamide, emtricitabine, and rilpivirine
Protease Inhibitors						
Atazanavir (Reyataz) Atazanavir + cobicistat (Evotaz)	150-, 200-, 300-mg capsules, 50 mg oral packet Evotaz: 300 mg atazanavr plus 150 mg cobicistat tablet	Atazanavir 300mg + ritonavir 100 mg or cobicistat 150 mg OR atazanavir 400 mg daily If taken with tenofovir, use the following: atazanavir 300 mg daily + ritonavir 100 mg daily If taken with efavirenz in treatment of naïve patients only: atazanavir 400 mg daily + ritonavir 100 mg daily (do not use with efavirenz in treatment of experienced patients)	Child-Pugh Class C: Not recommended Treatment-naïve patients on hemodialysis: atazanavir 300 mg + ritonavir 100 mg daily; treatment-experienced patients on hemodialysis: Not recommended	Take with food (AUC increases 30%); pH-sensitive dissolution—special considerations needed when coadministered with antacids	Indirect hyperbilirubinemia; prolonged PR interval (asymptomatic first-degree AV block); use with caution in patients with underlying conduction defects or on concomitant medications that can cause PR prolongation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor and substrate; UGT1A1 inhibitor
Darunavir (Prezista) Darunavir + Cobicistat (Prezcobix)	75-g, 150-mg, 600-mg, 800-mg tablets, 100 mg/mL oral suspension Prezcobix: 800 mg darunavir + 150 mg cobicistat tablet	Darunavir 600 mg + ritonavir 100 mg twice daily in treatment experienced patients with at least 1 darunavir resistance-associated subsitution Darunavir 800 mg daily + ritonavir 100 mg or cobicistat 150 mg daily in treatment naïve patients	Use with caution in patients with hepatic impairment	Take with food	Skin rash (has a sulfonamide moiety, Stevens-Johnson and erythema multiforme have been reported); diarrhea, nausea; headache; hyperlipidemia; transaminase elevation; hyperglycemia; fat maldistribution; possible increased bleeding episodes in patients with hemophilia	CYP3A4 inhibitor and substrate

(*Continued*)

Table 87–4

Summary of Currently Available, Commonly Used Antiretroviral Agents[a] (*Continued*)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments		Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Lopinavir + ritonavir (Kaletra)	Lopinavir 100 mg + ritonavir 25 mg tablet, Lopinavir 200 mg + ritonavir 50-mg tablet, lopinavir 400 mg + ritonavir 100 mg/5 mL oral solution (contains 42% alcohol)	Two 200/50 mg tablets or 5 mL twice daily, four 200/50 mg tablets once daily; with efavirenz or nevirapine: 3 tablets or 6.5 mL twice daily	Use with caution in patients with hepatic impairment	Take with food (AUC increases 48%–80%)	Nausea, vomiting, diarrhea; asthenia; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in hemophiliacs		CYP3A4 inhibitor and susbstrate CYP2C9, 2C19, 1A2 inducer
Ritonavir (Norvir)	100-mg tablet or capsule, 80 mg/mL solution (contains 43% alcohol)	100–200 mg/dose when used as pharmacokinetic enhancer	No dosage adjustment in mild hepatic impairment No data for moderate to severe impairment; use with caution	Take with food to improve tolerability	GI intolerance, nausea, diarrhea; paresthesias; hyperlipidemia; hepatitis; asthenia; taste perversion; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs		CYP3A4 inhibitor (potent) and substrate; CYP2D6 substrate; mixed dose-dependent induction and inhibition of other phase I and II enzymes
Fusion Inhibitors							
Enfuvirtide (Fuzeon)	Injectable, in lyophilized powder Each single-use vial contains 108 mg of enfuvirtide to be reconstituted with 1.1 mL of sterile water for injection for delivery of approximately 90 mg/1 mL	90 mg (1 mL) subcutaneously twice daily	No dosage recommendation	N/A	Local injection site reaction (pain, erythema, induration, nodules and cysts, pruritus, ecchymosis) in most patients; increased rate of bacterial pneumonia; < 1% hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, or elevated serum transaminases); do not rechallenge		Catabolism to amino acids, with subsequent recycling in the body pool
Chemokine Receptor Antagonists (CCR5 Antagonists)							
Maraviroc (Selzentry)	25-, 75-, 150-, 300-mg tablets; 20 mg/mL oral solution	150 mg twice daily when given with strong CYP3A inhibitors (with or without CYP3A inducers) including PIs (except tipranavir/ritonavir)	Patients with CrCl < 30 mL/min (0.83 mL/s) should receive maraviroc with a CYP3A inhibitor only if benefit outweighs the risk		No food restrictions	Abdominal pain; cough; dizziness; musculoskeletal symptoms; pyrexia; rash; upper RTI; hepatotoxicity; orthostatic hypotension	CYP3A substrate

		300 mg twice daily when given with NRTIs, enfuvirtide, tipranavir/ritonavir, nevirapine and other drugs that are not potent P450 inhibitors 600 mg twice daily when given with CYP3A inducers, including efavirenz, rifampin, etc. (without a CYP3A inhibitor)				
Integrase Inhibitors						
Dolutegravir (Tivicay)	50-mg tablet	50 mg daily if treatment naïve 50 mg twice daily if coadministered with efavirenz, fosamprenavir, tipranavir/ritonavir, rifampin OR if INSTI-experienced with known or suspected INSTI resistance If co-administered with etravirine, must add lopinavir/ritonavir, atazanavir/ritonavir or darunavir/ritonavir	Use with caution if CrCl < 30 mL/min (0.83 mL/s) No dosage adjustment for Child Pugh Class A or B Not recommended in Class C/has not been studied	Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn)	Insomnia, headache, increased serum creatinine	UGT1A1/3/9 and CYP3A4 (minor) substrate
Elvitegravir + cobicistat + tenofovir disoproxil fumarate + emtricitabine (Stribild)	Elvitegravir 150 mg + cobicistat 150 mg + tenofovir disoproxil fumarate 300 mg + emtricitabine 200-mg tablet	One tablet daily	CrCl < 70 mL/min (1.17 mL/s) at initiation of therapy: Not recommended CrCl < 50 mL/min (0.83 mL/s) during therapy: Continued use is not recommended	Take with food; separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn)	Nausea; diarrhea; proteinuria; increased serum creatinine	Elvitegravir: UGT1A1/3 and CYP3A substrate Cobicistat: CYP3A inhibitor See tenofovir and emtricitabine

(*Continued*)

Table 87–4

Summary of Currently Available, Commonly Used Antiretroviral Agents[a] (*Continued*)

Generic Name [Abbreviation] (Trade Name)	Dosage Forms	Commonly Prescribed Doses	Dose Adjustments	Food Restrictions	Significant Adverse Events	Drug Interaction Potential
Elvitegravir + cobicistat + tenofovir alafenamide + emtricitabine (Genvoya)	Elvitegravir 150 mg + cobicistat 150 mg + tenofovir alafenamide 25 mg + emtricitabine 200-mg tablet	One tablet daily	Do not use if CrCL < 30 mL/min (0.5 mL/s)	Take with food	Nausea; diarrhea; proteinuria; increased serum creatinine	Elvitegravir: UGT1A1/3 and CYP3A substrate Cobicistat: CYP3A inhibitor See tenofovir and emtricitabine
Raltegravir (Isentress)	400-mg tablet, 600 mg HD tablet, 25 mg and 100 mg chewable tablets, 100 mg packets for oral suspension. Formulations not interchangeable	400 mg twice daily 800 mg twice daily if coadministered with rifampin 1200 mg once daily (treatment naïve only)	No dosage adjustment	Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn)	Nausea; headache; diarrhea; pyrexia; CPK elevation	UGT1A1 substrate (glucuronidation)
Abacavir + lamivudine + Dolutegravir (Triumeq)	Abacavir 600 mg Lamivudine 300 mg Dolutegravir 50 mg	One tablet daily	Do not use if CrCl < 50 mL/min (0.83 mL/s) No dosage adjustment for Child Pugh Class A or B Not recommended in Class C/has not been studied		See adverse events of abacavir, lamivudine, and dolutegravir	See abacavir, lamivudine, and dolutegravir

[a]Note, this is not a comprehensive list of all available antiretroviral agents but represents the agents most commonly used based on guideline recommendations.

ARV, antiretroviral; AUC, area under the time-concentration curve; AV, atrioventricular; C_{max}, maximum concentration; CrCl, creatinine clearance; ESRD, end-stage renal disease; HD, hemodialysis; INSTI, integrase strand transfer inhibitor; LFT, liver function test; NRTI, nucleoside reverse transcriptase inhibitor; UGT, uridine diphosphate-glucuronsyltransferase.

Adapted from Panel on Antiretroviral Guidelines for Adults and Adolescents. Guidelines for the use of Antiretroviral Agents in HIV-1-infected Adults and Adolescents [online]. Department of Health and Human Services. July 14, 2016. Available at http://www.aidsinfo.nih.gov/ContentFiles/AdultandAdolescentGL.pdf.

cross-resistance occurs within the first generation of NNRTIs (nevirapine , delavirdine, and efavirenz), whereas the NRTIs and PIs have variable overlapping resistance patterns. For this reason, HIV resistance assays are important tools for choosing effective therapies. The use of antiretrovirals with unique mechanisms of action such as enfuvirtide (fusion inhibitor) or maraviroc (CCR5 antagonist) may be warranted as salvage therapy. If maraviroc is chosen, a tropism assay is a test that should be performed to determine if the patient's virus utilizes the CCR5 co-receptor to enter host cells (as opposed to CXCR4 co-receptors). If patients fail therapy with resistance to only one or more drugs, expert consultation is needed.

Given the complexity of selecting appropriate cART therapy and the ability of the virus to rapidly develop resistance, the concept of antiretroviral stewardship is important. Antiretroviral Stewardship encompasses practices aimed at improving antiretroviral medication use with the goal of minimizing medication errors related to cART and optimizing HIV treatment outcomes. Such efforts may entail routine review of patients admitted to an institution on antiretrovirals and provider education in order to ensure an appropriate and complete cART regimen is selected (with regards to drug, dose, formulation, administration considerations) and drug–drug interactions are minimized. Antiretroviral Stewardship can have a significant impact on cART medication error prevention, with a medication error rate reduction rate of 12% to 35% demonstrated in studies, depending on the type of intervention implemented.

Treatment Considerations in Special Populations

► *Acute HIV Infection*

Diagnosis of acute HIV infection is difficult, since many patients are asymptomatic or have nonspecific clinical symptoms similar to other common respiratory infections. The 4th generation antigen/antibody test increases the ability to detect acute HIV-1 infection, but no laboratory assay can detect HIV immediately after it is acquired.

There is limited outcome data for treating acutely infected patients. Treatment of acute infection can decrease the severity of acute disease and decrease the viral set point; this may decrease progression rates and reduce the rate of viral transmission.[8] Limitations include an increased risk of chronic drug-induced toxicities and the development of viral resistance. Resistance testing should be performed prior to initiation of therapy due to an increase in transmitted resistance in antiretroviral naïve patients.[8]

► *Adolescent and Young Adult Patients*

Adolescents infected after puberty acquire HIV in similar ways to adults, and are thus treated as adults. In this population, dosing of antiretroviral drugs should not be based on age, but on the Tanner stage (which considers external primary and secondary sexual characteristics).[8] Adolescents in early puberty should be dosed according to pediatric guidelines, whereas those in late puberty should be dosed as adults. During growth spurts, adolescents should be monitored closely for drug efficacy and toxicity, since rapid changes in weight can lead to altered drug concentrations. Adherence is of concern in this population due to denial of the disease, misinformation, distrust of health care professionals, low self-esteem, and lack of family and/or social support. Additionally, asymptomatic patients this age find it more difficult to adhere to therapy while feeling well.

► *Pediatric Patients*

There are unique considerations in the treatment of HIV-infected children. Specific treatment guidelines exist,[12] but a thorough review is outside the scope of this chapter. Most children acquire HIV infection through perinatal transmission either in utero, intrapartum, or postpartum through breast-feeding, although antiretroviral interventions have dramatically reduced transmission rates.[8] Antiretroviral therapy research is limited in pediatric patients, as some drugs have no dosing recommendations for this population or are not available in a formulation that can be easily administered to children. Additionally, drug exposures can change dramatically during early childhood development due to altered drug-metabolizing enzyme and drug transporter activities.

► *Pregnancy and Women of Reproductive Potential*

The goals of antiretroviral therapy for women of reproductive age and pregnant women are the same as for other adult patients. Specific guidelines for pregnant women living with HIV are available.[13] If a woman is already virally suppressed on an antiretroviral regimen at the time she becomes pregnant, it is recommended that she remain on that regimen. Of note, efavirenz has previously been recommended against during pregnancy. However, because the risk of neural tube defects with efavirenz is highest during the first 5 to 6 weeks of pregnancy, and pregnancy is often not detected before 4 to 6 weeks, it is reasonable for women virologically suppressed on an efavirenz-containing regimen to continue that regimen rather than switch regimens and risk viral rebound. If not already on antiretroviral therapy, recommended therapies in pregnancy include atazanavir + ritonavir, darunavir + ritonavir or raltegravir all administered with a two NRTI backbone (abacavir/lamivudine or TDF/emtricitabine). Alternate regimens include lopinavir/ritonavir or efavirenz administered with a two-NRTI backbone or rilpivirine/TDF/emtricitabine. A dual nucleoside reverse transcriptase inhibitor (NRTI) backbone that includes one or more NRTIs with high levels of transplacental passage, if possible, is recommended. The goal of therapy is to reduce plasma HIV RNA below detectable levels and prevent MTCT of HIV. Limited data are available on some antiretroviral pharmacokinetics in pregnancy, with close plasma HIV RNA and CD4 monitoring in the third trimester of pregnancy. Standard doses are currently recommended for most antiretroviral drugs, although higher doses of some PIs may be indicated depending on the trimester of pregnancy.

Efavirenz, nevirapine, ritonavir, atazanavir/ritonavir, lopinavir/ritonavir, tipranavir/ritonavir, darunavir/ritonavir, fosamprenavir/ritonavir, and saquinavir/ritonavir decrease the concentrations of different estrogens and/or progestins in oral contraceptives, which could lead to failure.[8] For patients prescribed these drugs, barrier forms of contraception are preferred to prevent pregnancy. Atazanavir may be taken with oral contraceptives with extreme caution, as it can increase or decrease the exposure to estrogen and progesterone, depending on whether it is used in combination with ritonavir. Depo-Provera(medroxyprogesterone) is likely the safest alternative, as studies have shown no significant interactions between depot medroxyprogesterone acetate and antiretrovirals.[14] Maraviroc, raltegravir, elvitegravir/cobicistat, and dolutegravir have not shown clinically significant effects when used with oral contraceptives.

► *Hepatitis B Coinfection*

Patients living with HIV coinfected with the hepatitis B virus (HBV) have higher concentrations of DNA and hepatitis B early antigen (HBeAg) and higher rates of HBV-associated liver disease than in patients with chronic HBV infection without HIV. Indications to initiate therapy for HBV/HIV coinfected patients are the same as in HIV-negative patients and are based on the HBV DNA level, serum alanine aminotransferase

(ALT), and severity of liver disease. One option to treat HBV is nucleoside/tide analogs. Nucleoside/tide analogs that treat HBV but not HIV are adefovir and entecavir. Entecavir, however, exhibits minimal antiviral activity against HIV, and should never be administered to coinfected patients who are not concurrently receiving fully suppressive HIV therapy. If given without suppressive antiretrovirals, entecavir can select for M184 resistance, leading to HIV resistance to emtricitabine and lamivudine. Nucleoside/tide analogs that are used to treat HBV and HIV are lamivudine, emtricitabine, and tenofovir. Combinations of tenofovir disoproxil fumarate + emtricitabine, tenofovir alafenamide + emtricitabine or tenofovir disoproxil fumarate + lamivudine should comprise the NRTI backbone of a fully suppressive regimen.[15] When changing HIV therapy in a patient with HBV viral suppression, the new regimen should also treat HBV; the lamivudine, emtricitabine, or tenofovir formulation should be continued for treatment of HBV in addition to the new HIV regimen.[8] Abrupt discontinuation of these antiretrovirals may result in significant hepatic injury due to the exacerbation of hepatitis B. Of note, HBV infection should not be treated if a patient is not being treated for HIV.

Vaccination against HBV can effectively prevent transmission. If there is no record of vaccination, or immunization history is unknown, patients living with HIV should be vaccinated.

▶ *Hepatitis C Coinfection*

All patients living with HIV should be screened for hepatitis C virus (HCV) infection. Patients coinfected with HCV and HIV have an increased rate of progression to cirrhosis, decompensated liver disease, hepatocellular carcinoma, and death compared with monoinfected HCV alone.[15] All HCV/HIV coinfected patients should be considered for therapy. Comprehensive treatment guidelines for HIV/HCV-coinfected patients are available and have recently been updated to reflect the rapidly evolving treatment options for HCV.[8,16] It is important to consider the potential for clinically significant drug–drug interactions when selecting an HCV regimen for a patient living with HIV on antiretroviral therapy.

Patient Encounter 2

A 23-year-old African American man presents to your clinic requesting medication to prevent the transmission of HIV. He had learned from his partner living with HIV partner that Truvada (emtricitabine + tenofovir disoproxil fumarate) was a drug used for the prevention of HIV. He also read that there was a newer form of Truvada that was safer for his kidneys and bones and he is interested in learning more about whether or not this is an option for him. He reports engaging in sexual activity with a male partner living with HIV and rarely uses condoms since he states his partner's viral load is always undetectable.

What additional information do you need to know before creating a treatment plan for this patient?

What laboratory tests do you recommend?

What pharmacologic and nonpharmacologic options are available for this patient to protect himself from acquiring HIV?

What monitoring assessments and follow-up would you recommend?

Patient Encounter 3

A 20-year-old woman with HIV and Hepatitis B (virologically suppressed) presents to your clinic for follow-up after initiating Odefsey 4 months ago (baseline HIV viral load: 95,000 copies/mL (95×10^6 copies/L), CD4+ T cell count= 370 cells/mm^3 (370×10^6/L). At her last appointment one month ago, her HIV viral load was 10,000 copies/mL (10×10^6 copies/L) and CD4+ T-cell count = 390 cells/mm^3 (390×10^6/L). Today, her HIV viral load is 12,000 copies/mL (12×10^6 copies/L). Today, she complains of depressed mood and reduced appetite. She states she is taking Odefsey daily as prescribed.

Was this patient initiated on a first-line guideline-recommended treatment regimen for HIV?

What component of Odefsey is likely to be causing depressed mood?

What factors should be considered when trying to determine causes of virologic failure?

You decide to switch the patient's regimen due to side effects and her inability to take the medication as prescribed.

What additional laboratory tests should be obtained at this visit?

Given the patient's comorbidity, what agents should you try to include in this new regimen?

What are some important general counseling points for this patient?

What monitoring assessments and follow-up would you recommend?

Preexposure Prophylaxis (PrEP)

Multiple large-scale clinical trials in populations at highest risk for acquiring HIV have demonstrated that antiretrovirals, particularly tenofovir disoproxil fumarate + emtricitabine, in combination with effective risk-reduction services (eg, counseling, access to condoms, treatment of sexually transmitted disease [STD], etc.), reduce the rate of HIV transmission. Data from these trials has led to the FDA approval of Truvada (fixed-dose combination of TDF 300 mg and emtricitabine 200 mg), as PrEP to reduce the risk of acquiring HIV-1 in adult homosexual men who have sex with men, heterosexually active men and women, and injection drug users who are at substantial risk of HIV acquisition.[17] Patients must be tested for HIV at baseline, and minimally every 3 months while taking PrEP. STD testing should occur at least every 6 months for patients taking PrEP. Additionally, due to the potential toxicities associated with TDF, renal function must be assessed at baseline and at 6-month intervals in patients taking Truvada as PrEP. Patient counseling including stressing the importance of medication adherence should be routinely provided as medication adherence has been linked to PrEP efficacy.[17] Note, at this time, tenofovir alafenamide + emtricitabine (Descovy) is not FDA approved for PrEP; however, studies are ongoing.

OUTCOME EVALUATION

LO 6

KEY CONCEPT The success of antiretroviral therapy is measured by the degree to which the therapy (a) restores and preserves immunologic function, (b) maximally and durably suppresses plasma HIV RNA, (c) improves quality of life, (d) reduces HIV-related morbidity and mortality, and (e) prevents opportunistic

Table 87–5

Serious Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Hepatotoxicity	Other NNRTIs, PIs, most NRTIs, and MVC	**Onset:** NNRTI—60% within first 12 weeks PI—weeks to months NRTI—months to years **Symptoms:** NNRTI—asymptomatic to nonspecific symptoms, such as anorexia, weight loss, or fatigue PI—generally asymptomatic, some with anorexia, weight loss, jaundice Didanosine NRTI—zidovudine, didanosine, stavudine may cause hepatotoxicity associated with lactic acidosis; lamivudine, emtricitabine, or tenofovir may cause HBV flare when these drugs are withdrawn	HBV or HCV coinfection Alcoholism Concomitant hepatotoxic drugs	Monitor LFTs at least every 3–4 months	Rule out other causes. For symptomatic patients: D/C all antiretrovirals and other potential hepatotoxic agents; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents). For asymptomatic patients: If ALT > 5–10 × ULN, may consider D/C antiretrovirals or continue with close monitoring; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents)
Lactic acidosis/ hepatic steatosis ± pancreatitis	NRTIs (esp. stavudine, didanosine, zidovudine)	**Onset:** Months after initiation **Symptoms:** Nonspecific GI (nausea, anorexia, abdominal pain, vomiting, weight loss, fatigue) Laboratory values: ↑ lactate, ↓ arterial pH, ↓ serum bicarbonate, ↑ AST/ALT, ↑ PT, ↑ T.bili, ↓ serum albumin, ↑ amylase/ lipase (with pancreatitis)	Stavudine + didanosine Female sex Obesity Pregnancy Didanosine + hydroxyurea or ribavirin ↑ Duration of NRTI use	None unless symptoms present Consider lactate concentrations in patients with ↓ serum bicarbonate or ↑ anion gap	D/C all antiretrovirals; symptomatic support with fluids; some patients require IV bicarbonate, hemodialysis, parenteral nutrition, or mechanical ventilation; once syndrome resolves, consider using NRTIs with ↓ mitochondrial toxicity (abacavir, tenofovir, lamivudine, or emtricitabine); monitor lactate after restarting NRTIs; some clinicians use NRTI-sparing regimens
Stevens-Johnson syndrome/toxic epidermal necrosis	Nevirapine > efavirenz, delavirdine, etravirine; also, amprenavir, abacavir, zidovudine, didanosine, indinavir lopinavir/r, atazanavir, darunavir, rilpivirine, raltegravir	**Onset:** First day–weeks after therapy start **Symptoms:** Skin eruption with mucosal ulcerations; fever, tachycardia, malaise, myalgia, arthralgia; for nevirapine may also have hepatic toxicity	Nevirapine—female, black, Asian, Hispanic	Nevirapine: use 2-week lead in 200 mg daily, then 200 mg twice a day Avoid corticosteroid use during dose escalation—may increase rash incidence Educate patients to report symptoms as soon as they appear	D/C all antiretrovirals as well as any other possible cause; aggressive symptom support; do not rechallenge patient with offending agent; if caused by nevirapine, avoid NNRTI class, if possible
Hypersensitivity reaction (HSR)	Abacavir	**Onset:** Median = 9 days; 90% within first 6 weeks **Symptoms:** Acute onset of symptoms (most frequent to least): high fever, diffuse skin rash, malaise, nausea, headache, myalgia, chills, diarrhea, vomiting, abdominal pain, dyspnea, arthralgia, respiratory symptoms	HLA-B*5701, HLA-DR7, HLA-DQ3 Antiretroviral-naïve patients Higher incidence with 600 mg every day compared with twice a day dosing	HLA-B*5701 screening prior to abacavir if (+), label as abacavir allergic in medical chart Educate patients about signs and symptoms of HSR and the need of prompt report	D/C abacavir and other antiretrovirals; rule out other causes of symptoms, most signs and symptoms resolve 48 hours after abacavir/D/C; do not rechallenge with abacavir after suspected HSR

(*Continued*)

Table 87–5

Serious Adverse Effects and Management (*Continued*)

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Bone marrow suppression	Zidovudine	**Onset:** Few weeks–months **Symptoms:** Fatigue, risk of ↑ bacterial infections due to neutropenia; anemia, neutropenia	Advanced HIV High-dose zidovudine Preexisting anemia or neutropenia Concomitant use of bone marrow suppressants	Avoid in patients at high risk for bone marrow suppression; avoid other suppressing agents; monitor CBC with differential at least every 3 months	Switch to another NRTI; D/C concomitant bone marrow suppressant, if possible; for anemia: Identify and treat other causes; consider erythropoietin treatment or blood transfusion, if indicated; for neutropenia: Identify and treat other causes; consider filgrastim treatment, if indicated
Nephrotoxicity	Indinavir, tenofovir disoproxil fumarate	**Onset:** Indinavir—months after therapy Tenofovir—weeks to months after therapy **Symptoms:** Indinavir—asymptomatic; rarely develop end-stage renal disease; ↑ serum creatinine, pyruria; hydronephrosis, renal atrophy Tenofovir—asymptomatic to symptoms of nephrogenic diabetes insipidus, Fanconi syndrome; ↑ serum creatinine, proteinuria, hypophosphatemia, glycosuria, hypokalemia, nonanion gap metabolic acidosis	History of renal disease Concomitant use of nephrotoxic drugs	Avoid use of other nephrotoxic drugs; adequate hydration if on indinavir; monitor creatinine, urinalysis, serum potassium and phosphorus in patients at risk	D/C offending agent, generally reversible; supportive care; electrolyte replacement as indicated

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood cell count; CPK, creatine phosphokinase; D/C, discontinue; HBV, hepatitis B virus; HCV, hepatitis C virus; LFT, liver function tests; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; PT, prothrombin time; T.bili, total bilirubin; ULN, upper limit of normal.

Table 87–6

Other Adverse Effects and Management

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Potential Long-Term Complications					
Cardiovascular	Potentially all PIs and other antiretrovirals (efavirenz, stavudine—unfavorable lipid effect; abacavir, didanosine—unknown)	**Onset:** months to years after therapy initiation **Symptoms:** premature CVD	Other risk factors for CVD	Consider non–PI-based regimen; lifestyle modification, counseling	Early diagnosis, prevention, and pharmacologic therapy for hyperlipidemia, HTN, insulin-resistance/diabetes mellitus; assess cardiac risk factors; switch to NNRTI- or atazanavir-based regimen; avoid stavudine
Hyperlipidemia	All PIs (except atazanavir); stavudine; efavirenz (to a lesser extent)	**Onset:** weeks to months after therapy initiation **Symptoms:** all PIs except atazanavir—↑ LDL and total cholesterol (TC), ↑↓ HDL; lopinavir/r and ritonavir—disproportionate ↑ TG; stavudine—↑ TG; may also ↑ LDL and TC; efavirenz or nevirapine—↑ HDL, slight ↑ TG	Underlying hyperlipidemia PI: Tipranavir/r > lopinavir/r and ritonavir > nelfinavir and amprenavir > indinavir and saquinavir > atazanavir NNRTI: < PIs; efavirenz > nevirapine, etravirine, or rilpivirine NRTI: stavudine > zidovudine and tenofovir most common	Use non-PI, nonstavudine-based regimens; use atazanavir-based regimen; monitor fasting lipid profile at baseline, 3–6 months after new regimen, then at least annually	Assess cardiac risk factor; lifestyle modification; switch to antiretrovirals with fewer lipid effects; consider statin therapy
Insulin resistance/ diabetes mellitus	All PIs	**Onset:** weeks to months after therapy initiation **Symptoms:** polyuria, polydipsia, polyphagia, fatigue, weakness; exacerbation of hyperglycemia in patients with underlying diabetes	Underlying hyperglycemia, family history of diabetes mellitus	Use PI-sparing regimens; monitor fasting blood glucose 1–3 months after starting new regimen, then at least every 3–6 months	Diet and exercise; consider switching to an NNRTI-based regimen; if need for pharmacologic therapy, consider metformin, sulfonylurea, "glitazones," or insulin, where indicated
Osteoporosis/ Osteonecrosis	All PIs, Tenofovir disoproxil fumarate	**Onset:** insidious **Symptoms:** mild to moderate periarticular pain; 85% of cases involve one or both femoral heads	Diabetes Prior steroid use Advanced age Alcohol use Hyperlipidemia	Risk reduction (limit steroid and alcohol use): for asymptomatic cases with < 15% bony head involvement, monitor with MRI every 3–6 months × 1 year, then every 6 months × 1 year, then annually	Conservative: reduce weight-bearing activity on affected joint; reduce risk factors; analgesics as needed; surgical: core decompression ± bone grafting (early disease); total joint arthroplasty (severe disease)
Quality-of-Life Complications					
CNS effects	Efavirenz	**Onset:** first few doses **Symptoms:** one or more of the following: drowsiness, insomnia, abnormal dreams, dizziness, impaired concentration, depression, hallucination; exacerbation of psychiatric disorders; psychosis; suicidal ideation	Preexisting or unstable psychiatric illness Use of other drugs with CNS effects May be more common in African Americans due to genetic predisposition of ↓ clearance	Take no earlier than 2–3 hours before bedtime; take on an empty stomach; counsel patients to avoid operating machinery during first 2–4 weeks of therapy	Symptoms usually diminish or resolve after 2–4 weeks; may consider discontinuing therapy if symptoms persist and significantly impair daily function or exacerbate psychiatric illness

(*Continued*)

Table 87–6

Other Adverse Effects and Management (*Continued*)

Adverse Effects	Drug	Signs and Symptoms	Risk Factors	Prevention/Monitoring	Management
Fat maldistribution	PIs, thymidine analogs (stavudine more common than zidovudine)	**Onset:** gradually, months after therapy initiation **Symptoms:** lipoatrophy—peripheral fat loss (facial thinning, thinning of extremities and buttocks); lipohypertrophy—increase in abdominal girth, breast size, and dorsocervical fat pad (buffalo hump)	Lipoatrophy—low baseline body mass index	DEXA scan; lipoatrophy: avoid thymidine analogs or switch from zidovudine or stavudine to abacavir or tenofovir	Switching to other agents may slow or stop progression, but may not reverse effects; injectable poly-L-lactic acid for facial lipoatrophy, human growth hormone
GI intolerance	All PIs, zidovudine, didanosine	**Onset:** first few doses **Symptoms:** nausea, vomiting, abdominal pain; diarrhea commonly seen with nelfinavir, lopinavir/ritonavir, and didanosine-buffered formulations	All patients	Taking with food may reduce symptoms (not for didanosine or unboosted indinavir); may preemptively need antiemetics or antidiarrheals	May spontaneously resolve or become tolerable with time; nausea and vomiting: consider antiemetic prior to dosing; switch to less emetogenic agent; diarrhea: consider antimotility agents, calcium tablets, bulk-forming agents, and/or pancreatic enzymes
Injection site reactions	Enfuvirtide	**Onset:** first new doses **Symptoms:** pain, pruritus, erythema, ecchymosis, warmth, nodules, rarely injection site infection	All patients	Educate regarding use of sterile technique, solution at room temperature, rotation of injection sites, avoidance of sites with little subcutaneous fat or existing reactions	Massaging the area vigorously before and after injection may reduce pain; wear loose clothing around injection site areas; take warm shower or bath prior to injection; rarely, warm compact or analgesics may be necessary

CVD, cardiovascular disease; D/C, discontinue; DEXA, dual-energy x-ray absorptiometry; GI, gastrointestinal; HTN, hypertension; LDL, low-density lipoprotein; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; TG, triglyceride.

infections. KEY CONCEPT The major outcome parameters are plasma HIV RNA, CD4 T-lymphocyte absolute count and percentage. Adequate virologic response in antiretroviral naïve patients is a 1-log decrease in plasma HIV RNA by 2 to 8 weeks after starting medications, followed by concentrations less than 50 copies/mL (50×10^3 copies/L) by 12 to 16 weeks based upon the assay available (if plasma HIV RNA < 100,000/mL [100×10^6/L] or by 16 to 24 weeks if plasma HIV RNA > 100,000/mL [100×10^6/L]). An immunologic response in antiretroviral naïve patients consists of an increase in CD4 cell count that averages 50 to 150 cells/mm^3 (50×10^6 to 150×10^6/L) during the first year of cART (with a faster response in the first 3 months). Virologic failure is defined as the inability to obtain or maintain a plasma HIV RNA less than 200 copies/mL (200×103 copies/L), whereas incomplete virologic response is defined as two consecutive plasma HIV RNA greater than 200 copies/mL (200×103 copies/L) after 24 weeks of therapy.

Upon initiating or changing antiretroviral therapy, plasma HIV RNA should be measured after 2 to 8 weeks and every 4 to 8 weeks until undetectable. Once the viral load is stable (eg undetectable), plasma HIV RNA is monitored generally every 3 to 6 months. In highly treatment-experienced patients, adequate immunologic response may be only a stable, or slightly increased, CD4$^+$ count and a stable HIV RNA. This may be enough to prevent clinical progression. However, with new agents available for treatment-experienced patients, the goal of treatment should be to reestablish maximal viral suppression to less than 20 to 75 plasma HIV RNA copies/mL (20 to 75×10^3 copies/L), depending on the assay used.[8]

There should be a plan for each patient to assess the effectiveness of antiretroviral therapy after initiation. Patients should have follow-up within the first week after initiating a new drug regimen. At each clinic visit, patients should be evaluated for the presence of adverse drug reactions, drug allergies, medication adherence, and potential drug interactions. Antiretrovirals have both class-associated and drug-specific adverse effects (see Table 87–4). If the patient experiences any of the serious, life-threatening effects (Table 87–5), the offending agent should be discontinued promptly, and in most cases the patient cannot be rechallenged. Potential long-term complications that may reduce the quality of life are listed in Table 87–6. If the patient does not tolerate a medication despite efforts to minimize or eliminate barriers to adherence, consider changing the drug.[8]

KEY CONCEPT Treatment of HIV is lifelong. Unplanned short-term treatment interruptions may be necessary due to illness that precludes administration of oral therapy. If a patient must interrupt therapy due to illness, all drugs of the regimen should be stopped at the same time, regardless of half-life. The strategy of scheduling elective treatment interruptions (where patients stop and start antiretroviral therapy based on CD4$^+$ T-cell count criteria) has been evaluated in several clinical trials. Viral rebound occurs quickly after stopping therapy and worsens immune function, causes clinical progression, and may even result in death. More information about treatment interruption can be found in the 2017 DHHS Guidelines.[8]

Patient Care Process: Newly Diagnosed

Collect Information:

- Confirm HIV infection, screen for additional sexually transmitted infections, and assess the risk for opportunistic infections and need for prophylaxis.
- Create a safe and comfortable environment to obtain a thorough medical and medication history (prescription, nonprescription, and natural drug product use). Review and update patient allergies.
- Acquire baseline laboratory data (see Table 87–1) to stage HIV disease and to assist in the selection of cART drug regimens (genotypic resistance testing, HLA-B*5701).

Assess the Information:

- Assess patient's readiness for initiating cART.
- Evaluate comorbid conditions (eg, mental illness, substance abuse) and social issues (economic stability, lack of social support, insurance coverage) that may impair medication adherence.
- Assess the potential for clinically significant drug–drug, drug–food, drug–disease interactions.

Develop a Care Plan:

- Utilize results of genotype in conjunction with patient specific factors to construct a recommended cART regimen.

Implement the Care Plan:

- Provide patient with basic information regarding HIV infection, progression of HIV/prognosis, treatment options, and support services available.
- Inform patient of the benefits of initiating cART, stressing the importance of 100% medication adherence.
- Educate patient on regimen-specific administration and common adverse drug effects (see Table 87–4). Warn patient of the key signs and symptoms of severe toxicity (ie, jaundice and abacavir hypersensitivity reaction [HSR]).
- Provide risk reduction counseling on effective strategies to prevent HIV transmission and disclosure to sexual and/or needle-sharing partners.

Follow-up: Monitor and Evaluate:

- Assess response to cART therapy by drawing plasma HIV RNA within 2 to 4 weeks (no later than 8 weeks) after initiation of cART and every 4 to 8 weeks until plasma HIV RNA is suppressed.
- Monitor immune reconstitution by measuring CD4 count 3 months after initiation of cART.
- Evaluate tolerability of regimen by assessing for adverse events and medication adherence.

Abbreviations Introduced in This Chapter

AIDS	Acquired immunodeficiency syndrome
ALT	Alanine aminotransferase
ART	Antiretroviral therapy
AST	Aspartate aminotransferase
cART	Combination antiretroviral therapy
CPK	Creatine phosphokinase
CVD	Cardiovascular disease
CYP	Cytochrome P-450 isoenzyme
D/C	Discontinue
DEXA	Dual-energy x-ray absorptiometry
DHHS	Department of Health and Human Services
DNA	Deoxyribonucleic acid
ELISA	Enzyme-linked immunosorbent assay
FDA	Food and Drug Administration
GERD	Gastroesophageal reflux disease
gp	Glycoprotein
HAART	Highly active antiretroviral therapy
HBeAg	Hepatitis B early antigen
HBV	Hepatitis B virus
HCV	Hepatitis C virus
HDL	High-density lipoprotein
HIV	Human immunodeficiency virus
HLA	Human leukocyte antigen
HSR	Hypersensitivity reaction
HTN	Hypertension
IAS-USA	International Antiviral Society–USA
INSTI	Integrase strand transfer inhibitor
LDL	Low-density lipoprotein
LFT	Liver function tests
MSM	Men who have sex with men
MTCT	Mother-to-child transmission
NAT	Nucleic acid test
NNRTI	Nonnucleoside reverse transcriptase inhibitor
NRTI	Nucleoside reverse transcriptase inhibitor
NtRTI	Nucleotide reverse transcriptase inhibitor
P-gp	P-glycoprotein
PCP	*Pneumocystis jiroveci* (formerly *carinii*) pneumonia
PI	Protease inhibitor
PrEP	Preexposure prophylaxis
PT	Prothrombin time
RNA	Ribonucleic acid
RT-PCR	Reverse transcriptase polymerase chain reaction
STD	Sexually transmitted disease
STI	Sexually transmitted infection
T.bili	Total bilirubin
TDF	Tenofovir disoproxil fumarate
TG	Triglyceride
ULN	Upper limit of normal

88 Cancer Chemotherapy and Treatment

Lisa M. Holle

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the etiology of cancer.
2. Define the tumor, nodes, metastases (TNM) system of cancer staging.
3. Classify each drug used in the treatment of cancer and compare and contrast the mechanisms of action, uses, and adverse effects.
4. Outline actions for all health professionals to prevent medication errors with cancer treatments.
5. Discuss the impact that increased use of oral chemotherapy agents may have on oncology practice.
6. Describe what cancer survivorship means and how this impacts future health care needs of an individual.
7. Describe the role of health professionals in the care of cancer patients.

INTRODUCTION

KEY CONCEPT The word cancer covers a diverse array of tumor types that affect a significant number of Americans and individuals worldwide and are a major cause of mortality. The term cancer actually refers to more than 100 different diseases. What is common to all cancers is that the cancerous cell is uncontrollably growing and has the potential for invading local tissue and spreading to other parts of the body, a process called **metastases**. Cancer is the second leading cause of death behind heart disease.[1] In 2018, it was projected that nearly 1.8 million Americans will be diagnosed with cancer, and that an estimated 609,640 Americans will die from the cancer.[1] Figure 88–1 describes cancers by gender, new cases, and deaths.

Once diagnosed, a cancer patient may encounter many different health professionals. All health professionals need to collaborate to ensure safe and appropriate prescribing, preparation, administration, and monitoring of anticancer agents; management of toxicities; resolution of reimbursement issues; and participation in clinical trials. The pharmacist is a pivotal member of the care team because of their medication expertise.[2,3]

As a result of advances in research and technology, available cancer treatments have increased dramatically in the last couple of decades. The fields of radiation therapy, surgery, and drug development have made enormous progress over the years; therefore, patients may not only be receiving less toxic treatments but also treatments that have better outcomes than in the past. Supportive care therapies have improved, and patients now may be at less risk for toxicity and have a better **quality of life** than patients in the past. Twenty years ago, most patients received chemotherapy in the hospital because of side effects. Today, most patients are able to receive chemotherapy in the outpatient clinics and/or take oral anticancer agents at home.

Cancer Prevention

Because most cancers are not curable in advanced stages, cancer prevention is an important and active area of research. Both lifestyle modifications and chemoprevention agents may significantly reduce the risk of developing cancer. Although still an active area of investigation, the Food and Drug Administration (FDA) has approved vaccines that can help prevent cancer. Available vaccines include those that prevent infection with human papillomavirus (HPV), responsible for many cancers of the cervix, vulva, vagina, and anus and a vaccine that prevents hepatitis B viral infections, which can cause liver cancer. Additionally, orally administered medications, such as the selective estrogen receptor modulator (SERM) tamoxifen, reduces the risk of breast cancer in premenopausal women. Another SERM, raloxifene and the aromatase inhibitor (AI) exemestane both have shown a reduction in breast cancer in high-risk postmenopausal women. Because these agents will have adverse effects and possible long-term complications (eg, an increased risk of endometrial cancer with the use of tamoxifen), benefits versus risks needs to be weighed when making a recommendation.

Tobacco

Tobacco smoking increases the risk of developing not only lung cancer but also many other types of cancer, including cancer of the bladder, mouth, pharynx, larynx, and esophagus as well as kidney cancer. Smoking cessation is associated with a gradual decrease in the risk of cancer, but more than 5 years is needed before a major decline in risk is detected. In addition, most studies have found that passive smoking (ie, secondhand smoke) also increases a person's risk of developing lung cancer.[4]

Ultraviolet Radiation

Ultraviolet light (sunlight or tanning booths and lamps) and increased skin exposure may increase the risk of melanoma and

Estimates are rounded to the nearest 10, and cases exclude basal cell and squamous cell skin cancers and in situ carcinoma except urinary bladder. Ranking is based on modeled projections and may differ from the most recent observed data.

FIGURE 88–1. Cancer incidences (*top*) and deaths (*bottom*) in the United States for males and females—2018 estimates. (Reproduced, with permission, from American Cancer Society. Cancer Facts and Figures 2018. Atlanta, GA: American Cancer Society, Inc.)

other skin cancers, especially in individuals who have a positive family history, fair skin, light-colored eyes, high degrees of freckling, and a tendency to burn instead of tan. Practitioners can counsel patients on proper sun protection, including minimizing sun exposure, using sunscreens with a sun protection factor (SPF) of 15 or greater on exposed areas, wearing protective clothing and sunglasses, avoiding tanning beds and sun lamps, and the importance of early detection.

CARCINOGENESIS

LO 1

The exact cause of cancer remains unknown and is probably very diverse given the vast array of diseases called cancer. It is thought that cancer develops from a single cell in which the normal mechanisms for control of growth and proliferation are altered. Current evidence indicates that there are four stages in the cancer development process. The first step, initiation, occurs when a carcinogenic substance encounters a normal cell to produce genetic damage and results in a mutated cell. The environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell during promotion, the second step. The main difference between initiation and promotion is that promotion is a reversible process. Third, transformation (or conversion) occurs when the mutated cell becomes malignant. Depending on the type of cancer, up to 20 years may elapse between the carcinogenic phases and the development of a clinically detectable tumor. Finally, progression occurs when cell proliferation takes over and the tumor spreads or develops metastases.

There are substances known to have carcinogenic risks, including chemicals, environmental factors, and viruses. Chemicals in the environment, such as aniline and benzene, are associated with the development of bladder cancer and leukemia, respectively. Environmental factors, such as excessive sun exposure, can result in skin cancer, and smoking is widely known as a cause of lung cancer. Viruses, including HPV, Epstein-Barr virus, and hepatitis B virus, have been linked to cervical cancers, lymphomas, and liver cancers, respectively. Anticancer agents such as the alkylating agents (eg, melphalan), anthracyclines (eg, doxorubicin), and epipodophyllotoxins (eg, etoposide) can cause secondary malignancies (eg, leukemias) years after therapy has been completed. Additionally, factors such as the patient's age, gender, family history, diet, and chronic irritation or inflammation may be considered to be promoters of carcinogenesis.

Cancer Genetics

Because the human genome has been sequenced and with the great improvements in genetic technology, growing knowledge regarding the genetic changes of cancer exist. Two major classes of genes are involved in carcinogenesis: **oncogenes** and **tumor suppressor genes**. **Protooncogenes** are normal genes that, through some genetic alteration caused by carcinogens, change into oncogenes. Protooncogenes are present in all normal cells and regulate cell function and replication. Genetic damage of the protooncogene may occur through point mutation, chromosomal rearrangement, or an increase in gene function, resulting in the oncogene. The genetic damage may either be inherited from an individual's parents (germline mutations) or by way of carcinogenic agents (eg, smoking). The oncogene produces abnormal or excessive gene product that disrupts normal cell growth and proliferation.[5] As a result, this may cause the cell to have a distinct growth advantage, increasing its likelihood of becoming cancerous. Table 88–1 provides examples of oncogenes by their cellular function and associated cancer.[6]

Table 88–1

Examples of Oncogenes and Tumor Suppressor Genes

Gene	Function	Associated Human Cancer
Oncogenes		
Genes for growth factors or their receptors		
EGFR or Erb-B1	Codes for epidermal growth factor (EGFR) receptor	Glioblastoma, breast, head and neck, and colon cancers
HER-2/neu or Erb-B2	Codes for a growth factor receptor	Breast, salivary gland, prostate, bladder, and ovarian cancers
RET	Codes for a growth factor receptor	Thyroid cancer
Genes for cytoplasmic relays in stimulatory signaling pathways		
K-RAS and N-RAS	Code for guanine nucleotide-proteins with GTPase activity	Lung, ovarian, colon, pancreatic cancers Neuroblastoma, acute leukemia
Genes for transcription factors that activate growth-promoting genes		
c-MYC	Codes for transcription factor	Leukemia and breast, colon, gastric, and lung cancers
N-MYC	Codes for transcription factor	Neuroblastoma, small cell lung cancer, and glioblastoma
Genes for cytoplasmic kinases		
BCR-ABL	Codes for a nonreceptor tyrosine kinase	Chronic myelogenous leukemia
ALK	Receptor tyrosine kinase	Lung cancer, lymphomas, neuroblastoma, and ovarian cancer
BRAF	Serine-threonine protein kinase	Colon cancer, lung cancer, melanoma, ovarian, thyroid cancer
KIT (CD117)	Receptor tyrosine kinase	Acute Leukemia, gastrointestinal, stromal tumor, and gastrointestinal stromal tumor
PIK2CA	Lipid kinases	Lung cancer, ovarian cancer
RET	Codes a receptor tyrosine kinase	Lung cancer, thyroid cancer
Genes for other molecules		
BCL-2	Codes for a protein that blocks apoptosis	Indolent B-cell lymphomas
BCL-1 or PRAD1	Codes for cyclin D_1, a cell-cycle clock stimulator	Breast, head, and neck cancers
MDM2	Protein antagonist of p53 tumor suppressor protein	Sarcomas
Tumor-Suppressor Genes		
Genes for proteins in the cytoplasm		
APC	Step in a signaling pathway	Colon and gastric cancer
NF-1	Codes for a protein that inhibits the stimulatory Ras protein	Neurofibroma, leukemia, and pheochromocytoma
NF-2	Codes for a protein that inhibits the stimulatory Ras protein	Meningioma, ependymoma, and schwannoma
Genes for proteins in the nucleus		
MTS1	Codes for p16 protein, a cyclin-dependent kinase inhibitor	Involved in a wide range of cancers
RB1	Codes for the pRB protein, a master brake of the cell cycle	Retinoblastoma, osteosarcoma, and bladder, small cell lung, prostate, and breast cancers
TP53	Codes for the p53 protein, which can halt cell division and induce apoptosis	Involved in a wide range of cancers
PTEN	Phosphatase and tensin homolog deleted on chromosome ten	Lung cancer, ovarian cancer
Genes for protein whose cellular location is unclear		
BRCA1	DNA repair, transcriptional regulation	Breast and ovarian cancers
BRCA2	DNA repair	Breast cancer
VHL	Regulator of protein stability	Kidney cancer
MSH2, MLH1, PMS1, PMS2, MSH6	DNA mismatch repair enzymes	Hereditary nonpolyposis colorectal cancer

From Kiel PJ, Fausel CA. Chronic Leukemias. In: DiPiro JT, Talbert RL, Yee GC, et al. (eds). Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York: McGraw-Hill; 2017: Table 135–2.

Tumor suppressor genes inhibit inappropriate cellular growth and proliferation by gene loss or mutation. This results in loss of control over normal cell growth. The *TP53* gene is one of the most common tumor suppressor genes, and mutations of *TP53* may occur in up to 50% of all malignancies. This gene stops the cell cycle to enable "repairs" of the cell. If *TP53* is inactivated, then the cell allows the mutations to occur. Although mutations of the *TP53* gene are found in many tumors, such as breast, colon, and lung cancer, it is also associated with drug resistance of cancer cells. Deoxyribonucleic acid (DNA) repair genes fix errors in DNA that occur because of environmental factors or errors in replication and can be classified as tumor suppressor genes. Mutations in DNA repair genes have been reported in hereditary nonpolyposis colon cancer and in some breast cancer syndromes.

KEY CONCEPT Numerous cellular changes occur in the genetic material of the cancer cell so that programmed cell death (PD), or apoptosis, does not occur. Proliferation of cancer cells goes unregulated. If mutations persist and cells are not repaired or suppressed, cancer may develop. **Apoptosis**, or PD, may prevent the mutated cell from becoming cancerous. Loss of *TP53* and

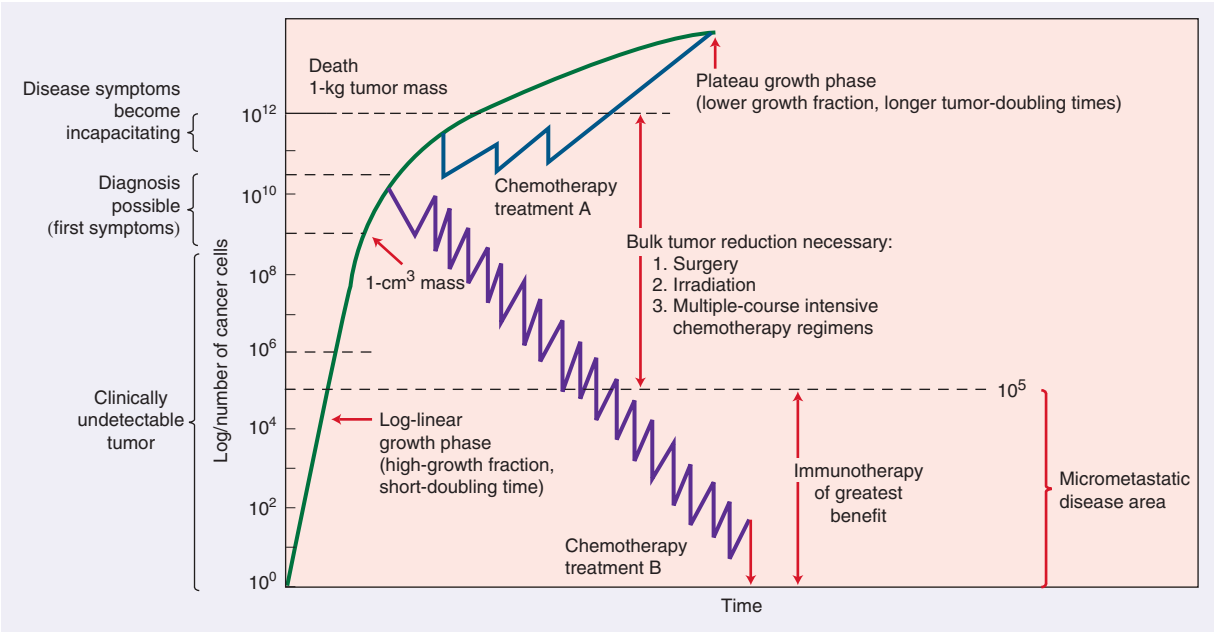

FIGURE 88–2. The Gompertzian growth curve demonstrating symptoms and treatments versus tumor volume.

overexpression of *Bcl-2* are two examples of changes within the cell that occur to result in enhanced cell survival. Cellular senescence refers to cell death that occurs after a preset number of cell doublings. Telomeres are DNA segments at the ends of chromosomes that shorten with each replication to the point where senescence is triggered.

Identification of genes involved in cancer may be conducted for various reasons, including cancer screening to determine if an individual is at an increased risk of cancer, to develop new anticancer agents, to aid in diagnosis, and to predict response and/or the toxicity of the agents used in individual patients.

Principles of Tumor Growth

It takes about 10^9 cancer cells to be clinically detectable by palpation or radiography. Figure 88–2 demonstrates the classic Gompertzian kinetics tumor growth cycle. From the diagram, one can see that malignant cell growth occurs many times before a mass may be detected. The number of malignant cells may decrease drastically because of surgery or in decreasing steps by each administration of chemotherapy. One dosing round, or cycle, of chemotherapy does not eliminate all malignant cells; therefore, repeated cycles of chemotherapy are administered to eliminate tumor cell burden. The cell kill hypothesis states that a fixed percentage of tumor cells will be killed with each cycle of chemotherapy. According to this hypothesis, the number of tumor cells will never reach zero. This theory assumes that all cancers are equally responsive and that anticancer drug resistance and metastases do not occur, which is not the case.[7]

Metastases

A metastasis is a growth of the same cancer cell found at some distance from the primary tumor site.[8] The metastasis may be large, or it may be just a few cells that may be detected through polymerase chain reaction (PCR); however, the presence of metastasis at diagnosis usually is associated with a poorer prognosis than the patient with no known metastatic disease. As the technology to detect malignant cells evolves, the dilemma exists on how to treat patients based on current guidelines that were not based on cellular detection technology.

Cancers spread usually by two pathways: hematogenous (through the bloodstream) or through the lymphatics (drainage through adjacent lymph nodes). The malignant cells that split from the primary tumor find a suitable environment for growth. It is believed that malignant cells secrete mediators that stimulate the formation of blood vessels for growth and oxygen, the process of angiogenesis. The usual metastatic sites for solid tumors are the brain, bone, lung, and liver.

PATHOPHYSIOLOGY

Tumor Origin

Tumors may arise from the four basic tissue types: epithelial, connective (ie, muscle, bone, and cartilage), lymphoid, or nerve tissue. The suffix *-oma* is added to the name of the cell type if the tumor cells are benign. A *lipoma* is a benign growth that resembles fat tissue.

Precancerous cells have cellular changes that are abnormal but not yet malignant and may be described as *hyperplastic* or *dysplastic*. Hyperplasia occurs when a stimulus is introduced and reverses when the stimulus is removed. Dysplasia is an abnormal change in the size, shape, or organization of cells or tissues.

Malignant cells are divided into categories based on the cells of origin. Carcinomas arise from epithelial cells, whereas sarcomas arise from muscle or connective tissue. Adenocarcinomas arise from glandular tissue. *Carcinoma* in situ refers to cells limited to epithelial origin that have not yet invaded the basement membrane. Malignancies of the bone marrow or lymphoid tissue, such as leukemias or lymphomas, are named differently.

Tumor Characteristics

Tumors are either benign or malignant. Benign tumors often are encapsulated, localized, and indolent; they seldom metastasize; and they rarely recur once removed. Histologically, the cells

resemble the cells from which they developed. Malignant tumors are invasive and spread to other locations even if the primary tumor is removed. The cells no longer perform their usual functions, and their cellular architecture changes. This loss of structure and function is called *anaplasia.* Despite improvements in screening procedures, many patients have metastatic disease at the time of diagnosis. Usually, once distant metastases have occurred, the cancer is considered incurable.[9]

DIAGNOSIS OF CANCER

Cancer can present as a number of different signs and symptoms. Unfortunately, many people fear a diagnosis of cancer and may not seek medical attention at the first warning signs when the disease is at its most treatable stage. After the initial visit with the clinician, a variety of tests will be performed, which are somewhat dependent on the initial differential diagnoses. Appropriate laboratory tests, radiologic scans, and tissue samples are necessary. The sample of tissue may be obtained by a biopsy, fine-needle aspiration, or exfoliative cytology. No treatment of cancer should be initiated without a pathologic diagnosis of cancer. During the pathologic workup, genetic analysis may be done. Depending on the type of cancer, the genetic analysis can provide the additional information on prognosis of the malignancy and whether certain therapies may be appropriate.

LO 2

Once the pathology of cancer is established, then staging of the disease is done before treatment is initiated. Cancer staging is usually done according to the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, also referred to as the tumor, nodes, metastases (TNM) system (Table 88–2).[10] The stage of the disease is a compilation of the primary tumor size, the nodal involvement, and metastases and is usually referred to as stages I, II, III, or IV. Not all cancers can be staged according to this system, but many of the solid tumors are.

Patient Encounter 1, Part 1

The patient is a 67-year-old previously healthy woman who has had symptoms of fatigue, diarrhea and bright red blood with bowel movements for 6 weeks. She has self-treated with dietary changes, occasional use of loperamide, and anti-hemorrhoidal over-the-counter products without relief. Today, she presents to her primary care provider for evaluation. Her complete blood count (CBC) reveals a low hemoglobin level. She is referred to a gastroenterologist for further evaluation.

After a colonoscopy and subsequent CT scans, a diagnosis of metastatic colorectal cancer is made and treatment is planned to start as soon as possible.

What signs and symptoms does this patient have that are consistent with a cancer presentation?

What is your desired outcome when treating this patient?

Staging of the disease is an important part of determining the prognosis of the cancer. Staging also allows comparison of patient groups when examining data from clinical trials; staging reflects the extent of disease. Finally, the clinician uses it as a guide to treatment and may use restaging after treatment to guide further treatment.

Some cancers produce substances (eg, proteins) that are detected by a blood test, that may be useful in following response to therapy or detecting a recurrence; these are referred to as tumor markers. An example of a clinically used tumor marker is the prostate-specific antigen (PSA). The PSA serum level is used to monitor response to treatment. Unfortunately, some tumor markers are nonspecific and may be elevated from nonmalignant causes. In the case of

Clinical Presentation and Diagnosis: Cancer Chemotherapy and Treatment

Signs and Symptoms

The seven warning signs of cancer are:

- Change in bowel or bladder habits
- A sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion or difficulty in swallowing
- Obvious change in a wart or mole
- Nagging cough or hoarseness

The eight warning signs of cancer in children are:

- Continued, unexplained weight loss
- Headaches with vomiting in the morning
- Increased swelling or persistent pain in bones or joints
- Lump or mass in abdomen, neck, or elsewhere
- Development of a whitish appearance in the pupil of the eye
- Recurrent fevers not caused by infections
- Excessive bruising or bleeding
- Noticeable paleness or prolonged tiredness

Diagnostic Procedures

- Laboratory tests: CBC, lactate dehydrogenase (LDH), renal function, and liver function tests
- Radiologic scans: x-rays, CT scans, MRI, position emission tomography (PET)
- Biopsy of tissue or bone marrow with pathologic evaluation
- Cytogenetics
- Tumor markers

Staging determination of the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, referred to as the TNM system (see Table 88–2). Most solid tumors are staged according to the TNM classification system. The size of the primary tumor, extent of nodal involvement, and presence of metastases are used to determine the stage. Metastases are cancer cells that have spread to sites distant from the primary tumor site and have started to grow. The most frequently occurring sites of metastases of solid tumors are the brain, bone, liver, and lungs.

Table 88–2

Tumor (T), Node (N), Metastasis (M) Staging for Non–Small Cell Lung Cancer

Primary Tumor	Description
Tx	Primary tumor cannot be assessed or tumor proven by presence of malignant cells in sputum or bronchial washings but not visualized by imaging or bronchoscopy
T0	No evidence of primary tumor
Tis	Carcinoma in situ
T_1	Tumor under 3 cm in greatest dimension, surrounded by lung or visceral pleura, without invasion more proximal than lobar bronchus
T_{1a} (mi)	Minimally invasive adenocarcinoma
T_{1a} ss:	Superficial spreading tumor in central airways (spreading tumor of any size but confined to the tracheal or bronchial wall)
T_{1a}	Tumor ≥ 1 cm in greatest dimension
T_{1b}	Tumor > 1 cm but ≤ 2 cm in greatest dimension
T_{1c}	Tumor > 2 cm but ≤ 3 cm in greatest dimension
T_2	Tumor > 3 cm but ≤ 5 cm, or tumor with any of the following features: • Involves main bronchus regardless of distance from the carina but without involvement of the carina • Invades visceral pleura • Associated with atelectasis or obstructive pneumonitis that extends to the hilar region but does not involve the entire lung • Involving part or all of the lung
T_{2a}	Tumor > 3 cm but ≤ 4 cm in greatest dimension
T_{2b}	Tumor > 4 cm but ≤ 5 cm in greatest dimension
T_3	Tumor > 5 cm but ≤ 7 cm in greatest dimension of associated with separate tumor nodule(s) in the same lobe as the primary tumor or directly invades any of the following structures: • chest wall (including the parietal pleura and superior sulcus) • phrenic nerve • parietal pericardium
T_4	Tumor > 7cm in greatest dimension or associated with separate tumor nodules(s) in a different ipsilateral lobe than that of the primary tumor or invades any of the following structures • diaphragm • mediastinum • heart • great vessels • trachea • recurrent laryngeal nerve • oesophagus • vertebral body • carina
Regional lymph nodes (N)	
Nx	Regional lymph nodes cannot be assessed.
N_0	No regional lymph node metastases
N_1	Metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension
N_2	Metastasis in ipsilateral mediastinal and/or subcarinal lymph node(s)
N_3	Metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node(s)
Distant metastasis (M)	
M_0	No distant metastasis
M_1	Distant metastasis
M_{1a}	Separate tumor nodule(s) in a contralateral lobe; tumor with pleural nodules or malignant pleural or pericardial effusion
M_{1b}	Single extrathoracic metastasis
M_{1c}	Multiple extrathoracic metastasis in one or more organs

Stage	T	N	M	5-Year Survival
Stage 0	Tis	N_0	M_0	
Stage Ia	T_{1a}	N_0	M_0	92%
Stage Ib	T_{2a}	N_0	M_0	68%
Stage IIa	T_{2b}	N_0	M_0	60%
Stage IIb	T_1, T_2	N_1	M_0	53%
	T_3	N_0	M_0	
Stage IIIa	T_1, T_2	N_2	M_0	36%
	T_3, T_4	N_1	M_0	
	T_4	N_0	M_0	
Stage IIIb	T_1, T_2	N_3	M_0	26%
	T_3, T_4	N_2	M_0	
Stage IIIc	T_3, T_4	N_3	M_0	13%
Stage IVa	Any T	Any N	M_{1a} or M_{1b}	10%
Stage IVb	Any T	Any N	M_{1c}	0%

From Detterbeck FC, Boffa DJ, Kim AW, Tanoue LT. The Eighth Edition Lung Cancer Stage Classification. Chest. 2017;151(1):193–203.

PSA, nonmalignant causes such as prostatitis, trauma, surgery, ejaculation, some medications, benign prostatic hypertrophy, or riding on an exercise bicycle can all cause increased PSA levels.[9] Some tumors may express a marker in some patients and not in others. The full role of tumor markers has not been fully elucidated.

TREATMENT

Desired Outcome

Surgery may be able to remove all macroscopic disease; however, microscopic cells may still be present near the surgical site or may have traveled to other parts of the body. When malignant cells have traveled to other parts of the body and become established there and are able to grow in this new environment, they are called metastatic cancer cells. Thus, for chemotherapy-sensitive diseases, systemic therapies may be administered after surgery to destroy these microscopic malignant cells; this is called **adjuvant chemotherapy**. The goals of adjuvant chemotherapy are to decrease the recurrence by eliminating microscopic malignant cells of the cancer and to prolong survival. Chemotherapy may also be given before surgical resection of the tumor; this is referred to as **neoadjuvant chemotherapy**. Chemotherapy given before surgery should decrease the tumor burden to be removed (which may result in a shorter surgical procedure or less physical disfigurement to the patient) and make the surgery easier to perform because the tumor has shrunk away from vital organs or vessels. Neoadjuvant chemotherapy also gives the clinician an idea of the responsiveness of the tumor to that particular chemotherapy.

Chemotherapy may be given to cure cancers, or it may be given to help control the symptoms of an incurable cancer (also known as palliation). **Palliative care**, however, is used throughout therapy to prevent or treat, as early as possible, the symptoms and side effects of the disease and treatment psychological, social, and spiritual problems. It will consist of pharmacologic and nonpharmacologic treatments and is most effective when initiated at the time of other treatments, improving quality of life.[11]

Response

The responses to chemotherapy for solid tumors are described as **complete response (CR)**, **partial response (PR)**, **stable disease (SD)**, or **disease progression**. A cure in oncology implies that the cancer is completely gone, and the patient will have the same life expectancy as a patient without cancer. The Response Evaluation Criteria in Solid Tumors (RECIST) was developed in 2000 and revised in 2009 and is considered to be the standard criteria to evaluate a response to therapy (**Table 88–3**).[12] The term overall objective response rate refers to all patients with a PR or a CR.

Anticancer treatments can be thought of as being analogous to anti-infectives treatments. Cancer cells may be **sensitive** to certain chemotherapy agents, but then with repeated exposure, the cells may become **resistant** to treatment. The resistant cells then may grow and multiply. In some cancers a number of genetic mutations, including epidermal growth factor *(EGFR)*, reticular activating system (*RAS*), and *BRAF* may be used to predict which patients will be sensitive to certain chemotherapy that targets these mutations. These mutations will be discussed in depth in the following cancer-specific chapters.

Nonpharmacologic Therapy

The three primary treatment modalities of cancer are surgery, radiation, and pharmacologic therapy. Surgery is useful to gain tissue for diagnosis of cancer and for treatment, especially those cancers with limited disease. Radiation plays a key role not only in the treatment and possible cure of cancer but also in palliative therapy. Together, surgery and radiation therapy may provide local control of symptoms of the disease. However, when cancer is widespread, surgery may play little or no role, but radiation therapy localized to specific areas may palliate symptoms.

Table 88–3

RECIST 1.1 Criteria: Target Lesion Evalusion

Term	Description
Complete response (CR)	Disappearance of all targeted lesion. All pathological lymph nodes must have decreased to < 10 mm in short axis
Partial response (PR)	At least a 30% decrease in the sum of the longest diameter (SLD) of target lesions from baseline
Progressive disease	SLD increased by at least 20% from the smallest value on study (including baseline, if that is the smallest) The SLD must also demonstrate an absolute increase of at least 5 mm. (Two lesions increasing from 2 mm to 3 mm, for example, do not qualify)
Stable disease (SD)	Neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for progressive disease

Adapted from Eisenhauer E, Therasse P, Bogaerts J, et al. New response evaluation criteria in solid tumours: revised RECIST guideline (version 1.1). Eur J Cancer. 2009;45:228–247.

Pharmacologic Therapy

Chemotherapy of cancer started in the early 1940s when nitrogen mustard was first administered to patients with lymphoma. Since then, numerous agents have been developed for the treatment of different cancers.

Dosing of Chemotherapy

Chemotherapeutic agents typically have a very narrow therapeutic index. If too much is administered, the patient may suffer from fatal toxicities. If too little is given, the desired effect on cancer cells may not be achieved. Many chemotherapy agents have significant organ toxicities that preclude using steadily increasing doses to treat the cancer. The doses of chemotherapy must be given at a frequency that allows the patient to recover from the toxicity of the chemotherapy; each period of chemotherapy dosing is referred to as a cycle. Each cycle of chemotherapy may have the same dosages; the dosages may be modified based on toxicity; or a chemotherapy regimen may alternate from one set of drugs given during the first, third, and fifth cycles to another set of different drugs given during the second, fourth, and sixth cycles. The **dose density** of chemotherapy refers to shortening of the period between cycles of chemotherapy. This can accomplish two things: First, the tumor has less time between cycles of chemotherapy to grow, and second, patients receive the total number of required cycles in a shorter time period. Administration of dose-dense chemotherapy regimens often requires the use of colony-stimulating factors (eg, filgrastim or granulocyte–colony stimulating factor [G-CSF]) to be administered. These agents shorten the duration and severity

of neutropenia. The chemotherapy regimens that are dose dense tend to be adjuvant regimens, and the goal of therapy is cure.

When a chemotherapy regimen is used as *palliation* (to control symptoms), the dosages of chemotherapy may be decreased based on toxicity or the interval between cycles may be lengthened to maintain quality of life.

Patient and tumor biology also affect how cancer therapy is dosed. Patients with a uridine diphosphate–glucuronosyltransferease 1A1 enzyme (UGT1A1* 28) deficiency can have life-threatening diarrhea and complications from irinotecan related to a decreased ability to metabolize the parent drug. The patient may have a blood test before irinotecan therapy to determine if this genetic mutation is present. In the case of some monoclonal antibodies and targeted agents, flow cytometry results reveal whether the tumor has the receptor where the drug will bind and exert the pharmacologic effect.[13] The therapeutic uses of oncology drugs with valid genomic biomarkers, called targeted therapies, will be discussed briefly in this chapter and in more detail in the following chapters.

Another consideration of chemotherapy administration is the patient. Factors that affect chemotherapy selection and dosing are age, concurrent disease states, and performance status. Performance status can be assessed through either the Eastern Cooperative Oncology Group (ECOG) Scale or the Karnofsky Scale (Table 88–4). Performance status is a very important prognostic factor for many types of cancer. If a patient has renal dysfunction and the chemotherapy is eliminated primarily by the kidney, dosing adjustments will need to be made. If a patient has had a myocardial infarction recently or preexisting heart disease, the clinician will weigh the risks of anthracycline therapy against the benefit of the treatment of the cancer.

Another important consideration for treatment of cancers is insurance coverage for off-label use. Off-label use is when a medication is used to treat a cancer that is not an FDA-approved indication. Because of rapid advancements in oncology, it is estimated that up to 75% of chemotherapy agents are prescribed "off-label." Drugs used according to FDA-approved indications are usually paid for by insurance. If sufficient supportive literature exists and the use is supported by one of the Medicare-approved compendia (eg, AHFS-DI, Clinical Pharmacology, Micromdex DrugDex, NCCN Compendium, others), an insurer should cover the cost of the anticancer treatment that does not have an FDA indication.

During the time of chemotherapy administration, patients will likely experience various toxicities. The National Cancer Institute (NCI) has provided a standardized system for evaluating and grading the toxicity from chemotherapy to provide uniform grading of toxicity and evaluation of new agents and new regimens (Table 88–5).[14]

Combination Chemotherapy

The underlying principles of using combination therapy are to use (1) agents with different pharmacologic actions, (2) agents with different organ toxicities, (3) agents that are active against the tumor and ideally synergistic when used together, and (4) agents that do not result in significant drug interactions (although these can be studied carefully and the interactions addressed). When two or more agents are used together, the risk of development of resistance may be lessened, but toxicity may be increased.

KEY CONCEPT Traditional chemotherapy agents have some similar side effects, usually manifested on the most rapidly proliferating cells of the body. However, there are unique toxicities of various pharmacologic categories of antineoplastic agents. Anthracyclines (eg, doxorubicin) have the potential to cause cardiac toxicity, which is related to the cumulative dose. Microtubule-targeting

Table 88–4

Performance Status Scales

Description: Karnofsky Scale	Karnofsky Scale (%)	Zubrod Scale (ECOG)	Description: ECOG Scale
No complaints; no evidence of disease	100	0	Fully active, able to carry on all predisease activity
Able to carry on normal activity; minor signs or symptoms of disease	90		
Normal activity with effort; some signs or symptoms of disease	80	1	Restricted in strenuous activity but ambulatory and able to carry out work of a light or sedentary nature
Cares for self; unable to carry on normal activity or to do active work	70		
Requires occasional assistance but is able to care for most personal needs	60	2	Out of bed > 50% of time; ambulatory and capable of self-care but unable to carry out any work activities
Requires considerable assistance and frequent medical care	50		
Disabled; requires special care and assistance	40	3	In bed > 50% of time; capable of only limited self-care
Severely disabled; hospitalization indicated, although death not imminent	30		
Very sick; hospitalization necessary; requires active supportive treatment	20	4	Bedridden; cannot carry out any self-care; completely disabled
Moribund; fatal processes progressing rapidly	10		
Dead	0	5	Dead

ECOG, Eastern Cooperative Oncology Group.

Table 88–5

Selected National Cancer Institute Common Toxicity Criteria

Toxicity	Grade 1	Grade 2	Grade 3	Grade 4	Grade 5
General	Mild	Moderate	Severe	Life-threatening	Death
Neutropenia	Lowest baseline: 1500/mm^3 (1.5 × 10^9/L)	< 1500–1000/mm^3 (1.5–1 × 10^9/L)	< 1000–500/mm^3 (1–0.5 × 10^9/L)	< 500/mm^3 (0.5 × 10^9/L)	
Thrombocytopenia	Lowest baseline: 75,000/mm^3 (75 × 10^9/L)	< 75,000–50,000/mm^3 (75–50 × 10^9/L)	< 50,000–25,000/mm^3 (50–25 × 10^9/L)	< 25,000 mm^3 (25 × 10^9/L)	Death
Diarrhea	Increase of < four stools per day over baseline or mild increase in ostomy output compared to baseline	Increase of four to six stools per day over baseline; moderate increase in ostomy output compared with baseline; limiting ADLs	Increase of greater than or equal to seven stools per day over baseline; hospitalization; severe increase in ostomy output compared with baseline; limiting self care ADL	Life-threatening consequences (eg, hemodynamic collapse); urgent intervention indicated	Death
Esophagitis	Asymptomatic clinical or diagnostic only. Intervention not indicated	Symptomatic altered eating or swallowing. Oral supplements indicated	Severely altered eating or swallowing; tube feedings, or TPN or hospitalization indicated	Life-threatening consequences; urgent operative intervention indicated	Death
Nausea	Loss of appetite without alteration in eating habits	Oral intake decreased without significant weight loss, dehydration, or malnutrition	Inadequate oral caloric or fluid intake; tube feedings, TPN or hospitalization indicated > 24 hours	Life-threatening consequences	Death
Vomiting	One to two episodes (separated by 5 minutes) in 24 hours	Three to five episodes in 24 hours; IV fluids indicated < 24 hours	Six episodes or more in 24 hours; IV fluids, tube feeding or TPN indicated ≥ 24 hours	Life-threatening consequences; urgent intervention indicated	Death

ADL, activity of daily living; IV, intravenous; TPN, total parenteral nutrition.

Protocol Development | CTEP. Cancer Therapy Evaluation Program (CTEP). https://ctep.cancer.gov/protocolDevelopment/electronic_applications/ctc.htm#ctc_50. Accessed July 20, 2018.

agents (eg, vincristine) are associated with various forms of neurotoxicity. Alkylating agents (eg, melphalan) are associated with secondary malignancies.

Currently, anticancer agents are categorized by the mechanism of action. As depicted in Figure 88–3, different agents work in different parts of the cell.[15]

Table 88–6 lists the currently FDA-approved anticancer drugs by drug class and name. The next section will describe the most commonly used anticancer agents or those with unique mechanisms of action.

LO 3

Antimetabolites: Pyrimidine Analogues

► *Fluorouracil and Capecitabine*

5-Fluorouracil (5-FU) is a fluorinated analogue of the pyrimidine uracil. Once administered, this prodrug is metabolized by dihydropyrimidine dehydrogenase (DPD). 5-FU ultimately is metabolized to fluorodeoxyuridine monophosphate (FdUMP), which interferes with the function of thymidylate synthase (TS), a requirement of thymidine synthesis. The triphosphate metabolite of 5-FU is incorporated into ribonucleic acid (RNA) to produce the second cytotoxic effect. Inhibition of TS occurs with the continuous infusion regimens, whereas the triphosphate form is associated with bolus administration. Capecitabine is an orally active prodrug of 5-FU and is enzymatically converted to 5-FU, sharing the same mechanism of action. Patients with a low activity of DPD appear to be at risk for life-threatening toxicities. Folates, such as leucovorin, increase the stability of FdUMP–TS

Patient Encounter 1, Part 2

The decision to treat the patient with a systemic chemotherapy regimen is made. She will be receiving the standard mFOLFOX6 regimen of fluorouracil 400 mg/m^2/day IV bolus followed by 1200 mg/m^2/day continuous IV infusion over 46 hours + leucovorin 400 mg/m^2/day IV + oxaliplatin 85 mg/m^2/day IV every day every 2 weeks.

Before initiating this chemotherapy regimen in the patient, what patient-specific issues need to be addressed?

What adverse effects will the patient likely experience with these two chemotherapy drugs?

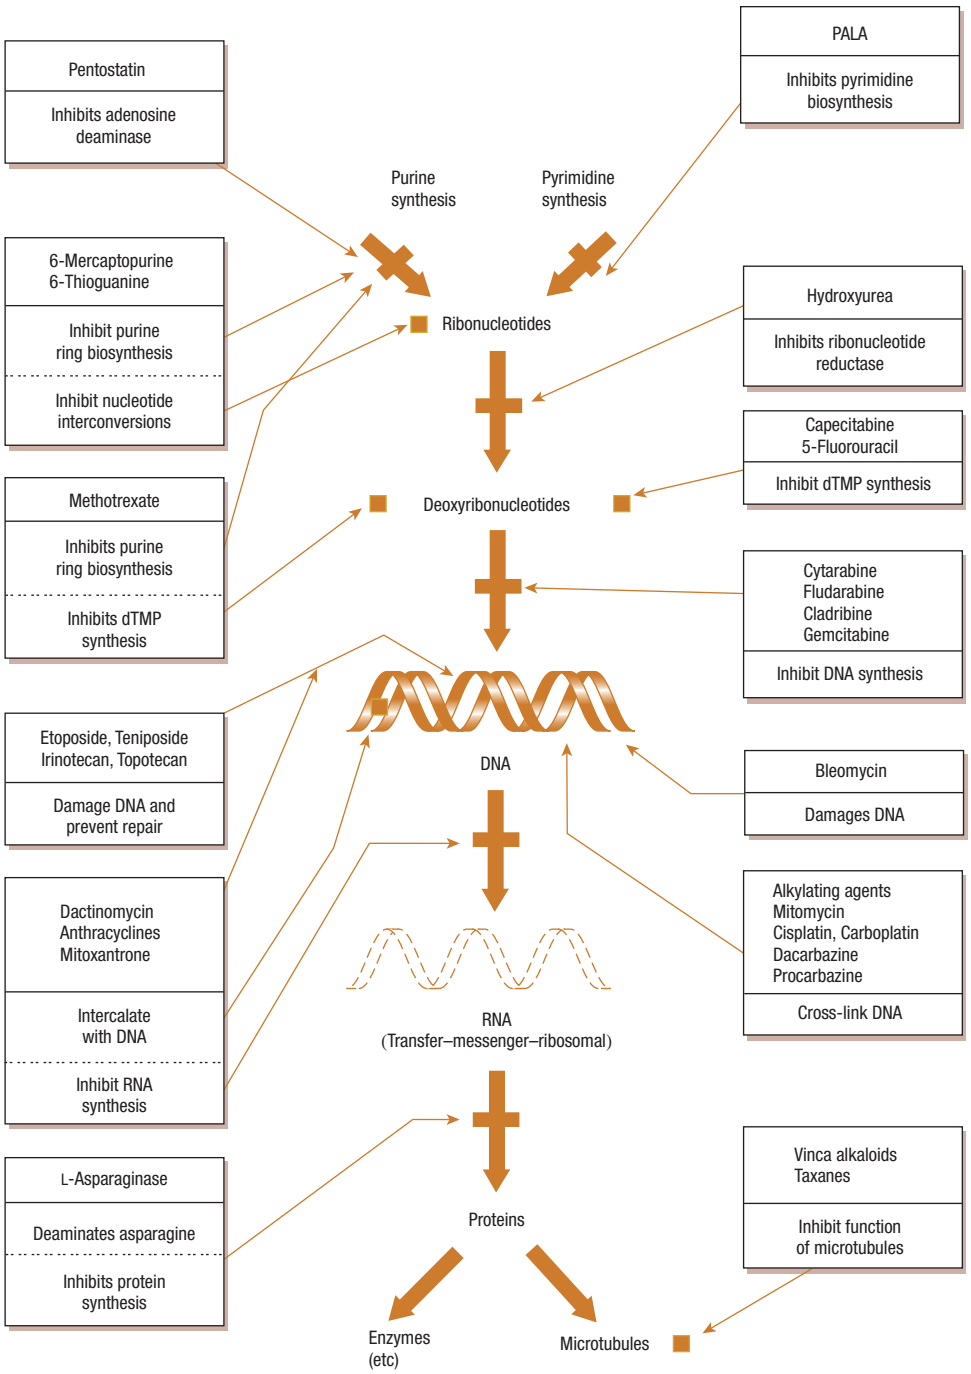

FIGURE 88–3. The mechanisms of action of commonly used antineoplastic agents. (Reproduced with permission from Chabner BA. General Principles of Chemotherapy. In: Brunton LL, Chabner BA, Knollman BC, eds. Goodman & Gilman's The Pharmacologic Basis of Therapeutics, 12th ed. New York, NY: McGraw-Hill, 2010.)

inhibition and enhance the drug activity in certain cancers. These agents have clinical activity in several solid tumors, and are frequently used to treat both breast and colon cancer. The most common toxicities include myelosuppression when administered by intravenous (IV) bolus and palmar-plantar erythrodysesthesia, and diarrhea, when administered as continuous IV infusion or orally. Palmar-plantar erythrodysesthesia, also called hand–foot syndrome (HFS), refers to redness, itching, and blistering of the palms of the hands and soles of the feet. Patients should be counseled to notify the prescriber when this adverse effect occurs. Significant increases in international normalization ratio (INR) and prothrombin time may occur within several days when capecitabine is initiated in patients concomitantly receiving warfarin. The INR should be monitored closely or the patient may be switched to a low-molecular-weight heparin. Other drug interactions can also occur. Patients should be instructed to take capecitabine within 30 minutes after a meal to increase absorption of the drug.

► *Cytarabine*

Cytarabine is a structural analogue of cytosine and is phosphorylated intracellularly to the active triphosphate form,

Table 88–6

Anticancer Drugs

Drug Class	Drug Name
Alkylating agents	
Alkyl sulfonate	Busulfan
Nitrogen mustards	Bendamustine
	Chlorambucil
	Cyclophosphamide
	Ifosfamide
	Melphalan
	Methchlorethamine
Nitrosureas	Carmustine
	Lomustine
Nonclassical	Mitomycin C
	Thiotepa
	Trabectedin
Platinum complexes	Carboplatin
	Cisplatin
	Oxaliplatin
Triazenes and hydrazine	Dacarbazine
	Procarbazine
	Temozolomide
Anthracene derivatives	Daunorubicin
	Doxorubicin
	Epirubicin
	Idarubicin
	Mitoxantrone
Antitumor antibiotics	Bleomycin
Antimetabolites	
Folate Antagonists	Methotrextae
	Pemetrexed
	Pralatrexate
Purine analogs	Cladribine
	Clofarabine
	Fludarabine
	6-Mercaptopurine
	Pentostatin
	Thioguanine
Pyrimidine analogs	Acazacitidine
	Capecitabine
	Cytarabine
	Decetabine
	5-Fluorouracil
	Gemcitabine
	Nelarabine
	Trifluridine/(tipiracil)[a]
Hedgehog inhibitor	Sonidegib
	Vismodegib
Histone deacetylase (HDAC) inhibitors	Belinostat
	Panobinostat
	Romidepsin
	Vorinostat
Hormonal therapies	Bicalutamide
Antiandrogens	Flutamide
	Nilutamide
Androgen receptor antagonist	Apalutamide
	Enzalutamide
Antiestrogens	Raloxifene
	Tamoxifen
Aromatase inhibitors	Anastrazole
	Exemestane
	Letrozole
CYP17 inhibitor	Abiraterone acetate
Luteinizing hormone–releasing hormone agonist	Goserlin
	Leuprolide
Luteinizing hormone–releasing hormone antagonist	Degarelix
Selective estrogen receptor degrader	Degarelix
Isocitrate dehydrogenase 2 (IDH2) inhibitor	Enasidenib
Immunomodulatory agents	Lenalidomide
	Pomalidomide
	Thalidomide
Immunotherapy	
Cell-based immunotherapy	Sipuleucel-T
CAR T-cell	Tisagenlecleucel
	Axicabtagene ciloleucel
Checkpoint inhibitors	Atezolizumab
	Avelumab
	Durvalumab
	Ipilimumab
	Nivolumab
	Pembrolizumab
Miscellaneous immune therapies	Interferons
	Aldesleukin
JAK inhibitor	Ruxolitnib
Microtubule-targeting agents	
Taxanes	Cabazitaxel
	Docetaxel
	Paclitaxel
Vinca alkaloids	Vinblastine
	Vincristine
	Vinorelbine
Other	Eribulin
	Estramustine
	Ixabepilone
Miscellaneous agents	Altretamine
	Arsenic trioxide
	Bexaroxtene
	Hydroxyurea
	Liposome encapsulated doxorubicin-cytarabine
	Omacetaxine mepesuccinate
	Tretinoin
	Ziv-alfibercept
Monoclonal antibodies	Alemtuzumab
	Bevacizumab
	Bevacizumab-awwb
	Blinatumomab
	Cetuximab
	Daratumumab
	Dinutuximab
	Elotuzumab
	Obinutuzumab
	Ofatumumab
	Olaratumab
	Necitumumab
	Panitumumab
	Pertuzumab
	Ramucirumab
	Rituximab
	Trastuzumab
	Trastuzumab-dkst
Antibody-drug conjugate	Berntuximab vedotin
	Inotuzumab ozogamicin
	Gemtuzumab ozogamicin
	Trastuzumab-emtansine
Antibody-radioimmunotherapy conjugate	Ibritumomab tiuxetan

(*Continued*)

Table 88–6

Anticancer Drugs (*Continued*)

Drug Class	Drug Name	Drug Class	Drug Name
mTOR inhibitors	Everolimus Temsirolimus	Bruton's tyrosine kinase (BTK)	Ibrutinib Acalabrutinib
Poly ADP ribose polymerase (PARP) inhibitors	Niraparib Olaparib Rucaparib	Cyclin-dependent kinase (CDK)	Abemaciclib Palbociclib Ribociclib
Proteosome inhibitors	Bortezomib Carflizomib Ixazomib	Epidermal growth factor receptor (EGFR)	Afatanib Erlotinib Osimertinib Vandetanib
Topoisomerase inhibitors			
Camptothecin derivatives	Irinotecan Topotecan	EGFR/HER2	Lapatinib Neratinib
Epidophyllotoxins	Etoposide Teniposide	Mitogen-activated extracellular kinase (MEK)	Trametinib
Tyrosine kinase inhibitors		Multikinase	Axitinib Brigatinib Cabozantinib Lenvatinib Midostaurin Pazopanib Regorafenib Sorafenib Sunitinib Vandetanib
Anaplastic lymphoma kinase (ALK)/tyrosine kinase met (c-met)	Alecitinib Ceritinib Crizotinib		
BCL-2	Venetoclax		
BCR-ABL	Bosutinib Dasatinib Imatinib Nilotinib Ponatinib		
BRAF	Cobimetinib Dabrafenib Vemurafenib	Phosphoinositide 3-kinase (PI3K)	Copanlisib Idelalisib

[a]Tipiracil is a thymidine phosphorylase inhibitor used to increase bioavailability of trifluridine.

which inhibits DNA polymerase. The triphosphate form also may be incorporated into DNA to result in chain termination to prevent DNA elongation. The drug may be administered as a low-dose continuous infusion, high-dose intermittent infusion, and into the subdural space via intrathecal or intraventricular administration. A liposomal formulation is also available for less frequent administration into the central nervous system (CNS). Cytarabine is eliminated by the kidneys with a renal clearance of 90 mL/min (1.5 mL/s). Cytarabine has shown efficacy in the treatment of acute leukemias and some lymphomas. The toxicities of cytarabine in high doses include myelosuppression; cerebellar syndrome (ie, nystagmus, dysarthria, and ataxia); and chemical conjunctivitis, an eye irritation that requires prophylaxis with steroid eye drops. The risk of neurotoxicity is increased with high doses (> 1 g/m^2), advanced age, and renal dysfunction. If cerebellar toxicity does occur, the drug needs to be discontinued immediately, and decisions regarding further therapy need to be carefully considered.[16]

► *Gemcitabine*

Gemcitabine is a deoxycytidine analogue that is structurally related to cytarabine. Gemcitabine inhibits DNA polymerase activity and ribonucleotide reductase to result in DNA chain elongation. Gemcitabine has shown activity in several solid tumors and some lymphomas. The toxicities include myelosuppression; flu-like syndrome with fevers during the first 24 hours after administration; rash that appears 48 to 72 hours after administration; and hemolytic uremic syndrome, a rare but life-threatening adverse effect. Patients should be counseled to use acetaminophen to treat the fevers during the first 24 hours; however, fevers occurring 7 to 10 days after gemcitabine are likely to be febrile neutropenia and need prompt treatment with broad-spectrum antibiotics.

► *Azacitidine and Decitabine*

Azacitidine and decitabine are nucleoside analogues approved for the treatment of patients with myelodysplastic syndrome, a hematopoietic disorder that can transform into acute myeloid leukemia (AML). Both of these agents cause cytotoxicity by directly incorporating in the DNA and inhibiting DNA methyltransferase, which causes hypomethylation of DNA. Hypomethylation of DNA appears to normalize the function of the genes that control cell differentiation and proliferation to promote normal cell maturation. The major side effects reported are myelosuppression and infections.

Antimetabolites: Purine Analogues

► *Mercaptopurine*

6-Mercaptopurine (6-MP) is an oral purine analogue that is converted to ribonucleotides that inhibit purine synthesis. Mercaptopurine is converted into thiopurine nucleotides, which are catabolized by thiopurine *S*-methyltransferase (TPMT). TPMT is subject to genetic polymorphisms and may cause severe myelosuppression; therefore, TPMT status may be assessed before therapy to reduce drug-induced morbidity and the costs of hospitalizations for neutropenic events. 6-MP is used in the treatment of acute lymphocytic leukemia (ALL) and chronic myeloid leukemia (CML). Significant side effects include myelosuppression, mild nausea, skin rash, cholestasis, and rarely, venoocclusive disease. Mercaptopurine is metabolized

by xanthine oxidase, an enzyme that is inhibited by allopurinol. This represents a major drug–drug interaction. To avoid toxicities of mercaptopurine when these drugs are used concomitantly, the dose of mercaptopurine must be reduced by 66% to 75%.

▶ *Fludarabine*

Fludarabine is an analogue of the purine adenine. It interferes with DNA polymerase to cause chain termination and inhibits transcription by its incorporation into RNA. Fludarabine is dephosphorylated rapidly and converted to 2-fluoro-Ara-AMP (2-FLAA), which enters the cells and is phosphorylated to 2-fluoro-Ara-ATP, which is cytotoxic. Fludarabine is used in the treatment of chronic lymphocytic leukemia (CLL), some lymphomas, and refractory AML. Significant and prolonged myelosuppression may occur, along with immunosuppression, so patients are susceptible to opportunistic infections. Prophylactic antibiotics and antivirals are recommended until CD4 counts return to normal. Mild nausea and vomiting and diarrhea have been observed. Rarely, interstitial pneumonitis has occurred.

Antimetabolites: Folate Antagonists

Folates carry one-carbon groups in transfer reactions required for purine and thymidylic acid synthesis. Dihydrofolate reductase is the enzyme responsible for supplying reduced folates intracellularly for thymidylate and purine synthesis.

▶ *Methotrexate*

Methotrexate inhibits dihydrofolate reductase of both malignant and nonmalignant cells. When high doses of methotrexate are given, the "rescue drug" leucovorin, a reduced folate, is administered to bypass the methotrexate inhibition of dihydrofolate reductase of normal cells and is usually initiated 24 hours after methotrexate administration. This is done to prevent potentially fatal myelosuppression and mucositis. For safety purposes, the term folinic acid, another term used for leucovorin, should not be used because of the potential for a medication error in which folic acid might be given instead. Methotrexate concentrations should be monitored to determine when to stop leucovorin administration. Generally, leucovorin administration may be stopped when methotrexate concentrations decrease to 5×10^{-8} M, although this may vary by the chemotherapy regimen. High dosages of methotrexate may place an individual at risk for methotrexate to crystallize in the acidic environment of the urine, often resulting in acute renal failure and decreased methotrexate clearance. Administration of IV hydration with sodium bicarbonate to maintain urinary pH greater than or equal to 7 is necessary to prevent methotrexate-induced renal dysfunction. Methotrexate is eliminated by tubular secretion; therefore, concomitant drugs (eg, probenecid, salicylates, penicillin G, and ketoprofen) that may inhibit or compete for tubular secretion should be avoided. Methotrexate doses must be adjusted for renal dysfunction and close monitoring of methotrexate concentrations is advised. In patients with toxic levels of methotrexate (> 1 μmol/L) because of impaired renal function, the antidote glucarpidase can be administered. However, efficacy can be compromised so it is not used in patients with normal or slightly elevated levels. Side effects of methotrexate include myelosuppression, nausea and vomiting, and mucositis. Methotrexate also may be administered via the intrathecal route or via an Ommaya reservoir in very low doses as small as 12 mg, so it is crucial for the clinician to know the correct dose by the correct route in order to avoid substantial toxicity. The methotrexate used for intrathecal and intraventricular injection must be preservative-free to prevent CNS toxicity.

▶ *Pemetrexed*

Pemetrexed inhibits four pathways in thymidine and purine synthesis. Pemetrexed has shown activity in the treatment of mesothelioma and non–small cell lung cancer (NSCLC). Side effects include myelosuppression, rash, diarrhea, and nausea and vomiting. Patients should receive folic acid and cyanocobalamin to reduce bone marrow toxicity and diarrhea. Doses of folic acid of at least 400 mcg/day starting 5 days before treatment and continuing throughout therapy, as well as for 21 days after the last pemetrexed dose, have been used. Cyanocobalamin 1000 mcg is given intramuscularly the week before pemetrexed and then every three cycles thereafter. Dexamethasone 4 mg twice daily the day before, the day of, and the day after pemetrexed administration helps to decrease the incidence and severity of rash.[17]

Microtubule-Targeting Agents

▶ *Vinca Alkaloids (Vincristine, Vinblastine, and Vinorelbine)*

The vinca alkaloids (vincristine, vinblastine, and vinorelbine) are derived from the periwinkle (vinca) plant and cause cytotoxicity by binding to tubulin, disrupting the normal balance between polymerization and depolymerization of microtubules, and inhibiting the assembly of microtubules, which interferes with the formation of the mitotic spindle. As a result, cells are arrested during the metaphase of mitosis. The vinca alkaloids are used in several malignancies, primarily hematologic. Even though these agents have similar structures, the incidence and severity of toxicities vary among the agents. The dose-limiting toxicity of vincristine is neurotoxicity, which can consist of depressed tendon reflexes, paresthesias of the fingers and toes, toxicity to the cranial nerves, or autonomic neuropathy (constipation or ileus, abdominal pain, and/or orthostatic hypotension). In contrast, the dose-limiting toxicity associated with vinorelbine and vinblastine is myelosuppression. All of the vinca alkaloids are vesicants and can cause tissue damage; therefore, the clinician must take precautions to avoid extravasation injury. Biliary excretion accounts for a significant portion of elimination of vincristine and its metabolites, so doses need to be adjusted for obstructive liver disease.

Vincristine, vinblastine, and vinorelbine have similar sounding names, which is a potential cause of medication errors. As with all chemotherapy prescribing, dispensing, and administration, the clinician must be very careful with sound-alike, look-alike medications. Unfortunately, vincristine has been involved in numerous cases of fatal chemotherapy errors, including inadvertent intrathecal administration. Because the drug is a vesicant, intrathecal administration of the drug can cause widespread tissue damage in the brain and death. An example of a strategy that health systems can use to decrease the likelihood of an error such as this is for the pharmacy to only dispense vincristine in a mini-bag for IV administration. Many clinicians cap IV vincristine doses at 2 mg to prevent severe neuropathic side effects; however, if the intent of chemotherapy is curative, the vincristine dose may be dosed above the 2-mg cap.[18]

▶ *Taxanes (Paclitaxel, Nanoparticle Albumin-Bound Paclitaxel, Docetaxel, and Cabazitaxel)*

Taxane plant alkaloids are similar to the vinca alkaloids, exhibiting cytotoxicity during the M phase of the cell cycle by binding to tubulin. Unlike the vinca alkaloids, however, the taxanes do not interfere with tubulin assembly. Rather, the taxanes promote microtubule assembly and inhibit microtubule disassembly. Once

the microtubules are polymerized, the taxanes stabilize against depolymerization.

Hepatic metabolism and biliary excretion account for the majority of paclitaxel's elimination. Paclitaxel has demonstrated activity in several solid tumors. The diluent for paclitaxel, Cremophor EL, is composed of ethanol and castor oil. Infusions must be prepared and administered in non–polyvinyl chloride–containing bags and tubings, and solutions must be filtered. Patients receive dexamethasone, diphenhydramine, and an H_2 blocker to prevent hypersensitivity reactions caused by Cremophor EL. Patients also may have asymptomatic bradycardia during the infusion. Approximately 3 to 5 days after administration, patients may complain of myalgias and arthralgias that may last several days. Myelosuppression, flushing, neuropathy, ileus, and total-body alopecia are other common side effects. Because paclitaxel is a substrate for CYP3A4, steady-state concentrations of paclitaxel were 30% lower in patients receiving phenytoin than in patients not receiving phenytoin. Paclitaxel clearance was decreased by 33% when it was administered after cisplatin, so paclitaxel is administered before cisplatin.

A nanoparticle albumin-bound nab-paclitaxel product is also available for the treatment of metastatic breast cancer resistant to conventional chemotherapy. The nab-paclitaxel formulation uses nanotechnology to combine human albumin with paclitaxel allowing for the delivery of an insoluble drug in the form of nanoparticles. This unique formulation allows for an increased bioavailability and higher intracellular concentrations of the drug. It does not have the serious hypersensitivity reactions encountered with paclitaxel solubilized in Cremophor EL, so premedication with H_1 and H_2 blockers and steroids is not necessary. Also, a significantly lower incidence of severe neutropenia occurs. The dose is infused over 30 minutes and does not require a special IV bag, tubing, or filter. The dosing of this product is different from that of the original paclitaxel, so practitioners need to be aware of which product is being prescribed. The pharmacokinetics of the albumin-bound paclitaxel displays a higher clearance and larger volume of distribution than paclitaxel. The drug is eliminated primarily via fecal excretion.[19] Bone marrow suppression, neuropathy, ileus, arthralgias, and myalgias still occur.

Docetaxel has activity in the treatment of several solid tumors also. Dexamethasone, 8 mg twice daily for 3 days starting the day before treatment, is used to prevent the fluid-retention syndrome associated with docetaxel and possible hypersensitivity reactions. The fluid-retention syndrome is characterized by edema and weight gain that is unresponsive to diuretic therapy and is associated with cumulative doses greater than 800 mg/m^2. Myelosuppression, alopecia, and neuropathy are other side effects associated with docetaxel treatment.

Cabazitaxel is a newer taxane used in combination with prednisone for the treatment of metastatic hormone-refractory prostate cancer. Cabazitaxel has shown to have similar adverse effects as paclitaxel and docetaxel. Premedication with an antihistamine, corticosteroid, and H_2 antagonist to prevent hypersensitivity reactions is required.

► *Halichondrins*

Eribulin mesylate is a nontaxane microtubule dynamics inhibitor. It is a synthetic analogue of halichondrin B, which is a product isolated from the sea sponge *Halichondria okadai*. While taxanes inhibit cell division by stabilizing microtubules, eribulin arrests the cell cycle through inhibition of the growth phase of microtubules without interfering with microtubule shortening. The cytotoxicity results from its effects via a tubulin-based antimitotic mechanism, resulting in G_2/M cell-cycle arrest and mitotic blockage. Apoptotic cell death results from prolonged mitotic blockage. Eribulin mesylate is an IV medication that is specifically indicated for the treatment of patients with metastatic breast cancer. The most common adverse effects reported are neutropenic fever, anemia, asthenia or fatigue, alopecia, peripheral neuropathy, nausea, and constipation. Eribulin has been reported to cause significant neutropenia and QT interval prolongation. It has vesicant properties. Dosages should be adjusted in renal and hepatic impairment.[20]

► *Ixabepilone*

Ixabepilone, an epothilone analogue, binds to β-tubulin subunits on microtubules, which results in suppression of microtubule dynamics. Ixabepilone is primarily eliminated by the liver by oxidation through the CYP3A4 system. Ixabepilone, in combination with capecitabine or alone if resistant to capecitabine, is indicated for the treatment of metastatic or locally advanced breast cancer. Studies have shown a possible synergy when used in combination with capecitabine. Side effects include hypersensitivity reactions, myelosuppression, and peripheral neuropathy. To minimize the occurrence of hypersensitivity reactions, patients must receive both H_1 and H_2 antagonists before therapy. If a reaction still occurs, corticosteroids should be added to the premedications.

Topoisomerase Inhibitors

Topoisomerase is responsible for relieving the pressure on the DNA structure during unwinding by producing strand breaks. Topoisomerase I produces single-strand breaks, whereas topoisomerase II produces double-strand breaks.

► *Epipodophyllotoxins (Etoposide and Teniposide)*

Etoposide and teniposide are semisynthetic podophyllotoxin derivatives that inhibit topoisomerase II, causing multiple DNA double-strand breaks. Etoposide has shown activity in the treatment of several types of lymphoma, testicular and lung cancer, retinoblastoma, and carcinoma of unknown primary. Oral bioavailability is approximately 50%, so oral dosages are approximate two times those of IV doses. Teniposide has shown activity in the treatment of ALL, neuroblastoma, and non-Hodgkin lymphoma. Both of these agents should be slowly administered to prevent hypotension. Side effects of these agents include mucositis, myelosuppression, alopecia, phlebitis, hypersensitivity reactions, and secondary leukemias. Hypersensitivity reactions are caused by the solubilizing agents, polysorbate 80 and may be life-threatening.

► *Camptothecin Derivatives (Irinotecan and Topotecan)*

Irinotecan and topotecan, both camptothecins, inhibit the topoisomerase I enzyme to interfere with DNA synthesis through the active metabolite SN38. Topoisomerase I enzymes stabilize DNA single-strand breaks and inhibit strand resealing. Irinotecan has shown activity in the treatment of cancers of the colon, rectum, cervix, and lung. Irinotecan-induced diarrhea is a serious complication and may be life-threatening. One form of diarrhea (early) can occur during or immediately after the infusion. This is a result of a cholinergic process in which the patient may experience facial flushing, diaphoresis, and abdominal cramping. IV atropine should be administered to treat diarrhea that occurs any time during the first 24 hours of administration. Another form of diarrhea (late) can occur several days after administration and can result in severe dehydration. This

adverse effect should be treated immediately with loperamide at a dosage of 2 mg every 2 hours or 4 mg every 4 hours until diarrhea has stopped for 12 hours. Other side effects include myelosuppression, fatigue, and alopecia. Individuals homozygous for *UGT1A1* 28* have an increased risk of febrile neutropenia and diarrhea and should be considered for an empiric dose reduction of one level; heterozygotes should receive closer monitoring, including more frequent complete blood counts (CBCs) to detect myelosuppression.

Topotecan has shown clinical activity in the treatment of ovarian and lung cancer, myelodysplastic syndromes, and AML. The IV infusion may be scheduled daily for 5 days or once weekly. Side effects include myelosuppression, mucositis, and diarrhea. Diarrhea is less common than with irinotecan.

Anthracene Derivatives

▶ *Daunorubicin, Doxorubicin, Idarubicin, and Epirubicin*

Anthracyclines (daunorubicin, doxorubicin, idarubicin, and epirubicin) are also referred to as antitumor antibiotics or topoisomerase inhibitors when considering their mechanism of action. All of the anthracyclines contain a four-membered anthracene ring, a chromophore, with an attached sugar portion. This chromophore results in red-orange urine after administration, which is an important counseling point for patients. Free radicals formed from the anthracyclines combine with oxygen to form superoxide, which can make hydrogen peroxide. These agents are able to insert between base pairs of DNA to cause structural changes in DNA. However, the primary mechanism of cytotoxicity appears to be the inhibition of topoisomerase II. These drugs are widely used in a variety of cancers.

Oxygen-free-radical formation is a cause of cardiac damage and extravasation injury, which is common with these drugs. The anthracyclines can cause cardiac toxicity as manifested by a congestive heart failure or cardiomyopathy symptomatology, alopecia, nausea or vomiting, mucositis, myelosuppression, and urinary discoloration. These drugs are vesicants.

To reduce the risk of cardiotoxicity associated with doxorubicin, the maximum lifetime cumulative dose is 550 mg/m^2; similarly, the other anthracyclines have maximum lifetime cumulative doses. Ventricular ejection fractions should be measured before therapy and periodically if therapy is continued. Therapy should be halted if there is a 10% to 20% decrease from baseline in ejection fraction. Patients at increased risk of cardiotoxicity include patients reaching the upper limit of cumulative lifetime dose; those taking concomitant or previous cardiotoxic drugs, concurrent paclitaxel, or bolus administration; patients with preexisting cardiac disease or mediastinal radiation; and the very young and elderly. Cardioprotectants (eg, dexrazoxane) have been used to decrease risk in some cases. Clinical guidelines exist recommending when cardioprotective agents are warranted.[21]

Liposomal doxorubicin is an **irritant**, not a vesicant, and is dosed differently from doxorubicin, so clinicians need to be very careful when prescribing these two drugs. Liposomal doxorubicin has shown significant activity in the treatment of breast and ovarian cancer along with multiple myeloma (MM) and Kaposi sarcoma. Side effects include mucositis, myelosuppression, alopecia, and palmar-plantar erythrodysesthesia. The liposomal doxorubicin may be less cardiotoxic than doxorubicin.

▶ *Mitoxantrone*

This royal blue–colored drug is an anthracenedione that inhibits DNA topoisomerase II. Mitoxantrone has shown clinical activity in the treatment of acute leukemias, breast and prostate cancer, and non-Hodgkin lymphomas. Myelosuppression, mucositis, nausea and vomiting, and cardiac toxicity are side effects of this drug. The total cumulative dose limit is 160 mg/m^2 for patients who have not received prior anthracycline or mediastinal radiation. Patients who have received prior doxorubicin or daunorubicin therapy should not receive a cumulative dose greater than 120 mg/m^2 of mitoxantrone. Patients should be counseled that their urine will turn a blue–green color.[22]

Alkylating Agents

Although still widely used for many malignancies, the alkylating agents are the oldest class of anticancer drugs. The agents cause cytotoxicity via transfer of their alkyl groups to nucleophilic groups of proteins and nucleic acids. The major site of alkylation within DNA is the N7 position of guanine, although alkylation does occur to a lesser degree at other bases. These interactions can either occur on a single strand of DNA (monofunctional agents) or on both strands of DNA through a cross-link (bifunctional agents), which leads to strand breaks. The major toxicities of the alkylating agents are myelosuppression, alopecia, nausea or vomiting, sterility or infertility, and secondary malignancies.

▶ *Nitrogen Mustards (Cyclophosphamide and Ifosfamide)*

Cyclophosphamide and ifosfamide are commonly used bifunctional alkylating agents, therefore, causing cross-linking of DNA. They each share similar adverse effects and spectrum of activity, being used in a variety of solid and hematologic cancers. Cyclophosphamide and ifosfamide are both prodrugs, requiring activation by mixed hepatic oxidase enzymes to get to their active forms, phosphoramide and ifosfamide mustard, respectively. During the activation process, additional byproducts (acrolein and chloroacetaldehyde) are formed. Acrolein has no cytotoxic activity but is responsible for the hemorrhagic cystitis associated with ifosfamide and high-dose cyclophosphamide. Acrolein produces cystitis by directly binding to the bladder wall. Prophylaxis is necessary with aggressive hydration, administration of 2-mercaptoethane sulfonate sodium (mesna, which binds to and inactivates acrolein in the bladder), frequent voiding, and monitoring in patients receiving ifosfamide and high-dose cyclophosphamide. Patients should be counseled to drink plenty of fluids; void frequently; and report any hematuria, irritation, or flank pain. Dosing regimens of mesna range from an equal milligram dose to the ifosfamide mixed in the same IV bag to 20% of the dose before ifosfamide and 20% of the dose repeated at 4 and 8 hours after the dose.

Chloroacetaldehyde, a metabolite of ifosfamide, can result in encephalopathy, especially in patients receiving ifosfamide that exhibit risk factors such as renal dysfunction or advanced age. This adverse effect can occur within 48 to 72 hours of administration and is usually reversible.

▶ *Busulfan*

Busulfan is an alkylating agent that forms DNA–DNA and DNA–protein cross-links to inhibit DNA replication. Oral busulfan is well absorbed, has a terminal half-life of 2 to 2.5 hours, and is eliminated primarily by metabolism. It is also available in an IV formulation, which is useful when using the high doses required in hematopoietic stem cell transplantation (HSCT). Busulfan has shown significant clinical activity in the treatment of AML and CML and has been used as a conditioning regimen before HSCT. Side effects include bone marrow suppression; hyperpigmentation of skin creases; and rarely, pulmonary fibrosis. High doses

used for HSCT preparatory regimens result in severe nausea and vomiting, tonic–clonic seizures, and sinusoidal obstruction syndrome. Patients receiving high-dose busulfan should receive anticonvulsant prophylaxis. Toxicities associated with busulfan dosing along with a discussion on adaptive dosing of busulfan can be found in Chapter 98.

▶ *Nitrosoureas (Carmustine and Lomustine)*

Carmustine (BCNU) and lomustine (CCNU) are nitrosoureas that are lipophilic in nature and therefore able to cross the blood–brain barrier. Carmustine, which is reconstituted with ethanol, crosses the blood–brain barrier when given IV. It also comes as a biodegradable wafer formulation that may be implanted to treat residual tumor tissue after surgical resection of brain tumors. Lomustine is available in an oral formulation. Carmustine has shown clinical activity in the treatment of lymphoma, MM, and brain tumors. Lomustine has shown clinical activity in the treatment of non-Hodgkin lymphoma and brain tumors. Patients should receive only enough lomustine for one cycle at a time to prevent confusion with their drug regimens and the prolonged neutropenia that can occur. Side effects include myelosuppression, severe nausea and vomiting, and pulmonary fibrosis with long-term therapy.

▶ *Nonclassic Alkylating Agents (Dacarbazine and Temozolomide)*

Although the exact mechanism of action remains unclear, dacarbazine and temozolomide appear to inhibit DNA, RNA, and protein synthesis. Dacarbazine has shown clinical benefit in the treatment of patients with melanoma, Hodgkin lymphoma, and soft tissue sarcomas. Side effects include myelosuppression, severe nausea and vomiting, and a flu-like syndrome that starts about 7 days after treatment and lasts 1 to 3 weeks.

Temozolomide is an orally active agent that is well absorbed and crosses the blood–brain barrier. Temozolomide is converted via pH-dependent hydrolysis to the active metabolite 5-(3-methyltriazeno)-imidazole-4-carboxamide. Temozolomide may be used in the treatment of melanoma, refractory anaplastic astrocytoma, and glioblastoma multiforme. Nausea may be minimized by administering the drug at bedtime. Because patients receiving temozolomide may have confusion secondary to their brain tumors and because dosing can consist of multiple capsule sizes, care must be taken by all providers to simplify regimens to prevent chemotherapy overdose.[23]

▶ *Procarbazine*

Although the exact mechanism of action of procarbazine is unknown, it does inhibit DNA, RNA, and protein synthesis. Procarbazine is used most often in the treatment of lymphoma. Myelosuppression is the major side effect. Nausea, vomiting, and a flu-like syndrome occur initially with therapy. Patients must be counseled to avoid tyramine-rich foods because procarbazine is a monoamine oxidase inhibitor. Patients should be provided a list of foods and beverages to avoid a hypertensive crisis. A disulfiram-like reaction can occur with the ingestion of alcohol.

Heavy Metal Compounds

Platinum drugs form reactive platinum complexes that bind to cells, so the pharmacokinetics of the individual drug may be of the platinum, both free and bound, rather than of the parent drug.

▶ *Cisplatin*

Cisplatin forms inter- and intrastrand DNA cross-links to inhibit DNA synthesis. Cisplatin has shown clinical activity in the treatment of numerous tumor types, from head and neck cancers to anal cancer, including many types of lymphoma and carcinoma of unknown primary. Cisplatin is highly emetogenic, even when low doses are given daily for 5 days, and causes delayed nausea and vomiting as well; patients require aggressive antiemetic regimens for both delayed and acute emesis. Significant nephrotoxicity and electrolyte abnormalities can occur if inadequate hydration occurs. Ototoxicity, which manifests as a high-frequency hearing loss, and a glove-and-stocking neuropathy may limit therapy.

▶ *Carboplatin*

Carboplatin has the same mechanism of action as cisplatin; however, its side effects are similar but less intense than those of cisplatin. Many chemotherapy regimens dose carboplatin based on an area under the curve (AUC), which is also called the Calvert equation. According to the Calvert equation for adults, the dose in milligrams of carboplatin = (CrCl + 25) × AUC desired, where CrCl is expressed in mL/min.[24] Carboplatin has shown clinical activity in the treatment of several solid tumors and lymphoma. Thrombocytopenia, nausea and vomiting, and hypersensitivity reactions are adverse effects.

▶ *Oxaliplatin*

Oxaliplatin has shown clinical activity in the treatment of colorectal cancer. Oxaliplatin, although similar in action to cisplatin and carboplatin in terms of adverse effects, also, causes a cold-induced neuropathy. Patients should be counseled to avoid cold beverages, to use gloves to remove items from the freezer, and to wear protective clothing in cold climates for the first week after treatment. A glove-and-stocking neuropathy also occurs with long-term dosing. Hypersensitivity reactions and moderate nausea and vomiting are also adverse effects.[25]

mTOR Inhibitors

▶ *Temsirolimus and Everolimus*

The mammalian target of rapamycin (mTOR) is a downstream mediator in the phosphatidylinositol 3-kinase/Akt signaling pathway that controls translation of proteins that regulate cell growth and proliferation but also angiogenesis and cell survival. The mTOR is an intracellular component that stimulates protein synthesis by phosphorylating translation regulators, and contributes to protein degradation and angiogenesis.

Temsirolimus is approved for the treatment of advanced kidney cancer. Temsirolimus and its metabolite sirolimus are substrates of the cytochrome CYP3A4/5 isoenzyme system. The primary side effects of temsirolimus include mucositis, diarrhea, maculopapular rash, nausea, leucopenia, thrombocytopenia, and hyperglycemia. Noninfectious pneumonitis can occur and must be identified immediately for best outcomes.

Everolimus is an oral inhibitor of mTOR that is approved for the treatment of patients with advanced kidney cancer, breast cancer, and neuroendocrine tumors. Drug interactions and adverse reactions are similar to those of temsirolimus.

Miscellaneous Agents

▶ *Bleomycin*

Bleomycin is a mixture of peptides with drug activity expressed in units, where 1 unit equals to 1 mg. Bleomycin causes DNA strand breakage. Bleomycin has shown clinical activity in the

treatment of patients with testicular cancer and malignant effusions, squamous cell carcinomas of the skin, and Kaposi sarcoma. Hypersensitivity reactions and fever may occur, so premedication with acetaminophen may be required. The most serious side effect is the pulmonary toxicity that presents as a pneumonitis with a dry cough, dyspnea, rales, and infiltrates. Pulmonary function studies show decreased carbon monoxide diffusing capacity and restrictive ventilatory changes. "Bleomycin lung" is associated with cumulative dosing greater than 400 units and occurs rarely with a total dose of 150 units. The pulmonary toxicity is potentiated by thoracic radiation and by hyperoxia. Additional side effects include fever with or without chills, mild to moderate alopecia, and nausea and vomiting. Bleomycin has been used to manage malignant plural effusions at doses of 15 to 60 units through installation into the affected area. The drainage tube of the effusion is clamped off for some period of time after administration of bleomycin and then the amount of drainage is monitored to determine efficacy of the treatment.[25]

▶ Hydroxyurea

Hydroxyurea is an oral drug that inhibits ribonucleotide reductase, which converts ribonucleotides into the deoxyribonucleotides used in DNA synthesis and repair. Hydroxyurea has shown clinical activity in the treatment of CML, polycythemia vera, sickle cell disease, and thrombocytosis. The major side effects are myelosuppression, nausea and vomiting, diarrhea, and constipation. Rash, mucositis, and renal tubular dysfunction occur rarely.

▶ L-Asparaginase

L-Asparaginase is an enzyme that may be produced by *Escherichia coli*. Asparaginase hydrolyzes the reaction of asparagine to aspartic acid and ammonia to deplete lymphoid cells of asparagine, which inhibits protein synthesis. L-Asparaginase has shown clinical activity in the treatment of ALL and childhood AML. Severe allergic reactions may occur when the interval between doses is 7 days or greater, so while a skin test result may be negative, patients should be observed closely after asparaginase administration. Pancreatitis and fibrinogen depletion may also occur during therapy. Repletion of fibrinogen should be done to prevent disseminated intravascular coagulation and fatal bleeding. If the patient suffers an allergic reaction to L-asparaginase, pegaspargase, which is L-asparaginase modified through a linkage with polyethylene glycol, which extends the half-life and allows for lower doses and less frequent administration, may be given. Cost and limited availability are some reasons pegaspargase may not be used first.

▶ Tretinoin

Tretinoin, also referred to as *ATRA*, which stands for all-trans-retinoic acid, is a retinoic acid that is not cytotoxic but promotes the maturation of early promyelocytic cells and is specific to the t(15;17) cytogenetic marker. The most significant side effect is the acute promyelocytic leukemia (APL) differentiation syndrome, which may occur anywhere from the first couple of days of therapy until the end of therapy and consists of symptoms of fever, respiratory distress, and hypotension. Chest radiographs are consistent with a pneumonia-like process. The syndrome can be confused easily with pneumonia in a patient with possible neutropenia. The treatment for retinoic acid syndrome is dexamethasone 10 mg IV every 12 hours; the syndrome may resolve within 24 hours of the start of dexamethasone therapy. However, the use of steroids in a febrile neutropenic patient may further compromise the treatment of infection.[26]

▶ Immunomodulatory Agents (Thalidomide, Lenalidomide, and Pomalidomide)

Thalidomide was introduced into the market in Europe on October 1, 1957, as a sedative–hypnotic, and when it was taken by pregnant women, it resulted in severe limb deformities (phocomelia) and subsequently was removed from the market. Thalidomide is an angiogenesis inhibitor, but the full mechanism of action is still unknown. Possible mechanisms of action include free radical oxidative damage to DNA, inhibiting tumor necrosis factor α production, altering the adhesion of cancer cells, and altering cytokines that affect the growth of cancer cells. Thalidomide has shown clinical activity in the treatment of MM. Because of thalidomide's potential to cause phocomelia, each patient must be enrolled in the STEPS program and counseled on the risks of thalidomide not only for the patient but also the patient's reproductive partner. Clinicians must be registered to prescribe thalidomide. Common adverse effects include somnolence, constipation, peripheral neuropathy, and deep vein thrombosis (DVT). Recommendations for DVT prophylaxis for all thalidomides include low-molecular-weight heparin or standard-dose warfarin for high-risk patients and aspirin for low-risk patients.[27]

Lenalidomide is approved for the treatment of myelodysplastic syndrome when the 5q deletion is present and MM. Because lenalidomide is an analogue of thalidomide, all of the same precautions must be taken to prevent phocomelia. However, lenalidomide has fewer adverse effects than thalidomide. Dosing adjustments are necessary for renal dysfunction. Lenalidomide is used in the treatment of myelodysplastic syndrome and MM. Other side effects are neutropenia, thrombocytopenia, DVT, and pulmonary embolus.

Pomalidomide is also used in treatment of refractory or progressive MM. Similar precautions to prevent phocomelia should also occur with this drug. Adverse effects include myelosuppression and infections. The use of the immunomudulatory agents in the treatment of MM is discussed thoroughly in Chapter 96.

▶ Proteasome Inhibitors (Bortezomib, Carfilzomib, and Ixazomib)

The proteasome is an enzyme complex that exists in all cells and plays an important role in degrading proteins that control the cell cycle. When the proteasome is inhibited, the numerous pathways that are necessary for the growth and survival of cancer cells are disrupted. Bortezomib specifically inhibits the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. This pathway plays an essential role in regulating the intracellular concentration of specific proteins, causing the cells to maintain homeostasis. Inhibition of the 26S proteasome prevents this to occur, ultimately causing a disruption in the homeostasis and cell death. Both carfilzomib and ixazomib inhibit 20S proteasome, which is the proteolytic core with the 26S proteasome.

Bortezomib is approved for the treatment of MM, mantle cell lymphoma, and in some cases of relapsed/refractory AML. It is administered as an IV injection. The most commonly reported adverse effects are asthenia, gastrointestinal (GI) disturbances (nausea, diarrhea, decreased appetite, constipation, vomiting), thrombocytopenia, peripheral neuropathy, anemia, headache, insomnia, and edema. Prophylactic anticoagulation is not routinely required. Reactivation of varicella zoster infection is also common with bortezomib, and antiviral prophylaxis with acyclovir should be considered.

Carfilzomib and ixazomib are second-generation proteasome inhibitors. Carflizomib is administered by IV, whereas ixazomib

is a capsule that should be taken on an empty stomach. Both of these drugs used in the treatment of refractory cases of MM and have similar but fewer side effects compared with bortezomib.

▶ *Omacetaxine Mepesuccinate*

Omacetaxine mepesuccinate is an alkaloid from *Cephalotaxus harringtonia*. The agent reversibly inhibits protein synthesis, causing cell death. It affects both malignant and nonmalignant cells. It is a subcutaneous injection and is indicated for the treatment of CML patients (including those patients with the T315I mutation) showing resistance and/or intolerance to two or more tyrosine kinase inhibitors (TKIs). The most common nonhematological adverse effects are GI disruption, fatigue, and hyperglycemia. Rare but serious adverse reactions include febrile neutropenia, infections, and cerebral hemorrhage.

▶ *Histone Deacetylase (HDAC) Inhibitors (Vorinostat and Romidepsin)*

Vorinostat is indicated for the treatment of cutaneous T-cell lymphoma in patients with progressive, persistent, or recurrent disease after treatment with two systemic therapies. Romidepsin is approved for the treatment of cutaneous or peripheral T-cell lymphoma in patients who have received at least one systemic therapy. These agents catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Vorinostat is an orally available agent, and romidepsin is only available in an IV formulation. These drugs are metabolized by CYP3A4, so caution should be exercised with monitoring for drug–drug interactions. Side effects include diarrhea, fatigue, nausea and anorexia, hypercholesterolemia, hypertriglyceridemia, and hyperglycemia. Despite anemia, thrombocytopenia, and neutropenia, patients have developed pulmonary embolism and DVT while on therapy.[28]

▶ *Poly ADP Ribose Polymerase (PARP) Inhibitors: Niraparib, Olaparib, and Rucaparib*

PARP enzymes are involved in normal cellular function, including DNA transcription and repair. Thus, PARP inhibitors inhibitor tumor growth. Niraparib, olaparib, and rucaparib are all used to treat ovarian, fallopian tube, or peritoneal cancer. Olaparib is available as both tablets and capsules, but they should not be substituted on a milligram-per-milligram basis due to differences in dosing and bioavailabilty of each formulation. Common side effects include myelosuppessive side effects, GI toxicities, fatigue, upper respiratory tract infections, and arthralgias and myalgias. Rarely, patients can develop myelodysplastic syndrome or AML and pneumonitis. Niraparib also causes hypertension and patients must undergo heart rate (HR) and blood pressure monitoring monthly for the first year.

Immunotherapy

▶ *Tisagenlecleucel*

Tisagenlecleucel is the first gene therapy approved in cancer. It is an autologous T cell immunotherapy comprised of T cells that are genetically modified using a vector to encode an anti-CD19 chimeric antigen receptor (CAR). Tisagenlecleucel is prepared from the patient's own peripheral mononculelar cells, which are obtained through a leukapheresis procedure.[29] The cells are sent to a laboratory whereby they are enriched with the lentiviral vector containing anti-CD19 CAR transgene. The transduced T cells are then expanded and formulated into a suspension that is cryopreserved. Once passing a sterility test, it is shipped back in a patient-specific infusion bag to the institution for administration. Tisagenlecleucel is approved for us in ALL. The most common side effect is a cytokine-release syndrome (CRS), which can be fatal. Immediate identification and treatment is necessary to prevent death. Other side effects include decreased appetite, headache, nausea/vomiting, infections, and diarrhea.

▶ *Aldesleukin*

Aldesleukin, which is a human recombinant *interleukin-2 (IL-2)*, is a lymphokine that promotes B- and T-cell proliferation and triggers a cytokine cascade to attack the tumor. Aldesleukin has shown clinical activity in the treatment of kidney cancer and melanoma. Side effects of IL-2 vary by dose and route. IV high-dose IL-2 causes a drug-induced shock-like picture. Patients may develop hypotension despite aggressive IV hydration. Patients develop a red, itchy skin; liver and kidney function tests change; via immune complex formation in the kidneys, fluid, and electrolyte imbalances occur; and high fevers occur while receiving scheduled acetaminophen and nonsteroidal anti-inflammatory agents. Severe rigors and chills may require symptom control. All the side effects reverse within 24 hours of stopping the drug. The toxicity profile is much less with subcutaneous administration. However, with subcutaneous administration, nodules form at the injection site and may take months to resolve. Corticosteroids should not be administered to patients while they are receiving aldesleukin unless a life-threatening emergency occurs. Steroids reverse all the symptoms and the antitumor effect even with topical administration. The itching, red skin may be treated with topical creams and antihistamines.

Monoclonal Antibodies

The cell surface contains molecules, which are referred to as *CD*, which stands for "cluster of differentiation." The antibodies are produced against a specific antigen. When administered, usually by an IV injection, the antibody binds to the antigen, which may trigger the immune system to result in cell death through complement-mediated cellular toxicity, or the antigen–antibody cell complex may be internalized to the cancer cell, which results in cell death. Monoclonal antibodies also may carry radioactivity, sometimes referred to as *hot antibodies*, and are referred to as *radioimmunotherapy*, so the radioactivity is delivered to the cancer cell. Antibodies that contain no radioactivity are referred to as *cold antibodies*.

All monoclonal antibodies end in the suffix *-mab*. The syllable before *-mab* indicates the source of the monoclonal antibody (Table 88–7).[30] When administering an antibody for the first time,

Table 88–7

Syllable Source Indicators for Monoclonal Antibodies[a]

U	Human
O	Mouse
A	Rat
E	Hamster
I	Primate
Xi	Chimeric: A cross between humanized and animal source
Axo	Rat/mouse hybrid
Xizu	Combination of humanized and chimeric chains

[a]These letters appear before mab, which stands for monoclonal antibody.

Data from Programme on International Nonproprietary Names (INN) Division of Drug Management and Policies, World Health Organization, Geneva. 1997.

one should consider the source. The less humanized an antibody, the greater the chance for the patient to have an allergic-type reaction to the antibody. The more humanized the antibody, the lower the risk of a reaction. The severity of the reactions may range from fever and chills to life-threatening allergic reactions. Premedication with acetaminophen and diphenhydramine is common before the first dose of any antibody. If a severe reaction occurs, the infusion should be stopped and the patient treated with antihistamines, corticosteroids, or other supportive measures.

▶ *Alemtuzumab*

Alemtuzumab is an antibody to the CD52 receptor present on B and T lymphocytes. Alemtuzumab has shown clinical activity in the treatment of CLL. Severe and prolonged (6 months) immunosuppression may result, which necessitates pneumocystis jirovecii pneumonia (PJP) prophylaxis and antifungal and antiviral prophylaxis to prevent opportunistic infections. Infusion-related reactions typically occur with the first dose and can be severe. Premedication with antihistamines and acetaminophen is recommended. Subcutaneous administration will also alleviate the severity of infusion reactions.

▶ *Bevacizumab and Bevacizumab-awwb*

Bevacizumab is a humanized monoclonal antibody that binds to vascular endothelial growth factor (VEGF), which prevents it from binding to its receptors, ultimately resulting in inhibition of angiogenesis. Bevacizumab has shown clinical activity in the treatment of colorectal, kidney, lung, breast, and head and neck cancer. The biosimilar bevacizumab-awwb is the first biosimilar approved in the United States for cancer treatment. A biosimilar is a type of biological product that is highly similar to the originator product and is expected to have no meaningful clinical difference. Patients treated with bevacizumab products may develop hypertension requiring chronic medication during therapy. Impaired wound healing, thromboembolic events, proteinuria, bleeding, and bowel perforation are serious side effects that occur with this drug.

▶ *Blinatumomab*

Blinatumomab is a bispecific CD19-directed CD3 T cell therapy. It activates T cells by connecting the CD3 antigen in the receptor complex with the CD19 surface antigen on both benign and malignant B cells, activating inflammatory cytokine release and T-cell proliferation resulting in apoptosis of CD19+ cells. It is effective in patients with Philadelphia negative B-cell precursor ALL. Common side effects include pyrexia, neutropenia, infections, and infusion-related reactions. Patients should receive dexamethasone before infusion and when restarting an infusion if interrupted for more than 4 hours. Rare but serious side effects include CRS and neurologic toxicity, such as paresthesia, confusion, dizziness, and tremor. CRS occurs when the cytokines are released by activated T cells, producing a systemic inflammatory response. Patients may initially present with a low-grade fever, fatigue, and anorexia which can quickly progress to high fever, hypoxia, and organ failure. Thus, patients are typically hospitalized for the first cycle and first two days of the second cycle. Medication errors can occur when preparing and administering blinatumomab because preparation instructions are more complicated than most other IV drugs. Doses are based on weight, dose, and duration of infusion. Additionally, specific instructions for use of an IV solution stabilizer are provided rather than mixing with the drug for reconstitution and the volume for infusion.

▶ *Brentuximab Vedotin*

Brentuximab vedotin is a CD30-directed antibody–drug conjugate (ADC) that consists of the antibody specific for CD30, a microtubule disrupting agent called monomethyl auristatin E (MMAE), and a protease-cleavable linker that covalently attaches MMAE to the antibody. It is reported that the cytotoxic activity is a result of the binding of the ADC to CD30-expressing cells followed by internalization of the ADC–CD30 complex, and then proteolytic cleavage and release of MMAE into the cell. Binding of MMAE to tubulin disrupts the microtubule network, resulting in cell cycle arrest and apoptosis. This IV agent is indicated for Hodgkin lymphoma patients after failure or ineligibility of autologous HSCT and for patients with systemic anaplastic large cell lymphoma who have failed at least one systemic chemotherapy regimen. In vitro data suggests that MMAE is a substrate and an inhibitor of CYP3A4/5; therefore, patients need to be monitored for drug–drug interactions. The most common adverse effects are neutropenia, peripheral neuropathy, fatigue, nausea and vomiting, diarrhea, anemia, thrombocytopenia, and upper respiratory infection. Dosing modification guidelines for peripheral neuropathy can be found in the prescribing information.[31]

▶ *Cetuximab, Necitumumab, and Panitumumab*

Cetuximab is a chimeric antibody that binds to the EGFR to block its stimulation. Panitumumab binds to the EGFR to prevent receptor autophosphorylation and activation of receptor-associated kinases, which results in inhibition of cell growth and induction of apoptosis. Necitumumab is an anti-EGFR recombinant human monoclonal antibody. Cetuximab has shown clinical activity in the treatment of colorectal and head and neck cancers, necitumumab in non–small cell lung cancer, and pantiumumab in colorectal cancers. Tumors that have *RAS* mutations do not respond to treatment with cetuximab or panitumumab; therefore, tumors should be tested for *RAS* mutations before initiating therapy. An acne-like rash may appear on the face and upper torso 1 to 3 weeks after the start of therapy. Preventive therapies with topical corticosteroids with moisturizer, sunscreen, and oral doxycycline are recommended. Other side effects include hypersensitivity reactions, fever, nausea and vomiting, and interstitial lung disease. Electrolyte disturbances, such as hypomagnesemia and hypocalcemia, can occur; these are more common with necitumumab and panitumumab.

▶ *Daratumumab*

Daratumumab is a monoclonal antibody to the CD38 receptor, highly expressed on myeloma cells and weakly on other hematopoietic stem cells. It is used in patients with MM. Infusion-related reactions are common so patients must be pretreated with acetaminophen, an antihistamine, and IV methylprednisolone and receive an oral corticosteroid for each of the 2 days following infusion to prevent delayed reactions. Also, this drug causes a positive interference with cross matching and red blood cell antibody screening, by causing a positive indirect Coombs test that can persist for 6 months after discontinuation of therapy. Thus, patients should be typed and screened before therapy, and blood banks should be informed when a patient has received daratumumab.

▶ *Elotuzumab*

Elotuzumab is a humanized recombinant monoclonal antibody that specifically targets signaling lymphocytic activation molecule family member 7 protein. It works by directly activating natural killer cells to mediate the killing of myeloma cells through antibody-dependent cellular cytotoxicity (ADCC). Premedications to

prevent infusion-related reactions should include dexamethasone, H_1 blocker, H_2 blocker, and acetaminophen. The most common side effects are fatigue, diarrhea, pyrexia, constipation, and cough.

▶ *Ibritumomab Tiuxetan*

Ibritumomab tiuxetan, a "*hot antibody*," is linked to yttrium and binds to the CD20 receptor of B lymphocytes. Similarly, hematologic toxicity may occur several weeks after administration and may take weeks to resolve.

▶ *Obinutuzumab, Ofatumumab, and Rituximab*

Obinutuzumab, ofatumumab, and rituximab are monoclonal antibodies to the CD20 receptor expressed on the surface of B lymphocytes; the presence of the antibody is determined during flow cytometry of the tumor cells. Cell death results from ADCC. All of these drugs have shown clinical activity in the treatment of B-cell lymphomas that are CD20 positive. Side effects include infusion-related reactions, hypotension, fevers, chills, rash, headache, and mild nausea and vomiting. Premedication with acetaminophen and an antihistamine is recommended for rituximab to minimize the first-dose infusion reaction; acetaminophen, antihistamine, and a glucocorticoid prior to obinutuzumab and ofatumumab. In patients with extensive disease, prevention of tumor lysis syndrome is also recommended. Serious adverse events, including fatal infections, progressive multifocal leukoencephalopathy, and reactivation of hepatitis B, have been reported. Thus, all patients should be tested for hepatitis B and treated before therapy commences.

▶ *Pertuzumab, Trastuzumab, and Trastuzumab-DM1 (T-DM1, Trastuzumab Emtansine)*

Pertuzumab and trastuzumab are humanized monoclonal antibody directed against human epidermal receptor 2 (HER-2). When compared to trastuzumab, pertuzumab recognizes different extracellular epitopes, binds uniquely which causes structural changes and therefore interrupts receptor dimerization. These differences were thought to be able to provide greater inhibition of HER-2 when compared to trastuzumab, but this has not been proven to be the case. Cancer tissue must be tested for the presence of HER-2 because patients who do not express HER-2 do not respond to trastuzumab. Trastuzumab-DM1 or ado-trastuzumab emtansine is a compound in which trastuzumab is used as a drug vehicle to deliver an anticancer agent known as emtansine (a maytansine derivative). Trastuzumab is used for the treatment of breast and gastric cancer. Severe congestive heart failure may occur with concurrent anthracycline administration. Cardiac toxicity may be seen when the drug is administered months after anthracycline administration, so patients must be counseled on the signs and symptoms of heart failure. A common side effect associated with trastuzumab is a first-dose infusion-related reaction which includes chills. The patient may be given acetaminophen and diphenhydramine and/or the infusion may be slowed. Other side effects which are rare include hypersensitivity reactions and pulmonary reactions.[32] Pertuzumab has similar adverse effects as trastuzumab. When used in combination with trastuzumab, it does not appear to increase the incidence of cardiac toxicity. A more detailed discussion of the use of trastuzumab and pertuzumab in breast cancer can be found in Chapter 89.

The most common serious adverse effect with ado-trastuzumab emtansine was thrombocytopenia. The platelet nadir usually occurs about 7 days after treatment and recovers within a week. Other adverse effects included abnormal liver function tests, fatigue, nausea, headache, and hypokalemia. Dosing adjustments for cardiac toxicity differ from trastuzumab.

Checkpoint Inhibitors

The immune system is in a continual state of balance between tolerating "normal" tissue and attacking foreign substances. Immunological tolerance is regulated by immune cells, suppressive cytokines, and immune checkpoint pathways.[33] Immune checkpoints become involved following immune activation, creating an inhibitory feedback loop to reduce involvement of normal tissues. Inhibitors of the immune checkpoints act by inhibiting key regulatory steps, promoting activation and proliferation of T cells to induce tumor infiltration and regression. Tumor responses to checkpoint inhibitors differ from those observed with other anticancer therapies. Responses can be seen long after the start of treatment, and pseudoprogression can be seen immediately after starting therapy which instead of representing a tumor progression can represent inflammation only within the tumor area. Adverse effects of checkpoint inhibitors are related to their effect on the immune system, whereby they attack normal cells as well. This can result in severe and fatal immune-mediated adverse reactions, including enterocolitis, hepatitis, toxic epidermal necrolysis, neuropathy, pneumonitis, and endocrine abnormalities. These symptoms can occur during treatment or weeks to months after discontinuation of the drug. Liver and thyroid function tests should be performed at baseline and before each dose and periodically, respectively. Patients should be monitored for symptoms of inflammatory responses (eg, diarrhea as early sign of colitis, shortness of breath as early sign of pneumonitis). If any of these reactions occur, treatment should be initiated with systemic corticosteroids and the drug should be discontinued permanently. Progressive multifocal leukoencephalopathy has been reported. Typically, these side effects can be more severe with the cytotoxic T lymphocytic–associated antigen 4 (CTLA-4) inhibitor than PD or PD-ligand (PD-L) inhibitors.

▶ *Ipilimumab*

Ipilimumab is a recombinant, human monoclonal antibody that binds to the CTLA-4, which is a molecule on T cells that causes a suppression of the immune response. CTLA-4 is a negative regulator of T-cell activation. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands. This blockage has been reported to enhance T-cell activation and proliferation. Ipilimumab is approved for patients with unresectable or metastatic melanoma and kidney cancer. The antitumor effects appear to be T-cell–mediated immune responses and are the highest with this drug of all the available checkpoint inhibitors.

▶ *Nivolumab and Pembrolizumab*

Nivolumab and pembrolizumab are human monoclonal antibodies that block the interaction of the binding to PD-1 and its ligands PD-L1 and PD-L2. These drugs are active in bladder, cervical (pembrolizumab), gastric, head and neck, kidney, liver, and non–small cell lung cancers; some lymphomas, melanoma, and some types of cancers that have high microsatellite instability. Side effects are much less common with PD-1 inhibitors compared with the CTLA-4 inhibitor ipilimumab.

▶ *Atezolizumab, Avelumab, and Durvalumab*

Atezolizumab, avelumab, and durvalumab are recombinant, human monoclonal antibodies that bind PD-L1 and block interaction with the PD-1 receptors. These drugs are active in

bladder (all) and non–small cell lung cancers (atezolizumab, durvalumab); and Merkel cell (avelumab). Side effects are much less common with PD-L1 inhibitors compared with the CTLA-4 inhibitor ipilimumab.

Tyrosine Kinase Inhibitors

More than 100 different types of tyrosine kinases are present in the body. TKIs have been developed to block either several or a specific tyrosine kinase (see Table 88–6). They are used to treat solid tumors, leukemias, and lymphomas and can be used as alone or in combination with IV chemotherapy, surgery, and/or radiation. Some are continuously administered until disease progression occurs or intolerance develops whereas others are given cyclically (eg, 2 weeks on, 1 week off; then repeat). Side effects often limit use if uncontrolled, and typically are different than those observed traditional chemotherapy or immunotherapy. Drug interactions are common as many of these drugs are metabolized through the CYP450 and p-glycoprotein systems and can have decreased concentrations in the presence of antacids, H_2 blockers and/or proton pump inhibitors.

▶ *Anaplastic Lymphoma Kinase (ALK) Inhibitors: Alecitinib, Crizotinib, and Ceritinib*

Crizotinib is a small-molecule inhibitor of the anaplastic lymphoma kinase gene (ALK) and mesenchymal epithelial transition growth factor (*c-MET*). This orally available agent is approved for the treatment of locally advanced or metastatic NSCLC that is ALK positive (about 2%–7% of NSCLC patients) as detected by an FDA-approved test. Adverse effects reported include mild GI symptoms, edema, and visual disturbances, which have been described as trails of light following objects as they move. Alecitinib and ceritinib are also used in ALK-positive NSCLC patients who have progressed on or are intolerant to crizotinib. Ceritinib, which has shown to be 20 times more potent than crizotinib in enzymatic assays, primarily targets ALK along with additional targets, including insulin-like growth factor 1 receptor, insulin receptor, and ROS1. Alecitinib also inhibits RET; neither inhibit *c-MET*. GI toxicities and elevated liver function tests are most common adverse reactions with these agents. Visual changes, pulmonary disease, and QT prolongation are also observed with both and CK elevations with alecitinib.

▶ *BCR-ABL TKIs: Bosutinib, Dasatinib, Imatinib, Nilotinib, and Ponatinib*

Imatinib was the first FDA-approved TKI. Imatinib inhibits phosphorylation during cell proliferation. The drug was designed to block the breakpoint cluster region tyrosine kinase (BCR-ABL) produced by the Philadelphia chromosome associated with CML and ALL. Imatinib also has shown activity against gastrointestinal stromal tumors (GIST) that are positive for c-kit (CD117). Imatinib is usually well tolerated, but common adverse effects include myelosuppression, rash, GI upset, edema, fatigue, arthalgias, myalgias, and headaches. A cumulative cardiotoxicity is a serious but rare adverse effect; therefore it is recommended to closely monitor patients with preexisting cardiac conditions.

Advanced generation BCR-ABL TKIs are more potent than imatinib and can overcome most BCR-ABL mutations that lead to imatinib resistance. Bosutinib, dasatinib, and nilotinib are second-generation BCR-ABL TKIs and are used frontline in the treatment of CML and in CML with resistance or intolerance to imatinib. Side effects of dasatinib and nilotinib are similar to imatinib and include myelosuppression, nausea and vomiting, headache, fluid retention, and hypocalcemia. Pleural effusions have been reported with dasatinib and imatinib but not with nilotinib. QT prolongation can occur with dasatinib and nilotinib. Abnormalities in indirect bilirubin have been reported with nilotinib.

Nilotinib is a competitive inhibitor of UGT1A1 in vitro, which could increase the concentrations of nilotinib. In a pharmacogenetic analysis, patients with (TA)7/(TA)7 genotype (*UGT1A1∗ 28*) had a statistically significant increase in bilirubin over other genotypes.[39]

Bosutinib is indicated for the first- and second-line treatment of CML in cases of resistance or intolerance to prior TKI therapy. With the exception of *T315I*, bosutinib overcomes most BCR-ABL domain mutations. GI disturbances and rash are common. Bosutinib appears to have a milder side effect profile than other TKIs.

Ponatinib is a third-generation multikinase inhibitor and the only advanced generation TKI that overcomes the *T315I* mutation. Serious adverse effects reported included thrombosis, hepatotoxicity (rare), and death (rare). These are included as black-box warnings. Less serious adverse effects include abdominal pain, dry skin, and rash.

▶ *BRAF Inhibitors: Dabrafenib, Trametinib, and Vemurafenib*

Vemurafenib is a potent inhibitor of mutated *BRAF* and is indicated for the treatment of unresectable or metastatic melanoma in patients with documented *BRAFV600E* mutation as determined by an FDA-approved test. Common adverse effects include arthralgia, rash, fatigue, alopecia, keratoacanthoma or squamous cell cancer, photosensitivity, nausea, and diarrhea. Approximately 40% of patients require dosage modifications because of adverse effects.[41]

Trametinib is a reversible inhibitor of mitogen-activated extracellular kinases (MEK)-1 and MEK-2 that is also active against *BRAF V600*-mutated forms of BRAF kinases in melanoma cells. It is indicated as monotherapy and in combination with dabrafenib for unresectable or metastatic malignant melanoma. It is not indicated in patients previously treated with a BRAF inhibitor. Rash, diarrhea, and lymphedema were commonly reported. Cardiomyopathy (defined as heart failure) and bleeding have also been reported.

Dabrafenib is a kinase inhibitor that has activity against BRAF kinases. It is indicated for the treatment of unresectable or metastatic malignant melanoma as monotherapy in patients with *BRAF V600E* mutation or in combination with trametinib in patients with *BRAF V600E* or V600K mutations. Adverse effects associated with this agent include arthralgias, alopecia, headache, palmar-plantar erythrodysesthesia syndrome, elevated liver enzymes, pyrexia, and papilloma.

▶ *Cyclin-Dependent Kinase (CDK) Inhibitors: Abemaciclib, Palbociclib, and Ribociclib*

Abemacicilib, palbociclib, and ribociclib all inhibit CDKs 4 and 6, which prevent phosphorylation and subsequent inactivation of the retinoblastoma tumor suppressor protein, ultimately causing cell cycle arrest and inhibiting cancer cell proliferation. Each of the available CDK4/6 inhibitors is used in the treatment of postmenopausal women with hormone receptor positive but HER2 negative breast cancer. Palbociclib and ribociclib are administered daily for 21 days, followed by 7 days off, whereas abemaciclib is administered daily. Common side effects include neutropenia, GI toxicities, and hair loss. Rarely, abemacicilib is associated with venous thromboembolism, ribociclib with QT prolongation, and both with hepatotoxicity.

▶ *EGFR Pathway Inhibitors: Afatinib, Erlotinib, Lapatinib, Neratinib, and Osimertinib*

Patients with NSCLC in which the tumors have mutations in exon 19 and/or 21 in the EGFR pathway will likely respond to EGFR TKIs such as afatinib and erlotinib. Those with EGFR *T790M* mutations will likely respond to osimertinib. These agents are believed to inhibit the intracellular phosphorylation of the EGFR. Food increases bioavailability to almost 100%, but is variable; experts recommend administering erlotinib on an empty stomach. Smoking increases the clearance of erlotinib by 24%, which may result in treatment failure and different doses are used for smokers versus nonsmokers.[34] Side effects of afatinib and erlotinib include interstitial lung disease, acneiform rash, diarrhea, anorexia, pruritus, conjunctivitis, and dry skin.

Lapatinib and neratinib inhibit the intracellular kinase domains of both EGFR and HER-2 and have been shown to retain activity against breast cancer cells that have become resistant to trastuzumab. Both are indicated for the treatment of patients with breast cancer whose tumors overexpress HER-2. Common side effects include diarrhea, nausea/vomiting, and fatigue; lapatinib is also associated with hand–foot skin reaction (HFSR). HFSR differs than HFS in that it initially develops as erythema and soreness, progressing to blisters and eventually hyperkeratosis.

▶ *Multikinase Inhibitors (Axitinib, Sorafenib, Sunitinib, and Pazopanib)*

Multikinase inhibitors inhibit multiple tyrosine kinases and are used for many different solid tumors. A full list of available multikinase inhibitors is found in Table 88–6. Some of the more common ones are described here. Sorafenib is a multikinase inhibitor that inhibits both intracellular and extracellular kinases and is used in treatment of hepatic, kidney, and thyroid cancers. The primary side effects of sorafenib include rash, HFSR, diarrhea, pruritus, and elevations in serum lipase.

Cabozantinib and pazopanib both primarily inhibit VEGF receptor–1 (VEGFR)-1, VEGFR-2, VEGFR-3, and several other tyrosine kinases. Cabozantinib is available in two dosage forms: tablets and capsules. The tablet formulation and lower dose is to be used for patients with advanced kidney cancer, whereas the capsules are larger dose for patients with medullary thyroid cancer. Pazopanib is used to treat advanced kidney cancer and sarcomas. Common side effects of these drugs are diarrhea, nausea, anorexia, HFSR syndrome, hypertension, and fatigue. Pazopanib also is associated with hair color changes. Serious toxicities that have been observed are fatal hepatotoxicity, prolonged QT intervals and torsades de pointes, hemorrhagic events, arterial thrombotic events, GI perforation, and proteinuria.

Regorafenib is another small molecule inhibitor of multiple membrane-bound and intracellular kinases used in treatment of metastatic colorectal cancer and GI stromal tumor. The proposed mechanism of action is through inhibition of vascular endothelial receptors involved in angiogenesis. GI effects, hypertension, mucositis, infection, rash, and fever are commonly occurring adverse effects. Hepatotoxicity is listed as a black-box warning; therefore, hepatic function should be monitored closely. It is an orally administered agent given for the first 21 days per 28-day cycle and should be taken with a low-fat breakfast (30 grams or less).

▶ *Phosphoinositide 3-Kinase (PI3-K) Inhibitors: Copanlisib and Idelalisib*

Copanlisib and idelalisib are approved for follicular lymphoma and CLL, respectively, and target PI3-K, an essential lipid kinase. Adverse effects associated with copanlisib are associated with hyperglycemia, hematologic abnormalities, fatigue, diarrhea, and hypertension. Idealisib causes GI disturbances, rash, hematological side effects, fatigue, and musculoskeletal pain. Idelalisib has hepatotoxicity, colitis, pneumonitis, infections, and intestinal perforation as black-box warnings.

Hormonal Therapies

Hormonal or endocrine therapies have shown activity in the treatment of cancers whose growth is affected by gonadal hormonal control. Hormonal treatments either block or decrease the production of endogenous hormones. You will learn more about these treatments and outcomes in Chapters 89 and 91, including the breast and prostate cancer chapters.

▶ *Antiandrogens: Bicalutamide, Flutamide, and Nilutamide*

The antiandrogens block androgen receptors (ARs) to inhibit the action of testosterone and dihydrotestosterone in prostate cancer cells. Unfortunately, prostate cancer cells may become hormone refractory. Side effects common to these agents are hot flashes, gynecomastia, and decreased libido. Flutamide tends to be associated with more diarrhea and requires three times daily administration, whereas bicalutamide is dosed once daily. Nilutamide may cause interstitial pneumonia and is associated with the visual disturbance of delayed adaptation to darkness.

▶ *Pure Androgen Receptor Antagonist: Apalutamide, Enzalutamide*

These are antagonists that work by competitively inhibiting androgen binding to ARs and by inhibiting AR nuclear translocation and coactivator recruitment of the ligand-receptor complex. These agents have shown to competitively inhibit androgen binding to ARs and inhibit AR nuclear translocation and interaction with DNA. Both are indicated for nonmetastatic castrate-resistant prostate cancer and enzalutamide is indicated for the treatment of metastatic castration-resistant prostate cancer. The most common side effect of this therapy is fatigue; otherwise it is well tolerated.

▶ *Luteinizing Hormone–Releasing Hormone Agonists: Goserelin and Leuprolide*

Initially, luteinizing hormone–releasing hormone (LHRH) agonists increase levels of luteinizing hormone and follicle-stimulating hormone, but testosterone and estrogen levels are decreased because of continuous negative-feedback inhibition. Major side effects are testicular atrophy, decreased libido, gynecomastia, and hot flashes. Goserelin is injected as a pellet under the skin; therefore, subcutaneous injection of lidocaine around the injection site before administration helps to decrease the pain associated with goserelin administration. Numerous dosage forms are available for leuprolide with varying strengths and dosing intervals. Antiandrogens may be administered during initial therapy to decrease symptoms of tumor flare (eg, bone pain and urinary tract obstruction).

▶ *Gonadotropin-Releasing Hormone Antagonist: Degarelix*

Degarelix is a gonadotropin-releasing hormone (GnRH) receptor antagonist that works by binding reversibly to the pituitary GnRH receptors, thereby reducing the release of gonadotropins and consequently testosterone. Degarelix is indicated for the treatment of advanced prostate cancer. Adverse events include hot

flashes, injection site reactions, and an increase in liver enzymes. An advantage of degarelix over LHRH agonists is the lack of the tumor flare.[35]

▶ *Abiraterone*

Abiraterone is an orally available androgen biosynthesis inhibitor that inhibits 17α-hydroxylase/C17,20-lyase (CYP17), which is expressed in testicular, adrenal, and prostatic tumor tissues. Abiraterone is indicated in combination with prednisone for the treatment of metastatic prostate cancer. Adverse effects include hypokalemia, edema, muscle discomfort, fatigue, hot flashes, nocturia, urinary frequency, and hypertension. The patient must be counseled to take the oral medication on an empty stomach because food increases absorption and results in adverse reactions.[36]

▶ *Aromatase Inhibitors*

Three AIs are currently available: anastrozole, letrozole, and exemestane. Anastrozole and letrozole are selective nonsteroidal AIs that lower estrogen levels. Anastrozole is a standard adjuvant treatment of postmenopausal women with hormone-positive breast cancer. The length of therapy is usually 5 years; however, evidence exists that suggests a benefit of prolonged treatment in certain situations. Exemestane, a steroidal compound, is an irreversible aromatase inactivator that binds to the aromatase enzyme to block the production of estrogen from androgens. This difference in activity does not appear to translate into improved clinical outcomes when compared to other AI therapies. When compared to tamoxifen, there are less endometrial and uterine cancers, vaginal bleeding, and thrombosis with AI therapy. Common adverse effects associated with the AI therapy include hot flashes and arthralgias. Serious adverse effects include osteoporosis, skeletal-related events, and atherosclerotic cardiovascular disease. The AIs are used exclusively for postmenopausal women. More information on the pharmacology and clinical use of AI therapy can be found in Chapter 89.

▶ *Antiestrogens*

Antiestrogens bind to estrogen receptors (ERs) and block the effect of estrogen on tissue. Two classes of antiestrogens exist: SERMs (tamoxifen, raloxifene) and selective estrogen-receptor downregulators (SERDs, fulvestrant). SERDs were developed in an effort to eliminate the unwanted estrogenic side effects from the SERMs. Tamoxifen is used for the treatment of ER positive premenopausal or postmenopausal metastatic hormone receptor–positive breast cancer, as adjuvant and primary treatment of breast cancer, and in the prevention of breast cancer in high-risk women. The agent has a beneficial effect on bone density and the lipid profile. Unwanted side effects include hot flashes, fluid retention, and mood swings. Thrombosis, endometrial and uterine cancer, corneal changes, and cataracts are harmful adverse effects that occur more frequently with this agent. Although uncommon, there is a disease/tumor flare which can occur during the initiation of therapy in metastatic breast cancer patients with bone metastases. Because tamoxifen is a substrate of CYP3A4, decreased tamoxifen levels have occurred with use of St. John's wort and rifampin. Tamoxifen is also a substrate for CYP450 2D6, and evidence suggests that those who are *CYP2D6*4/*4* may have a poorer response and more toxicity with tamoxifen.[37] Routine pharmacogenomics screening of these patients is not currently recommended. Significant drug interactions exist and drug–drug interactions affecting this enzyme should be avoided if possible.

Raloxifene is another SERM and is used for the treatment of osteoporosis in postmenopausal women and is the chemopreventative agent of choice for the prevention of breast cancer in high-risk women. When compared head to head with tamoxifen for breast cancer prevention, it was demonstrated to have equal efficacy with less toxicity. Raloxifene was not studied in premenopausal women; therefore, tamoxifen is still the preventative agent of choice in these women. Hot flashes, arthralgias, and peripheral edema occur frequently with raloxifene, but thrombosis and endometrial cancer is less common than with tamoxifen.

Fulvestrant is used as second-line treatment in hormone receptor–positive metastatic breast cancer, postmenopausal women with disease progression following antiestrogen therapy. Fulvestrant is given as a monthly intramuscular injection, which might be a deterrent to some patients.

ADMINISTRATION ISSUES

Extravasation

One issue of chemotherapy safety is extravasation. Antineoplastic agents that cause severe tissue damage when they escape from the vasculature are called vesicants. The tissue damage may be severe, with tissue sloughing and loss of mobility, depending on the area of extravasation. Patients need to be educated to notify the nurse immediately if there is any pain on administration. If extravasation of a vesicant occurs, the injection should be stopped and any fluid aspirated out of the injection site. The prevention, risk factors, signs and symptoms, causative agents, and treatment will be discussed thoroughly in Chapter 99.

Hypersensitivity Reactions

Hypersensitivity reactions of cancer treatments are problematic because of cross-reactivity between agents and the desire to continue active therapies against the cancer.[38] For documented immediate hypersensitivity reactions to a particular agent, further administration of the agent may be achieved through extensive premedication with H_1 and H_2 antihistamines and corticosteroids and through use of desensitization protocols which include escalating doses of the offending agent given at doses of one-hundredth, one-tenth, and the balance of the dose (so the total dose administered is equivalent to the normally prescribed dose) administered over a much longer period of time. These treatments must be given in an environment where resuscitation is readily available in case of medical emergency.

Patient Encounter 1, Part 3

The patient has progressed following therapy with mFOLFOX6 and subsequently received 6 cycles of FOLFIRI before progressing a second time. She now will be receiving a new prescription for regorafenib 160 mg orally, once daily.

What education and training should be provided to the patient to ensure their understanding of safe handling procedures as well as thorough knowledge of proper administration?

How should the patient be instructed to take this medication, in regards to meals or the time of day?

Secondary Malignancies

Chemotherapy and radiation therapy treatments may cause cancers later in life; these are referred to as secondary cancers. The most common type of secondary cancer is myelodysplastic syndrome, or AML. The antineoplastic agents most commonly associated with secondary malignancies are alkylating agents, etoposide, teniposide, topoisomerase inhibitors, and anthracyclines. Although the risk for secondary cancers is extremely low, it must outweigh the risk of survival produced by treatment of the primary malignancy. Because secondary malignancies may not occur for several years after treatment, patients with relatively short-term survival owing to the primary malignancy should consider the more immediate benefits of chemotherapy. Radiation therapy rarely may cause solid tumors as secondary cancers decades after treatment. The most common example of radiation therapy–induced secondary malignancy is breast cancer, which rarely occurs after mantle field radiation therapy for Hodgkin disease.

CHEMOTHERAPY SAFETY

One of the first Institute of Medicine (IOM) reports, the health arm of the National Academy of Sciences, starts out with a patient who died from an overdose of chemotherapy; the patient did not have an immediately life-threatening cancer, so her death was hastened by a medication error. Chemotherapy agents may cause harm to patients, health professionals, and the environment if not handled correctly.

KEY CONCEPT Because of the risk of severe toxicities associated with many of the chemotherapy agents, safety precautions must be in place to prevent chemotherapy errors or accidental chemotherapy exposures of health professionals or patients. The American Society of Clinical Oncology, Hematology/Oncology Pharmacy Association, Oncology Nursing Society, and the American Society of Health-System Pharmacists have information to assist in the safe handling of chemotherapy agents.[18,39-41] National, state, and local regulations regarding the safe disposal of chemotherapy agents and the equipment used to administer them need to be followed to protect the environment.

LO 4

KEY CONCEPT Each organization should have chemotherapy safety checks built into the prescribing, preparation, and administration of chemotherapy.[16,39] Dosing based on patient-specific information should be included on every order for chemotherapy, whether it is oral or parenteral. Many chemotherapy regimens are referred to by acronyms (eg, AC, which is doxorubicin cyclophosphamide); these should not be allowed as the only reference to drugs in the prescribing of chemotherapy. Also, abbreviations for the names of chemotherapy agents should be avoided because one abbreviation may stand for two different drug entities. For drugs such as doxorubicin and liposomal doxorubicin, the names should be written out fully, and in this case, the addition of the brand name may help to prevent a mistake.

The measured height and weight, along with the body surface area (BSA), if applicable, should be readily available, along with the dosage in milligrams per meter squared or kilogram, so that the dosage may be checked. If a chemotherapy regimen is a continuous infusion of 800 mg/m^2/day for 4 days, an added safety feature would be to include the total dosage of 3200 mg in order to prevent any ambiguity. In cases where the clinician wants to decrease the dosage based on a laboratory value or side effect, it is recommended that the clinician include that information with the order so that everyone understands what the correct dosage is for that patient. Chemotherapy dosages should be checked for route and dose to determine that the dosages prescribed are correct according to the regimen and do not exceed dosing guidelines. Appropriate laboratory values should be checked to verify that dosages are correct for any organ dysfunction present, drug interactions should be scrutinized closely (Tables 88–8 and 88–9), and if applicable the patient has the appropriate indication (eg, presence of EGFR mutation for use of erlotinib).[42] Health professionals administering chemotherapy should check the dosage calculation for the patient's weight or BSA along with the five Rs of administering medication (ie, right patient, right medication, right dose, and right route, at the right time). If there is any question about the safe dosage or safe administration of a chemotherapy agent, the chemotherapy should not be administered until the question is resolved.

An area of controversy with chemotherapy dosing: What weight should be used for patients who are morbidly obese currently? Based on clinical practice guidelines published by the American Society of Clinical Oncology, it is recommended that clinicians routinely use an obese patient's actual body weight, instead of an ideal body weight or other measurement.[43]

Patient Encounter 2

A 28-year-old man is receiving high-dose methotrexate 12 grams/m^2/day as part of a multi-drug regimen for a newly diagnosed osteosarcoma. While receiving chemotherapy, his serum creatinine has risen from 0.8 mg/dL to 2.1 mg/dL (71–186 µmol/L) in the last 3 days.

What is the likely diagnosis?

What medication should always be included as part of this regimen?

What measures should be taken by patients while receiving high-dose methotrexate therapy?

ORAL CHEMOTHERAPY

KEY CONCEPT Over the past decade, self-administration of oral chemotherapy has increased because of the availability of oral, novel anticancer agents. Although oral chemotherapy has many advantages, such as convenience for the patient, potential increase in quality of life, and decreased treatment-associated costs, it also comes with an increased risk of medication errors, less monitoring of adverse effects and drug, dietary supplements, over-the-counter (OTC) medication, and/or food interactions and accidental exposure to other individuals. Health professionals have an important role in ensuring safe handling of oral anticancer agents, and should be properly trained and perform competently within guidelines for the storage, handling, and disposal of oral agents. The health professionals are also expected to provide proper training and education on safe handling and proper administration (see Table 88–10) for the patient and caregivers.[39,40,44]

LO 5

CANCER SURVIVORSHIP

KEY CONCEPT As early detection of cancers and effective therapies have improved over the last several years, the number of cancer survivors has increased. A cancer survivor by definition, according to the National Coalition for Cancer Survivorship, starts at the point of diagnosis. It is estimated that two out of every three people with cancer live at least 5 years after diagnosis. In 2005, the IOM released a report, "From Cancer Patient to Cancer Survivor: Lost in Transition," which emphasized that a lack of definitive guidance in

LO 6

Table 88–8

Empiric Dose Modifications in Patients with Renal Dysfunction

Agent	Organ Dysfunction	Dose Modification
Aldesleukin	Serum Creatinine > 1.5 mg/dL	Do not initiate
Bendamstine	CrCL < 40 mL/min	Do not use
Bleomycin	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 40–50 mL/min	70% of normal dose
	CrCl = 30–40 mL/min	60% of normal dose
	CrCl = 20–30 mL/min	55% of normal dose
	CrCl = 10–20 mL/min	45% of normal dose
	CrCl = 5–10 mL/min	40% of normal dose
Bosutinib (initial dosage adjustment)	CrCl > 50–80 mL/min	No dosage adjustments
	CrCl = 30–50	Initial: 400 mg once daily
	CrCl < 30 mL/min	Initial: 300 mg once daily
Brentuximab	CrCl ≥ 30 mL/min	Initial: no dosage adjustment
	CrCl < 30 mL/min	Avoid use
Cabazitaxel	CrCl > 30 mL/min	No dosage adjustment
	CrCl < 30 mL/min	Use caution; monitor closely
Capecitabine (initial dosage adjustment)	CrCl > 51 mL/min	Initial: no dosage adjustment
	CrCl = 30–50 mL/min	Initial: 75% of normal dose
	CrCl < 30 mL/min	Contraindicated
Carboplatin (initial dosage adjustment)	CrCl equal to 41–59 mL/min	Initiate at 250 mg/m^2 and adjust subsequent doses based on bone marrow toxicity
	CrCl = 16–40 mL/min	Initiate at 200 mg/m^2 and adjust subsequent doses based on bone marrow toxicity
	CrCl < 15 mL/min	No dosage adjustments provided in the manufacturer's labeling (has not been studied)
Carmustine	CrCl = 46–60 mL/min	80% of normal dose
	CrCl = 31–45 mL/min	75% of normal dose
	CrCl < 30 mL/min	Consider use of alternative drug
Cisplatin	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	50% of dose
Cladribine	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	60% of normal dose
Clofarabine (initial dosage adjustment)	CrCl > 60 mL/min	No dosage adjustment
	CrCl = 30–60 mL/min	50% of normal dose
	CrCl < 30 mL/min	No dosage adjustments provided in the manufacturer's labeling (has not been studied)
Crizotinib	CrCl = 30–89 mL/min	Do dosage adjustment
	CrCl < 30 mL/min	Decrease dose to 250 mg once daily
Cyclophosphamide	CrCl > 10	No dosage adjustment
	CrCl < 10	75% of normal dose
Cytarabine	CrCl = 46–60 mL/min	60% of normal dose
	CrCl = 31–45 mL/min	50% of dose
	CrCl < 30 mL/min	Consider use of alternative drug
Dacarbazine	CrCl = 46–60 mL/min	80% of normal dose
	CrCl = 31–45 mL/min	75% of normal dose
	CrCl < 30 mL/min	70% of normal dose
Daunorubicin	SCR > 3 mg/dL	50% of normal dose
Eribulin	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 15–49 mL/min	Reduce dose to eribulin mesylate 1.1 mg/m^2
Etoposide	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 15–50 mL/min	75% of dose
	CrCl < 15 mL/min	Data not available; consider further dose reductions
Fludarabine	CrCl > 80 mL/min	No dosage adjustment
	CrCl = 50–79 mL/min	Reduce dose to 20 mg/m^2
	CrCl = 30–49 mL/min	Reduce dose to 15 mg/m^2
	CrCl < 30 mL/min	Do not use
Gemcitabine	Mild-to-severe renal impairment	No dosage adjustment
Hydroxyurea	CrCl > 60 mL/min	No dosage adjustment
	CrCl < 60 mL/min	50% of normal dose, titrate to response/avoidance of toxicity
Idarubicin	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	50% of normal dose
Ifosfamide	CrCl > 10 mL/min	No dosage adjustment
	CrCl < 10 mL/min	75% of normal dose

(*Continued*)

Table 88–8

Empiric Dose Modifications in Patients with Renal Dysfunction (*Continued*)

Agent	Organ Dysfunction	Dose Modification
Ixazomib (initial dosage adjustment)	CrCl > 30 mL/min	No dosage adjustment
	CrCl < 30 mL/min	Reduce initial dose to 3 mg once weekly
Lenalidomide (initial dosage adjustment)	CrCl > 60 mL/min	No dosage adjustment
	CrCl = 30–60 mL/min	10 mg once daily (for multiple myeloma, may increase to 15 mg once daily after 2 cycles if nonresponsive but tolerating treatment)
	CrCl < 30 mL/min	15 mg every 48 hours
Lomustine	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	25%–50% of normal dose
Methotrexate[a]	CrCl = 10–50 mL/min	50% of normal dose
	CrCl < 10 mL/min	Do not use
Mercaptopurine	eGFR < 50 mL/min/1.73 m^2	Administer every 48 hours
Mitomycin	CrCl < 10 mL/min	75% of normal dose
Oxaliplatin	CrCl > 30 mL/min	No dosage adjustment
	CrCl < 30 mL/min	Reuce dose from 85 mg/m^2 to 65 mg/m^2
Pralatrexate	eGFR > 30 mL/min/1.73m^2	No dosage adjustment
	eGFR = 15–30 mL/min/1.73m^2	Reduce dose to 15 mg/m^2
Peginterferon alpha-2b	CrCl = 30–50 mL/min	Reduce dose by 25%
	CrCl = 10–29 mL/min	Reduce dose by 50%
Pemetrexed	CrCl > 45 mL/min	No dosage adjustment
	CrCl < 45 mL/min	Do not use
Pentostatin	CrCl = 46–60 mL/min	70% of normal dose
	CrCl = 31–45 mL/min	60% of normal dose
	CrCl < 30 mL/min	Consider use of alternative drug
Pomalidomide	CrCl > 45 mL/min	No dosage adjustment
	CrCl < 45 mL/min	Insufficient data to make determination
Streptozocin	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 10–50 mL/min	75% of normal dose
	CrCl < 10 mL/min	50% of normal dose
Topotecan (IV)	CrCl > 40 mL/min	No dosage adjustment
	CrCl = 20–39 mL/min	Reduce dose to 0.75 mg/m^2/dose
	CrCl < 20 mL/min	No dosage adjustments provided in manufacturer's labeling (insufficient data)
Topotecan (oral)	CrCl > 50 mL/min	No dosage adjustment
	CrCl = 30–49 mL/min	Reduce dose to 1.5/mg/m^2/day; may increase after 1st cycle by 0.4 mg/m^2/day if no severe hematologic or gastrointestinal toxicities occur
	CrCl < 30 mL/min	Reduce dose to 0.6 mg/m^2/day; may increase after 1st cycle by 0.4 mg/m^2/day if no severe hematologic or gastrointestinal toxicities occur
Vandetanib	CrCl > 50 mL/min	No dosage adjustment
	CrCl < 50 mL/min	Reduce initial dose to 200 mg once daily

[a]Monitor levels closely in all patients receiving high-dose therapy (eg, 150 mg/m^2 or greater).

this area and identified that increased efforts were needed to raising awareness. In addition to facing a risk of a cancer recurrence, secondary malignancy, and an increased risk of developing other health conditions, cancer survivors often face physical, emotional, financial, and social challenges as a result of the cancer diagnosis and treatment.[45] The American Cancer Society (ACS), Centers for Disease Control (CDC), American Society of Clinical Oncology (ASCO), and the National Comprehensive Cancer Network (NCCN) all have guidelines that describe strategies to meet the needs of these individuals who experience the long-term effects of cancer and its treatment.[46-49]

OUTCOME EVALUATION

Once a pathologic diagnosis of cancer is made, the patient may be evaluated by a radiation oncologist, a surgical oncologist, and a medical oncologist. Options for treatment are presented that may include surgery, radiation, pharmacologic therapy, or some combination of these modalities. The goals of treatment vary by the cancer and the stage of disease. For example, the patient who has metastatic kidney cancer could be presented with several options. They may have a possible cure with high-dose aldesleukin or receive palliative therapy with pazopanib or sunitinib, or the patient may decline any therapy because of fears of significant toxicity that would decrease quality of life. In this case, if the patient's performance status is poor, such as an ECOG performance status 3, then the patient would not be a candidate for aldesleukin therapy because of significant toxicity or even death from treatment. The patient with the poor performance status will receive palliative therapy to control symptoms of the disease to improve the quality of life at the end of life. For the patient with a poor performance status and extensive metastatic disease, no treatment of the cancer may be appropriate, and the patient may be enrolled in a hospice program or provided comfort care.

Table 88–9

Empiric Dose Modifications for Patients with Hepatic Dysfunction

Agent	Organ Dysfunction	Dose Modification
Abiraterone (initial dosage adjustment)	Child-Pugh Class A	No dosage adjustment
	Child-Pugh Class B	Decrease dose to 250 mg daily
	Child-Pugh Class C	Do not give
Asparaginase (dose modifications during treatment)	ALT/AST > 3–5 × ULN	Continue therapy
	ALT/AST > 5–20 × ULN	Delay next dose until transaminases < 3 × ULN
	ALT/AST > 20 × ULN	Discontinue therapy if it takes > 1 week for transaminases to return to < 3× ULN
	Direct bilirubin < 3 mg/dL	Continue therapy
	Direct bilirubin = 3.1–5 mg/dL	Hold asparaginase and resume when direct bilirubin < 2 mg/dL
	Direct bilirubin > 5 mg/dL	Discontinue
Axitinib	Child-Pugh Class A	No modification needed
	Child-Pugh Class B	Reduce starting dose by 50%
	Child-Pugh Class C	Has not been studied
Bendamustine	Mild impairment	Use with caution
	Bilirubin > 1.5 × ULN and/or AST/ALT 2.5 × ULN	Do not use
Bortezomib	Bilirubin > 1.5 × ULN	Reduce initial dose to 0.7 mg/m^2 in the first cycle
Cabazitaxel	Mild impairment	Reduce dose to 20 mg/m^2
	Moderate impairment	Reduce dose to 15 mg/m^2
	Severe impairment	Contraindicated
Cabozantinib	Mild or moderate impairment	40 mg daily (Cabometyx); 80 mg daily (Cometriq)
	Severe impairment	Do not use
Carfilzomib	Mild or moderate impairment	75% of normal dose
	Severe impairment	Has not been studied
Crizotinib (during treatment)	Grade 3/4 ALT/AST elevation (> 5 × ULN) or bilirubin ≥ 1.5× ULN	200 mg twice daily
	Recurrent grade 3/4 ALT/AST elevation	250 mg once daily
	Recurrent grade 3/4 ALT/AST elevation at 250 mg	Permanently discontinue
Daunorubicin	Serum bilirubin 1.2–3 mg/dL	75% of normal dose
	Serum bilirubin > 3 mg/dL	50% of normal dose
Docetaxel	Total bilirubin > ULN, or AST and/or ALT > 1.5 × ULN concomitant with alkaline phosphatase > 2.5 × ULN	Do not give
	AST/ALT > 2.5 but 5 × or less ULN and alkaline phosphate 2.5 × ULN or less	Decrease dose by 20%
	AST/ALT > 1.5 but 5 × ULN or less and alkaline phosphate > 2.5 but ≤ 5 × ULN	Decrease dose by 20%
	AST/ALT > 5 × ULN and/or alkaline phosphate > 5 × ULN	Discontinue use
Doxorubicin	Serum bilirubin 1.2–3 mg/dL	50% of normal dose
	Serum bilirubin 3.1–5 mg/dL	25% of normal dose
	Child-Pugh Class C or bilirubin > 5 mg/dL	Use is contraindicated
Epirubicin	Bilirubin 1.2–3 mg/dL or AST 2 to 4 × ULN	50% of normal dose
	Bilirubin > 3 mg/dL or AST > 4 × ULN	25% of normal dose
	Severe hepatic impairment	Do not use
Eribulin	Child-Pugh A	Reduce dose to 1.1 mg/m^2
	Child-Pugh Class B	Reduce dose to 0.7 mg/m^2
	Child-Pugh Class C	Do not use
Etoposide	Bilirubin 1.5–3 mg/dL or AST > 3 × ULN	50% of normal dose
Everolimus (for breast cancer)	Child-Pugh Class A	Reduce to 7.5 mg once daily
	Child-Pugh Class B	Reduce dose to 5 mg once daily
	Child-Pugh Class C	Reduce dose to 2.5 mg once daily
Fluorouracil	Bilirubin > 5 mg/dL	Do not use
Flutamide	Mild to moderate impairment	No dosing adjustments in manufacturer's labeling
	Severe impairment	Contraindicated
Idarubicin	Bilirubin 2.6–5 mg/dL	50% of normal dose
	Bilirubin > 5 mg/dL	Do not use
Imatinib	Mild-to-moderate impairment	No dosage adjustment
	Severe impairment	75% of normal dose
	During therapy, if elevations of bilirubin > 3 × ULN or transaminases > 5 × ULN	Withhold treatment until bilirubin < 1.5 × ULN and transaminases < 2.5 × ULN

(*Continued*)

Table 88–9

Empiric Dose Modifications for Patients with Hepatic Dysfunction (*Continued*)

Agent	Organ Dysfunction	Dose Modification
Irinotecan	Bilirubin > ULN but < 2 mg/dL	Consider reducing initial dose
	Bilirubin > 2 mg/dL	Do not use
Ixabepilone	AST&ALT ≤ 2.5 × ULN and bilirubin ≤ 1 × ULN	No dosage adjustments
	AST&ALT > 2.5 but ≤ 10 × ULN and bilirubin ≥ 1.5, but ≤3 × ULN	Reduce dose to 32 mg/m^2
	AST&ALT ≤ 10 × ULN and bilirubin > 1.5 but ≤ 3 × ULN	Reduce dose 20–32 mg/m^2
	AST or ALT > 10 × ULN or bilirubin > 3 × ULN	Do not use
Ixazomib	Mild impairment	No dosage adjustment
	Moderate impairment	Reduce initial dose to 3 mg once weekly
Lapatinib	Child-Pugh Classes A or B	No dosage adjustment
	Child-Pugh Class C	In combination with capecitabine—reduce dose from 1250 mg once daily to 750 mg once daily; In combination with letrozole—reduce dose from 1500 mg once daily to 1000 mg once daily
Paclitaxel	Hepatic impairment	Adjustments vary depending on diagnosis/regimen
Albumin-bound paclitaxel (Abraxane)	Hepatic impairment	Adjustments vary depending on diagnosis/regimen
Pralatrexate	AST or ALT > 5–20 × ULN or bilirubin > 3–10 × ULN	Omit dose; decrease to 20 mg/m^2 when recovery to grade 2 or better
	AST or ALT > 20 × ULN or bilirubin > 10 × ULN	Discontinue treatment
Pazopanib	Mild impairment	No dosage adjustment
	Moderate impairment	Consider alternative therapy or reduce to 200 mg once daily
	Severe impairment	Do not use
Pemetrexed	Grade 3 or 4 elevation during treatment	Reduce dose to 75% of previous dose (and cisplatin)
Pomalidomide	Mild or moderate impairment	Initial: 3 mg once daily
	Severe impairment	Initial: 2 mg once daily
	Impairment during treatment	Stop and evaluate; after liver enzymes return to baseline, may consider restarting at lower dose
Ponatinib	Mild-to-severe impairment	Initial: 30 mg once daily; monitor closely for toxicity
Ramucirumab	Mild-to-moderate impairment	No dosage adjustment
	Severe impairment	Has not been studied
Ribociclib	Mild impairment	No dosage adjustment
	Moderate-to-severe impairment	Reduce initial dose to 400 mg/day
Temsiroliumus	Mild impairment	Reduce dose to 15 mg once weekly
	Moderate-to-severe impairment	Contraindicated
Thiotepa	Hepatic impairment	No dosage adjustments in labeling; use with caution; thiotepa is extensively hepatically metabolized
Trabectedin	Mild impairment	No dosage adjustment
	Moderate impairment	Reduce dose from 1.5 mg/m^2 to 0.9 mg/m^2
	Severe impairment	Do not give
Vandetanib	Mild impairment	No dosage adjustments provided in manufacturer's labeling
	Moderate-to-severe impairment	Do not use
Vinblastine	Serum bilirubin 1.5–3 mg/dL or transaminases 2–3 × ULN	50% of normal dose
	Serum bilirubin > 3 × ULN	Do not use
Vincristine	Serum bilirubin 1.5–3 mg/dL or transaminases 2–3 × ULN or alkaline phosphatase increased	50% of normal dose
	Serum bilirubin > 3 mg/dL	Do not use
Vinorelbine	Serum bilirubin > 2.1–2 mg/dL	50% of normal dose
	Serum bilirubin > 3 mg/dL	25% of normal dose
Vorinostat	Mild-to-moderate impairment	300 mg once daily
	Severe impairment	Not studied

Mild preexisting impairment: Bilirubin > 1 to 1.5 × ULN or AST > ULN

Moderate preexisting impairment: Bilirubin > 1.5 but 3 × ULN or less, or AST or ALT 2.5 to 10 × ULN

Severe preexisting impairment: Bilirubin > 3 × ULN

AST, aspartate transaminase; ALT, alanine transaminase; ULN, upper limit of normal.

Table 88–10

Oral Chemotherapy Administration with Respect to Food

	With Food	Empty Stomach	With or Without Food
Abiraterone		X	
Afatinib		X	
Alectinib	X		
Altretamine	X (and at bedtime)		
Anastrozole			X
Axitinib			X
Bexarotene	X		
Bicalutamide			X
Brigatinib			X
Bosutinib	X		
Cabozantinib		X	
Capecitabine	X		
Ceritinib		X	
Crizotinib			X
Cobimetinib			X
Dabrafenib		X	
Dasatinib			X
Enzalutamide			X
Erlotinib		X	
Estramustine		X	
Etoposide		X	
Everolimus			X
Exemestane	X

LO 7

Patient Care Process

Collect Information:

- Patient characteristics (eg, age, race, sex, patient preferences)
- Patient history (lifestyle factors—alcohol use, tobacco use, diet, physical activity)
- Patient medical and family history (eg, ECOG performance status, concurrent disease states)
- Clinical presentation signs and symptoms (eg, changes in bowel habits, unusual bleeding, weight loss, recurrent fevers)
- Current medications (prescription, over-the-counter, and complimentary alternative, medical marijuana)
- Objective data
  - BP, heart rate (HR), height, weight, and BSA
  - Labs (eg, serum electrolytes, renal function, liver chemistries, complete blood count, coagulation studies, tumor markers)
  - Other diagnostic test (eg, left ventricular ejection fraction)
  - Physical examination data (eg, hepatomegaly, lymphadenopathy)
  - Cancer staging
  - Colorectal tumor genomics (eg, *BRAF, HER-2, PIK3CA, RAS*)

Assess the Information:

- Risk factors for treatment-related toxicities (eg, *UGT1A1*28* genotype, poor nutritional intake, uncontrolled blood pressure or hypertension, baseline peripheral neuropathy)
- Type of and response to prior treatments
- Potential for disease responsiveness to specific agents and risk factors for disease recurrence
- Patient characteristics (eg, social history/situation, insurance coverage, pregnancy) and treatment preferences
- Potential problems with medication adherence to oral treatment regimens
- Goals of treatment
- Need for drug dose reductions or supportive care

Develop a Care Plan*:

- Drug therapy regimen including specific anticancer agent(s), dose (calculated correctly for patient characteristics and disease), route, frequency, and duration
- Supportive care plan (eg, antiemetics, prophylactic antidiarrheals, infusion reaction prophylaxis)
- Monitoring parameters including efficacy (eg, cancer imaging studies-chest, abdominal, and/or pelvic CT scans and radiographs, tumor markers if previously elevated, symptoms of recurrence), safety (medication-specific adverse effects, including major-dose limiting toxicities), and timeframe
- Patient education (eg, goals of treatment; expected and potential serious toxicities; drug therapy; monitoring and management plan; safe administration, storage, and disposal)

Implement the Care Plan*:

- Provide patient education regarding all elements of treatment plan
- Survivorship care plan (eg, primary prevention of other diseases, such as infections, and other cancers, support systems for maintaining healthy lifestyle choices and BMI)

Follow-up: Monitor and Evaluate:

- Determine disease response to treatment and occurrence of disease progression or recurrence (cancer imaging studies, tumor markers previously elevated)
- Presence of adverse effects
- Patient adherence to treatment plan using multiple sources of information (eg, patient self-report, medication administration records or refill data)
- Patient's satisfaction with treatment, including understanding of adherence

*Collaborate with patient, caregivers, and other health professionals

Abbreviations Introduced in This Chapter

2-FLAA	2-Fluoro-Ara-AMP
5-FU	Fluorouracil
6-MP	6-Mercaptopurine
ACS	American Cancer Society
ADC	Antibody–drug conjugate
ADCC	Antibody-dependent cellular cytotoxicity
AI	Aromatase inhibitor
ALK	Anaplastic lymphoma kinase gene
ALL	Acute lymphocytic leukemia
AML	Acute myeloid leukemia
APL	Acute promyelocytic leukemia
AR	Androgen receptor
ASCO	American Society of Clinical Oncology
ATRA	All-trans-retinoic acid
AUC	Area under the curve
BSA	Body surface area
BCNU	Carmustine
c-MET	Mesenchymal epithelial transition growth factor
CAR	Chimeric antigen receptor
CBC	Complete blood count
CCNU	Lomustine
CDC	Centers for Disease Control
CDK	Cyclin-dependent kinase
CLL	Chronic lymphocytic leukemia
CML	Chronic myeloid leukemia
CRS	Cytokine-release syndrome
CTC	Common toxicity criteria
CTLA-4	Cytotoxic T-lymphocytic-associated antigen 4
CNS	Central nervous system
DPD	Dihydropyrimidine dehydrogenase
DVT	Deep vein thrombosis
ECOG	Eastern Cooperative Oncology Group
EGFR	Epidermal growth factor receptor
ER	Estrogen receptor
FDA	Food and Drug Administration
FdUMP	Fluorodeoxyuridine monophosphate
G-CSF	Granulocyte–colony stimulating factor
GI	Gastrointestinal
GIST	Gastrointestinal stromal tumor

GnRH	Gonadotropin-releasing hormone receptor
HDAC	Histone deacetylase
HER-2	Human epidermal receptor-2
HFS	Hand–foot syndrome
HFSR	Hand–foot–skin reaction
HPV	Human papillomavirus
HSCT	Hematopoietic stem cell transplantation
IL	Interleukin
INR	International normalization ratio
IV	Intravenous
LDH	Lactate dehydrogenase
LHRH	Luteinizing hormone–releasing hormone
MEK	Mitogen-activated extracellular kinases
MM	Multiple myeloma
MMAE	Monomethyl auristatin E
mTOR	Mammalian target of rapamycin
NCI	National Cancer Institute
NCCN	National Comprehensive Cancer Network
NSCLC	Non–small cell lung cancer
PARP	Poly ADP ribose polymerase
PCR	Polymerase chain reaction
PD	Programmed cell death
PD-L	Programmed cell death ligand
PET	Position emission tomography
PI3-K	Phosphoinositide 3-kinase
PSA	Prostate-specific antigen
RECIST	Response evaluation criteria in solid tumors
SERDs	Selective estrogen-receptor downregulators
SERMs	Selective estrogen receptor modulator
SPF	Sun protection factor
TKI	Tyrosine kinase inhibitor
TNM	Tumor, nodes, metastases
TPMT	Thiopurine *S*-methyltransferase
TS	Thymidylate synthase
UGT1A1* 28	Uridine diphosphate–glucuronosyltransferease 1A1 enzyme
VEGF	Vascular endothelial growth factor
VEGFR	Vascular endothelial growth factor receptor

89 Breast Cancer

Gerald Higa

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the relative importance of various risk factors.
2. Summarize the surrogate definitions of the intrinsic breast cancer subtypes.
3. Articulate some of the reasons for improved patient survival.
4. Recognize signs and symptoms related to early and late stages of the disease.
5. Distinguish between good and poor prognostic factors.
6. Determine treatment goals for early stage, locally advanced, and metastatic breast cancers.
7. State the rationale for inclusion of adjuvant and neoadjuvant therapies.
8. Describe the relevance of hormone and HER2 receptors.
9. Discuss the benefits and risks associated with various endocrine therapies.

INTRODUCTION

The increasing prevalence of breast cancer in the United States is related to a number of factors including the predominance of early stage disease at diagnosis, better understanding of tumor biology, improvements in treatment outcomes and survival, and the relatively high incidence rate. Of note, the incidence, which has been increasing slightly over the past decade, appears to be driven almost exclusively by new breast cancer diagnoses in nonwhite women.

EPIDEMIOLOGY AND ETIOLOGY

Breast cancer is the most common type of cancer and second only to lung cancer as a cause of cancer death in American women. In 2018, female breast cancer will account for 99% of the projected 269,000 new cases; the median age at diagnosis will be 62 years; and approximately 41,000 deaths will occur as a result of the disease.[1] KEY CONCEPT Even though the disease occurs more frequently in white women than any other ethnic group, the mortality rate is highest among African Americans.

Tumor size of most breast cancers at diagnosis is usually small (< 2 cm); and localized disease predominates in all racial and ethnic groups. However, African American women have proportionally more cases of advanced disease compared with white women. It has been suggested that reduced access to proper medical care, including breast cancer screening programs, as well as certain biological factors, contribute to late diagnoses.

KEY CONCEPT The etiology of breast cancer remains largely unknown though a number of factors have been associated with risk of developing the disease. Evidence also strongly suggests that breast cancer biology involves complex interactions between sex hormones, genetic factors, environment, and lifestyle. The intrinsic and extrinsic components associated with the disease are discussed further.

Intrinsic Components

LO 1

Aside from gender, the variable most strongly associated with breast cancer is age as disease risk and incidence increase with age. One of the most frequently quoted breast cancer statistic is the probability that one in eight females will develop the disease sometime in their lifetime. The probability of developing breast cancer is presented in Table 89–1. Although the probability of developing breast cancer increases with age, more than half the risk occurs after 60 years of age.

Both personal and family history can influence the risk of developing breast cancer. For example, a woman who has a history of breast cancer has a fivefold increase in risk of developing contralateral breast cancer. Prior histories of cancers involving the uterus and ovary also appear to be associated with an increased risk of developing breast cancer. Even though family history is often linked to disease risk, the percentage of familial breast cancer is quite low (ie, ~10%). KEY CONCEPT The following key elements describe family history-associated breast cancer risk factors:

- A first-degree relative (ie, mother or sister) with breast cancer is associated with a threefold increase in risk.
- Multiple first-degree relatives with breast cancer have not been consistently shown to be associated with risk greater than one first-degree relative.
- A second-degree relative with breast cancer is associated with a 1.5-fold increase in risk.
- Family members on the paternal side contribute to risk similar to the maternal side.

KEY CONCEPT The endocrine factor most closely linked to breast cancer is estrogen. The risk is partially related to duration of exposure to the hormone. Hence, early menarche and late menopause and long-term use of hormone replacement therapy appear to contribute to breast cancer risk.

Table 89–1

Risk of Developing Breast Cancer: SEER Areas, Women, All Races, 2008–2010

Age Interval (years)	Probability (%) of Developing Invasive Breast Cancer during the Interval
30–40	0.44 or 1 in 227
40–50	1.45 or 1 in 69
50–60	2.31 or 1 in 43
60–70	3.49 or 1 in 29
From birth to death	12.15 or 1 in 8

SEER, Surveillance, Epidemiology, and End Results.

Probability derived by Devcan 6.7.0, June 2013 (http://surveillance.cancer.gov/devcan).

Use of postmenopausal estrogen replacement therapy in women with a history of breast cancer is generally contraindicated. However, most experts believe that the safety and benefits of low-dose oral contraceptives currently outweigh the potential risks and that changes in the prescribing practice for the use of oral contraceptives are not warranted. Moreover, oral contraceptives are known to reduce the risk of ovarian cancer by about 40% and the risk of endometrial cancer by about 60%.

KEY CONCEPT In the early 1990s, the *BRCA1* gene (locus 17q21) was found to be mutated in a large percentage of hereditary breast and ovarian cancer patients. A second breast cancer gene, called *BRCA2*, has been mapped to chromosome 13. Since *BRCA1* and *BRCA2* are tumor suppressor genes, mutations or functional aberrations result in loss of key inhibitory activities of both proteins.[2] Compelling evidence of their critical importance is the observation that women who carry germline mutations of *BRCA1* have a lifetime risk of breast cancer between 65% and 90%; the 10-year risk of contralateral breast cancer is approximately 25% to 30%. Carriers of the mutated *BRCA2* have a similar risk for breast cancer. Jewish people of Eastern European descent (Ashkenazi Jews) have an unusually high (2.5%) carrier rate of germline mutations in *BRCA1* and *BRCA2* compared with the rest of the US population. Women with strong family histories of breast cancer are candidates for *BRCA1* and *BRCA2* mutation analysis. If being considered, genetic testing should be done under the guidance of a professional genetic counselor.

Extrinsic Components

KEY CONCEPT Experimental and epidemiologic evidence suggest an association between breast cancer and a diet high in calories, fat, and cooked meats. Obesity in postmenopausal women and distribution of body fat around the abdominal region also appear to increase the risk of breast cancer. This risk factor may be related, in part, to peripheral conversion of androgens to estrogens in adipose tissue. Interestingly, obesity may not impact only disease risk. A recent review provides compelling evidence of the negative effect of obesity on distant disease-free and overall survival (OS) in patients with hormone receptor-positive breast cancer.[3] Data also indicate a modest ingestion-dependent relationship between alcohol and breast cancer. While exercise may have a modest protective effect against breast cancer, neither cigarette smoking nor breast augmentation appears to modify disease risk.

Radiation is also associated with an increased risk of breast cancer. Although the risk appears to be dosage-related, the minimal level of exposure is not well defined. Even therapeutic doses of radiation administered in the management of patients with postpartum mastitis, tuberculosis, and certain hematologic malignancies appear to increase breast cancer risk. Notably, this risk appears to be confined to exposure before 40 years of age, which suggests that a "window of initiation" for breast cancer occurs relatively early. On the other hand, it is currently accepted that exposure to radiation doses utilized in diagnostic x-rays, including screening mammography, are not of clinical concern.

Despite what is known to confer risk, the majority of women diagnosed with breast cancer do not have any of the identified factors (other than age). A number of calculators now accessible through the Internet can be used to estimate breast cancer risk. The National Cancer Institute (NCI) has an online version of the Breast Cancer Risk Assessment Tool that is considered to be the most authoritative and accurate (www.cancer.gov/bcrisk-tool). This tool was designed for health professionals to project individualized 5-year and lifetime risks for invasive breast cancer.

Prevention of Breast Cancer

Even though breast cancer is not the most lethal malignancy, disease-related morbidity and mortality is still significant. Current efforts at breast cancer prevention are directed toward the identification and removal of risk factors. Unfortunately, a number of risk factors such as age and family or personal history of the disease or other gynecologic malignancies cannot be modified.

The idea that prevention can be achieved pharmacologically was based on clinical trials of tamoxifen, a selective estrogen receptor modulator (SERM), as **adjuvant therapy** for women with early, **hormone receptor-positive** breast cancer. These trials demonstrated a reduction of contralateral breast cancer events as well as a survival advantage of patients who received the drug for 2 to 5 years following mastectomy.[4] Several clinical trials conducted with SERMs provided proof of principle that breast cancer risk reduction in premenopausal and postmenopausal women could be achieved through **chemoprevention**.[5-7]

In addition, a class of drugs known as the aromatase inhibitors (AIs) has been shown to be more effective than tamoxifen as adjuvant breast cancer therapy in postmenopausal women. This finding suggested that the AIs could also reduce the risk of developing breast cancer in postmenopausal women at high risk for the disease. Indeed, results of the International Breast Cancer Intervention (IBIS)-II study demonstrated a 53% reduction in new breast cancer diagnoses with anastrozole compared to placebo.[8] Similar findings have been reported with the steroidal AI, exemestane, in high-risk postmenopausal women.[9]

These positive findings are accompanied by a number of caveats. First, chemoprevention effectively reduces the incidence without a significant proven benefit in OS. Second, risk reduction appears to apply to hormone-dependent breast cancer only. Third, results of these trials confirmed the increased incidence of thromboembolic and gynecological adverse events of tamoxifen but not raloxifene. Fourth, if approved, the AIs would be indicated only for postmenopausal women at increased risk

for breast cancer. And though better tolerated, musculoskeletal events, asthenia, and hot flushes associated with the AIs can still be troublesome. Fifth, the role of tamoxifen in *BRCA* mutation carriers is still not clear. In women with familial breast cancer bilateral mastectomy remains the best, though not absolute, risk-reducing option.

It should be noted that even though the side-effect profiles of the SERMs and AIs can have a negative impact on patient acceptance, pharmacologic prevention could spare some patients from surgery-, radiation- and even chemotherapy-related morbidity.

PATHOPHYSIOLOGY

Histologic evaluation of breast lesions serves to establish a pathologic diagnosis and confirm the presence or absence of other factors believed to influence prognosis. These prognostic factors are discussed later.

Invasive Breast Cancer

LO 2

Breast cancers typically arise in the ducts or lobules of the mammary gland. When tumor cells infiltrate surrounding breast tissue, a diagnosis of invasive breast cancer is made. Even though the vast majority of tumors are adenocarcinomas, this does not imply that breast cancer is one disease. Furthermore, breast cancers can be grouped in one of four intrinsic subtypes with luminal B having two distinct surrogate features. When defined by clinical and pathological features, this classification system can be used for prognositication as well as a guide to treatment (Table 89–2).

Noninvasive Carcinoma

Notably, the annual breast cancer incidence does not include thousands of cases of carcinomas in situ (ie, noninfiltrating tumors confined to the ducts and lobules). Ductal carcinoma in situ (DCIS) accounts for approximately 85% of all in-situ breast cancers; while lobular neoplasia may not be a true cancer, but rather a high-risk premalignant lesion that does not always require active treatment. The overwhelming majority of cases can be cured by surgery followed by whole breast radiation therapy (after breast conserving surgery). Although there is no proven role for the application of cytotoxic chemotherapy, patients with hormone receptor-positive tumors may benefit from the addition of tamoxifen.

Patient Encounter Part 1

At a gathering of women who have been friends since high school, a 42-year-old mother of two expresses that one of her greatest fears is being diagnosed with breast cancer. Although there is no family history of breast or gynecological cancers, she mentions a younger aged friend who died recently of the disease. She has never had a mammogram but has been thinking about participating in a breast cancer screening program.

Discuss integral aspects women should know about screening mammography.

CLINICAL PRESENTATION AND DIAGNOSIS

Early Detection

LO 3

The rationale for early detection of breast cancer is based on the clear relationship between early stage disease at diagnosis and greater probability of long-term survival. KEY CONCEPT Screening guidelines for early detection of breast cancer have been put forward by the American Cancer Society, the United States Preventive Services Task Force (USPSTF), and the NCI (Table 89–3). All include recommendations for women at average risk, with some general statements regarding screening for high-risk women as well. Regular screening mammography contributes to reduction in breast cancer mortality by 20% to 40%, primarily in postmenopausal women.

Controversy regarding the use of screening mammography is largely confined to women 50 years of age or younger. After many years of debate, three organizations recommended

Table 89–2

Intrinsic Subtypes of Breast Cancer

Subtype	Tumor Features	Treatment Approach	Added Comment
Luminal A	All of the following: ER and PR positive, HER2 negative, and low Ki-67 (proliferation marker)	Endocrine only (usually)	May add chemotherapy if 4 or more positive nodes, grade 3 disease, Oncotype Dx recurrence score higher than 25, or age younger than 35 years
Luminal B (HER2 negative)	ER positive, HER2 negative, and either high Ki-67 or PR negative	Endocrine and chemotherapy (for most cases)	Add chemotherapy for most patients
Luminal B (HER2 positive)	ER positive, HER2 positive	Endocrine, HER2 targeted therapy and chemotherapy	
HER2 amplified or overexpressed (nonluminal)	HER2 positive	HER2 targeted and chemotherapy	Opinion differs regarding use of anti-HER2 therapy in tumors
Basal (triple-negative)	ER, PR, and HER2 negative	Chemotherapy only	Less than 5 mm

Table 89–3

Guidelines for Early Detection of Breast Cancer in Average Risk Individuals

	American Cancer Society	U.S. Preventive Services Task Force	National Cancer Institute
BSE	Age ≥ 20 years: Risk-to-benefit discussion	NR	NR
CBE	Age 20–30 years: Every 3 years Age ≥ 40 years: Every year	Not specifically addressed	All ages: Every year
Mammography	Annual beginning at age 40 years	Age 50–74 years: Every 2 years (with or without CBE)	Age 40–49: Every 1–2 years Age ≥ 50 years: Every 1–2 years

BSE, breast self-examination; CBE, clinical breast examination; NR, not recommended.

mammograms in this age group of women every 1 to 2 years except for the USPSTF, which modified its recommendation in 2009.[10]

Diagnosis

LO 4

Unless following up on abnormalities found during screening, the initial workup for women presenting with signs or symptoms (see Clinical Presentation and Diagnosis) suggestive of breast cancer should include a careful history, physical examination of the breast, three-dimensional mammography, and possibly other imaging techniques such as magnetic resonance imaging. Most (80%–85%) breast cancers are visualized on a mammogram as a mass, a cluster of calcifications, or a combination of both. A breast biopsy is indicated for a mammographic abnormality that suggests malignancy or for a palpable mass on physical examination.

Clinical Staging

Stage is determined by the tumor, node, metastasis (TNM) system (see Table 88–2 for an example). Aside from carcinoma in situ (stage 0) multiple combinations of T and N are possible within a given stage. Simplistically, stage I disease is represented by tumors less than 2 cm in diameter and usually no lymph node involvement. KEY CONCEPT Stages I and II are referred to as early breast cancer, which carries a relatively good prognosis and correlates with the highest probability of cure (Table 89–4). Stage III, or locally advanced breast cancer, has poorer disease features, including larger tumor size, positive node involvement, and tumor invasion of the chest wall. Stage IV disease is characterized by the presence of metastases to organs or tissue distant from the primary tumor and is often referred to as advanced or metastatic breast cancer.

Patient Encounter Part 2

Since the woman in the previous encounter is deemed to be of "average risk," she decided against having a screening mammogram. Five years later, she discovers a lump in her left breast. She is seen by her primary care physician who confirms the abnormality and one palpable ipsilateral axillary lymph node. Bilateral mammography indicated showed a large mass in the upper outer quadrant of the left breast. A core needle biopsy of the suspicious breast lesion and regional node was performed; pathology confirmed a diagnosis of invasive breast cancer with node involvement. The patient continues to have menses.

Briefly discuss the relevance of several intrinsic tumor characteristics that should be assessed and integrated in the final pathological report.

Clinical Presentation and Diagnosis of Breast Cancer

Common early signs and symptoms include:

Painless lump (90% of cases) that is:

- Solitary
- Unilateral
- Solid
- Irregular
- Nontender

Stabbing or aching pain (10% of cases) as the first symptom

Uncommon early signs and symptoms include:

Nipple discharge (3% of women and 20% of men), retraction, or dimpling

- Eczema appearance of the nipple (Paget carcinoma)
- Prominent skin edema, redness, warmth, and induration of the underlying tissue (inflammatory carcinoma)

Signs and symptoms associated with metastasis—tissues most commonly involved with are lymph nodes (other than axillary or internal mammary), skin, bone, liver, lungs, and brain. The following symptoms of metastases will be present in about 10% of patients when they first seek treatment:

- Bone pain
- Difficulty breathing
- Jaundice
- Mental status changes

Table 89–4

Estimated Stage at Presentation and 5-Year Disease-Free Survival (DFS): Breast Cancer

	Percentage of Total Cases	5-Year DFS[a] (%)
Stage I	40	70–90
Stage II	40	50–70
Stage III	15	20–30
Stage IV	5	0–10[b]

[a]With current conventional local and systemic therapy.

[b]Patients in stage IV are rarely free of disease; however, 10% to 20% of these patients may survive with minimal disease for 5 to 10 years.

LO 5

Prognostic Factors

Good prognostic factors include:

- Luminal A subtype (ER and PR highly positive, Ki67 low)
- Absence of tumor cells in regional nodes (node-negative)
- Tumors smaller than 2 cm
- Early stage (I and II)
- Well-differentiated tumor
- Normal tumor grade

Poor prognostic factors include:

- Age younger than 35 years
- High nuclear grade (correlates with tumor growth)
- Triple-negative disease (ie, absence of ER, PR, and HER2 receptors)
- Overexpression of HER2 alone

Patient Encounter Part 3

The pretreatment workup is summarized below.

Pathology: 47-year-old female with new diagnosis of infiltrating intraductal adenocarcinoma involving the left breast and regional node. Further tests on tumor samples indicated ER (8%), PR (negative), HER2 (negative), Ki-67 (72%), and grade (poorly differentiated). Intrinsic subtype (luminal B, HER2-negative).

Radiology: FDG-PET/CT indicated a 5.3 × 2.5 cm mass in the left breast which appeared to extend to the epidermis of the skin; one node in the left axilla was also involved with tumor. No other evidence of distant disease was visualized.

Laboratory: CBC, liver, and kidney function tests WNL, alkaline phosphatase and calcium are normal also.

Stage: IIIB (T_4, N_1, M_0)

List the most important prognostic factors in this patient with newly diagnosed breast cancer.

Assess the patient's level of risk for relapse.

EARLY BREAST CANCER TREATMENT

Desired Outcome

KEY CONCEPT Most patients presenting with invasive breast cancer today have small tumors with negative lymph nodes (stage I or II).

LO 6

The goal of therapy for early breast cancer is cure. While surgery alone may be able to cure approximately one-third to one-half of all patients with early stage breast cancer, certain tumor features warrant addition of systemic therapy.

Surgical procedures have changed significantly over the past 50 years. KEY CONCEPT Less aggressive surgical options for early invasive breast cancer include total mastectomy and breast conserving surgery (BCS) such as lumpectomy. The reason for favoring the latter is based on findings that BCS achieves similar survival outcomes as more extensive surgical procedures and is cosmetically superior.[11] Additionally, breast conservation aids in preserving the emotional and psychological well-being of the patient.[12] Only two contraindications to BSC considered absolute (or nearly absolute) include persistence of tumor on surgical margins and inability to perform postsurgery radiation, if indicated.

KEY CONCEPT Equally important is the issue related to complete axillary lymph node dissection (CALND). Because of the morbidity associated with the procedure, clinical trials were conducted to determine when biopsy of the sentinel lymph nodes was sufficient. Results of these studies indicated that CALND can be avoided in patients with microscopic disease in the sentinel nodes as well as in patients undergoing BCS with postsurgery radiation to the breast.[13,14]

Except for the elderly and patients with substantial comorbid medical conditions, radiation therapy is an integral adjunct to BCS. However, radiation therapy should also be considered in certain postmastectomy situations, especially in patients with more than three positive nodes or patients with positive sentinel nodes without CALND. What used to entail 4 to 6 weeks of external-beam radiation, newer clinical evidence supports the efficacy of a 3-week course of whole breast irradiation.[15] Complications associated with radiation therapy are usually minor and include erythema of the breast tissue and shrinkage of total breast mass beyond that predicted on the basis of surgical resection alone.

Systemic Adjuvant Therapy

LO 7

Breast cancer cells can spread by contiguity, lymphatic channels, and blood to distant sites. Tumor cells often metastasize early in cancer growth. Because these deposits cannot always be detected with current diagnostic techniques, they are referred to as occult metastases. Hence, administration of adjuvant therapy (at a time when the tumor burden is low) should theoretically increase the likelihood of cure and minimize the emergence of drug-resistant tumor cell clones. KEY CONCEPT Most published results confirm that chemotherapy (in selected patients), hormonal therapy (in patients with hormone receptor–positive disease), anti-HER2 therapy (in tumors with amplification or overexpression of HER2) or appropriate combinations of these therapies improved **disease-free survival** (DFS) and/or overall survival (OS) in patients with early-stage breast cancer (see Table 89–2).

Among the most influential groups that provide treatment recommendations is the St. Gallen International Expert Consensus panel (see Table 89–2).[16]

▶ *Adjuvant Chemotherapy*

Cytotoxic drugs that are used most frequently as adjuvant therapy of breast cancer include cyclophosphamide, anthracyclines, and taxanes. The most common chemotherapy regimens used in the adjuvant setting are listed in Table 89–5. Dose-limiting and other significant toxicities have been previously described in Chapter 88 and are discussed succinctly in Table 89–6.

Chemotherapy is usually initiated within 2 to 6 weeks from the surgical procedure; the efficacy of systemic therapy decreases if delayed more than 12 weeks following surgery. Currently, four to eight cycles of chemotherapy is administered for 12 to 24 weeks. Dose reduction for standard chemotherapy regimens should be avoided in the absence of severe acute toxicity because of the negative impact on DFS and OS.[17] Even though most patients are able to maintain a reasonable level of functional, emotional, and social well-being during treatment, there are some compelling data indicating that some toxicities can have chronic debilitating effects on quality of life.[18] Various forms of supportive therapy including antiemetics and hematopoietic growth factors for patients receiving systemic adjuvant chemotherapy are discussed in Chapter 99.

As mentioned previously, the usefulness of the intrinsic subtype classification also extends to treatment strategies (see Table 89–2). Since the magnitude of the 10-year survival benefit with cytotoxic agents appears to be only 5% and 10% for patients with negative and positive nodes, respectively, there has been intensive research to identify patients with low-risk disease that could avoid treatment with chemotherapy. One validated

Table 89–5

Common Chemotherapy Regimens for Breast Cancer

Adjuvant Chemotherapy Regimens

AC
Doxorubicin 60 mg/m^2 IV, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 21 days for four cycles[a]

FAC[w]
Fluorouracil 500 mg/m^2 IV, days 1 and 4
Doxorubicin 50 mg/m^2 IV continuous infusion over 72 hours[w]
Cyclophosphamide 500 mg/m^2 IV, day 1
Repeat cycles every 21–28 days for six cycles[c]

CAF
Cyclophosphamide 600 mg/m^2 IV, day 1
Doxorubicin 60 mg/m^2 IV bolus, day 1
Fluorouracil 600 mg/m^2 IV, day 1
Repeat cycles every 21–28 days for six cycles[e]

FEC
Fluorouracil 500 mg/m^2 IV, day 1
Epirubicin 100 mg/m^2 IV bolus, day 1
Cyclophosphamide 500 mg/m^2 IV, day 1
Repeat cycle every 21 days for six cycles[g]

CEF
Cyclophosphamide 75 mg/m^2 orally on days 1–14
Epirubicin 60 mg/m^2 IV, days 1 and 8
Fluorouracil 500 mg/m^2 IV, days 1 and 8
Repeat cycles every 28 days for six cycles (requires prophylactic antibiotics or growth factor support)[i,j]

AC → Paclitaxel (CALGB 9344)
Doxorubicin 60 mg/m^2 IV, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 21 days for four cycles
Paclitaxel 175 mg/m^2 on day 1

TAC (BCIRG 001)
Docetaxel 75 mg/m^2 IV, day 1
Doxorubicin 50 mg/m^2 IV bolus, day 1
Cyclophosphamide 500 mg/m^2 IV, day 1
(doxorubicin should be given first)
Repeat cycles every 21–28 days for six cycles[d]

Paclitaxel → FAC[f,w]
Paclitaxel 80 mg/m^2/week IV over 1 hour every week for 12 weeks
Followed by:
Fluorouracil 500 mg/m^2 IV, days 1 and 4
Doxorubicin 50 mg/m^2 IV continuous infusion over 72 hours
Cyclophosphamide 500 mg/m^2 IV, day 1
Repeat cycles every 21–28 days for four cycles[n]

CMF
Cyclophosphamide 100 mg/m^2/day orally, days 1–14
Methotrexate 40 mg/m^2 IV, days 1 and 8
Fluorouracil 600 mg/m^2 IV, days 1 and 8
Repeat cycles every 28 days for six cycles[h,j]
or
Cyclophosphamide 600 mg/m^2 IV, day 1
Methotrexate 40 mg/m^2 IV, day 1
Fluorouracil 600 mg/m^2 IV, days 1 and 8
Repeat cycles every 28 days for six cycles[i]

Dose-Dense AC → Paclitaxel
Doxorubicin 60 mg/m^2 IV bolus, day 1
Cyclophosphamide 600 mg/m^2 IV, day 1
Repeat cycles every 14 days for four cycles (must be given with growth factor support)
Followed by:
Paclitaxel 175 mg/m^2 IV over 3 hours[i]
Repeat cycles every 14 days for four cycles (must be given with growth factor support)[k]
Followed by:
Paclitaxel 175 mg/m^2 IV over 3 hours
Repeat cycles every 21 days for four cycles[b]

Metastatic Single-Agent Chemotherapy

Paclitaxel
Paclitaxel 175 mg/m^2 IV over 3 hours
Repeat cycles every 21 days
or
Paclitaxel 80 mg/m^2/week IV over 1 hour
Repeat dose every 7 days[m]

Vinorelbine
Vinorelbine 30 mg/m^2 IV, days 1 and 8
Repeat cycles every 21 days
or
Vinorelbine 25–30 mg/m^2/week IV
Repeat cycles every 7 days (adjust dose based on absolute neutrophilcount; see product information)[n]

(*Continued*)

Table 89–5

Common Chemotherapy Regimens for Breast Cancer (*Continued*)

Metastatic Single-Agent Chemotherapy

Docetaxel
Docetaxel 60–100 mg/m^2 IV over 1 hour
Repeat cycles every 21 days[o]
or
Docetaxel 30–35 mg/m^2/week IV over 30 minutes
Repeat dose every 7 days[p]

Capecitabine
Capecitabine 2000–2500 mg/m^2/day orally, divided twice daily for 14 days
Repeat cycles every 21 days[q,r]

Docetaxel + Capecitabine
Docetaxel 75 mg/m^2 IV over 1 hour, day 1
Capecitabine 2000–2500 mg/m^2/day orally divided twice daily for 14 days
Repeat cycles every 21 days[t]

Epirubicin + Docetaxel[x]
Epirubicin 70–90 mg/m^2 IV bolus
Followed by:
Docetaxel 70–90 mg/m^2 IV over 1 hour
Repeat cycles every 21 days[v]

Gemcitabine
Gemcitabine 600–1000 mg/m^2/week IV, days 1, 8, and 15
Repeat cycles every 28 days (may need to hold day-15 dose based on blood counts)[q]

Liposomal Doxorubicin
Liposomal doxorubicin 30–50 mg/m^2 IV over 90 minutes
Repeat cycles every 21–28 days[s]

Doxorubicin + Docetaxel[x]
Doxorubicin 50 mg/m^2 IV bolus, day 1
Followed by:
Docetaxel 75 mg/m^2 IV over 1 hour, day 1
Repeat cycles every 21 days[u]

[w]FAC may also be given with bolus doxorubicin administration, and the fluorouracil dose is then given on days 1 and 8. [x]Paclitaxel may also be given concurrently with doxorubicin or epirubicin as a combination regimen. Pharmacokinetic interactions make these regimens more difficult to give.

IV, intravenous.

Table 89–6

Toxicities of Common Chemotherapies Used for Breast Cancer

Class	Drug	Dose-Limiting Toxicities	Other Toxicities
Anthracyclines	Doxorubicin, epirubicin	Myelosuppression, cardiomyopathy	Alopecia, nausea, vomiting, stomatitis, ulceration, and necrosis with extravasation, red-colored urine, radiation-recall effect
	Liposomal doxorubicin	Myelosuppression, palmar-plantar erythrodysesthesia (hand–foot syndrome)	Alopecia, infusion reactions, stomatitis, fatigue, nausea, vomiting
Taxanes	Paclitaxel	Neutropenia, peripheral neuropathy, hypersensitivity reactions	Alopecia, fluid retention, myalgia, skin reactions, ulceration, and necrosis with extravasation, bradycardia, stomatitis
	Docetaxel	Myelosuppression, severe fluid retention	Alopecia, fatigue, stomatitis, nausea, vomiting, diarrhea, peripheral neuropathy, nail disorder, skin reactions, hypersensitivity reactions
Antimetabolites	Capecitabine	Diarrhea, palmar-plantar erythrodysesthesia (hand–foot syndrome)	Myelosuppression, stomatitis, nausea, vomiting
	Gemcitabine	Myelosuppression (especially thrombocytopenia)	Flulike syndrome (fever, chills, myalgias, and arthralgias), nausea
	Fluorouracil	Myelosuppression	Stomatitis, diarrhea, alopecia
	Methotrexate	Myelosuppression, stomatitis	Diarrhea, nausea, vomiting, renal toxicity
Vinca alkaloids	Vinorelbine	Neutropenia	Fatigue, nausea, vomiting, ulceration, and necrosis with extravasation
Alkylating agents	Cyclophosphamide	Myelosuppression, hemorrhagic cystitis	Alopecia, stomatitis, amenorrhea, aspermia

multigene assay known as Oncotype DX is used to identify patients with luminal A disease, regardless of nodal involvement, who can be treated with endocrine therapy alone.[19]

KEY CONCEPT It is generally agreed that patients with high-risk luminal B, HER2 overexpression, and basal-like subtypes should receive chemotherapy (both anthracycline and taxane) with hormonal and/or HER2-targeted therapy if indicated.[20]

▶ Adjuvant Anti-HER2 Therapy

LO 8

HER-2 amplification or overexpression is found in approximately 15% to 20% of all breast cancers. Because of its aggressive features, trastuzumab (plus chemotherapy) is usually indicated in this subset of patients, especially for tumors greater than or equal to 0.5 cm in size. Most experts also agree that HER2-positive tumors appear to derive greater benefit from anthracycline or taxane-based chemotherapy regimens.[21] When used with these agents, trastuzumab is given either following completion of the anthracycline or concurrently with the taxane. Current evidence indicates that the duration of trastuzumab therapy is 12 months.[22]

▶ Adjuvant Endocrine Therapy

LO 8

Hormone receptors are used clinically as indicators of prognosis, predictors of response to endocrine therapies, and more recently, discriminators of luminal breast cancer subtypes. Estrogen receptors (ERs) and progesterone receptors (PRs) are cytoplasmic proteins that bind to nuclear DNA and function as transcription factors. Approximately 50% to 70% of patients with primary and metastatic breast cancer have hormone receptor–positive tumors. However, receptor-positivity refers to tumors expressing both ER and PR, as well as either ER or PR alone. Furthermore, "ER-positive" tumors traditionally refer to ERα only. Although it is beyond the scope of this discussion, it is noteworthy to mention the existence, and accumulating data regarding the roles of ERβ and the ERα/ERβ heterodimer in breast cancer.[23,24] Tumors with high expression of both ER and PR (ie, luminal A subtype) are associated with favorable prognoses, superior responses to endocrine therapy, and longer disease-free intervals following initial treatment. Hormone receptor–positive tumors are more common in postmenopausal patients. Many experts also believe that postmenopausal breast cancer is biologically less aggressive than breast cancers diagnosed before menopause.

KEY CONCEPT Hormonal therapies that have been studied in the treatment of early breast cancer include tamoxifen, ovarian suppression (surgical and pharmacologic), and the AIs.

LO 9

Tamoxifen has been used in the adjuvant setting for nearly five decades. Analysis of long-term data indicates the drug's antagonist (anti-estrogen) effect was associated with a significant reduction in disease recurrence and mortality. This observation, coupled with evidence of the drug's beneficial agonist activity on the lipid profile and bone density, supported tamoxifen's role as standard endocrine therapy. However, the agonist properties are also associated with detrimental effects on endometrial tissue and blood coagulation.

In premenopausal women, tamoxifen alone is considered the adjuvant hormonal therapy of choice. Some disagreement exists among experts regarding the utility of combining ovarian function suppression with tamoxifen particularly in chemotherapy-treated patients and women 40 years of age or younger. Tamoxifen is initiated shortly after surgery or as soon as pathology results are known. However, when chemotherapy is also indicated, tamoxifen is given after all cytotoxic agents have been completed. The rationale for sequential therapy is supported by some data which show a small negative effect on DFS when tamoxifen and chemotherapy are given concurrently.

Treatment with adjuvant tamoxifen (20 mg/day) has historically been for 5 years. Several years ago, results of a well-designed clinical trial indicated a survival benefit associated with extending therapy to a total of 10 years.[25] These data were further supported by additional evidence in women who were premenopausal when starting, and postmenopausal at completion, of tamoxifen therapy. In this subset of women, continuation of endocrine therapy with an AI was associated with a significant improvement in breast cancer-related events, including new primaries in the contralateral breast, disease recurrence, and DFS.[26] Collectively, these findings led to new recommendations regarding the use of endocrine therapies in the adjuvant setting.

However, recent data from three clinical trials of extended endocrine therapy were presented at the 2016 San Antonio Breast Cancer Symposium. None of the trials achieved statistical significance with regards to DFS, the primary endpoint. Even before these results were publicized, drug-related toxicities and medication compliance associated with the longer duration of therapy made extended therapy less appealing. And while there may be a subset of patients likely to benefit, recommendations regarding extended adjuvant endocrine therapy is now even more uncertain.

Finally, the issue regarding the role of pharmacogenomics in tailoring tamoxifen therapy is both persuasive and controversial.[27,28] As such, routine screening for germline variants of *CYP2D6* has not been endorsed. Nonetheless, drugs that do inhibit the enzyme should be avoided if possible.

In postmenopausal women, the use of adjuvant AIs has been studied in three different ways: (a) direct comparison with tamoxifen, (b) after 5 years of tamoxifen therapy, and (c) sequentially after 2 to 3 years of tamoxifen.[29] Based on the positive results of several studies, expert panels strongly recommend AIs for postmenopausal women with hormone-dependent breast cancer.[30] Five years of adjuvant AI therapy is considered standard. Extended therapy can be considered after careful assessment of potential clinical benefits and risks related to tumor features and patient characteristics including comorbidities, bone mineral density, and prior tolerance with AI therapy. While these recommendations can be applied to most postmenopausal patients, tamoxifen can still be used first line or as an alternative in those who do not tolerate AI therapy.

LO 9

AI therapy is associated with several adverse effects, including hypercholesterolemia, atherosclerotic cardiovascular disease, and skeletal-related events. The three available AIs are anastrozole, letrozole, and exemestane (Table 89–7).

Patient Encounter Part 4

After extensive discussion of the multidisciplinary committee which included patient preferences, the choice of treatment strategy was systemic neoadjuvant followed by breast conserving surgery (BCS), if possible, followed by radiation and adjuvant therapy.

Discuss the rationale for each component of the planned treatment with a focus on selection of specific agents in the neoadjuvant and adjuvant settings for this patient.

Table 89–7

Endocrine Therapies Used for Metastatic Breast Cancer

Class	Drug	Dose	Side Effects
Aromatase inhibitors			
Nonsteroidal	Anastrozole	1 mg/day PO	Hot flashes, arthralgias, myalgias, headaches, diarrhea, mild nausea
	Letrozole	2.5 mg/day PO	
Steroidal	Exemestane	25 mg/day PO	
Antiestrogens			
SERMs	Tamoxifen	20 mg/day PO	Hot flashes, vaginal discharge, mild nausea, thromboembolism, endometrial cancer
	Toremifene	60 mg/day PO	
SERDs	Fulvestrant	250 mg IM every 28 days	Hot flashes, injection site reactions, possibly thromboembolism
LHRH analogues	Goserelin	3.6 mg SC every 28 days	Hot flashes, amenorrhea, menopausal symptoms, injection site reactions
	Leuprolide	7.5 mg IM every 28 days	
	Triptorelin	3.75 mg IM every 28 days	
Progestins	Megestrol acetate	40 mg PO 4 for a day	Weight gain, hot flashes, vaginal bleeding, edema, thromboembolism
	Medroxyprogesterone	400–1000 mg IM every week	
Androgens	Fluoxymesterone	10 mg PO twice a day	Deepening voice, alopecia, hirsutism, facial or truncal acne, fluid retention, menstrual irregularities, cholestatic jaundice

IM, intramuscular; LHRH, luteinizing hormone-releasing hormone; PO, oral; SC, subcutaneous; SERD, selective estrogen-receptor downregulator; SERM, selective estrogen receptor modulator.

LOCALLY ADVANCED BREAST CANCER TREATMENT

Desired Outcome

Locally advanced breast cancer is defined by tumors 5 cm or greater and a high likelihood of nodal involvement in the absence of demonstrable distant metastasis. A wide variety of clinical scenarios can be seen within this group of patients, including tumors that have been neglected for a period of time and inflammatory breast cancer, which is a unique clinical entity. Inflammatory breast cancer has, at times, been misdiagnosed as cellulitis.

LO 6 LO 7 Treatment of stage III breast cancer consists of all modalities used in the management of early breast cancer. The goal of therapy is to achieve optimal systemic control of the disease. However, despite treatment, systemic relapse and death are common even when local-regional control is accomplished. One major difference related to the systemic therapies is the use of chemotherapy plus anti-HER2 therapy (if indicated) before surgery; notably, endocrine therapy can be used in postmenopausal women but is not routinely recommended in premenopausal women. This approach, referred to as **neoadjuvant therapy**, can render initially inoperable tumors resectable, even with the possibility of BCS. It is also conceivable that earlier administration of systemic therapy could have therapeutic benefits beyond surgical resection. Other potential advantages include in vivo assessment of treatment response, and an opportunity to evaluate the biologic effects of the systemic therapy. However, nodal status will not be assessable.

Pharmacologic Therapy

For patients with inoperable breast cancer, including inflammatory breast cancer, one of the treatment objectives is to obtain tumor resectability. The guidelines for selection and duration of systemic neoadjuvant chemotherapy are similar to the adjuvant setting. Available data support the use of anthracycline-containing regimens, incorporation of the taxanes, and approaches to improve dose-density or dose-intensity. Neoadjuvant endocrine therapy may be an option for patients who have unresectable, strongly hormone receptor–positive tumors, low risk factors, or are unable to receive chemotherapy because of comorbid medical conditions. Endocrine therapy is usually given for 4 to 8 months or until maximal response. In September 2013, the FDA approved the use of pertuzumab in combination with trastuzumab and docetaxel as neoadjuvant therapy in patients with HER2-overexpressing tumors. Regardless of therapeutic approach, about two-thirds of the tumors can be downsized.

In terms of local therapy, the extent of surgery will be determined by tumor response to neoadjuvant therapy, patient wishes, and cosmetic results likely to be achieved. To minimize local recurrence, adjuvant radiation therapy should be administered to all patients with locally advanced breast cancer who undergo mastectomy or BCS. Inoperable tumors that are unresponsive to systemic chemotherapy may require radiation for local management; however, these tumors may be ineligible for subsequent surgical resection. This situation is associated with a very poor prognosis though not commonly seen.

METASTATIC BREAST CANCER (STAGE IV) TREATMENT

Desired Outcome

LO 6 The goals of therapy for patients with metastatic breast cancer (MBC) are maintaining or improving quality of life and prolonging survival. In order to achieve these goals, an important consideration is selecting therapy with good activity and tolerability.

General Approach to Treatment

LO 8 The choice of therapy for metastatic disease is based on receptor expression status (ie, hormone and HER2) and distant disease sites. In many instances, age and comorbid medical problems will also be considered. While the choice between endocrine and cytotoxic chemotherapy is usually the hormone receptor status of the tumor, sites of metastatic disease may also influence treatment

decisions. For example, in patients with ER-positive breast cancer with soft tissue or bone-only metastasis (without impending fracture), endocrine therapy alone is usually warranted. Hormonal therapy can even be considered in patients with asymptomatic visceral involvement. In contrast, chemotherapy is usually the initial treatment option for hormone-dependent breast cancer in patients who present with significant life-threatening metastasis to liver and/or lung. When used, chemotherapy is continued to maximal response. Patients with tumors responding initially to endocrine therapies are often treated with chemotherapy when endocrine options are exhausted or symptomatic visceral metastasis develops. Approximately 75% to 80% of tumors positive for both ER and PR respond to initial hormonal therapy; responses decrease to 50% to 60% for ER-positive/PR-negative tumors. The best predictor of response to second- and, possibly, third-line endocrine therapies is extent and duration of the initial response. Nevertheless, tumor responses are frequently lower and durations shorter with subsequent hormonal therapies.

KEY CONCEPT Endocrine therapy is not indicated for tumors that do not express at least one of the hormone receptors. Patients with receptor negative tumors should be treated with cytotoxic chemotherapy. Objective responses are achieved in 50% to 60% of patients who have not received prior chemotherapy though less than 20% of the responses are complete. The duration of response to first-line therapy is usually less than 12 months. Although very uncommon, responses to initial treatment can be extremely durable with patients living years without evidence of disease. The response rate to second- and third-line chemotherapy varies from 20% to 40%. Combinations of different hormonal therapies or chemotherapy plus endocrine therapy are not used in the metastatic disease setting because of increased toxicity without added benefit.

Even though incurable, it has been recently reported that the 5-year relative survival rate has increased twofold from 18% to 36%. Notably, the improvement was observed primarily in women 50 years of age or younger.

Pharmacologic Systemic Therapy

▶ *Endocrine Therapy*

The operative mode of all endocrine therapies is estrogen deprivation. The pharmacologic goals of treatment include decreasing the levels of circulating estrogen and/or preventing the effects of estrogen on tumor tissue through hormone receptor blockade or downregulating receptor expression. Achievement of these goals is independent of menopausal status. Many available endocrine therapies can accomplish these goals. Combined endocrine therapies also have been studied in an attempt to improve patient outcomes with negative results. As such, patients usually receive sequential endocrine therapies before chemotherapy is considered.

Until the turn of the century, evidence did not support the superiority of one type of endocrine therapy with regards to response or survival. Because of the similarity in efficacy, selection of endocrine therapy was based primarily on their toxicity prolife (see Table 89–7), which favored tamoxifen. The only exception to this choice of therapy occurred in patients who received adjuvant tamoxifen and subsequently developed metastatic disease within 1 year of drug cessation.

Over the past 15 years, accumulating evidence related to the AIs has changed the way postmenopausal women with hormone-dependent metastatic breast cancers are treated. After menopause, estrogens continue to be produced by extragonadal conversion of androstenedione and testosterone to estrone and estradiol. This biosynthetic process, which is dependent on aromatase, occurs in peripheral tissue, including muscle, adipose, and even the breast itself. Therefore, AIs effectively reduce the level of circulating estrogens, as well as estrogens in the target gland. Their toxicity profile has been described in Chapter 88 and Table 89–7. Anastrozole and letrozole are nonsteroidal compounds that competitively inhibit aromatase. Exemestane is a steroidal compound that binds irreversibly (by forming a covalent bond) to aromatase. However, this biochemical distinction does not translate into clinical superiority with exemestane.

LO 9 In general, the AIs are preferred as first-line therapy for ER-positive advanced breast cancer in postmenopausal women.[32] Results of large clinical trials comparing these agents against tamoxifen demonstrated improved **progression-free survival** (PFS) or time to progression (TTP) among patients receiving AI therapy. A consistent observation in these trials was a lower incidence of thromboembolic events, endometrial cancer, and vaginal bleeding in patients treated with an AI. Of note also, several small studies indicated that regardless of which subclass of AI used initially, approximately 50% of the patients will have further antitumor benefit after switching to the other subclass suggesting that cross-resistance is incomplete. Therefore, postmenopausal patients may receive two AIs as first- and second-line therapies.

While the therapeutic benefit of the AIs is well accepted, targeted interruption of the cell cycle has recently been investigated to further enhance the treatment of patients with hormone-dependent MBC. The biological rationale is based on the critical role cyclin dependent kinases (CDKs) have in regulating phase transition for cell cycle progression, cell division, and cell proliferation. Of the four stimulatory kinases, CDKs 4 and 6 are believed to be key promoters of tumor proliferation and hence, attractive targets for inhibition. Published results of two clinical trials demonstrating a significant reduction in risk of disease progression or death with combined CDK 4/6 inhibitor plus AI compared to the AI alone led to the recent approval of palbociclib with letrozole and ribociclib with any AI as first-line therapy for ER-positive MBC in postmenopausal women.[33,34] In February 2018, a third CDK 4/6 inhibitor, abemaciclib (in combination with an AI), was approved as front-line therapy.

The AIs are only used in postmenopausal women. Even though ovarian estrogen production relies on the same enzymatic pathway discussed earlier, premenopausal or perimenopausal women with functioning ovaries are not appropriate candidates for these therapies. The reason is physiologic as evidence indicates that negative endocrine feedback will overcome aromatase inhibition. Clinical data also suggested that the strategy of combining an AI with ovarian suppression (ie, oophorectomy or LHRH agonists) can also be considered in treatment-naïve premenopausal women.

The use of AIs in men with advanced breast cancer should be avoided. Available data suggest the use of these agents in men increases circulating levels of testosterone, which may negate the therapeutic effects of the drug.

Antiestrogens bind to ERs, preventing receptor-mediated gene transcription, and therefore are used to block the effect of estrogen on the end target. This class of agents is subdivided into two pharmacologic categories: SERMs and SERDs. SERMs like tamoxifen have tissue-specific estrogenic and antiestrogenic activities. The effort to minimize or eliminate the adverse estrogenic effects led to the development of SERDs, which are pure ER antagonists. The distinguishing feature of SERDs is their ability to degrade the ligand–ER complex.

Fulvestrant is the only SERD approved for clinical use in the United States. As a single agent, the drug is indicated as

second-line therapy for postmenopausal patients. However, results from clinical trials of fulvestrant plus an AI as first-line therapy demonstrated significant TTP and OS rates compared to the AI alone.[35,36] These data support offering the combination as initial treatment for patient with MBC who have not been exposed to adjuvant endocrine therapy. The side effect profile of fulvestrant is generally similar to the antiestrogens except for dermal reactions at the injection site. Even though fulvestrant is a good option for patients who are unable to take an oral medication, some patients may be averse to the drug because it must be given intramuscularly. There is no biological reason why fulvestrant should not produce similar outcomes in premenopausal women; however, safety or efficacy data are lacking.

Resistance to frontline therapy inevitably occurs in patients with advanced disease. One of the mechanisms of endocrine resistance appears to involve the mammalian target of rapamycin (mTOR), a protein downstream of the phosphatidylinositol 3-kinase (PI3K)/Akt signaling pathway. Results of a clinical trial involving everolimus, an mTOR inhibitor, plus exemestane showed a 2.5-fold prolongation of PFS in postmenopausal women previously treated with nonsteroidal AIs.[37] As such, the combination is currently recommended as a second-line option for postmenopausal women (and premenopausal women with continued ovarian suppression).

Tamoxifen can be used in both premenopausal and postmenopausal women with ER positive, metastatic breast cancer. Toxicities associated with tamoxifen have been previously described. The only additional acute adverse effect, which occurs in about 5% of the patients with bone metastasis is tumor flare or hypercalcemia following initiation of tamoxifen. Generally, this acute reaction is not an indication to discontinue treatment. Conversely, this finding appears to correlate with subsequent response to endocrine therapy.

Ovarian ablation or suppression in premenopausal women can be effectively achieved surgically or pharmacologically. Even though the efficacy of oophorectomy and tamoxifen are comparatively similar, secondary response rates to oophorectomy after tamoxifen treatment were somewhat higher than response rates achieved with tamoxifen after oophorectomy (33% vs 11%). Interpretation of these findings suggests that tamoxifen does not completely antagonize available estrogen, particularly in premenopausal women. Ovarian ablation is still commonly performed in parts of the United States and is considered by some to be the endocrine therapy of choice in premenopausal women with advanced disease. The mortality rate with surgical oophorectomy is less than 3% in appropriately selected patients.

Castration can also be achieved pharmacologically with LHRH agonists. An initial surge in luteinizing hormone (LH) and estrogen production during the first few weeks of treatment can cause a tumor flare reaction similar to tamoxifen. With continued therapy, this strategy induces remission in about one-third of unselected patients. LHRH agonists purportedly downregulates LHRH receptors in the pituitary resulting in decreased LH release and castrate levels of estrogens. Of the three agents available in the United States (ie, leuprolide, goserelin, and triptorelin), only goserelin is approved for the treatment of metastatic breast cancer.

Although tamoxifen alone can be considered, guidelines developed by the American Society of Clinical Oncology recommend offering ovarian ablation or suppression in combination with antiestrogen or AI in premenopausal women with endocrine-responsive MBC.

In randomized trials, progestins such as megestrol acetate and medroxyprogesterone acetate have been shown to induce noninferior response rates when compared with tamoxifen. Megestrol acetate is used more frequently in the United States. Despite their efficacy, these agents have been relegated to third-line status. The most common side effects are listed in Table 89–7. One side effect, weight gain, occurs in 20% to 50% of patients. Patients experiencing weight gain may have fluid retention, but fluid retention is not responsible for all of the weight gain. In cachectic cancer patients, the weight gain may be desirable, but this is not uniformly true of all patients with metastatic breast cancer.

High-dose estrogens and androgens are rarely used because they are more toxic than other hormonal agents and in some cases less effective. About one-third of patients placed on high-dose estrogens will discontinue the use of these agents because of side effects, the most important of which are thromboembolic events, vomiting, and fluid retention.

▶ *Cytotoxic Chemotherapy*

Except for brain and spine (with impending cord compression), chemotherapy is given as initial treatment of metastasis in patients with hormone receptor–negative tumors. The median time to an objective response is 2 to 3 months, but this period depends largely on the site of measurable disease. For example, time to response is 3 to 6 weeks for disease localized primarily to skin and lymph nodes; 6 to 9 weeks lung lesions; 15 weeks for liver metastasis; and 18 weeks for bone involvement. Once chemotherapy has been initiated, it is usually continued until maximal response, disease progression, or intolerable toxicity.

Unlike endocrine therapy, no clinical characteristic or established test has been shown to predict benefit from chemotherapy. However, a number of factors are associated with likelihood of tumor response, including good performance status, limited number (one or two) of disease sites, treatment-naïve status, and previous response to chemotherapy with a long disease-free interval. Tumors that progress while being treated may respond to different agents. Importantly, tumors that do not respond to endocrine therapy are as likely to respond to chemotherapy as tumors treated with cytotoxic agents first. If not used initially, chemotherapy is eventually required in most patients with advanced breast cancer.

KEY CONCEPT The most active classes of chemotherapy in metastatic breast cancer are the anthracyclines and the taxanes with response rates as high as 50% to 60% in patients who have not received prior chemotherapy for metastatic disease. Although many chemotherapeutic agents have demonstrated activity in the treatment of breast cancer, the most frequently used agents include all of the agents used in the adjuvant setting. A brief discussion of the taxanes, capecitabine, and gemcitabine extends upon what is described in Chapter 88.

Taxanes

In the metastatic setting the most effective weekly dose of paclitaxel appears to be 80 mg/m^2/week with no breaks in therapy. With this approach, the toxicity profile of paclitaxel changes with less myelosuppression and delayed onset of peripheral neuropathy but slightly more fluid retention and skin and nail changes.

A dose-response relationship has been demonstrated with docetaxel. Dosages in the range of 60 mg/m^2 to 75 mg/m^2 can be given every 21 days in asymptomatic patients who may not require a rapid clinical response. While less neuropathy, myalgia, and hypersensitivity reactions are observed with docetaxel (compared to paclitaxel), the incidence of febrile neutropenia, fluid retention, and skin reactions is higher. A weekly schedule

of docetaxel, 35 mg/m^2, six doses of an 8-week cycle is also very active and more tolerable than the 3-weekly schedule.

Antimetabolites

Capecitabine has activity against tumors progressing on anthracycline- and taxane-containing regimens. Moreover, the drug exhibits somewhat selective activity against cancer cells. This belief is supported by the presence of higher tumor cell levels of thymidine phosphorylase, the enzyme which catalyzes the final step in the conversion of capecitabine to 5-FU. In previously treated patients, capecitabine produced response rates of about 25%, which was impressive compared with other tested chemotherapy agents.

Gemcitabine is another agent that is used frequently in patients with advanced breast cancer. This nucleotide analogue has a unique mechanism of action and a favorable toxicity profile. As a single agent, response rates of nearly 40% have been achieved in the first-line setting. However, overall response rates (ORRs) up to 90% have been obtained when gemcitabine was combined with doxorubicin or epirubicin and paclitaxel as first-line treatment. Response rates to gemcitabine monotherapy in the second- and third-line settings are approximately 18% to 26%. When combined with one other agent such as a taxane, vinorelbine, cisplatin, or an anthracycline, results of clinical studies consistently demonstrated higher efficacy than either single agent. In patients who have been exposed to an anthracycline and a taxane, gemcitabine appears to provide similar benefit to capecitabine.

General Comments

Combination chemotherapy regimens are usually associated with higher response rates than are single-agent therapies, but the higher response rates do not necessarily translate into significant differences in OS. The use of sequential single-agent therapy versus combination chemotherapy regimens has been debated widely for metastatic breast cancer.[39] In the metastatic setting, the least toxic approach is preferred when efficacy is considered equal. In clinical practice, patients who require a rapid response to chemotherapy (ie, those with symptomatic bulky metastases) often receive combination therapy despite the added toxicity. This decision is complex and should be made on an individual patient basis.

Because many patients receive adjuvant chemotherapy, regimens chosen for first-line use in the metastatic setting often are different from those used in the adjuvant setting with the following caveat. If the patient's cancer recurs more than 1 year after the end of adjuvant chemotherapy, the same agents may have activity in the metastatic disease setting.

▶ *Targeted Biologic Therapy*

LO 8

Anti-HER2 therapies are only indicated for breast cancers that meet the definition for HER2-positivity (ie, 3+ by immunohistochemistry and/or *HER2* gene/chromosome 17 ratio ≥ 2 by fluorescence in-situ hybridization).

Trastuzumab targets a specific extracellular epitope of HER2. Single-agent treatment with trastuzumab produces responses in approximately 15% to 20% of patients; the clinical benefit rate, which includes CRs, PRs, and stable disease, is nearly 40%. Trastuzumab has additive and perhaps synergistic activity with chemotherapeutic agents.[40] Because cardiac toxicity is associated with the antibody, trastuzumab is given after all cycles of the anthracyclines have been completed. A nonanthracycline-containing regimen with excellent activity is the combination of docetaxel and carboplatin with concurrent trastuzumab.[41] Other chemotherapy agents that are being evaluated in combination with trastuzumab include vinorelbine, gemcitabine, capecitabine, and cisplatin or carboplatin.

The most notable adverse effects associated with trastuzumab include cardiac dysfunction, first dose infusion-related chills, hypersensitivity, and pulmonary reactions.

Close monitoring for clinical signs and symptoms of heart failure is imperative. Although cardiac toxicity is usually reversible, some patients may require pharmacologic therapy. In addition, it is important to educate patients regarding the latter two adverse effects because they may occur up to 24 hours after the infusion and can be fatal if not treated promptly.

Lapatinib inhibits the intracellular kinase domains of HER2 and HER1 (epidermal growth factor receptor). A pivotal phase 3 clinical trial was conducted to assess the efficacy and safety of lapatinib plus capecitabine versus capecitabine alone in patients with disease progressing on trastuzumab. The trial was terminated early when a preplanned interim analysis indicated a significant reduction in risk of disease progression that favored the combination arm. Of note, the incidence of brain metastasis was significantly lower in the lapatinib-treated group.[42]

The side-effect profile of lapatinib is described in Chapter 88. A few side effects such as diarrhea, dyspepsia, and rash occurred more frequently when lapatinib was combined with capecitabine. Importantly, the lapatinib doublet was not associated with cardiac events resulting in subject withdrawal.

In May 2014, the American Society of Clinical Oncology (ASCO) issued two clinical practice guidelines related to lapatinib for the treatment of advanced, HER2-positive breast cancer. First, depending on hormone receptor status, third-line therapy may include hormonal therapy or chemotherapy with trastuzumab and in some cases with lapatinib or the combination of trastuzumab and lapatinib; and second, in patients with brain metastases systemic therapies with lapatinib and capecitabine is one option that can be considered for patients with a poor prognosis for survival.

An additional HER2-targeted agent called pertuzumab received FDA approval in June 2012. Although both pertuzumab and trastuzumab are monoclonal antibodies that inhibit HER2-mediated signaling, a number of differences exist. First, each agent recognizes different extracellular epitopes, a finding that could have important therapeutic ramifications. Second, the unique binding site of pertuzumab induces structural changes that hinder receptor dimerization. Theoretically, by inhibiting HER2 signaling initiated by ligand-activated HER1 or HER3, pertuzumab could provide even greater inhibition of HER2 than trastuzumab. However, this does not appear to be the case. In fact, compared to trastuzumab, pertuzumab has exhibited less activity. Based on the results of a phase 3 clinical trial, pertuzumab is indicated for use as first-line therapy (in combination with trastuzumab and docetaxel) for HER2-positive metastatic breast cancer.[43] The most frequently reported adverse effect observed in clinical trials involving pertuzumab was diarrhea; cardiac toxicity was similar to, but does not appear to be increased when used concurrently with, trastuzumab.

One of the most significant limitations of cytotoxic chemotherapy is the lack of tumor specificity. Coupling target selectivity with the observation that trastuzumab's modest antitumor effect was substantially improved by the addition of

chemotherapy led to the idea that antibodies could be used to deliver chemotherapy rather specifically to tumor cells. However, the efficacy of antibody-chemotherapy (drug) conjugates (ADCs) has historically been limited by variable expression of the target antigen, defective tumor cell uptake mechanisms, and unreliable linkers used in the conjugation process.

A novel therapeutic compound known as trastuzumab-DM1 (T-DM1, trastuzumab emtansine) has been developed that appears to have resolved all of the above issues. Because HER2 is overexpressed in approximately 20% of breast cancers, trastuzumab was identified as a reasonable vehicle for drug delivery. In order to improve the therapeutic index of the attached chemotherapeutic agent, a maytansine derivative was synthesized. The resulting maytansinoid, emtansine, was configured to have an easily cleavable linker to trastuzumab. The resulting ADC has the potential not only of retaining the antitumor properties of the individual agents but also maintaining a tolerable side-effect profile.

The most significant results were reported in a phase 3 clinical trial which compared T-DM1 against the combination of lapatinib plus capecitabine as second-line therapy for patients with HER2-positive breast cancer progressing on trastuzumab and a taxane.[44] Primary end points were PFS, OS, and tolerability. Compared to the capecitabine/lapatinib arm, T-DM1 significantly reduced the risk of disease progression or death by 35%. Median OS at the second interim analysis crossed the prespecified efficacy stopping boundary. The most common grade ≥ 3 toxicity observed in patients receiving T-DM1 arm was thrombocytopenia. Platelet nadirs occurred 7 days after drug administration and recovered within a week. Other frequently occurring side effects included liver function test abnormalities, hypokalemia, fatigue, nausea, and headache. However, none of these adverse events were greater than grade 2. Cardiac toxicity requiring treatment discontinuation was not observed. The results of this study led to FDA approval in February 2013.

Several other clinical trials involving TDM-1 are being conducted. One that has been recently completed is the TH3RESA trial. Final results of this trial demonstrated that compared to physician's choice of treatment, significantly longer PFS and OS rates were associated with TDM-1 in women with previously treated HER2-positive MBC.[45]

▶ *Bisphosphonates*

For women whose breast cancer has metastasized to bone, bisphosphonates are recommended, in addition to chemotherapy or endocrine therapy, to reduce bone pain and fractures. Zoledronic acid, a potent bisphosphonate, is used most frequently. Although usually dosed every 4 weeks, a 12 weekly schedule has been reported to be noninferior.[46] Supplemental calcium and vitamin D are usually prescribed.

Patient Encounter Part 5

The planned dose-dense chemotherapy regimen was completed with only a week delay in the schedule due to neutropenic fever. Other than fatigue, which was minimized by exercise and yoga, she tolerated the entire neoadjuvant and radiation therapies without additional treatment-limiting toxicities. Not only was a pCR achieved, but also downsizing of the primary tumor which allowed BCS to be performed. She is currently in her first year of tamoxifen therapy.

Discuss aims of follow-up and long-term implications.

Local-Regional Control

▶ *Radiation Therapy*

Radiation is an important modality in the treatment of symptomatic metastatic disease. The most common indication for treatment with radiation therapy is painful bone metastases or other localized sites of disease refractory to systemic therapy. Approximately 90% of patients who are treated for painful bone metastases experience significant pain relief with radiation therapy. Additionally, radiation is an important modality in the palliative treatment of metastatic brain lesions and spinal cord lesions, which respond poorly to systemic therapy.

OUTCOME EVALUATION

Early breast cancer is resected completely with curative intent and adjuvant chemotherapy and/or hormonal therapy with trastuzumab in selected patients are initiated to prevent recurrence. During adjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle of treatment. After completion of adjuvant therapy, patients are monitored every 3 months for the first few years after diagnosis, with intervals between examinations extended as time from diagnosis lengthens. Evaluation includes:

- Physical examination to detect breast cancer recurrence
- Annual mammography
- Symptom-directed workup

Patients with locally advanced breast cancer are often treated with neoadjuvant therapy to make the tumor surgically resectable. However, many believe that neoadjuvant therapy may have benefits that extend beyond downsizing. During neoadjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle and weekly thereafter while on treatment; physical and ultrasound examinations are conducted to determine the size of the tumor following a complete course of neoadjuvant therapy. Surgical resection is then performed. Although no further chemotherapy is given following surgery, a recent study demonstrated a DFS and OS benefit with adjuvant capecitabine in patients with pathologically assessed residual tumor cells after preoperative chemotherapy.[47] Metastatic breast cancer is not curable, and therapy is intended to palliate symptoms and prolong survival. In most cases, hormonal therapy is the mainstay for tumors that are ER positive. While on therapy, patients are monitored monthly for signs of disease progression or metastasis to common sites, such as the bones, brain, or liver. Evaluations include:

- Pain
- Mental status or other neurologic findings
- Laboratory tests
- Liver function tests
- Complete blood count
- Calcium, electrolytes

Patient Care Process

Collect Information:

- Review medical/medication history and current laboratory values
- Document components of the medical history related to risk factors, breast cancer screening and surveillance programs, menopausal status
- Discuss overall health and performance status with the patient
- Address issues related to quality of life, psychosocial support, and survivorship needs
- Gather information related to insurance coverage

Assess the Information:

- Detail key aspects of the patient's history related to breast cancer risk level (ie, age, family history of breast/ovarian and other cancers, exposure to estrogens and ionizing radiation, and atypia)
- Determine the circumstance(s) that led to the diagnosis
- Determine the intrinsic subtype and stage of the disease
- Evaluate overall prognosis for a patient with early breast cancer based on intrinsic subtype, stage, regional node status, proliferation markers, tumor grade

Develop a Care Plan:

- Provide sufficient time for patient to process and cope with the diagnosis
- Explore the appropriateness of testing for possible hereditary cancers and fertility-preservation in premenopausal women
- Assess treatment goals
- Formulate treatment strategy based on tumor burden, nodal involvement, tumor biology, health and menopausal status, and patient preference
- Identify key endpoints (especially with regards to quality of life issues) related to pharmacotherapeutic management of the patient
- Develop a supportive care plan

Implement the Care Plan:

- Ensure that the patient understands details related to the overall treatment plan (ie, timing and duration of systemic therapy relative to other treatment modalities)
- Assess pharmacologic treatment for drug interactions
- Address concerns and appraise comprehension and communication of drug-related side effects and possible adverse events (both acute and delayed)

Follow-up: Monitor and Evaluate:

- Reinforce compliance regarding clinic visit and medications prescribed
- Address acute therapy-related complications and recommend or modify therapy as appropriate
- Recommend treatment of delayed therapy-related complications (ie, menopausal symptoms, osteoporosis, etc)
- Reeducate patient regarding any change(s) in medication(s)
- Assess quality of life issues especially for women receiving long-term endocrine therapy

Abbreviations Introduced in This Chapter

AI	Aromatase inhibitor
DFS	Disease-free survival
ER	Estrogen receptor
HER2	Human epidermal growth factor receptor 2
LHRH	Luteinizing hormone-releasing hormone
ORR	Overall response rate
OS	Overall survival
PFS	Progression-free survival
PR	Progesterone receptor
SERD	Selective estrogen-receptor downregulators
SERM	Selective estrogen receptor modulator
TNM	Tumor, node, metastasis (staging system)
TTP	Time to progression

90 Lung Cancer

Val Adams and Justin M. Balko

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Identify major risk factors for the development of lung cancer.
2. Explain the pathologic progression of lung cancer and its relationship with signs and symptoms of the disease.
3. Make appropriate recommendations for screening and preventive measures in high-risk patients.
4. Understand staging of lung cancer patients and how it influences treatment decisions.
5. Explain how histology, biomarkers, and genetic mutational testing are used to select therapy.
6. List the rationale, advantages, and disadvantages for neoadjuvant and adjuvant chemotherapy in non–small cell lung cancer (NSCLC).
7. Identify the treatment of choice and treatment goals for limited and extensive small cell lung carcinoma.
8. Identify the treatment of choice and treatment goals for local, locally advanced, and advanced non–small cell lung carcinoma.

INTRODUCTION

Lung cancer continues to be one of the most commonly diagnosed cancers and the leading cause of cancer-related mortality. Although treatment can cure some patients, most therapies only prolong survival and improve symptoms. Recent advances in lung cancer research has provided a number of new therapies that provide significant benefit for some populations of patients; however, antismoking campaigns still appear to offer the best opportunity to reduce lung cancer incidence and mortality.

EPIDEMIOLOGY AND ETIOLOGY

Incidence and Mortality

Cancers of the lung and bronchus remain to be the second most common cancer diagnosis in the United States in 2018 (behind breast cancer). Lung cancer is the number one cause of cancer-related mortality, comprising more than 25% of cancer-related deaths in the United States. A close correlation exists between incidence and mortality of lung cancer, reflecting the reality that approximately 80% of lung cancer patients ultimately die of the disease.[1]

Clinical Risk Factors

▶ *Smoking*

LO 1 KEY CONCEPT The most important risk factor for the development of lung cancer is smoking. One of the most predictive factors of lung cancer incidence is cigarette smoking prevalence. Although rates of lung cancer have nearly doubled in never smokers over the past 25 years, this population still only represents about 15% of all cases and ~85% of cases occur in current or former smokers.[2] Correlation between smoking and lung cancer continues to drive antismoking and clean indoor air campaigns and should be considered an investment in the future health care of the nation. Furthermore, smoking cessation plays an important role in reducing lung cancer risk on a patient-to-patient basis, and appropriately guiding such therapy is a crucial part of preventing lung cancer in at-risk patients. Both total smoke exposure and current use correlate with the individual's risk of developing malignancy. The risk of lung cancer decreases to near-normal levels 10 to 15 years following successful smoking cessation. Total smoke exposure is reported as pack-years. One pack-year is equivalent of smoking one pack per day for 1 year. A patient who smokes 40 cigarettes per day (two packs) for 5 years would have a 10 pack-year history (2 packs/day for 5 years).

▶ *Other Air-Related Risks*

LO 1 In addition to direct inhalation of cigarette smoke, other environmental are risks for the development of primary lung tumors. Environmental tobacco smoke (ETS) presents a significant occupational hazard for nonsmokers working in environments that have a high-smoking population, such as bars or restaurants. Each year approximately 3000 cases of lung cancer in nonsmokers are caused by ETS. In response, the majority of states have enacted clean indoor air act, which are legislative ordinances restricting smoking in public places. Other environmental factors linked to lung cancer include **radon**, arsenic, nickel, and chloromethyl ethers. Those who live in an urban environment are also at an increased risk for lung cancer owing to exposure to high concentrations of combustion fumes.[3] Asbestos exposure increases the risk of developing a distinct but rare type of lung cancer called **mesothelioma**.

Hereditary or Genetic Risk Factors

Although smoking is a key risk factor for lung cancer, the majority of smokers never develop lung cancer. Genetic risk factors may predispose certain smokers to lung cancer. After adjustments for age, smoke exposure, occupation, and gender, relatives of a lung cancer patient have approximately a twofold risk of developing lung cancer. The degree of inherited risk inversely correlates with the age of the relative at the time of diagnosis. First-degree relatives of a lung cancer patient diagnosed between the ages of 40 and 59 years have a sixfold relative risk for lung cancer. Familial lung cancer that develops at an early age in nonsmokers fits a Mendelian codominant inheritance model. However, a lung cancer gene has not been identified.

Chemoprevention

LO 3

Many studies of potential **chemoprevention** agents, including nonsteroidal anti-inflammatory drugs, retinoids, inhaled glucocorticoids, vitamin E, selenium, and green tea extracts, have been conducted, but none have been successful. A large randomized trial testing the effects of selenium, previously considered a promising chemopreventative agent for lung cancer, was stopped early due to lack of any observable effect at its first interim analysis.[4]

Interestingly, data from a placebo-controlled, double blind study demonstrated that selective cyclooxygenase-2 (COX-2) inhibition with celecoxib reduces the proliferation of bronchial epithelial cells, lowers inflammatory markers, and may resolve benign or premalignant lung nodules in former smokers.[5] Existing data suggest that bronchial epithelial cell proliferation may be a surrogate endpoint for chemopreventative lung cancer trials. However, at this time, routine use of celecoxib as a chemopreventative agent is not warranted.

Screening and Early Detection

LO 3

Five-year survival is greater than 50% for patients diagnosed with localized lung cancer. Unfortunately, most patients have regional or advanced disease at the time of diagnosis, which negatively impacts survival (**Figure 90–1**). Screening and detecting lung cancer tumors when they are localized should improve overall survival which is the basis for lung cancer screening.

The landmark trial, the National Lung Screening Trial (NLST) randomized more than 53,000 patients at high risk for lung cancer to three annual low-dose spiral computed tomography (CT) scans or chest x-ray. Chest x-ray has been shown in large trials to be equivalent to no screening and can be considered a placebo control for mortality. In the CT arm 6.9% of patients were diagnosed with localized lung cancer with over 90% having surgery with curative intent. Screening by CT reduced lung cancer mortality by 20% and was subsequently approved and recommended for high-risk patients. High-risk patients are defined by all of the following criteria:

1. Age between 55 and 74 years old
2. If former smoker, had quit within the previous 15 years
3. Greater than or equal to a 30 pack-year history

While screening reduces lung cancer mortality, implementation has been slow. This is likely due to the small absolute change in mortality of 0.3% (1.3% vs 1.6%) combined with the high false positive findings. In the NLST, the CT screening arm had positive findings in 26% of scans and nearly 40% of all patients; meaning 96.4% of the lesions discovered were benign (false positives). Due to this high false positive rate, research continues to look for methods to lower the false positive rates.[7]

The United States Preventative Services Task Force guidelines provide lung cancer screening a grade B recommendation, which means the magnitude of benefit is moderate. The proposed action for grade B recommendations is to offer or provide this service for qualifying patients. The most rational addition is smoking cessation in combination with screening.[6]

PATHOPHYSIOLOGY

Histologic Classification

Most lung cancers arise from the respiratory epithelium and are classified as **carcinomas**.

Histologic classification of lung cancer involves determining the cellular origin of the tumor. Knowing the histology of the tumor influences treatment decisions as well as prognosis.

There are four major histologic types of lung cancer that are divided into different classes based on response to treatment and prognosis: small cell lung cancer (SCLC), squamous cell

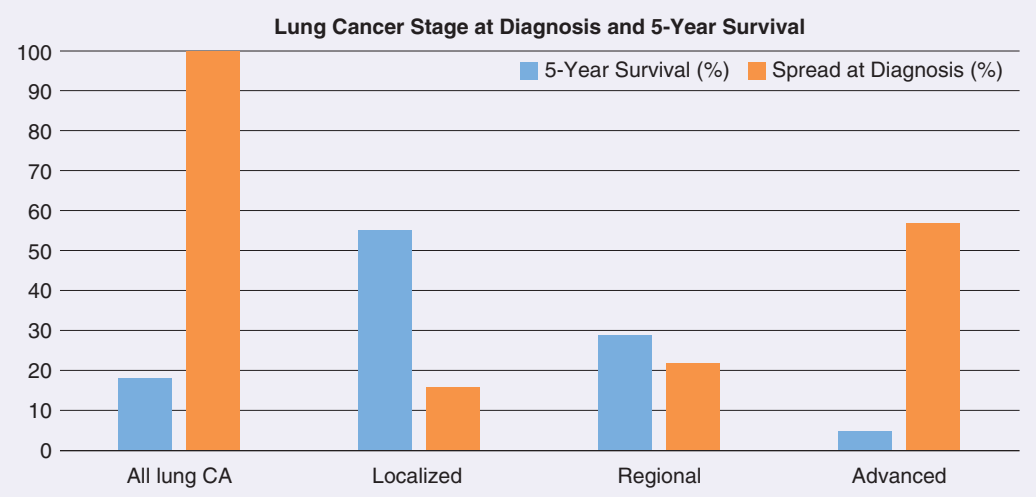

FIGURE 90–1. Spread of lung cancer disease at diagnosis and corresponding 5-year survival in the United States. Data from National Cancer Institute. SEER Database https://seer.cancer.gov/statfacts/html/lungb.html accessed 8/14/2017.

Table 90–1

Lung Tumor Histopathology[7]

Tumor Type	Percent of Tumors	Targetable Mutation	Frequency
Small cell	15–20	None	
Non–small cell			
Adenocarcinoma	35–40	*EGFR*	15%–20%
		ALK	5%
		BRAF	1%–3%
		ROS1	1%–2%
Squamous (epidermoid)	25–30	None	
Large cell (giant)	10	None	

non–small cell lung cancer (NSCLC), adenocarcinoma, and large cell lung cancer. These histology types of lung cancer are further divided by driver mutations or biomarkers as outlined by class in Table 90–1.[7] Mutation (genetic) and surface protein expression testing plays a key role in the treatment plan for NSCLC. Tumors where more than 50% of viable cells express programmed death ligand 1 (aka B7-H1 and CD274) (PD-L1) (TPS ≥ 50%, PD-L1+) and tumors with driver mutations or rearrangements of *ALK, BRAF, EGFR,* or *ROS1* have specific treatment options that offer improved response rates and survival compared to traditional cytotoxic therapies. PD-L1 testing should be performed on all patients, whereas, mutational testing should be performed on all nonsquamous histologies.[8]

However, it is important to note that certain other rare malignancies can be seen and many lung cancers may consist of multiple histologic subtypes. Furthermore, a recent phenomenon has been observed where pharmacologic treatments may selectively kill different components of the tumor, resulting in a conversion of the remaining tumor to a different subtype (ie, NSCLC becomes SCLC after treatment).

Clinical Staging

LO 4

Once the diagnosis of lung cancer is confirmed through visualization and biopsy, the extent of disease must be determined. Clinical staging serves two primary purposes: predicting prognosis and guiding therapy. Both NSCLC (squamous and nonsquamous subsets) and SCLC are staged using the American Joint Committee on Cancer (AJCC) tumor, node, and metastasis (TNM) staging system.[9]

Patient Encounter Part 1

A 68-year-old man presents at your clinic complaining of worsening cough with occasional hemoptysis. He has had 1 to 2 severe upper respiratory infections annually for the past 4 to 5 years and 1 last month. He smoked about a pack of cigarettes per day beginning since he was 15 years old. He lives in a small rural town where he worked as a coal miner. A year after retiring at age 62 he purchased a restaurant/bar where he now works.

What risk factors for lung cancer are present?

Calculate this patient's pack-year history.

▶ *Non–Small Cell Lung Cancer*

Clinical staging of NSCLC with the TNM system evaluates the size of the tumor (T), extent of nodal involvement (N), and presence of metastatic sites (M). The combination of these three evaluations determines the stage. Clinical stages are grouped together as localized, regional, or metastatic disease for real world prognosis by the National Cancer Institute Surveillance Epidemiology and End Results (SEER). Local disease (stages 1 and 2) includes tumors that are confined to a single hemithorax and those cancers which have spread to the ipsilateral hilar lymph nodes. Once malignancy invades the mediastinal lymph nodes or contralateral hilar nodes, the disease becomes locally advanced (regional, stage 3). When lung cancer is detected outside the pleural cavity, it is considered as advanced disease (metastatic, stage 4). Local disease is associated with the highest cure and survival rates, whereas those with advanced disease have a 5-year survival rate of less than 5%.

▶ *Small Cell Lung Cancer*

The most common system for staging SCLC was developed originally by the Veterans Administration Lung Cancer Study Group, and has now been incorporated into the TMN staging system.[10] This system categorizes SCLC into two classifications, limited and extensive disease.

- Limited disease: Stages I–III that can be safely treated with definitive radiation doses.
- Extensive disease: Stage IV or T3–T4 due to multiple nodules that are too extensive to be encompasses in a tolerable radiation plan.

CLINICAL PRESENTATION AND DIAGNOSIS

KEY CONCEPT Signs and symptoms of lung cancer can be classified into three subdivisions: pulmonary, extrapulmonary, and paraneoplastic syndromes. Distinguishing among these classes of symptoms is important because it can aid in determining the severity of the disease, guide treatment options, and affect prognosis.

TREATMENT

General Treatment Considerations

LO 5

The treatment of lung cancer depends on tumor histology, biomarkers (driver mutations, PD-L1 expression), stage of disease, patient characteristics, and performance status (PS). All these aspects must be assessed before appropriate treatment can be recommended. In the development of a patient care plan, keep in mind the ultimate goals of therapy. Treatment modality based on histology and stage is outlined in Figure 90–2. Some treatments may prolong survival by a few months, but at the expense of significant decreases in patient quality of life. Treatment decisions must include both the health care team and a well-informed patient. KEY CONCEPT In general patients with early stage disease, a definitive cure is the primary goal of treatment, although this end point is not always met. Additional goals of treating lung cancer patients include prolongation of survival and improvement of quality of life through alleviation of symptoms.

▶ *Performance Status*

The performance status (PS) of an individual patient predicts response and likelihood of toxicity to chemotherapy as well as

LO 2

Clinical Presentation and Diagnosis[11]

Pulmonary Symptoms

Symptoms related to the direct effects of the primary tumor often appear first and are the most common. These include the following:

- Cough
- Chest pain
- Shortness of breath
- Dysphagia
- Hemoptysis

Extrapulmonary Symptoms[11]

Once the tumor invades tissues outside the pleural cavity, it can produce a wide array of symptoms, including:

- General bone pain
- Adrenal insufficiency
- Confusion
- Personality changes
- Enlarged lymph nodes
- Weight loss
- Seizures
- Nausea and vomiting
- Focal neurologic symptoms
- Horner syndrome
- Fatigue
- Headache
- Pancoast syndrome
- Subcutaneous skin nodules

Paraneoplastic Syndromes[11]

Symptoms that are not a result of the direct effects of the tumor are termed paraneoplastic syndromes. They may be caused by substances secreted by the tumor or in response to the tumor and often occur in tissues far from the site of malignancy. Paraneoplastic syndromes are numerous and affect a wide variety of systems, including the endocrine, neurologic, skeletal, renal, metabolic, vascular, and hematologic systems.

Diagnosis

Diagnosis requires visualization of one or more lesions as well as biopsy of the lesion to confirm malignancy. Both visualization and sampling can be performed by invasive or noninvasive methods. These methods are summarized in Table 90–2.

overall survival. The PS evaluation system used most frequently was developed by the Eastern Cooperative Oncology Group (ECOG) (see Chapter 88). Patients with localized disease may be treated more aggressively in this scenario because the intent of treatment is curative. KEY CONCEPT Categorizing patients by their ECOG PS allows for a standardized approach to predict the capability to tolerate systemic therapies that may severely compromise the patient's health. Patients with a good PS 0 to 1 are more likely to tolerate intense therapy. PS 2 may receive chemotherapy, and PS 3 to 4 may receive supportive therapy or treatment with targeted therapies if they have targetable activating mutations.

Treatment Modality

▶ *Surgery (NSCLC)*

KEY CONCEPT Of all treatment modalities, surgical resection is associated with the greatest improvement in survival for patients with early stage NSCLC tumors (clinical stage IA, IB, or IIA). Surgery is not recommended in locally advanced and metastatic disease as it has not been proven to prolong survival. However, surgery for advanced disease is an important palliative treatment that can improve quality of life in some patients. In this respect, surgery is limited to local sites where the tumor is causing significant morbidity (eg, spinal cord compression).

▶ *Surgery (SCLC)*

Patients with SCLC are rarely treated with surgery because the results of a randomized trial published in 1969 showed that surgery did not result in any 5- or 10-year survivors in comparison to radiation which produced a 4% survival rate at 5 and 10 years.[12] With improved imaging and surgical techniques as well as the use of effective adjuvant therapy, some clinicians believe that surgery does have a role in early stage SCLC. However, this has yet to be proven in a clinical trial.

Diagnostic Tools[13,14]

	Technique	Description
Visualization	Chest x-ray	The least expensive visualization method in the diagnosis of lung cancer. Readily accessible and does not require systemic administration of contrast dye. However, it often detects lesions that are not cancerous and is not capable of assessing lymph node status.
	CT	More accurate when providing information on size, location, and invasion than chest radiography. It is recommended as part of the standard workup in most cases.
	PET scanning	Uses a substance called 5-FDG to produce a functional image of the lungs. Cells that are actively growing and dividing use greater amounts of glucose and therefore take up more 5-FDG. Focal regions of fluorescence can be visualized in cancerous lesions. PET scanning combined with a CT scan is more accurate than CT scan alone; however, the exact role of PET scanning in staging and monitoring is unclear. The apparent benefit and common role in staging is to evaluate mediastinal disease when it can influence the tumor resectability.
Tumor sampling	Fine-needle aspiration	A method of aspirating cells from the tumor via insertion of a small-bore needle into the lesion and aspirating. Commonly used to evaluate lymph nodes or other poorly accessible sites, it has the advantage of being faster and less invasive than other biopsy methods; however, it does not preserve the architecture of the tumor and may return cells that are undergoing cell death, which negates histologic analysis.
	Bronchoscopy	A fiberoptic camera is inserted through the airways to examine the site of the suspected lesion. Once the lesion is visualized, a tool attached to the camera allows for a tissue biopsy. Newer technologies incorporate fluorescence to differentiate malignant tissue from premalignant lesions.
	Core needle biopsy	A method of obtaining tissue and preserving the tumor architecture. A large-bore needle is inserted into a lesion, where it cuts a core of tissue out that then can be evaluated.
	Thoracentesis	Involves removal of fluid in the pleural cavity via a needle. The fluid then is assayed for the presence of cancerous cells. This procedure has low sensitivity and depends on the presence of a pleural effusion.
	Sputum cytology	Detects cancerous cells that become dislodged from the airways into the sputum. Sputum cytology is useful because it is not invasive, but it has much lower sensitivity for detecting cancer.

CT, computed tomography; 5-FDG, 5-fluorodeoxyglucose; PET, positron-emission tomography.

▶ *Radiotherapy (NSCLC)*

Patients with localized NSCLC are best treated with surgery; however, many of these patients are inoperable because of comorbidities (eg, lung disease from smoking). In these situations, radiation therapy can be used with curative intent in place of surgery, and the success rate is approximately 50% that of surgery.[15] Patients with locally advanced (stage IIIB, nonsurgically resectable) disease have prolonged survival with combined chemotherapy and radiotherapy. Patients with late stage NSCLC can receive radiation therapy to palliate symptomatic metastases. Although radiation is less invasive than surgery, it can have marked toxicity on normal tissue, and patients may experience esophagitis, pneumonitis, cardiac abnormalities, myelosuppression, and skin irritation. These adverse events can be decreased by using stereotactic radiation and/or hyperfractionated administration.[16]

Postoperative radiotherapy (PORT) is thought to eliminate remnants of the resected tumor that might be deposited in nearby tissue, but is only recommended for patients with positive margins after surgical resection when a local recurrence is of concern.[9]

Patient Encounter Part 2: Medical History, Physical Examination, and Diagnosis

PMH: Moderate hypertension (controlled)

FH: Father died from lung and colorectal cancer at age 62, mother is 85, alive, and living in a nursing home due to heart failure and dementia

Meds: Lisinopril 20 mg daily

ROS: (+) Chest pain, shortness of breath, hemoptysis; (–) recent weight loss

PE:

VS: BP 125/69 mm Hg, RR 26 breaths/min, P 80 beats/min, T 99°F (37.2°C)

CV: RRR

Labs: Slightly elevated LFTs and platelets, mild anemia (Hgb 11.8 gm/dL); all others WNL; CXR reveals a solitary nodule in right lobe; fine-needle aspiration confirms squamous cell carcinoma of the lung that stains positive for PD-L1; further evaluation with CT and PET scans reveal a 3-cm mass, with bilateral mediastinal lymph node involvement and a lesion on his adrenal gland.

What clinical stage is this patient's disease?

What is the estimated survival time for this stage of NSCLC?

Does this patient have any factors that may negatively or positively influence survival?

▶ *Radiotherapy (SCLC)*

Radiotherapy (concurrent with chemotherapy) is the treatment of choice for limited-stage SCLC. Limited- and extensive-stage SCLC patients who respond to therapy should also receive prophylactic cranial irradiation (PCI), which treats micrometastatic disease in the CNS. This improves cure rates for limited-stage disease and prolongs survival for extensive-stage disease.[17]

Cytotoxic Chemotherapy (NSCLC)

LO 6

Traditional chemotherapy remains the mainstay of lung cancer treatment, despite recent advances with immunotherapy and targeted therapy. While patients with PD-L1 positive, ROS1, EGFR, BRAF, and ALK mutations are treated with targeted therapies, the majority of patients do not have actionable mutations. Cisplatin and carboplatin are arguably the most effective traditional chemotherapy agents regardless of histology.[7,8] KEY CONCEPT Platinum doublet chemotherapy regimens offer superior response rates compared with single-agent chemotherapy regimens and should be used when the patient can tolerate the increased toxicity. Effective chemotherapy agents that are added to platinum include paclitaxel, albumin bound paclitaxel, docetaxel, gemcitabine, vinorelbine, and pemetrexed. Patients with squamous histology do not benefit from pemetrexed, while they seem to benefit more from gemcitabine (see Table 90–3 for regimen details). The duration of therapy has also been intently studied. Doublet therapy is generally given for four to six cycles; patients with nonsquamous histology receive benefit from maintenance therapy with pemetrexed with or without bevacizumab. Those with squamous histology can be treated with maintenance gemcitabine.[9]

Cytotoxic Chemotherapy (SCLC)

Cytotoxic chemotherapy with platinum and etoposide are the mainstay of treatment for SCLC. With limited-stage disease, cisplatin is thought to be slightly superior to carboplatin, but more toxic. Extensive-stage disease is treated with either agent, although most commonly carboplatin. Cisplatin combined with irinotecan, which was superior to cisplatin

Table 90–3

Select Chemotherapy Regimens and Their Efficacy

Regimen	Comparison	PFS	OS
	NSCLC Adjuvant Therapy[18]		
Cisplatin–vinorelbine (JBR.10)	Cisplatin 50 mg/m² IV day 1 and 8 every 4 weeks × 4 weeks Vinorelbine 25 mg/m² IV day 1 Every 3 weeks for 16 weeks vs Observation		Median 7.8 years vs 6.1 years (p = 0.05)
	NSCLC First Line for Advanced Disease[19-21]		
Cisplatin–paclitaxel	Paclitaxel 135 mg/m² CIV over 24 h day 1 + cisplatin, 75 mg/m² IV day 2 repeat q3week	Median 3.4 months vs	Median 7.8 months vs
Cisplatin–docetaxel	Cisplatin 75 mg/m² IV day 1 and docetaxel 75 mg/m² IV day 1 repeat q3week	3.7 months vs	7.4 months vs
Cisplatin–gemcitabine	Cisplatin 100 mg/m² IV day 1 and gemcitabine 1000 mg/m² IV days 1, 8, and 15 repeat q4week	4.2 months vs	8.1 months vs
Carboplatin paclitaxel (ECOG 1594)	Carboplatin, dosed to AUC of 6 IV day 1 and paclitaxel 225 mg/m² IV over 3 hours day 1 repeat q3week	3.1 months (p = NS)	8.1 months (p = NS)
Cisplatin–pemetrexed	Cisplatin 75 mg/m² IV day1 + Pemetrexed 500 mg/m² IV day 1 Repeat q3week × 6	Median 4.8 months vs	Median 10.3 months vs
Cisplatin–gemcitabine	Cisplatin 75 mg/m² IV day 1 + Gemcitabine 1250 mg/m² IV days 1 and 8 Repeat q3week × 6	5.1 months (p = NS)	10.3 months (p = NS)
Carboplatin–Paclitaxel +/– Bevacizumab (ECOG 4599)	Paclitaxel 200 mg/m² IV Day 1 + Carboplatin AUC 6 IV Day 1 Repeat q3week × 6 vs Paclitaxel 200 mg/m² IV Day 1 + Carboplatin AUC 6 IV Day 1 + Bevacizumab 15 mg/kg IV day 1 Repeat q3week × 6	Median 4.5 months vs 6.2 months (p < 0.001)	Median 10.3 months vs 12.3 months (p = 0.003)
	SCLC First-Line Regimens[17]		
Limited stage			
EP	Etoposide 100 mg/m²/d IV days 1–3 + Cisplatin 80 mg/m² IV day 2+ Radiation Repeat every 4 weeks vs	Median 1.1 year vs	Median 3.2 years vs
IP	Irinotecan 60 mg/m² IV days 1, 8, 15 + Cisplatin 60 mg/m² IV day 1 Repeat every 4 weeks	1.0 year (p = 0.74)	2.8 years (p = 0.70)
Limited and extensive stage			
EC	Etoposide 100 mg/m²/d IV days 1–3 + Carboplatin 300 mg/m² IV day 1 Repeat every 3 weeks		Median 12.5 months

and etoposide in a Japanese study, was found to be equivalent in the United States. Although it is not commonly used, it is a reasonable alternative.

Immunotherapy

Immunotherapy is considered a unique modality and is often referred to as the 4th cornerstone of treatment. Although it involves targeted monoclonal antibodies, it is separate because the goal is to activate the immune system. Programmed cell death protein 1 receptor (PD1) and PD-L1 inhibitors have become a mainstay in NSCLC and research is being done to determine if they have a role in SCLC. Pembrolizumab is currently approved for first-line therapy both as monotherapy in PD-L1 positive patients and in combination with chemotherapy regardless of PD-L1 positivity. Additionally, nivolumab, atezolizumab, and pembrolizumab are effective as second-line therapy. Key studies are shown in Table 90–4.

Targeted Therapy

Monoclonal antibodies targeting vascular endothelial growth factor (VEGF) signaling (bevacizumab and ramucirumab) and epidermal growth factor receptor (EGFR; necitumumab) have been combined with traditional chemotherapy to improve outcomes. Their use is currently limited to stage IV NSCLC; investigation in SCLC indicates no role at this time.

Tyrosine kinase inhibitors (TKIs) are the front-runners in precision medicine. Monotherapy with a TKI in genetically selected patients frequently outperforms cytotoxic chemotherapy. Multiple agents are approved for *EGFR* mutations, *ALK* mutations (generally a rearrangement), *ROS1* mutations, and *BRAF* mutations. The TKIs are all oral medications, which allow the pharmacist to play a more integral role in the patient's therapy. Consequently, optimizing outcomes requires pharmacists to obtain a complete medication history and be knowledgeable about preventing and managing therapy-induced toxicity (see Chapter 88). Everyone involved in this process should be adequately knowledgeable about toxicity prevention and management.[9,17] Results of key studies for targeted therapies are shown in Table 90–5.

Therapeutic decisions to start therapy must include the full consent and understanding of risks by the patient. Counseling on the therapeutic regimen and risk of toxicity is imperative before dosing. Refer to Chapter 88 for dosing recommendations in renal and hepatic failure.

Treatment of Small Cell Lung Cancer

LO 7

SCLC typically presents as an extensive disease (approximately 60%–70% of new cases) and progresses very quickly. SCLCs are very responsive to chemotherapy and radiation but have a short duration of response. Radiotherapy became the standard in 1969, when a randomized trial showed that it offered the potential for cure, whereas surgery did not.[22] In the vast majority of patients, chemotherapy with or without radiotherapy is the treatment of choice. Even after a complete response to therapy, the cancer usually recurs within 6 to 8 months, and the survival time following recurrence is typically short (~4 months). This yields an average survival rate of 14 to 20 months for limited disease and 8 to 13 months for extensive disease.[18]

Table 90–4

Select Clinical Trials in Advanced NSCLC with Immunotherapy

Regimen	Comparison	PFS	OS
	PD-L1 Positive First Line[23,24]		
Pembrolizumab (KEYNOTE-024)	Pembrolizumab 200 mg IV q3week vs Platinum Doublet	Median 10.3 months vs 6.0 months ($p < 0.001$)	6 month survival 80% vs 72% ($p = 0.005$)
Carboplatin – Pemetrexed – Pembrolizumab (KEYNOTE-021)	Pemetrexed 500 mg/m^2 IV + Carboplatin AUC 5 IV Pembrolizumab 200 mg IV Repeat q3week vs Pemetrexed 500 mg/m^2 IV + Carboplatin AUC 5 IV Repeat q3week	Median 13 months vs 8.9 months ($p < 0.0001$)	Not Reported
	Second Line[29-31]		
Atezolizumab (OAK)	Atezolizumab 1200 mg IV q3week vs Docetaxel 75 mg/m^2 IV q3week	Median 2.8 months vs 4 months	Median 13.8 months vs 9.6 months ($p = 0.0003$)
Nivolumab (CheckMate 017) Squamous Histology	Nivolumab 3mg/kg IV q2week vs Docetaxel 75 mg/m^2 IV q3week	Median 3.5 months vs 2.8 months	Median 9.2 months vs 6.0 months ($p < 0.001$)
Nivolumab (CheckMate 057) Nonsquamous	Nivolumab 3 mg/kg IV q2week vs Docetaxel 75 mg/m^2 IV q3week	Median 2.3 months vs 4.2 months	Median 12.2 months vs 9.4 months ($p = 0.002$)
Pembrolizumab (KEYNOTE-010)	Pembrolizumab 2 mg/kg IV q3week vs Docetaxel 75 mg/m^2 IV q3week	Median 3.9 months vs 4 months	Median 10.4 months vs 8.5 months ($p = 0.0008$)

Table 90–5

Select Clinical Trials in Advanced NSCLC with a Targetable Mutation

Agent	Comparison	PFS	OS
	EGFR Positive First Line[29-31]		
Gefitinib (IPASS)	Gefitinib 250 mg PO daily vs Paclitaxel 200 mg/m² IV + Carboplatin AUC 5-6 IV every 3 weeks	In EGFR+ patients: HR 0.48 (95% CI 0.34-0.67)	In EGFR+ patients: HR 1.00 (95% CI 0.76-1.33)
Erlotinib (EURTAC)	Erlotinib 150 mg PO daily vs Chemotherapy	9.7 months vs 5.2 months (p < 0.0001)	19.3 months vs 19.5 months (p = 0.87)
Afatinib (LUX-Lung 3)	Afatinib 40 mg PO daily vs Cisplatin 75 mg/m² IV + Pemetrexed 500 mg/m² IV every 3 weeks	Median 11.1 months vs 6.9 months (p = 0.001)	Median 28.2 months vs 28.2 months (p = 0.39)
	EGFR T790M Positive Second Line[32]		
Osimertinib (AURA3)	Osimertinib 80 mg PO daily vs Pemetrexed 500 mg/m² IV + Carboplatin AUC 5 IV or Cisplatin 75 mg/m² IV q3week	Median 10.1 months vs 4.4 months (p < 0.001)	Not reported
	ALK Positive First Line		
Crizotinib (PROFILE 1014)	Crizotinib 250 mg PO BID vs Pemetrexed 500 mg/m² IV + Cisplatin 75 mg/m² IV or Carboplatin AUC 5-6 IV every 3 weeks	Median 10.9 months vs 7.0 months (p < 0.001)	HR for death with crizotinib 0.82 (95% CI, 0.54–1.26; p = 0.36)
Alectinib vs Crizotinib (ALEX)	Alectinib 600 mg PO BID vs Crizotinib 250 mg PO BID	Median 25.7 months vs 10.4 months (p < 0.001)	Not mature
Ceritinib (ASCEND-4)	Ceritinib 750 mg PO daily vs Pemetrexed 500 mg/m² IV + Cisplatin 75 mg/m² IV or Carboplatin AUC 5-6 IV every 3 weeks	16.6 months vs 8.1 months (p < 0.00001)	Not reached ceritinib vs 26.2 months chemotherapy (p = 0.056)
	ALK Positive Second Line[36,37]		
Ceritinib (ASCEND-5)	Ceritinib 750 mg PO daily vs Pemetrexed 500 mg/m² IV OR Docetaxel 75 mg/m² IV every 3 weeks	5.4 months vs 1.6 months (p < 0.0001)	HR 1.0 (95% CI 0.67–1.49; p = 0.5)
Brigatinib (ALTA)	Brigatinib 90 mg PO daily OR 180 mg PO daily	9.2 months Arm A and 12.9 months Arm B	1 year OS probability 71% Arm A and 80% Arm B
	ROS1 Positive First Line[38]		
Crizotinib	Crizotinib 250 mg PO BID	Median 19.2 months	12 month OS = 85%
	***BRAF*V600E Positive First Line**[39]		
Dabrafenib and Trametinib (BRF113928)	Dabrafenib 150 mg PO BID + Trametinib 2 mg PO daily	Median 9.7 months	Not mature

Patient Encounter Part 3

The patient's condition has caused symptoms and periodic interruptions to his tasks, but he has been able to work and complete daily activities up to this point.

What is this patient's ECOG PS score?

Are there any nonpharmacologic interventions you would suggest?

Limited Disease

The regimen of choice for limited-stage disease SCLC is etoposide–cisplatin (EP). In patients who are able to tolerate combined modality therapy, concomitant chemoradiotherapy offers the greatest survival benefit. Carboplatin may be substituted for cisplatin in patients who cannot tolerate cisplatin toxicity. Cisplatin is associated with significantly more nephrotoxicity and more emetogenicity than carboplatin. Cisplatin is preferred over carboplatin because of a small study that randomized patients to

cisplatin or carboplatin plus etoposide. There was a numerically higher complete response rate with cisplatin, which is believed to be requisite for cure. Consequently, the guidelines recommend that the EP regimen be used with concurrent radiotherapy.[19]

Because patients with SCLC commonly have a recurrence in the CNS, trials have been performed to evaluate the benefit of PCI. A pivotal study showed that PCI reduces the incidence of brain metastasis and increases the 3-year survival rate from 15% to 21%.[40] Patients with limited-stage SCLC who achieve a complete response with treatment should be offered PCI.

▶ *Extensive Disease*

In the first line setting platinum regimens, particularly EP, are the treatment of choice in extensive disease. Carboplatin is commonly used in place of cisplatin because it is generally thought to have less toxic and demonstrated similar outcomes in progression-free survival and overall survival. Another regimen that is acceptable, albeit uncommonly used, is cisplatin–irinotecan. This regimen became relevant due to a Japanese study, where a combination of irinotecan and cisplatin demonstrated an increased median survival time by approximately 3 months over the EP regimen. This irinotecan–cisplatin regimen also had a lower incidence of severe neutropenic side effects but exhibited higher rates of moderate to severe diarrhea. However, this study was repeated in the United States and did not show an improvement over the EP regimen.[17] Therefore, EP remains the regimen of choice for treating extensive SCLC in the United States.

Concurrent radiotherapy is not used routinely in extensive disease; however, PCI provides significant benefit in patients responding to chemotherapy. A pivotal study demonstrated that median survival from the time of randomization increased from 5.4 to 6.7 months and 1-year survival rates increased from 13.3% to 27.1% with PCI. An additional benefit was a lower rate of brain metastases (14.6% vs 40.4%).[41]

▶ *Recurrent Disease*

The treatment of recurrent SCLC depends on the time to recurrence. If the time to recurrence is less than 6 months, second-line therapy should be considered if the patient has an acceptable PS (0–2) (see Patient Care Process). The most widely accepted second-line therapies in SCLC are topotecan alone or CAV (cyclophosphamide, doxorubicin [Adriamycin], and vincristine). Relapses occurring more than 6 months after treatment warrant a repeat of the initial regimen. Patients with a poor PS (3–4) are typically managed with best supportive care, including palliative care therapies.[17]

Treatment of Non–Small Cell Lung Cancer

LO 8

The first step in treatment of NSCLC involves confirmation of the clinical stage and determination of likelihood of resection of the tumor. Tumors that are resectable require histology confirmation; while advanced (nonsurgically resectable) disease requires genetic and biomarker analysis. PD-L1 testing needs to be done on all tumors, while the genomic analysis of driver mutations is only required on nonsquamous histology (adenocarcinoma and large cell) tumors. Treatment options depend on the stage of disease (ie, eligibility for resection), PS, histology, PD-L1 expression, and genetic findings.[8]

▶ *Local Disease (Stages IA, IB, and IIA)*

Local disease encompasses stages IA through IIA and is associated with a favorable prognosis. Approximately 40% to 60% of these patients are expected to live more than 5 years from diagnosis. Goals of therapy are curative in local disease, and surgery is the mainstay of treatment regardless of histology or genetics. Stage IA tumors are rarely seen clinically and may be treated with surgery alone. If surgical margins are positive, radiotherapy or re-resection is recommended.[9] Stage IB, IIA, and locally advanced IIB NSCLC are treated with adjuvant chemotherapy. The rationale behind adjuvant chemotherapy is to eradicate micrometastases or other tumor cells that may have been missed during removal of the primary tumor. The recent results of five relatively large prospective trials suggest that there is benefit from adjuvant chemotherapy leading to a survival advantage of 4% to 15%.[42,43] Consequently, adjuvant therapy has become the standard of care in resectable NSCLC and should be offered to patients after resection, particularly those with stage II or III disease.

Although the regimen of choice is unclear, studies evaluating pemetrexed in squamous cell histology demonstrate that it has minimal to no activity in this histology. Thus, regimens containing pemetrexed should be avoided in patients with squamous cell histology. Cisplatin vinorelbine regimens appear to have the most evidence, regardless of histology or genetics. Carboplatin-based regimens may be used in patients unable to tolerate cisplatin or with comorbidities precluding cisplatin use.

▶ *Locally Advanced Disease (Stages IIB and IIIA)*

Patients with locally advanced disease should also be considered for surgery, which would be followed with adjuvant treatment as outlined in local disease. However, neoadjuvant chemotherapy could also be considered before surgery. The rationale behind neoadjuvant therapy is to decrease the size of the tumor so that it can be resected more easily with clean margins, as well as to eliminate distant micrometastases before invasive local treatment. Meta-analysis of neoadjuvant trials suggests that neoadjuvant chemotherapy in all early stages improves 5-year survival by 5%.[44] However, the methods used in many of these studies did not give adjuvant chemotherapy, which could also improve survival by about the same degree. One concern of giving neoadjuvant therapy is that the toxicity of regimens may delay surgery, and if the tumor does not respond to the treatment, there is a risk of disease progression. Nonetheless, current data suggest that more than 90% of patients who are treated with neoadjuvant therapy maintain their scheduled surgery.[45] The utilization of neoadjuvant chemotherapy is inconsistent, but is most common in patients with locally advanced tumors (stage III).[46] Neoadjuvant chemotherapy regimens are platinum-based doublets that do not include a targeted therapy. None of the large studies prospectively controlled or individualized therapy choices based on histology or genetics, which could improve results. Three cycles of carboplatin and paclitaxel administered on a 3-week schedule is a common and supported approach. The benefit of combining neoadjuvant therapy and surgery with additional adjuvant therapy is being investigated but is of unknown value at this time. Relatively small studies have compared using three treatment modalities (chemotherapy, radiation, and surgery) to two treatment modalities (chemotherapy and radiation). Improvements have been shown for progression-free survival, but not overall survival. Consequently, the value of trimodal therapy is unknown and does not have a clear role.

▶ *Advanced or Metastatic Disease (Stages IIIB and IV)*

Advanced disease is treated with systemic therapy if the patient has an acceptable ECOG PS score. The selection of

therapy is determined by the histology, biomarker, and patient characteristics. The most common first-line therapy still includes a platinum doublet, which represents those patients who are biomarker negative and do not benefit from targeted and immunotherapies. In some patients with stage IIIB disease, cisplatin and etoposide may be given concurrently with radiotherapy. However, treating unresectable stage III patients with a platinum-containing doublet regimen and omitting the radiation is common. A large randomized trial comparing four platinum doublets reported similar response rates and survival, although there were less life-threatening toxicity and treatment-related deaths associated with paclitaxel–carboplatin.[21] Consequently, some argued that paclitaxel–carboplatin was the treatment of choice. Guideline recommended platinum doublets that are considered generally equivalent; key trials are listed in Table 90–3.

This historic approach indicates use of a platinum-containing doublet given for four to six cycles. This approach produces an overall response rate of 25%–35% and 1-year survival rates of 30%–40%.

For nonsquamous histology patients who are PD-L1 negative and have no targetable mutational drivers, pembrolizumab or bevacizumab can be used in addition to a platinum doublet. The addition of bevacizumab to carboplatin and paclitaxel improves survival by about 2 months (median OS = 12.3 months); however, the survival curve still had the same shape (without plateau at the end of the curve) indicating that patients would have a lung cancer event it was just delayed. The addition of pembrolizumab to carboplatin and pemetrexed has recently been published and the overall survival data is not mature; however, the progression-free survival was 4 months longer when pembrolizumab was added to the chemotherapy regimen.

Patients who fail doublet therapy will benefit from second-line therapy. The choice of therapy depends on prior therapies, comorbidities, PS, PD-L1 status, and mutation status. For those treated without immunotherapy, the preferred therapy is a PD1 or PD-L1 inhibitor. If patients received immunotherapy in the first-line setting their options include docetaxel, pemetrexed, ramucirumab + docetaxel and gemcitabine. Second-line treatment with atezolizumab, nivolumab, or pembrolizumab improves overall survival by 2 to 4 months when compared to docetaxel (the prior standard).[9] For patients treated with chemoimmunotherapy second-line treatment with docetaxel would be the standard. This is the situation where adding ramucirumab should be considered. The pivotal study that led to FDA approval of ramucirumab reported an overall survival benefit (10.5 months vs 9.1 months); however, the clinical significance of this difference is questionable and this has not become a clear standard of care.[9]

Patients with ***squamous*** histology, who are PD-L1 negative, and have ***no targetable genetic driver mutation*** are treated with a platinum doublet. As mentioned earlier, pemetrexed does not provide benefit for this population and should be avoided. Based on secondary endpoints, it appears that a platinum-gemcitabine regimen is most effective. After failing doublet therapy, the preferred therapy is a PD1 or PD-L1 inhibitor. The historical standard was docetaxel, which is inferior to atezolizumab, nivolumab, and pembrolizumab. The pivotal studies for these three drugs showed an improved overall survival by 2 to 4 months, although crossover from docetaxel to immunotherapy may have diminished the survival impact. Although not formally tested, patients who progress or fail to respond to immunotherapy could be treated with additional therapy in the third-line setting.

First-line immunotherapy for patients with PD-L1 positive tumor score of greater than or equal to 50% provides a clinically significant improvement in response rate, progression-free survival and overall survival when compared to a platinum doublet.[24] Consequently PD-L1 assessment should be done on all advanced stage NSCLC and for those who are PD-L1 positive (50%) without a contraindication should be treated with pembrolizumab monotherapy. A similar trial comparing nivolumab to chemotherapy in the first-line setting did not find any improvement with nivolumab.[47] After patients progress on monotherapy pembrolizumab, they can be treated similarly to patients who are PD-L1 negative and no mutational driver tumors and combination chemotherapy plus pembrolizumab may be an option without prior adverse effects on pembrolizumab (see Figure 90–2).[9]

Patients whose tumor has a targetable mutation do significantly better with a targeted agent and traditional chemotherapy. Currently, there are four targetable mutations: (1) *EGFR*, (2) *ALK*, (3) *BRAF*, and (4) *ROS1*; they occur almost exclusively in nonsquamous histologies and are generally mutually exclusive. The *EGFR* activating mutations (most commonly exon 19 deletion and exon 21 substitution) are present in about 15% of nonsquamous tumors, *ALK* mutations (most commonly *ALK-EML4* rearrangement) are found in about 5% to 7% of nonsquamous histology tumors, while *BRAF* and *ROS1* mutated tumors are less common (~1% of nonsquamous histologies).[8] Once patients fail appropriate targeted therapies, treatment options are similar to first-line treatment for no driver mutation (consider PD-L1 status and histology). See Figure 90–2.[9]

EGFR mutation positive patients should be treated with osimertinib, afatinib, erlotinib, or gefitinib in the first-line setting. In large randomized trials they have all been shown to be superior to chemotherapy with a median PFS of about 11 months. Osimertinib was recently compared to erlotinib and gefitinib in the first-line setting of *EGFR*-mutated NSCLC. Osimertinib demonstrated superior progression-free survival (18.9 months vs 10.2 months; hazard ratio for disease progression or death, 0.46; 95% confidence interval [CI], 0.37–0.57; P<0.001) with fewer serious adverse effects.[48] Ultimately, all patients have a recurrence and the most common acquired mutation conveying resistance is *T790M*. Upon recurrence patients should be tested for this mutation with a tissue or liquid biopsy. A liquid biopsy refers to a PCR-based test that can detect this mutation in circulating cell-free DNA. Since a tissue biopsy is considered the gold standard, negative liquid biopsy results are generally followed up with a tissue biopsy. Those who are positive should be treated with osimertinib (a second-generation EGFR TKI) if they have not received it in the first-line setting. A prospective randomized trial compared second-line osimertinib to a platinum doublet. The results showed that osimertinib was superior in terms of ORR (71% vs 31%) and PFS (10.1 months vs 4.4 months); however, the overall survival data was not mature at the time of analysis.[32]

ALK mutation positive patients should be treated with alectinib. Recently second-generation alectinib was studied head to head with crizotinib showing superiority of alectinib over crizotinib. The median PFS with crizotinib was 10.4 months (similar to previous trials), which was inferior to alectinib (PFS 25.7 months).[33] Although the overall survival data is not mature, a 15-month improvement in PFS is unprecedented. Ceritinib, another second-generation ALK inhibitor was approved as first-line therapy based on a trial showing its superiority to chemotherapy. In that trial the ceritinib PFS was 16.6 months.[37]

Brigatinib is the most recently approved ALK inhibitor. It was approved as second-line therapy for patients who had failed crizotinib. *In vitro* studies suggest that it is active against resistance mutations, but the clinical significance of this is unknown. Ceritinib, alectinib, and brigatinib are all approved as second line and choice depends on what was received in first-line therapy.

According to the guidelines, patients whose tumor harbors an *ROS1* mutation should be treated with crizotinib. Since this mutation is only present in ~1% of tumors it is relatively uncommon and we do not have randomized controlled trial data. The approval for crizotinib in this subset population came from a single arm trial where 50 ROS1+ patients had a remarkable response (6% CR and 66% PR) and PFS (19.2 months).[38] Although other agents inhibit this pathway, none have been compared to crizotinib and are not indicated at this time. After progression on crizotinib, patients should be treated with systemic chemotherapy or clinical trial.

A small number of lung cancer patients harbor a mutation in *BRAF*, where dabrafenib and trametinib are indicated. A pivotal single arm, phase II trial enrolled 57 previously treated patients and reported an overall response rate of 63%. The progression-free survival for this trial was 9.7 months with a median duration of response of 9 months. Similar to the *ROS1* population, this mutation is rare (~1% of patients) and consequently we don't have large randomized trials. However, nonrandomized comparison of dabrafenib to dabrafenib plus trametinib support the combination based on ORR (27% vs 63%), and duration of response (9.9 months vs 12.6 months).[39] For this population, dabrafenib and trametinib are recommended to be used first line. The other BRAF and MEK inhibitors do not have enough data to be used in this setting at this time. When patients fail dabrafenib and trametinib, they should be treated into the no targetable mutation pathway (see Figure 90–2).

Special Populations

Patients who cannot tolerate platinum can be treated with gemcitabine–paclitaxel or gemcitabine–docetaxel. Randomized trials have produced response durations and survival times similar to the platinum-containing doublet regimens. However, these regimens are only recommended for patients who are unlikely to tolerate the toxicity of platinum regimens owing to comorbidities or other factors.[9]

Patients with poor PS, defined as those with a PS of 2, is a subject of debate. Although patients with a PS of 2 typically have inferior survival rates and higher toxicity to platinum chemotherapy than higher performing patients, low-toxicity single-agent regimens may offer a survival advantage in this subset. Use of these regimens also presents a method of providing symptomatic care for advanced stage patients. Agents such as pemetrexed, gemcitabine, and docetaxel may be used in this scenario. In patients with a PS of 3 or 4, chemotherapy typically results in high rates of toxicity and fails to convey a survival benefit. Consequently, treatment should be aimed at relief of symptoms instead of a definitive cure. Because targeted agents typically have lower rates of severe toxicity, they also have been used in appropriate subsets of patients with a poor PS (ECOG PS of 2 or 3). Unfortunately, we do not have adequate clinical trial data regarding the efficacy and toxicity of immunotherapy or targeted agents in these patients. In summary, debilitated patients should not be treated with combination chemotherapy with or without targeted agents because of historically high rates of toxicity without benefit. Single-agent therapy with less toxicity can be used to help palliate symptoms.[9]

Duration of Therapy

Because advanced stage lung cancer is not curable, an argument can be made that the goal is to extend the number of quality days, rather than just overall survival. With this goal in mind and an assumption that quality of life is lower during chemotherapy treatment, it is important to consider the duration of therapy. Over the last decade, treatment has moved toward fewer chemotherapy cycles. Typical cytotoxic doublet therapy regimens have decreased from planning eight cycles to six cycles, to four cycles; however, maintenance therapy with a single cytotoxic chemotherapy agent or with targeted therapies or immunotherapies has become the standard.

The duration of therapy for patients with SCLC is four to six cycles of cytotoxic chemotherapy with or without radiation. First-line treatment beyond six cycles has not been shown to be beneficial. This means the duration of therapy in the absences of dose delays would be 3 to 4 months (standard 21-day cycle). Second-line therapy is generally continued until progression or intolerable toxicity.

The duration of therapy for NSCLC depends on which pathway and agents you are treated with. For patients with a PD-L1 positive tumor or those with a targetable genetic mutation the duration is clearest. First-line pembrolizumab is continued for 35 cycles or until toxicity or progression. This duration of therapy is not proven to be the best, but is the result of the study design in the single positive pivotal trial. All of the targeted therapies (oral TKIs) for targetable mutational drivers are continued until progression. Some people believe they provide value after progression, but this belief has not been tested in well-controlled trials.

The population that are PD-L1 negative and have a tumor without a targetable genetic mutation have a variety of practices that can generally be described as continuation maintenance or switch maintenance. As mentioned previously, platinum doublets are the historical standard. These regimens have been improved by adding a monoclonal antibody (bevacizumab, pembrolizumab, necitumumab). In these pivotal trials the monoclonal antibody was continued until progression or toxicity, which is considered continuation maintenance. The pembrolizumab maintenance was only continued for 2 years, although few patients made it that long until progression. When the cisplatin and pemetrexed study was performed, the pemetrexed was continued as monotherapy after completing the doublet therapy. This is also considered continuation maintenance and led to switch maintenance; treating patients with pemetrexed after six cycles of a platinum doublet not including pemetrexed. Key studies regarding maintenance therapy included patients who had a response or stable disease after four cycles of a platinum-based doublet and then randomized them to placebo or treatment. The pemetrexed switch maintenance study reported a 3-month survival advantage with maintenance therapy. A subgroup analysis of this study demonstrated that patients with squamous histology did not benefit from therapy leaving an overall survival benefit of 5 months for the nonsquamous cell group. Similarly, an erlotinib maintenance study reported a 1-month overall survival advantage, which does not appear as robust; however, the subset analysis showed benefit was much more likely in nonsmokers and those with adenocarcinoma histology and particularly in patients who had an activating mutation (exon 19 or 21). Similar to the pemetrexed study, patients whose tumor was of squamous cell histology did not appear to benefit from maintenance. There is some data suggesting a benefit gemcitabine or docetaxel maintenance for squamous histology patients. The NCCN

Patient Encounter Part 4

The patient is treated with pembrolizumab 200 mg IV q3weeks as first-line treatment. Six weeks after starting therapy a repeat CT scan is performed, which shows that the primary 3 cm lesion is now 5 cm in diameter.

Does that mean he has progressed on this treatment?

Discuss how this influences assessments moving forward and propose a treatment and monitoring plan.

guidelines report the level of evidence as 2b, which means there is a low level of evidende, but concensus that the treatment is appropriate.[9] In summary, the duration of therapy depends highly on treatment pathway, histology, and therapy; doublet cyctotoxic chemotherapy rarely exceeds six cycles, while monotherapy is commonly administered until progression except in patients with squamous cell histology.[9]

OUTCOME EVALUATION

LO 8

Evaluating outcomes is a goal-oriented process and should begin from that perspective. Patients with localized disease are treated with localized therapy with or without systemic therapy with curative intent as the goal. Monitoring for toxicity and recurrence on a regular basis is essential.

Following surgery or pharmacologic treatment, the patient should be monitored regularly to detect recurrence or progression of disease. Methods include a physical examination and chest x-ray every 3 to 4 months for 2 years. If no disease is detected during this time, follow-up frequency can be prolonged to every 6 months for 3 years and then annually. Low-dose spiral CT scanning is also recommended annually.[9]

For patients who have advanced stage disease, response of target lesions is performed with a radiologic scan every 6 to 8 weeks. Response Criteria In Solid Tumors (RECIST) is then applied to classify response as follows: complete remission (CR) is complete disappearance of tumor, partial remission (PR) is a reduction target tumor unilateral diameters by 30% or more, progressive disease (PD) is defined as new lesions or a growth of the target lesion diameter by more than 20%, and stable disease (SD) is defined by not meeting the PR or PD criteria. These criteria have been altered for patients on immune therapy because the checkpoint inhibitors have a delayed time to effect, which correlates to the pharmacology. It takes time to activate an exhausted T-cell population, once activated they migrate to and infiltrate the tumor. Combining the increased cell burden and inflammatory-related edema, tumors can appear larger on radiologic evaluation prior to responding. The revised criterion most commonly used is the immune RECIST (iRECIST). The big difference is that the first progression based on RESIST v1.1 criterion is considered an immune Unconfirmed Progressive Disease (iUPD). The confirmatory radiology would then occur 4 to 8 weeks later. Progressive disease is confirmed if target lesions grow. If they do not grow or shrink to any degree it would become the new set point and future scans would again progress through iUPD prior to having confirmed progressive disease.[49]

Smoking cessation counseling with or without pharmacologic treatment should be a priority. Although studies have shown that patients who continue to smoke through treatment in NSCLC do not perform more poorly compared with those that quit before treatment, those who respond to treatment and continue to smoke probably have an increased risk of developing secondary malignancies.[2] In contrast to NSCLC, some data suggest that SCLC patients with limited-stage disease have poorer outcomes if they continue to smoke during treatment.[17]

Patient Care Process

Collect Information:

- Determine stage and histology of cancer.
- Perform PD-L1 expression and mutation analysis if clinically indicated.

Assess the Information:

- Comorbidities and organ and hematological function.
- Starting doses and schedules of planned chemotherapy.
- Need for supportive care therapies.

Develop a Care Plan:

- Ensure the patient has access and insurance coverage for chemotherapy and supportive therapies.
- Educate the patient on expected outcomes, potential adverse effects, and their management.

Implement the Care Plan:

- Evaluate the appropriateness of a patient's regimen at every visit (every week, 3 weeks, or 4 weeks).
- Inquire about toxicity or issues.
- Include a medication reconciliation process.
- Laboratory and/or radiology evaluations can be prompted by the initial assessment or at a scheduled interval for the treatment regimen.
- Findings of tumor growth or significant toxicity should prompt a change in the therapeutic plan.
- Grade and monitor toxicity—Grade 3 or 4 toxicity (see Chapter 88) requires a change in therapy with the next cycle of treatment. Common changes include a chemotherapy dose reduction or pharmacologic intervention to prevent or treat the toxicity.
- Manage toxicity—*Knowing when and how to treat adverse events from therapy is an important aspect of patient care. Unmanaged events may cause delays in therapy administration and reduced therapy doses and may contribute to treatment failure.* This includes managing neutropenic episodes (see Chapter 99) and chemotherapy-induced nausea and vomiting (see Chapter 99). The emetogenic potential of selected chemotherapy regimens is listed in Chapter 99. For patients on immunotherapy, they must be monitored for immune-related adverse events with early recognition and intervention (see Chapter 88).
- Counsel patients on appropriate use and adherence of oral medications.

Follow-up: Monitor and Evaluate:

- Monitor for recurrence. Follow recommendations of the NCCN, as outlined in Outcome Evaluation.
- Smoking cessation plans. For NSCLC patients, all long-term care plans should include options and recommendations for smoking cessation (see Chapter 36).

For those with advanced disease, the goal of treatment is to prolong the duration of life, particularly the number of quality days. Ultimately, most lung cancer patients succumb to their disease. Palliative care involves management of symptoms and improvement of quality of life when curative treatment options are no longer available. Often, problematic metastases can be removed by surgery (depending on location) or can be treated with radiotherapy to reduce tumor size. In selecting options at this point in treatment, it is important to keep the goals of therapy (ie, maximizing the duration and quality of life) in mind. Low-toxicity single-agent chemotherapy, targeted therapy, and best supportive care (including fatigue and pain management) are commonly the mainstays of palliative care.

Abbreviations Introduced in This Chapter

5-FDG	5-Fluorodeoxyglucose
ALK	Anaplastic lymphoma kinase
BRAF	A proto-oncogene kinase that is a sarcoma viral oncogene homolog B
CT	Computed tomography
ECOG	Eastern Cooperative Oncology Group
EGF	Epidermal growth factor
EGFR	Epidermal growth factor receptor
EML4	Echinoderm microtubule-associated protein-like 4
EP	Etoposide–cisplatin
ETS	Environmental tobacco smoke
NSCLC	Non–small cell lung cancer
PCI	Prophylactic cranial irradiation
PD1	Programmed cell death protein 1 receptor
PD-L1	Programmed death ligand 1 (aka B7-H1 and CD274)
PET	Positron-emission tomography
PS	Performance status
ROS1	ROS Proto-Oncogene 1, Receptor Tyrosine Kinase
SCLC	Small cell lung cancer
TNM	Tumor, node, and metastasis staging
VEGF	Vascular endothelial-derived growth factor

91 Colorectal Cancer

Emily B. Borders and Allison Baxley

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Identify the risk factors for colorectal cancer.
2. Outline preventive and screening strategies for individuals at average and high risk for colorectal cancer.
3. Recognize the signs and symptoms of colorectal cancer.
4. Describe the treatment options for colorectal cancer based on patient-specific factors, such as stage of disease, age of patient, genetic mutations, and previous treatment received.
5. Outline the pharmacologic principles for agents used to treat colorectal cancer.
6. Develop a monitoring plan to assess the efficacy and toxicity of agents used in colorectal cancer.
7. Educate patients about the adverse effects of chemotherapy that require specific patient counseling.

INTRODUCTION

Colorectal cancer is one of the four most common cancers diagnosed in the United States and includes cancers of the colon and rectum. In 2018, an estimated 140,250 new cases of colorectal cancer are expected to be diagnosed, with an estimated 50,680 deaths expected, making colorectal cancer the second leading cause of cancer-related deaths in the United States.[1] The prognosis is primarily determined by the stage of disease with the majority of patients with early stage (I or II) disease cured. Treatment options for colorectal cancer include surgery, radiation, chemotherapy, and targeted molecular therapies.

EPIDEMIOLOGY AND ETIOLOGY

Colorectal cancer occurs more frequently in industrialized regions such as North America and Europe, while the lowest rates are seen in less-developed areas, suggesting that environmental and dietary factors influence the development of colorectal cancer. In addition to environmental factors, colorectal cancers develop more frequently in certain families, and genetic predisposition to this cancer is well known.

The incidence of colorectal cancer in men is approximately 1.3 times greater than observed in women. Overall, colon and rectal cancers make up approximately 12% of all cancer diagnoses in men and women in the United States. The median age at diagnosis is 67 years with very few cases occurring in individuals younger than 45 years of age.[2] KEY CONCEPT Age appears to be the biggest risk factor for the development of colorectal cancer with 57% of cases diagnosed in adults older than 65 years of age.

Although still the second leading cause of cancer death, mortality rates for colorectal cancer have declined over the past 30 years as a result of better and increasingly used screening modalities and more effective treatments.

RISK FACTORS

LO 1

In addition to age, dietary or environmental factors, inflammatory bowel disease, and genetic susceptibility increase the risk of colorectal cancer. Table 91–1 lists well-known risk factors for developing colorectal cancer.

KEY CONCEPT Diets high in fat and low in fiber are associated with increased colorectal cancer risk. While data is not entirely consistent, long-term consumption of red and processed meats is associated with an increased risk of colorectal cancer. A large pooled analysis of 13 prospective cohort studies found dietary fiber intake to be inversely associated with the risk of colorectal cancer; however, upon multivariate analysis for other dietary risk factors, the benefit was no longer observed.[3] This analysis does not consider the known benefits of a fiber-rich diet for noncancerous conditions such as diabetes and coronary artery disease.

Foods that are high in fiber include vegetables, fruit, and grains. The protective effects of fiber may be a result of reduced absorption of carcinogens in the bowel, reduced bowel transit time, or a reduction in dietary fat intake associated with high-fiber diets.[3]

Physical inactivity and elevated body mass index (BMI) are associated with up to a twofold increase in the risk of colorectal cancer. Decreased bowel transit time and exercise-induced alterations in body glucose, insulin levels, and other hormones may reduce tumor cell growth.[4,5] Type 2 diabetes mellitus, independent of body mass size and physical activity level, is also associated with an increased risk of colorectal cancer in women and supports a role for hyperinsulinemia as a possible link between obesity, sedentary lifestyle, diabetes mellitus, and colorectal cancer.[5] Additional lifestyle choices that increase the risk of colorectal cancer include alcohol consumption and smoking which may increase the risk of colorectal cancer by generating carcinogens with direct toxic effects on bowel tissue.[4]

Table 91–1

Risk Factors for Colorectal Cancer

General	
	Age is the primary risk factor
Dietary	
	High-fat, low-fiber diets
Lifestyle	
	Alcohol
	Smoking
	Obesity or physical inactivity
Comorbid Conditions	
	Inflammatory bowel disease (ulcerative colitis and Crohn disease)
Hereditary or Genetic	
	FAP and HNPCC
	Family history

FAP, familial adenomatous polyposis; HNPCC, hereditary nonpolyposis colorectal cancer.

Inflammatory bowel diseases, such as chronic ulcerative colitis, particularly when it involves the entire large intestine, and to lesser extent Crohn disease, confer increased risk for colorectal cancer. Overall, individuals with inflammatory bowel disease account for about 1% to 2% of all new cases of colorectal cancer each year.

Finally, as many as 10% of cases are thought to be hereditary. The two most common forms of hereditary colorectal cancer are familial adenomatous polyposis (FAP) and hereditary nonpolyposis colorectal cancer (HNPCC). FAP is a rare autosomal dominant trait that is caused by mutations of the **adenomatous polyposis coli (*APC*)** gene and accounts for 1% of all colorectal cancers. The disease is manifested by hundreds to thousands of **polyps** arising during adolescence.[6] The risk of developing colorectal cancer for individuals with untreated FAP is virtually 100%, and patients require early screening for the disease and likely prophylactic total colectomy. HNPCC, also an autosomal dominant syndrome, accounts for up to 5% of colorectal cancer cases.[6] In contrast to FAP, juvenile polyps occur rarely, and the average age of colorectal cancer in these patients is closer to that of average risk patients, with most patients diagnosed in their 40s. Testing for HNPCC mutations is available but reserved for individuals who meet strict diagnostic criteria.

Up to 25% of patients who develop colorectal cancer have a family history of colorectal cancer unrelated to a mutation described earlier.[7] First-degree relatives of patients diagnosed with colorectal cancer have an increased risk of the disease that is at least two to four times that of persons in the general population without a family history.

Summary of Risk Factors

In summary, the true association between most dietary factors and the risk of colorectal cancer is unclear. The protective effects of fiber and a diet low in fat are not completely known at this time. Physical inactivity, alcohol use, and smoking appear to increase the risk of colorectal cancer. Clinical risk factors and genetic mutations are well-known risks for colorectal cancer.

SCREENING

LO 2

KEY CONCEPT Effective colorectal cancer screening programs incorporate annual fecal occult blood testing or regular examination of the entire colon starting at age 50 years for average-risk individuals and should be recommended by all health care providers. Appropriate screening of patients at normal and high risk for colorectal cancer leads to the detection of smaller, localized lesions and higher cure rates.[8] Screening techniques include fecal occult blood tests (FOBTs) and imaging of the colon. The use of FOBTs annually in combination with digital rectal examinations has led to diagnosis of early stages of disease and may reduce colorectal cancer mortality by up to one-third.[8] However, FOBT using a single stool sample collected during a digital rectal examination is not a recommended option for screening because this method has a decreased sensitivity for detecting advanced disease.[7] Recommendations for adequate FOBT require the patient to collect two stool samples from three consecutive specimens using at-home testing procedures.[8] Two main methods are available to detect occult blood in the feces: guaiac dye and immunochemical methods. The Hemoccult II is the most commonly used FOBT in the United States and is a guaiac-based test. Proper counseling by health care providers is required to receive accurate test results. Consumption of red meat, blood sausages, peroxidase-containing vegetables, iron products, or nonsteroidal anti-inflammatory drugs (NSAIDs) may result in false-positive results. Vitamin C and dehydrated samples may lead to false-negative results. These products should be avoided for 3 days prior to testing. Fecal immunochemical tests (FITs) (InSure and others), which use antibodies to detect hemoglobin, are also available for use. Though more expensive, an advantage of FITs is that they do not react with dietary factors or medications. Both FOBTs can be recommended in screening protocols for patients.

Imaging of the colon with a sigmoidoscopy, colonoscopy, or CT colonography is recommended every 5 to 10 years for most individuals. Colonoscopy is the preferred procedure as it allows for greater visualization of the entire colon and simultaneous removal of lesions found during screening.[8] A sigmoidoscopy only examines the lower half of the colon, and a double-contrast barium enema requires a supplemental colonoscopy to remove any lesions found during the screening process. Several revisions to the colorectal cancer screening guidelines have been made in an attempt to increase the compliance to screening guidelines. These include the use of computed tomographic colonography (CTC) and stool

Patient Encounter Part 1

A 68-year-old man presents to your clinic with a chief complaint of fatigue, abdominal discomfort, and occasional diarrhea and blood in his stool for 3 months. He has a medical history positive for chronic back pain, hyperlipidemia, hypertension, and obesity. He states that he consumes a moderate amount of alcohol (three to four beers most days of the week after work), is a previous smoker (quit over 20 years ago), and has tried to eat healthy the last month because his wife cooks and is concerned for his weight. Previously his diet mostly consisted of red meat and fried foods. Additionally he is unable to work or exercise due to back injury.

What risk factors does this patient have for colon cancer?

Does he have clinical symptoms suggestive of colon cancer?

What additional tests need to be ordered to diagnosis colon cancer?

Table 91–2

Colon Cancer Screening Guidelines

Average risk	Annual FOBT or FIT after age 50 years Stool DNA testing may be used as an alternative *or* One of the following after age 50 years: Sigmoidoscopy every 5 years Colonoscopy every 10 years CTC every 5 years
Family history	Screening at ages 40 years or 10 years before the youngest case in the immediate family, whichever is earlier
HNPCC	Screening at age 20–25 years or 10 years before the youngest case in the immediate family, whichever is earlier
FAP	Screening at ages 10–12 years
IBD	8 years after the onset of pancolitis; 12–15 years after onset of left-sided colitis

CTC, computed tomographic colonography; FAP, familial adenomatous polyposis; FIT, fecal immunochemical tests; FOBT, fecal occult blood tests; HNPCC, hereditary nonpolyposis colorectal cancer; IBD, inflammatory bowel disease.

DNA testing as acceptable screening methods. CTC, also known as "virtual colonoscopy," uses integrated two- and three-dimensional images to detect and characterize polyps. Although noninvasive compared with colonoscopy, adequate bowel preparation, which is often cited as the reason for noncompliance, is still required. In addition, any lesions found on examination require a follow-up colonoscopy.

Stool DNA testing detects molecular markers associated with advanced colorectal cancer. Because this test is not dependent on the detection of bleeding, which can be sporadic, it requires only a single stool collection. How often and what molecular markers to test for are undergoing further evaluation. KEY CONCEPT Table 91–2 is a summary of the current NCCN guidelines for screening and surveillance for early detection of colorectal polyps and cancer.[8]

COLORECTAL CANCER PREVENTION

There are currently no pharmacologic agents approved for colorectal cancer prevention. Strategies under investigation to prevent colorectal cancer include pharmacologic and surgical interventions and involve either preventing the initial development of colorectal cancer (primary prevention) or preventing cancer in patients who demonstrate early signs of colorectal cancer (secondary prevention).

The most widely studied agents for the chemoprevention of colorectal cancer are agents that inhibit cyclooxygenase-2 (COX-2) (aspirin, NSAIDs, and selective COX-2 inhibitors) and calcium supplementation.[9] Individual studies have demonstrated that regular (at least two doses per week) NSAID and aspirin use is associated with a 20% to 40% reduction in risk of colorectal cancer in individuals at average risk.[10,11] However, a meta-analysis of over 40 trials suggests the benefit of these agents may be limited to individuals at high risk for developing colorectal cancer.[12] Chronic use of aspirin and other NSAIDs are associated with significant potential adverse effects, including gastrointestinal (GI) and cardiovascular toxicities. These risks limit health care professionals from routine recommendations for use in patients of average risk for colorectal cancer.

The risk of colorectal cancer appears to be inversely related to calcium and folate intake. Calcium supplementation appears to be associated with a moderate reduction in risk of recurrent colorectal adenomas with prospective studies demonstrating a nonstatistical decrease in adenoma recurrence, its role as a chemoprevention agent in the average-risk patient remains under investigation.[9,12]

Additional agents, including selenium and folic acid, show promise as chemopreventive agents in colorectal cancer and preliminary, and confirmatory studies evaluating their effectiveness have been completed or are ongoing.[9] Exogenous hormone use, particularly postmenopausal hormone replacement therapy, is associated with a significant reduction in colorectal cancer risk in most studies with the greatest benefit in women who are on current hormone replacement therapy.[13] Unfortunately, the known risks of hormone replacement therapy outweigh this benefit, and routine use of hormone replacement therapy to prevent colorectal cancer is not recommended.

Surgical resection remains an option to prevent colorectal cancer in individuals at extremely high risk for its development such as patients diagnosed with FAP. Individuals with FAP who are found to have polyps on screening examinations require total abdominal colectomy. In addition, removal of noncancerous polyps detected during screening colonoscopy is considered the standard of care to prevent the progression of premalignant polyps to cancer.

PATHOPHYSIOLOGY

Anatomy and Bowel Function

The large intestine consists of the cecum; ascending, transverse, descending, and sigmoid colon; and rectum (Figure 91–1).

Four major tissue layers, from the lumen outward, form the large intestine: the mucosa, submucosa, muscularis externa, and serosa. Complete replacement of surface epithelial cells occurs every 7 to 10 days with the total number of epithelial cells remaining constant in normal colonic tissue. As patients age, abnormal cells accumulate on the surface epithelium and protrude into the stream

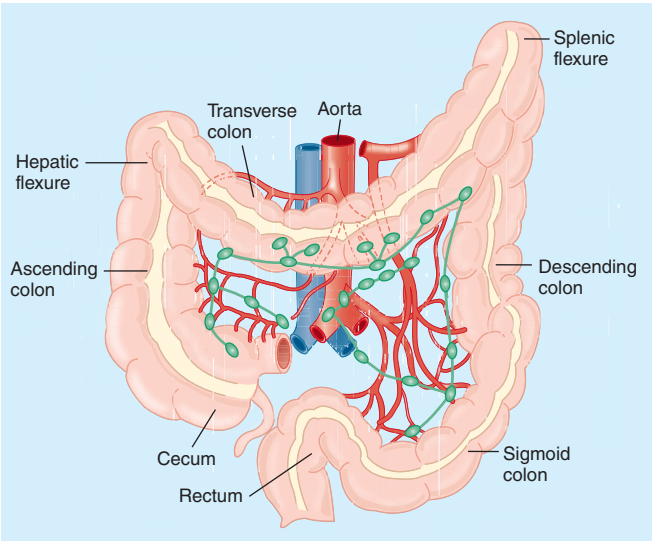

FIGURE 91–1. Colon and rectum anatomy. (From Davis LE, Sun W, Medina PJ. Colorectal Cancer. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill, 2014; Figure 107–2.)

of fecal matter; their contact with fecal mutagens can lead to further cell mutations and eventual adenoma formation.[6]

Colorectal Tumorigenesis

The development of a colorectal neoplasm is a multistep process of several genetic and phenotypic alterations of normal bowel epithelium leading to unregulated cell growth, proliferation, and tumor development. A genetic model has been proposed for colorectal tumorigenesis that describes a process of transformation from adenoma to carcinoma. This model of tumor development reflects an accumulation of mutations within colonic epithelium that gives a selective growth advantage to the cancer cells.[6] Genetic changes include activating mutations of **oncogenes**, mutations of **tumor suppressor genes**, and defects in **DNA mismatch repair genes**.

Additional genes and protein receptors are believed important in colorectal tumorigenesis. COX-2, which is induced in colorectal cancer cells, influences apoptosis and other cellular functions in colon cells, and overexpression of the EGFR, a transmembrane glycoprotein involved in signaling pathways that affect cell growth, differentiation, proliferation, and angiogenesis, occurs in the majority of colon cancers.[14] These mechanisms are potentially important because of the availability of pharmacologic agents targeted to inhibit these processes.

CLINICAL PRESENTATION AND DIAGNOSIS

LO 3

The signs and symptoms associated with colorectal cancer can be extremely varied, subtle, and nonspecific. Most patients are asymptomatic but may develop changes in bowel or eating habits, fatigue, abdominal pain, and blood in the stool.

LO 3

Clinical Presentation and Diagnosis of Colorectal Cancer

General

Patients are often asymptomatic in early stages of disease

Symptoms

Changes in bowel habits, abdominal pain, anorexia, nausea and vomiting, weakness (if anemia is severe), and tenesmus

Signs

Blood in stool and weight loss

Laboratory Tests

- Patients may have a low-hemoglobin level from blood loss
- Positive FOBT
- Liver function tests (INR, activated partial thromboplastin time, and bilirubin) may be abnormal if disease has metastasized to the liver
- CEA level may be high; normal level is less than 2.5 ng/mL (2.5 mcg/L) in nonsmokers and less than 5 ng/mL (5 mcg/L) in smokers

Imaging Tests

Chest x-ray, CT scan, or PET scan results may be positive if cancer has spread to the lungs, liver, or peritoneal cavity

TREATMENT

Desired Outcomes

Patients are staged with the tumor, node, metastasis (TNM) classification system (see Chapter 88) to determine treatment options and assess prognosis. **Figure 91–2** depicts how the three categories are used in combination to determine the stage of disease. KEY CONCEPT The stage of colorectal cancer upon diagnosis is the most important prognostic factor for survival and disease recurrence. Stages I, II, and III disease are considered potentially curable and are aggressively treated in an attempt to cure these patients. Patients who develop stage IV disease are treated to reduce symptoms, avoid disease-related complications, and prolong survival.

General Approach to Treatment

LO 4

The treatment approaches for colorectal cancer reflect two primary treatment goals: curative therapy for localized disease (stages I–III) and palliative therapy for metastatic cancer (stage IV). Surgical resection of the primary tumor is the most important part of therapy for patients in whom cure is possible.[16] Depending on the stage of disease and whether the tumor originated in the colon or rectum, further **adjuvant** chemotherapy or chemotherapy plus radiation may be needed after surgery to cure these patients. In the metastatic setting, pharmacologic intervention is the main treatment option.

Pharmacogenetic and pharmacogenomic testing has become an integral component to designing the optimal pharmacologic intervention for patients with colorectal cancer. The choice of treatment agents is largely dictated by individualized patient and tumor-specific factors. For example, data have demonstrated specific tumor characteristics that may assist clinicians in predicting who will respond to EGFR inhibitors. Early immunohistochemical staining for EGFR status is not useful in predicting response because both EGFR-positive and EGFR-negative patients respond at the same rate. However, *RAS* gene mutation status has demonstrated predictive value. Patients should be tested for both *KRAS* and *NRAS*; patients with mutated *RAS* are unlikely to benefit from cetuximab or panitumumab therapy.[15] In particular, testing for *RAS* mutational status is now part of the disease workup to define patients who may derive benefit from cetuximab or panitumumab. Characteristics of the tumor are also vital in making treatment decisions for patients with stages II and III disease. The degree of **microsatellite instability (MSI)** within a tumor tells clinicians information about both prognosis and treatment options. More detail on specific pharmacogenetic and pharmacogenomic information is provided in the pertinent pharmacologic therapy sections.

Nonpharmacologic Therapy

▶ *Operable Disease (Stages I–III)*

Surgery Individuals with stages I to III colorectal cancer should undergo a complete surgical resection of the tumor mass with removal of regional lymph nodes as a curative approach for their disease.[16] Surgery for rectal cancer depends on the region of tumor involvement with attempts to retain rectal function as a goal of the surgical procedure. Overall, surgery for colorectal cancer is associated with low morbidity and mortality rates. Common complications include infection, anastomotic leakage, obstruction, adhesion formation, and malabsorption syndromes.

Radiation Therapy There is currently no role for adjuvant radiation in colon cancer. However, patients who receive surgery

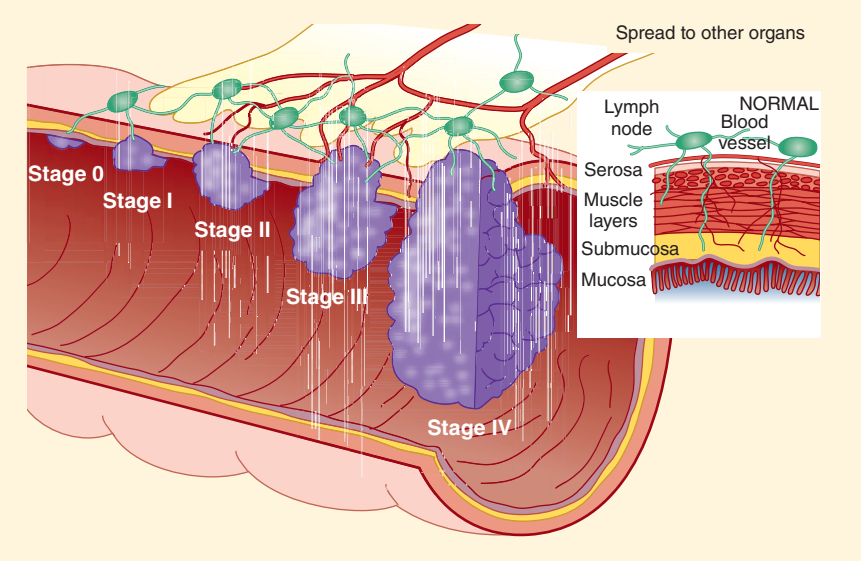

FIGURE 91–2. Stage I: cancer is confined to the lining of the colon. Stage II: cancer may penetrate the wall of the colon into the abdominal cavity but does not invade any local lymph nodes. Stage III: cancer invades one or more lymph nodes but has not spread to distant organs. Stage IV: cancer has spread to distant locations in the body, which may include the liver, lungs, or other sites. (From National Cancer Institute, Washington, DC.)

for rectal cancer receive radiation therapy to reduce local tumor recurrence. Adjuvant radiation plus chemotherapy is considered standard treatment for patients with stage II or III rectal cancer after the surgical procedure is complete.[17] Preoperative radiation may be used to reduce the initial size of rectal cancers to make the surgical procedure less extensive.

▶ *Metastatic Disease (Stage IV)*

Surgery Unlike stages I to III disease, the benefit of surgical resection in most patients with metastatic disease is limited to symptomatic improvement. Selected patients who have one to three small nodules isolated to the liver, lungs, or abdomen may have a prolongation of survival, although cure is rare. Five-year survival for patients who undergo surgical resection of metastases isolated to the liver is approximately double that of patients who are not surgical candidates with approximately 33% of patients alive at 5 years.[18] Alternatives to surgery include destroying the tumor through freezing and thawing (cryoablation), heat (radiofrequency), or alcohol injection, although these appear to be less successful than surgical resection.[16,18] Because the majority of these patients will relapse, many practitioners offer adjuvant chemotherapy to select patients following potentially curative resection, but further studies are needed to determine an optimal treatment regimen.[18]

Radiation Symptom reduction is the primary goal of radiation for patients with advanced or metastatic colorectal cancer.

Pharmacologic Therapy

Table 91–3 lists common chemotherapy regimens used in colorectal cancer and the abbreviations used in the literature to describe them.

▶ *Operable Disease (Stages I–III)*

KEY CONCEPT Adjuvant chemotherapy is administered after tumor resection to decrease relapse rates and improve survival in patients with colon cancer by eliminating micrometastatic disease that is undetected on imaging studies. Patients diagnosed with stage I colon or rectal cancer are usually cured by surgical resection,

Patient Encounter Part 2

PMH: Chronic back pain since 50 years, hyperlipidemia since 35 years, hypertension since age 36 years; obesity; the patient is 40% over his ideal body weight.

FH: Father died at age 78 years after a myocardial infarction; mother is living; older brother with testicular cancer; maternal uncle died at age 53 years from rectal cancer.

SH: Does not work. Previously an electrician. Married with two grown children.

Meds: Lisinopril/HCTZ 25 mg daily; amlodipine 10 mg daily; pravastatin 40 mg daily, tramadol 100 mg daily.

ROS: (+) Abdominal cramping, diarrhea, blood in stool, and fatigue.

PE:

VS: 138/84 mm Hg, P 80 beats/min, RR 18 breaths/min, T 37.1°C (98.8°F), Ht 187 cm (74 in), Wt 115 kg (253 lb).

Abd: Distended and tender to touch, (+) bowel sounds.

Labs: Positive hemoglobin 11.8 g/dL (118 g/L or 7.32 mmol/L) decreased from 13.4 g/dL (134 g/L or 8.32 mmol/L) last year. Positive lipid panel: triglycerides 250 mg/dL (13.9 mmol/L).

Imaging and Diagnostic Studies

- Colonoscopy revealed multiple polyps in his transverse colon.
- Biopsy revealed three polyps positive for adenocarcinoma of the colon.
- Staging CT scan negative for disease outside of the colon.
- Four lymph nodes positive for disease.

Because the patient has stage III colon cancer, how does this affect the goal of your treatment plan compared with stage IV disease?

What nonpharmacologic and pharmacologic options are available to this patient?

Table 91–3

Dosing Schedules of Chemotherapy Regimens for Colon Cancer[a]

Regimen	Dosing
5-FU + leucovorin (continuous infusion)	Leucovorin 200 mg/m^2 IV 5-FU 400 mg/m^2 IV bolus and then 600 mg/m^2 of 5-FU as a 22-hour continuous infusion on days 1 and 2; repeat every 2 weeks
FOLFIRI	Irinotecan 180 mg/m^2 IV day 1 Folinic acid (leucovorin) 400 mg/m^2 IV day 1 5-FU 400–500 mg/m^2 IV bolus after folinic acid; then 2400–3000 mg/m^2 of 5-FU IV over 46 hours Repeat every 14 days
FOLFOX4	Oxaliplatin 85 mg/m^2 IV + leucovorin 200 mg/m^2 IV followed by 5-FU 400 mg/m^2 IV bolus and then 5-FU 600 mg/m^2 IV over 22 hours day 1 Leucovorin 200 mg/m^2 IV, followed by 5-FU 400 mg/m^2 IV bolus and then 5-FU 600 mg/m^2 IV over 22 hours day 2 Repeat every 2 weeks
mFOLFOX6	Oxaliplatin 85 mg/m^2 IV day 1 Leucovorin 400 mg/m^2 IV over 2 hours, followed by 5-FU 400 mg/m^2 IV bolus day 1 followed by 2400 mg/m^2 IV over 48 hours Repeat every 2 weeks
FOLFOXIRI	Irinotecan 165 mg/m^2 IV day 1 Oxaliplatin 85 mg/m^2 IV day 1 Leucovorin 200 mg/m^2 IV over 2 hours, followed by 5-FU 3200 mg/m^2 IV over 48 hours Repeat every 2 weeks
Bevacizumab + 5-FU regimen	Bevacizumab 5 mg/kg IV every 2 weeks + a 5-FU–containing regimen (FOLFOX, FOLFIRI, or 5-FU + leucovorin) Bevacizumab 7.5 mg/kg IV every 3 weeks with CapeOX
Cetuximab ± irinotecan	Cetuximab 400 mg/m^2 IV first infusion, then 250 mg/m^2 weekly ± irinotecan 125 mg/m^2 IV every week for 4 weeks Repeat irinotecan every 6 weeks (after a 2-week break)
Panitumumab	6 mg/kg IV every 2 weeks
Capecitabine	1250 mg/m^2 twice a day orally for 14 days Repeat every 3 weeks
CapeOX	Capecitabine 1000 mg/m^2 twice a day orally for 14 days Oxaliplatin 130 mg/m^2 IV on day 1 Repeat every 3 weeks

[a]Note that many variations exist, and current literature should be checked before administering any chemotherapy regimen.

5-FU, 5-fluorouracil; CapeOX, capecitabine–oxaliplatin; IV, intravenous.

and adjuvant chemotherapy is not indicated in these patients.[16] The role of adjuvant chemotherapy for stage II colon cancer is controversial but may benefit certain high-risk groups. Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer. Table 91–4 lists adjuvant treatment regimens based on stage and performance status (PS). Adjuvant chemotherapy for patients with stage II disease has not been shown to be superior to surgery alone with the possible exception of high-risk patients, including those with inadequate nodes sampled for staging, bowel perforation upon diagnosis, T4 lesions, and those with unfavorable histology.[15] The risks and benefits of adjuvant chemotherapy should be discussed with medically fit patients who have stage II disease with high-risk features. However, the American Society of Clinical Oncology does not recommend the routine use of adjuvant chemotherapy in the general patient population unless part of a clinical trial.[19]

There is currently insufficient data to recommend the use of tumor gene profiling to determine need for adjuvant therapy in stage II disease, but it is an area of active research.[15] An additional consideration for deciding on adjuvant therapy is the status of MSI within the tumor. MSI results from defective DNA mismatch repair (dMMR) genes leading to damaged DNA. Patients with tumors that display high levels of MSI may have better prognosis than patients with microsatellite-stable (MSS) tumors. Despite being associated with a better prognosis, tumors that display high levels of MSI (MSI-H) do not respond as well to certain chemotherapy, including 5-fluorouracil (5-FU).[20] It is recommended that stage II patients should be tested for the status of MSI if 5-FU is being considered for therapy, and an

Table 91–4

Treatment Regimens for Adjuvant Colon Cancer

Stage II[a]	Stage III
High Risk • Capecitabine or 5-FU plus leucovorin • FOLFOX • CapeOx • FLOX	**Good Performance Status** • FOLFOX • CapeOX • FLOX • Capecitabine or 5-FU plus leucovorin
Low Risk[b] • Observation or clinical trial • Capecitabine or 5-FU plus leucovorin	**Poor Performance Status** • Capecitabine

[a]Individualized assessment of patient risk is necessary to determine if treatment is required. Clinical trials or observation may be an appropriate option.

[b]T3 lesions may be considered high risk by some clinicians.

5-FU, 5-fluorouracil.

alternative therapy should be considered if high levels of MSI are displayed.[15] In general, patients with stage II colon cancer should be enrolled into clinical trials to assess the impact of new agents and prognostic models.

Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer. The presence of lymph node involvement in the resected specimen places patients with stage III colon cancer at high risk for relapse; the risk of death within 5 years of surgical resection alone is as high as 70%.[16] In this population of patients, adjuvant chemotherapy significantly decreases the risk of cancer recurrence and death and is considered the standard of care.

KEY CONCEPT 5-FU, leucovorin, and oxaliplatin (FOLFOX)–based chemotherapy is the standard regimen used in adjuvant colon cancer. It is usually given for 6 months. Refer to Tables 91–3 and 91–4 for recommended treatment regimens and schedules. 5-FU alone results in a small improvement in survival that can vary based on the method of 5-FU administration and the status of MSI.[20]

The combination of 5-FU plus leucovorin has undergone extensive study in the adjuvant setting with decreased rates of recurrence and improved survival seen in patients receiving 5-FU plus leucovorin compared with surgery alone. Though various schedules of 5-FU and leucovorin can be administered, continuous infusions may be less toxic and have improved response rates (although no survival advantage) compared with bolus regimens. Capecitabine is an oral prodrug of 5-FU that is also effective in the adjuvant setting and is being used as a replacement in certain regimens for 5-FU. Data suggest that capecitabine is at least equivalent to bolus 5-FU and leucovorin in efficacy and is better tolerated by patients in the adjuvant setting.[21] An increase in hand–foot syndrome and decreased mucositis and neutropenia are seen with capecitabine compared with bolus 5-FU.

More often, 5-FU or capecitabine is administered as part of a combination regimen with oxaliplatin and leucovorin (FOLFOX or CapeOx). FOLFOX is considered standard of care for patients with stage III disease unless their PS is so poor that clinicians do not believe the patients could tolerate intensive combination therapy. Every effort should be made to minimize adverse treatment effects and use this regimen in patients with stage III colon cancer because this is the only regimen demonstrated to improve overall survival in these patients.[16,22] Several variations on the original FOLFOX regimen have been studied with mFOLFOX6 being the most routinely used in clinical practice (refer to Table 91–4). CapeOx resulted in improved disease-free survival (DFS) compared with bolus 5-FU–leucovorin, but no overall survival benefit in stage III patients and is considered an acceptable adjuvant regimen in this patient population.[15,23]

Targeted therapies, including cetuximab and bevacizumab, have been evaluated for their role in their adjuvant treatment of colon cancer. At this time, no targeted agents are approved for use as adjuvant therapy in stage II or III colorectal cancer patients. Additionally, irinotecan should not be used in the adjuvant setting because its addition to 5-FU–based regimens has increased toxicity without therapeutic benefit.[15]

▶ *Metastatic Disease (Stage IV)*

Traditional chemotherapy and targeted biological therapies are the mainstay of treatment for metastatic colon or rectal cancer and have improved the median survival time of these patients to more than 2 years.[16] Most often, a combination of chemotherapy agents with biological therapies is administered to these patients. Currently, metastatic colorectal cancer is incurable, and treatment goals are to reduce patients' symptoms, improve quality of life, and extend survival. Combination chemotherapy regimens have been demonstrated to result in prolongation of survival with tolerable adverse effects. Similar to the adjuvant setting, 5-FU plus leucovorin continues to be in most first-line chemotherapy regimens used for metastatic colorectal cancer. A variety of continuous intravenous (IV) infusion 5-FU and bolus regimens can be used; however, compared with IV bolus 5-FU, response rates with continuous infusion 5-FU are approximately doubled. In a large meta-analysis of patients with advanced colorectal cancer, continuous infusions of 5-FU had a significantly higher tumor response rate, a small increase in survival, and lower incidence of myelosuppression, diarrhea, and mucositis when compared with bolus regimens.[24]

Additional agents including irinotecan and oxaliplatin have been added to the 5-FU and leucovorin regimen with superior response and survival rates compared to the two drugs used alone.[25,26] A large European study compared a combined bolus and infusional 5-FU regimen plus irinotecan (FOLFIRI) with the FOLFOX regimen (using a slightly different schedule) with crossover to the opposite arm upon relapse.[27] No difference in patient survival was seen with either regimen, and toxicity was as expected. Neuropathy and neutropenia were more common with FOLFOX, while diarrhea, nausea, vomiting, dehydration, and febrile neutropenia were more common with FOLFIRI. Based on improved survival data with the FOLFOX and FOLFIRI regimens, irinotecan-based regimens should only be administered outlined as described in Table 91–3.

Capecitabine also has activity in the metastatic setting. When combined with oxaliplatin in regimens known as CapeOx or XELOX, capecitabine appears to be as safe as 5-FU–based regimens.[15] Additionally, **progression-free survival** (PFS) with CapeOX is similar to that of FOLFOX and is considered noninferior to the FOLFOX regimen as first-line therapy in advanced disease.[28] This noninferiority with capecitabine may be specific to its use with oxaliplatin because capecitabine in combination with irinotecan (CAPIRI) demonstrated decreased PFS compared with FOLFIRI and the routine substitution of 5-FU with capecitabine in irinotecan-based regimens is not recommended.[15,29]

5-FU plus leucovorin, or capecitabine alone, are appropriate first-line treatment options for individuals for whom three-drug combination regimens are believed to be toxic. The site(s) of tumor involvement, history of prior chemotherapy, and patient-specific factors help define the appropriate management strategy. KEY CONCEPT The most important factor in patient survival is not the initial regimen but whether or not patients receive all three active chemotherapy drugs (5-FU, irinotecan, and oxaliplatin) at some point in their treatment course.[30] Some clinicians choose to use all three agents in combination in the first-line setting in a regimen termed FOLFOXIRI, although only in patients who are able to tolerate intensive therapy.

Targeted or biologic agents are approved for use in metastatic colorectal cancer. Bevacizumab in combination with IV 5-FU–based chemotherapy (either FOLFOX or FOLFIRI) is approved by the FDA for initial treatment of patients with metastatic colorectal cancer. Results from randomized trials show increased benefit compared with chemotherapy alone.[15] The efficacy of bevacizumab in this patient population shows the relevance of **angiogenesis** as an important target for the treatment of metastatic colorectal cancer. The addition of bevacizumab to first-line oxaliplatin-based chemotherapy has also been demonstrated to improve PFS but did not positively impact response rates

or overall survival.[31] Similar results were demonstrated with bevacizumab in combination with capecitabine and oxaliplatin.[42]

Based on these results, bevacizumab is recommended as part of 5-FU–based chemotherapy regimens used for the first-line treatment of metastatic colorectal cancer unless contraindicated. Bevacizumab is contraindicated in patients with GI perforation or fistulas involving a major organ, recent (within 28 days) major surgeries or open wounds, wound dehiscence requiring medical intervention, hypertensive crisis or uncontrolled severe hypertension, hypertensive encephalopathy—serious bleeding, a severe arterial thromboembolic event, moderate or severe proteinuria (urine protein excretion 2 g/24 hours or more), nephrotic syndrome, and reversible posterior leukoencephalopathy syndrome.

Monoclonal antibody EGFR inhibitors, cetuximab and panitumumab, demonstrate improved PFS as first-line therapy in the metastatic setting when individually combined with either the FOLFOX or FOLFIRI regimens in *KRAS* wild-type individuals.[32-35] KEY CONCEPT Before using these agents, testing for KRAS mutation status should occur. Extensive literature exists demonstrating poor response rates of EGFR inhibitors in patients whose tumors have a mutation in codon 12 or codon 13 of the *KRAS* gene.[15,36] Consequently, cetuximab or panitumumab may be used in the first-line setting in combination with traditional chemotherapy agents in *KRAS* WT patients only.[15]

Attempts to combine the vascular endothelial growth factor (VEGF) inhibitor bevacizumab with cetuximab and panitumumab as part of traditional chemotherapy regimens have resulted in inferior outcomes to regimens with bevacizumab alone.[37] Based on these results, the use of bevacizumab with either EGFR inhibitor is not recommended.[15]

KEY CONCEPT In summary, most practitioners select first-line treatment for metastatic colorectal cancer from among these treatments: oxaliplatin plus 5-FU plus leucovorin (FOLFOX); irinotecan plus 5-FU plus leucovorin (FOLFIRI); capecitabine plus oxaliplatin (CapeOx or XELOX); oxaliplatin plus irinotecan plus 5-FU plus leucovorin (FOLFOXIRI); bevacizumab plus 5-FU– or capecitabine-based chemotherapy (FOLFIRI or FOLFOX or CapeOx or FOLFOXIRI); or cetuximab or panitumumab plus 5-FU–based chemotherapy (FOLFOX or FOLFIRI) in *KRAS* WT patients.[15]

▶ *Second-Line Therapy*

KEY CONCEPT Treatment of relapsed or refractory metastatic disease uses agents not given in the first-line setting. Patients who receive all effective chemotherapy options have improved outcomes compared with those who do not. Because most patients will have received a combination of 5-FU or capecitabine with either irinotecan or oxaliplatin, second-line therapy with the alternate regimen should be considered.[15] For example, a patient who received FOLFOX plus bevacizumab as first-line therapy for metastatic disease should be offered FOLFIRI as part of their second-line regimen. EGFR inhibitors are an additional option for use in the second-line setting in patients with WT *KRAS* only. Patients who did not have an EGFR inhibitor in their first-line regimens are candidates for single-agent cetuximab or panitumumab or either agent in combination with 5-FU and irinotecan (FOLFIRI + EGFR inhibitor). Additionally cetuximab plus irinotecan can be used without the inclusion of 5-FU. The use of EGFR inhibitors may be beneficial as monotherapy, but response rates and PFS appear to be increased in combination with irinotecan-based chemotherapy.[38-42] The results appear to be best when irinotecan is continued because of synergy demonstrated between the two classes of agents.[15,38]

If targeted agents such as bevacizumab were not part of the initial regimen, addition to the second-line regimen should be strongly considered. The addition of bevacizumab to FOLFOX has been shown to increase overall survival.[43] Bevacizumab as monotherapy was shown to be inferior to FOLFOX4 in efficacy and should not be considered as a treatment option in the second-line setting. In patients receiving bevacizumab as part of first-line therapy, continuation of bevacizumab with second-line therapy is associated with increased survival.[44] Based on these findings, continuation of bevacizumab in combination with traditional second-line chemotherapy regimens (5-FU-irinotecan or 5-FU-oxaliplatin based) can be considered in patients treated with a first-line bevacizumab containing regimen. Additional agents targeting VEGF, ziv-aflibercept or ramucirumab, in combination with FOLFIRI can also be considered for use in the second-line setting in patients who have progressed following an oxaliplatin-based first-line regimen. A modest increase in overall and PFS was found in patients receiving FOLFIRI plus ziv-aflibercept compared to FOLFIRI alone.[45] In two separate clinical trials, the addition of ramucirumab or ziv-aflibercept to FOLFIRI led to a modest increase in overall and PFS when compared to FOLFIRI alone.[45,46] Adverse events and warnings for use with ziv-aflibercept or ramucirumab are similar to those with bevacizumab and described in the section of specific agents. Table 91–5 lists treatment options for first- and second-line treatment of metastatic colorectal cancer. Patients with good PS are treated more aggressively than those with poor PS because of their ability to better tolerate chemotherapy.

▶ *Salvage Therapy*

Several salvage therapy options exist for patients with colorectal cancer who have progressed beyond standard first- and second-line

Table 91–5

Treatment Options for Metastatic Colon Cancer[a]

First-Line Therapy	Second-Line Therapy
Good Performance Status	**If First-Line Irinotecan**
• FOLFOX or FOLFIRI with bevacizumab • FOLFOX or FOLFIRI with cetuximab or panitumumab[c] • FOLFOXIRI with or without bevacizumab • 5-FU + leucovorin or capecitabine with or without bevacizumab	• FOLFOX with or without bevacizumab[b] • Irinotecan with or without cetuximab[c,d] • Capecitabine or 5-FU plus leucovorin
Poor Performance Status	**If First-Line Oxaliplatin**
• Capecitabine or 5-FU plus leucovorin with or without bevacizumab	• FOLFIRI with or without bevacizumab • FOLFIRI with ziv-aflibercept • Irinotecan with ziv-aflibercept • FOLFIRI or irinotecan with or without cetuximab or panitumumab[c,d]

[a]CapeOX may replace FOLFOX in selected patients.

[b]Bevacizumab may be given if not part of the first-line therapy.

[c]If KRAS wild type.

[d]Cetuximab or panitumumab may be given if not part of first-line therapy.

5-FU, 5-fluorouracil.

Patient Encounter Part 3

Based on the information presented, create a care plan for this patient's colon cancer. Your plan should include:

(a) The patient's drug- and nondrug-related needs and problems.

(b) The goals of therapy.

(c) A treatment plan specific to this patient that includes strategies to prevent adverse effects of chemotherapy.

(d) A follow-up plan to determine whether the goals have been achieved and the adverse effects of chemotherapy have been minimized.

therapy. Panitumumab is approved for patients who have progressed after 5-FU, oxaliplatin, and irinotecan. Compared with best supportive care, it improves time to disease progression.[15] Based on improvement in PFS compared to best supportive care, the multiple tyrosine kinase inhibitor, regorafenib, was approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[47] Trifluridine and tipiracil is another oral treatment option for patients who have been previously treated with all standard therapies. This agent gained FDA approval after demonstrating improved overall survival when compared with placebo.[48]

A final option in patients with metastatic colorectal cancer and who also demonstrate high MSI or dMMR disease is pembrolizumab. Patients with these particular tumor characteristics have demonstrated notable clinical benefit in early clinical trial data, thus prompting FDA approval in this setting.[49] Although several salvage options exist, patients who fail standard treatment for metastatic colorectal cancer should be encouraged to participate in a clinical trial evaluating new treatment approaches for this incurable disease.

LO 5 SPECIFIC AGENTS USED IN COLORECTAL CANCER

Table 91–6 lists all FDA-approved drugs used in colorectal cancer along with their mechanisms of action, common toxicities, and recommended dose adjustments for hepatic and renal dysfunction as well as pharmacogenetic considerations.

5-Fluorouracil

5-Fluorouracil (5-FU) acts as a "false" pyrimidine inhibiting the formation of the DNA base thymidine as described in Chapter 88.[16]

5-FU is commonly used in the adjuvant and metastatic treatment of colon and rectal cancers with common regimens listed in Table 91–3. Clinical studies comparing efficacy of bolus and continuous infusion schedules generally favor continuous infusion of 5-FU. This is consistent with evidence that suggests that the duration of infusion may be an important determinant of the biologic activity of 5-FU, particularly because of its short plasma half-life, S-phase specificity, and relatively slow growth of colon tumors.[16,50]

Clinically significant differences in toxicity also differ based on the dose, route, and schedule of 5-FU administration. Leukopenia and mucositis are the primary dose-limiting toxicities of bolus 5-FU, whereas palmar-plantar erythrodysesthesia ("hand–foot syndrome") and diarrhea occur most frequently with continuous infusions of 5-FU.[16,50] Health care practitioners can offer valuable patient advice to decrease the impact of these adverse effects. Patients can be informed to suck on ice chips before and for up to 30 minutes after 5-FU boluses to decrease the incidence of mucositis. Hand–foot syndrome, characterized by painful swelling and redness of the soles of the feet and palms of the hand, can be minimized with loose-fitting clothing and keeping skin moist. Additional toxicities include moderate nausea and vomiting, skin discoloration, nail changes, photosensitivity, and neurologic toxicity.

An additional determinate of 5-FU toxicity, regardless of the method of administration, is related to its catabolism and **pharmacogenomic** factors. Dihydropyrimidine dehydrogenase (DPD) is the main enzyme responsible for the catabolism of 5-FU to inactive metabolites.[48] A number of polymorphisms in DPD have been identified in which patients have a complete or near-complete deficiency of this enzyme. This results in unusually severe toxicity, including death, after the administration of 5-FU. Approximately 3% of patients have a complete lack of DPD activity with other patients demonstrating a partial deficiency in enzyme activity. Although patients may be tested for level of DPD activity, it is not routinely done but may be considered in patients who develop severe toxicity after 5-FU administration. The response to 5-FU is also influenced by the status of MSI within the tumor. Tumors with high levels of MSI are generally more resistant to 5-FU despite being associated with better prognosis.

Leucovorin is commonly given with 5-FU. Leucovorin acts to increase the affinity of 5-FU to thymidine synthase, thus increasing the pharmacologic activity of 5-FU.[16] Leucovorin is most effective when administered before 5-FU and can be given by IV bolus or as a continuous infusion. 5-FU toxicities (leukopenia, mucositis, and diarrhea) are increased when leucovorin is given in combination with 5-FU.

Capecitabine

Capecitabine (Xeloda) is an oral prodrug of 5-FU that is designed to be selectively activated by tumor cells. Capecitabine undergoes a three-step conversion to 5-FU, the last step being phosphorylation by thymidine phosphorylase (TP). TP levels are reported to be higher in tumor cells than normal tissues; therefore, the systemic exposure of active drug is minimized, and tumor concentrations of the active drugs are optimized.[16,22] After the drug is converted to 5-FU, it has the same mechanism of action. The current FDA-approved indication for capecitabine is for use in metastatic and adjuvant colorectal cancer when monotherapy is desired, although it is actively being investigated as a replacement for 5-FU in most combinations of colon and rectal cancer regimens. Hand–foot syndrome and diarrhea are common with capecitabine because its toxicities (and pharmacologic activity) appear to mimic those of continuous infusions of 5-FU.

The dose of capecitabine ranges from 1000 to 1250 mg/m^2 twice a day when used by itself; lower doses are often used when it is given in combination with irinotecan or oxaliplatin or in patients with renal insufficiency. The dose should be taken on a full stomach with breakfast and dinner. Capecitabine administered with warfarin can result in significant increases in patients' international normalized ratio (INR) and requires close monitoring. The convenience of oral administration, potentially requiring fewer clinic visits, and an improvement in toxicity make capecitabine a useful alternative to IV 5-FU both by itself and incorporated into other regimens used in colorectal cancer.

LO 5

Table 91–6

FDA-Approved Drugs Used in Colon Cancer

Generic Name (Trade Name)	Mechanism of Action	LO 7 Common Toxicities	Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations
5-FU	Inhibition of the enzyme thymidylate synthase, the rate-limiting step in thymidine formation	*Dose limiting:* Myelosuppression and mucositis with bolus administration Diarrhea and hand–foot syndrome with continuous infusion *Additional toxicities:* Skin discoloration, nail changes, photosensitivity, and neurologic toxicity	Do not give if bilirubin greater than 5 mg/dL (86 μmol/L) DPD deficiency may result in increased toxicity. Testing not routine, but may be considered in those with excessive toxicity
Capecitabine (Xeloda)	Orally active prodrug of 5-FU. Once activated, the mechanism of action is the same	Similar to continuous infusion 5-FU	CrCl 30–50 mL/min (0.50–0.83 mL/s) decrease starting dose to 75% of the original dose Do not give if CrCl < 30 mL/min (0.50 mL/s)
Irinotecan (Camptosar)	Topoisomerase inhibitor that forms a complex with the covalently bound DNA topoisomerase enzyme and interferes with the DNA breakage-resealing process	*Dose limiting:* Early and late diarrhea *Additional toxicities:* Neutropenia, nausea, and vomiting	Decrease dose one level in patients with a homozygous UGT1A1*28 allele. Having this allele decreases the hepatic metabolism of irinotecan and increases the toxicity
Oxaliplatin (Eloxatin)	Similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine, which results in cross-linking of DNA and double-stranded DNA breaks	*Dose limiting:* Acute (within first 2 days) and persistent (> 14 days) neuropathies *Additional toxicities:* Anaphylactic-like reactions, dyspnea, nausea, vomiting	No formal dose adjustment, though use with caution in patients with mild to moderate renal dysfunction
Bevacizumab (Avastin)	Monoclonal antibody that binds to VEGF and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding episodes, thrombotic events *Additional toxicities:* Rare perforation of the bowel, proteinuria	None
Ziv-aflibercept (Zaltrap)	Recombinant fusion protein that binds to VEGF and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding episodes, thrombotic events, infection, diarrhea *Additional toxicities:* Rare perforation of the bowel, proteinuria	None
Ramucirumab (Cyramza)	Monoclonal antibody that binds to VEGF-2 and inhibits angiogenesis	*Dose limiting:* Hypertension, bleeding, thrombosis *Additional toxicities:* Gastrointestinal perforation, proteinuria, delayed wound healing	None
Regorafenib (Stivarga)	Multiple protein kinase inhibitor, including VEGF KIT, PDGFR, RET, FGFR, TIE2, DDR2, TrkA, Eph2A, RAF-1, BRAF, SAPK2, PTK5, and Abl	*Dose limiting:* Hypertension, hand–foot skin reaction *Additional toxicities:* GI perforation, impaired wound healing, hemorrhage, RPLS, fatigue, electrolyte imbalance, hepatotoxicity	Do not use if Child-Pugh Class C hepatic impairment Specific recommendations exist for hepatotoxicity developing while on therapy
Cetuximab (Erbitux)	Binds to the cell surface EGFR, preventing EGF and TGF-α binding. This decreased cell proliferation of cancer cells	*Dose limiting:* Infusion-related reactions, acneiform skin rash *Additional toxicities:* Diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	*KRAS* WT only
Panitumumab (Vectibix)	Similar to cetuximab	*Dose limiting:* Acneiform skin rash *Additional toxicities:* Infusion-related reactions, diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease	*KRAS* WT only

(*Continued*)

Table 91–6

FDA-Approved Drugs Used in Colon Cancer (*Continued*)

Generic Name (Trade Name)	Mechanism of Action	LO 7 Common Toxicities	Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations
Trifluridine/tipiracil (Lonsurf)	Thymidine analog, inhibits DNA synthesis	*Dose limiting:* Myelosuppression *Additional toxicities:* Nausea, diarrhea, stomatitis	Do not initiate therapy in moderate or severe hepatic impairment
Pembrolizumab (Keytruda)	Monoclonal antibody that inhibits PD-1 receptor and prevents PD-1 pathway activation	*Toxicities:* Immune mediated colitis, dermatitis, hepatitis, etc	Indicated for MSI-H

5-FU, 5-fluorouracil; CrCl, creatinine clearance; EGF, epidermal growth factor; EGFR, epidermal growth factor receptor; PD, programmed death; RPLS, reversible posterior leukoencephalopathy syndrome; TGF, transforming growth factor; VEGF, vascular endothelial growth factor; WT, wild type.

Irinotecan

Irinotecan (Camptosar) is a **topoisomerase-I** inhibitor that forms a complex with the covalently bound DNA topoisomerase I enzyme and interferes with the DNA breakage–resealing process. Binding permits uncoiling of the double-stranded DNA, but it prevents subsequent resealing of the DNA, resulting in double-stranded DNA breaks. Irinotecan is a prodrug that is converted by carboxylesterases to its active form, SN-38. Irinotecan is indicated for the first-line treatment of metastatic colorectal cancer in combination with 5-FU and leucovorin or as a single agent in patients who fail first-line therapies. Irinotecan is not recommended as part of the adjuvant treatment of colorectal cancer at this time.

The major toxicity of irinotecan is diarrhea, which can occur both early and late in therapy.[15,50] The early diarrhea is a cholinergic reaction that occurs in the first 24 hours (often during the infusion) in up to 10% of patients and responds to atropine 0.25 to 1 mg IV. The late diarrhea seen in a larger percent of patients occurs 7 to 14 days after the irinotecan infusion. Health care practitioners have to be diligent in counseling patients on this adverse reaction and counseling them on the proper use of antidiarrheals. At the first change in bowel habits, an intensive loperamide regimen should be started by patients (4 mg initially followed by 2 mg every 2 hours until diarrhea free for 12 hours). If diarrhea does not stop or if it worsens, patients should be instructed to call their health care provider immediately. Late-onset diarrhea may require hospitalization or discontinuation of therapy, and fatalities have been reported. Additional toxicities with irinotecan include leukopenia (including neutropenic fever) and moderate nausea and vomiting. Toxicities of irinotecan appear to be greater when the drug is given weekly compared with other administration schedules.

Similar to 5-FU, a pharmacogenomic abnormality is associated with irinotecan toxicity. UDP-glucuronosyltransferase (UGT1A1) is an enzyme that is responsible for the glucuronidation of SN-38 to inactive metabolites, and reduced or deficient levels of this enzyme correlate with irinotecan-induced diarrhea and neutropenia.[15,50] The FDA approved a blood test that detects variations in this gene. This test may assist health care providers in predicting which patients may develop severe toxicities from "normal" doses of irinotecan and can be ordered before patients receive irinotecan.[15] The package insert recommends dose reductions of one level in patients who are UGT1A1 homozygous variants. Irinotecan is administered as an IV bolus over 60 to 90 minutes in a variety of dosing schedules.

Oxaliplatin

Oxaliplatin (Eloxatin) is similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine that results in cross-linking of DNA and double-stranded DNA breaks.[50] Oxaliplatin differs from cisplatin in that the DNA damage induced by oxaliplatin may not be as easily recognized by DNA repair genes often seen in colorectal cancer. Oxaliplatin, in combination with 5-FU-based regimens, is indicated for the first- and second-line treatment of metastatic colorectal cancer as well as the adjuvant treatment of colorectal cancer.

The dose-limiting toxicity of oxaliplatin is acute and chronic neuropathy.[16] Acute neuropathies occur within 1 to 2 days of dosing, resolve within 2 weeks, and usually occur peripherally. These acute neuropathies occur in almost all patients to some degree and are exacerbated by exposure to cold temperature or cold objects. Health care providers should instruct patients to avoid cold drinks, avoid use of ice, and cover skin before exposure to cold or cold objects. In addition, carbamazepine, gabapentin, amifostine, and calcium and magnesium infusions have been used to both prevent and treat oxaliplatin-induced neuropathies, although use of these agents is not widely accepted.[16] Persistent neuropathies generally occur after eight cycles of oxaliplatin and are characterized by defects that can interfere with daily activities (eg, writing, buttoning, swallowing, and walking). Patients may receive predefined breaks from oxaliplatin to decrease the onset of these toxicities with reinitiation of therapy.[26] This strategy varies among protocols but involves administering a certain number of predefined oxaliplatin cycles and then stopping. Maintenance therapy with another agent is usually administered and then the oxaliplatin-based regimen is restarted based on the protocol. These neuropathies occur in up to half of patients receiving oxaliplatin but usually resolve with dosage reductions or after oxaliplatin is stopped.[16] Oxaliplatin has minimal renal, myelosuppressive effects, and nausea and vomiting when compared with other platinum drugs. Oxaliplatin is given IV in a variety of dosing schedules with a typical dose of 85 mg/m^2 IV every 2 weeks.

Bevacizumab

Bevacizumab (Avastin) is a recombinant, humanized monoclonal antibody that inhibits VEGF. VEGF is a proangiogenic growth factor found in many cancers, including colorectal, and is thought to promote blood vessel formation and metastasis of the tumor by binding to VEGF receptors on tumors. Bevacizumab inhibits circulating VEGF, preventing it from binding to receptors and

decreasing the formation of new blood vessels.[15,16] Additionally, bevacizumab may allow for increased concentrations of traditional chemotherapy such as irinotecan to reach the tumor to exert its pharmacologic effect. Bevacizumab is not effective alone and must be used in combination with other agents effective in colorectal cancer. It is indicated for first-line and second-line treatment of patients with metastatic colorectal cancer in combination with IV 5-FU–based regimens. Bevacizumab is also approved for use in combination with 5-FU-irinotecan or 5-FU-oxaliplatin–based chemotherapy for treatment of patients with metastatic colorectal cancer whose disease has progressed on a first-line bevacizumab-containing regimen.

Adverse effects associated with bevacizumab include hypertension, which is common but easily managed with oral antihypertensive agents. Thrombotic events (including myocardial infarctions, pulmonary embolisms, and deep vein thrombosis) occur more frequently in the elderly patients with cardiovascular risk factors and need to be monitored carefully. Because bevacizumab interferes with normal wound healing, it should not be given shortly before or after surgical procedures.[15] Initiation within 28 days of surgery is not recommended to allow for proper wound healing and decrease the risk of bleeding. The amount of time needed after bevacizumab discontinuation to perform elective surgical procedures is less clear, but health care providers should take into consideration bevacizumab's half-life of approximately 20 days when making clinical decisions.[33] Patients should have their urine checked for protein before each dose of bevacizumab to check for potential kidney damage. Patients who have developed 2+ protein on the urinalysis require additional testing before receiving therapy. These patients will have their 24-hour urine collected and assessed for protein. Therapy is interrupted if urine protein excretion exceeds 2 g/24 hours or more and resumed when urine protein excretion decreases to less than 2 g/24 hours.

Finally, there is a risk of GI perforation that is rare but potentially fatal. Patients complaining of abdominal pain associated with vomiting or constipation should be counseled to call their physician immediately. Bevacizumab is commonly given at a dose of 5 mg/kg IV every 14 days until disease progression. Once disease progresses and salvage chemotherapy is initiated, the benefit of continuing bevacizumab is unclear.

Ziv-aflibercept

Ziv-aflibercept (Zaltrap) is a soluble recombinant fusion protein developed by fusing sections of the VEGFR-1 and VEGFR-2 immunoglobulin domains to the F_c portion of human IgG1 antibody. This results in trapping the VEGF-A, VEGF-B, and PIGF ligands before they get to the native transmembrane receptors, and therefore, inhibiting the angiogenic process.[15,45] It is FDA approved for the treatment of metastatic colorectal cancer in combination with FOLFIRI after progression on an oxaliplatin-based regimen. The dose is 4 mg/kg as an IV infusion over 1 hour every 2 weeks in combination with FOLFIRI.

Toxicities include severe and potentially fatal hemorrhage, GI perforation, and compromised wound healing for which the FDA has given ziv-aflibercept a black-box warning. Other adverse effects common to VEGF inhibition (thromboembolic events, hypertension, proteinuria) are seen. As a result ziv-aflibercept shares similar monitoring parameters and warnings to those mentioned in the bevacizumab section. Finally additional warnings for neutropenia, diarrhea and dehydration, and reversible posterior leukoencephalopathy syndrome (RPLS) require monitoring patients for signs and symptoms of these toxicities.

Ramucirumab

Ramuricumab (Cyramza) is a fully human IgG-1 monoclonal antibody that targets and binds to the VEGFR-2, inhibiting ligand activation of the receptor and subsequent vascular tumor growth.[46] For the treatment of colorectal cancer ramucirumab is FDA-approved at a dose of 8 mg/kg IV in combination with FOLFIRI in patients who have progressed on or after therapy with 5-FU, oxaliplatin, and bevacizumab.

Ramucirumab shares an adverse effect profile similar to that of the previously discussed VEGF inhibitors bevacizumab and ziv-aflibercept, including black-box warnings for risk of hemorrhage, GI perforation, and impaired wound healing.

Regorafenib

Regorafenib (Stivarga) is an oral medication that inhibits multiple protein kinases. Its main mechanism of action in colorectal cancer appears to be related to inhibition of vascular endothelial receptors involved in angiogenesis. The importance of additional protein kinase inhibited by regorafenib is unknown in colorectal cancer. Regorafenib is FDA approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[47] The dose of regorafenib is 160 mg orally, once daily for the first 21 days of each 28-day cycle and it must be taken with a low-fat breakfast to improve absorption.

Adverse effects for regorafenib include those typical for VEGF inhibition (hemorrhage, hypertension, wound healing complications, GI perforation) mentioned with bevacizumab and ziv-aflibercept. Regorafenib has a black-box warning for hepatotoxicity that requires baseline liver function tests (ALT, AST, and bilirubin), then every 2 weeks during the first 2 months of therapy, and then monthly. In patients with elevated liver function tests holding doses, dose reductions, or permanent discontinuation of regorafenib may be necessary. Also, asthenia, fatigue, decreased appetite, hand–foot syndrome, diarrhea, mucositis, weight loss, infection, and dysphonia occurred in over 30% of patients. Refer to Chapter 99 on supportive care for management. Finally, regorafenib is a substrate of CYP3A4 and patients should be screened for potential drug interactions.

Cetuximab and Panitumumab

Cetuximab (Erbitux) and panitumumab (Vectibix) are monoclonal antibodies directed against the EGFR. Cetuximab is a chimeric antibody, whereas panitumumab is a fully human monoclonal antibody. EGFR is overexpressed in colorectal cancers and leads to an increase in tumor proliferation and growth. Cetuximab received FDA approval for use in EGFR-expressing metastatic colorectal cancer in irinotecan-relapsed or irinotecan-refractory patients. Cetuximab should be administered in combination with irinotecan but can be used as a single agent in patients who cannot tolerate irinotecan-based chemotherapy. Panitumumab is approved as monotherapy agent and as first-line therapy in combination with FOLFOX in metastatic colorectal cancer.

Both agents are well tolerated with infusion-related reactions being the dose-limiting toxicity of cetuximab and rash most commonly seen with panitumumab. Patients receiving cetuximab require premedication with diphenhydramine and may require modifications to their administration schedule or permanent discontinuation if they develop severe allergic toxicity. A skin rash and diarrhea are also commonly seen with both agents, and health care practitioners should provide counseling to patients about these adverse effects. Treatment options include common medications used to treat acne (doxycycline), topical

and systemic steroids, and general skin care. Patients may be offered these agents prophylactically, upon initiation of therapy, to decrease the potential impact the rash has on their quality of life. Development of rash may be a surrogate marker of response, and clinicians should attempt to minimize the complications of the rash before discontinuing therapy.[15] Other toxicities common to both agents include low magnesium, calcium, and potassium levels that require checking levels and replacement therapy as clinically indicated. A rare adverse effect (< 1%), interstitial lung disease is seen with all agents that inhibit EGFR, and patients should be instructed to report any new-onset shortness of breath. Cetuximab has an initial loading dose of 400 mg/m^2 IV infusion. Weekly doses of 250 mg/m^2 are then administered starting the following week. Panitumumab is given 6 mg/kg IV every 2 weeks.

Trifluridine and Tipiracil

Trifluridine/tipiracil (Lonsurf) is an oral agent which incorporates two components. The active component is trifluridine, a thymidine-based nucleic acid analog which is incorporated into DNA and interferes with DNA synthesis. Tipiracil hydrochloride inhibits TP and thereby prevents degradation of the active trifluridine and allows for adequate plasma concentration of active drug.[48] The FDA-approved dose of 35 mg/m^2 orally is based on the trifluridine component and is administered twice daily on days 1 to 5 and 8 to 12 of a 28-day treatment cycle. It is given as a single-agent in patients who have previously received 5-FU, oxaliplatin, irinotecan, anti-VEGF therapy and anti-EGFR therapy (if *KRAS* WT).

Adverse effects include myelosuppression (particularly neutropenia and anemia), fatigue, stomatitis, diarrhea, and nausea. Trifluridine/tipiracil has moderate emetic potential and pretreatment for nausea is recommended. Each dose should be taken within 1 hour of completion of the morning and evening meals. The unusual dosing schema of this agent may be difficult for some patients and negatively affect compliance, thus careful counseling and written dosing guidelines should be offered to all patients.

Pembrolizumab

Pembrolizumab is a humanized IgG4 monoclonal antibody which inhibits the programmed death 1 (PD-1) receptor to prevent ligand binding and subsequent pathway activation. The PD-1 pathway is an immune pathway that typically serves as a negative feedback system to suppress T-cell response. Many tumors upregulate the PD-1 pathway to encourage immune suppression and prevent host immune activity against tumor cells.[49] Pembrolizumab blocks this negative feedback mechanism to induce T-cell activation and subsequent antitumor immune response. Pembrolizumab is FDA approved in colon cancer patients with dMMR or MSI-H tumors after failure of standard chemotherapies. Patients with dMMR tumors typically have many mutations resulting in production of many abnormal proteins which serve as antigens to the immune system. Reactivation of the immune system by pembrolizumab is often an effective strategy in these patients. Pembrolizumab is given intravenously at a flat dose of 200 mg every 3 weeks for up to 24 months. Adverse effects are mainly related to overactivation of the immune system. Though most patients tolerate it quite well, patients may exhibit immune-mediated toxicity in nearly any organ in their body, particularly dermatitis, colitis, and endocrinopathies.[15,49] These and most other immune-mediated toxicities must be managed by temporary or permanent drug discontinuation and initiation of oral corticosteroids.

Patient Encounter Part 4

Despite completing six cycles of adjuvant chemotherapy, this patient's disease progresses, and a CT scan reveals metastases to his bone and liver. The tumor is sent for pharmacogenomic profiling and is found to have the mutated *KRAS* gene.

What pharmacologic treatment options are available for the treatment of his metastatic disease?

RECTAL CANCER

Although often treated similarly to colon cancer, there are some important differences in the treatment of rectal cancer, especially in the adjuvant setting. Rectal cancer involves tumors found in the distal 15 cm of the large bowel and, as such, is very distinct from colon cancer in that it has a propensity for both local and distant recurrence. The higher incidence of local failure and poorer overall prognosis associated with rectal cancer are attributable to limitations in surgical techniques. Therefore, multimodality therapies with a combination of chemotherapy, radiation, and surgery are at the forefront in the treatment of rectal cancer with the main goal of survival and quality of life by preserving the function of the anal sphincter. In addition, because treatment with surgery, radiation, or systemic chemotherapy at the time of the recurrence is often suboptimal, adjuvant therapy after tumor resection is an important aspect of treatment of the primary tumor. Similar to adjuvant therapy for colon cancer, 5-FU provides the basis for chemotherapy regimens for rectal cancer.

KEY CONCEPT Adjuvant therapy consisting of 5-FU–based chemotherapy in combination with radiation therapy should be offered to patients with stage II or III cancer of the rectum.[50] Radiation therapy decreases the rate of local recurrences, but 5-FU decreases the risk of distant tumor recurrence as well as acting as a radiosensitizer. Toxicities from combined modality therapy include severe hematologic toxicity, enteritis, and diarrhea. Additional trials have sought to determine optimal combinations of concurrent radiation and 5-FU. Similar to tumors in the colon, continuous infusions of 5-FU appear to be superior to bolus doses. However, leucovorin does not appear to improve efficacy of adjuvant treatment for rectal cancer. Use of oral alternatives to 5-FU that are also known to enhance radiation effects, such as capecitabine, are under investigation with preliminary data suggesting the combination of capecitabine and radiation is likely to be safe and effective. In addition, based on the efficacy in colon cancer, FOLFOX regimens have moved into clinical trials in the adjuvant setting.

Another unique aspect of rectal cancer is the use of neoadjuvant therapy. Preoperative radiation (with or without chemotherapy) is given to downstage the tumor before surgical resection to improve sphincter preservation.[50]

KEY CONCEPT Metastatic rectal cancer is treated with similar regimens as outlined in the colon cancer section that are used for palliation of symptoms.[50]

OUTCOME EVALUATION

LO 6

The goals of monitoring are to evaluate whether the patient is receiving any benefit from the management of the disease, detect recurrence, and minimize the adverse effects of treatment. During treatment for active disease, patients should undergo monitoring for measurable tumor response, progression, or new

metastases; these tests may include chest CT scans or x-rays, abdominal or pelvic CT scans or x-rays, depending on the site of disease being evaluated for response; and carcinoembryonic antigen (CEA) measurements every 3 months if the CEA level is or was previously elevated.[17] A positron emission tomography (PET) scan can be considered to identify localized sites of metastatic disease when a rising CEA level suggests metastatic disease but results of CT scans and other imaging studies are negative. Symptoms of recurrence such as pain, changes in bowel habits, rectal bleeding, pelvic masses, anorexia, and weight loss develop in fewer than 50% of patients. Patients who undergo curative surgical resection, with or without adjuvant therapy, require close follow-up because early detection and treatment of recurrence could still result in patient cures. In addition, early treatment for asymptomatic metastatic colorectal cancer appears superior to delayed therapy. Colorectal cancer surveillance guidelines published by the American Society of Clinical Oncology recommend against routinely monitoring liver function tests, complete blood count (CBC), FOBT, CT scans, annual chest x-rays, or pelvic imaging in asymptomatic patients.

In addition, a CBC should be obtained before each course of chemotherapy administration to ensure that hematologic values are adequate. In particular, white blood cell counts and absolute neutrophil counts can be decreased in patients receiving chemotherapy such as irinotecan and 5-FU. Baseline liver function tests and an assessment of renal function should be evaluated before and periodically during therapy. Other selected laboratory tests include checking for the presence of protein in the urine in patients receiving bevacizumab and monitoring of magnesium, calcium, and potassium in patients receiving cetuximab or panitumumab.

Patients should be evaluated during every treatment visit for the presence of anticipated side effects from their treatment, and health care practitioners should anticipate these adverse reactions and aggressively treat and prevent them from occurring. These generally include loose stools or diarrhea from irinotecan, 5-FU, and capecitabine; hand–foot syndrome from 5-FU and capecitabine; nausea or vomiting from irinotecan, 5-FU, and oxaliplatin; mouth sores from 5-FU; neuropathies from oxaliplatin; bleeding and hypertension from bevacizumab; and skin rash associated with cetuximab and panitumumab.

SUMMARY

Recent advances in the treatment of cancer of the colon and rectum now offer the potential to improve patient survival, but for many patients, improved DFS and PFS represent equally important therapeutic outcomes. In the absence of the ability of a specific treatment to demonstrate improved survival, important outcome measures should include the effects of the treatment on patient symptoms, daily activities, PS, and other quality-of-life indicators. Individualized patient care to balance the risks associated with treatment and benefits of a specific treatment regimen is necessary to optimize patient outcomes.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings. Identify the stage of malignancy.
- Review patient-specific factors, tumor-specific factors, and laboratory information that may influence chemotherapy selection and drug dosing.
- Speak with the patient and review records to identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and other aspects of care.
- Compile a list of appropriate chemotherapy treatment regimens.

Assess the Information:

- Determine the goal of therapy and prognosis based on stage of disease.
- Review the medication history (including prescription and OTC medications) to identify agents that may worsen the patient's symptoms of colon cancer. Identify agents that effect bowel function (resulting in diarrhea or constipation) or agents such as NSAIDs that may cause GI bleeding.
- Determine whether the patient is taking any substance that could potentiate chemotherapy toxicities or interact with prescribed medications.
- Based on the medical history, determine whether the patient has compelling indications or contraindications for specific chemotherapy.
- Review relevant laboratory tests (eg, CBC, electrolytes, complete metabolic panel to determine liver and hepatic function, tumor markers, tumor genetic profile) which might impact drug selection or dosing.
- Identify a list of the potential appropriate chemotherapy regimens and the related toxicities.
- Determine supportive care needs including nausea and vomiting control, pain management, prevention of infections, electrolyte supplementation, and toxicity management.
- Determine PS of the patient (see Chapter 88).

Develop a Care Plan:

- Review the chemotherapy order and assess efficacy, dosages, drug interactions, and possible adverse effects from the regimen (see Tables 91–3 and 91–5).

Implement the Care Plan:

- Discuss lifestyle modifications that may assist in symptom and disease management.
- Calculate the body surface area (BSA) and determine if doses are optimal and correct for this patient. Evaluate laboratory values to assist in this process.
- Review supportive care options to decrease the impact of adverse effects for this patient (see Chapters 88 and 99).

(*Continued*)

Patient Care Process (*Continued*)

- Determine whether the patient has insurance coverage or whether recommended agents are included on the institution's formulary.
- Counsel patient on potential adverse effects of the regimen.

Follow-up: Monitor and Evaluate:

- Follow-up when the patient is scheduled for their next round of chemotherapy. Assess the patient for adverse effects of the regimen or other supportive care measures that may need to be added (eg, pain management).
- Review medication history, physical examination, laboratory results, and other imaging and diagnostic tests to evaluate if the patient should continue on their current chemotherapy regimen.

Abbreviations Introduced in This Chapter

APC	Adenomatous polyposis coli
CapeOX	Capecitabine and oxaliplatin
CBC	Complete blood count
CEA	Carcinoembryonic antigen
COX-2	Cyclooxygenase-2
CTC	Computed tomographic colonography
dMMR	DNA mismatch repair
DFS	Disease-free survival
DPD	Dihydropyrimidine dehydrogenase
EGFR	Epidermal growth factor receptor
FAP	Familial adenomatous polyposis
FIT	Fecal immunochemical test
FOBT	Fecal occult blood test
FOLFIRI	Folinic acid, fluorouracil, and irinotecan
FOLFOX	Folinic acid, fluorouracil, and oxaliplatin
GI	Gastrointestinal
HNPCC	Hereditary nonpolyposis colorectal cancer
INR	International normalized ratio
MSI	Mircrosatellite instability
NSAID	Nonsteroidal anti-inflammatory drug
PET	Positron emission tomography
PFS	Progression-free survival
PS	Performance status
TNM	Tumor, node, metastasis
TP	Thymidine phosphorylase
UGT	UDP-glucuronosyltransferase
VEGF	Vascular endothelial growth factor

92 Prostate Cancer

Daniel J. Crona and Amber E. Proctor

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Identify risk factors associated with prostate cancer development.
2. Discuss the benefits and risks associated with prostate cancer screening.
3. Appraise the prognostic- and patient-specific data needed to determine appropriate treatment options.
4. Evaluate pharmacotherapeutic treatment options for patients with prostate cancer.
5. Formulate a monitoring plan for patients receiving androgen deprivation therapy for prostate cancer based on patient-specific factors and the prescribed regimen.
6. Recognize the common adverse effects associated with androgen deprivation therapy.
7. Evaluate appropriate pharmacotherapeutic treatment options for patients with metastatic castration-resistant prostate cancer.
8. Formulate a monitoring plan for patients receiving treatment for metastatic castration-resistant prostate cancer based on patient-specific factors and the prescribed regimen.
9. Recognize the common adverse effects associated with pharmacotherapeutic treatments for metastatic castration-resistant prostate cancer.

INTRODUCTION

Prostate cancer is the most commonly diagnosed cancer in the United States in men, and is the second leading cause of cancer-related death in men.[1] The disease course ranges from indolent, asymptomatic tumors that may not require treatment to rapidly progressing, aggressive tumors that result in distant metastases, morbidity, and mortality.

EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT Prostate cancer is the most frequently diagnosed cancer among men in the United States, and represents the second leading cause of cancer-related deaths in all men. In the United States alone, it is estimated that 164,690 new cases of prostate cancer will be diagnosed, and more than 29,430 deaths will occur in 2018.[1] Although prostate cancer incidence increased during the late 1980s and early 1990s, due to widespread **prostate-specific antigen** (PSA) screening, prostate cancer-related deaths have declined since 1995.[2]

LO 1

Prostate cancer risk factors include age, race/ethnicity, and family history of prostate cancer (Table 92–1).[3] Age is the greatest predictor of risk, and while the disease is rare among men under age 40, the incidence sharply increases with each subsequent decade of life.[2] An evaluation of autopsies from men who died of unrelated causes revealed prostate cancer in 2%, 29%, 32%, 55%, and 64% of men in their third, fourth, fifth, sixth, and eighth decades of life, respectively.[4]

Race

The incidence of clinical prostate cancer varies across geographic regions. Scandinavian countries and the United States report the highest incidences of prostate cancer, while it remains relatively rare in Japan and other Asian countries.[2] African American men have the highest rate of prostate cancer in the world, and prostate cancer mortality among African Americans is approximately twice that observed among Caucasian patients. Hormonal, dietary, and genetic differences, as well as differences in access to health care, may contribute to the variability in prostate cancer incidence and mortality among different populations.[2] Testosterone, commonly implicated in the pathogenesis of prostate cancer, is 15% higher in African American men, when compared to Caucasian men. Japanese men demonstrate decreased activity of 5-α-reductase, when compared with African American and Caucasian men.[5,6] In addition, variations in the androgen receptor gene (*AR*) exist. *AR* transcription is inversely correlated with the length of trinucleotide (CAG) repeats in the *AR* transactivation domain. Shorter CAG repeat sequences have been found in African Americans, and thus a combination of increased testosterone and increased *AR* activation may account for the increased prostate cancer risk among African Americans.[5]

Family History

Men with a brother or father with prostate cancer have twice the risk for prostate cancer compared to the rest of the population, and 5% to 10% of all prostate cancers are thought to be inherited.[7] Genome-wide studies have identified potential prostate cancer susceptibility candidate genes, and there appears to be prostate cancer familial clustering. Carriers of germline mutations in one of 16 DNA repair genes (eg, *BRCA1*, *BRCA2*, and *CHEK2*) are known to have an increased risk for developing prostate cancer,[8] although currently gene sequencing is not routinely performed. Interestingly, early studies have also indicated that mutations

Table 92–1

Risk Factors Associated with Prostate Cancer

Factor	Possible Relationship
Probable Risk Factors	
Age	More than 70% of cases are diagnosed in men older than 65 years
Race	African Americans have a higher incidence and death rate
Genetic	Familial prostate cancer inherited in an autosomal dominant manner
	Germline mutations in one of 16 DNA repair genes (eg, *BRCA1*, *BRCA2*, *ATM*, and *CHEK2*) are associated with increased prostate cancer risk and severity
Possible Risk Factors	
Environmental	Clinical carcinoma incidence varies worldwide
	Latent carcinoma similar between regions
	Nationalized men adopt intermediate incidence rates between that of the United States and their native country
Occupational	Increased risk associated with cadmium exposure
Dietary	Mediterranean diet associated with reduced risk of prostate cancer
	Increased risk associated with high-meat and high-fat diets
	Decreased intake of 1,25-dihydroxyvitamin D, lycopene, and β-carotene increases risk
Hormonal	Does not occur in castrated men
	Low incidence in cirrhotic patients
	Up to 80% are hormonally dependent
	African Americans have 15% increased testosterone
	Japanese have decreased 5-α-reductase activity
	Polymorphic expression of the androgen receptor gene

in these DNA repair genes may be predictive of clinical benefit of poly-ADP ribose polymerase (PARP) inhibitors. Another analysis identified five single nucleotide polymorphisms (SNPs) at 8q24, 17q12, and 17q24.3 that associated with an increased risk of prostate cancer, particularly for those with a family history of the disease. Men harboring all five SNPs had a nearly 10-fold increased risk for prostate cancer.[9] Notably, inherited mutations in *HOX13B* at 17q21-22 have been implicated in hereditary prostate cancer.[7] Consideration of germline testing is now recommended for all men with metastatic, regional, or high to very high risk localized prostate cancer. Common exposure to environmental and other risk factors may also contribute to increased risk among patients with first-degree relatives with prostate cancer.[2]

Diet

The diet associated with the lowest risk of developing prostate cancer is the Mediterranean diet, which includes: high intake of fruits, vegetables, legumes, fish, olive oil, and red wine, combined with moderate intake of red meat, poultry, and dairy.[10] Dietary factors that have been investigated as potential protectors against prostate cancer include retinol, carotenoids, lycopene, calcium, and vitamin D. Studies have suggested that lycopenes, which are found in tomatoes, grapefruit, and watermelon, may lower prostate cancer risk, but prospective clinical trials are needed. Selenium and vitamin E supplementation have failed to yield benefit in prostate cancer risk reduction.[11]

Other Factors

Benign prostatic hyperplasia (BPH) is common among elderly men, affecting more than 40% of men older than 70 years. BPH results in urinary symptoms (eg, hesitancy and frequency). Because prostate cancer affects a similar age group and often has similar presenting symptoms, the presence of BPH often complicates the diagnosis of prostate cancer, although it does not appear to increase the risk of prostate cancer.[6] Smoking has not conclusively been associated with an increased risk of prostate cancer, but smokers with prostate cancer have an increased mortality from the disease, when compared with nonsmokers with prostate cancer.[6]

PATHOPHYSIOLOGY

The prostate gland is a solid, round, walnut-shaped organ positioned between the neck of the bladder and the urogenital diaphragm (Figure 92–1). More than 95% of prostate cancer cases are adenocarcinomas.[12] Rarer tumor types include small cell neuroendocrine cancers, sarcomas, and transitional cell carcinomas.

Prostate cancer can be graded systematically according to the histologic appearance of the malignant cell and then categorized into well-, moderately-, or poorly-differentiated grades.[12,13] Gland architecture is examined, and then rated on the Gleason scale of 1 (well differentiated) to 5 (poorly differentiated). At least two different specimens are examined, and the score for each specimen is added together. Groupings for total **Gleason score** are 2 to 4 for well-differentiated, 5 to 6 for moderately-differentiated, and 7 to 10 for poorly-differentiated tumors. Poorly-differentiated tumors grow rapidly (poor prognosis), while well-differentiated tumors grow slowly (better prognosis).

Metastatic spread can occur by local extension, lymphatic drainage, or hematogenous dissemination.[12,13] Lymph node metastases are more common in patients with large, undifferentiated tumors that

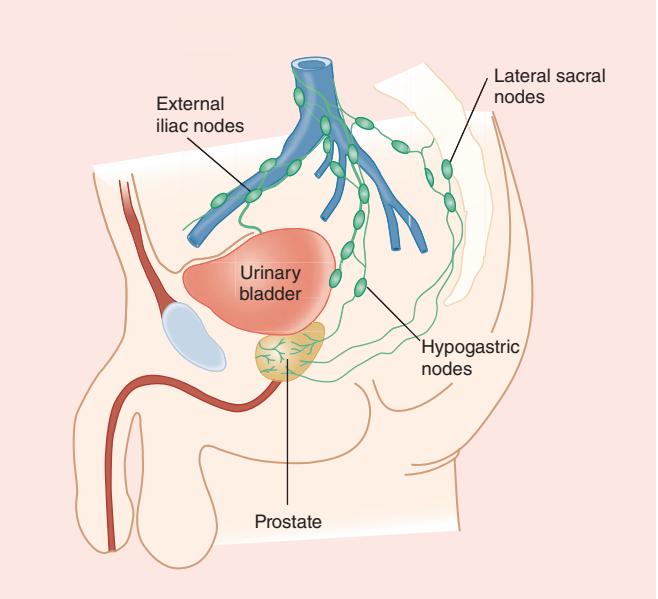

FIGURE 92–1. The prostate gland. (From DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 10th ed. New York, NY: McGraw-Hill, 2017:2168.)

invade the seminal vesicles. Pelvic and abdominal lymph nodes are the most common sites of lymph node involvement (see Figure 92–1). Osseous skeletal metastases from hematogenous spread are the most common sites of distant spread. Typically, the bone lesions are osteoblastic, or a combination of osteoblastic and osteolytic. The most common site of bone involvement is the lumbar spine. Other sites of bone involvement include the proximal femurs, pelvis, thoracic spine, ribs, sternum, skull, and humerus. The lung, liver, brain, and adrenal glands are the most common sites of visceral involvement; however, initial metastatic invasion does not occur in visceral organs, and the prostate is rarely a site for the metastatic spread of other solid tumors. About 25% to 35% of patients have evidence of lymphangitic or nodular pulmonary infiltrates at autopsy.

Normal growth and differentiation of the prostate depends on the presence of androgens, specifically dihydrotestosterone (DHT).[13,14] The testes and the adrenal glands are the major sources of circulating androgens. Hormonal regulation of androgen synthesis is mediated through a series of biochemical interactions among the hypothalamus, pituitary, adrenal glands, and testes (Figure 92–2).

Testosterone, the major androgenic hormone, accounts for 95% of the androgen concentration.[14] The primary source of testosterone is the testes; however, 3% to 5% of testosterone is derived from direct adrenal cortical secretion of testosterone or C19 steroids such as androstenedione.[13,15,16] In the prostate, 5-α-reductase converts testosterone to a more active form, DHT, and DHT is the active ligand that binds and activates the AR.

In early stage prostate cancers, aberrant tumor cell proliferation is promoted by DHT-induced activation of the AR signaling axis. Blockade and reduction of circulating androgens can induce tumor regression in most patients. Hormonal manipulations to reduce circulating androgens can occur through several mechanisms (Table 92–2).[15,16] The testes can be removed surgically (orchiectomy) to limit androgen production, or chemical interference of hormonal pathways that modulate prostatic growth can be accomplished at several steps using androgen deprivation therapy (ADT) (see Figure 92–2). Reduction in the release of luteinizing hormone (LH) and luteinizing hormone–releasing hormone (LHRH) (also known as gonadotropin-releasing hormone [GnRH]) by estrogens, LHRH agonists, direct GnRH antagonists, progesterones, and cyproterone acetate can also reduce testosterone secretion from the testes. Estrogen administration reduces androgens by directly inhibiting LH release, acting directly on the prostate cell, or decreasing free androgens by increasing steroid-binding globulin levels.[13,15,16]

The physiologic response to LHRH depends on both the dose and the mode of administration. Intermittent pulsed LHRH administration, which mimics the endogenous release pattern, results in sustained release of both LH and FSH; however, high dose or continuous infusions of LHRH inhibit gonadotropin release via receptor downregulation. Structural modification of the naturally occurring LHRH, combined with innovative delivery methods, has produced a series of LHRH agonists that cause a similar downregulation of pituitary receptors, and a decrease in testosterone production.[17]

Androgen synthesis can also be inhibited in the testes or adrenal gland. Aminoglutethimide inhibits the desmolase–enzyme complex in the adrenal gland, thereby preventing the conversion of cholesterol to pregnenolone. Pregnenolone is the precursor substrate for all adrenal-derived steroids, including: androgens, glucocorticoids, and mineralocorticoids. Abiraterone is a specific and potent inhibitor of CYP17A1, decreasing the conversion of pregnenolone to dehydroepiandrosterone (DHEA), a required precursor for testosterone. Ketoconazole, an imidazole antifungal agent, causes a dose-related reversible reduction in serum cortisol and testosterone concentration through a similar mechanism. Megestrol is a synthetic derivative of progesterone that also inhibits the synthesis of androgens. This inhibition appears to occur at the adrenal level, but circulating levels of testosterone are also reduced, suggesting that inhibition at the testicular level may also occur.[17]

Table 92–2

Hormonal Manipulations in Prostate Cancer

Androgen Source Ablation	Antiandrogens
Orchiectomy	Flutamide
Adrenalectomy	Bicalutamide
Hypophysectomy	Nilutamide
LHRH or LH inhibition	Enzalutamide
Estrogens	Cyproterone acetate[b]
LHRH agonists	Progesterones
Progesterones[a]	5-α-Reductase inhibition
Cyproterone acetate[b]	Finasteride[b]
Androgen synthesis inhibition	Dutasteride[b]
Abiraterone	GnRH antagonists
Aminoglutethimide	Degarelix
Ketoconazole	
Progesterones[a]	

[a]Minor mechanisms of action.

[b]Investigational compounds or use.

GnRH, gonadotropin releasing hormone; LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone.

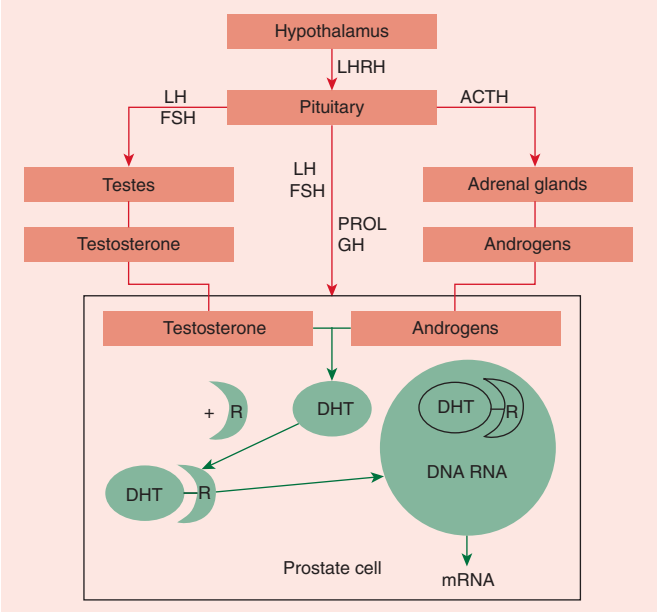

FIGURE 92–2. Hormonal regulation of the prostate gland. (ACTH, adrenocorticotropic hormone; DHT, dihydrotestosterone; DNA, deoxyribonucleic acid; FSH, follicle-stimulating hormone; GH, growth hormone; LH, luteinizing hormone; LHRH, luteinizing hormone–releasing hormone; PROL, prolactin; R, receptor; RNA, ribonucleic acid.) Patient Encounter 1: Prevention and Screening

A 56-year-old Asian man with a past medical history significant for BPH presents to the pharmacy for a refill of his finasteride. He wants to know what he can do to reduce his risk of prostate cancer. He does not have a family history of prostate cancer, and he has never been screened for prostate cancer.

What do you recommend for prostate cancer screening?

What therapeutic options are available to the patient for prostate cancer chemoprevention?

The conversion of testosterone to DHT may be inhibited by 5-α-reductase inhibitors, but ultimately, it is the antiandrogens that inhibit the formation of the DHT–receptor complex, and thereby interfere with androgen-mediated action at the cellular level.[17]

In advanced stages of the disease, prostate cancer cells may be able to survive and proliferate without the growth signals normally provided by circulating androgens. When this occurs, these tumors are referred to as **castration-resistant prostate cancer (CRPC)** (previously described as "hormone-refractory" or "androgen-independent"). Because tumors remain amenable to secondary hormonal manipulations, and because the reintroduction of androgens can continue to promote tumor growth, the term castration-resistant more accurately reflects the clinical picture.

PREVENTION AND EARLY DETECTION

Screening

Early detection of potentially curable cancers is the goal of prostate cancer screening. For cancer screening to be beneficial, it must reliably detect cancer at an early stage, and identify those cancers that would benefit from an early intervention to decrease mortality. Whether prostate cancer screening fits these criteria has generated considerable controversy.[18,19] Digital rectal examination (DRE) has been a recommended prostate cancer screening method since the early 1900s. Primary advantages of DRE include specificity for detecting prostate cancer (> 85%), low cost, safety, and ease of performance. However, DRE has only moderate sensitivity (approximately 60%), and is subject to interclinician variability. LO 2

KEY CONCEPT Prostate-specific antigen (PSA) is a useful marker for detecting prostate cancer at early stages, predicting outcome for localized disease, monitoring disease-free status, and monitoring response to treatment of advanced-stage disease. PSA is a member of the human kallikrein gene family of serine proteases. PSA is produced by columnar secretory cells in the prostate, and plays a role in the liquefaction of seminal fluid. PSA levels are detected via a blood test, and levels greater than 10 ng/mL (mcg/L) are associated with prostate cancer. While the relative ease and noninvasive nature of the PSA test make it the preferred method for screening, the low specificity for prostate cancer detection is a significant limitation.[20,21] In addition to patients with prostate cancer, PSA may also be elevated in men who are smokers, cases of acute urinary retention, acute prostatitis, and prostatic ischemia or infarction, as well as in patients with BPH (an extremely common condition in men at risk for prostate cancer). PSA elevations between 4.1 and 10 ng/mL (mcg/L) cannot distinguish between BPH and prostate cancer, which limits the utility of PSA alone for the early detection of prostate cancer. Additionally, not all men with clinically significant prostate cancer have a serum PSA outside of the reference range.[18] LO 2

Chemoprevention

The use of 5-α-reductase inhibitors, such as finasteride and dutasteride, as chemopreventive strategies for prostate cancer has been debated for many years.[22,23] Both type I and II 5-α-reductase isoenzymes have been implicated in prostate cancer development. Finasteride selectively inhibits the 5-α-reductase type-II isoenzyme, whereas dutasteride inhibits both type I and type II.[13] Both finasteride and dutasteride can falsely lower PSA by approximately 50%, which should be a consideration for clinicians initiating these medications. Although no prospective studies have validated PSA monitoring thresholds in patients receiving 5-α-reductase inhibitors, the PSA threshold can be lowered by 50% (eg, a PSA of 4 ng/mL [mcg/L] for a patient receiving dutasteride which would be equivalent to a PSA of 8 ng/mL [mcg/L] for a patient not prescribed a 5-α-reductase inhibitor).

Data regarding the effectiveness of finasteride and dutasteride on reducing the risk of prostate cancer were assessed in individual studies, and then later evaluated in a comprehensive Cochran Review of 41,638 patients.[22] The use of 5-α-reductase inhibitors reduced the risk of prostate cancer by 25%, when compared to placebo; however, patients who were diagnosed with prostate cancer presented with higher-grade (Gleason 7–10) prostate tumors, when compared to those diagnosed from the placebo arm. Adverse effects observed more commonly in the 5-α-reductase inhibitor treatment arms included: decreased libido, erectile dysfunction, and gynecomastia.

Based on the risk of development of more aggressive prostate tumors, combined with a lack of overall survival benefit and increased risk of adverse effects, the use of 5-α-reductase inhibitors for prostate cancer prevention is not recommended. The American Society of Clinical Oncology and the American Urological Association (AUA) guidelines recommend that asymptomatic men who have a PSA of 3 ng/mL or less, and continue to be screened with regular PSA levels, may benefit from a discussion of both the benefits (eg, possible reduced risk of prostate cancer) and potential risks (eg, adverse effects and the possibility of high-grade tumors) of 5-α-reductase inhibitor therapy.[24] Patients who are prescribed 5-α-reductase inhibitors for benign conditions (eg, lower urinary tract symptoms) may benefit from a similar discussion.

Benefits related to prostate cancer screening remain controversial. PSA measurements can identify small, subclinical prostate cancers, where no intervention may be required. Detecting prostate cancer in those not needing therapy can subject patients to unnecessary health care costs, invasive diagnostic workups, and psychological stress that are related to a potential cancer diagnosis.[19] The AUA does not recommend routine screening for patients with average risk who are between 40 and 54 years old. For men between the ages of 55 and 69 years, the AUA recommends that clinicians discuss the risks and benefits of screening with their patients.[25] In 2018, the US Preventive Task Force recommended that men age 55 to 69 make an individual decision about prostate cancer screening with their clinician (recommendation grade C), and recommended against routine screening for men age 70 and older (recommendation grade D).[26]

CLINICAL PRESENTATION AND DIAGNOSIS (TABLE 92–3)

KEY CONCEPT The prognosis for patients with prostate cancer depends on the histologic grade and stage of the prostate cancer. Details of staging are discussed in Chapter 88. One of the most

Table 92–3

Diagnostic and Staging and Classification Systems Workup for Prostate Cancer

Initial tests	DRE PSA TRUS (if either DRE is positive or PSA is elevated) Biopsy
Staging tests	Gleason score on biopsy specimen Bone scan CBC Liver function tests Serum phosphatases (acid/alkaline) Excretory urography Chest x-ray
Additional staging tests (dependent on tumor classification, PSA, and Gleason score)	Skeletal films Lymph node evaluation Pelvic CT ^{111}In-labeled capromab pendetide scan Bipedal lymphangiogram Transrectal MRI

CBC, complete blood count; CT, computed tomography; DRE, digital rectal examination; MRI, magnetic resonance imaging; PSA, prostate-specific antigen; TRUS, transrectal ultrasonography.

important prognostic criteria appears to be the histologic grade, assessed by Gleason score, because poorly-differentiated tumors ultimately impact disease staging. Poorly-differentiated tumors are highly associated with both regional lymph node involvement and distant metastases.[12] Once the tumor has spread into regional lymph nodes, there is a significantly increased risk of disease recurrence after curative intent therapy.[23]

TREATMENT

Desired Outcome

The desired outcome in early-stage prostate cancer is to minimize morbidity and mortality from prostate cancer, with an acceptance that some degree of morbidity may occur as a result of treatment.[27,28] Early-stage disease may be treated with surgery, radiation, or observation/active surveillance. Although surgery and radiation are curative, they are associated with significant morbidity. Because the overall goal is to minimize morbidity and mortality associated with the disease, observation/active surveillance are appropriate in selected individuals who wish to avoid morbidity, or for whom aggressive interventions may not be clinically appropriate (eg, comorbid conditions). Advanced prostate cancer, where there is evidence of metastatic spread, is not curable. Treatment of advanced disease should focus on providing symptom relief and maintaining quality of life. The cornerstone treatment for advanced prostate cancer is ADT, with the goal of reducing testosterone to castration levels through surgical or chemical treatment modalities.

General Approach to Treatment

The initial treatment for prostate cancer depends on the disease stage, Gleason score, presence of symptoms, and life expectancy of the patient.[21,28] Asymptomatic patients with a very low risk of recurrence, defined as a T_{1c} tumor, with a Gleason score 2 to 6, and PSA less than 10 ng/mL (mcg/L), may be managed by observation if their life expectancy is less than 10 years, or active surveillance if their life expectancy is between 10 and 20 years. Radiation therapy (external beam or brachytherapy), radical prostatectomy (with or without a pelvic lymph node dissection [PLND]), or active surveillance may be offered to patients with a life expectancy greater than 20 years (Table 92–4).[27,28] Because

LO 3 LO 3

Table 92–4

Management of Prostate Cancer with Very Low, Low, and Intermediate Recurrence Risk

Recurrence Risk	Expected Survival (years)	Initial Therapy
Very Low		
T_{1c} and Gleason ≤ 6 and PSA < 10 ng/mL (mcg/L) and < 3 biopsy cores positive with ≤ 50% cancer in each core and PSA density < 0.15 ng/mL/g	< 10 10–20 20 or more	Observation Active surveillance Active surveillance or RP with or without PLND or radiation therapy
Low		
T_1-T_{2a} and Gleason ≤ 6 and PSA < 10 ng/mL (mcg/L)	< 10 10 or more	Observation Active surveillance or RP with or without PLND or radiation therapy
Intermediate		
T_{2b}-T_{2c} or Gleason 7 or PSA 10–20 ng/mL (mcg/L)	< 10 10 or more	Observation or radiation therapy with or without 4–6 months of ADT RP with or without PLND or radiation therapy with or without 4–6 months of ADT

ADT, androgen deprivation therapy; PLND, pelvic lymph node dissection; PSA, prostate-specific antigen; RP, radical prostatectomy.

Patient Encounter 2: Early Stage Disease

A 62-year-old man was found to have an abnormal DRE. His PSA was found to be elevated at 7 ng/mL. A prostate biopsy was performed by TRUS that reveals adenocarcinoma with a Gleason score of 5 (2+3) and is staged as T_{2a} (tumor involves less than one-half of a lobe of the prostate). He has a past medical history of hypertension but is otherwise healthy. He expresses a wish to pursue aggressive therapy.

How would you stratify this patient's risk of developing progressive or metastatic prostate cancer?

What treatment options are available to this patient?

What patient-specific factors would you consider when choosing a treatment?

patients with asymptomatic, early-stage disease generally have an excellent 10-year survival rate, the immediate morbidities associated with prostatectomy or radiation must be balanced with the lower likelihood of dying from prostate cancer. In general, more aggressive treatments for early-stage prostate cancer are reserved for younger men, although patient preference is a major consideration in all treatment decisions.

Radical prostatectomy and radiation therapy are generally considered therapeutically equivalent for localized prostate cancer.[27] Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients; and 50% to 80% regain sexual potency within the first year. Acute complications from radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).[12,27] Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence.[12] Because radiation and prostatectomy have significant and immediate morbidity compared with observation alone, some patients may elect to postpone therapy until they become symptomatic.

Patients with a low risk of recurrence, defined as T_1-T_{2a} tumors, a Gleason score of 2 to 6 and PSA less than 10 ng/mL (mcg/L), may be managed by observation if their life expectancy is less than 10 years. If their life expectancy is 10 years or greater, they may be offered radiation therapy, radical prostatectomy (with or without PLND), or active surveillance (see Table 92–4). LO 3

Patients with an intermediate risk of recurrence, defined as T_{2b}-T_{2c} tumors, or a Gleason score of 7, or PSA ranging from 10 to 20 ng/mL (mcg/L), may be managed by observation (with or without 4–6 months of ADT). Patients with life expectancy of 10 years or greater may be offered either radical prostatectomy (with or without PLND), or radiation therapy (with or without 4–6 months of ADT) (see Table 92–4).[28] LO 3 LO 4

Patients at high risk of recurrence, defined as T_3 tumors, or Gleason score of 8 to 10, or PSA greater than 20 ng/mL (mcg/L), may be managed with 2 to 3 years of ADT with radiation therapy (Table 92–5). Selected individuals with a low tumor volume may receive a radical prostatectomy (with or without PLND).[28] LO 3 LO 4

Patients at very high risk of recurrence, with locally advanced disease, defined as T_{3b}-T_4 tumors, or tumors with a primary Gleason pattern of 5, or greater than 4 biopsy cores with Gleason 8 to 10, may be managed with ADT monotherapy, radiation and 2 to 3 years of ADT, or a radical prostatectomy (with or without PLND). However, these patients are not often candidates for radical prostatectomy because of extensive local spread of the disease (see Table 92–5).[28] KEY CONCEPT Androgen deprivation with an LHRH agonist should be used with radiation therapy for patients with locally advanced prostate cancer to improve outcomes over radiation therapy alone. Patients at very high risk of recurrence due to nodal spread of disease may be managed with 2 to 3 years of ADT (with or without radiation), while patients at very high risk of recurrence due to evidence of distant metastases may be managed with ADT only (see Table 92–5).[28]

Table 92–5

Management of Prostate Cancer with High and Very High Recurrence Risk

Recurrence Risk	Initial Therapy
High	
T_{3a} or Gleason 8–10, PSA > 20 ng/mL (mcg/L)	ADT[a] (2–3 years) and radiation therapy or RP with or without PLND
Very High (Locally Advanced)	
T_{3b}–T_4 or primary Gleason pattern 5 or > 4 cores with Gleason 8–10	ADT[b] (for patients who are not candidates for definitive therapy) or radiation therapy + ADT (2–3 years), RP with PLND
Metastatic

Any T, Any N, M_1	ADT, ADT + abiraterone, ADT + docetaxel

[a]ADT = serum testosterone levels < 50 ng/dL (1.74 nmol/L).

[b]Medical, or surgical ADT are equivalent.

ADT, androgen deprivation therapy; LHRH, luteinizing hormone–releasing hormone; PLND, pelvic lymph node dissection; RP, radical prostatectomy.

KEY CONCEPT Androgen deprivation therapy, with either orchiectomy, an LHRH agonist alone, or an LHRH agonist plus an antiandrogen (combined androgen blockade) can be used to provide palliation for patients with advanced prostate cancer. Secondary hormonal manipulations, therapies that target the AR signaling axis, cytotoxic chemotherapy, immunotherapy, radiopharmaceutical therapy, or best supportive care are used for patients who progress after initial therapy.[26] LO 7

Nonpharmacologic Therapy

▶ *Observation/Active Surveillance*

Observation involves monitoring the course of disease and initiating palliative treatment if the cancer progresses, or the patient becomes symptomatic. PSA and DRE testing are performed every 6 to 12 months, but invasive biopsies are not performed if progression is suspected. The goal of observation is to maintain quality of life in the setting of a prostate cancer diagnosis, and is most appropriate in elderly, frail men with

limited life expectancy. In subtle contrast, patients treated with active surveillance have the intent of initiating curative treatment approaches should the cancer appear to progress. PSA and DRE testing are performed every 6 to 12 months, and prompt biopsies are indicated if progression is expected. Active surveillance is employed in younger patients with long life expectancies who want to delay the morbidity associated with curative treatments, such as surgery, radiation, or ADT.

▶ *Orchiectomy*

Bilateral orchiectomy, or surgical removal of the testes, is a form of ADT that rapidly reduces circulating androgens to castration levels (ie, serum testosterone levels < 50 ng/dL [1.7 nmol/L]).[27,28] However, many patients find this procedure psychologically unacceptable, while others are simply not surgical candidates because of age. Orchiectomy may be the preferred initial treatment for patients with impending spinal cord compression or ureteral obstruction.

▶ *Radiation*

The two commonly used methods for radiation therapy are **external beam radiotherapy (EBRT)** and **brachytherapy**.[27–29] In EBRT, doses of 75 to 79 Gray (Gy) are delivered in 35 to 41 fractions in patients with low-grade prostate cancer and up to 81 Gy for those with intermediate- or high-grade prostate cancer. Brachytherapy involves the permanent implantation of radioactive beads of 145 Gy of ^{125}iodine or 125 Gy of ^{103}palladium, and is generally reserved for individuals with low-risk cancers. Radiation therapy may be used to treat local, or locally advanced prostate cancer with curative intent. In later stages of disease, short courses of EBRT can be used to palliate symptoms.[28,29]

▶ *Radical Prostatectomy*

Radical prostatectomy is performed in patients with resectable disease who are surgical candidates, and who require definitive therapy based on both risk factors and patient preference. Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence.

Pharmacologic Therapy for Early-Stage Disease

LO 4

▶ *Luteinizing Hormone-Releasing Hormone Agonists*

LHRH agonists are a reversible method of ADT and are as effective as orchiectomy in treating prostate cancer.[27,30] Currently, the list of approved LHRH agonists include leuprolide, leuprolide depot, leuprolide implant, triptorelin depot, triptorelin implant, histrelin LA, and goserelin acetate implant. Leuprolide can be administered every 4, 12, 16, or 24 weeks; gosrelin every 4 or 12 weeks; triptorelin every 4, 12, or 24 weeks; and histrelin every 12 months. The leuprolide depot formulation contains leuprolide acetate in coated pellets. The dose is administered intramuscularly, and the coating dissolves at different rates to allow sustained leuprolide levels throughout the dosing interval. The goserelin implant contains goserelin acetate dispersed in a plastic matrix of D,L-lactic and glycolic acid copolymer, and is administered subcutaneously. Hydrolysis of the copolymer material provides continuous release of goserelin over the dosing period. Triptorelin LA is administered as an intramuscular injection (11.25 mg) every 84 days. Triptorelin depot is a 3.75 mg formulation injected every 28 days. Histrelin LA is surgically implanted every 12 months.

Several randomized trials have demonstrated that leuprolide, goserelin, histrelin, and triptorelin are effective agents when used alone in patients with advanced prostate cancer.[16] Response rates of approximately 80% have been reported. The choice between the four LHRH agonists is usually made on the basis of cost, as well as patient and prescriber administration schedule preferences.

LO 6

The most common adverse effects reported with LHRH agonist therapy include vasomotor symptoms, such as hot flashes, erectile dysfunction, decreased libido, and injection site reactions. Long-term adverse effects include decreased bone mineral density and metabolic syndrome.[29] Disease flare within the first week of therapy can be caused by an initial induction of LH and FSH that is induced by the LHRH agonist, leading to an initial period of increased testosterone production. Tumor flare manifests clinically as an exacerbation of disease-related symptoms, primarily increased bone pain or urinary symptoms.[27] The reaction usually resolves after 2 weeks and has a similar onset and duration pattern for the various depot LHRH agonist formulations. Initiating an antiandrogen (see Table 92–2) prior to LHRH agonist administration, and continuing for 2 to 4 weeks, is a frequently used strategy to minimize initial tumor flare.

LHRH agonist monotherapy can be used as initial therapy of advanced prostate cancer, with response rates similar to orchiectomy.[27] A lower incidence of cardiovascular-related adverse effects associated with LHRH agonist therapy has been observed, when compared to estrogens. Patients should be advised that a tumor flare could occur in the first week, but could be mitigated by the addition of an antiandrogen during that period. Caution should be exercised if initiating LRHH agonists in patients with the potential for ureteral obstruction or spinal cord impingement because irreversible complications may occur.

LO 5

Another potentially serious complication of ADT is a resultant decrease in bone-mineral density, leading to an increased risk for osteoporosis, osteopenia, and an increased risk for skeletal fractures.[31] Men initiated on long-term ADT should generally have a baseline bone mineral density test, and be initiated on calcium and vitamin D supplementation.[28]

LO 5

▶ *Gonadotropin-Releasing Hormone Antagonists*

An alternative to LHRH agonists is the GnRH antagonist, degarelix.[32] Degarelix reversibly binds to GnRH receptors on cells in the pituitary gland, reducing the production of testosterone to castration levels. The major advantage of direct GnRH antagonists is the speed at which they can achieve the drop in testosterone levels; castration levels are achieved in 7 days or less with degarelix (compared against 28 days with leuprolide), which eliminates the risk of tumor flare and the need to initiate a concomitant antiandrogen. Degarelix is equivalent to leuprolide in lowering testosterone levels for up to 1 year, and is approved for the treatment of advanced prostate cancer. Degarelix is available as 40 mg/mL (mcg/L) and 20 mg/mL (mcg/L) vials for subcutaneous injection, and the starting dose is 240 mg followed by 80 mg every 28 days. The starting dose should be split into two 120 mg injections.

LO 6

The most frequently reported adverse effects include injection site reactions, including pain, erythema, swelling, induration, and nodules. Most adverse effects are transient and mild to moderate, leading to discontinuation in less than 1% of patients. Other adverse effects include liver function test (LFT) elevations and

Table 92–6

First-Generation Antiandrogens

Antiandrogen	Usual Dose	Adverse Effects
Flutamide	750 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (diarrhea) Liver function test abnormalities Breast tenderness Methemoglobinemia
Bicalutamide	50 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (diarrhea) Liver function test abnormalities Breast tenderness
Nilutamide	300 mg/day for first month; then 150 mg/day	Gynecomastia Hot flushes Gastrointestinal disturbances (nausea or constipation) Liver function test abnormalities Breast tenderness Visual disturbances (impaired dark adaptation) Alcohol intolerance Interstitial pneumonitis

LO 5 osteoporosis. Because of the risk for developing osteoporosis, calcium and vitamin D supplementation should be considered. Degarelix is not approved in combination with antiandrogens.

▶ *Antiandrogens*

Antiandrogens bind cytosolic AR, thereby decreasing available binding sites for endogenous androgens to activate the AR. First-generation nonsteroidal antiandrogens are flutamide, bicalutamide, and nilutamide (Table 92–6). Monotherapy with first-generation antiandrogens is less effective than LHRH agonist therapy. Therefore, for advanced prostate cancer, all currently available antiandrogens are indicated only in combination with ADT: flutamide and bicalutamide are indicated in combination with an LHRH agonist, while nilutamide is indicated after orchiectomy.

LO 6 The most common antiandrogen-related adverse effects are listed in Table 92–6. Diarrhea is reported more frequently with flutamide than bicalutamide. Few clinical trials have been conducted to directly compare the first-generation antiandrogens.[28]

▶ *Combined Androgen Blockade*

Although up to 80% of patients with advanced prostate cancer respond to initial hormonal manipulation, almost all patients progress within 2 to 4 years after initiating therapy. Two main mechanisms of androgen reactivation have been proposed: (1) the tumor could be heterogeneously composed of cells that are hormone dependent and hormone independent, or (2) the tumor could be stimulated by extratesticular androgens (including intratumoral synthesis of androgens) that are converted intracellularly to DHT. Combined androgen blockade (CAB), which is the combination of LHRH agonists or orchiectomy with first-generation antiandrogens, aims to interfere with multiple hormonal pathways to more completely ablate androgens.

Many studies have been performed comparing CAB with conventional medical or surgical castration. A meta-analysis of 27 trials revealed a small (3.2%), but statistically significant, improvement in 5-year survival for patients treated with CAB, when compared to ADT alone.[33] However, adverse effects are far more common in patients who receive CAB, and include diarrhea, LFT elevations, and anemia. Because the benefits of CAB are relatively small, and the increased adverse effects are not insignificant, it is appropriate to use either LHRH agonist monotherapy or CAB as initial therapy for metastatic prostate cancer. CAB may be most beneficial for improving survival in patients with minimal disease and for preventing tumor flare.[27,28]

LO 5 All other patients may be started on LHRH agonist monotherapy, and an antiandrogen may be added after several months if androgen ablation is incomplete, or if disease progression occurs despite a castration level of testosterone.[34]

There is considerable debate about when to start ADT in advanced prostate cancer patients.[16] The original recommendation to start therapy when symptoms appeared was based on trials that revealed no overall survival difference between patients who started diethylstilbestrol (DES) initially versus those who crossed over to DES treatment when symptoms arose. More recent data demonstrates that early intervention, before symptoms appear, may be appropriate; however, this continues to be balanced by patient goals and quality of life considerations.[35]

Given the morbidity of ADT, intermittent dosing strategies that allow for a break in therapy to restore quality of life (and some suggest possibly resensitize cancer cells to hormonal blockade) have been investigated. A meta-analysis of 15 separate studies representing over 6000 patients found intermittent ADT noninferior for overall survival and revealed some improvements in quality of life scores, when compared to continuous ADT dosing.[36] Intermittent ADT should be considered in men who experience significant adverse effects from ADT, and who are willing to undergo more frequent PSA and testosterone monitoring during off-treatment periods.

Pharmacologic Therapies in Metastatic and Refractory Disease

Treatment of men who present with highly aggressive or metastatic disease may involve combinations of ADT with

Patient Encounter 3: Presentation of Metastatic Disease

A 58-year-old man presents to the clinic for follow-up of routine DRE and PSA screening tests. Physical examination is positive for a 1-cm nodule in the prostate, and his laboratory results reveal the following: PSA, 22 ng/mL (mcg/L); PSA from 2 years ago was 2.4 ng/mL (mcg/L). A prostate biopsy by TRUS reveals adenocarcinoma of the prostate with a Gleason score of 7 (3+4). A CT scan and bone scan reveal metastatic disease to regional lymph nodes and the lumbar vertebrae, respectively.

Based on his metastatic disease, what are treatment options for this patient?

second generation antiandrogens or cytotoxic chemotherapy. Secondary (or salvage) therapies for patients who progress after their initial treatments depend on the treatment modalities initially employed. For patients diagnosed with localized prostate cancer, radiotherapy may be used for local disease recurrence after radical prostatectomy. Alternatively, ADT can be used in patients who progress after either radiation therapy or radical prostatectomy.[34]

In patients treated initially with ADT only, secondary hormonal manipulations may be considered. This may include adding an antiandrogen for a patient who either incompletely suppresses testosterone secretion with an LHRH agonist or experiences disease progression after castration levels of testosterone have been previously achieved. In patients who progress during CAB, withdrawing antiandrogens, or using agents that inhibit the AR signaling axis may be considered.[34]

KEY CONCEPT Antiandrogen withdrawal can provide additional symptomatic relief for patients who progress while receiving combined hormonal blockade with an LHRH agonist and an antiandrogen. For patients who receive CAB with an LHRH agonist with an antiandrogen, antiandrogen withdrawal can be the first salvage manipulation.[28,34] Somatic genetic mutations in *AR* arise in patients treated with antiandrogens, and cause these agents to exhibit receptor agonist properties. Objective and subjective responses have been reported in patients following antiandrogen discontinuation from their CAB regimen. Patient responses to antiandrogen withdrawal manifest as significant PSA reductions and improved clinical symptoms. Antiandrogen withdrawal responses lasting 3 to 14 months have been reported in up to 35% of patients, and patient responses seem to closely correlate with longer antiandrogen exposure times. Incomplete cross-resistance has been noted in select patients who received bicalutamide after they had progressed on flutamide, which suggests that patients who fail one antiandrogen may still respond to another agent.[34]

KEY CONCEPT When advanced prostate cancer progresses, despite castration levels of testosterone, it is known as CRPC. For patients who initially received an LHRH agonist alone, castration testosterone levels should be documented. Patients with inadequate testosterone suppression (eg, levels > 20 ng/dL [0.7 nmol/L]) can be treated by adding an antiandrogen, or performing an orchiectomy. If castration testosterone levels have been achieved, but symptoms of progression are evident or a PSA rise is observed, the patient's disease is considered to have progressed to CRPC. Because androgens remain a growth signal for the cancer, ADT is continued throughout the treatment course of CRPC, and the cancer may continue to respond to treatments that target the AR signaling axis (eg, enzalutamide or abiraterone).

LO 7 KEY CONCEPT Second-generation therapies that target the AR signaling axis, such as abiraterone and enzalutamide, improve survival in patients with metastatic CRPC (mCRPC). They can both be considered as first-line therapies for mCRPC, or after disease progression following chemotherapy with docetaxel.

Second-Generation Antiandrogen

Despite initial responses to ADT and first-generation antiandrogens, disease progression eventually occurs. Enzalutamide is a second-generation antiandrogen that is effective in mCRPC, even when first-generation antiandrogens have failed. This may be because enzalutamide prevents the AR from translocating into the cell nucleus, further inhibiting androgen signaling. Enzalutamide is an effective first-line treatment option in chemotherapy naive patients, as well as a viable second-line option in patients that have failed prior to docetaxel chemotherapy.[37,38] Enzalutamide improves overall survival in mCRPC, when compared to placebo. Primary adverse effects include fatigue, diarrhea, hot flashes, musculoskeletal pain, and hepatotoxicity (ie, LFT elevations).[37,38] Seizures and posterior reversible encephalopathy syndrome are rare but serious adverse effects. Enzalutamide is a strong inducer and inhibitor of CYP3A4, as well as a moderate inducer and inhibitor of both CYP2C9 and CYP2C19, so drug–drug interactions are a consideration.

LO 7 LO 8 LO 9 LO 8

Patient Encounter 4: Progressive Disease

A 66-year-old man was initially diagnosed with metastatic prostate cancer 5 years ago. He was initiated on ADT (leuprolide), but his treatment summary (discussed next) provides evidence of suspected disease progression. Today, he presents to the clinic with bone pain and a serum PSA of 67 ng/mL (mcg/L). A bone scan reveals evidence of new osseous metastases.

Treatment Summary

Date	PSA	Intervention
1/10/16	25 ng/mL (mcg/L)	Leuprolide initiated (7.5 mg IM monthly)
3/10/16	21 ng/mL (mcg/L)	Leuprolide continued
6/2/16	22 ng/mL (mcg/L)	Bicalutamide added (50 mg PO daily)
9/2/16	5 ng/mL (mcg/L)	Leuprolide and bicalutamide continued
10/2/16	12 ng/mL (mcg/L)	Leuprolide continued; bicalutamide discontinued
11/1/16	7 ng/mL (mcg/L)	Leuprolide continued, but new dose initiated (22.5 mg IM every 3 months)
2/2/17	5 ng/mL (mcg/L)	Leuprolide continued
5/1/17	12 ng/mL (mcg/L)	Leuprolide continued
8/2/17	27 ng/mL (mcg/L)	Leuprolide continued, but patient to be seen 1 month

Why was bicalutamide initiated on 6/2/16, and why was it likely discontinued on 10/2/16?

How would you characterize this patient's disease?

What pharmacotherapeutic options are available to the patient?

Androgen Synthesis Inhibitors

Despite ADT, androgen synthesis can continue to occur in the periphery (eg, adrenal glands) or via intratumoral synthesis. Cytochrome P450 enzymes play a critical role in androgen synthesis. CYP17A1 inhibition prevents the conversion of pregnenolone to DHEA, a requisite precursor for testosterone. Abiraterone acetate is a potent and specific inhibitor of CYP17A1, resulting in further testosterone reductions, when combined with continued ADT. Abiraterone has demonstrated benefit in combination with ADT in hormone-sensitive prostate cancer as initial treatment, as well as in mCRPC.[28,39,40] Inhibition of CYP17A1 can result in mineralocorticoid excess, which underlies

many of the adverse effects associated with abiraterone, and is the reason why it is prescribed concomitantly with twice daily prednisone (prednisone serves to prevent activation of a response to perceived cortisol deficit via negative feedback). Symptoms of mineralocorticoid excess include fluid retention, hypokalemia, and hypertension. Hepatotoxicity (eg, LFT abnormalities) is a less common but sometimes severe adverse effect. Abiraterone should be administered on an empty stomach (1 hour before or 2 hours after a meal), as food significantly increases absorption. As a CYP3A4 substrate, abiraterone should be used cautiously with concomitant CYP3A4 inhibitors and inducers (Table 92–7).

Androgen synthesis inhibitors, such as aminoglutethimide 250 mg orally every 6 hours or ketoconazole 400 mg orally three times daily, can provide symptomatic relief for a short time in approximately 50% of patients with progressive disease despite previous ADT.[41] Adverse effects during aminoglutethimide therapy occur in approximately 50% of patients. Central nervous system effects that include lethargy, ataxia, and dizziness are the major adverse effects. A generalized morbilliform, pruritic rash has been reported in up to 30% of patients. The rash is usually self-limiting and resolves within 5 to 8 days with continued therapy. Adverse effects from ketoconazole include diarrhea, transient rises in liver and renal function tests, and hypoadrenalism. Additionally, ketoconazole is a strong inhibitor of CYP1A2 and CYP3A4. Ketoconazole absorption requires gastric acidity; therefore, ketoconazole should not be administered with H_2-blockers, proton pump inhibitors, or antacids. Ketoconazole should be combined with hydrocortisone to prevent symptomatic hypoadrenalism.[28]

KEY CONCEPT Chemotherapy with docetaxel and prednisone improves survival in patients with mCRPC. Chemotherapy with cabazitaxel and prednisone improves survival in patients with mCRPC who have either progressed on or are intolerant to docetaxel.

▶ *Chemotherapy*

Docetaxel is an antimicrotubule taxane, which has been shown to improve survival in mCRPC patients when administered at 75 mg/m^2 every 3 weeks, and combined with twice daily prednisone.[42] More recently, docetaxel in combination with ADT has demonstrated improved overall survival in hormone-sensitive prostate cancer, and is an option in metastatic patients who are treatment naive.[28] The most common adverse effects include nausea, alopecia, bone marrow suppression, fluid retention, and peripheral neuropathy. Docetaxel undergoes extensive hepatic metabolism; patients with hepatic impairment may not be eligible for treatment with docetaxel due to an increased risk for adverse effects (Table 92–8).

Cabazitaxel is also an antimicrotubule taxane with demonstrated activity in docetaxel-resistant cell lines and animal models of human cancer. Low-affinity for the P-glycoprotein efflux transporter, when compared to docetaxel, could conceivably be

Patient Encounter 5: Metastatic Castration Resistance Prostate Cancer

An 80-year-old man has metastatic prostate cancer, with evidence of bone metastases on bone scan. He has a PMH significant for hypertension (controlled on lisinopril), restless leg syndrome (untreated, but currently controlled), and a mechanical mitral valve replacement in 2009 (currently receiving warfarin).

He has received leuprolide acetate 22.5 mg subcutaneously every 3 months for the last 4 years, but recently his medical oncologist observed a biochemical recurrence (PSA rise with rapid doubling time) despite castration level testosterone. It was determined that his prostate cancer was now castration resistant, and he presents to clinic today with symptomatic bone metastases. Notably, a recent ECHO revealed an ejection fraction of 33%.

Which available pharmacotherapeutic options would be preferable for this patient?

Are there any pertinent drug–drug interactions that should be considered with the pharmacotherapy you have selected for this patient?

Table 92–7

AR Axis Targeted Therapies for Metastatic Castration Resistant Prostate Cancer

Drug	Usual Dose	Adverse Effects	Dose Adjustments
Androgen Synthesis Inhibitor			
Abiraterone	1000 mg/day	Gastrointestinal disturbances (diarrhea), edema, hypokalemia, hypophosphatemia, hypertension, LFT abnormalities, hypertriglyceridemia	*Hepatic* Reduce starting dose to 250 mg/day for moderate hepatic impairment (Child-Pugh class B), and avoid in Child Pugh class C; withhold treatment if AST/ALT > 5 × ULN or bilirubin > 3 × ULN; *DDI* Use cautiously with concomitant CYP3A4 inhibitors and inducers
Second Generation Antiandrogen			
Enzalutamide	160 mg/day	Gastrointestinal disturbances (diarrhea), musculoskeletal issues (eg, arthralgias and myalgias), asthenia, fatigue, peripheral edema, LFT abnormalities, seizures, PRES	*No renal or hepatic dose adjustments* *DDI* Strong CYP3A4 inducer Moderate CYP2C9 and CYP2C19 inducer Avoid CYP3A4, CYP2C9, and CYP2C19 sensitive substrates Avoid strong inducers and inhibitors of CYP2C8

ALT, alanine aminotransferase; AR, androgen receptor; AST, aspartate aminotransferase; CYP, cytochrome P450; DDI, drug–drug interaction; PRES, posterior reversible encephalopathy syndrome; ULN, upper limit of normal.

Table 92–8

Chemotherapy and Immunotherapy for Metastatic Castration Resistant Prostate Cancer

Drug	Usual Dose	Adverse Effects	Dose Adjustments
Antimicrotubule Agents			
Docetaxel	75 mg/m^2 IV every 3 weeks	Fluid retention, alopecia, mucositis, myelosuppression, hypersensitivity	*Hepatic* Do no administer if AST/ALT > 1.5 × ULN and ALP > 2.5 ULN *DDI* Avoid concomitant use of CYP3A4 inhibitors *Hematologic* Ensure CBC recovery prior to administration
Cabazitaxel	20 mg/m^2 IV every 3 weeks	Fluid retention, constipation, mucositis, myelosuppression, hypersensitivity	*Hepatic* Discontinue if patient ALT > 2 × ULN, or if patient develops jaundice *DDI* Avoid concomitant use of CYP3A4 inhibitors and inducers *Hematologic* Ensure CBC recovery prior to administration
Immunotherapy			
Sipuleucel-T	> 50 million autologous CD54+ cells obtained from leukapheresis. CD54+ cells are activated with PAP-GM-CSF. 3 total doses given.	Hypersensitivity, chills, fever, fatigue, headache, and myalgias	*No renal or hepatic dose adjustments* *DDI* The use of immunosuppressants may lessen the therapeutic effects of sipuleucel-T

ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood count; CYP, cytochrome P450; DDI, drug–drug interaction; IV, intravenous; PAP-GM-CSF, prostatic acid phosphatase granulocyte-macrophage colony-stimulating factor; ULN, upper limit of normal.

the reason why cabazitaxel remains effective in the setting of docetaxel resistance. In docetaxel-pretreated patients, cabazitaxel (25 mg/m^2 every 3 weeks with prednisone 10 mg/daily) significantly improved progression-free survival and overall survival compared with mitoxantrone and prednisone.[43] Recently, the cabazitaxel dose was reduced to 20 mg/m^2 every 3 weeks based on evidence of similar efficacy but better tolerability, when compared to 25 mg/m^2.[44] The most significant adverse effects associated with cabazitaxel include neutropenia, neuropathy, and diarrhea. Hypersensitivity reactions can occur with cabazitaxel, so premedication with an antihistamine, corticosteroid, and H_2 antagonist is recommended. Cabazitaxel undergoes extensive hepatic metabolism, and should be avoided in patients with hepatic dysfunction. Cabazitaxel is a CYP3A4 substrate, so concomitant use of CYP3A4 inhibitors and inducers should be avoided (see Table 92–8).

LO 9 LO 8

► *Immunotherapy*

LO 7

Sipuleucel-T is an autologous immunotherapy that was approved for patients with asymptomatic or minimally symptomatic mCRPC.[45] Eligible patients first undergo leukapheresis to collect peripheral blood mononuclear cells (the cellular fraction that contains dendritic cells), which are sent to a central processing laboratory. These are stimulated with a fusion protein of prostatic acid phosphatase (PAP) and granulocyte macrophage colony-stimulating factor (GM-CSF). PAP is a specific tumor antigen, while GM-CSF is an immune cell activator. The cultured cells are then returned and infused into the patient. This procedure is performed every 2 weeks for a total of three treatments. Adverse effects associated with sipuleucel-T are generally mild to moderate, and include transient chills, fever, and headache (see Table 92–8). Sipuleucel-T was shown to improve overall survival, when compared to placebo.[45] Despite a modest improvement in survival, sipuleucel-T did not decrease the time to disease progression, and thus does not offer significant relief from disease-related symptoms. It is not appropriate in symptomatic patients with rapidly progressing disease for whom treatments that delay tumor progression are feasible.

LO 9

► *Bone Protective Therapies*

LO 7

Radium-223 is an alpha particle-emitter and calcium-mimetic radiopharmaceutical that provides significant palliation to mCRPC patients with bone metastases.[46] Radium-223, infused every 4 weeks for six total treatments, has been shown to significantly improve overall survival, as well as skeletal pain and patient quality of life. Common adverse effects are nausea, vomiting, peripheral edema, and moderate myelosuppression. Radium-223 has been associated with lower rates of myelosuppression compared to other alpha-emitting radiopharmaceuticals. Radium-223 is appropriate for first-, second-, or third-line treatment of patients with mCRPC and symptomatic bone pain.

LO 9

Skeletal metastases from hematogenous spread are the most common sites of distant spread of prostate cancer. Typically, the bone lesions are osteoblastic or a combination of osteoblastic and osteolytic. Bisphosphonates may prevent skeletal-related events, and improve bone mineral density. Zoledronic acid, 4 mg infused every 3 weeks, reduces the incidence of skeletal-related events (such as the need for palliative radiation or pathologic fracture) by 25%, when compared to placebo.[47]

Denosumab, a monoclonal antibody targeted against the receptor activator of nuclear factor kappa-B (RANK) ligand, also decreases the incidence of skeletal-related events in mCRPC patients with bone metastases. Denosumab is a 120-mg

Patient Care Process

Collect Information:

- Obtain complete past medical history, family history, and social history.
- Obtain complete list of any concomitant prescription and over-the-counter medications; be sure to include herbal, vitamin, and mineral supplements.
- Verify completion of prostate cancer workup and staging, including PSA level, pathology results, and staging scans if indicated.
- Discuss symptom burden with the patient to identify bothersome symptoms that should be addressed by treatment plan.
- Obtain labs to evaluate organ function in order to appropriately choose therapy plan.

Assess the Information:

- Identify prognostic factors that influence the development of metastatic prostate cancer.
- Risk stratify the patient with regard to stage of disease, Gleason score, PSA level, comorbid conditions, and life expectancy.
- Assess laboratory values and organ function with regard to treatment options.
- Identify treatment-related morbidity that would be a barrier to adherence based on the patient's current symptoms and goals of care.

Develop a Care plan:

- Using cancer stage, risk level, and patient-directed goals of therapy, determine if drug therapy is indicated.
- Identify appropriate pharmacotherapy that maximizes efficacy while minimizing toxicity based on patient-specific comorbidities, organ function, and care goals.
- Assess cost of proposed therapies and ensure that they are affordable and reasonable for the patient.

Implement the Care Plan:

- Discuss the benefits and risks of appropriate treatment options with the health care team and patient.
- If drug therapy is selected, review patient medical history for drug–drug and drug–herbal interactions.
- Discuss clear goals of care with the patient.
- Initiate therapy.

Follow-up: Monitor and Evaluate:

- If patient is asymptomatic, monitor PSA and circulating androgens for castration level of testosterone. If patient is symptomatic, monitor symptoms for improvement or worsening. Obtain imaging studies to evaluate response of distant metastases.
- Monitor for any new signs or symptoms of progression, and adverse effects from therapy. Evaluate adherence to ADT. Consider intermittent ADT if patient reports intolerance or significant decrease in quality of life.
- Consider removal of antiandrogen if CAB approach is chosen and patient demonstrates progression.
- Consider PSA velocity and symptom burden when assessing for the need for treatment changes.

subcutaneous injection administered every 4 weeks. While it may cause a higher incidence of hypocalcemia compared to zoledronic acid, it also provides greater protection against skeletal-related events. Similar to zoledronic acid, patients should be counseled to supplement with calcium and vitamin D.[48] Both denosumab and zoledronic acid are associated with osteonecrosis of the jaw. Dental procedures should be avoided while receiving these agents, and dental screening prior to initiation is recommended.[49]

OUTCOME EVALUATION

LO 5 LO 8

Prostate cancer monitoring depends on the grade and stage of the cancer. When definitive, curative therapy is attempted, check objective parameters (eg, imaging studies, DRE) to assess tumor response, and monitor PSA to assess for recurrence or progression. Following definitive therapy, PSA is checked every 6 months for the first 5 years and then annually thereafter.[27,28] Local recurrence in the absence of a rising PSA may occur, so annual DRE and radiologic studies based on patient-reported symptoms are also performed. In the metastatic setting, treatments that target AR signaling and traditional chemotherapies have been shown to increase survival. Clinical efficacy is measured using imaging studies, symptom scores, weight changes, analgesic requirements, and PSA response. When using PSA as a surrogate for disease progression, it is important to consider not only the degree of elevation, but also the velocity at which the marker changes. A rapid PSA velocity has been associated with an increased risk of all-cause mortality, and should warrant consideration of therapeutic intervention. Monitoring for adverse effects is different for each treatment modality, but is similarly important.[50] For oral agents, medication adherence is also an important monitoring parameter at each clinic visit.

Abbreviations Introduced in This Chapter

ADT	Androgen deprivation therapy
AR	Androgen receptor
AUA	American Urological Association
BPH	Benign prostatic hyperplasia
CAB	Combined androgen blockade
CRPC	Castration-resistant prostate cancer
CT	Computed tomography
CYP	Cytochrome P450
DES	Diethylstilbestrol
DHT	Dihydrotestosterone
DRE	Digital rectal examination
EBRT	External beam radiation therapy
FDA	Food and Drug Administration
FSH	Follicle-stimulating hormone
GnRH	Gonadotropin-releasing hormone
Gy	Gray
LFT	Liver function test
LH	Luteinizing hormone

LHRH	Luteinizing hormone–releasing hormone
mCRPC	Metastatic castration resistant prostate cancer
PAP-GM-CSF	Prostatic acid phosphatase granulocyte macrophage colony-stimulating factor
PLND	Pelvic lymph node dissection
PSA	Prostate-specific antigen
RANK	Receptor activator of nuclear factor kappa-B
SNP	Single nucleotide polymorphism
TRUS	Transrectal ultrasound

93 Skin Cancer

Alice C. Ceacareanu and Treavor T. Riley

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Identify the risk factors associated with skin cancer.
2. Devise a plan of lifestyle modifications for the prevention of skin cancer.
3. Discuss the importance of mutation testing in the therapy selection for metastatic melanoma treatment.
4. Explain the goals of therapy for the treatment of the different nonmelanoma and melanoma stages.
5. Compare and contrast the available pharmacologic treatment options for nonmelanoma and melanoma skin cancer.
6. Suggest management options for patients experiencing adverse effects of pharmacologic therapy.

INTRODUCTION

Skin cancer is the most common malignancy in the United States with over 5 million new diagnoses reported in roughly 3 million individuals as of 2012. Of these, more than 95% are diagnosed with nonmelanoma skin cancer (NMSC), while the rest of skin cancer diagnoses are accounted for by malignant melanoma (MM).[1,2] NMSC incidence increased 300% since 1994 and continues to rise due to increasing high-risk populations, such as organ transplant and photosensitizing medication users. NMSC consists of basal cell carcinomas (BCCs) and squamous cell carcinomas (SCCs), which originate in the basal cell layer and the hair follicle stem cells, respectively.[3] MM differs substantially from NMSC with regard to its metastatic potential, prognosis, and treatment options.

MALIGNANT MELANOMA

EPIDEMIOLOGY AND ETIOLOGY

MM is the most diagnosed malignancy in young adults and ranks among top five most incident cancer diseases in the United States, representing approximately 5% of all cancer cases. Although accounting for less than 3% of the skin cancer diagnoses, MM is responsible for the majority of skin cancer deaths (75%).[1,4] With a median age at diagnosis of 64, about half of the MM cases were diagnosed between ages 55 and 74. Approximately 91,270 new cases are predicted to occur in 2018, a forecast impacting males more than females, according to the Surveillance Epidemiology and End Results (SEER) age-adjusted analyses.[5] However, these figures may be underestimated since many superficial and in-situ melanomas are treated in outpatient settings and, thus, not included in the SEER registry.

RISK FACTORS

LO 1

MM risk factors include environmental and host factors. KEY CONCEPT Sun exposure and ultraviolet-based artificial tanning are the main environmental triggers for melanoma occurrence. While MM can occur in any ethnic group and also on less exposed areas of the body, individuals with genetic susceptibility may develop exacerbated skin reactions to sun or ultraviolet radiation (UVR), particularly UVB. Interestingly, although UVB-induced DNA damage was determined to be lifetime cumulative, the most prevalent (over 70%) UV-induced genetic modification—C to T—is, paradoxically, irrelevant for most well-known melanoma mutations, *BRAF V600E*, and *NRAS Q61L/R*.[6] Yet, recent evidence supports a UVR-induced mutation mechanism for melanoma occurrence: the hot-spot mutations in *RAC1*, *STK19*, and *PPP6C*.[7]

Further, well-documented UVR-induced *TP53* tumor suppressor gene mutations are responsible for ineffective DNA-repair, resulting in apoptosis dysregulation, modified keratinocyte expansion, and initiation of skin cancer. Today, it is estimated that over two-thirds of MMs are attributable to UVR. Moreover, childhood severe sunburns were associated with twice the risk of developing melanoma.

According to Narayanan, epidermal melanin acts as sun protection factor in individuals with darker skin tones, providing an SPF of up to 13.4 in blacks.[8] Family history of MM in a first-degree relative is associated with twice the risk for MM. Benign melanocytic nevi (benign moles) are also consistently identified as a risk factor for MM development. The risk of developing MM is also higher in patients with a personal history of MM, NMSC, or dysplastic nevus syndrome.[9] Having five or more dysplastic nevi increases the risk of MM up to six times. A similarly increased risk was noted in cases with congenital melanocytic nevi (bigger than 20 cm diameter).[9] A set of host-related risk factors used in the assessment of MM risk is provided in Table 93–1.

LO 1

PRIMARY PREVENTION OF SKIN CANCER

LO 2

Educating patients to avoid excessive exposure to the sun is strongly supported by the American Academy of Dermatology, American Cancer Society, Environmental Protection Agency, and Centers for Disease Control and Prevention. These programs

Table 93–1

Host-Related Risk Factors for Melanoma Development

Demographics
- Gender: male
- Age: > 60 years

Skin Phenotype
- Fitzpatrick skin type: pale white skin, blue or green eyes, blond or red hair
- Tanning ability: tendency to sunburn
- Moles: increased count and size with atypical features and pattern

Past Medical History
- Sunburns: multiple with or without blistering
- Cancer: benign or malign skin cancer or childhood cancers
- Impaired immune system: hematopoietic or solid organ transplant, HIV/AIDS
- Genodermatoses: *Xeroderma pigmentosum*

Genotype
- First degree family history
- Susceptibility genes (*CDKN2A, CDK4, MC1R, BRCA2*)

Data from Refs. 4 and 7.

aim at increasing public awareness about the mutagenic effect of UVR exposure and at changing social norms related to sun protection and tanning, their ultimate goal being to lower skin cancer incidence and deaths related to MM. The following are expert-approved strategies to minimize UVR exposure:

LO 2
- Seek shade when outdoors, especially between 10 AM and 2 PM
- Wear hats that provide shade for the face, ears, and neck
- Wear protective clothing made of tightly woven fabric that covers the arms, legs, and torso
- Avoid sun-bathing and indoor tanning
- Take extra caution when located near water, sand, and snow
- Use UVA/B sunscreen with a minimum skin protection factor (SPF) of 30; reapply every 2 hours if sweating or swimming
- If wearing makeup, use one with SPF and reapply high SPF makeup setting mist every 2 hours

Protective sunscreen lotion or spray should not be the sole agent used for skin cancer prevention as they have only been proven to reduce the risk of actinic keratosis (AK) and SCC. Limited evidence exists that sunscreen application has protective effects against BCC and MM. It is well documented that sunprotection options can lead to or increase the risk of vitamin D deficiency or insufficiency.[10] Therefore, vitamin D level should be closely monitored and appropriate supplementation is recommended for blood levels lower than 30 ng/dL.

Patient Encounter 1, Part 1

A 65-year-old Caucasian man presents to his dermatologist with complaints of pain surrounding a mole located on his left breast.

History: He has a family history of dysplastic nevus syndrome and has been getting his moles checked regularly for the past 10 years. He has three prominent moles located on his chest, neck, and stomach, but six larger, notable nevi on his back. Over the last month, he noted a new mole appearing on his left shoulder blade and has increasing pain surrounding the mole on his chest.

The man reports that he loves swimming in his outdoor pool and has done so three to five times weekly for the last 5 years. He does use sunscreen but never reapplies after coming out of the water.

What risk factors does this patient have for the development of melanoma?

Are any of his risk factors modifiable?

What concerns exist with the development of a new mole at his age?

SECONDARY PREVENTION OF SKIN CANCER

Secondary prevention of skin cancer involves early detection of premalignant cancers for early intervention to increase the likelihood of cure and lower mortality. Regular screening by skin self-examination or total skin examination performed by health care providers consistently identify smaller and thinner lesions in high-risk patients.[11] To date, the recommendations for melanoma screening are conflicting because there are no randomized, controlled, prospective melanoma trials demonstrating that routine screening reduces mortality. However, evidence exists that clinical whole-body skin examination reduces the incidence of thick melanomas, a pathological feature known to be directly associated with MM mortality.

PATHOPHYSIOLOGY

Although the vast majority of MMs originate from the skin, few may arise from various other epithelial tissues, including the conjunctiva, oral mucosa, penis, urethra, and others. The malignant process originates in abnormal melanocyte proliferation as a consequence of genetic susceptibility and/or exposure to a mutagenic agent, such as UVB. Interestingly, in individuals with high genetic susceptibility, MM may develop on body sites only exposed intermitently, such as the trunk or thighs, while it requires significant chronic UVB exposure of areas such as face and neck, in individuals with low genetic susceptibility.[12] Thus location alone may be an indication regarding the occurrence mechanism.

Genetic Basis of Melanoma Development

LO 3 MM has the highest prevalence among the cancers caused by chronic mutagenic exposure.[6] Approximately half of MM cases carry *BRAF V600* mutations and are expected to derive a clinical benefit from BRAF inhibitors.[7] BRAF is a serine/threonine protein kinase that is a member of the RAF kinase family, which is a part of the RAF/MEK/ERK serine threonine cascade (also known as ERK/MAP kinase pathway or "classical" MAPK pathway).[12] Mutations in *BRAF* activate the ERK/MAP pathway and thus trigger melanocyte proliferation and clonal expansion. *BRAF* mutant melanomas tend to occur in individuals younger than 55 years with Fitzpatrick skin types I or II, lower cumulative UV exposure, and on skin areas intermittently exposed to sun. Out of more than 50 *BRAF* mutations described, the valine to glutamic acid (*BRAF V600E*) substitution accounts for over 75% of all *BRAF* mutations.[13] KEY CONCEPT BRAF kinase inhibitors are the mainstay treatment for *BRAF* mutation positive metastatic melanoma.

Table 93–2

Characteristics of Different Types of Skin Cancer

	Malignant Melanoma				Nonmelanoma Skin Cancer	
	Superficial Spreading	Nodular	Lentigo Maligna	Acral Lentiginous	Basal Cell Carcinoma	Squamous Cell Carcinoma
Frequency	70%	10%–15%	10%	< 10%	75%	20%
Location	Female: Head, neck, legs Male: Trunk	Trunk, head, neck	Face, head, neck	Palms, soles, nailbeds	Head and neck	Face, hands, forearms
Age	Fifth decade	Seventh decade	Eighth decade	Sixth decade	> 40 years	> 40 years
Ethnicity	White	White	White	Ethnic groups of color	Nonspecific	African Americans
Prognosis	Good	Very poor	Good	Very poor	Good	Poor
Clinical features	Long horizontal growth phase (5–7 years)	Very aggressive, deeply invasive, no identifiable horizontal growth phase	Long horizontal growth phase (10 years) In-situ, only 5% are malignant	Aggressive, rapid progression from horizontal to vertical growth	Rarely metastasizes Several subtypes	Metastasizes Premalignant and in-situ variants

Data from Refs. 8 and 10.

Since melanocytes' differentiation, proliferation and survival regulation is controlled by a microphthalmia-associated transcription factor (MITF), its alteration impacts antiapoptotic proteins leading to uncontrolled growth and tumor development. Other relevant MM mutations include *CDKN2A* and *PTEN* deletions, as well as *RAC1*, *NRAS*, *PPP6C*, and *STK19*.

Clinical Presentation and Diagnosis

There are four major subtypes of cutaneous MM: superficial spreading, nodular, lentigo maligna melanoma, and acral lentiginous (Table 93–2). They each vary in clinical and growth characteristics.[14]

SEER data show that 84% of diagnosed MM are locally confined, 9% are diagnosed after the cancer has spread regionally, 4% are diagnosed with distant metastasis, and the remaining 3% cannot be staged.[5] KEY CONCEPT Once skin cancer is diagnosed, the disease is staged to determine confinement to the original location or any spread to other sites, such as the lymph nodes, liver, brain, lungs, or bone. The purpose of staging is to determine prognosis and aid in clinical decision making. As with most solid tumors, the tumor, node, metastasis (TNM) classification is used to stage MM. Staging of solid tumors is described in Chapter 88.

Determination of lymph node involvement is an independent prognostic factor and it provides therapy selection guidance. MM patients whose peripheral and deep margin status after biopsy indicate a risk for disease spread to the lymph nodes also receive a **sentinel lymph node** (SLN) biopsy. An SLN is the nearest lymph node to receive lymph draining directly from the biopsied tumor.

Other prognostic factors considered for assessment include primary tumor thickness (Figure 93–1), the presence of ulceration at the primary site, local mitotic activity, the presence of tumor infiltrating lymphocytes (TIL), and gender.[15,16] Male sex is associated with poor prognosis and adverse outcome in MM.[17]

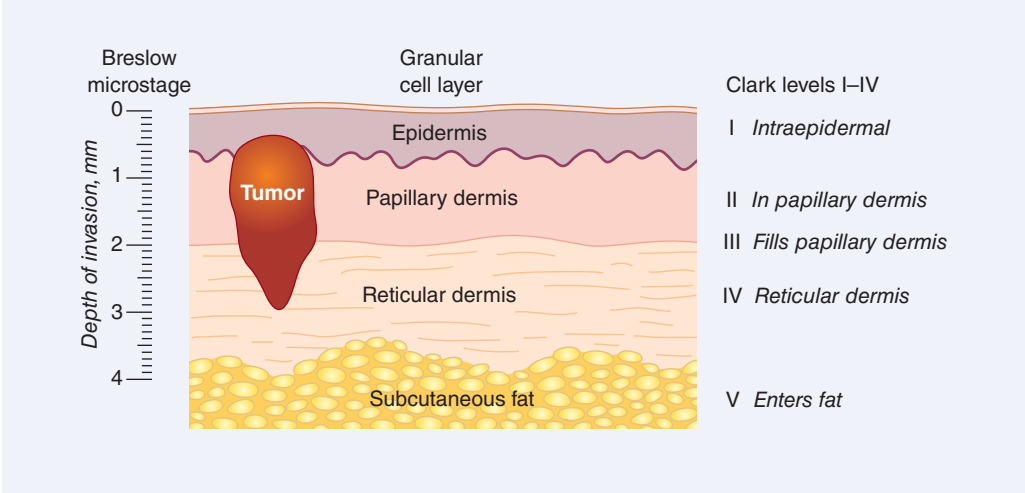

FIGURE 93–1. Skin anatomy: Breslow microstaging and Clark levels. Clark level refers to the level of penetration into the dermis. Breslow classification measures tumor thickness in millimeters from the epidermis to the deepest depth of penetration into the dermis. (From Langley RGB, Barnhill RL, Mihm Jr MC, et al. Neoplasms: Cutaneous melanoma. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatologyin General Medicine, 6th ed. New York: McGraw-Hill; 2003:938.)

Clinical Presentation of MM

MM lesions may occur anywhere on the body. The most common sites are the head, neck, trunk, and extremities. MM appearance such as thickness, presence, or absence of ulceration, as well as any lesion characteristic changes are important risk indicators. Abnormal presentations of a mole or lesion indicate the need for further assessment.

- **Asymmetry:** Half the lesion does not mirror the other half
- **Border:** Sharp, ragged, uneven, and irregular borders
- **Color:** Multiple shades of brown, black, red, blue, or gray
- **Diameter:** Larger than 6 mm or the size of a pencil head eraser
- **Evolving:** Significant change in shape, size, symptoms, surface, or shades of color

Other signs and symptoms to monitor for in a lesion, in addition to ABCDE, include:

- Sudden or continuous lesion enlargement or elevation
- Changes in the skin surrounding the nevus
- Presence of redness, swelling, itching, tenderness, or pain
- Friability of the lesion with bleeding or oozing (ie, ulceration) is an indicator of poor outcomes

Less Common Sites and Manifestations of MM

It is important to examine these sites for "hidden" MM:

- Nailbed
- Mucosal tissue
- Scalp
- Eye

In the nailbed, a black streak or wide variegated brown streak, elevation of nailbed, darker skin surrounding the nail, deformed or destroyed nail, or an increasing nail streak size over time are all possible manifestations of MM.

Diagnostic Tests

- Dermoscopy
- Biopsy

Staging Tests (Depending on Patient's Presentation)

- Baseline chest radiography
- Tumor cell mitotic rate
- LDH level
- CT of chest, abdomen, pelvis
- SLN biopsy: KEY CONCEPT The status of the SLN involvement is one of the most powerful independent prognostic factors predicting survival. It also provides the clinician with guidance for therapy decisions and accurate staging.
- PET
- MRI

Skin Examination

The *ABCDE* acronym is a helpful mnemonic for recognizing the signs and symptoms of early MM (Figure 93–2).[9] Not all MMs, including nodular melanoma, have all ABCDE characteristics, thus *ABCDE* is not meant to provide a comprehensive evaluation of all MM features. The characteristics for each of the letters are described in Figure 93–2. It should be noted that evolution of a lesion is one of the most important warning signs of danger in the assessment of moles for MM.

TREATMENT

LO 4

Early diagnosis of MM is key to improved prognosis. New onset melanoma cases usually present with a recent history of unusual melanocyte growth or an area of irritation around a patch of melanocyte cells. Alternately, the melanoma may have gone undetected for years. In either of the two possibilities, a definitive diagnosis of any suspected cutaneous malignancy should be confirmed by a biopsy before treatment could be initiated. MM treatment options depend on the tumor size, location,

Patient Encounter 1, Part 2

PMH: HTN since 5 years ago, NSTEMI with stent placement 2 years ago, dysplastic nevus syndrome. Patient has developed an intolerance for fluoroquinolones and his current UTI is treated with doxycycline.

FH: Father had dysplastic nevus syndrome but no melanoma. Mother had diabetes and hypertension.

SH: Patient is a recently retired office worker. Married with one adult child.

Examination: Reveals an asymmetrical new nevus of ~5 mm with irregular reddish borders and a lighter center on the left breast with no lesions noted.

Biopsy: Excisional biopsy of the chest nevus reveals melanoma

CT Scan: No distant metastases

Laboratory Data: Normal

He underwent wide surgical excision of the lesion with a 3-mm margin resection after lymphatic mapping with sentinel lymph node biopsy. Pathology revealed negative margins and one of three nodes positive for melanoma. His melanoma is diagnosed as a stage IIB. Lymphadenectomy of the left axilla has been performed as well.

Would surgical excision of the lesion be curative in this patient?

Could medications typically used to treat his current disease states increase his risk of developing melanoma?

Considering the patient has stage IIB melanoma, what pharmacologic treatment would you recommend?

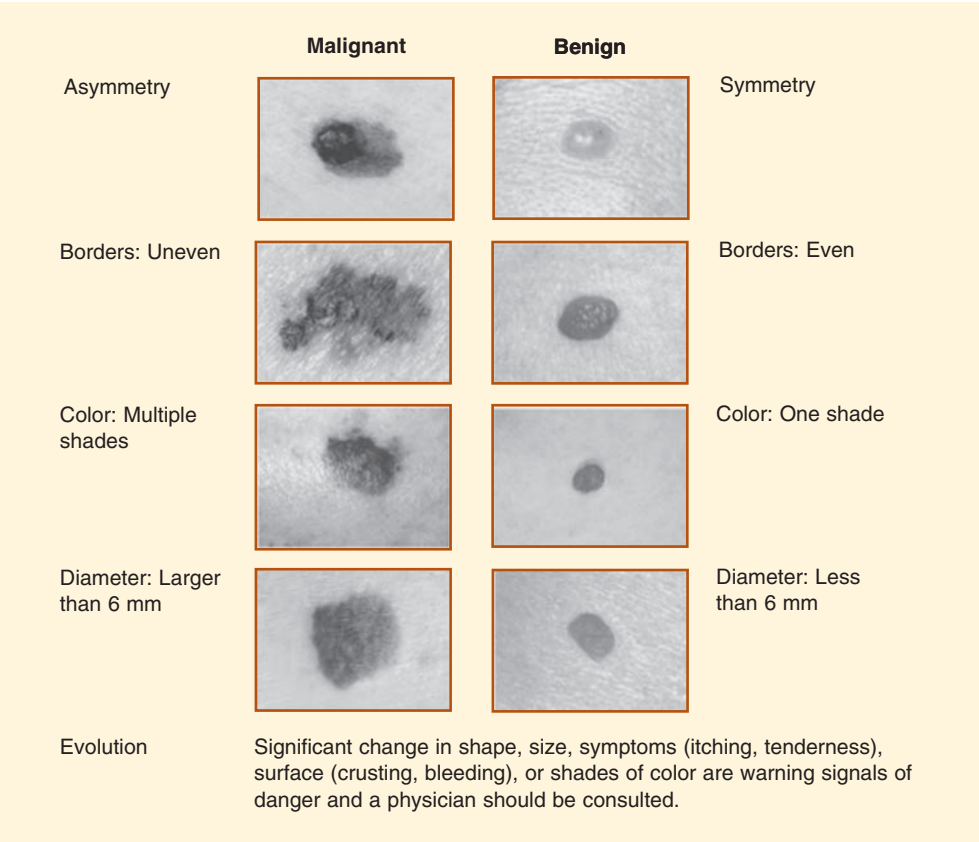

FIGURE 93–2. ABCDE features of early melanoma. (Images courtesy of the Skin Cancer Foundation, New York, www.skincancer.org.)

pathological features and stage. The age of the patient and past medical history, including the results of genotyping studies, all play a role in the clinical decision making. The considered options include surgery, radiation, **immunotherapy**, **targeted therapy**, and biochemotherapy, a combination of immunotherapy and chemotherapy.

Desired Outcomes

LO 4

The primary goal in MM treatment is the eradication of the tumor, lowering the risk of recurrence and metastasis. Secondary goals of MM therapy include preserving skin tissue integrity, appearance, and function while providing optimal cosmetic outcomes. For localized MM (stages I and IIA), surgical resection of the tumor is curative. Thus, probability of cure may be considerably improved with early diagnosis. Patients with regional disease, however—stages IIB, IIC, and III—have a poorer prognosis, characterized by a higher chance for recurrence. In cases with regional disease the goal of therapy is relapse prevention and maintenance of the quality of life. Lastly, in melanoma patients with disseminated disease, neither cure nor prevention of relapse is achievable outcomes; the goal of therapy becomes rather the local control of the disease and the palliation of symptoms.

MM treatment outcomes largely depend on the clinical disease stage at the time of diagnosis. Based on the data published in the SEER Cancer Statistics Review, the 5-year survival rate for patients with localized MM is 98%, the rate decreases to 62% in cases with regional disease, and drops below 20% in individuals diagnosed with distant disease.[5]

Nonpharmacologic Therapy

▶ *Surgery*

KEY CONCEPT The primary treatment modality for local/regional disease (stages I to III) is surgical excision of the tumor with lymphadenectomy in patients with positive SLN. The goals of surgical excision are to gain local control and achieve potential cure, while minimizing morbidity. Achieving adequate surgical margins for the primary tumor is important in preventing local recurrence and improving overall survival. The extent of the surgical margin is, generally, dictated by the tumor thickness, but also by the result of the SLN.[18] The most common first site of recurrence in primary melanoma after tumor excision is the lymph nodes. In patients with regional or distant melanoma, surgical excision provides temporary symptomatic relief. Individuals with regional disease presenting with a good performance status and less aggressive tumor biology may observe longer disease-free intervals after surgery; however, this is only possible if disease can be successfully contained within the anatomical region. By contrast, in patients with stage IV melanoma median survival ranges from 5 to 8 months and the 5-year survival rate is under 5%. Surgical resection of symptomatic or life-threatening brain lesions may be an option to reduce neurologic deficits, seizures, and intracranial hypertension in patients with MM disseminated to the brain.[18]

▶ *Radiation*

Radiation is rarely indicated for the treatment of primary melanoma except for when surgery cannot be performed or is unreasoable. Radiation treatment may be administered as

adjuvant therapy in areas where complete excision of the tumor is difficult, such as the face; or may be employed in lymphatic areas when complete lymphadenectomy is not feasible. In cases with bone metastasis, radiation may be indicated as palliative therapy to decrease fracture risk, control spinal cord compression, and improve pain management.[19]

Brain metastasis is common in melanoma, between 10% and 40% of patients presenting with central nervous system (CNS) disease.[18] In such cases life expectancy ranges from 3 to 5 months and the chance of survival after 1-year is roughly 1 in 10. Headaches and seizures are common presenting symptoms; radiation therapy is indicated for CNS symptoms' palliation and as adjuvant treatment after resection of the CNS metastasis.[19]

Whole-brain radiation therapy (WBRT) WBRT is indicated if more than three CNS metastases are present, for surgically inaccessible lesions, and extensive systemic disease. WBRT does not improve survival in melanoma with CNS metastasis, nor provide a cure; however, it is effective in relieving neurologic symptoms,[18] preventing further disease dissemination, reducing symptomatic recurrence, and decreasing the need for salvage therapy.[19] WBRT also improves neurologic deficits in 50% to 75% of cases and relieves headaches in 80% of patients.[20]

Pharmacologic Therapy

▶ *Immunotherapy*

Infrequent reports of spontaneous remissions and the documentation of improved outcomes in cases with brisk lymphocytic infiltrates indicate that melanoma responds to immunotherapy.[21] Spontaneous serologic and cellular immunities were reported in a high proportion of patients with advanced melanoma.[22] Thus, enhancing patients' immune response with the goal of erradicating melanoma led to the development of several immune-modulating therapies and vaccines. Melanoma is an immunogenic tumor and strategies to enhance tumor-kill by modulating a patient's immune response are an area of active research and drug development.

LO 5

Interferon-α-2b Interferon is naturally-produced signaling protein with diverse mechanisms of action, including antiviral activity, impact on cellular metabolism and differentiation, and antitumor activity. The latter is attributable to both direct antiproliferative effects on the tumor and indirect immune-mediated effects.[23] It is believed that the indirect immune-mediated effects result from the interferon-driven TH_1 lymphocyte traffic to the primary tumor.[24] KEY CONCEPT Interferon-α-2b and peginterferon-α-2b are approved adjuvant therapies for patients who are free of disease after surgical resection but are at high risk for recurrence. This includes patients with bulky disease or regional lymph node involvement, such as stages IIB, IIC, or III (Table 93–3). High-dose (HD) interferon demonstrated a significant risk reduction in relationship with both recurrence and death when compared to observation and vaccine treatment.[24,25] However, close evaluation of the patient's medical history is essential as immunotherapy may not be tolerated by individuals with an autoimmune disorder history.

LO 5

LO 6

Substantial toxicities associated with interferon treatment should also be accounted for in the decision making for treatment selection. Both acute and chronic side effects have been reported with interferon utilization and they can be categorized in four major groups: constitutional, neuropsychiatric, hematologic, and hepatic. Patient counseling with regard to the expected and potential side effects as well as the interventions available to minimize the toxicities is mandatory. HD-interferon duration is

LO 5

LO 6

Table 93–3

Systemic and Regional Therapy for Primary Melanoma and Metastatic Disease

	Stage II_B/II_C	Stage III (SLN+)	Stage III (Clinical Node +)	Stage III with Local Disease	Metastatic or Recurrent Disease
IFN	X	X	X	X	
HD-Ipilimumab		X	X		
Biochemotherapy[a] IFN + IL-2 + Dacarbazine or Cisplatin or Vinblastine			X		
Biochemotherapy[b] Dacarbazine or Temozolomide + Cisplatin or Carboplatin +/– Vinblastine or Nitrosourea + IFN + IL-2					X
Intralesional therapy T-VEC, BCG, or IL-2				X	X[c]
Isolated limb infusion/perfusion Melphalan				X	
Topical therapy Imiquimod				X	

[a]Indicated in regionally disseminated disease.

[b]Indicated in recurrent or metastatic disease.

[c]T-VEC.

BCG, Bacile Calmette-Guerin; HD, high-dose; IFN, interferon; IL-2, Interleukin-2; SLN+, sentinel lymph node positive; T-VEC, talimogene laherparepvec.

Data from NCCN Melanoma Treatment Guidelines 2017; www.nccn.org. Last accessed December 15, 2017.

1 year for stages IIB to III, or up to 5 years if stage III at first dose. Low or intermediate dose are not recommended (Table 93–4). Doses prescribed and the duration of action differ between interferon and pegylated-interferon, the latter having a longer effect that is compatible with weekly administration. The side effects are similar, although the incidence seems to be less in the pegylated form. The monitoring recommendations are identical for both drugs.

Table 93–4

Melanoma Treatment Dosing Recommendations[a]

Immunotherapy

High-dose interferon: 20 million units/m^2 IV daily ×5 days/week × 4 weeks, then 10 million units/m^2 SC 3 days/week ×48 weeks

Peginterferon: 6 mcg/kg/week SC ×8 weeks, then 3 mcg/kg/week up to 5 years

Interleukin-2: 600,000 international units/kg IV every 8 hours (over 15 min) × 14 doses; may repeat after 9 days drug-holiday for up to 28 doses

Intralesional Therapy

Talimogene laherparepvec: 4 × 10^6 PFUs in ≤ 4 mL injected by intralesional fanning; inject 4 × 10^8 PFUs in ≤ 4 mL injected by intralesional fanning after 3 weeks, and biweekly thereafter for up to 24 doses

Immune Checkpoint Inhibitors

Ipilimumab: 3 mg/kg IV (over 90 min) every 3 weeks ×4 doses; permanently discontinue if not completed within 16 weeks;[e]

Nivolumab: 3 mg/kg IV (over 1 hour) every 2 weeks until;[c,d,e]

Pembrolizumab: 2 mg/kg IV (over 30 min) every 3 weeks;[d,e]

RAF-MEK-ERK Pathway Inhibitors

Vemurafenib: 960 mg orally twice daily every 12 hours;[b,d]

Dabrafenib: 150 mg orally every 12 hours;[d,f]

Trametinib: 2 mg orally once daily;[d,e,f]

Cobimetinib: 60 mg orally once daily days 1–21 of each 28 day cycle

Chemotherapy

Dacarbazine: 250 mg/m^2/day IV, days 1–5, every 21 days[g]

Temozolomide: 150–200 mg/m^2 orally ×5 days, every 4 weeks

Vinblastine: 2 mg/m^2 days 1–4 and 22–25 of 6 week cycle

Cisplatin: 75 mg/m^2 IV day 1 with temozolomide 200 mg/m^2 orally ×5 days, cycled every 4 weeks

Carboplatin: target AUC 6 day 1 of a 21 days cycle

Carmustine: 150 mg/m^2 IV day 1 with cisplatin 25 mg/m^2 IV days 1–3; repeat cycle with dacarbazine and cisplatin every 21 days; repeat cycle of carmustine every 42 days

[a]Refer to clinical trials to determine the specific dose based on the regimen the patient is receiving.

[b]Caution in severe renal or hepatic impairment; no dose adjustment needed for mild to moderate impairment.

[c]Baseline renal, liver, and thyroid function required; monitor periodically during treatment.

[d]Continue regimen until disease progression or unacceptable toxicity occurs.

[e]No formal studies have been done to assess cytochrome p450 interactions interactions[32].

[f]Take on empty stomach.

[g]Inactive until metabolized by the liver; it requires reasonably good liver function.

IV, intravenous; SC, subcutaneous.

Data from U.S. Food and Drug Administration. http://www.accessdata.fda.gov/scripts/cder/drugsatfda/. Last accessed December 15, 2017.

Patient Encounter 1, Part 3

This patient presents 1 month later after the initiation of interferon-α-2b with unbearable flu-like symptoms and new-onset depression.

What, if any, changes would be appropriate to this patient's stage IIB melanoma treatment?

What additional laboratory tests are appropriate to request at this time?

LO 5 **Interleukin-2** Interleukin-2 (IL-2) is a biologically-occuring cytokine capable of inducing tumor lysis by stimulating the proliferation and activation of the cytotoxic T lymphocytes (CTLs). The overall response rate in patients with metastatic melanoma receiving HD IL-2 is 16%, result that provides proof of the immunotherapy concept.[26] Its approval relies on the benefit noted in 270 patients enrolled in eight clinical trials performed between 1985 and 1993. High-dose IL-2 therapy is associated with significant severe toxicities and morbidity and is not an option for the majority of patients. Treatment must be performed inpatient and requires experienced personnel for administration. Nevertheless, among the few eligible responding patients, benefit is seen for extended periods (see Table 93–4 for dosing). While IL-2 is no longer the primary option for metastatic melanoma patients, this immunotherapy is part of biochemotherapy options for patients with regional recurrent and metastatic melanoma. Table 93–5 lists the most common IL-2 side effects and current recommendations for management.

LO 5 LO 6

▶ *Biochemotherapy*

LO 5 Given the responsiveness of melanoma to immunotherapy, cytoxic chemotherapy is not a first-line treatment. However, a treatment option combining both cytotoxic and immunotherapies or "*biochemotherapy*" regimen is an option for some patients. KEY CONCEPT Patients eligible to receive biochemotherapy are cases with metastatic or inoperable MM who are not candidates for targeted therapy. The goal of biochemotherapy is to reduce tumor size, and it is an accepted palliative therapy for stage IV melanoma. Among the cytotoxic agents used in melanoma treatment are dacarbazine, temozolomide, cisplatin, carboplatin, vinblastine, carmustine, and paclitaxel (see Table 93–3).[27]

▶ *Intralesional Therapy*

Intralesional therapies show promising results in patients with intralymphatic metastases and are options for advanced melanoma treatment. Advantages include good local response rates and tolerable side effects.

Talimogene Laherparepvec

LO 5 One of the newest additions to the arsenal against MM, Talimogene laherparepvec is the first FDA-approved intralesional therapy for the treatment of unresectable or metastatic melanoma. It is a genetically modified herpes simplex oncolytic virus therapy administered directly into the cutaneous or subcutaneous melanoma lesions or into the visible or palpable nodal lesions.[23]

LO 5 The virus is designed to selectively multiply in the tumor cells. Its mechanism of action is still investigated; however, the therapeutic benefit likely occurs via the involvement of the tumor antigens which are thought to serve as an autologous vaccine.

Table 93–5

IL-2 Toxicities

Cardiovascular
SE: Hypotension (64%), supraventricular tachycardia (17%)
Management: fluid management for SBP > 80–90 mm Hg; discontinue BP meds; PRN α-agonist vasopressor

Gastrointestinal
SE: Vomiting and diarrhea (55%), nausea (24%), stomatitis (14%)
Management: 5-HT_3 antagonist, prochlorperazine; H_2-blocker; loperamide/diphenoxylate/atropine PRN diarrhea

Neurologic
SE: Confusion (30%), somnolence agitation, anxiety, insomnia
Management: haldol PRN agitation, lorazepam PRN anxiety, zolpidem PRN insomnia

Pulmonary
SE: Dyspnea (31%), pulmonary edema, ARDS
Management: quit smoking 2 weeks before therapy; discontinue if > 4 L O_2 or 40% O_2 mask required for 95% Sat

Hepatic
SE: Elevated bilirubin (51%), transaminase (39%)
Management: if severe, consider discontinuation

Renal
SE Oliguria (49%), elevated serum creatinine (35%), anuria (8%)
Management: normal saline or 2 mcg/kg/min dopamine for oliguria; monitor electrolytes

Hematologic
SE: Thrombocytopenia (43%), anemia (29%), leukopenia (21%)
Management: PRN packed red blood cells and/or platelets

Skin
SE: Rash (27%), exfoliative dermatitis (15%), pruritus
Management: hydroxyzine, diphenhydramine, oatmeal powder baths, lubriderm lotion

General
SE: Fever and or chills (47%), malaise (34%), infection (15%)
Management: acetaminophen/NSAIDs around the clock for fever; meperidine if chills are severe; prophylactic clindamycin or cefazolin

Hypothyroidism
SE: May occur in one-third of patients
Management: monitor thyroid function tests

ARDS, adult respiratory distress syndrome; 5-HT_3, serotonin; IV, intravenous; NSAID, nonsteroidal anti-inflammatory drug; PRN, as needed; SBP, systolic blood pressure.

Data from Robert, C., Long, G.V., Brady, B., et al. Nivolumab in previously untreated melanoma without BRAF mutation. N Engl J Med. 2015;372(4):320–330.

The drug is delivered by injection using a "fanning" technique (one needle entry with multiple direction of administration). Grade 3 or 4 treatment-related adverse events were reported in 7.3% of the treated patients and included nausea and vomiting, abdominal pain, fever and chills, and wound infection.[23] Of the treated patients, 12.2% achieved a complete response. Talimogene laherparepvec is currently approved in the United States, European Union, and Australia.

Bacille-Calmette-Guerin

LO 5

An attenuated strain of *Mycobacterium bovis* originally developed as a vaccine against tuberculosis, the Bacille-Calmette-Guerin is sometimes used for intralesional administration to stimulate an immune respone toward the injected site. Its utilization as a therapy for advanced melanoma aims at stimulating patient's own immune system to fight against the injected lesion.[28]

Other intralesion-injected agents for advanced melanoma are the rose bengal dye, the granulocyte macrophage colony-stimulating factor, velimogene aliplasmid, IL-2, and interferon. However, the intralesional administration of many of these therapies remains experimental.

▶ *Immune Checkpoint Inhibitors*

T-cell activation involves two different signals that enhance the host immune response:[29]

- T-cell receptor binding to the major histocompatibility complex presented peptide located on the antigen-presenting cell (APC)
- T-cell costimulatory receptor (CD28) interaction with a costimulatory ligand (B7) on the APC surface

The Cytotoxic T-Lymphocyte Associated Protein 4 (CTLA-4) is expressed in CD4+ and CD8+ T-cells and regulatory T-cells. CTLA-4 is a member of the immunoglobulin (Ig) super family that migrates to the T-cell surface upon its activation allowing binding with a higher affinity to the B7 ligand than CD28. This results in a downregulation on the immune response; in other words, CTLA-4 acts as a "brake" on the activation of the immune system.[29]

Ipilimumab As a monoclonal CTLA-4-specific antibody, ipilimumab has a high affinity for CTLA-4 and prevents CTLA-4 from binding to B7, an action that inhibits the downregulation of the immune response.[29] Ipilimumab increases proliferation of activated T-cells and increases the interactions between T-cells and cancer cells. Ipilimumab is FDA approved for unresectable metastatic melanoma, either as a single agent or incombination with nivolumab, as well as the adjuvant treatment of stage III melanoma.[30] The median overall survival among ipilimumab users with metastatic melanoma was 13.5 months as compared to 10.7 months in the ipilimumab-naive group.[31] T-cell activation can lead to severe adverse events, such as enterocolitis, hepatitis, dermatitis including toxic epidermal necrolysis, neuropathy, and endocrinopathy, both providers and patients have to be enrolled in the FDA Risk Evaluation and Mitigation Strategy (REMS).[32] Corticosteroids are the treatment of choice for ipilimumab-induced adverse events. The administration of steroids to treat the side effects does not affect ipilimumab's effectiveness. Interestingly, there may be a correlation between immune-related adverse events and treatment success[33] (Table 93–6 for adverse effects and their management).

LO 5
LO 6

Nivolumab Many tumor cells express programmed death-ligand 1 (PD-L1), a surface marker that can interact with programmed death-1 (PD-1) receptor on T-cells and B-cells thus diminishing the body's immune response. Nivolumab is an IgG4 fully humanized antibody that targets PD-1 hence preventing the PD-L1 binding to PD-1. As a result, T-cells remain active to mount an immune response against the tumor. Nivolumab is indicated for both unresectable and metastatic MM following ipilimumab and, if *BRAF V600* mutation positive, a BRAF inhibitor. It is also used frequently in the adjuvant setting for stage III, resected melanoma. Patients with confirmed unresectable, previously treated, stage III or IV melanoma without *BRAF* mutation receiving nivolumab had 72.9% overall survival rate at 1 year, as compared to 42.1% in the dacarbazine group.[34] Common side effects may include rash, puritus, peripheral edema, and cough. Rare but serious adverse events may include ventricular arrhythmia, infection, hepatotoxicity, and neuropathy.

LO 5
LO 3

Table 93–6

Ipilimumab Toxicities[a]

Dermatologic (47%–68%)
SE: Maculopapular rash, pruritus, vitiligo
Management: do not stop or reduce dose; topical corticosteroid and urea-containing cream; antipruritic agent (hydroxyzine); for grade 3–4, give oral corticosteroid with prednisone 1 mg/kg or dexamethasone 4 mg every 4 hours with a 4-week taper

GI (31%–46%)
SE: Mild diarrhea, severe diarrhea, or colitis
Management: loperamide, hydration, electrolyte replacement; budesonide 9 mg/day or prednisone 1 mg/kg or high-dose IV steroids (methylprednisolone 2 mg/kg once or 2× daily or dexamethasone 4 mg every 4 hours), upon symptom resolution taper over 4 weeks (up to 8 weeks may be needed); ensure slow taper. If no response to steroids in 48–72 hours, give biweekly infliximab 5 mg/kg. Discontinue antibody if severe colitis occurs

Inflammatory Hepatoxicity (3%–9%)
Management: methylprednisolone 2 mg/kg/day up to 2× daily for LFT > 8× ULN or total bilirubin > 5× ULN; give mycophenolate 1 g IV or 1.5 g orally 2× daily if symptoms persist

Endocrine (4%–6%)
SE: Hypophysitis
Management: monitor thyroid function tests, serum cortisol levels, ACTH, testosterone, FSH, LH, and prolactin; if confirmed, dexamethasone 4 mg every 4 hours ×7 days; taper over > 4 weeks; hormone substitution PRN; consult endocrinologist

Neurologic (1%)
SE: Guillain–Barré syndrome, sensory or motor neuropathy, myasthenia gravis
Management: give corticosteroids; if severe, discontinue antibody therapy

[a]In general, for severe grade 3 or 4 ipilimumab toxicities, therapy should be discontinued permanently. Women of childbearing age should receive contraceptive treatment throughout the duration of ipilimumab treatment.

ACTH, adrenocorticotropic hormone; FSH, follicle-stimulating hormone; LFT, liver function tests; LH, luteinizing hormone; ULN, upper limit of normal.

Data from Kähler, C., Hauschild, A. Treatment and side effect management of CTLA-4 antibody therapy in metastatic melanoma. J Dtsch Dermatol Ges. 2011;9:277–285.

Pembrolizumab Previously known as lambrolizumab, this checkpoint inhibitor is an anti-PD-1 humanized antibody. The FDA-approved indication includes unresectable and metastatic MM following ipilimumab and, if *BRAF* V600 mutation positive, a BRAF inhibitor. In patients with measurable locally advanced unresectable metastatic melanoma having adequate organ function and performance score, the Response Evaluation Criteria in Solid Tumors (RECIST) confirmed response rate to pembrolizumab was 38%.[35] Common side effects may include arthralgia and constipation/diarrhea while rare but serious adverse events may include colitis, hepatitis, pancreatitis, pneumonitis, and hypophystitis. According to a recent study comparing the incidence of immune-related adverse events associated with ipilimumab versus pembrolizumab, significantly fewer gastrointestinal and dermatological adverse events were reported with pembrolizumab use; however, a higher incidence of thyroiditis and pneumonitis was noted.[36]

▶ *RAF-MEK-ERK Pathway Targeted Therapy for BRAF Mutant MM*

KEY CONCEPT BRAF/MEK combined regimens provide a considerable therapeutic advantage against occurrence of melanoma resistance in patients with metastatic melanoma.

Vemurafenib/Cobimetinib The serine/threonine kinase B-Raf (BRAF) is an intermediary in the signal transduction through the RAF-MEK-ERK mitogen-activated protein kinase (MAPK) pathway. BRAF activation is followed downstream by the activation of ERK with increase in the cyclin D1 levels, and enhanced cellular proliferation.[37] The proto-oncogene B-Raf *(BRAF)* is mutated in approximately 50% of melanomas, and over 75% of these mutations are *BRAF V600E*.[13] Vemurafenib is an oral serine/threonine kinase inhibitor that binds to the adenosine triphosphate binding domain of *BRAF* mutant, hence presence of the mutation is required for treatment effect.[38]

KEY CONCEPT Vemurafenib selectively targets the BRAF V600E isoform and has an indication for the treatment of unresectable stage III_C or metastatic melanoma that is *BRAF V600* mutation positive. Although vemurafenib was initially approved as a single agent, resistance develops rapidly via activation of MEK and the combination of vemurafenib and the MEK inhibitor cobimetinib demonstrates improved progression-free survival compared to vemurafenib alone in patients with BRAF mutant metastatic melanoma[39] (see Figure 93–3 and Table 93–4 for dosing recommendations).

Common side effects associated with vemurafenib may include photosensitivity, rash, arthralgia, and alopecia. Rare but serious side effects may include QT interval prolongation, hand–foot syndrome, vision changes, and SCC, although the latter can be excised without discontinuation of the agent.[37] Vemurafenib is metabolized by CYP3A4 and thus may interact with its inducers or inhibitors. It may increase the serum concentration of substrates of CYP1A2 and 2D6. It may decrease the serum concentration of substrates of CYP3A4.

Cobimetinib commonly causes photosensitivity, diarrhea, elevations in liver function tests (LFTs), as well as electrolyte abnormalities. Decreases in ejection fraction and hypertension can occur in up to 20% of the patients. Rare but serious adverse effects include bleeding and secondary neoplasms, including squamous and basal cell skin cancer and melanoma. Cobimetinib is metabolized by CYP3A4 and thus may interact with its inducers or inhibitors.

Dabrafenib/Trametinib Similar to vemurafenib, dabrafenib is a selective inhibitor of BRAF V600E kinase. While it is approved as both monotherapy for unresectable and metastatic MM with *BRAF V600E* mutation and as combination therapy with trametinib for unresectable and metastatic MM with BRAF *V600E* or *V600K* mutation, the drugs are used almost exclusively in combination, as the combination has demonstrated superior efficacy than either drug administered as a single agent. The combination also significantly reduces the risk of recurrence of melanoma in completely resected patients with stage III melanoma when compared to placebo.[40] Common side effects with dabrafenib include hypoglycemia, arthralgia, and neutropenia while rare but serious adverse events may include QT prolongation, serious febrile reactions, uveitis, iritis, and SCC. Similar to vemurafenib, SCC can be excised without discontinuing dabrafenib. Dabrafenib is metabolized by CYP3A4 and 2C8 and thus may interact with its inducers or inhibitors. It may decrease the serum concentration of substrates of CYP3A4 and 2C9.

FIGURE 93–3. RAF inhibition resistance in melanoma. A 38-year-old man with BRAF-mutant melanoma. **(A)** Before initiation of RAF inhibitor. **(B)** After 15 weeks of therapy with a RAF inhibitor. **(C)** After relapse, after 23 weeks of therapy. Dissecting therapeutic resistance to RAF inhibition in melanoma by tumor genomic profiling. J Clin Oncol. 2011;29(22):3085–3096.)

LO 3

Trametinib is a MEK-1 and MEK-2 kinase inhibitor targeting MAPK pathway downstream of BRAF. The drug is approved as monotherapy or in combination with dabrafenib for *BRAF V600E* or V600K mutation positive unresectable and metastatic melanoma, although currently only used in combination. Common side effects with trametinib include dry skin and nail changes while rare but serious adverse events may include vision changes and rhabdomyolysis.

OUTCOMES EVALUATION

When evaluating MM therapy outcomes, refer to the primary and secondary goals for the respective MM stage, treatment selection, and case-related particularities, such as cosmetic considerations. Always evaluate the awareness and approach to avoid sun or UVR exposure, including compliance with regular total-body skin self-examination, regardless of disease stage and implemented treatment. Advise for appropriate changes if needed.

Patient Encounter 1, Part 4

Several weeks later, while awaiting enrollment in a clinical trial, the patient presents with general malaise, weakness, and acute shortness of breath. His labs are insignificant except for an LDH of 1500 units/L. He has no new lesions.

New imaging studies confirm metastases to the lung, the workup resulting in a new diagnosis of stage IV metastatic melanoma.

What laboratory workup is necessary to direct the next clinical decision?

Depending on the results of the laboratory workup, what therapy changes can be made?

For localized disease:

- Evaluate skin integrity after tumor resection, appearance, and function.
- Assess the quality of life after surgery and whether any skin graft-related complications have been reported.
- Verify patient and family understanding regarding recurrence prevention.

For regional disease:

- Assess skin appearance and recovery after radiation therapy, as well as the quality of life and motor function recovery after lymphadenectomy.
- Evaluate effectiveness of any antibiotic treatment.
- Review the relevant labs and make necessary treatment changes.
- Review treatment adverse events and the appropriateness of their management.
- Discuss treatment alternatives and options for recurrence prevention.

For disseminated disease:

- Identify patient's and family goals and their compatibility with the observed treatment outcomes.
- Review the relevant labs and evaluate the effectiveness of palliative treatment.
- Assess chronic therapy side effects and evaluate to the appropriateness of adverse event reporting and management.
- Assess patients' psychological, physical, and social functioning.
- Evaluate the use of current resources, such as the hospital's social service department or the American Cancer Society for assistance in dealing with the disease emotionally. Recommend attending support group meetings or talking to a counselor if or before they become overwhelmed with the diagnosis.

PATIENT CARE PROCESS

Refer to the section at the end of the chapter for the patient care process recommended for both MM and NMSC care.

KERATINOCYTE CARCINOMA

EPIDEMIOLOGY AND ETIOLOGY

Also known as nonmelanoma skin cancer (NMSC), keratinocyte carcinoma[41] accounts for the vast majority of all newly diagnosed cancers each year. BCC is the most common form of keratinocyte carcinoma followed by the SCC as the second most common in the United States (see Table 93–2).

The true prevalence of keratinocyte carcinoma may be underestimated due to its treatment in outpatient settings, without formal reporting to cancer registries. Yet, understanding its incidence is critical to designing treatment strategies and providing proper resource allocation for its prevention.[42] The number of individuals with at least one NMSC procedure in the Medicare fee-for-service database increased by over 14% between 2006 and 2012. Although, BCC was previously reported as the most common form of NMSC, comprising of 75% of the NMSC, the most recent study indicates a 50-50 ratio of BCC to SCC diagnosed in a Medicare population.[42] The majority of NMSCs are curable, and the mortality rate is low, however not negligible; cure rates approach 98%, and the overall 5-year survival rate is considerably greater than 95%. Metastasis occurs in fewer than 0.1% of BCCs compared to 3.6% of SCCs. Roughly 75% of all keratinocyte carcinoma deaths are attributed to SCC.[43] Keratinocyte carcinoma is associated with considerable morbidity related to functional and cosmetic deformity. In addition, it is an economic burden; the associated costs for NMSC treatment reaching $4.7 billion between 2007 and 2011, nearly double as compared to NMSC expenditure between 2002 and 2006. Importantly, both these figures exceed the costs of MM expenditure for the corresponding time-frame.[44]

RISK FACTORS

LO 1

The risk of developing keratinocyte carcinoma is multifactorial. Skin phenotype plays a similar role as in the MM development; individuals with pale skin, blue or green eyes, and blond or red hair are at risk for developing NMSC as well. A tendency to sunburn or an increased cumulative lifetime UVR exposure, particularly UVB due to its penetrability and higher energy, leads to biologically damaging effects including direct DNA damage, signaling receptor-mediated pathways activation, and reactive oxygen species (ROS) formation.[3] Greater cumulative lifetime sun exposure is associated with a higher risk of developing SCC, but intermittent and childhood sun exposure correlates more with BCC. Individuals with a keratinocyte carcinoma have a 10-fold increased risk of developing subsequent skin cancer as compared to the general population.[45]

The vast majority of BCC cases are sporadic, although a small number occur in patients with Gorlin syndrome, an autosomal dominant disorder caused by mutations in the *PTCH1* gene. Additionally, up to 70% of patients with sporadic BCC have a mutation in the *PTCH1* gene.[45] By contrast, individuals with previous SCC are more likely to acquire additional SCC and, potentially melanoma.[3] SCC has been reported to occur 100-fold more often in organ transplant recipients as compared to the general public, possibly due to the immunosuppressive therapy requirements in transplant patients.

Table 93–7

Photosensitizing Drugs

Antidepressants: citalopram, bupropion, fluoxetine
Glucose lowering meds: glimepiride, glyburide, glipizide
Immunosuppressants: methotrexate, cyclosporine
Antibiotics: azithromycin, doxycycline, sulfonamides, ketoconazole, voriconazole, griseofulvin, trimethoprim
Insomnia/seizure/anxiety meds: alprazolam, quetiapine, zolpidem, valproic acid, gabapentin
Antiarrhytmics: amiodarone
Other: estrogens, cholesterol-lowering meds, NSAIDs, isotretinoin, vitamin A, St. John's wort
Blood pressure meds: lisinopril, labetalol, hydralazine, diuretics

LO 1

Although responsible for a smaller number of keratinocyte carcinomas, arsenic has been shown to promote the expression of SCC-related keratins possibly by epigenetic modifications. Other reported offenders linked to the occurrence of NMSCs include photosensitizing drugs (Table 93–7), human papilloma virus and smoking, with the latter being reported rather in association with SCC than BCC.[46]

PATHOPHYSIOLOGY

NMSCs arise from epidermal keratinocytes and involve primarily squamous cells and basal cells of the epidermis and dermis skin layers. BCCs arise from interfollicular basal cells or keratinocytes in hair follicles or sebaceous glands.[46] Among them, AKs are the most common premalignant lesions. Incidence of AKs is primarily driven by increased cumulative UVR exposure. It is estimated that up to 16% of the AKs will progress to SCC, while approximately a quarter will undergo regression within a year.[46]

CLINICAL PRESENTATION AND DIAGNOSIS

BCC is characterized as *circumscribed* or *diffuse*, and within these two groups, it is further classified according to the type, degree of differentiation, and depth of invasion. The circumscribed types include nodular BCC, adenoid BCC, fibroepithelioma, and basosquamous or metatypical carcinoma. The diffuse BCC types are plaque-like with horizontal spread and poorly differentiated margins and include the superficial BCC, the morpheaform BCC, and the micronodular BCC.

Patient Encounter 2, Part 1

A 33-year-old woman presents to her dermatologist with a raised lesion located in front of her left ear. She states that it got enlarged over the past few months.

History: The lesion began as a "reddish spot" nearly a year ago, then has raised, becoming gradually enlarged and more noticeable over the last 3 months.

The woman reports being an occasional tanning bed user due to her pale complexion but uses sunscreen regularly while outside, especially when vacationing on the beach. However, she does not typically reapply sunscreen on her face due to her makeup.

What are some characteristics that differentiate BCC from SCC?

What counseling points can be provided concerning the use of sunscreen or UV protective sprays on the head and face?

Nodular BCC is the most common type of BCC followed by superficial BCC. The morpheaform BCC is the most aggressive subtype while superficial BCC is the least.[13] BCC has indolent growth characteristics with a very low metastatic and mortality rate.[47] Paradoxically, BCCs can cause extensive local destruction and significant disfigurement. Approximately 80% of BCCs occur on the head and neck. Superficial BCC occurs predominantly on the trunk. Early-stage BCC is usually small, translucent or pearly with raised telangiectatic edges.[47] BCC may also appear as raised, yellowish-reddish lesions with a border resembling a string of pearls and telangiectasia. Dermatoscopy may distinguish between a benign and malignant lesion; however, clinical examination is usually sufficient for diagnosis of BCC. Depending on the size of the tumor, subtype, and treatment planned, a biopsy may be needed.

SCC usually presents on sun-exposed sites because of UVR damage to the skin. Unlike BCC, SCCs are preceded by premalignant lesions such as dysplastic leukoplakia (DL), AK, or SCC in situ (Bowen disease).[47] DL appears as a thickened skin formed in response to trauma or benign human papilloma virus infections. Its occurrence in other locations, such as the oral mucosa, may be due to chronic exposure to chewing tobacco. AK presents as a small papule on areas of sun damage to the skin. The rate of AK progression to SCC is 1% to 10% in 10 years and may be higher if a patient has more than five AKs.[47] Patients with a Bowen lesion present with slowly enlarging erythematous scaly or crusted plaques and have a 3% to 5% risk of progressing to SCC. A typical SCC lesion has an adherent crust and ill-defined edges; the first sign of malignant SCC is the induration of the lesion. The rate of metastasis for SCC is 2% to 6% and may be as high as 10% to 14% in high-risk sites such as the ear and lip and 30% in the genital area.[48] If progressing to metastasis, this may occur 1 to 2 years after the diagnosis of the primary SCC with 80% of metastasis involving the regional lymph nodes.

Keratinocyte carcinoma staging follows the TNM staging system recommended by the American Joint Committee on Cancer, based on tumor size, lymph node involvement, and dissemination. It is seldom done for patients with BCC because nodal and visceral metastasis are rare for this type of keratinocyte carcinoma.[47] Dermatoscopy may be employed for such instances, a technique involving the use of epiluminescence microscopy or surface microscopy. This test is usually performed by the dermatologist and may improve early detection.

TREATMENT

LO 4

KEY CONCEPT In patients diagnosed with BCC and SCC, the primary goal of therapy is cure and prevention of recurrence. Despite the low mortality rate, the tissue destruction, functional impairment, and disfigurement associated with keratinocyte carcinoma diagnosis and treatment are very significant issues. Therefore, secondary goals of therapy for NMSC are preservation of function and restoration of cosmesis. The treatment options for NMSC involve surgery, pharmacologic therapy, or a combination thereof. Treatment selection depends on factors such as tumor size, the site of the lesion, patient comorbidities, histologic particularities, and clinical nature of the cancer.

Nonpharmacologic Therapy

▶ *Surgery*

Surgery is the primary treatment modality for all patients diagnosed with keratinocyte carcinomas. Full-thickness ablative procedure in the form of surgical excision of the tumor along with a margin of normal tissue surrounding the tumor is the preferred method for high-risk tumors. Obtaining negative surgical margins is critical for cure and decreasing the risk of tumor recurrence. A margin of 4 to 5 mm in the case of well-defined keratinocyte carcinomas ensures peripheral clearance in 95% of cases. Depending on the tumor size, degree of differentiation, and invasion of surrounding structures, larger margins of resection may be necessary.[47] The two most common surgical techniques used are electrodessication and curettage (ED&C) and Mohs micrographic surgery (MMS). The indications of each of these procedures are described below.

Low-risk tumors defined as small, well-differentiated, and slow growing can be treated with superficial ablative techniques, including ED&C and cryotherapy.[47] ED&C is a simple, cost-effective technique that uses repeated cycles of using a curette to cut through malignant tissue followed by the application of high voltage low current to the skin causing drying or desiccation of the tissue. ED&C is indicated for well-defined superficial lesions that are not located in areas with increased risk for metastasis. The disadvantage of this technique is that histologic confirmation of complete tumor removal is not possible.[43] This procedure is not recommended for treatment of recurrent disease, tumors of the face, and high-risk tumors.[43]

For high-risk NMSC or for tumors located in cosmetically or anatomically sensitive areas, MMS is the procedure of choice. The goal of this therapy is complete removal of the cancer with preservation of as much surrounding normal tissue as possible. MMS involves careful dissection, staining of frozen sections, and anatomic mapping of the tumor specimen. Sections are assessed immediately under the microscope by the surgeon, and the process is repeated until a tumor-free margin is attained. MMS cures 93% of primary NMSC and 90% to 94% of recurrent disease compared with 92% and 77% cure rate with standard excision for primary and recurrent disease, respectively.[49] Cure rates for all modalities decrease with the presence of high-risk features but are still superior with MMS.[49]

Cryotherapy is a procedure used primarily for smaller, low-risk keratinocyte carcinomas with clearly defined margins. It involves delivering liquid nitrogen at subzero temperatures as a spray or with a supercooled metal probe to destroy the malignant tissue in a single cycle or multiple cycles.[43] This technique can achieve comparable results to conventional surgery for well-differentiated, not too large, superficial tumors in older patients with BCC.[43] The procedure is contraindicated in the hair-bearing scalp, upper lip, and distal portion of lower leg because of delayed healing and high rates of recurrence.[43]

Patient Encounter 2, Part 2

PMH: The patient is 2 years status postrenal transplantation.

FH: Father has HTN and atherosclerosis. Mother has osteoporosis.

Examination: Reveals a round, flesh-colored, waxy papule 0.5 cm in diameter positioned 1 cm from the tragus of the left ear with a pearly appearance and slight pigmentation in the center. Two irregular blood vessels are visible.

Which type of NMSC is most likely present on this patient?

What risk factors, if any, does this patient have for recurrence of the disease or progression to metastases?

What is the most appropriate initial treatment option in this patient?

▶ *Radiation*

Radiation is not standard therapy for the treatment of keratinocyte carcinomas; however, there are circumstances in which radiation may be preferred. It may be offered to patients in whom surgery is not possible because the tumor is inoperable or surgery would lead to unacceptable cosmetic or functional impairment.[49] Radiation to the lip, ear, and nasal entrance for SCC may provide the best cosmetic and functional result. On the other hand, some patients may develop dyspigmentation, radiodystrophy, or telangiectasia at the irradiated site, resulting in poorer cosmetic outcomes. It should be used with caution in patients younger than 65 years because latent NMSC can develop after 15 to 20 years of radiation exposure.[47]

▶ *Photodynamic Therapy*

Photodynamic therapy (PDT) involves the topical application of a photosensitizing light-activated agent that causes tumor cell damage and death. The photosensitizer is converted to protoporphyrin IX after it is preferentially taken up by active tumor cells. Damage to cell membranes, organelles, and surrounding vasculature occurs when protoporphyrin IX is activated after exposure to a light source. Protoporphyrin IX has absorption bands at 408, 510, 543, 583, and 633 nm; therefore, blue light (corresponding to 408-nm band) and red light (corresponding to 633-nm band) are the most commonly used light wavelengths.[46] Blue light is used for superficial lesions because of its shorter wavelength and because it does not penetrate the skin as well as red light.[43]

δ-Aminolevulinic acid (ALA) and methyl aminolevulinate (MAL) are two photosensitizing agents that have FDA approval for the treatment of AK (Table 93–8 for dosing).[27] PDT has also been shown to be effective in the treatment of SCC in situ, but it is not indicated for SCC because of its extensive invasiveness and metastatic potential.[27] In patients with superficial BCC, MAL-PDT may be considered when surgery may result in suboptimal cosmetic outcomes or complications.[27] For patients with nodular BCC, MAL-PDT may be considered but not ALA-PDT.[27,43]

Table 93–8

Topical Therapy for Actinic Keratosis

Methyl Aminolevulinate Hydrochloride
Apply maximum 1 g topically on lesion(s) for one PDT session, followed by occlusive dressing for 2.5–4 hours, then red light illumination for 7–10 minutes. Two PDT sessions 1 week apart are required.

Aminolevulinic Acid
Apply topically to lesion(s) and let dry, then repeat once; rinse and pat dry after 14–18 hours, then expose to blue light photodynamic therapy illuminator; may repeat after 8 weeks. Cover and protect lesions with light-opaque material for 40 hours; sunscreen is ineffective.

Topical Fluorouracil
Apply 2% or 5% solution or cream topically twice daily over lesions for 2–6 weeks or apply 0.5% microsphere formulation once daily for up to 4 weeks.

Imiquimod
Apply topical formulation at bedtime daily 5 × per week for 6 weeks; leave on skin for 8 hours

The doses presented here are general. Clinicians should refer to reference materials to determine the specific dose based on the regimen the patient is receiving.

PDT, photodynamic therapy.

Pharmacologic Therapy

▶ *Fluorouracil*

LO 5

Nonsurgical treatment is used frequently for superficial keratinocyte carcinomas. Topical 5-fluorouracil has been used for the treatment of dermatologic disorders for approximately 45 years, and it has FDA approval for the treatment of AK and superficial BCC. Fluorouracil is available as both solution and cream with strengths ranging from 1% to 5%. There is also a microsphere-encapsulated 0.5% cream that has reduced systemic absorption with enhanced skin retention to reduce systemic side effects. The microsphere formulation is applied only once a day, providing patient preference and convenience over the twice-daily application with the other formulations. The FDA has approved 2% to 5% cream or solution and 0.5% microsphere formulation for AK. For superficial BCC, only the 5% strength is FDA approved for this indication. The most common side effects with topical fluorouracil are expected to occur within the initial 5 to 10 days of treatment, and include possible erythema, irritation, burning sensation, pruritus, and pain along with hypo- or hyperpigmentation. Patients may also experience inflammatory reactions that include crusting, edema, and oozing. The fluorouracil strength or frequency of application may be reduced if severe reactions occur. Topical steroids may be used concurrently with fluorouracil cream and for 1 to 2 weeks after treatment.[27] Caution should be used in administering fluorouracil to patients with dihydropyrimidine dehydrogenase deficiency, an enzyme critical in the metabolism of fluorouracil, because increased toxicity may occur.

LO 5

▶ *Imiquimod*

This therapy option works by stimulating innate and cell-mediated immune responses. It is FDA approved for the treatment of AK and for superficial BCC of the trunk, neck, or extremities when surgery may not be employed and follow-up is assured. Imiquimod has been shown to have complete clearing of AK in 50% of patients and partial clearing in 75% of patients with AK compared with 5% for those treated with placebo. Cure rates for imiquimod 5% in patients with superficial BCC are greater than 90%. The response rate is much lower for nodular BCC at 75%; therefore, it should be used in these patients only if they are not able to undergo surgery, radiation, or cryotherapy and the tumor is small and in a low-risk area. Imiquimod is not recommended for the treatment of invasive SCC, but data for SCC in situ showed a 93% cure rate; thus, it may be considered for this patient population.

Imiquimod is available in 3.75% strength, which may be applied daily on larger areas of skin, the balding scalp, or the full face, and 5% strength, which may be used on areas of skin that are 25 cm^2 or smaller (see Table 93–4). Imiquimod should be applied before bedtime and left on the skin for 6 to 10 hours. The most common side effects with imiquimod involve the area of application and present as erythema, pruritus, a burning or stinging sensation, and tenderness. Less commonly, hypopigmentation, fever, diarrhea, and fatigue may also occur. Temporary discontinuation of imiquimod and application of topical steroids may be necessary to alleviate the irritation symptoms. Imiquimod may be resumed at a decreased frequency after the symptoms have resolved.[27]

LO 6

▶ *Vismodegib*

Genetic alterations in the Hedgehog signaling pathway cause loss of function of *PTCH1*, which normally inhibits the signaling

Patient Care Process

Collect Information:

- Review current diagnosis with emphasis on skin cancer clinical signs (ABCDE)
- Obtain demographic information, family history, geographical location, and any specific lifestyle habits that may constitute risk factors
- Document medical and treatment history with emphasis on immune conditions, immunodeficiencies and immunosuppressive therapies, and medications associated with increased sun-related sensitivity (see Table 93–8)
- Any allergy or history of intolerance to biologics
- Understand cosmetic expectations and identify socioeconomic factors that may interfere with access to treatment and regular follow-ups

Assess the Information:

- Assess the possible causes of tumor occurrence (medical history, lifestyle, treatment, etc)
- Evaluate current performance status and assess other medications compliance
- Evaluate any treatment history that may (have) cause(d) photosensitivity
- Determine eligibility for immunotherapy and other current pharmacotherapy options
- Assess BRAF genotype status
- Review relevant laboratory tests (eg, electrolytes, liver panel, renal panel)
- Identify any predisposition to expected adverse events

Develop a Care Plan:

- Identify any contraindications for specific treatment options and select the best therapy
- Identify counseling points relevant to the patient and family
- Design a medication administration plan
- Design an adverse event monitoring and management plan

Implement the Care Plan:

- Educate the patient about the current options, explain the therapy selection, medication administration, common adverse events, reporting and management
- Review the patient's practices for skin cancer prevention
- Discuss importance of medication adherence and lifestyle modifications to reduce skin cancer risk
- Address any patient concerns about treatment outcomes
- Determine access to health care insurance and ensure smooth delivery of the treatment
- Assess patient expectations and verify their understanding regarding the course of treatment

Follow-up: Monitor and Evaluate:

- Evaluate how tumor resection affected the skin integrity, appearance, and function, the quality of life postoperative
- Assess skin recovery after radiation
- Verify patient and family understanding regarding subsequent prevention and systematic skin self-examination
- Review reported adverse events and appropriateness of their management
- Discuss treatment alternatives and options for recurrence prevention
- Review the appropriateness of lab monitoring for the ongoing treatment plan
- Address any palliative care symptoms and assess patients' psychological, physical, and social functioning

LO 3

activity of Smoothened (SMO), a transmembrane protein involved in Hedgehog signal transduction. This first-in-class, oral inhibitor of the Hedgehog signaling pathway is a small molecule that binds to and inhibits SMO. Vismodegib is approved by the FDA for the treatment of adult locally advanced or metastatic BCC that has recurred following surgery or has not been a candidate for surgery or radiation.

OUTCOMES EVALUATION

- Evaluate awareness and approach to avoid sun exposure and perform total-body skin self-examination.
- Assess treatment tolerance at every visit and ensure proper administration technique with topical treatments, such as fluorouracil or imiquimod: cleaning of treatment area before application, lesion area coverage with a 1-cm margin, and use of gloves, as well as hands washing after application.
- Assess side effects' management such as pain, itching, and inflammation and reinforce the need for dermatologist consult if worsening.
- Verify the presence of the *PTCH1* mutation before initiation of oral SMO inhibitor treatment and assess compliance.

ACKNOWLEDGMENTS

The author and editors wish to acknowledge and thank Drs. Kenneth Lin and Jill Kolesar, the authors of this chapter in the fourth edition of this book, and Dr. Trinh Pham, the primary author of this chapter in the second and third editions.

Abbreviations Introduced in This Chapter

AK	Actinic keratosis
ALA	δ-Aminolevulinic acid
APC	Antigen-presenting cell
BCC	Basal cell carcinoma
BRAF	Proto-oncogene B-raf
CDKN2A	Cyclin-dependent kinase inhibitor-2A
CNS	Central nervous system
CTL	Cytotoxic T lymphocyte
CTLA-4	Cytotoxic T-lymphocyte associated protein 4
CYP	Cytochrome P-450
DL	Dysplastic leukoplakia
ED&C	Electrodessication and curettage
ERK	Extracellular-signal-regulated kinase
HD	High dose

IFN	Interferon-α-2b
Ig	Immunoglobulin
IL-2	Interleukin-2
LFT	Liver function test
MAL	Methyl aminolevulinate
MAL-PDT	Methyl aminolevulinate–photodynamic therapy
MAP	Microtubule-associated protein
MAPK	Mitogen-activated protein kinase
MEK	MAPK/ERK kinases
MITF	Microphtalmia-associated transcription factor
MM	Malignant melanoma
MMS	Mohs micrographic surgery
NMSC	Nonmelanoma skin cancer
NRAS	Neuroblastoma RAS viral oncogene
PD-1	Programmed death-1
PD-L1	Programmed death-ligand 1
PDT	Photodynamic therapy
PPP6C	Protein phosphatase 6 catalytic subunit
PTCH1	Patch homolog-1
PTEN	Phosphatase and tensin homolog
RAC-1	Ras-related protein C3 botulinum toxin substrate 1 precursor
RAF	Protooncogene raf-1
RECIST	Response Evaluation Criteria in Solid Tumors
REMS	Risk Evaluation and Mitigation Strategy
SCC	Squamous cell carcinoma
SEER	Surveillance, Epidemiology, and End Results
SLN	Sentinel lymph node
SMO	Smoothened
SPF	Skin protection factor
SRS	Stereotactic radiosurgery
STK19	Serine/threonine-protein kinase 19
TIL	Tumor infiltrating lymphocytes
TNM	Tumor, node, metastasis
UVA/B	Ultraviolet (radiation) A/B
UVR	Ultraviolet radiation
WBRT	Whole-brain radiation therapy
XP	Xeroderma pigmentosum

94 Ovarian Cancer

Judith A. Smith

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Demonstrate understanding of the etiology and risk factors associated with the development of ovarian cancer.
2. Justify the risk and benefits of the surgical and chemoprevention options available for decreasing the potential risk of developing ovarian cancer.
3. Interpret and understand the utility of the screening tests and serologic markers for diagnosing ovarian cancer.
4. Distinguish the nonspecific physical signs and symptoms of ovarian cancer.
5. Recommend the appropriate surgical and chemotherapy treatment options for newly diagnosed, persistent, and recurrent ovarian cancer patients.
6. Discuss the role of maintenance treatment for improving overall survival for ovarian cancer patients.
7. Compare and contrast chemotherapy options for women with recurrent platinum-resistant ovarian cancer.

INTRODUCTION

Ovarian cancer is relatively uncommon but is the most incurable of the gynecologic cancers. Ovarian cancer is often denoted as the "silent killer." KEY CONCEPT The primary reason for the high mortality rate associated with ovarian cancer is the nonspecific symptoms and difficulty for early detection or screening that result in patients presenting with advanced disease. The majority of ovarian cancers are of epithelial origin. Each time ovulation occurs, the epithelium of the ovary is broken followed by occurrence of cell repair. The incessant ovulation hypothesis proposes that the increasing number of times the ovary epithelium undergoes cell repair is associated with the increasing risk of mutations and ultimately ovarian cancer. Although the majority of patients will achieve a complete response (CR) to primary surgery and chemotherapy, disease recurs in more than 50% of patients in the first 2 years after completion of primary treatment. KEY CONCEPT Ovarian cancers often cause metastasis via the lymphatic and blood systems to the liver, and/or lungs. Common complications of advanced and progressive ovarian cancer include **ascites** and small bowel obstruction (SBO), which often are associated with the end of life.

EPIDEMIOLOGY AND ETIOLOGY

In 2018, there were an estimated 22,240 new cases of ovarian cancer diagnosed with an associated 14,070 deaths.[1] Ovarian cancer remains the number one gynecologic killer and the fifth leading cause of cancer-related death in women. Despite great efforts and extensive research, addition of new agents and routes of administration, there has been little change in the mortality rate associated with ovarian cancer over the past six decades. Again, this high mortality rate associated with ovarian cancer can be attributed to its insidious onset of nonspecific symptoms, resulting in the majority of patients not presenting until the cancer has progressed to stages III to IV disease.

LO 1

As with many other disease states, a significant risk factor associated with ovarian cancer is aging. Risk of ovarian cancer increases from age 40 to 79 years, with the mean age at diagnosis being 63 years and the majority of women being diagnosed between 55 and 64 years.[2]

LO 1

Ovarian cancer is a sporadic disease; fewer than 10% of ovarian cancers can be attributed to heredity. KEY CONCEPT The majority of cases of ovarian cancer occur sporadically, making it difficult to screen and prevent. Although hereditary accounts for fewer than 10% of all ovarian cancer cases, when there is a family history, it appears to be an important risk factor in the development of ovarian cancer in some patients.[3] If one family member has a diagnosis of ovarian cancer, the associated risk is about 9%, but this risk increases to greater than 50% if there are two or more first-degree relatives (ie, mother and sister) with a diagnosis of ovarian cancer or multiple cases of ovarian and breast cancer.[3] Both breast cancer activator gene 1 (*BRCA1*) and breast cancer activator gene 2 (*BRCA2*) mutations have been associated with ovarian cancer. However, *BRCA1* is more prevalent, being associated with 90% of hereditary and 10% of sporadic cases of ovarian cancer.[3] Hereditary breast and ovarian cancer (HBOC) syndrome is one of the two different forms of hereditary ovarian cancer and is associated with germline mutations in *BRCA1* and *BRCA2*.[3,4] The hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome is a familial syndrome with germline mutations causing defects in enzymes involved in DNA mismatch repair, which has been associated with up to 12% of hereditary ovarian cancer cases.[4]

Patient Encounter 1

The patient is a 71-year-old active, nonobese woman, who has been in good health up until recently (about 8 weeks or so) when she started to feel fatigued often and have difficulties with bowel movements. On New Year's Day she mentioned to her daughter that she felt so bloated because she has had not been able to have a bowel movement in over a week despite use of OTC laxative medications. The following Monday she saw her general physician that recommended dietary modifications and new aggressive bowel regimen including an enema that evening. One month later, her symptoms persisted, so her physician ordered an abdominal CT scan which came back positive for fluid in abdominal cavity and 20 cm noncystic mass on right ovary extending to outside of colon wall. Of note, she has been married for 35 years with only two sexual partners in her lifetime. They have two daughters who are all grown adults. Her first menses was when she was 13 years old and menopause was at age 57 years. She has had infrequent alcohol on social occasions only and denies any tobacco use.

Based on the results from the abdominal CT scan, what laboratory tests are needed and what type of specialist should she be referred to complete her workup?

In the context of this patient, discuss why ovarian cancer is often denoted the "silent killer" and what needs to be done for earlier diagnosis of ovarian cancer.

Discuss the type of surgery recommended and outcome goal for this surgery.

Patient Encounter 2

A 37-year-old woman diagnosed with stage IIIC adenocarcinoma of the ovary with positive *BRCA1* mutation status post optimal debulking surgery completed six cycles of paclitaxel 175 mg/m^2 IV plus carboplatin AUC 5 IV. Her CT scan findings suggest no detectable disease and CA-125 within the normal range (28 U/mL [28 kU/L]) upon completion of her chemotherapy. She feels great and has no obvious symptoms of ovarian cancer at this time.

Discuss the advantages and disadvantages of treatment options for maintenance treatment with PARP-inhibitor versus bevacizumab for this patient.

Describe the role of second-look surgery for this patient.

LO 1

Although it is not clearly defined, hormones and reproductive history are associated with the risk of developing ovarian cancer. **Nulliparity**, infertility, early menarche, or late menopause is associated with an increased risk of ovarian cancer.[5]

Ovarian cancer is associated with certain dietary and environmental factors as well. A diet that is high in galactose and animal fat and meat increases the risk of ovarian cancer, whereas a vegetable-rich diet is suggested to decrease the risk.[6,7]

Screening and Prevention

▶ *Screening*

Currently, there is no standard effective screening tool that is adequately specific or sensitive for early detection.

Pelvic examinations are effective for detecting obvious tumors present with a sensitivity of 67% for detecting all tumors; however, minimal or microscopic disease cannot be detected on physical examination.[8] Pelvic examinations are noninvasive and well accepted, but they do not usually detect ovarian cancer until it is in advanced stage. Transvaginal ultrasound (TVUS) is a component of current screening practices. Typically, it is used in combination with cancer antigen-125 (CA-125) or could be used as a single modality. TVUS releases sonic sound waves that create an image of the ovary to evaluate the size and shape and detect the presence of cystic or solid masses. Limitations of this technique are lack of specificity and an inability to detect peritoneal cancer or cancer in normal size ovaries.[2,9] Most prevention clinics use this multimodality approach to screen high-risk women and recommend yearly ultrasound in combination with CA-125 blood test every 6 months.

LO 3

Serum CA-125 is the most extensively evaluated tumor marker for ovarian cancer. KEY CONCEPT Because CA-125 is a nonspecific marker, it is not a standard recommendation for routine screening for prevention of ovarian cancer. Unfortunately, since CA-125 is nonspecific, elevated levels can be associated with a number of other gynecologic and GI-related diseases. CA-125 levels in a woman without ovarian cancer are static or tend to decrease over time, but levels associated with malignancy continue to rise.[9,10]

▶ *Prevention*

Ovulation is considered a hostile event to the ovarian epithelium, making it more susceptible to damage and cancer. Interventions or conditions that limit the number of ovulations in a woman's reproductive history, including **multiparity**, have a protective effect.

LO 2

Chemoprevention Investigational chemoprevention strategies used for ovarian cancer include oral contraceptives (OCs), aspirin, nonsteroidal anti-inflammatory agents, and retinoids, although none of these is currently accepted as standard treatment for the prevention of ovarian cancer. The theory that OCs reduce the number of ovulatory events is a basic explanation of its protective effect. Recent studies have suggested that progestin-induced apoptosis of the ovarian epithelium is responsible for the chemopreventive effect of OCs. The theory is that cells that have genetic damage but are not yet neoplastic have an increased chance of undergoing apoptosis.[11] OCs decrease the relative risk to less than 0.4% in women that use OCs for longer than 10 years.[12] However, the maximum protective effect of OC use in women with *BRCA* mutations has been reported to be between 3 and 5 years.[12] At the same time, OC use has been associated with an increased risk of breast cancer.[11,13] Thus, women with a family history of breast cancer would not be ideal candidates for this preventive measure.

LO 2

Nonsteroidal anti-inflammatory agents, aspirin, and acetaminophen have been suggested for use in the prevention of different cancers, especially hereditary nonpolyposis colon cancer.[13] Although observational studies have linked these to a reduction of ovarian carcinoma risk, evidence is still lacking. Potential mechanisms include effects on normal ovulation shed and inhibition of ovulation.[13] Other pharmacologic interventions that have been suggested but are still being evaluated include vitamin A, lutein, and other carotenoids.[14,15] The protective effect of these agents is associated with inhibition of cell growth as well as promotion of cellular differentiation.[14]

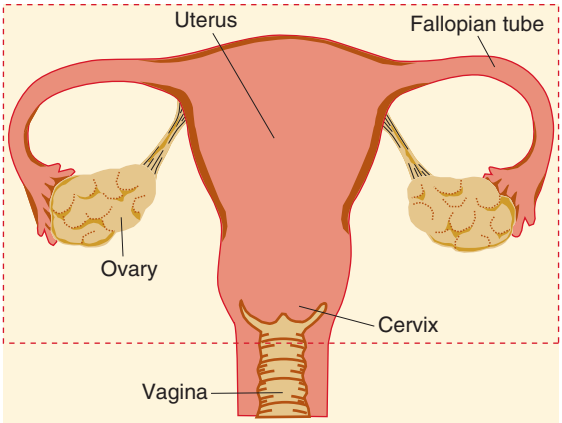

FIGURE 94–1. Diagram of female reproductive tract (uterus, fallopian tubes, ovaries, vagina). The *dashed line box* outlines what is removed during the total abdominal hysterectomy with bilateral salpingo-oophorectomy (TAH/BSO).

Prophylactic Surgery Surgical strategies are also used in the prevention of ovarian cancer. The goal is to remove healthy, at-risk organs and ultimately reduce the risk of developing cancer. These surgeries include prophylactic **bilateral salpingo-oophorectomy** (BSO) or tubal ligation (**Figure 94–1**).

LO 2 Prophylactic oophorectomy should be considered in any woman with a high risk of developing ovarian cancer.[16] The criteria for defining high risk includes any woman with two or more first-degree relatives with epithelial ovarian carcinoma; a family history of multiple occurrences of **nonpolyposis** colon cancer, endometrial cancer, and ovarian cancer; and a family history of multiple cases of breast and ovarian cancer.[17] Patients undergoing prophylactic oophorectomy need to be made aware that complete protection is not guaranteed.[17–19] Although a 67% reduction in risk has been shown, a potential 2% to 5% risk of peritoneal **carcinomatosis** remains.[18–20]

LO 2 **Tubal Ligation** Tubal ligation is another procedure that has shown potential for risk reduction. However, it is not recommended as a sole procedure in prophylaxis. The protective effect may be attributable to limiting exposure of the ovary to environmental carcinogens. A case-control study conducted by Narod and colleagues[19] found that a history of tubal ligation in *BRCA*-positive women was associated with a statistically significant 63% reduction in risk.

Genetic Screening Genetic screening is recommended for high-risk patients. Patients should be screened for genes such as *BRCA1* and *BRCA2* or other genes such as those associated with HNPCC or the HBOC syndrome.[3,21] Patient and family counseling and genetic counseling should be available for the patient and family to prepare and deal with the health and psychosocial implications of the genetic test results. Before this decision, the potential preventive options should be discussed, such as prophylactic BSO and/or total **hysterectomy**. Cancer risk and patient's health need to be balanced, but typically surgery can be held off until after the childbearing years.[20,21]

PATHOPHYSIOLOGY

The three current theories are the incessant ovulation hypothesis, the pituitary gonadotropin hypothesis, and the chronic inflammatory processes hypothesis.[2] The incessant ovulation hypothesis proposes that the pathogenesis of ovarian cancer is connected to continual ovulation. Ovulation is considered a "hostile" event to the ovaries, perhaps with not enough time for adequate repair. Each time ovulation occurs, the ovary epithelium is disrupted, and cell damage occurs. Thus, repeated ovulations may lead to a greater number of repairs of the ovarian epithelium and increase the possibility of aberrant repairs, mutation, and **carcinogenesis**.[22] The pituitary gonadotropin hypothesis associates the disease with elevations in gonadotropin and estrogen levels.[2] This leads to an increase in the number of follicles and therefore an increased risk of malignant changes. Finally, the chronic inflammatory processes may be involved with various environmental carcinogens to cause cancer.[2,13]

The three major pathologic categories of ovarian tumors include sex-cord stromal, germ cell, and epithelial. About 85% to 90% of ovarian cancers are of epithelial origin. Epithelial ovarian tumors are composed of cells that cover the surface of the ovary such as serous, mucinous, endometrioid, clear cell, and poorly differentiated adenocarcinomas. Germ cell tumors involve the precursors of ova with the most common type being dysgerminoma, which are most commonly diagnosed in women younger than the age of 40 years and generally have a better prognosis.[2] Sex-cord stromal tumors are not only indolent tumors that produce excess estrogen and androgens but also have a better overall prognosis.[2] Although the histologic type of the tumor is not a significant prognostic factor, it is important to know the histopathologic grade with high-grade being more aggressive and low-grade slower growing. Similar to other solid tumors, clear cell histology tends to be high grade and often chemotherapy-resistant. Undifferentiated tumors are associated with a poorer prognosis than lesions that are considered to be well or moderately differentiated.

TREATMENT

Desired Outcomes

Health care providers use a multimodality approach, including surgery and chemotherapy, in initial treatment of patients with ovarian cancer with a curative intent, or restoring a normal life span. KEY CONCEPT Although the majority of patients initially achieve a CR, disease will recur within the first 2 years in more than 50% of patients.[2,23] CR to treatment is defined as no evidence of disease can be detected by physical examination or diagnostic tests and patient has a normalized CA-125.

The stage of disease at the time of diagnosis is the most important prognostic factor affecting overall survival in ovarian cancer patients.[24] The estimated 5-year survival rates of patients with localized, regional, distant, and unstaged ovarian cancer are 92.1%, 73.2%, 28.3%, and 22.8%, respectively.[24] The histology of the disease is another predominant prognostic factor influencing treatment outcomes. Clear cell and undifferentiated tumors do not respond as well to chemotherapy.[2] The extent of residual disease and tumor grade are also predictive of response to chemotherapy and overall survival.[2] There are other prognostic factors that may predict how well a patient will respond to adjuvant chemotherapy.

The treatment goals shift when a patient presents with recurrent ovarian cancer. The desired outcomes focus on relief of symptoms such as pain or discomfort from ascites, slowing disease progression, and prevention of serious complications such as SBO. When a patient relapses, the prognostic factors are similar as after initial surgery except that the amount of time that has lapsed since the completion of chemotherapy should

Clinical Presentation and Diagnosis of Ovarian Cancer

General

Ovarian cancer typically has delay in diagnosis due to the common nonspecific signs and symptoms often initially suggesting GI-related complications. By the time symptoms become unrelenting and bothersome, patients most likely have advanced stage disease.

Symptoms

LO 4

Patients may experience episodes or persistent symptoms such as abdominal pain, constipation or diarrhea, flatulence, urinary frequency, or incontinence.

Signs

The degree of abdominal swelling secondary to fluid accumulation may present like "pregnant abdomen" and irregular vaginal bleeding.

Laboratory Test

- CA-125. The normal level is less than 35 U/mL (35 kU/L). Note: This test is associated with a lack of specificity. CA-125 can be elevated in a number of other states such as different phases of the menstrual cycle, endometriosis, and nongynecologic cancers. Therefore, it is important to rule out other cancers associated with the abdominal cavity.
- Carcinoembryonic antigen (CEA). CEA is a marker for colon cancer. A normal value is less than 3 ng/mL (3 mcg/L). However, this can also be elevated in serous papillary carcinomas of ovary.
- CA-19–9 is a marker for many GI tumors such as cholangiocarcinomas.

Chemistries with Liver Function Tests (LFTs)

- LFTs and serum creatinine might be suggestive of extent of disease. The majority of this information is needed to determine if the patient is a surgical candidate. Laboratory study results should be within normal limits.

Complete Blood Count (CBC)

- Abnormalities in CBC are not associated with ovarian cancer; however, this information is needed to determine if the patient is a surgical candidate. Laboratories should be within normal limits.

Other Diagnostic Tests

To characterize local disease, one or both of the following are completed:

- TVUS
- Abdominal ultrasound

To evaluate the extent of disease, only one of the following is completed:

- CT scan
- MRI
- PET scan

Chest x-ray is also often done as part of clearance for surgery.

Ovarian cancer is usually confined to the abdominal cavity, but spread can occur to the lung and liver and less commonly to the bone or brain. Disease is spread by direct extension, peritoneal seeding, lymphatic dissemination, or bloodborne metastasis. Lymphatic seeding is the most common pathway and frequently causes ascites.

be considered to determine if drug resistance is emerging in the tumor. Recurrent platinum-sensitive ovarian cancer patients generally have a better prognosis than platinum-resistant patients.

Nonpharmacologic Therapy

KEY CONCEPT Surgery is the primary treatment intervention for ovarian cancer.[25–27] A total hysterectomy with BSO (TH-BSO) (see Figure 94–1), **omentumectomy**, and lymphonectomy (or lymph node dissection) is the standard initial surgical treatment of ovarian cancer.[25] The objective of the surgery is to debulk the patient to less than 1 cm of residual disease remains. Residual disease less than 1 cm correlates with better CR rates to chemotherapy and better overall survival compared with patients with bulky residual disease (> 1 cm).[26,27] The size of residual tumor masses after primary surgery is found to be another important prognostic factor in patients with advanced ovarian cancer.[27]

LO 5

A thorough exploratory **laparotomy** is essential for the accurate staging of the patient.[25–27] KEY CONCEPT Ovarian cancer is staged surgically using the International Federation of Gynecology and Obstetrics (FIGO) staging algorithm. For certain patients with limited stage disease, surgery may be curative.

Other surgical procedures have been evaluated to improve overall survival. Debulking surgery is intended to relieve symptoms associated with complications such as SBO and help improve the patient's quality of life but does not have a curative intent. Interval debulking that is completed after two to three cycles of chemotherapy has not translated to an improved survival benefit. Often debated, the benefit of the "second-look laparotomy" to evaluate residual disease after the patient has completed chemotherapy remains controversial because it has been difficult to establish any impact on patients' overall survival. It has questionable benefit because although approximately 40% of patients with advanced disease have a negative second look, 50% still relapse.[2] The role of **laparoscopic** surgery is somewhat controversial for initial surgery but is more often considered in debulking of recurrent or advanced disease when the intent is palliative rather than curative.[25]

Pharmacologic Therapy

▶ *First-Line Chemotherapy*

KEY CONCEPT After initial surgery, the gold standard of care is six cycles of taxane/platinum-containing regimen for patients with advanced ovarian cancer.[28–30] Patients with limited disease, that is, stage IA, will have observation alone after surgery (**Figure 94–2**).

LO 5

Majority of patients though will receive adjuvant chemotherapy within 3 to 4 weeks after surgery. Most often, paclitaxel is the taxane agent used in combination with carboplatin as the preferred platinum agent.[28–30] Depending on patients' preexisting comorbidities and how well they tolerate chemotherapy regimens, substitution with docetaxel or cisplatin might be considered.

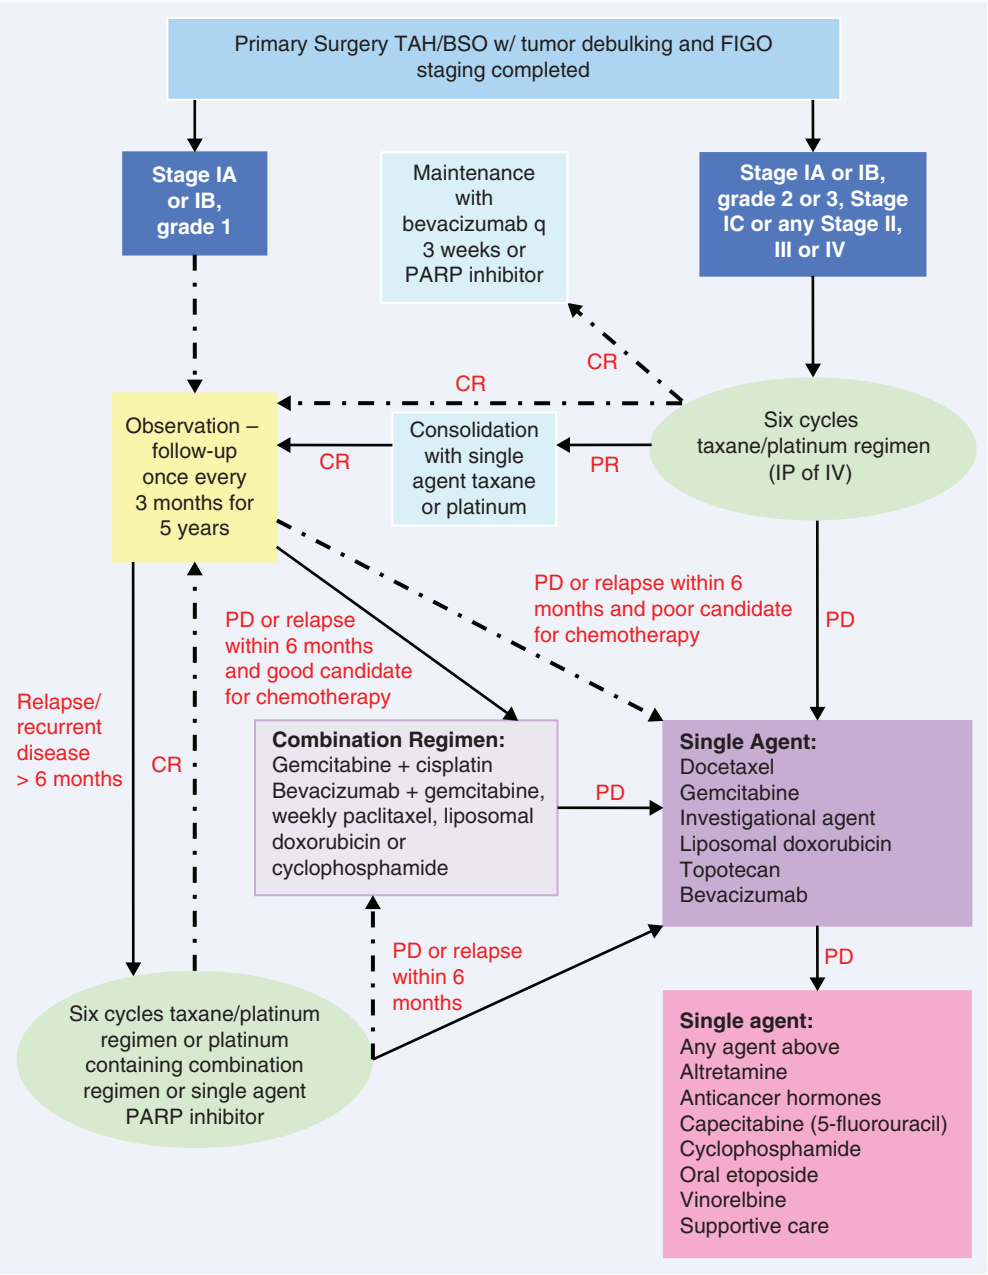

FIGURE 94–2. Summary of a chemotherapy treatment algorithm for epithelial ovarian cancer. (CR, complete response; FIGO, Federation of Gynecology and Obstetrics; PD, progressive disease; PR, partial response; TAH-BSO, total abdominal hysterectomy with bilateral salpingo-oophorectomy.)

The route of administration should also be discussed. Although intravenous (IV) administration is often used, intraperitoneal (IP) administration has been shown to improve overall survival and should be considered as an option for first-line treatment; however, patient selection for IP therapy is critical[31] (Table 94–1). Close monitoring of organ function, nausea/vomiting, myelosuppression, and neuropathies is necessary for all taxane/platinum regimens (Table 94–2).

▶ *Intraperitoneal Chemotherapy*

For more than four decades, numerous investigators have evaluated the IP route for administration of chemotherapy; however, it was not until the third report of an improvement in overall survival that brought its use to the forefront in the first-line setting.[32] The principal theory supporting IP administration is to increase drug concentration in the site of disease, specifically the abdominal cavity. Patient characteristics greatly influence response and tolerability of IP chemotherapy. To be selected to receive IP chemotherapy for first-line treatment of ovarian cancer, the patient should have tumor optimally debulked and no bowel resection with primary surgery, normal renal and liver function, younger age, and no significant comorbidities.

When IP therapy is administered, the placement of an IP catheter should occur at the time of surgery unless otherwise contraindicated. During IP administration, chemotherapy is delivered to the peritoneal space in 1 L of normal saline (NS) that has been warmed followed by another liter of NS to enhance

Table 94–1

Summary of First-Line Chemotherapy Regimens for Advanced Ovarian Cancer

Gold standard first-line chemotherapy after initial surgery for treatment of ovarian cancer:

Paclitaxel 175 mg/m^2 IV infused over 3 hours + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles (+/– bevacizumab 7.5 mg/kg once every 3 weeks × 6 cycles followed by additional 12 cycles after completion of primary chemotherapy)

Alternative first-line regimen: Paclitaxel IV with substitution of carboplatin IV with cisplatin IP and addition of paclitaxel IP therapy:

Patient selection is critical: must have optimally debulked disease (< 1 cm) and no significant comorbidities; younger patients tolerate better

Day 1: paclitaxel 135 mg/m^2 IV infused over 24 hours + day 2: cisplatin 100 mg/m^2 IP infused over 1 hour + day 8: paclitaxel 60 mg/m^2 IP infused over 1 hour. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Dose density. Consider for patients with optimal debulking, no comorbidities, good performance status:

Paclitaxel 80 mg/m^2 IV infused over 1 to 3 hours once a week with carboplatin AUC = 6 IV infused over 1 hour on day 1 only of 21-day cycle

Alternative first-line regimen: Substitution of cisplatin in place of carboplatin. Consider for patients experiencing difficulty with maintaining platelet counts:

Paclitaxel 135 mg/m^2 IV infused over 24 hours + day 2: cisplatin 75 mg/m^2 IV infused over 4 hours. Regimen is given once every 21 days × 6 cycles

Alternative first-line regimen: Substitution of docetaxel in place of paclitaxel. Consider for patients with preexisting or increased risk of neuropathies:

Docetaxel 75 mg/m^2 IV infused over 1 hour + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles

AUC, area under the curve; IV, intravenous.

drug distribution as tolerated.[33,34] The current standard IP regimen includes the administration of paclitaxel IV on day 1 followed by cisplatin IP on day 2 and then paclitaxel IP on day 8 given on a 21-day cycle for a total of six cycles (see Table 94–2). The most common toxicities associated with IP administration include abdominal pain, myelosuppression, neurotoxicity, and catheter-related infections. The substitution of carboplatin IP in place of cisplatin remains investigational and should not be recommended outside a clinical trial protocol.

► *Neoadjuvant Chemotherapy*

Neoadjuvant chemotherapy is first-line treatment for patients who are poor surgical candidates or patients with bulky or significant tumor burden.[23] For patients who are poor surgical candidates because of significant comorbidities, a combination of taxane with platinum agent is administered every 21 to 28 days as tolerated with the intent to relieve symptoms and slow progression of disease. In some cases, especially in elderly patients, single-agent carboplatin is used as palliative treatment instead. Chemotherapy alone has not been curative for patients with advanced ovarian cancer.[23]

In patients with bulky disease or significant tumor burden, neoadjuvant chemotherapy can be used to decrease tumor burden to increase the likelihood of optimal tumor debulking during surgery.[31] Typically, three cycles of the standard combination taxane/platinum regimen is administered once every 21 days. After surgery, patient will receive another three to six cycles depending on their response to chemotherapy.

► *Consolidation and Maintenance Chemotherapy*

Consolidation chemotherapy is the addition of cycles of the taxane/platinum regimen or the addition of single-agent platinum or single taxane after completion of first-line chemotherapy.[35,36] If the tumor has a partial response (PR) to first-line chemotherapy evident by a significant decline in CA-125 by greater than 50% presurgery level and/or tumor regression or decrease in size, then cancer is still considered taxane/platinum sensitive. Additional cycles of chemotherapy are given until CR is achieved (see Figure 94–2). In 2014, bevacizumab was approved as the first targeted therapy for maintenance treatment for ovarian cancer based on the improved overall survival observed in the ICON-7 study.[37] Maintenance chemotherapy is similar to consolidation chemotherapy except maintenance chemotherapy is given to patients who have achieved a clinically CR.[38] The rationale for maintenance chemotherapy is used to extend progression-free and overall survival by eliminating any microscopic disease present after completion of primary chemotherapy. Two agents from the class of poly(ADP-ribose) polymerase (PARP) inhibitors, niraparib and olaparib, have also demonstrated benefit in improving progression-free survival as maintenance therapy following achieving clinical CR to primary treatment.[39–41] PARP inhibitors were the second class of targeted therapy agents approved for maintenance treatment of ovarian cancer. While greater benefit has been observed in the presence of BRCA1 mutations, clinical benefit has been observed even in the absence of BRCA1 mutations as well.[40,41]

LO 6

For an extensive description of the common agents used in first-line, consolidation, and maintenance chemotherapy of ovarian cancer, please see Chapter 88. A brief overview of the regimens is provided in Table 94–1 and adverse effects are provided in Table 94–2.

Chemotherapy After Recurrence

In the recurrent setting, platinum sensitivity of the tumor is assessed first. If recurrence occurs in less than 6 months or disease progresses while the patient is receiving a platinum-based regimen, the cancer is considered platinum resistant (see Figure 94–2). These parameters are also used to determine if tumors are taxane sensitive or resistant. However, patients resistant to paclitaxel may still respond to docetaxel.[42] If the treatment goal is palliative care, then often single therapy will be used, but curative care typically is an aggressive combination regimen (see Figure 94–2 and Table 94–3). Sometimes an investigational agent may achieve responses equivalent or surpassing standard therapy, and should be considered for most patients.

► *Platinum Sensitive*

LO 7

In patients who experienced a CR to first-line chemotherapy and have had greater than a 6-month platinum-free interval, retreatment with a platinum-containing regimen is appropriate. The combination of carboplatin with gemcitabine, liposomal doxorubicin, or paclitaxel for the treatment of platinum-sensitive recurrent ovarian cancer with a curative intent is recommended[31,43,44] (see Table 94–3). However, in patients who

Table 94–2

Summary of Chemotherapy Agents Used for First-Line and Maintenance Treatment of Advanced Ovarian Cancer

Mechanism of Action of First-Line Agents
Platinum analogues: Produce intra- and interstrand cross-links and DNA adducts to disrupt DNA replication
Taxanes agents: Stabilize microtubules and prevent depolymerization of tubulin

Mechanism of Action of Maintenance Agents
PARP Inhibitors: Result in double stranded DNA breaks that cannot be repaired in cancer cells with BRCA mutations
Anti-angiogenic Agents: Inhibit VEGF-R, decrease microvasculator growth

Agent	Common Adverse Effects	Monitoring/Comments
First-Line		
Paclitaxel	Peripheral neuropathy (DLT), nausea/vomiting, alopecia, hypersensitivity reactions	1. Use caution with any elevation in AST (SGOT) 2. Give proper dosing for liver dysfunction. At least a 50% dose reduction generally recommended 3. Do not give if total bilirubin is > 5 mg/dL (86 µmol/L) 4. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine
Docetaxel	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	1. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases > 1.5 times, the ULN should not receive docetaxel 2. Do not give if biliary tract is obstructed 3. Premedicate for hypersensitivity reactions: dexamethasone
Carboplatin	Myelosuppression (DLT), nephrotoxicity, nausea/vomiting, electrolyte wasting, diarrhea, stomatitis, hypersensitivity reactions	1. Prehydration not required 2. If using BSA dosing, then give proper dosing for renal dysfunction CrCl ≥ 60 mL/min (1.00 mL/s): no dosage adjustment needed CrCl 41–59 mL/min (0.68–0.99 mL/s): give 250 mg/m^2 CrCl 16–40 mL/min (0.26–0.67 mL/s): give 200 mg/m^2 CrCl ≤ 15 mL/min (0.25 mL/s): do not give NOTE: Calvert formula (AUC dosing) is based on renal function, so no additional dose adjustment is needed 3. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea
Cisplatin	Neurotoxicity (DLT), nausea/vomiting, ototoxicity, nephrotoxicity, myelosuppression, electrolyte wasting, diarrhea	1. Prehydration and posthydration with electrolyte replacement (ie, potassium chloride 10 mEq [10 mmol] and magnesium sulfate 16 mEq [8 mmol]) required 2. Do not use if SrCr > 1.5 mg/dL (133 µmol/L) or BUN > 25 mg/dL (8.9 mmol/L) 3. Give proper dosing for renal dysfunction CrCl 46–60 mL/min (0.77–1.00 mL/s): decrease dose by 50%. CrCl 31–50 mL/min (0.51–0.83 mL/s): decrease dose by 75%. CrCl ≤ 30 mL/min (0.50 mL/s): do not use 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea
Maintenance		
Niraparib	Fatigue, nausea, thrombocytopenia, neutropenia, elevated liver function tests	1. Monitor CBC closely for first 4–6 weeks of treatment then monthly thereafter; 2. Consider antiemetic PRN
Olaparib	Edema, fatigue, hypomagensemia, nausea, thrombocytopenia, neutropenia	1. Monitor CBC monthly 2. Recommend antiemetics PRN
Rucaparib	Nausea, fatigue, elevations in liver function tests, rash, thrombocytopenia	1. Monitor CBC monthy 2. Recommend antiemetics PRN
Bevacizumab	Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression	1. Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio > 2 or measure urine protein every cycle and addition testing if positive for proteinuria 2. Use caution in patients with a history of thrombosis

AST, aspartate aminotransferase; AUC, area under the curve; BSA, body surface area; BUN, blood urea nitrogen; CrCl, creatinine clearance; DLT, dose-limiting toxicity; SrCr, serum creatinine; ULN, upper limit of normal.

are unable to tolerate additional combination chemotherapy regimens, carboplatin alone or any one of the second-line agents would be appropriate.[45] The PARP inhibitors (niraparib, olaparib, and rucaparib) are also approved for the treatment of platinum sensitive recurrent ovarian cancer[39–41] (see Table 94–2).

▶ *Platinum Resistant*

Recurrent or persistent ovarian cancer after platinum-based regimens has a discouraging prognosis. KEY CONCEPT Single-agent chemotherapy is standard practice for recurrent platinum-resistant ovarian cancer and any active agent that has not been used during initial treatment can be used. However, two combination regimens have demonstrated promising activity in the recurrent setting: (a) gemcitabine plus cisplatin because gemcitabine may modulate platinum resistance allowing it to regain its cytotoxic activity, and (b) bevacizumab with metronomic oral cyclophosphamide.[46–49] Other active agents include altretamine (formerly hexamethylmelamine), anastrozole, capecitabine (5-fluorouracil), cyclophosphamide, docetaxel, gemcitabine, liposomal doxorubicin, oral etoposide, vinorelbine, topotecan, bevacizumab, or investigational agents. In 2016, the FDA approved the addition of bevacizumab with paclitaxel, gemcitabine, or liposomal doxorubicin to improve

LO 7

Table 94–3

Summary of Combination Chemotherapy Regimens Used for Treatment of Recurrent Ovarian Cancer

Drug(s)	Regimen Dosing	Drug Monitoring Comments[b]
Combination Regimens		
Platinum Sensitive		
Paclitaxel and carboplatin	175 mg/m^2 IV (3-hour infusion) AUC 5–7.5 IV every 21 days	• Monitor closely for hypersensitivity reactions
Paclitaxel and cisplatin	135 mg/m^2 IV (24-hour infusion) 75 mg/m^2 IV	• Monitor closely for hypersensitivity reactions
Docetaxel and carboplatin	75 mg/m^2 IV AUC 5 IV every 21 days	• Monitor closely for hypersensitivity reactions
Gemcitabine and carboplatin	800 mg/m^2 IV days 1 and 8 AUC 5 IV day 1 every 21 days	• Monitor platelet counts closely • Monitor closely for hypersensitivity reactions
Liposomal doxorubicin and carboplatin	30 mg/m^2 IV over 1–3 hour AUC 5 IV every 28 days	• Monitor closely for hypersensitivity reactions • Liposomal doxorubicin infusion starts over 3 hour and decreases to 1 hour as tolerated • Counsel patient for PPE prevention
Niraparib	300 mg cap PO once daily	• Monitor CBC closely for first 4–6 weeks of treatment then monthly thereafter • Consider antiemetics PRN
Olaparib	300 mg tab PO BID	• Monitor CBC monthly • Recommend antiemetics PRN
Rucaparib	600 mg tab BID	• Monitor CBC monthly • Recommend antiemetics PRN
Platinum-Resistant[a]		
Gemcitabine and cisplatin	1000 mg/m^2 IV days 1 and 15 40 mg/m^2 IV days 1 and 15 every 28 days	• Monitor renal function closely • Monitor ANC closely, consider primary use of growth factor • Monitor closely for hypersensitivity reactions
Liposomal doxorubicin and bevacizumab	40 mg/m^2 IV day 1 only and 10 mg/kg day 1 and day 15 every 28 days	• Liposomal doxorubicin infusion starts over 3 hour and decreases to 1 hour as tolerated • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Gemcitabine and bevacizumab	800 mg/m^2 IV day 1 and day 15 & 10 mg/kg IV day 1 and day 15 every 28 days	• Use with caution in renal or liver dysfunction. No specific guidelines available • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Paclitaxel and bevacizumab	80 mg/m^2 IV weekly days 1, 8, 15, & 21 and 10 mg/kg IV day 1 and 15 every 28 days	• Monitor closely for hypersensitivity reactions • Counsel patient for PPE prevention • Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis
Cyclophosphamide and bevacizumab	50 mg PO once daily 10 mg/kg IV once every 2 weeks every 28 days (continuous)	• Monitor for hypertension; hold therapy blood pressure > 140/90 mm Hg • Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is > 2 or measure urine protein every cycle and addition testing if positive for proteinuria • Use caution in patients with history of thrombosis

[a]*Platinum resistance* = disease progression while on platinum agent or recurrence within 6 months of completion of platinum-based therapy.

[b]See Table 94–2 for specific monitoring parameters.

ANC, absolute neutrophil count; AUC, area under the curve; IV, intravenous; PO, oral; PPE, palmar-plantar erythrodysesthesia.

outcomes in the recurrent ovarian cancer setting[50] (see Figure 94–2). KEY CONCEPT Because the efficacy of the agents is similar, the selection of agent for treatment of recurrent platinum-resistant ovarian cancer is dependent on residual toxicities, clinician preference, and patient convenience. Table 94–4 gives a short summary of the adverse effects and monitoring parameters for chemotherapy agents commonly used for the treatment of recurrent ovarian cancer.

OUTCOME EVALUATION

Overall survival is impacted by success of initial surgery to debulk tumor to less than 1 cm of disease and response to first-line chemotherapy. The CA-125 level should be monitored with each cycle, and at least a 50% reduction in CA-125 after four cycles of taxane/platinum chemotherapy is related to an improved prognosis. Patients who achieve CR should have

Table 94–4

Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Docetaxel	75 mg/m^2 IV over 1 hour repeat every 21–28 days vs 30–40 mg/m^2 IV over 1 hour once every week	22 NR	Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression	1. Premedicate for hypersensitivity reactions with dexamethasone 2. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases > 1.5 times the ULN should not receive docetaxel 3. Do not give if the biliary tract is obstructed
Gemcitabine	800 mg/m^2 IV infused over 30 minutes once a week on days 1, 8, and 15 followed by 1 week of rest	13.9–27	Myelosuppression (DLT), flulike symptoms, headache, somnolence, nausea/vomiting, stomatitis, diarrhea, constipation, rash	1. Use with caution in renal or liver dysfunction. No specific guidelines available
Liposomal doxorubicin	40 mg/m^2 IV infused over 3 hours cycle 1 and 2; then infused over 1 hour; thereafter repeat every 28 days	12.3–18	Myelosuppression, stomatitis, mucositis, alopecia, flushing, shortness of breath, hypotension, headaches, cardiotoxicity, hand–foot syndrome	1. Give proper dosing for liver dysfunction; total bilirubin 1.2–3 mg/dL (21–51 µmol/L): reduce dose by 50%; total bilirubin ≥ 3 mg/dL (51 µmol/L): reduce dose by 75% 2. Do not give if total bilirubin is > 5 mg/dL (86 µmol/L)
Topotecan	1.5 mg/m^2 IV infused over 30 minutes on days 1, 2, 3, 4, and 5; repeat every 21 days *OR* 4 mg/m^2 IV infused over 30 minutes once a week for 3 consecutive weeks followed by 1-week rest	6.5–17 31	Myelosuppression (DLT), nausea/vomiting, diarrhea, stomatitis, abdominal pain, alopecia, AST/ALT elevation	1. Give proper dosing for renal dysfunction; CrCl 40–60 mL/min (0.67–1.00 mL/s): no dosage adjustment needed; CrCl 20–39 mL/min (0.33–0.66 mL/s): reduce dose by 50% 2. Do not give if CrCl < 20 mL/min (0.33 mL/s)
Altretamine (Hexalen)	260 mg/m^2 PO daily for 14–21 days; repeat every 28 days	9.7	Nausea/vomiting, diarrhea, abdominal cramping, myelosuppression	1. Monitor for potential CYP450 drug interactions
Capecitabine	1800–2500 mg/m^2 PO as divided dose twice daily for 14 consecutive days followed by 1 week of rest	29	Myelosuppression, hand–foot syndrome, nausea/vomiting, edema, stomatitis, diarrhea, cardiotoxicity, rash	1. Monitor for PPE and recommend regular use of lotions on hands and feet 2. Use with caution in renal dysfunction; CrCl ≥ 51 mL/min (0.84 mL/s): no dose adjustment; CrCl 30–50 mL/min (0.50–0.83 mL/s): reduce dose by 25%; CrCl < 30 mL/min (0.50 mL/s): do not give 3. Use with caution in liver dysfunction; no specific guidelines available
Etoposide	50 mg/m^2/day PO in divided doses given daily for 3 weeks followed by 1 week of rest	18	Myelosuppression, nausea/vomiting, anorexia, alopecia, headache, fever, hypotension	1. Give proper dosing for liver dysfunction; total bilirubin 1.5–3 mg/dL (26–51 µmol/L): decrease dose by 50%; total bilirubin 3–5 mg/dL (51–86 µmol/L): decrease dose by 75% 2. Do not give if total bilirubin is > 5 mg/dL (86 µmol/L) 3. Give proper dosing for renal dysfunction; CrCl 60–45 mL/min (1.00–0.75 mL/s): reduce dose by 15%; CrCl 44–30 mL/min (0.74–0.50 mL/s): reduce dose by 20%; CrCl < 30 mL/min (0.50 mL/s): reduce dose by 25%

Table 94–4

Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer (*Continued*)

Agent	Dose	Response Rate (%)	Common Adverse Effects	Monitoring/Comments
Letrozole	2.5 mg once daily	15	Headache, nausea, dyspepsia, skin rash	1. No protective effect on bone; recommend calcium supplementation
Tamoxifen	20 mg PO twice a day continuously until PD	10	Thrombocytopenia, anemia, thromboembolism, hot flashes, decreased libido, nausea/vomiting	1. Protective effect on bone and lipids 2. Increased risk for endometrial cancer
Vinorelbine	30 mg/m^2 IV infused over 15 minutes on days 1 and 8; repeat every 21 days	29	Constipation, neutropenia, anemia, thrombocytopenia, neurotoxicity	1. Consider bowel regimen to prevent constipation
Bevacizumab	15 mg/kg IV infused over 30–90 minutes every 21 days	NR	Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression	1. Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio > 2 or measure urine protein every cycle and addition testing if positive for proteinuria 2. Use caution in patients with a history of thrombosis

CrCl, creatinine clearance; DLT, dose-limiting toxicity; IV, intravenous; NR, not reported; PD, progressive disease; PO, oral; PPE, palmar-plantar erythrodysesthesia; ULN, upper limit of normal.

follow-up examinations once every 3 months, including CA-125, physical examination, and pelvic examination, and appropriate diagnostic scans (ie, computed tomography [CT], magnetic resonance imaging [MRI], or positron emission tomography [PET] scan) should be evaluated for the detection of disease. While evaluating the patient, specifically assess resolution of any residual chemotherapy-related adverse effects including neuropathies, nephrotoxicity, ototoxicity, myelosuppression, or nausea/vomiting. Younger patients with an active menstrual cycle before surgery will encounter "surgical menopause" and often experience intense hot flushes. Because there are concerns about potential of hormones in the pathogenesis of ovarian cancer, the use of hormone replacement therapy is controversial. The use of phytoestrogen supplements, such as black cohosh or soy, is also controversial. Alternative nutritional supplements with less controversy may include omega3 (fish oil), fiber supplement, or maca root. An effective alternative has been the use of the class of serotonin reuptake inhibitors such as venlafaxine or sertraline.

In the PD or recurrent setting, CA-125 levels should still be monitored with each cycle, but no change in therapy is recommended until after minimum of three cycles of chemotherapy. In addition, appropriate diagnostic scans (ie, CT scan, MRI, or PET scan) should be evaluated once every three cycles. Patients should also have routine physical examinations with each cycle of chemotherapy to evaluate for any physical toxicity associated with chemotherapy such as neuropathies, fluid retention, palmar-plantar erythrodysesthesia, myelosuppression, or nausea/vomiting.

Unfortunately, most patients will eventually progress through all chemotherapy options, and supportive care measures should be provided to maintain patient comfort and quality of life. Common complications while developing a plan for treatment of advanced or progressive ovarian cancer include ascites, uncontrollable pain, and SBO. Precaution should be used in removal of ascites because of the potential complications associated with rapid fluid shifts. Liberal use of opioids to control pain is appropriate as ovarian cancer patients cope with PD and approaching end

Patient Encounter 3

A 53-year-old woman with history of stage IIIC high-grade, clear cell carcinoma of the ovary had optimal tumor debulking and achieved clinical complete response to adjuvant chemotherapy with paclitaxel/carboplatin returns for her 6-month surveillance visit. Previous genetic testing revealed she and her tumor were negative for presence of any mutations. CT scan reveals peritoneal implants and two enlarged lymph nodes and slight fluid accumulation in abdominal cavity. Her CA-125 is 234 U/mL (234 kU/L) today. Her peripheral neuropathy has significantly improved.

Explain how to decide patient's tumor is platinum sensitive or resistant.

What tumor characteristics can you identify that would have suggested this patient was at higher risk for early recurrence?

Today is patient's first recurrence, compare and contrast treatment options to offer to this patient.

of life. Appropriate bowel regimens with laxatives and stool softeners should be used to prevent constipation. However, when a patient with a well-controlled bowel regimen presents with new onset of constipation, additional workup is required before altering the bowel regimen. KEY CONCEPT In ovarian cancer patients, SBO is a common complication of progressive disease. In general, laxatives should not be used in patients with SBOs. Before treating constipation, patients should have a physical examination and abdominal x-ray to rule out SBO. Often, palliative surgery is required to correct SBO and alleviate patient pain. Patients should not eat any solid or liquids until resolution of SBO. If inoperable SBO exists, then parenteral nutrition can be considered but weighed against ultimate treatment objectives. Overall, providing any measures needed to maintain patient comfort is the priority for patients with progressive ovarian cancer.

Patient Care Process

Collect Information:

- Perform medication history for use of prescription and nonprescription medications and nutritional/herbal supplements. Confirm drug allergies/intolerances.
- Review the medical history, family cancer history, and current physical and laboratory assessment findings.
- Speak with patient and review records to identify socioeconomic factors that may affect medication access or compliance with care plan.

Assess the Information:

- Evaluate current symptoms and signs that are disease-related that would be associated with new diagnosis or drug-related side effects from prior treatment.
- Evaluate medication list to determine if there are any potential interactions, therapy duplication, or unnecessary medications. Determine if there is any need for acute or chronic pain medications.
- Review laboratory tests, diagnostic testing, and BRCA1/2 testing.
- Based on family cancer history, determine if additional genetic testing is recommended.
- Review chemotherapy history to determine potential for platinum sensitivity/resistance and consider genetic mutation status in selection of treatment options.

Develop a Care Plan:

If patient is a surgery candidate:

- Evaluate patient comorbidities to determine if additional workup is necessary before tumor debulking surgery.
- Decide if any medications or supplements need to be stopped or changed before surgery (ie, aspirin, warfarin, nonsteroidal anti-inflammatory agents, omega3s, etc).

If patient is a chemotherapy candidate:

- Evaluate patient medications, residual toxicities, renal function, and liver function to determine if any potential dose adjustments ought to be recommended for the selected chemotherapy regimen (see Figure 94–2).
- Determine whether patient has insurance coverage for planned chemotherapy regimen and supportive care medications as indicated. Discuss if potential co-pays are financially feasible as well.

Implement the Care Plan:

Surgery:

- Review plan to use low molecular weight heparin for postoperation thrombosis prevention and submit request for insurance approval. Teach nonpharmacologic recommendations for thrombosis prevention postsurgery.
- Discuss when any medications/supplements should be stopped and when to resume in relation to timing of surgery.
- Review the plan for acute pain management postoperation as well as bowel regimen to prevent constipation/reduce straining after abdominal surgery.

Chemotherapy:

- Provide appropriate patient education on chemotherapy agents. Explain treatment intent—curative verses palliative (relief of symptoms) and the plan for monitoring response to treatment.
- Explain prevention and management of expected side effects such as infection, nausea and vomiting, neuropathy, electrolyte wasting, and bowel habits.

Follow-up: Monitor and Evaluate:

- After surgery, patient should have follow-up 2 to 3 weeks to evaluate wound healing, pain control/resolution, and determine if adjuvant chemotherapy is required.
- While on chemotherapy patient should have a follow-up every cycle to assess symptom control and chemotherapy tolerability.
- A CBC with differential should be checked prior to each chemotherapy dose with complete laboratory values evaluated each cycle.
- Chemotherapy doses should be decreased or discontinued for unacceptable toxicity or organ dysfunction when indicated.
- Tumor markers are also monitored with each cycle but not acted upon unless greater than 50% increase or consistent trend upward each cycle.
- Assess tumor response to chemotherapy once every 3 months with CT scan/MRI/PET scan as indicated. Follow current RECIST criteria to determine stable disease, response, or progression of disease.

Abbreviations Introduced in This Chapter

AUC	Area under the curve
BRCA1	Breast cancer activator gene 1
BRCA2	Breast cancer activator gene 2
BSO	Bilateral salpingo-oophorectomy
CA-125	Cancer antigen-125
CA-19	Cancer antigen 19
CEA	Carcinoembryonic antigen
CR	Complete response
CrCl	Creatinine clearance
DLT	Dose-limiting toxicity
FIGO	International Federation of Gynecology and Obstetrics
HBOC	Hereditary breast and ovarian cancer
HNPCC	Hereditary nonpolyposis colorectal cancer
IP	Intraperitoneal
LFT	Liver function test
NS	Normal saline
OC	Oral contraceptive
PARP	Poly(ADP-ribose) polymerase
PD	Progressive disease
PET	Positron emission tomography
PR	Partial response
SBO	Small bowel obstruction
TAH	Total abdominal hysterectomy
TVUS	Transvaginal ultrasound

95 Acute Leukemias

Nancy Heideman and Lisa Anselmo

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Describe the pathogenesis of acute leukemia.
2. Identify new agents for the treatment of leukemia.
3. Identify the risk factors associated with a poor outcome for the acute leukemias.
4. Explain the importance of minimal residual disease (MRD) and its implication on early bone marrow relapse.
5. Explain the role of induction, consolidation, and maintenance phases for acute leukemia.
6. Define the role of central nervous system preventive therapy for acute leukemia.
7. Recognize the treatment complications associated with therapy for acute leukemias.
8. Describe the late effects associated with the treatment of long-term survivors of acute leukemias.

INTRODUCTION

KEY CONCEPT The acute leukemias are hematologic malignancies of bone marrow precursors characterized by excessive production of immature hematopoietic cells. This proliferation of "blast" cells eventually replaces normal bone marrow and leads to the failure of normal hematopoiesis and the appearance in peripheral blood as well as infiltration of other organs. These blast cells proliferate in the marrow and inhibit normal cellular elements, resulting in anemia, neutropenia, and thrombocytopenia. Leukemia also may infiltrate other organs, including the liver, spleen, bone, skin, lymph nodes, testis, and central nervous system (CNS). Virtually anywhere there is blood flow, the potential for extramedullary (outside the bone marrow) leukemia exists.

KEY CONCEPT Acute leukemias are classified according to their cell of origin. Acute lymphocytic leukemia (ALL) arises from the lymphoid precursors. Acute nonlymphocytic leukemia (ANLL) or acute myelogenous leukemia (AML) arises from the myeloid or megakaryocytic precursors. As a result of clinical trials defining various prognostic (risk) factors that helped guide treatment modifications, the outcomes of acute leukemias, especially ALL, has improved dramatically over the past 50 years.[1] Risk-based treatment strategies that consider multiple phenotypic and biological risk factors and attempt to match the aggressiveness of therapy with the presumed risk of relapse and death are now the standard of care. Despite the overall success in treating patients with acute leukemias, minimal advances have been made in the treatment of relapsed ALL.[1]

EPIDEMIOLOGY AND ETIOLOGY

Epidemiology

Leukemia is a relatively uncommon disease. The current overall age-adjusted annual incidence of acute leukemia in the United States has remained relatively stable at 10 per 100,000 in children and 1 to 2 per 100,000 in adults.[2] In 2018, it is estimated there will be 60,300 new cases of leukemia, or 3.5% of all new cancer cases.[3]

In the pediatric population, leukemia is a common cancer, accounting for almost one-third of all childhood malignancies. ALL accounts for 75% to 80% of all cases of childhood leukemia, whereas AML accounts for no more than 20%. Males generally are affected more often than females in all but the infant age group, and its incidence is higher in whites than among other racial groups.

The incidence of AML in children is bimodal: It peaks at 2 years of age, decreases steadily thereafter to age 9 years, and then increases again at around age 16.[4] The average age of diagnosis for AML is about 65 years and is a result of an increasing incidence of AML with age.

Etiology

The cause of acute leukemias is unknown; multiple influences related to genetics, socioeconomics, infection, environment, hematopoietic development, and chance may play a role.[4] Table 95–1 lists the major conditions associated with acute leukemias. In most cases, however, there is no identifiable cause of the leukemia.

Although leukemia is rarely a hereditary disease, some genetic associations are evident. For example, among identical twins, the concordance for ALL in the initially unaffected twin is 20% to 25% within 1 year. Although the incidence in fraternal twins is much less, there is still a fourfold increase in the risk of leukemia in the initially unaffected twin compared with the healthy population. One explanation for this association may be a shared placental circulation, which allows for transmission of disease from one twin to the other. Additionally, leukemia has an increased incidence in several chromosomally abnormal populations. For example, patients with Down syndrome have a 20 times increased risk of developing leukemia compared with the rest of the population.

Table 95–1

Clinical Conditions Associated with an Increased Frequency of Acute Leukemias

Drugs
Alkylating agents
Epipodophyllotoxins

Genetic Conditions
Down syndrome
Bloom syndrome
Fanconi anemia
Klinefelter syndrome
Ataxia telangiectasia
Langerhans cell histiocytosis
Shwachman syndrome
Severe combined immunodeficiency syndrome
Kostmann syndrome
Neurofibromatosis type 1
Familial monosomy 7
Diamond-Blackfan anemia

Chemicals
Benzene

Pesticides

Radiation
Ionizing radiation

Viruses
Epstein-Barr virus
Human T-lymphocyte virus (HTLV-1 and HTLV-2)

Social Habits
Cigarette smoking
Maternal marijuana use
Maternal ethanol use

Adapted from Bickert-Poon B, Hatfield-Seung A. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill; 2014.

Exposure to environmental agents, such as agricultural chemicals, pesticides, and radiation, is associated with leukemia, but none is conclusively related to the development of leukemia. An increased frequency of ALL is associated with higher socioeconomic status. It is postulated that less social contact in early infancy and thus a late exposure to some common infectious agents may have some impact.[4]

Risk factors for the development of AML include exposure to environmental toxins, Hispanic ethnicity, and genetics.[5] Also of concern is the increased prevalence of AML as a secondary malignancy, resulting from chemotherapy and radiation treatment for other cancers. Alkylating agents, such as ifosfamide and cyclophosphamide, and topoisomerase inhibitors, such as etoposide, are linked to an increased risk of AML and **myelodysplastic syndrome** (MDS).[5]

PATHOPHYSIOLOGY

Hematopoiesis is defined as the development and maturation of blood cells and their precursors. In utero, hematopoiesis may occur in the liver, spleen, and bone marrow; after birth, this process occurs exclusively in the bone marrow. All blood cells are generated from a common hematopoietic precursor, or stem cell. These stem cells are self-renewing and pluripotent and thus are able to commit to any one of the different lines of maturation that give rise to platelet-producing megakaryocytes, lymphoid, erythroid, and myeloid cells. The myeloid cell line produces monocytes, basophils, neutrophils, and eosinophils, whereas the lymphoid stem cell differentiates to form circulating B and T lymphocytes, natural killer (NK) cells, and dendritic cells. In contrast to the ordered development of normal cells, the development of leukemia seems to represent an arrest in differentiation at an early phase in the continuum of stem cell to mature cell.[1]

LO 1

Both AML and ALL are thought to arise from clonal expansion of these "arrested" cells. As these cells expand, they acquire one and often more chromosomal aberrations, including translocations, inversions, deletions, point mutations, and amplifications.[4] The translocation t(12;21) or *TEL–AML1* is found in approximately 25% of cases of pediatric ALL and is associated with a favorable prognosis.[6] This translocation is uncommon in adults. Another example is the t(9;22) translocation (Philadelphia chromosome, Ph^+), which results in the *BCR–ABL* fusion protein. This translocation produces a novel kinase that leads to uncontrolled proliferation, survival, and self-renewal of cells. It is uncommon in childhood ALL and commonly found in adult ALL, especially in older patients.

Patients with MDS or AML as a secondary neoplasm are often characterized by having had prior alkylator-based or etoposide-based chemotherapy. Patients who have received treatment for Hodgkin disease or solid tumors are most at risk for this problem because they often treated with these agents. Patients with MDS have an abnormal bone marrow and a variety of cytopenias involving one or more of their marrow cell lines. They are at high risk of converting to overt leukemia over time. A variety of complex cytogentic findings and monosomies of chromosome 5 or 7, and 11q23 translocations are often present in this population.[5]

Leukemia Classification

Classification methods for leukemia have evolved from simple schemes that were largely phenotypic and considered only age, gender, white blood cell (WBC) count, and blast morphology to now-complex methods that include biological features such as cell-surface receptors, DNA content (ploidy; more or less than normal chromosomal DNA content), and a variety of cytogenetic abnormalities.

For all newly diagnosed patients with leukemia, an aspirate of the liquid marrow and a bone marrow core biopsy are obtained. Analysis of the leukemic cell surface markers (immunophenotyping) establishes three types of ALL, pre-B, mature B, and T-cell precursor ALL. There are eight subtypes of AML (M0 to M7) as classified by the French-American-British (FAB) scheme. The World Health Organization identifies specific entities within the diagnosis of AML based on a combination of karyotypic and molecular mutations (**Tables 95–2** and **95–3**).

Immunophenotyping by **flow cytometry** has taken on an increasingly important role in the diagnosis of leukemia. Owing to the ease of application, sensitivity, and quantifiable results, flow cytometry is the preferred method for leukemic lineage as well as prognostic assignment.[7] This approach takes advantage of the development of diagnostic monoclonal antibodies (MABs) to many cell-surface antigens that are differentially expressed during hematopoietic differentiation. The antigens are referred to as antibody cluster determinants (CDs) that define cells at various stages of development and can easily separate ALL from AML and T-cell from pre–B-cell ALL.[4,7] The combined approach of flow cytometric identification and cytogenetic DNA content, much of which is also revealed by flow cytometry and fluorescent in situ hybridization (**FISH**; microscopic, fluorescence identification of chromosomal features) has facilitated diagnosis and delineation of specific subtypes of the acute leukemias. Common immunophenotypic markers seen in AML and ALL are provided in **Table 95–4**.

Prognostic Factors

KEY CONCEPT The goal of treatment is to match treatment to risk and minimize overtreatment or undertreatment. Patients with leukemia are categorized based on clinical and biological features that mirror their risk of relapse. Risk assessment is an important

Table 95–2

Morphologic (FAB) Classification of AML

Subtype		Frequency of FAB Subtype		
		Adults (%)	Children Older Than 2 Years (%)	Children Younger Than 2 Years (%)
M0	Acute myeloblastic leukemia without maturation	5	Low	Low
M1	Acute myeloblastic leukemia with minimal maturation	15	17	7
M2	Acute myeloblastic leukemia with maturation	25		27
M3	Acute promyelocytic leukemia	10		5
M4	Acute myelomonocytic leukemia	20	30	26
M5a	Acute monoblastic leukemia, poorly differentiated	10	52	26
M5b	Acute monoblastic leukemia, well differentiated	5		
M6	Acute erythroleukemia	5		2
M7	Acute megakaryoblastic leukemia	5		7

FAB, French-American-British.

factor in the selection of treatment. Age, WBC, leukemic cell-surface markers, DNA content, and specific cytogenetic abnormalities predict response to therapy and are used to assign risk and associated treatment.[4] On the basis of these prognostic variables, patients are assigned to standard-, high-, or very-high-risk groups that determine the aggressiveness of treatment.

Table 95–3

WHO Classification of AML and Related Neoplasms

AML with recurrent genetic abnormalities:
AML with t(8;21)(q22;q22); *RUNX1-RUNX1T1*
AML with inv(16)(p13.1q22) or t(16;16)(p13.1;q22); *CBEB-MYH11*
Acute promyelocytic leukemia (APL) with t(15;17)(q22;q12); *PML-RARA*
AML with t(9;11)(p22;q23); *MLLT3-MLL*
AML with t(6;9)(p23;q34); *DEK-NUP214*
AML with inv(3)(q21q26.2) or t(3;3)(q21;q26.2); *RPN1-EVI1*
AML (megakaryoblastic) with t(1;22)(p13;q13); *RBM15-MKL1*
Provisional entity: AML with mutated NPM1
Provisional entity: AML with mutated CEBPA

AML with myelodysplasia-related change

Therapy-related myeloid neoplasms

AML, not otherwise specified:
Undifferentiated AML (M0)
AML with minimal differentiation (M1)
AML without maturation (M2)
AML with maturation (M2)
Acute myelomonocytic leukemia (M3)
Acute monoblastic/monocytic leukemia (M4)
Acute erythroid leukemia (M5)
Pure erythroid leukemia (M6)
Erythroleukemia, erythroid/myeloid (M6)
Acute megakaryoblastic leukemia (M7)

Acute basophilic leukemia

Acute panmyelosis with myelofibrosis

Myeloid sarcoma

Myeloid proliferations related to Down syndrome:
Transient abnormal myelopoiesis
Myeloid leukemia associated with Down syndrome

Blastic plasmacytoid dendritic cell neoplasm

AML, acute myeloid leukemia.

▶ *Prognostic Factors in ALL*

In both children and adults with ALL, clinical trials have identified several risk factors that correlate with outcome (Table 95–5). Prognostic features include age, WBC count, cytogenetic abnormalities, ploidy (DNA content), leukemic cell immunophenotype, and degree of initial response to therapy, and minimal residual disease (MRD; the degree of subclinical disease remaining at various times after starting treatment).[4,7,8] When these factors are combined, they predict groups of patients with varying degrees of risk for treatment failure. LO 3

The importance of age is evident in both children and adults. Children younger than 1 year or older than 10 years of age have a poorer outcome than others. Likewise, in adults, there is a steady decline in the rate of survival with increasing age. LO 3

Similar to age, the WBC count at presentation is a reliable indicator of complete response (CR) rate and outcome. The WBC count is indicative of tumor burden, although the underlying biological mechanisms that account for the unfavorable outcomes associated with an elevated WBC count are unclear. Patients with WBC counts of less than $50 \times 10^3/mm^3$ ($50 \times 10^9/L$) are considered being at standard risk and have a better outcome than those with higher WBC counts at presentation, which is associated with higher risk of treatment failure (see Table 95–5).

Specific chromosomal abnormalities in leukemic cells also possess prognostic significance. Blast cells with a translocation of parts of chromosome 12 and 21 (the *TEL–AML1* fusion) or trisomies of 4, 10, and 17 are considered to have favorable genetic

Table 95–4

Common Immunophenotypes in Acute Leukemia

Leukemia	Common Immunophenotypes
AML	CD13, CD15, CD33, CD14, CD64, CD65, and C-KIT
B-cell ALL	CD19, CD20, CD10, CD22, CD79a, HLA-DR, Tdt
T-cell ALL	CD2, CD3, CD4, CD5, CD7, Tdt

ALL, acute lymphoblastic leukemia; AML, acute myeloid leukemia; CD, cluster determinant.

Table 95–5

Prognostic Factors in ALL

	Risk for Leukemic Relapse	
Factor	**Standard/Low**	**High**
Immunologic phenotype	pre–B cell	Null cell, T cell, pre–B cell, mature B cell
WBC count at diagnosis	$< 50 \times 10^3/mm^3$ ($50 \times 10^9/L$)	$> 50 \times 10^3/mm^3$ ($50 \times 10^9/L$)
Patient age	1–10 years	< 1 year or > 10 years
Cytogenetics	Normal karyotype, t(12;21), trisomy 4,10,17	t(9;22); t(4;11); t(17;19), iAmp21, ph-like
Ploidy	Hyperdiploidy	Hypodiploidy, near haploid
CNS leukemia	Absent	Present
MRD at end of induction	< 0.01%	> 0.01%

WBC, white blood cell.

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. Pediatr Clin North Am. 2008;55(1):1–20.

LO 3

features.[4] The presence of the Philadelphia chromosome (Ph^+), the result of a specific translocation between chromosome 9 and 22, t(9;22)(q34;q11.2), is a high-risk feature, which is present in about 3% of children but is much more common in adults with ALL. This translocation results in a novel tyrosine kinase that drives cell proliferation.[7,8]

Among children younger than 1 year of age, as many as 70% possess a poor prognostic genotype represented by the presence of the *MLL* (11q22) gene rearrangement. This finding is rare among older patients. Leukemias with the *MLL* gene rearrangement are highly resistant to the key antileukemic drugs such as glucocorticoids and L-asparaginase.[9]

The DNA content of blast cells, hyper-, hypo-, or diploid, corresponding to increased, decreased, or normal chromosome numbers, is also a prognostic factor. Lower risk patients with hyperdiploidy (> 50 chromosomes per leukemic cell) generally include approximately 25% of children who have B-cell lineage ALL.[6] These children are between the ages of 1 and 9 years, but the higher risk patients with normal diploidy (50 chromosomes) generally are older. Hypodiploid ALL with less than 44 chromosomes occurs in 1% to 5% of pediatric patients with ALL and is an independent risk factor for poor prognosis with declining prognosis with decreased chromosome number.[10]

Patients with cell-surface markers indicating that the blasts are early in the B-cell lineage (CD markers) are considered favorable and standard risk, whereas those with mature B-cell and T-cell blasts are considered high risk. T-cell ALL is found in approximately 15% of childhood ALL. Compared with B-lineage ALL, T-cell ALL is relatively resistant to different classes of drugs, including methotrexate and cytarabine.

Patients completing induction treatment and in apparent remission still harbor malignant cells in their bone marrow even though they appear disease free by peripheral blood and bone marrow morphology. Assuming that most patients present with about a 10^{11} leukemic cell burden at diagnosis, at least 10^9 cells remain after initial treatment. These residual leukemic cells are below the limits of detection using standard morphologic examination. Measurement of this population of cells has become an increasingly significant prognostic factor and a determinant of the aggressiveness of postinduction therapy. Through flow cytometric analysis and **polymerase chain reaction**, it is possible to detect one leukemic cell among 10^6 normal cells, representing 1000-fold greater sensitivity than morphologic examination.[11,12]

LO 4

KEY CONCEPT Minimal residual disease (MRD) is a quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission. This measure has become one of the strongest predictors of outcome for patients with acute leukemia. The elimination of MRD is a principal objective of postinduction leukemia therapy. Several studies in children, in whom ALL is common, have evaluated disease levels at the end of induction and correlated

Patient Encounter 1, Part 1

A 22-year-old male presents to the emergency department with a history of a sore throat for the past 4 days. He felt slightly feverish 4 days ago and noticed some slight swelling in his neck. He has not lost any weight, and had a good appetite up until he started having a sore throat. He has not had any recent contact with anyone who is sick. He denies any upper respiratory infection symptoms. He does not have any headaches and visual changes. Upon physical examination his neck is supple with multiple cervical lymphadenopathies that are not tender. His complete blood count shows a total white blood count (WBC) of 284.5×10^9/L (reference range 4–10) with 10% blasts; platelet count 48×10^9/L (reference range 150–400). His serum creatinine is 144 umol/L (reference is 54–146), potassium 3.3 mmol/L (3.5–5.1), Uric acid 517 umol/L (190–541). Bone marrow biopsy has 60% blasts.

His diagnosis is AML.

Is this patient at risk for tumor lysis syndrome?

What are the prognostic factors for this patient?

What is the role of pediatric treatment protocols for this patient?

Patient Encounter 1, Part 2

The patient is admitted to the inpatient hematology service in the hospital. Mutational analysis is negative for *FLT3* and *NPM1* mutations. He is started on a pediatric research protocol consisting of cytarabine, daunorubicin, and etoposide.

Would this patient benefit from midostaurin?

Would this patient benefit from an allogeneic stem cell transplant?

Patient Encounter 1, Part 3

He receives two induction chemotherapy regimens and two intensification regimens. Less than a year after his initial diagnosis he develops worsening anemia and thrombocytopenia concerning for relapsed AML.

Would he be a candidate for azacitidine?

Table 95–6

Risk Category According to Cytogenetic Abnormalities Present

	Risk Category		
Disease	**Good Risk**	**Intermediate Risk**	**High Risk**
AML	t(8;21) (q22;q22); inv(16); t(15;17); t(9;11), trisomy 21	Normal karyotype; trisomy 8; 1 1q23; del(7q); del(9q); trisomy 22	Complex karyotype; –5; –7; del (5q); inv(3P)
Probability of relapse	25% or less	50%	70% or more
4-Year survival	70% or more	40%–50%	20% or less
ALL	Hyperdiploidy; t(12;21), trisomy 4, 10, 17		t(9;22); t(8;14); t(4;11); t(17;19), hypodiploid, near haploid
Probability of relapse	< 10%	< 20%	30%–40%
4-Year survival	> 80%	> 60%	40%–50%

ALL, acute lymphocytic leukemia; AML, acute myelogenous leukemia.

Adapted from Pieters R, Carroll WL. Biology and treatment of acute lymphoblastic leukemia. Pediatr Clin North Am. 2008;55(1):1–20.

these values with event-free survival (EFS). For a patient with detectable MRD less than 0.1% at the end of induction, EFS is 88% at 3 years. Conversely, a patient with high MRD (> 1%) has a 3-year EFS of only 30%.[13] Assessment of MRD is also emerging as an important indicator of disease recurrence in the adult population and in patients with AML.

▶ *Prognostic Factors in AML*

The major prognostic factors in newly diagnosed AML are age, subtype, chromosome status, ethnicity, and body mass index.

Older adults with AML (> 60 years), compared with younger patients with the same disease, have a dismal prognosis and represent a distinct population in terms of disease biology, treatment-related complications, and overall survival (OS). Older patients with secondary AML have an even poorer prognosis. Older patients also have a higher incidence of unfavorable chromosomal abnormalities, such as aberrations of chromosomes 5, 7, or 8, FLT_3-internal tandem duplication (ITD) and fewer abnormalities that are associated with a more favorable outcome, such as t(8;21) or inv(16) (Table 95–6).[5,13]

Clinical Presentation and Diagnosis of ALL[3,6,11]

General

- Typically, patients have symptoms for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Patients often present with bone pain secondary to expansion of the marrow cavity from leukemic infiltration.
- CNS involvement is common at diagnosis.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.
- Patients may present with organ involvement, such as peripheral adenopathy, hepatomegaly, and splenomegaly.
- T-lineage ALL may present with a mediastinal mass.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic. Approximately 50% of children present with platelet counts of less than $50 \times 103/mm^3$ (50×10^9/L). The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts over $100 \times 10^3/mm^3$ (100×10^9/L), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus often are elevated. Calcium usually is low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

Other Laboratory Tests

Flow cytometric evaluation of bone marrow and peripheral blood is performed to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. At diagnosis, an LP is performed to determine if CNS leukemia is present.

Clinical Presentation and Diagnosis of AML[3,6,11]

General

- Patients may have symptoms of AML for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

Symptoms

- The patient may present with weakness, bone pain, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Chloromas (localized leukemic deposits named after their color) may be seen, especially in the periorbital regions and as skin infiltrates.
- Gum hypertrophy is indicative of AML M4 and AML M5 subtypes.
- Disseminated intravascular coagulation may be present in all AML subtypes, but is common in AML M3 and is associated with generalized bleeding or hemorrhage.
- Lymphadenopathy, massive hepatosplenomegaly, and bone pain are not as common in AML as in ALL.

Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.

Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic.
- Approximately 50% of children present with platelet counts of less than $50 \times 10^3/mm^3$ ($50 \times 10^9/L$).
- The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts of over $100 \times 10^3/mm^3$ ($100 \times 10^9/L$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus are often elevated. Calcium is usually low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

Other Diagnostic Tests

Flow cytometric evaluation of bone marrow and peripheral blood to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. The presence of greater than 20% blasts in the bone marrow is diagnostic for AML. At diagnosis, an LP is performed to determine if CNS leukemia is present. The CNS is involved at diagnosis in approximately 15% of patients.[14]

Recent studies suggest that ethnicity may be an important predictor of outcome in children with AML. Investigators found that African Americans treated with chemotherapy had a significantly worse outcome than whites, perhaps suggesting race-related pharmacogenetic differences. Body mass index may also affect the prognosis of children with AML. Underweight patients and overweight patients were less likely to survive than normal weight patients because of a greater risk of treatment-related deaths.[15] Current clinical trials in adults and pediatrics strongly suggest that patients with detectable MRD at the end of induction therapy or consolidation is strongly associated with the risk of relapse.[14]

TREATMENT

Desired Outcome

The primary objective in treating patients with acute leukemia is to achieve a continuous complete remission (CCR). **Remission** is defined as the absence of all clinical evidence of leukemia with the restoration of normal hematopoiesis. For both ALL and AML, remission induction is achieved with the use of myelosuppressive chemotherapy that initially induces a state of bone marrow aplasia as the leukemic cells die followed by a slow return and proliferation of normal cells. After this period, hematopoiesis is restored. Failure to achieve remission in the first 7 to 14 days of therapy is highly predictive of later disease recurrence. This again represents the growing importance of MRD in prognosis and treatment.

Nonpharmacologic Therapy

This year, roughly 1.7 million people will be diagnosed with cancer in the United States. With improvements in detection and treatment, approximately two-thirds of those diagnosed with the disease can expect to be alive in 5 years. With improving longevity, the cumulative adverse effects of both the disease and treatment are becoming an increasingly important issue. "Late-effects" data show that both adult and pediatric cancer survivors are at greater risk for developing second malignancies, cardiovascular disease, diabetes, and osteoporosis than those in the general population. With respect to the growing population of pediatric cancer survivors, data confirm that they are eight times more likely than their siblings to have a severe or life-threatening chronic health condition. For example, the survivors of pediatric ALL have an increased risk of obesity, osteopenia, and associated comorbidities. Thus, it is important to provide supportive care and counseling related to nutrition, smoking cessation, and exercise as a part of their active treatment. Health care professionals should think beyond the immediate treatment-related issues of their patients and provide appropriate, active assistance to promote healthy lifestyles and encourage patients to take active roles in pursuing general preventive health strategies.[15]

Pharmacologic Therapy: ALL

The treatment for ALL consists of five main elements: remission induction (the initial tumor reduction leading to

morphologic remission), CNS-directed treatment, intensive postremission consolidation regimens, interim maintenance/delayed intensification followed by a prolonged maintenance phase. The total duration of treatment is 2 to 3 years (Table 95–7).

► *Remission Induction*

LO 5

KEY CONCEPT The initial treatment for acute leukemias is called induction. The purpose of induction is to induce a remission, a state in which there is no identifiable leukemic cells in the bone marrow or peripheral blood with light microscopy.

Table 95–7

Representative Chemotherapy Regimens for Adult ALL

Remission Induction		CNS Prophylaxis		Consolidation		Maintenance
Drug and Dose	**Days**	**Prophylaxis**	**Days**	**Drug and Dose**	**Days**	**Drug, Dose, and Timing**

Patient Encounter 2, Part 1

An 8-year-old male returns to the emergency room after completion of his third course of antibiotics for a presumed ear infection. His father states that he has been more lethargic lately and that he has bruising that cannot be explained. On physical examination, he appears pale and has significantly splenomegaly.

The pediatrician orders a CBC with differential which reveals a normochromic, normocytic anemia with a hemoglobin of 6 g/dL (60 g/L, 3.6 mmol/L; normal 11.7–15.7 g/dL, 117–150 g/L, 7.3–9.7 mmol/L), hematocrit of 18% (0.18; normal 35%–47%, or 0.35–0.47), and white blood cell (WBC) count of $2.6 \times 10^3/\mu L$ ($2.6 \times 10^9/\mu L$). The differential on the WBC count reveals 75% (0.75) lymphocytes (normal 20%–40%, or 0.2–0.4), 20% (0.2) neutrophils (normal 55%–62%, or 0.55–0.62), and 5% (0.05) lymphoblasts (normal 0%). Based on this information, a bone marrow aspirate and biopsy are performed, which reveal 85% (0.85) lymphoblasts. A lumbar puncture is also performed, which shows no evidence of leukemia.

What chemotherapy drugs should this patient receive as part of his ALL induction?

a. Dexamethasone, vincristine, and pegaspargase
b. Prednisone, vincristine, pegaspargase, daunorubicin
c. Daunorubicin, vincristine, pegaspargase
d. Dexamethasone, vincristine, pegaspargase, daunorubicin

What is the role of CNS prophylaxis?

KEY CONCEPT Current induction therapy for ALL typically consists of vincristine, L-asparaginase, and a steroid (prednisone or dexamethasone). An anthracycline is added for higher risk patients. Although induction treatment produces 95% CR in children, it declines to no more than 60% in patients older than 60 years of age.

Adults, unlike children, are universally considered to be at high risk for relapse; therefore, their induction regimens include an anthracycline (daunorubicin or doxorubicin) in addition to the standard steroid and vincristine treatment that have been the backbone of treatment for this disease for the last 40 years.[16,17] Dexamethasone often replaces prednisone because of its longer half-life and better CNS penetration.[17] Although dexamethasone possesses more favorable pharmacologic characteristics than prednisone, its use may be associated with more aseptic osteonecrosis of the femoral and humoral heads as well as an increase in life-threatening infections and septic deaths.[17]

Patient Encounter 2, Part 2

This patient had a bone marrow aspiration performed on days 8 and 29 that showed morphologic remission. The MRD on day 29 was less that 0.01%. This patient completed his induction therapy and started consolidation.

What is the role of MRD?

▶ CNS Prophylaxis

LO 6

KEY CONCEPT Leukemic invasion of the CNS is an almost universal event in patients even in those whose cerebrospinal fluid (CSF) cytology shows no apparent disease. Thus, all patients with ALL and AML leukemia receive intrathecal (IT) chemotherapy. Although this is often referred to as "prophylaxis," it more realistically represents treatment. CNS prophylaxis relies on IT chemotherapy (eg, methotrexate, cytarabine, and corticosteroids), systemic chemotherapy with dexamethasone and high-dose methotrexate, and craniospinal irradiation (XRT) in selected high-risk patients.[16] Cranial radiation use diminished substantially after the efficacy of IT treatment was evident, and the toxicities associated with radiation; learning disabilities, growth retardation, and secondary malignancies (particularly with the use of 6-mercaptopurine), were recognized. IT therapy has replaced cranial XRT as CNS prophylaxis for all except the very high-risk patients and those with T-cell ALL who are at higher risk of CNS disease.

Inexplicably, the treatment of CNS leukemia has not impacted the OS of adults as it has for childhood ALL. With IT chemotherapy alone, the incidence of CNS relapse in adults is 9% to 13% compared with less than 3% in children.[5,12]

▶ Postremission Consolidation Regimens

LO 6

Consolidation After completion of induction and restoration of normal hematopoiesis, patients begin consolidation. The goal of consolidation is to administer dose-intensive chemotherapy to reduce the burden of residual leukemic cells. It is in this and subsequent treatment phases that the remaining leukemic burden is eliminated. Several regimens use agents and schedules designed to minimize the development of drug cross-resistance. Consolidation is an effective strategy to prevent relapse in children with ALL, but its benefits in adults are less clear.

In children, the intensity of the consolidation treatment is determined by the child's risk classification and the degree of cytoreduction during induction (MRD). Patients who respond slowly to induction therapy (as determined by bone marrow examination early in induction) are at higher risk of relapse and are treated with more aggressive regimens.[18]

Reinduction (Delayed Intensification and Interim Maintenance) The typical duration of Interim Maintenance is approximately 8 weeks. Treatment usually consists of low intensity therapy added to continue remission and to lower cumulative toxicity. The Berlin-Frankfurt-Munster (BFM) Study Group introduced a treatment element called delayed intensification (or reinduction) therapy. This therapy consisted of repetition of the initial remission induction therapy administered approximately 3 months after remission. This regimen, similar to consolidation, has been adopted as a component of treatment for children by virtually all institutions.[12]

Intensification regimens vary in their aggressiveness and drug regimens depending on the patient's risk group and immunophenotype. For example, the use of high-dose methotrexate (5 g/m^2) appears to improve outcome in patients with T-cell ALL. The use of intensive asparaginase treatment in T-cell ALL patients also has improved outcomes significantly.[17]

▶ Maintenance

LO 6

The purpose of maintenance therapy is to further eliminate leukemic cells and produce an enduring CCR. The two most

important agents in maintenance chemotherapy are a combination of oral methotrexate and 6-mercaptopurine. Improved outcome is associated with increasing 6-mercaptopurine doses to the limits of individual tolerance based on absolute neutrophil count (ANC). The benefit of adding intermittent "pulses" of vincristine and a steroid (usually dexamethasone) to the antimetabolite backbone remains unclear, but it is common practice in most modern treatment regimens.[17] The goal is to induce a moderate immunosuppression and leukemic cell kill.

6-Mercaptopurine is a key agent in maintenance therapy. It has a complex metabolism and is initially metabolized by thiopurine methyltransferase (TPMT).[19] TPMT activity is variable with about 90% of patients having normal activity, about 10% having intermediate activity, and fewer than 1% having very low or no activity. Genetic polymorphisms in *TPMT* are inherited in an autosomal recessive fashion and have a profound influence on 6-mercaptopurine tolerance.[20,21]

TPMT screening is recommended for children starting therapy with 6-mercaptopurine. Children who possess alleles that have diminished activity require 6-mercaptopurine dose reductions of 50% to 90% to prevent severe immunosuppression and infection. Despite these reductions, these children have equivalent OS when compared with those receiving full-dose 6-mercaptopurine. The optimal duration of maintenance therapy in both children and adults is unknown, but most regimens are given for 2 to 3 years; extension of the regimen beyond 3 years has not shown any additional benefit.

ALL in Infants and Young Children

Infants and children younger than 1 year of age account for approximately 5% of all children with ALL and have the worst outcome of any group with this disease. These patients have several poor prognostic features at diagnosis, including hyperleukocytosis, hepatomegaly, splenomegaly, and CNS leukemia.[9]

A characteristic finding in up to 70% in this group is a chromosomal translocation involving the *MLL* gene located at 11q23. There are multiple possible rearrangements of this gene with other chromosomes, and all confer a poor prognosis. In vitro, blasts of these patients showed greater drug resistance to prednisolone and L-asparaginase than those from other patients, although they are more sensitive to cytarabine.[22] Based on this information, several studies are testing the efficacy of intensified chemotherapy that includes high-dose cytarabine. Another achievement is the prevention of CNS relapse using IT cytarabine in conjunction with high-dose systemic cytarabine. This combination has eliminated the need for cranial XRT in this young population. Even with major advances in cure rates for the general pediatric ALL population, in whom survival is 80% or more, the long-term survival of infants is only about 40% (Table 95–8).

ALL in Adolescents and Young Adults

As noted previously, age is an important prognostic factor in ALL. Adolescents and adult patients have generally been shown to have poorer survival than children. However, the group of patients between late adolescence and age 30 years (adolescents and young adults) have a substantially better outcome than older adult patients, but worse outcomes when compared to pediatric patients. When treated with pediatric protocols the disease-free survival is 60% to 70%, compared historically to 30% to 45%.[23]

Table 95–8

Representative Chemotherapy Regimens for Pediatric ALL

Induction (1 month)
IT cytarabine on day 0
Prednisone 40 mg/m^2/day or dexamethasone 6 mg/m^2/day po for 28 days
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV weekly for four doses
Pegaspargase 2500 units/m^2/dose IM for one dose or asparaginase 6000 units/m^2/dose IM Monday, Wednesday, and Friday for six doses
IT methotrexate weekly for two to four doses

Consolidation (1 month)
Mercaptopurine 50–75 mg/m^2/dose po at bedtime for 28 days
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV on day 0
IT methotrexate weekly for one to three doses
Patients with CNS or testicular disease may receive radiation

Interim Maintenance (one or two cycles) (2 months)
Methotrexate 20 mg/m^2/dose po at bedtime weekly
Mercaptopurine 75 mg/m^2/dose po daily on days 0–49
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV on days 0 and 28
Dexamethasone 6 mg/m^2/day po on days 0–4 and 28–32

Delayed Intensification (one or two cycles) (2 months)
Dexamethasone 10 mg/m^2/day po on days 0–6 and 14–20
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV weekly for three doses
Pegaspargase 2500 units/m^2/dose IM for one dose
Doxorubicin 25 mg/m^2/dose IV on days 0, 7, and 14
Cyclophosphamide 1000 mg/m^2/dose IV on day 28
Thioguanine 60 mg/m^2/dose po at bedtime on days 28–41
Cytarabine 75 mg/m^2/dose SC or IV on days 28–31 and 35–38
IT methotrexate on days 0 and 28

Consolidation Option (2- to 3-week intervals for six courses on weeks 5–24)
Mercaptopurine 50 mg/m^2/dose po at bedtime
Prednisone 40 mg/m^2/day for 7 days on weeks 8 and 17
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV on the first day of weeks 8, 9, 17, and 18
Methotrexate 200 mg/m^2/dose IV + 800 mg/m^2/dose over 24 hours on day 1 of weeks 7, 10, 13, 16, 19, and 22
IT methotrexate on weeks 5, 6, 9, 12, 15, and 18

Late Intensification (weeks 25–52)
Methotrexate 20 mg/m^2/dose IM weekly or 25 mg/m^2/dose po every 6 hours for four doses every other week
Mercaptopurine 75 mg/m^2/dose po at bedtime
Prednisone 40 mg/m^2/day po for 7 days on weeks 25 and 41
Vincristine 1.4 mg/m^{2}w/dose (maximum, 2 mg) IV on the first day of weeks 25, 26, 41, and 42
IT methotrexate on day 1 of weeks 25, 33, 41, and 49

Maintenance (12-week cycles)
Methotrexate 20 mg/m^2/dose po at bedtime or IM weekly with dose escalation as tolerated
Mercaptopurine 75 mg/m^2/dose po at bedtime on days 0–83
Vincristine 1.5 mg/m^2/dose (maximum, 2 mg) IV on days 0, 28, and 56
Dexamethasone 6 mg/m^2/day po on days 0–4, 28–32, and 56–60
IT methotrexate on day 0

IM, intramuscular; IT, intrathecal; po, oral; SC, subcutaneous.

Adapted from Leather HL, Bickert B. Acute leukemias. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 6th ed. New York, NY: McGraw-Hill; 2005:2458–2511.

Patient Encounter 3

A 13-year-old Caucasian male presents with a 4-week history of intermittent fevers, loss of appetite, headaches, and weight loss. A few days prior to presentation, he had a brief nose bleed, mild abdominal pain, and an episode of emesis. Patient's father noted a bruise on his left arm about 4 days prior. Physical examination reveals pallor, cervical lymphadenopathy, and hepatosplenomegaly. Electrolytes are within normal limits. A CBC shows a hemoglobin of 7.8 g/dL (78 g/L, 4.8 mmol/L; reference range 11.7–15.7 g/dL, 117–157 g/L, 7.26–9.74 mmol/L), hematocrit of 24% (0.24; reference range 35%–47% or 0.35–0.47), and a WBC count of 140 $\times 10^3$/mm^3 (140 $\times$ 10^9/L). The differential on the WBC count reveals 45% (0.45) lymphoblasts (reference range 0). Flow cytometry reveals B-cell ALL. A diagnostic lumbar puncture (LP) is performed which is negative for CNS leukemia. During the LP, the patient receives intrathecal cytarabine.

What are the prognostic factors for this patient?

What is the role of flow cytometry in identifying ALL?

The pediatric regimens used to treat this group of patients contain the BFM backbone: steroids, vincristine, asparaginase, and CNS prophylaxis.[24] The reasons for improved survival in this age group are not entirely clear, and multiple factors are likely to play a role. Among the likely explanations is that pediatric protocols use more aggressive and prolonged postremission consolidation therapy before maintenance. Other proposed explanations are the potential differences in disease biology in this versus older age patients, more intense CNS prophylaxis, and the greater degree of social support and better compliance fostered in a pediatric environment. Current and planned trials are focusing on the potential of extending this treatment approach to patients age 40 years and possibly older.

ALL in Adults

The incidence of ALL in adults ages 30 to 60 years is only 2 per 100,000 persons per year compared with almost 10 per 100,000 in children. The conventional risk factors such as high WBC counts, older age, and CNS disease hold true in adults as in children. However, the significance of cytogenetic and molecular markers that are so important in children seems to be less predictive of outcome in adults. An exception is the adverse prognostic factor, the presence of the *BCR-ABL* translocation (Ph$^+$) just as in childhood ALL. This occurs in 15% to 30% of adults and is even more common in patients older than 60 years of age.[24] The use of second-generation tyrosine kinase inhibitors, potent inhibitors of the Ph$^+$-associated BCR-ABL tyrosine kinase, has now become a standard of practice for all patient groups with Ph$^+$ disease.[7,25] Results show that the combination of these agents with conventional chemotherapy improves remission rates as well as OS compared with the use of conventional chemotherapy alone.[7,8,26]

Currently, induction and consolidation regimens in adults are similar to pediatric regimens. Aggressive postinduction regimens are not as well tolerated in this population, particularly in patients older than 60 years and are associated with a much higher incidence of toxicity and treatment-related deaths.[7] Some investigators are studying "moderate-dose" consolidation regimens that are better tolerated, although long-term efficacy data is lacking. Even though remissions are achieved in 80% to 90% of adult patients, 5-year disease-free survivals (DFSs) are only in the 30% to 40% range. Among elderly patients, the outcome is even poorer with no more than 20% having long-term survival.

Relapsed ALL

Relapse is the recurrence of leukemic cells at any site after remission has been achieved. Leukemic blasts are much more drug resistant than the blasts at initial diagnosis.[1] KEY CONCEPT Bone marrow relapse is the major form of treatment failure in 15% to 20% of patients with ALL. Most relapses have the same immunophenotype and cytogenetic changes seen of the original disease. Extramedullary sites of relapse include the CNS and the testicles.[24] Extramedullary relapse, although once common, has decreased to 5% or less because of effective prophylaxis. Site of relapse and the length of the first remission are important predictors of second remission and OS. Marrow relapses occurring less than 18 to 24 months into first remission are associated with a poor survival, but longer periods of remission (> 36 months) have a much higher chance of survival.[26] Treatment strategies for relapsed ALL include chemotherapy or allogeneic hematopoietic stem cell transplant (allo-HSCT). Even though patients undergoing allo-HSCT are less likely to relapse, treatment-related toxicity leads to a higher incidence of morbidity and mortality compared with chemotherapy alone.[6] Clofarabine, a next-generation deoxyadenosine analogue, has shown considerable activity in children and adults with refractory acute leukemias. Blinatumomab, a monoclonal antibody (MAB) that targets CD19, was recently approved for Ph negative relapsed or refractory ALL in adults and pediatric patients.[27]

LO 2

Treatment of AML

As with ALL, the primary aim in treating patients with AML is to induce remission and thereafter prevent relapse. Treatment of AML is divided into two phases: induction and consolidation. The prognosis of children with AML has improved dramatically over the past 30 years. Rates of complete remission as high as 80% to 90% and OS rates of 60% are reported.[28] This improvement is a result of better understanding of the biology of AML and the development of molecular targets that are used in combination with conventional chemotherapy.[14]

KEY CONCEPT The current induction therapy for AML usually consists of a combination of cytarabine, daunorubicin, and etoposide. The second phase of treatment for AML is called consolidation. The purpose of this phase is to further enhance remission with more cytoreduction.[14]

▶ *Remission Induction*

The goal of induction chemotherapy in AML is essentially identical to that in ALL—"empty" the bone marrow of all hematopoietic precursors and allow repopulation with normal cells. The combination of an anthracycline (eg, daunorubicin, doxorubicin, or idarubicin) and the antimetabolite cytarabine forms the backbone of AML induction therapy. The most common induction regimen (7 + 3) combines daunorubicin for 3 days with cytarabine on days 1 to 7.[13] The remission rate for this combination is approximately 80% in children and younger adults but declines to 60% in patients older than 60 years of age.[5,13] Adding gemtuzumab ozogamicin to induction therapy for older patients improved relapsed rates and OS, but no improvement in

response rates were demonstrated. Midostaurin, an oral multitarget kinase inhibitor, was recently approved by the FDA for treatment of FLT3 positive AML. It is added on days 8 to 21 of the convention 7+3 induction chemotherapy and also on days 8 to 21 of high-dose cytarabine consolidation.[29]

▶ *Postremission Chemotherapy*

In AML, postremission chemotherapy is often referred to as consolidation therapy. Several cycles of intensive postremission chemotherapy combining non–cross-resistant agents given every 4 to 6 weeks substantially improves DFS. Without postremission treatment, all patients would relapse within several weeks. This is analogous to the consolidation and other phases of postremission chemotherapy in ALL. The use of high-dose cytarabine in postremission therapy seems to be important for improving survival, but the most effective dose has yet to be determined.[14] Although the optimal number of courses remains to be determined, at least four are probably required.[13]

Allogeneic Hematopoietic Stem Cell Transplantation

Hematopoietic stem cell transplantation (HSCT) is the most effective treatment for AML. Its promising benefit must be weighed against the potential risk of transplantation related sequelae. HSCT has become a less attractive option as the results of increasingly intensive chemotherapy and postrelapse salvage therapy have improved.[14]

The availability of human leukocyte antigen (HLA)-matched sibling donors determines whether patients undergo HSCT as postremission treatment. To facilitate this process, it is important to obtain HLA typing on all younger patients and siblings shortly after diagnosis. Patients who do not have an HLA-matched sibling proceed to postremission therapy with chemotherapy alone.

Complications and benefits of allogeneic HSCT are described in Chapter 98. Transplant-related mortality following matched-sibling allo-HSCT is 20% to 30% in most series. Complications from transplantation increase with age; therefore, patients older than 60 years of age rarely receive a myeloablative allo-HSCT. Because the average age of AML patients is 65 years, most patients with this disease are not candidates for this form of therapy. For older patients up to 70 years of age, a reduced-intensity (mini or nonmyeloablative allogeneic) transplant may be an option. These transplants use less intensive preparative regimens and rely on the allogeneic graft-versus-leukemia (GVL) effect to eliminate their disease.[13]

The role of HSCT, particularly whether it should be performed during the first CR or reserved for second remission, remains the most controversial issue in pediatric AML. In certain institutions, HSCT is often reserved for patients that are considered high risk.[14] Some types of AML patients may be curable with conventional-dose chemotherapy alone.

Autologous Hematopoietic Stem Cell Transplantation

Because the majority of AML patients lack an HLA-identical donor, investigators began to consider the use of the patient's own bone marrow, obtained while in CR, as a source of hematopoietic regeneration. However, relapse continues to be a problem secondary to the presence of residual disease in the graft. Despite the reduced morbidity and mortality associated with auto-HSCT, this type of transplant does not compare favorably to standard postremission chemotherapy.[13]

▶ *CNS Therapy*

The prevalence of CNS disease at diagnosis of AML is approximately 15%.[14] Features associated with the risk of CNS leukemia include hyperleukocytosis, monocytic, or myelomonocytic leukemia (FAB M4 or M5), and young age. Adequate CNS prophylaxis is an essential component of therapy. Patients with CNS disease at diagnosis can be cured with IT therapy alone without the use of cranial XRT. In most cases, IT cytarabine with or without methotrexate and systemic high-dose cytarabine provide effective treatment.

AML in Infants

AML in infants younger than 12 months of age shows clinical and biological characteristics different from those of older children. The disease phenotype is more commonly monoblastic or myelomonoblastic (M4, M5), and the patients usually present with hyperleukocytosis. Extramedullary involvement is common, often involving skin and other organs. As in infant ALL, there is a high incidence of translocations involving the *MLL* gene in infant AML. The number of infant AML trials reported is limited, but the EFS of this population is similar to that of older children with AML. This is in marked contrast to the outcomes for infants with ALL for whom the EFS is much lower than in older children.[30]

AML in the Elderly

AML is the most common acute leukemia in the elderly. Compared with younger patients with the same disease, older adults have a poor prognosis and represent a distinct population with regard to the biology of their disease. Older adults have a lower incidence of favorable chromosomal aberrations and a higher incidence of unfavorable aberrations.[5,13] Fms-like tyrosine kinase 3 (*FLT3*) which is an AML oncogene plays an important role in AML pathogenesis and was associated with a poor outcome. *FLT3*-ITD is common in adults, but is only found in 12% of the pediatric population.[14] Older patients also have more comorbidities, such as type 2 diabetes, obesity, and other physiologic limitations. Thus, the poor prognosis of AML in this population is only partly the result of unfavorable biology.

In older adults, in contrast to children, AML is more likely to arise from a proximal bone marrow–stem cell disorder, such as MDS, or present as a secondary, prior treatment-related leukemia. These forms of AML are notoriously poorly responsive to conventional chemotherapy and thus have a lower CR rate and poorer survival.[26]

As previously noted, age is an important prognostic factor. Older adults are not as tolerant of or as responsive to remission induction and consolidation chemotherapy as younger patients. Furthermore, long-term survival for patients older than 60 years is only 5% to 15% compared with 30% DFS for younger adults.[5,13]

Relapsed AML

Even though 75% to 85% of patients with AML achieve a remission, only about 50% survive. Patients who relapse usually respond poorly to additional treatment and have a shorter duration of remission. This is probably related to drug resistance induced during induction and certain chromosomal abnormalities.

Even though there is no standard therapy for relapse, most studies have shown that high-dose cytarabine-containing regimens have considerable activity in obtaining a second remission. Cytarabine has been used in combination with mitoxantrone, etoposide, fludarabine, 2-chlorodeoxyadenosine, and (more recently) clofarabine.[5,13] For patients unable to tolerate intensive chemotherapy, low dose cytarabine and the hypomethylating agent, azacitidine, are also options for relapsed disease.[31]

After a patient has achieved a second remission with conventional chemotherapy, allo-HSCT is the therapy of choice.

For patients without an HLA-matched sibling, a matched unrelated donor (MUD) or cord blood transplant may be a reasonable alternative. The combination of myeloablative high-dose chemotherapy and the GVL effect is thought to offer the best chance of survival in AML.

Complications of Treatment

LO 7

▶ *Tumor Lysis Syndrome*

Tumor lysis syndrome (TLS) is an oncologic emergency that is characterized by metabolic abnormalities resulting from the death of blast cells and the release of large amounts of purines, pyrimidines, and intracellular potassium and phosphorus. Uric acid, the ultimate breakdown product of purines, is poorly soluble in plasma and urine. Deposition of uric acid and calcium phosphate crystals in the renal tubules can lead to acute renal failure. Many patients with acute leukemia, especially those with a high tumor burden, are at risk for TLS during the first several days of chemotherapy. Measures to prevent TLS include aggressive hydration to increase urine output, and allopurinol to reduce uric acid production. Hyperhydration and potentially using a diuretic to increase urine output is generally an effective method of dealing with this issue. However, on some occasions, the use of rasburicase is indicated. Rasburicase is a urate oxidase that catalyzes the oxidation of uric acid to allantoin, which is much more soluble than uric acid and excreted more easily.[32] Given its high cost, rasburicase generally is restricted to patients with high WBC counts ($> 50 \times 10^3/mm^3$, $50 \times 10^9/L$) and uric acid levels greater than 8 mg/dL (476 μmol/L).

▶ *Infection*

Infection is a primary cause of death in acute leukemia patients. Both the disease and aggressive chemotherapy cause severe myelosuppression, placing the patient at risk for sepsis.

The therapy for AML is extremely myelosuppressive. Children with AML have a 10% to 20% induction mortality rate secondary to infection and bleeding complications. Therefore, patients receiving induction therapy usually are hospitalized for the first 4 to 6 weeks of therapy. The induction therapy for ALL is far less myelosuppressive, and these patients recover their neutrophil counts quicker and usually do not require prolonged hospitalizations.[6]

It is important to recognize that symptoms and signs of infection may be absent in a severely immunosuppressed or neutropenic patient. Fever (> 38.3°C [100.9°F]) in a neutropenic patient is a medical emergency. Because the progression of infection in neutropenic patients can be rapid, empirical antibiotic therapy is started whenever a fever is documented. Currently, the most commonly used initial antibiotic agent is cefepime, a fourth-generation cephalosporin that has good antipseudomonal coverage as well as adequate coverage against *Streptococcus viridans* and pneumococci.[33]

Disseminated fungal infections most commonly caused by Candida and Aspergillus species can be life threatening in children with AML. From the results of clinical trials in adults, many pediatric institutions recommend antifungal prophylaxis with voriconazole, posaconazole, micafungin, or caspofungin. Fluconazole and itraconazole are not considered ideal, because they are not effective against aspergillus species and other molds.[33]

Trimethoprim–sulfamethoxazole is started in all patients with any acute leukemia for the prevention of *Pneumocystis jiroveci* pneumonia (PJP). Patients normally continue this therapy for 6 months after completion of treatment. The use of additional antibiotic prophylaxis is not encouraged because of concerns for antibiotic resistance.

LO 7

Of note is that up to 10% of patients seem to exhibit excessive myelosuppression with trimethoprim–sulfa antibiotics (presumably the result of the antifolate trimethoprim in combination with other systemic cytotoxic agents). Changing to another anti-PJP agent such as dapsone or inhaled pentamidine may help to alleviate this problem.

▶ *Secondary Malignancies*

Secondary malignancies are a risk of the successful treatment of a prior cancer or the use of cytotoxic agents in a variety of autoimmune diseases. The chemotherapy agents used, especially alkylating agents and topoisomerase II inhibitors, predispose patients to secondary hematopoietic neoplasms. As the aggressiveness of treatment and the number of survivors of AML increase, the risk of secondary neoplasms also may rise. There are two different types of second malignancies: acute leukemia, which is generally myeloid in origin, or MDS. There are also reports of secondary solid tumors, especially within regions of prior radiation exposure. The latency period between the end of treatment and the development of a secondary leukemia is generally in the range of 5 to 10 years. For those patients who develop secondary solid malignancies, the latency may be as long as 10 to 20 years.

The incidence of second cancers attributed to alkylators peaks 4 to 6 years after exposure and plateaus after 10 to 15 years. Higher cumulative doses and older age at the time of treatment are risk factors for this type of cancer.

Epipodophyllotoxins (etoposide and others) can induce a second malignancy characterized by balanced chromosomal translocations and short latency periods (2–4 years). The risk of this leukemia is related to schedule (dose intensity) and the concomitant use of other agents (L-asparaginase, alkylating agents, and possibly antimetabolites). The prognosis for topoisomerase II inhibitor–related secondary leukemia is extremely poor. Only about 10% of these patients survive after salvage chemotherapy, and only 20% survive after HSCT.

Ionizing radiation therapy is also a cause of secondary malignancies. These secondary tumors generally develop within or adjacent to the previous radiation field. These cancers often have a prolonged latency, typically 15 or more years, but shorter latencies (5–14 years) are known. Higher doses of radiation and younger age are associated with an increased risk of secondary malignancy.

Unlike children, adults may have other factors that predispose them to secondary malignancies. Lifestyle choices such as tobacco use, alcohol use, and diet are implicated in influencing the development of secondary neoplasms in the adult population.

Now that 80% or more of children survive their primary cancers, the incidence of secondary neoplasms may increase. Recognizing this potential, many treatment regimens for children are being modified appropriately to reduce exposure to alkylators, topoisomerase inhibitors, and radiation. Children in long-term follow-up are screened for secondary malignancies and other disease and treatment-related disabilities that accompany childhood cancer. Similar screening and educational opportunities are not as established in adult survivors.

▶ *Late Effects*

With increased success in pediatric clinical trials, the OS rate for pediatric cancers has increased markedly over the last 35 years. For some diseases (acute lymphoblastic leukemia, Wilms tumor, low-grade and common germ cell tumors), the OS rate is now

at or above 80%. KEY CONCEPT Despite this significant increase in survival, many patients, particularly pediatric cancer survivors, have disease-related or treatment-related disabilities. As many as 50% to 60% of these survivors are estimated to have at least one chronic or late-occurring complication of treatment.[34] In leukemia, the intensified use of methotrexate may be responsible for some sporadic neurotoxicity seen in children and adults. Likewise, the use of pharmacologic doses of glucocorticoids has been associated with avascular necrosis of bone in older children and adults. High cumulative doses of anthracyclines can cause irreversible cardiomyopathy. Cranial XRT is now less frequently used for CNS leukemia prophylaxis but can cause neuropsychological and neuroendocrine abnormalities that may lead to obesity, short stature, or precocious puberty.[4] As newer and more intensive treatments enter clinical trials, close observation for long-term side effects will assume even greater importance.

LO 8

Supportive Care

Because of the need for repeated venous access, a central venous catheter or infusion port is placed before starting treatment. These devices are useful not only for delivery of chemotherapy but also to support patients during periods of myelosuppression. Infection and bleeding complications are the primary causes of mortality in patients with leukemia.

Platelet transfusions are a common tool to prevent hemorrhage. Patients with uncomplicated thrombocytopenia can be transfused when the platelet count falls below $10 \times 10^3/mm^3$ ($10 \times 10^9/L$). Patients who are either highly febrile or actively bleeding may require transfusions at higher levels. Red blood cell transfusions generally are not necessary for a hemoglobin concentration greater than 8 g/dL (80 g/L, 4.97 mmol/L).

There is much controversy regarding the routine use of colony-stimulating factors (CSFs) (eg, granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage colony-stimulating factor [GM-CSF]) in neutropenic patients. Even though several clinical trials have shown the time to ANC recovery is decreased with a CSF, none have demonstrated that CSFs statistically influence infection-related mortality. At present, the use of CSFs (G-CSF most commonly) generally is limited to those chemotherapy regimens that place the patient at highest risk for prolonged neutropenia.

OUTCOME EVALUATION

Developing strategies for the treatment and monitoring of acute leukemias begins with risk stratification. Understanding the likely risk of relapse determines the aggressiveness and length of therapy. Remission status and MRD after the induction phase of treatment must be closely observed. Failure to obtain morphologic bone marrow remission by day 28 is a very adverse prognostic sign and dictates further induction treatment. For those who have a morphologic remission, quantification of MRD has become an increasingly important prognostic factor. Levels of residual less than 0.01% appear to be associated with better outcomes.

A clinician is generally charged with developing a plan to educate patients and families about their drugs and doses. This is a critical responsibility; it is imperative that the patients and their families understand why they are receiving their medications and how to take them. Frank, open discussion (with the family or patient in possession of their prescriptions) goes a long way toward preventing errors that occur as a result of "assuming" that they understand their medications. If modifications are necessary secondary to toxicity or inadequate response, establish a plan for treatment change. Remember that individual patients often do not fit the "average" patient profile, and dose modifications are frequently needed. The practitioner should be familiar with dosing ranges, WBC count, and other parameters that indicate appropriate treatment response. Based on response to prior phases of treatment, the clinician should recognize potential toxicities in subsequent phases of treatment with the same or different drugs at similar or different doses.

Patient Care Process

Collect Information:

- Using the medical record collect the pertinent information on the presenting symptoms that made the patient seek out a health care provider.
- Perform a medication history, including over the counter and herbal medications.
- Speak with patient, or patient's family in the instance of a pediatric patient, and assess patient or family's socioeconomic situation to evaluate ability to obtain prescription medications and/or resources for transplantation if necessary.

Assess the Information:

- Review patient's medication history prior to admission, making sure all medications have a diagnosis and are necessary.
- Review patient's medications for drug interactions with antifungals and oral chemotherapy regimens.
- Review the patient's medical history looking for any medical condition that might predispose the patient to adverse effects from chemotherapy and supportive care medications, for example, look for a history of prolonged QT interval, or heart failure.
- Speak to the patient about any risk factors that may predispose them to adverse effects.
- Ascertain the patient's understanding of the process for the treatment of acute leukemias and the need for compliance in prophylactic medications.

Develop a Care Plan:

- If patient has baseline hepatic, renal, QT prolongation, or other cardiac issues, anticipate the need for dose modifications or changes in therapy.
- If there is a barrier to acquiring medications, develop a plan early in the patient's treatment to ensure that the patient can get the medications needed when discharged.
- Review and discuss the importance of being compliant with prophylactic medications with the patient or patient's family.

(*Continued*)

Patient Care Process (*Continued*)

- Educate patient and patient's families about adverse effects of treatment for leukemia, and what supportive care medications will help in preventing and treating the adverse effects.

Implement the Care Plan:

- When the patient is discharged from the hospital and seen at a clinic appointment, perform a medication history and reeducate about the need for all of the medications and the importance of compliance.
- Review all new laboratory and cardiac data to make sure all medications are dosed appropriately.
- Review medication list for drug interactions.
- Review side effect management with patient and patient's family, reeducating on need for home medications to treat side effects.
- Suggest nonpharmacological ways to minimize adverse effects.
- If patient is not tolerating or unable to manage adverse effects at home, work with providers to implement a new strategy.

Follow-up: Monitor and Evaluate:

- At each clinic visit review medication list with patient.
- Check for drug interactions with new medications.
- Review hepatic, renal, and any changes in clinical status; reduce dose or eliminate medications based on those results.
- Review effectiveness of symptom management plan with patient and patient's family.
- Reeducate as needed.

Abbreviations Introduced in This Chapter

ALL	Acute lymphocytic/lymphoblastic leukemia
allo-HSCT	Allogeneic hematopoietic stem cell transplant
AML	Acute myelogenous leukemia
ANC	Absolute neutrophil count
ANLL	Acute nonlymphocytic leukemia
BFM	Berlin-Frankfurt-Munster
CCR	Continuous complete remission
CD	Cluster determinant
CR	Complete remission
CSF	Cerebrospinal fluid
CSF	Colony-stimulating factor
DFS	Disease-free survival
EFS	Event-free survival
FISH	Fluorescent in situ hybridization
G-CSF	Granulocyte colony-stimulating factor
GM-CSF	Granulocyte-macrophage colony-stimulating factor
GVL	Graft-versus-leukemia
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem cell transplantation
ITD	Internal tandem duplication
MAB	Monoclonal antibody
MDS	Myelodysplastic syndrome
MRD	Minimal residual disease
MUD	Matched unrelated donor
OS	Overall survival
Ph^+	Philadelphia chromosome
TLS	Tumor lysis syndrome
XRT	Irradiation

96 Chronic Leukemias and Multiple Myeloma

Amy M. Pick

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. Explain the role of the Philadelphia chromosome in the pathophysiology of chronic myelogenous leukemia (CML).
2. Identify the clinical signs and symptoms and laboratory findings associated with CML, chronic lymphocytic leukemia (CLL), and multiple myeloma (MM).
3. Discuss first- and second-line treatment options for CML, including options for those patients with drug-resistant disease.
4. Describe the clinical course of CLL and distinguish which patients may be observed and who require treatment.
5. Outline the treatment options available for CLL, noting treatment differences based on variations in the tumor's molecular profile.
6. Describe the clinical presentation and symptoms of MM.
7. Recommend the appropriate treatment for patients with MM, recognizing the importance of combination therapy and the role of autologous hematopoietic stem cell transplant.

INTRODUCTION

Several diseases comprise chronic leukemia. The two most common forms are chronic myelogenous leukemia (CML) and chronic lymphocytic leukemia (CLL). The slower progression of the disease contrasts it from acute leukemia, with the survival of chronic leukemia often lasting several years without treatment. This chapter covers CML and CLL. The chapter also discusses the hematologic cancer MM.

CHRONIC MYELOGENOUS LEUKEMIA

CML is a hematologic cancer that results from an abnormal proliferation of an early myeloid **progenitor** cell. The clinical course of CML has three phases: chronic phase (CP-CML), accelerated phase (AP-CML), and **blast** crisis (BP-CML), with 90% of patients diagnosed in chronic phase.[1] Criteria for these phases are largely based on the percent blasts in the peripheral blood or bone marrow. Chemotherapy can be used to control white blood cell (WBC) counts in the chronic phase, but as CML slowly progresses, the cancer becomes resistant to treatment. Blast crisis resembles acute leukemia, and immediate aggressive treatment is required.

EPIDEMIOLOGY AND ETIOLOGY

There were an estimated 8430 new cases of CML diagnosed in 2018, accounting for 14% of all adult leukemias.[2] The incidence of CML increases with age, with the median age of diagnosis being 65 years.[3] In most newly diagnosed cases, the etiology cannot be determined, but high doses of ionizing radiation and exposure to solvents such as benzene are recognized risk factors.

PATHOPHYSIOLOGY

Cell of Origin

CML arises from a defect in an early progenitor cell. The pluripotent (noncommitted) stem cell is implicated as the origin of the disease; therefore, multiple cell lineages of hematopoiesis may be affected, including myeloid, erythroid, megakaryocyte, and (rarely) lymphoid lineages. These cells remain functional in CP-CML, which is why patients in this phase are at low risk for developing infections.

Ph Chromosome

LO 1

KEY CONCEPT The Philadelphia chromosome (Ph) results from a translocation between chromosomes 9 and 22, leaving a shortened chromosome 22. The Ph results in the formation of an abnormal fusion gene between the breakpoint cluster region and the Abelson proto-oncogene (*BCR-ABL*), which encodes an overly active tyrosine kinase. The loss of control of tyrosine kinase activity causes abnormal cellular proliferation and inhibition of apoptosis.[1] Molecular tools such as quantitative reverse transcriptase-polymerase chain reaction (Q-PCR) and fluorescence in situ hybridization (FISH) are used in the detection and monitoring of *BCR-ABL* transcripts found in CML.[4]

Clinical Presentation and Diagnosis of CML[5]

Signs and Symptoms

- 30%–50% are asymptomatic at diagnosis
- Symptoms may include fatigue, fever, weight loss, and bleeding
- Organomegaly consisting of splenomegaly and hepatomegaly

Diagnostic Procedures

- Peripheral blood
- Bone marrow biopsy (percentage of blasts)
- Cytogenetic studies (presence of Ph and additional chromosomal abnormalities)
- Molecular testing (Q-PCR to detect *BCR-ABL1* transcripts)

Laboratory Findings

- Peripheral blood
  - Leukocytosis (most present with WBC count > 100 × 10^9/L [100 × 10^3/mm^3])
  - Thrombocytosis (~50% of patients in chronic phase)
  - Anemia
  - Basophilia
  - Presence of blasts
  - Elevated uric acid
- Bone marrow
  - Hypercellularity with presence of blasts
  - Cytogenetics including the presence of Ph

Poor Prognostic Factors

- Older age
- Splenomegaly
- High percent blasts in the blood (ie, AP- or BP-CML at time of diagnosis)
- Abnormal platelet count (high or low)
- Additional chromosomal abnormalities (ie, clonal evolution)

TREATMENT

Desired Outcome

The primary goal in the treatment of CML is to achieve a clinical response with tyrosine kinase inhibitor (TKI) therapy. Ideally, this is a deep, long-lasting molecular response which is achievable for many patients with CP-CML.[6] A complete molecular response is defined as undetectable *BCR-ABL* transcripts by the international scale.[7] International standardization of molecular response reflects a percentage of *BCR-ABL1* compared to control gene.[4] Approximately 50% to 70% of patients with CML will achieve a major molecular response (> 3 $\log_{10}$ reduction in *BCR-ABL1* transcripts) and another 10% to 20% will achieve an even deeper molecular response.[8] Additional goals include achieving a complete hematologic and cytogenetic response. A complete hematologic response is defined as a normalization of peripheral blood counts and complete cytogenetic response being the elimination of the Ph.[7] A cure from CML can only come from complete eradication of the Ph clone.

General Approach to Treatment

There have been significant advances in the treatment of CML since the discovery of the Ph in 1960. The success of therapy is largely dependent on the clinical phase of the disease. Treatment decisions are based on patient's age, phase of CML, and comorbidities. The National Comprehensive Cancer Network (NCCN) provides recommendations on the therapeutic treatment approach.[7] Nearly all patients with CML are initially treated with a TKI. Depending on the clinical phase, newer generation TKIs or omacetaxine may be options for patients who fail to respond or do not tolerate initial TKI therapy. Hydroxyurea may be used after diagnosis to rapidly reduce high WBC counts and prevent potentially serious complications (respiratory and neurologic) associated with large numbers of circulating neutrophils. Hydroxyurea, though, does not alter the disease process. TKIs can also reduce peripheral WBC counts over several weeks; therefore, many patients are started on a TKI alone. **Allogeneic** hematopoietic stem cell transplant (HSCT) is the only curative therapy for CML and is reserved for patients with TKI resistance. **Figure 96–1** illustrates one approach for clinically managing newly diagnosed CP-CML patients.

Nonpharmacologic Therapy

▶ *Hematopoietic Stem Cell Transplantation*

LO 3

KEY CONCEPT Allogeneic HSCT is the only curative treatment option for CML; however, the impressive outcomes with TKIs have limited the role of transplant. Allogeneic HSCT may be considered for the rare patient with *BCR-ABL* mutations that are resistant to or who fail TKI therapy. Transplant should also be considered for patients who present in BP-CML or who progress on a TKI with advanced disease.[7] There are significant risks and long-term complications with allogeneic HSCT including early mortality and **graft-versus-host disease**. For patients who do not achieve a complete molecular response or have a relapse, the infusion

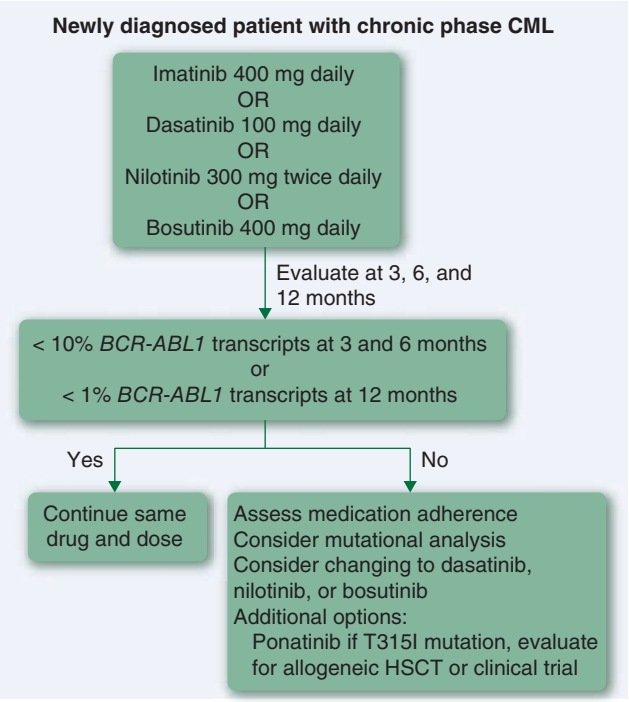

FIGURE 96–1. Algorithm for TKI therapy in newly diagnosed patient with CP-CML. (Data from NCCN.)

of donor lymphocytes may place the patient back into a durable remission.[7]

Pharmacologic Therapy

LO 2

The treatment of CML has dramatically changed since the introduction of TKIs. KEY CONCEPT Nearly all patients with CML are initially treated with a TKI. These oral agents do not cure CML but produce long-term response in the vast majority of patients. Four TKIs (imatinib, dasatinib, nilotinib, and bosutinib) may be used may be used as first-line therapy for newly diagnosed CP-CML.[7]

▶ *Imatinib Mesylate (Gleevec)*

Imatinib mesylate (Gleevec) is a first-generation TKI and was the first TKI to show efficacy in the treatment of CML. Imatinib inhibits phosphorylation of various proteins involved in cell proliferation by binding to the adenosine triphosphate–binding pocket of *BCR-ABL*.[9] The almost 11 year follow-up data show that the use of imatinib in CP-CML results in an estimated overall survival of 83.3%, a complete cytogenetic response of 82.8%, and an estimated event-free survival of 79.6%.[10] Lower response rates are reported in accelerated phase and BP-CML.[9] Disease progression is typically attributed to imatinib primary or secondary resistance.[1,7] The *ABL* kinase mutation *T315I* is one mechanism of secondary resistance that results in reactivation of *BCR-ABL* activity. The *T315I* mutation renders imatinib and the second-generation TKIs ineffective; therefore, alternative therapy with agents that overcome this mutation (ie, ponatinib) must be selected.[4] Imatinib is generally well tolerated. Common side effects include myelosuppression, gastrointestinal disturbances, and myalgias. Dosing and additional adverse effects may be found in Table 96–1.

Table 96–1

Drugs Used in CML

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bosutinib (Bosulif)	Diarrhea, nausea vomiting, thrombocytopenia, neutropenia, increased liver function tests, fluid retention	Dose: 400–500 mg po once daily depending on phase Dose may be increased to 600 mg po once daily if complete hematologic response not seen at 8 weeks or complete cytogenetic response by 12 week Take with food Drug interactions: metabolized by CYP 3A4; inhibitor and substrate of P-glycoprotein	CrCl 30–50 mL/min (0.50–0.83 mL/s): 500 mg daily and may decrease to 400 mg if cannot tolerate CrCl < 30 mL/min (0.50 mL/s): 300 mg daily	Any baseline liver impairment: 200 mg daily
Dasatinib (Sprycel)	Thrombocytopenia, neutropenia, headache, rash, edema, pleural effusions	Dose: 100 mg po once daily for chronic phase CML or 140 mg po daily for accelerated phase or blast crisis Avoid concomitant medications that prolong the QT-interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4 Dasatinib exhibits pH-dependent absorption; avoid medications that alter gastric pH (eg, H_2 antagonists and PPIs)	No reductions	No reductions
Imatinib mesylate (Gleevec)	Neutropenia, thrombocytopenia, diarrhea, rash, nausea, edema, fatigue, arthralgias, myalgias, headache, increased liver function tests, congestive heart failure (rare)	Dose range: 400–800 mg po per day depending on phase Take with meals and a full glass of water Drug interactions: metabolized by CYP 3A4; weak inhibitor of CYP 2D6 and 2C9 Avoid taking with acetaminophen to reduce hepatic toxicity Diarrhea usually responds to loperamide	CrCl 20–39 mL/min (0.33–0.66 mL/s): 50% reduction in dose CrCl < 20 mL/min (0.33 mL/s): use with caution	Mild to moderate impairment: no adjustment Severe impairment: reduce dose by 25% Discontinue imatinib if liver transaminases are > 5 × upper limit of normal or if serum bilirubin > 3 × upper limit of normal
Nilotinib (Tasigna)	Thrombocytopenia, neutropenia, elevated bilirubin, elevated serum lipase	Dose: 400 mg po twice daily Take on an empty stomach Black-box warning for QT prolongation; avoid concomitant medications that prolong the QT interval; low levels of potassium and magnesium should be corrected before initiating therapy Drug interactions: metabolized by CYP 3A4; competitive inhibitor of CYP 2C8, 2C9, 2D6, and UGT1A1 Pharmacogenomic testing of UGT1A1 polymorphisms can be used to identify patients who may have hyperbilirubinemia	No reductions	Child-Pugh class A, B, or C: 200 mg po twice daily for chronic phase CML; may increase to 300 mg if tolerating nilotinib therapy; discontinue nilotinib if experiencing grade 3 or 4 elevations in bilirubin or liver transaminases

(*Continued*)

Table 96–1

Drugs Used in CML (*Continued*)

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Omacetaxine mepesuccinate (Synribo)	Myelosuppression, hyperglycemia	Dose: 1.25 mg/m^2 subcutaneous injection twice daily × 14 days, repeat every 28 days until hematologic response achieved Maintenance therapy: 1.25 mg/m^2 subcutaneous injection twice daily × 7 days every 28-day cycle Drug interactions: P-glycoprotein substrate	No reductions	No reductions
Ponatinib (Iclusig)	Arterial and venous thromboembolisms, hepatotoxicity, congestive heart failure, pancreatitis, gastrointestinal bleeding, fluid retention, myelosuppression, fatigue, headaches	Dose: 45 mg daily Black-box warnings for thromboembolism stroke, myocardial infarction, hepatotoxicity, and heart failure Monitor CBC, lipase and liver function tests Drug interactions: metabolized by CYP 3A4,2C8, 2D6 competitive inhibitor of P-glycoprotein	No reductions	Child-Pugh class A, B, or C: 30 mg daily Hold ponatinib if liver transaminases are > 3 × upper limit of normal May resume but reduce dose when < 3 × upper limit of normal

CML, chronic myeloid leukemia; CrCl, creatinine clearance; po, oral; PPI, proton pump inhibitor.

▶ *Advanced-Generation TKIs*

LO 3

KEY CONCEPT Dasatinib (Sprycel), nilotinib (Tasigna), bosutinib (Bosulif), and ponatinib (Iclusig) are advanced generation TKIs that may overcome imatinib resistance or intolerance. These inhibitors are anywhere from 10 to 325 times more potent than imatinib in inhibiting *BCR-ABL* and overcome most *BCR-ABL* mutations that lead to imatinib resistance.[1] Of the four, only ponatinib can overcome the *T315I* mutation.[4]

Bosutinib, dasatinib, and nilotinib are indicated for first-line therapy in CP-CML. Studies suggest bosutinib, dasatinib, and nilotinib are superior to imatinib in achieving faster and deeper cytogenetic and molecular responses.[11–14] Fewer patients may progress to accelerated or blast phase on bosutinib, dasatinib, or nilotinib compared to imatinib although there are no differences in overall survival reported between the agents. Common side effects are similar to those of imatinib and may be found in Table 96–1. A significant and potentially severe side effect of pleural effusions has been reported with the use of imatinib and dasatinib but not with the use of nilotinib.[10] Additional side effects of nilotinib include QT prolongation and increases in indirect bilirubin.[1]

Ponatinib is a third-generation multikinase inhibitor that overcomes the *BCR-ABL* domain mutation *T315I*. Ponatinib was initially approved for the treatment of patients in all phases that were resistant or intolerant to prior TKI therapy. In postmarketing analysis, an increase in serious arterial thrombotic events was shown in 24% of patients.[15] The revised label indicates the use of ponatinib in patients harboring the *T315I* mutation or have failed multiple prior TKIs. Rare yet serious adverse effects include heart failure, liver failure, and death, which are black-box warnings.[6] Ponatinib is available through a Risk Evaluation and Mitigation Strategy (REMS) program.

▶ *Omacetaxine Mepesuccinate*

Omacetaxine mepesuccinate (Synribo) is a semisynthetic formulation of homoharringtonine. Omacetaxine reversibly inhibits protein synthesis thereby causing cell death.[16] Unlike TKIs, the mechanism of action affects both normal and malignant hematopoietic cells. Omacetaxine is a subcutaneous injection indicated for patients in CP- or AP-CML who are resistant or intolerant to two or more TKIs.[6] It may also be used in patients with the *T315I* mutation. Nonhematologic adverse reactions may be found in Table 96–1. Clinicians should note omacetaxine may cause hyperglycemia, requiring monitoring, particularly in patients with diabetes.[6,16]

OUTCOME EVALUATION

Successful treatment for CML depends on an optimal response to TKI therapy (ie, hematologic, cytogenetic, and molecular). Nearly all newly diagnosed CP-CML patients will be placed on a TKI and will remain on TKI therapy for an indefinite amount of time. First-line treatment options include imatinib, bosutinib, dasatinib, and nilotinib. Which agent to use depends on several factors, including disease risk score, age, comorbid conditions, medication safety profile, and financial accessibility. Patients should be counseled on the importance of medication adherence. Patients should understand that poorer outcomes may result if they are not adherent to daily TKI therapy. The NCCN guidelines provide response criteria.[7] Molecular response at 3, 6, and 12 months is assessed, as it has been associated with improved progression free and overall survival.[7,17] If patients fail to achieve these milestones, a change in therapy is recommended. If TKI treatment failure occurs, patients should undergo *BCR-ABL* domain mutation testing and be evaluated for patient adherence and possible drug interactions. Second-line CP-CML therapy should be selected based on mutational analysis with second-generation TKIs (utilized). These agents may also be used in patients who have AP-CML. Ponatinib may be considered if the *T315I* mutational status is present with an understanding that it is associated with serious vascular effects. Omacetaxine, allogeneic stem cell transplantation, and clinical trials are options for those patients that do not respond to a TKI. Some patients will not respond to treatment and will progress to BP-CML where they

Patient Encounter 1

A 38-year-old Hispanic female presents to her primary care physician with complaints of "feeling tired over the past couple months" and "occasional abdominal pain". Her past medical history consists of poorly type 2 diabetes. Her A1C is 10.8% despite treatment on metformin 1 g twice daily and 30 units of glargine (weight: 100 kg). She also takes OTC omeprazole for GERD. A CBC is drawn and shows the following:

Total WBC: 104×10^9/L (104×10^3/mm^3) (5% [0.05] blasts, 75% [0.75] segs, 20% [0.20] lymphs)

Hgb/Hct: 9.7 g/dL (97 g/L; 6.014 mmol/L)/29% (0.29)

Platelets: 190×10^9/L (190×10^3/mm^3)

The patient is referred to an oncologist for further workup. A bone marrow biopsy is performed and reveals hypercellular marrow with 5% (0.05) blasts. Cytogenetics are positive for t(9:22) via FISH.

What information is suggestive of CP-CML?

Which specific treatment do you recommend for initial treatment and why?

Identify your treatment goals for this patient.

What drug information and patient counseling will you provide to the patient?

Identify factors that may contribute to this patient's having a suboptimal response.

Assuming this patient has a suboptimal response to your initial therapy, what would you recommend for second-line therapy?

will receive treatment for acute leukemia. Although its use is limited, allogeneic transplant offers the only cure for CML and may be useful in patients with advanced disease who have failed other options.

CHRONIC LYMPHOCYTIC LEUKEMIA

EPIDEMIOLOGY AND ETIOLOGY

CLL is the most common type of leukemia diagnosed in adults, accounting for 30% of all adult leukemias. It was estimated that in 2018, 20,940 new cases were diagnosed in the United States.[2] The median age at diagnosis is 70 years with the incidence increasing with age.[18] The etiology of CLL is unknown, but hereditary factors may have a role, with family members of CLL patients having a twofold to sevenfold increased risk of CLL.[19]

PATHOPHYSIOLOGY

Cell of Origin

CLL is characterized by small, relatively incompetent B lymphocytes that accumulate in the blood and bone marrow over time. The lack of apoptotic mechanisms, including BCL-2 overexpression, leads to the persistence and accumulation of B lymphocytes.[20] The exact cell of origin is controversial but has been described as an antigen-activated B lymphocyte.[19] Chromosomal abnormalities have been identified in 80% cases of CLL and often correlate with progressive disease.[21] Numerous tyrosine kinases appear to be involved in CLL, including the activation of Bruton tyrosine kinase (BTK).[20] Detection of some of these markers may predict clinical course and prognosis and may influence treatment decisions.[19,22]

Clinical Course

LO 4

KEY CONCEPT CLL can have a variable clinical course with survival ranging from months to decades. Patients are classified as low, intermediate, or high risk. Approximately 90% of patients are diagnosed with asymptomatic, low-risk CLL, where the median survival times exceed 10 years.[23] The typical low-risk patient is an asymptomatic elderly patient who is diagnosed on routine blood draw. Intermediate risk is associated with lymphadenopathy and has median survival times of about 7 years. High-risk patients with anemia have median survival times of only 2 years.[24] The typical high-risk patient is a symptomatic middle-aged patient. Some patients with slightly elevated B lymphocytes may not meet the diagnostic criteria for CLL and may be diagnosed with monoclonal B-lymphocytosis (MBL). The progression from MBL to CLL is approximately 1.1% per year.[25]

Clinical Presentation and Diagnosis of CLL

Signs and Symptoms (50% Are Asymptomatic at Diagnosis)[19]

- Lymphadenopathy
- Organomegaly consisting of splenomegaly and hepatomegaly
- Fatigue, weight loss, night sweats, fevers
- Chronic infections caused by immature lymphocytes

Diagnostic Procedures

- Peripheral blood smear
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

Laboratory Findings

- Peripheral-blood
  - Leukocytosis (WBC count > 100×10^9/L [100×10^3/mm^3])
  - Lymphocytosis (absolute lymph count > 5×10^9/L [5×10^3/mm^3])
  - Anemia
  - Thrombocytopenia
  - Hypogammaglobulinemia
- Bone marrow
  - Hypercellular with increased mature lymphocytes
- Molecular markers
  - Cytogenetic abnormalities

Poor Prognostic Factors

- Lymphocytosis with accompanying:
  - Anemia (hemoglobin ≤ 11.0 g/dL [110 g/L; 6.83 mmol/L])
  - Thrombocytopenia (platelets < 100×10^9/L [100×10^3/mm^3])
  - ZAP-70, CD49d, and CD38 antigen expression
  - Cytogenetics such as deletions of chromosomes 17p and 11q
  - *TP53* and *IgVH* mutations

PROGNOSTIC FACTORS

Two staging systems, Rai and Binet, have been developed to help practitioners determine the overall prognosis of patients with CLL. They are comparable systems and are useful to broadly determine good, intermediate, and poor prognostic disease.[24] Risk stratification criteria included in these systems are lymphadenopathy, splenomegaly, hepatomegaly, and cytopenias. Increasingly, biological markers of the disease such as deletions of chromosome 17p (del(17p)) and 11q (del(11q)) and mutational status of immunoglobulin heavy chain variable region gene (IgVH) are being used to predict the likely clinical course.[20,26] Patients with del(17p) tend to have a poor response to therapy. These biological markers are not included in the Rai or Binet staging systems.

TREATMENT

Desired Outcomes

The primary goals in the treatment of CLL are to provide palliation of symptoms and achieve a long-term remission. Because the current treatments for CLL are not curative, reduction in tumor burden and improvement in disease symptoms are reasonable end points, particularly in older patients. A complete response (CR) to therapy can be defined as a resolution of lymphadenopathy and organomegaly, normalization of peripheral blood counts, and elimination of lymphoblasts in the bone marrow.

Nonpharmacologic Therapy

LO 4

KEY CONCEPT Asymptomatic early stage CLL can be observed without treatment until evidence of disease progression. Past studies with chlorambucil suggest that chemotherapy does not improve overall survival in early stage CLL although there is question whether this remains true with the development of newer therapies. In addition, deferring therapy until a patient becomes symptomatic does not alter overall survival.[23,26] For this reason, the notion of "watch and wait" is considered reasonable for older patients with low risk disease. Several factors will influence this approach, including life expectancy, disease characteristics, and ability to tolerate therapy.[23,26]

▶ *Hematopoietic Stem Cell Transplantation*

The use of HSCT in CLL is limited. Allogeneic HSCT offers longer disease-free remissions in patients with poor prognosis than autologous HSCT but is associated with higher treatment morbidity and mortality. Several factors must be considered before allogeneic HSCT. The lack of a donor, older age, and poor performance status make transplant an uncommon procedure in this population. Allogeneic HSCT remains an option for younger patients with aggressive disease who have failed prior therapies.[24,26]

Pharmacologic Therapy

The treatment options for CLL have significantly expanded in the past decade. Combination chemoimmunotherapy is typically initiated in the symptomatic patient. There are numerous agents that can be used in combination as initial therapy. The NCCN guidelines provide recommendations on first-line and subsequent therapies based on mutational status.[24] Many of the chemotherapy regimens have not been compared directly with one another, so there is not one preferred regimen. Selection of the appropriate chemotherapy depends on the individual patient, the tumor's molecular abnormalities (particularly with or without del(17p)), and the practitioner's preference. Chemoimmunotherapy has shown limited success in patients with del(17p); however, recently, the immunomodulatory agent lenalidomide has shown promise as maintenance therapy for patients with del(17p) CLL following first-line therapy.[23,27]

Figure 96–2 illustrates one approach for initial therapy in newly diagnosed patients with CLL.

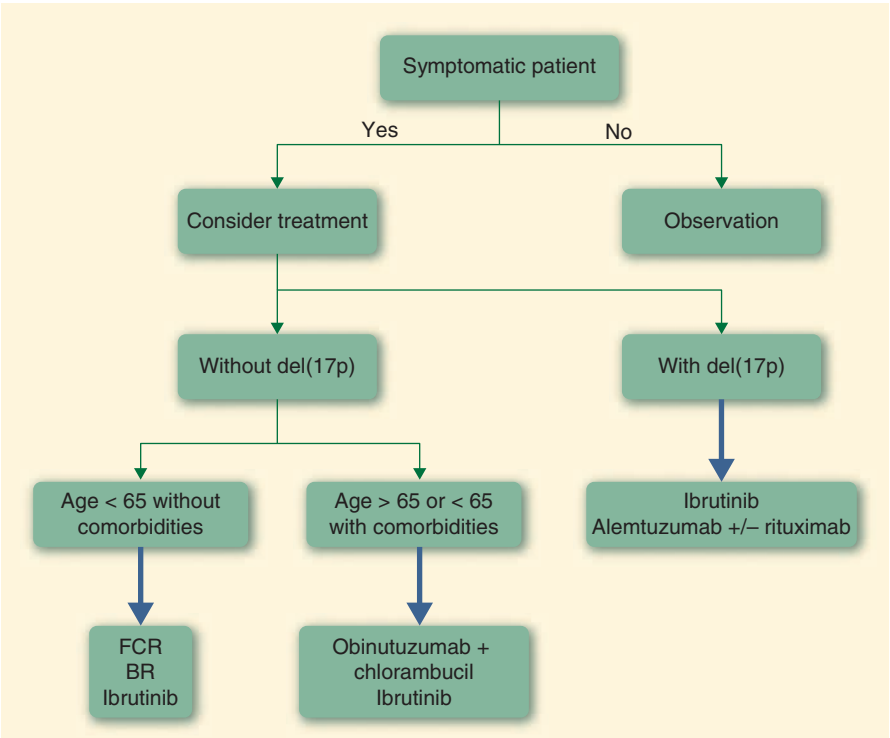

FIGURE 96–2. Selected treatment approach for primary therapy in newly diagnosed CLL patients. (B, bendamustine; C, cyclophosphamide; F, fludarabine; R, rituximab.) (Data from NCCN.)

▶ Cytotoxic Chemotherapy

Historically, chlorambucil (Leukeran), an oral alkylating agent, was considered the standard treatment for CLL. Today, the treatment for CLL has changed with the development of the purine analogs. There are three purine analogs used in the treatment of CLL: fludarabine (Fludara), pentostatin (Nipent), and cladribine (Leustatin) with fludarabine being the most studied. KEY CONCEPT Fludarabine-based chemoimmunotherapy is commonly used as first-line therapy for younger patients with CLL without a del(17p) mutation.[19,26,27]

Randomized clinical trials have shown that fludarabine is superior to chlorambucil in achieving higher response rates and producing a longer duration of response.[24,26] Although fludarabine is one of the most effective agents in the treatment of CLL, it is rarely used as a sole agent. Instead fludarabine is given in combination with cyclophosphamide and rituximab (FCR) to improve response rates.[24,26,27]

Fludarabine is associated with more toxicities than chlorambucil, including myelosuppression and prolonged immunosuppression. Resultant infectious complications may occur during the periods of prolonged immunosuppression. Clinicians should consider antibacterial and antiviral prophylaxis for *Pneumocystis* and varicella zoster when using fludarabine-based therapy.[24] Chlorambucil in combination with anti-CD20 monoclonal antibody remains a practical option for symptomatic elderly patients and those with comorbidities.[26]

Bendamustine (Treanda) is an alkylating agent used in the treatment of CLL. The combination of bendamustine and rituximab was shown to have a lower median progression-free survival (PFS) compared to FCR in younger patients, but less toxicities.[24,27] Bendamustine in combination with an anti-CD20 monoclonal antibody in an option for those patients without a del(17p) mutation who cannot tolerate the toxicities of FCR, including patients older than 65 or with comorbities.[24,26,27]

▶ Monoclonal Antibodies

KEY CONCEPT Combination chemoimmunotherapy with anti-CD20 monoclonal antibodies are widely used in the treatment of CLL. Rituximab (Rituxan) is a naked chimeric monoclonal antibody directed against the CD20 antigen on B-lymphocytes.[28] Similar to other B-cell malignancies, CLL expresses CD20 antigens. Dose escalation studies suggest higher doses are required than those used in non-Hodgkin lymphoma.[29] The higher dose required in CLL is probably a combined effect of lower CD20 antigen expression and higher concentrations of soluble CD20 antigen than in non-Hodgkin lymphoma.[29] Rituximab is given in combination with other therapies since these combinations result in higher CRs than rituximab alone.[28] The most common side effects of rituximab include infusion reactions consisting of fever, chills, hypotension, nausea, vomiting, and headache.[24] Premedication with diphenhydramine and acetaminophen is recommended to minimize infusion reactions.

Ofatumumab (Arzerra) and obinutuzumab (Gazyva) are two additional anti-CD20 monoclonal antibodies. Ofatumumab is a CD20 antigen-directed monoclonal antibody that is often used in combination with chlorambucil in patients with untreated CLL who cannot tolerate fludarabine-based therapy.[30] Obinutuzumab is different than the other anti-CD20 monoclonal antibodies having a higher binding affinity to the CD20 epitope and causing direct cell death.[30] The combination of obinutuzumab and chlorambucil was shown to have a clinically meaningful improvement in PFS compared to rituximab and chlorambucil in untreated CLL in patients without del(17p). This regimen is often used in combination with chlorambucil for the treatment of previously untreated CLL in patients without del(17p) who are not able to tolerate purine analogs. Table 96–2 lists some of the adverse effects seen with the anti-CD20 monoclonal antibodies.

▶ Small Molecule Inhibitors

KEY CONCEPT An understanding of the B-cell receptor signaling pathways of CLL has led to the approval of oral targeted therapies. Many of these therapies have improved the median overall survival of CLL.[27] Ibrutinib (Imbruvica) is an inhibitor of BTK which is an essential enzyme in the B-cell receptor pathway and may be used as first-line therapy for all patients, including patients with del(17p) and age older than 65.[23,24] The overall response rate as a single-agent in patients with relapsed CLL was 71%, an impressive percentage for this subset of patients.[31] Additional positive studies expanded ibrutinib's indications to first-line therapy. Idelalisib (Zydelig) targets phosphatidylinositol-3-kinase (PI3-K), an essential lipid kinase that is a regulator of the B-cell receptor pathway and involved in cellular survival and proliferation.[32] Idelalisib has been studied as monotherapy as well as combination therapy with rituximab in patients with relapsed disease.[32] Nonhematologic side effects for both drugs may be found in Table 96–2. Black-box warnings for idelalisib include hepatotoxicity, colitis, pneumonitis, and intestinal perforation. Most patients experience a transient increase in absolute lymphocyte count when initiating ibrutinib or idelalisib.[24] The lymphocytosis will persist for several weeks and then subside. Continuation of therapy is warranted and does not suggest disease progression.

Venetoclax (Venclexta) is a small molecular inhibitor that targets B-cell lymphoma 2 (BCL-2) protein and is approved for patients with relapsed/refractory CLL in patients with del (17p).[23,24] Adverse effects for venetoclax include tumor lysis syndrome, in which prophylaxis with allopurinol or rasburicase and oral hydration is recommended, and prolonged neutropenia, which may require growth factor support.[24]

▶ Chemoimmunotherapy

Combination chemoimmunotherapy is the standard for younger patients with symptomatic CLL in patients without del(17p).[24] The specific drug regimen is often selected based on age and cytogenetics. There are numerous first-line options for patients without del(17p). Combination therapy generally consists of an anti-CD20 antibody in combination with chemotherapy. The combination of fludarabine, cyclophosphamide, and rituximab (FCR) is often utilized in those that can tolerate chemotherapy.[24] A 2013 multiple-treatment meta-analysis was not able to show a significant survival benefit of one regimen compared to another.[33]

OUTCOME EVALUATION

Successful outcomes depend on the appropriate treatment selection for a specific patient. Risk-versus-benefit should be determined in the treatment of older CLL patients. Because CLL is incurable, watch and wait is a reasonable approach for those with indolent, asymptomatic disease. Treatment can then begin when the patient becomes symptomatic. Aggressive chemoimmunotherapy with fludarabine is often reserved for younger patients with high-risk CLL, with the goal being prolonged disease-free survival. A desirable response to therapy includes a reduction in lymphocytes, decrease in stage of the disease, and resolution of symptoms. Supportive care, including herpes virus and *Pneumocystis* prophylaxis, may be required depending on the treatment chosen.

Table 96–2

Drugs Used in CLL

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bendamustine (Treanda)	Myelosuppression, fever, nausea, vomiting, infusion reactions, tumor lysis syndrome	Consider using allopurinol for tumor lysis syndrome during first few cycles of therapy	CrCl < 40 mL/min (0.67 mL/s): do not use	Mild impairment: use with caution Moderate to severe impairment: do not use
Chlorambucil (Leukeran)	Myelosuppression; allergic reactions (skin rash); secondary malignancies	Take on an empty stomach because food decreases absorption Dose range: 4–10 mg po daily	No reductions	No reductions
Fludarabine (Fludara)	Myelosuppression; prolonged immunosuppression, resulting in secondary infectious complications; edema; neurotoxicity	Dose: 20 mg/m^2 IV daily for 5 days Often given in combination	CrCl 30–70 mL/min (0.50–1.17 mL/s): 20% reduction of dose (IV and po) CrCl < 30 mL/min (0.50 mL/s): do not use IV; reduce dose of oral by 50%	No reductions
Ibrutinib (Imbruvica)	Risk of bleeding, neutropenia, thrombocytopenia	Dose: 420 mg po once daily Avoid the use of concomitant CYP 3A4 inhibitors/inducers Drug metabolism: CYP 3A4 and 2D6	No reductions in CrCl > 25 mL/min (0.42 mL/s) Insufficient data in < 25 mL/min (0.42 mL/s)	Insufficient data exists; interruption if hepatotoxicity occurs
Idelalisib (Zydelig)	Black-box warnings: severe hepatotoxicity, diarrhea, colitis, pneumonitis, intestinal perforation Serious allergic reactions	Given in combination with rituximab Dose: 150 mg po twice daily Drug metabolism: CYP 3A4; strong inhibitor of 3A4, 2C8, 2C9, 2C19	No reductions in CrCl > 15 mL/min (0.25 mL/s) Insufficient data in < 15 mL/min (0.25 mL/s)	Insufficient data exists
Obinutuzumab (Gazyva)	Infusion reactions, reactivation of hepatitis B, progressive multifocal encephalopathy, tumor lysis syndrome, neutropenia	Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions Consider antimicrobial, antiviral, and antifungal prophylaxis Hold antihypertensives 12 hours prior, during, and after due to the risk of hypotension	No reductions in CrCl > 30 mL/min (0.50 mL/s) Insufficient data in < 30 mL/min (0.50 mL/s)	No reductions
Ofatumumab (Arzerra)	Severe infusion-reactions: bronchospasm, edema, fever, chills, rigors, hypotension; prolonged myelosuppression	Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions
Rituximab (Rituxan)	Infusion reactions: fever, chills, rigors, hypotension	Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion related reactions Rate of infusion should be increased gradually to minimize reactions Monitor for reactivation of hepatitis B	No reductions	No reductions
Venetoclax (Venclexta)	Tumor lysis syndrome requiring hydration and anti-hyperuricemics, neutropenia, thrombocytopenia, infections	Initial dose: 20 mg po once daily × 7 days; then increased weekly over 5 weeks to a max dose of 400 mg po once daily Drug metabolism: do not coadminister with a strong CYP3A inhibitor and caution with strong/moderate CYP3A inducers	No reductions in CrCl > 30 mL/min (0.50 mL/s) Insufficient data in < 30 mL/min (0.50 mL/s)	No reductions for mild to moderate; insufficient data exists for severe

CrCl, creatinine clearance; IV, intravenous; po, oral; PCP, pneumocystits pneumonia; SC, subcutaneous.

Patient Encounter 2

A 77-year-old man presents to his health care provider with complains of a "lump in his neck". Past medical history includes an acute myocardial infarction and benign prostatic hypertrophy. Physical examination reveals cervical lymph node enlargement and splenomegaly. Blood work reports the following:

WBC: 30×10^9/L (30×10^3/mm^3)

Hgb: 11.2 g/dL (112 g/L; 6.944 mmol/L)

Platelets: 182×10^9/L (18.2×10^3/mm^3)

Peripheral Smear: Lymphocytosis with small, mature-appearing cells suggestive of chronic lymphocytic leukemia

FISH analysis: del(17p)

Identify your treatment goals for this patient.

How does the del(17p) influence your treatment approach?

What treatment do you recommend and what would you monitor?

Would your treatment options change if this patient were asymptomatic? If so, what would be your new treatment?

MULTIPLE MYELOMA

Multiple myeloma is a malignancy of the plasma cell and is characterized by an abnormal production of a monoclonal protein in the bone marrow. Features of the disease include bone lesions, anemia, and renal insufficiency. MM is an incurable disease; however, advancements in the treatment of myeloma have significantly extended survival.

EPIDEMIOLOGY AND ETIOLOGY

Multiple myeloma is the second most common hematologic malignancy. It is estimated that approximately 30,770 new cases would be reported in 2018, accounting for approximately 2% of all cancers.[2] The median age at diagnosis is 69 years, and fewer than 2% are diagnosed before the age of 40 years.[34] The incidence of myeloma is highest in African Americans, lowest in Asians, and occurs more frequently in men than women.[35] The etiology of MM remains largely unknown although a exposure to ionizing radiation and genetic factors have been implicated.[35]

PATHOPHYSIOLOGY

The pathogenesis of MM is quite complex with multiple-step models created to postulate the process. Myeloma must be distinguished from a condition called monoclonal gammopathy of unknown significance (MGUS), which is characterized by a monoclonal immunoglobulin without malignant plasma cells, and smoldering myeloma, which lacks clinical manifestations from the high monoclonal immunoglobulin. Yearly, about 1% of patients with MGUS will develop MM. Chromosomal abnormalities and changes in gene expression lead to cell cycle dysregulation and appear to be involved early in the disease process.[36] The pathophysiology of MM involves complex bone marrow microenvironment and cytokine interactions. Interleukin-6, tumor necrosis factor, vascular endothelial growth

Clinical Presentation and Diagnosis of Multiple Myeloma

Signs and Symptoms

- "CRAB"
  - "C"—hyperCalcemia
  - "R"—Renal failure (serum creatinine > 2 mg/dL [177 µmol/L])
  - "A"—Anemia (fatigue)
  - "B"—Bone disease (pain, lesions, fractures)
- Weight loss
- Recurrent infections

Diagnostic Procedures

- Laboratory
  - CBC, chemistry panel, β_2-microglobulin
  - Peripheral blood smear
  - Serum protein electrophoresis and immunofixation
  - Urine protein electrophoresis and immunofixation
  - Serum free light chains
- Radiologic evaluation (MRI, bone densitometry)
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

Laboratory Findings

- Peripheral blood
  - Monoclonal protein (M protein) in serum (usually IgG or IgA)
  - High β_2-microglobulin
  - Low platelets and hemoglobin
  - High creatinine, urea, lactate dehydrogenase, C-reactive protein, and calcium
  - Rouleaux formation
- Urinalysis
  - Urinary free light chains (Bence-Jones Protein)
- Bone marrow
  - Plasma cells (10% or more)
  - Abnormal cytogenetics
- Radiologic findings
  - Bone lesions, fractures, osteoporosis

Poor Prognostic Factors

- High serum β_2-microglobulin and low serum albumin
- Elevated C-reactive protein
- Elevated lactate dehydrogenase
- IgA isotype
- Low platelet count
- Chromosome 13 deletions and other cytogenetic abnormalities

factor, and stromal-derived factor-1 support the establishment and proliferation of myeloma cells.[36,37] The understanding of these interactions has led to novel agents used in the treatment of MM.

PROGNOSTIC FACTORS

Prognostic factors for myeloma include tumor-, treatment-, and patient-related factors. The International Staging System is used to predict outcomes after therapy. Staging is stratified based on the levels of serum β_2-microglobulinemia and serum albumin. High β_2-microglobulinemia and low albumin are poor prognostic factors and are indicative of high tumor load.[38] Although cytogenetic abnormalities are not included in the International Staging System, many abnormalities are associated with poor outcomes. The Mayo Stratification for Myeloma and Risk-Adapted Therapy (mSMART) classification incorporates tumor biology to stratify patients according to their disease risk.[39] Chromosomal changes are being used to predict high-risk patients with perhaps the most important being deletions of the long arm of chromosome 13 and translocation of chromosomes 4 and 14.[40] Older patients, renal impairment, and other comorbidities also predict for poorer outcomes.[33]

TREATMENT

Desired Outcomes

The primary goal in the treatment of MM is to prolong progression free and overall survival while minimizing complications associated with the disease.[40] A watch and wait approach is an option for patients with smoldering myeloma who have no lytic lesions in the bone. When symptoms occur, treatment is required. The treatment of MM often includes induction, transplantation, and maintenance therapy. All patients should be evaluated early on to see if they are transplant eligible candidates. Autologous stem cell transplantation prolongs overall survival in patients who can tolerate high-dose chemotherapy. Regardless of transplant eligibility, all patients will be placed on primary therapy to reduce tumor burden. Maintenance therapy following transplant with lenalidomide is being used to prolong the duration of response. Almost all patients become refractory to primary treatment, requiring the use of salvage therapies. Figure 96–3 illustrates possible treatment approaches for transplant-eligible and transplant-ineligible patients.

Patient Encounter 3, Part 1

A 68-year-old woman presents to the emergency room after a fall in her home. Her past medical history includes controlled hypertension and osteoporosis. She notes severe bilateral hip pain. Workup reveals:

Radiology: X-ray of right and left hips: Pathologic fracture of right hip; Osteolytic lesions in both right and left hip

Labs: Hemoglobin: 8.4 g/dL (84 g/L; 5.208 mmol/L); platelets: 220×10^9/L (220×10^3/mm^3); corrected calcium: 11.8 mg/dL (2.95 mmol/L); serum creatinine: 2.3 mg/dL (203 µmol/L); serum IgG: 6200 mg/dL (42 g/L) (normal: 620–1500 mg/dL) (6.2–15 g/L); serum IgM: 80 mg/dL (8 g/L) (normal: 50–200 mg/dL [0.5–2 g/L]); bone marrow: 72% plasma cell infiltrates

What signs and symptoms are suggestive of multiple myeloma?

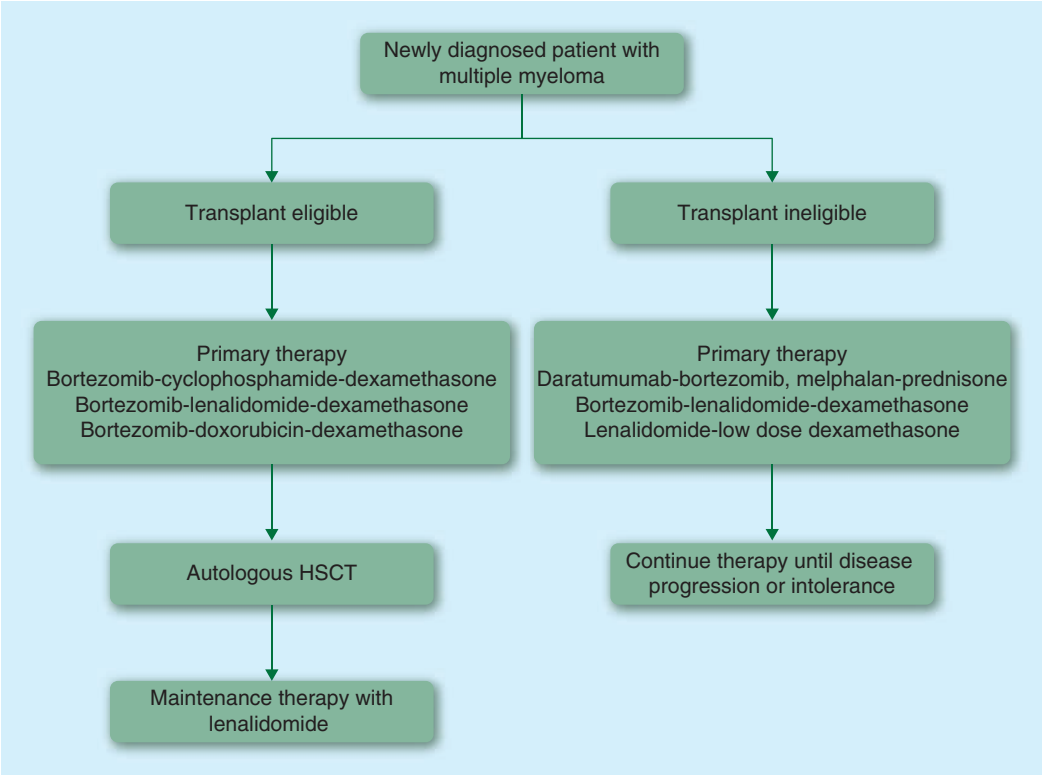

FIGURE 96–3. Possible approach for treatment in newly diagnosed patients with multiple myeloma. (HSCT, hematopoietic stem cell transplantation.) (Data from NCCN.)

Nonpharmacologic Therapy

▶ *Autologous Hematopoietic Stem Cell Transplantation (HSCT)*

LO 7

KEY CONCEPT Autologous hematopoietic stem cell transplantation results in higher response rates and extends PFS compared with those who receive conventional chemotherapy.[37,40] Autologous HSCT remains the standard of care and should be considered in all patients who can tolerate high-dose chemotherapy.[40] High-dose melphalan is the most common preparative regimen. Two sequential transplants (tandem transplants) improve overall survival in patients who do not have a good partial response after one transplant.[37] The use of maintenance therapy after autologous transplantation with lenalidomide may be used in select patients to extend PFS.[40,41]

Pharmacologic Therapy

See Table 96–3. Symptomatic MM requires treatment. There are five main classes of drugs used in the treatment of MM: alkylating agents, anthracyclines, corticosteroids, immunomodulatory agents, and proteasome inhibitors. A three-drug regimen is often utilized in the treatment of myeloma.

▶ *Conventional-Dose Chemotherapy*

The use of conventional-dose chemotherapy with alkylating agents or anthracyclines has declined with the advent of

Table 96–3

Drugs Used in Multiple Myeloma

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Bortezomib (Velcade)	Constipation; decreased appetite; asthenia; fatigue; fever; thrombocytopenia; dose related, reversible peripheral neuropathy	Dose: 1.3 mg/m^2 IV bolus or SC twice weekly for 2 weeks; week 3 off; repeat Concentration for IV is 1 mg/mL and 2.5 mg/mL for SC Consider herpes zoster prophylaxis with daily acyclovir	No reductions	Bilirubin > 1.5 × the upper limit of normal: reduce dose to 0.7 mg/m^2
Carfilzomib (Kyprolis)	Neutropenia, thrombocytopenia, cardiac toxicity including cardiac arrest, congestive heart failure, infusion-reactions, tumor lysis syndrome	Dose: 20 mg/m^2 IV bolus on days 1, 2, 8, 9, 16, and 16; days 17–28 off; repeat every 28 days Patients with a BSA greater than 2.2 m^2 should have dose calculated based on 2.2 m^2 Premedicate with dexamethasone 4 mg to reduce infusion-related reactions Hydration with normal saline prior to carfilzomib is recommended	No reductions	May need to dose reduce or hold dose depending on degree of hepatic dysfunction
Daratumumab (Darzalex)	Infusion-reactions, diarrhea, nausea, vomiting, respiratory concerns including cough and dyspnea, infection	Dose: 16 mg/kg IV weekly on weeks 1–8, every other week starting week 9–24 and every 4 weeks starting week 25 Premedicate with acetaminophen, steroid, and antihistamine to reduce infusion-related reactions Bronchodilators may be needed Antiviral prophylaxis should be initiated and continued for 3 months post-last dose Corticosteroid should be started for 2 days following each infusion	No reductions	Mild/moderate: No reductions Severe: Insufficient data exists
Dexamethasone	Hyperglycemia, edema, adrenal cortical insufficiency	Dose given po once daily	No reductions	No reductions
Doxorubicin (Adriamycin)	Myelosuppression; alopecia; cumulative dose-limiting toxicity: myocardium damage	Given in combination with lenalidomide and dexamethasone	No reductions	Bilirubin 1.2–3 mg/dL (21–51 µmol/L): 50% reduction in dose Bilirubin 3.1–5 mg/dL (53–85 µmol/L): 75% reduction in dose Bilirubin > 5 mg/dL (85 µmol/L): use with caution
Elotuzumab (Empliciti)	Infusion-reactions, infections including opportunistic, diarrhea, secondary malignancies	Given in combination with lenalidomide and dexamethasone Premedicate with acetaminophen, ranitidine, diphenhydramine and dexamethasone to reduce infusion-related reactions	No reductions	Mild: No reductions Moderate/severe: Insufficient data exists

(*Continued*)

Table 96–3

Drugs Used in Multiple Myeloma (*Continued*)

Drug	Adverse Effects	Comments	Renal Dosing	Hepatic Dosing
Ixazomib (Ninlaro)	Neutropenia, thrombocytopenia, rash, peripheral neuropathy, drug-induced hepatotoxicity	Dose: 4 mg po on days 1, 8, and 15 in combination with lenalidomide 25 mg po on days 1–21 and dexamethasone 40 mg po on days 1, 8, 15, and 28. Repeat every 28 day cycle Thromboprophylaxis is recommended with this regimen	CrCl > 30 mL/min (0.50 mL/s): no adjustments CrCl < 30 mL/min (0.50 mL/s): reduce dose to 3 mg	Mild: no reductions Moderate/severe: reduce dose to 3 mg
Lenalidomide (Revlimid)	Possible birth defects neutropenia, thrombocytopenia, DVT, PE, pruritus, fatigue	Dose: 25 mg taken with water once daily Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required	CrCl 30–60 mL/min (0.50–1.00 mL/s): 10 mg/day CrCl < 30 mL/min (0.50 mL/s): 15 mg every 48 hours Dialysis and CrCl < 30 mL/min (0.50 mL/s): 5 mg every 24 hours given after dialysis	No reductions
Melphalan (Alkeran)	Myelosuppression, secondary malignancies, pulmonary fibrosis, sterility, alopecia	Dose given po once daily IV formulation used for stem cell transplantation	No recommendation but may consider an initial dose reduction	No reductions
Pomalidomide (Pomalyst)	Severe birth defects, DVT, neutropenia	Dose: 4 mg po daily on days 1–21; off 21–28 and repeat Drug metabolism: CYP 1A2 and 3A4	Do not use if SCr > 3 mg/dL (265 µmol/L)	Do not use if bilirubin > 2 mg/dL (34 µmol/L) and AST/ALT > 3 × the upper limit of normal
Thalidomide (Thalomid)	Severe birth defects, peripheral neuropathy, DVT, somnolence, constipation	Titrate initial doses; doses are taken nightly Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required	No reductions	No reductions

DVT, deep venous thrombosis; IV, intravenous; PE, pulmonary embolism; po, oral; SC, subcutaneous.

immunomodulators and proteasome inhibitors. The combination of melphalan and prednisone (MP) was once the most common initial treatment combination for myeloma. Today, MP is no longer recommended due to cytopenias and inferior effectiveness.[40] The anthracycline doxorubicin may be incorporated into treatment regimens, with the combination of doxorubicin, bortezomib, and dexamethasone selected for primary therapy in patients who are transplant eligible.[40]

▶ *Immunomodulatory Drugs*

LO 7

KEY CONCEPT The immunomodulatory drug lenalidomide (Revlimid) is often used in combination therapy for the treatment of MM. The precise mechanism of action is unknown, but its antimyeloma activity may be attributable to its antiangiogenic and anticytokine properties.[42] Response rates are improved when an immunomodulatory agent is added to a treatment regimen. Thalidomide was the first immunomodulatory agent to be studied with impressive responses (87%) in combination with a steroid and bortezomib.[43] Today lenalidomide has largely replaced thalidomide due to high potency and a more favorable safety profile over thalidomide.[40] The combination of lenalidomide, bortezomib, and dexamethasone has emerged as one of the most commonly used primary regimens in the treatment of transplant-eligible and transplant-ineligible patients with myeloma.[40,43,44] Low-dose dexamethasone with lenalidomide offers improved overall survival compared with high-dose dexamethasone.[40] Lenalidomide may also be used in combination dexamethasone and the other proteasome inhibitors, carfilzomib or ixazomib.[40,44] Lenalidomide lacks many of the common side effects seen with thalidomide. Significant adverse effects of lenalidomide include myelosuppression and VTEs. VTE prophylaxis is recommended in patients at high risk for thrombosis.[40] Stem cells should be collected shortly after starting lenalidomide because CD34-positive stem cell counts tend to decrease with prolonged lenalidomide exposure.[40] Maintenance lenalidomide after autologous HSCT is widely utilized. Although it has been associated with an increase in PFS, there has also been an increase in the incidence of secondary malignancies.[40,45]

▶ *Proteasome Inhibitors*

LO 7

Bortezomib (Velcade), carfilzomib (Kyprolis), and ixazomib (Ninlaro) are **proteosome** inhibitors approved for the treatment of MM. Proteosome inhibitors induce myeloma cell death by modulating **nuclear factor kappa-B** products, including inflammatory cytokines and adhesion molecules that support myeloma cell growth.[43] These drugs also disrupt the myeloma microenvironment by inhibiting the binding of myeloma cells to the bone marrow stromal cells.[43] Bortezomib-based regimens are frequently used as primary therapy for MM. The response rates with bortezomib have been reported as high as 97%

in newly diagnosed myeloma.[43] Bortezomib has also shown impressive outcomes in patients with high risk disease, making it a preferred agent for these patients. Adverse effects of bortezomib include fatigue, nausea, peripheral neuropathy, and hematologic effects.[43] Subcutaneous bortezomib may be given to patients with preexisting neuropathy to lessen peripheral neuropathy.[40] The incidence of VTE is lower than the immunomodulators; thus, bortezomib does not routinely require prophylactic anticoagulation. However, prophylactic antiviral therapy should be considered to reduce the risk of herpes zoster reactivations.[40]

Carfilzomib and ixazomib are second-generation proteasome inhibitors that are used in the treatment of refractory MM. While carfilzomib is administered intravenously, ixazomib is the first oral proteasome inhibitor and is given in an all orally administered regimen with lenalidomide and dexamethasone. Phase I/II studies have shown promising results with carfilzomib or ixazomib as primary therapy in combination regimens with an immunomodulator and dexamethasone.[40] The adverse effect profile is similar to bortezomib with potentially less neurotoxicity. Clinicians should note that carfilzomib requires monitoring for cardiac and pulmonary toxicities.

▶ *Additional Agents*

Several new drugs have been approved for the treatment of relapsed and refractory MM. The monoclonal antibodies daratumumab (Darzalex) and elotuzumab (Empliciti) target CD38 and signaling lymphocytic activation molecular F7 (SLAMF7), respectively.[46] Both glycoproteins are expressed on MM cells. These monoclonal antibodies are used in combination with dexamethasone and bortezomib or lenalidomide.[40] Panobinostat (Farydak) is an inhibitor or histone deacetylase used in combination with bortezomib and dexamethasone.[40,46] This regimen has significant toxicity consisting of thrombocytopenia, ischemic events, arrhythmias, diarrhea, and peripheral neuropathy.

▶ *Bisphosphonates*

Bone disease is a common manifestation of MM. Bisphosphonates or denosumab should be initiated in symptomatic patients with bone lesions to slow osteopenia and reduce the fracture risk associated with the disease. Pamidronate 90 mg and zoledronic acid 4 mg have equivalent efficacy in the management of osteolytic lesions.[47] The use of zoledronic acid decreases pain and bone-related complications and improves quality of life. Denosumab 120 mg Q4 weeks was recently shown to be noninferior to zoledronic acid 4 mg Q4 weeks and is preferred in patients with renal insufficiency.[40] Osteonecrosis of the jaw is a major concern with bisphosphonate therapy. Risk factors are unclear, but osteonecrosis of the jaw is more common in patients receiving IV administration of bisphosphonates and having dental procedures performed. It is recommended that patients have dental restoration work before starting bisphosphonate therapy. Several consensus guidelines have been published on the use of bisphosphonates and myeloma.[48,49] Recommendations on the duration of therapy and which bisphosphonate to use have largely been left up to the practitioner.[40]

Patient Encounter 3, Part 2

The patient was diagnosed with multiple myeloma.

What treatment options are available for this patient?

What would be an appropriate regimen for primary therapy?

What may be used for maintenance therapy after an autologous stem cell transplantation?

OUTCOME EVALUATION

Newly diagnosed, asymptomatic patients with MM may be observed without treatment. This asymptomatic period may last for months to several years. All patients with MM become symptomatic, and when this occurs, treatment is required. All patients should be evaluated for an autologous stem cell transplant. For patients who are eligible for transplant, induction therapy often consists of lenalidomide, bortezomib, and dexamethasone. Maintenance therapy with lenalidomide may be used posttransplant. There are numerous treatment options for transplant ineligible patients including MPT, MPB, or MPL. Nearly all patients progress at some point, and second-line therapy usually includes bortezomib. Monthly bisphosphonates or denosumab should be given to patients who have bone lesions with the hope of reducing pain and fractures.

Patient Care Process

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements.
- Review medical history, including patient's age, comorbid conditions, and current medications to avoid drug–drug interactions.
- Review laboratory values and physical assessment findings.

Assess the Information:

- Determine whether the patient requires immediate treatment based on laboratory values, physical assessment and medical history.
- Identify whether the patient is taking any medications that could interact with the possible treatment selections for the given cancer.
- Discuss with the patient the financial costs of the possible treatment and determine if one agent is more cost-effective than another.
- If goals are not achieved, assess whether a change in medication is warranted or if nonadherence is suspected.
- If the patient experiences intolerance to therapy including any severe adverse effects, a change in medication may be warranted.

Develop a Care Plan:

- Select the most appropriate treatment based on the assessment findings for the patient.
- Consider whether additional supportive care medications are needed such as prophylactic antimicrobials, growth factors, or anticoagulants.

(*Continued*)

Patient Care Process (*Continued*)

- Discuss the importance of medication adherence and long-term outcomes.
- Address any concerns about the selected medication including cost and management of adverse effects.
- Identify the required monitoring and determine treatment outcomes and goals.

Implement the Care Plan:

- Educate the patient on the selected drug therapy, medication administration, importance of adherence, potential adverse effects, and how to manage and report adverse effects that occur.
- Address any patient concerns about the selected drug therapy and its management.

Follow-up: Monitor and Evaluate:

- Drug therapy should be frequently monitored to assess treatment efficacy and safety.
  - For CML, follow-up should be scheduled every 3 months to determine whether molecular, cytogenetic, and hematologic goals of therapy are being met.
  - For CLL, follow-up should include a review of symptoms and laboratory findings including lymphocytes and hemoglobin.
  - For MM, monitor myeloma monoclonal protein in urine and serum, renal function, hemoglobin, and platelets.
- Review medication adherence.
- If patients continue to have disease progression or have relapsed disease, another regimen should be utilized.
- Out of office follow-up (ie, phone calls) may be helpful to reinforce the importance of adherence and to identify and manage any adverse effects.

Abbreviations Introduced in This Chapter

AP	Accelerated phase
BP	Blast phase/crisis
CLL	Chronic lymphocytic leukemia
CML	Chronic myelogenous leukemia
CP	Chronic phase
CR	Complete response
FISH	Fluorescence in situ hybridization
HSCT	Hematopoietic stem cell transplantation
MGUS	Monoclonal gammopathy of unknown significance
Ph	Philadelphia chromosome
Q-PCR	Quantitative polymerase chain reaction
TKI	Tyrosine kinase inhibitor
WBC	White blood cell

97 Malignant Lymphomas

Keith A. Hecht and Susanne E. Liewer

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Discuss the underlying pathophysiologic mechanisms of the lymphomas and how they relate to presenting symptoms of the disease.
2. Differentiate the pathologic findings of Hodgkin lymphoma (HL), follicular indolent non-Hodgkin lymphoma (NHL), and diffuse aggressive NHL and how this information yields a specific diagnosis.
3. Describe the general staging criteria for the lymphomas and how it relates to prognosis; evaluate the role of the prognostic systems such as the International Prognostic Score for HL, the Follicular Lymphoma International Prognostic Index (IPI), and the IPI for diffuse, aggressive NHL.
4. Compare and contrast the treatment algorithms for early and advanced stage disease for HL.
5. Assess the role of autologous hematopoietic stem cell transplantation for relapsed lymphomas.
6. Delineate the clinical course of follicular indolent and diffuse aggressive NHL and the implications for disease classification schemes and treatment goals.
7. Outline the general treatment approach to follicular indolent and diffuse aggressive NHL for localized and advanced disease.
8. Interpret the current role for monoclonal antibody therapy in NHL.

INTRODUCTION

The malignant lymphomas are a clonal disorder of hematopoiesis with the primary malignant cells consisting of lymphocytes of B-, T-, or natural killer (NK) cell origin. Lymphoma cells predominate in the lymph nodes; however, they can infiltrate lymphoid and nonlymphoid tissues, such as the bone marrow, central nervous system (CNS), gastrointestinal (GI) tract, liver, mediastinum, skin, and spleen. An overview of the lymph node regions is depicted in Figure 97–1. KEY CONCEPT There are two broad classifications of lymphoma, Hodgkin lymphoma (HL) and non-Hodgkin lymphoma (NHL), and both contain numerous histologic subtypes that are pathologically distinct disease entities.

The clinical course varies widely among histologies of lymphoma. More aggressive subtypes are highly proliferating cells that require aggressive therapeutic intervention with chemotherapy, radiation therapy, or both. By contrast, certain subtypes of NHL are characterized by a disease course that flares and remits intermittently over a period of years regardless of treatment.

HODGKIN LYMPHOMA

EPIDEMIOLOGY AND ETIOLOGY

Approximately 8500 new cases of HL were estimated to be diagnosed in the United States in 2018, with 1050 deaths attributed to the disease.[1] The incidence of HL is bimodal, with peaks occurring in the third decade of life and in patients over 50 years of age.[2] The precise cause of HL is unknown, but certain associations have been reported and provide insight about possible etiologic factors. Epstein-Barr virus (EBV) has been associated with HL, its viral genome is detected in Reed-Sternberg (RS) cells in up to 40% of cases in developed countries. Other viruses (cytomegalovirus, human herpes viruses, human immunodeficiency virus [HIV], and adenoviruses) have been associated with HL; however, data is conflicting.[3] Other possible risk factors identified include woodworking and a familial history of HL.

PATHOPHYSIOLOGY

LO 1

Pluripotent stem cells in the bone marrow are able to differentiate to both lymphoid and myeloid progenitor cells. Lymphoid progenitor cells undergo normal gene rearrangement to yield either B-cell or T-cell lineage precursor cells. Normal maturation for naive B cells includes expression of cell surface antibody or the cells typically undergo **apoptosis**. These cells are differentiated from other B cells, such as memory cells, by virtue of cell surface antigen ($CD5^+$ or $CD5^-$ and $CD27^-$) and bound antibody (IgM+ and IgD+). When naive B cells recognize antigen with their cell surface antibody, they accumulate in the lymph nodes, spleen, or other lymphoid tissue. The DNA of these B cells is susceptible to three different types of genetic modification: **receptor editing**, somatic hypermutation, and class switching within the germinal center of the lymph node. Germinal centers are microanatomic structures located within lymph nodes that develop with clonal B-cell expansion secondary to antigen stimulation. Under normal circumstances, these genetic changes allow for adaptation of the immune system to the repeated exposure to environmental antigens.

LO 2

The pathophysiology of HL is defined by the presence of the RS cell in a grouping of lymph nodes. The RS cell is a morphologically large cell with a multinucleated structure possessing pronounced eosinophilic nucleoli, thought to be B cell in origin.[4]

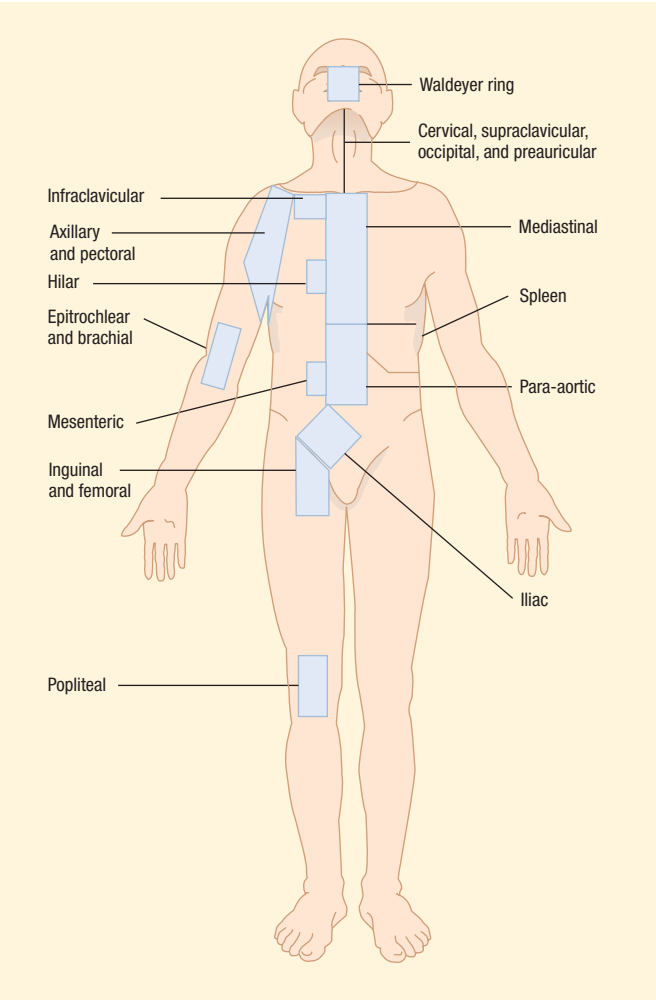

FIGURE 97–1. Representation of the anatomic regions used in the staging of Hodgkin disease. (From Rosenberg SA. Staging of Hodgkin disease. Radiology. 1966;87:146.)

In the affected lymph nodes, the RS cells are contained within an inflammatory background that is believed to be essential for their survival.

RS cells have lost the expression of most B-cell markers. Common cell-surface antigens expressed by RS cells include CD30 and CD15, but other common B-cell antigens, such as CD20 are inconsistently expressed.[4] The Janus kinase-signal transduction and transcription (JAK-STAT) signaling pathway has also been found to be active in HL. Additionally, the overexpression of nuclear factor kappa-B (NF-κB), a proliferative and antiapoptotic transcription factor nuclear factor is believed to contribute to the expansion and survival of RS cells.

HL is classified into disease subtypes based on the number and morphologic appearance of RS cells and the background cellular milieu. These are listed in the World Health Organization (WHO) classification of lymphoid neoplastic diseases in Table 97–1.[5] Nodular sclerosing (75%) is the most common form of classical HL. It is more common in young adults and is marked by the presence of the RS variant cell, the lacunar cell. The second most common form of HL is mixed-cellularity variant (19%), with others accounting for the remainder of cases.[6] Factors identified as negative disease prognostic indicators are listed in Table 97–2.

LO 3

Table 97–1

Abbreviated WHO Classification of Lymphoid Neoplasms

B-Cell Neoplasms
Chronic lymphocytic leukemia/small lymphocytic lymphoma
Monoclonal B-cell lymphocytosis
B-cell proliferative leukemia
Splenic marginal zone B-cell lymphoma
Hairy cell leukemia
Lymphoplasmacytic lymphoma
Monoclonal gammopathy of undetermined significance
Plasma cell myeloma
Plasmacytoma
Monoclonal immunoglobulin deposition disease
Extranodal marginal zone B-cell lymphoma of MALT type
Nodal marginal zone lymphoma
Follicular lymphoma
Primary cutaneous follicle center lymphoma
Mantle cell lymphoma
Diffuse large B-cell lymphoma (DLBCL)
Primary DLBCL of central nervous system
Primary cutaneous DLBCL
Lymphomatoid granulmatosis
Primary mediastinal large B-cell lymphoma
Plasmablastic lymphoma
Primary effusion lymphoma
Burkitt lymphoma

T-Cell and NK-Cell Neoplasms
T-cell prolymphocytic leukemia
T-cell large granular lymphocytic leukemia
Aggressive NK cell leukemia
Hydroa vacciniforme-like lymphoproliferative disorder
Adult T-cell lymphoma/leukemia (HTLV1+)
Extranodal NK/T-cell lymphoma, nasal type
Enteropathy-associated T-cell lymphoma
Monomorphic epitheliotropic intestinal T-cell lymphoma
Hepatosplenic T-cell lymphoma
Subcutaneous panniculitis-like T-cell lymphoma
Mycosis fungoides
Sézary syndrome
Primary cutaneous T-cell lymphoproliferative disorders
Peripheral T-cell lymphoma
Angioimmunoblastic T-cell lymphoma
Follicular T-cell lymphoma
Anaplastic large-cell lymphoma

Hodgkin Lymphoma
Nodular lymphocyte-predominant HL
Classical HL
- Nodular sclerosis HL
- Lymphocyte-rich classical HL
- Mixed cellularity HL
- Lymphocyte depletion HL

Posttransplant Lymphoproliferative Disorders

Histiocytic and Dendritic Cell Neoplasms

AML, acute myeloid leukemia; HL, Hodgkin lymphoma; MALT, mucosa-associated lymphoid tissue; NK, natural killer.

TREATMENT OF HL

Desired Outcome

LO 3

Staging of HL with a standard classification is necessary to guide treatment. The extent and location of involvement, localized or disseminated extranodal disease, and B symptoms are factors in assignment of stage. The Lugano modification

Table 97–2

Negative Prognostic Factors for HL

International Prognostic Score—Advanced HL
Albumin < 4 g/dL (40 g/L)
Hemoglobin < 10.5 g/dL (105 g/L; 6.52 mmol/L)
Male sex
Age > 45 years
Stage IV disease
WBC ≥ 15,000/mm^3 (15 × 10^9/L)
Lymphocytopenia (count < 600/mm^3 [0.6 × 10^9/L], < 8% [0.08] of WBC count, or both)

WBC, white blood cell.

of the original Ann Arbor classification is used in staging lymphomas and is outlined in Table 97–3.[7]

KEY CONCEPT The principal goal in treating HL is to cure the patient of the primary malignancy. HL is sensitive to both radiation and chemotherapy, resulting in an 80% rate of cure with modern therapy. Treatment strategy is generally divided into approaches for early stage I/II disease and stage III/IV advanced disease. Patients with stage I/II disease are further classified into favorable, unfavorable with bulky disease, and unfavorable with nonbulky disease. Regardless of stage, all patients are treated with curative intent. Other treatment goals include:

- Complete resolution of disease symptoms
- Incorporation of supportive care measures to optimize quality of life
- Minimization of acute and long-term treatment-related toxicity

Nonpharmacologic Therapy

Radiation therapy is effective in the treatment of HL and has cured patients of their disease. Historically, patients with favorable early stage I/II disease were treated with radiation alone. However, long-term toxicities associated with this practice have precluded this approach. Current treatment strategies combine radiation with chemotherapy. This has been reported to reduce the irradiated volume and dose as well as the number of cycles of chemotherapy.

Table 97–3

Lugano Staging Classification for Lymphomas (2014 Modification of Ann Arbor Staging)

Stage	Involvement	Extranodal (E) Status
Limited		
Stage I	One node or a group of adjacent nodes	Single extranodal lesions without nodal involvement
Stage II	Two or more nodal groups on the same side of the diaphragm	Stage I or II by nodal extent with limited contiguous extranodal involvement
Stage II bulky	Same as II but with "bulky" disease	
Advanced		
Stage III	Nodes on both sides of diaphragm or nodes above the diaphragm with spleen involvement	Not applicable
Stage IV	Additional noncontiguous extralymphatic involvement	Not applicable

"A" (absence of B-symptoms) or "B" (presence of B-symptoms) is only used for Hodgkin lymphoma.

Clinical Presentation and Diagnosis of Malignant Lymphomas

General

Nonspecific; can range from an asymptomatic patient with a less aggressive lymphoma to a patient who is gravely ill with advanced disease.

KEY CONCEPT Symptoms

- Lymphadenopathy, generally in the cervical, axillary, supraclavicular, or inguinal lymph nodes
- Splenomegaly
- Shortness of breath, dry cough, chest pressure (patients with mediastinal mass)
- GI complications (nausea, vomiting, early satiety, constipation, and diarrhea)
- Back, chest, or abdominal pain

Signs

- Fever[a]
- Night sweats[a]
- Weight loss greater than 10% within last 6 months[a]
- Pruritus

Laboratory Tests

- LDH
- ESR
- Serum chemistries
- CBC with differential

KEY CONCEPT Other Diagnostic Tests

- Physical examination with careful attention to lymph node inspection.
- Imaging—chest x-ray, chest CT, abdominal or pelvic CT; integrated PET and CT are recommended as part of the initial workup.
- Bone marrow biopsy.
- Biopsy of suspected lymph node(s)—either open lymph node biopsy (preferred) or core biopsy; fine-needle aspiration should only be performed if preferred biopsy methods are unobtainable.
- Hematopathology evaluation of biopsy specimen—morphologic inspection, immunohistochemistry for cell surface antigens to characterize lymphoma cells, cytogenetic analysis.

[a]Known collectively as B symptoms.

CBC, complete blood count; CT, computed tomography; ESR, erythroid sedimentation rate; LDH, lactate dehydrogenase; PET, positron emission tomography.

Patient Encounter Part 1: Initial Presentation

A 59-year-old man with a medical history of hypertension and coronary artery disease presents to the oncologist on referral from his primary care provider. He presented to his PCP with swollen lymph nodes and facial swelling. He was in her usual state of health until 2 months ago when he began experienceing "lumpy spots" in his bilateral axillary region and swelling and tenderness in the neck. He states that he has experienced a 20-pound weight loss over the last several months. The PCP referred him for biopsy of palpable cervical lympho node. A fine-needle aspiration was performed that showed a "lymphoproliferative process." Complete blood count revealed a WBC of 3500/mm^3 (3.5 × 10^9/L), hemoglobin of 8.5 g/dL (8.5 g/L; 5.27 mmol/L), and platelets were 137,000/mm^3 (137 × 10^9/L). Lactate dehydrogenase was 353 U/L (5.9 μkat/L). The chemistry panel was unremarkable.

What tests should be performed to confirm a diagnosis of lymphoma and determine its overall stage?

Based on the information provided, what is his International Prognostic Index (IPI), and how does it impact treatment selection?

Historically in the treatment of HL, the radiation fields were large and often included the lungs, liver, heart, and breast. Today, the use of involved-site radiotherapy (ISRT) and involved-node radiotherapy (INRT) limits radiation to the involved area. In addition to the smaller radiation volumes, other organs have reduced exposure.[8] Treatment with radiotherapy produces significant toxicity of acute and delayed onset. Acute effects of irradiation include nausea, anorexia, xerostomia, dysgeusia, pharyngitis, dry cough, fatigue, diarrhea, and rash. These effects are typically transient, resolving shortly after completion of treatment. Delayed effects from radiotherapy are concerning as they may be permanent and present months to years after therapy. Pneumonitis, pericarditis, hypothyroidism, infertility (with pelvic field irradiation), coronary artery disease, deformities in bone and muscle growth in children, herpes zoster reactivation, and **Lhermitte sign** are not uncommon. Patients cured with radiotherapy are at increased risk for new cancers of the breast, lung, and stomach, as well as melanoma and new NHL, depending on the radiation field.

Pharmacologic Therapy

▶ *Early Stage Disease*

KEY CONCEPT Initial treatment of HL includes combination chemotherapy; these regimens are effective and have acceptable long-term toxicities. Combined modality therapy of two to four cycles ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine) plus 20 to 30 Gy (Gray, the absorbed radiation dose) of ISRT or two cycles Stanford V chemotherapy plus 30 Gy of ISRT or chemotherapy alone (ABVD) are treatment options for patients with favorable stage I/II HL. Patients with favorable disease have: no B symptoms, an erythrocyte sedimentation rate less than 50 mm/hour, no extralymphatic lesions, and only one or two involved nodal sites. Chemotherapy alone can be considered in patients with a negative PET scan after three cycles of ABVD.[9] When combined modality treatment is favored, ISRT should be initiated for patients who achieve a complete response (CR) or a partial response (PR) to chemotherapy. After completion of ISRT, no further treatment is necessary for patients with a CR; further restaging is required for patients with PR to therapy.

LO 4

ABVD followed by escalated BEACOPP or Stanford V followed by ISRT is recommended for patients with unfavorable, bulky disease. Interim staging after 2–3 cycles of chemotherapy can help guide further treatment, such as two cycles of ABVD are given before interim restaging. Patients with a response to therapy are treated with two additional cycles (total of 4) of ABVD or two cycles of escalated BEACOPP (consider with PR to ABVD) followed by ISRT.[10] Stanford V is administered for three cycles and restaged at the completion of chemotherapy prior to beginning ISRT. ISRT may also be incorporated into ABVD based on provider preference or response to chemotherapy. The use of the Stanford V regimen should be considered for patients with mediastinal disease, bulky disease, B symptoms, or unfavorable nonbulky disease.[11] A list of chemotherapy regimens used in HL is presented in Table 97–4.

▶ *Advanced Disease*

LO 4

Patients with advanced disease can be further classified into two groups based on International Prognostic Score (see Table 97–2). Patients with three or fewer poor prognostic factors are considered to have favorable disease while patients with four or more factors have unfavorable disease. Patients with unfavorable disease may warrant more aggressive treatment.

Trials have focused on the use of multiagent chemotherapy for six to eight cycles. The chemotherapy regimen MOPP (mechlorethamine, vincristine, procarbazine, and prednisone)

Table 97–4

Common Treatment Regimens in HL

ABVD—Every 28 Days
Doxorubicin 25 mg/m^2 IV × 1, days 1 and 15
Bleomycin 10 units IV × 1, days 1 and 15
Vinblastine 6 mg/m^2 × 1, days 1 and 15
Dacarbazine 375 mg/m^2 IV × 1, days 1 and 15

Stanford V
Doxorubicin 25 mg/m^2 IV weeks 1, 3, 5, 7, 9, and 11
Vinblastine 6 mg/m^2 IV weeks 1, 3, 5, 7, 9, and 11
Mechlorethamine 6 mg/m^2 IV weeks 1, 5, and 9
Etoposide 60 mg/m^2 IV weeks 3, 7, and 11
Vincristine 1.4 mg/m^2 IV weeks 2, 4, 6, 8, 10, and 12
Bleomycin 5 mg/m^2 IV weeks 2, 4, 6, and 8
Prednisone 40 mg po every other day for 12 weeks, start taper at week 10

BEACOPP (Escalated)—Every 21 Days
Bleomycin 10 mg/m^2 IV, day 8
Etoposide 200 mg/m^2 IV daily × days 1–3
Doxorubicin 35 mg/m^2, day 1
Cyclophosphamide 1200 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, day 8
Procarbazine 100 mg/m^2 po daily, days 1–7
Prednisone 40 mg po daily, days 1–14

BEAM (High-Dose with Autologous SCT)[a]
Carmustine 300 mg/m^2 IV × 1 day
Etoposide 100–200 mg/m^2 IV every 12 hours × 4 days
Cytarabine 100–200 mg/m^2 IV every 12 hours × 4 day
Melphalan 140 mg/m^2 IV × 1 day

[a]Used for both Hodgkin lymphoma and non-Hodgkin lymphoma.
IV, intravenous; po, oral; SCT, stem cell transplantation.

Table 97–5

Practical Information for ABVD and CHOP

Regimen	Drug Class	Pharmacokinetics	Unique Toxicities
ABVD			
Doxorubicin	Anthracycline	Hepatic metabolism[a]	Highly emetogenic Cardiomyopathy Maximum cumulative lifetime dose, 550 mg/m^2
Bleomycin	Antitumor antibiotic	Renal clearance[a]	Pulmonary fibrosis Maximum cumulative lifetime dose, 400 units
Vinblastine	Vinca alkaloid	CYP 3A4/5 metabolism[a]	Neuropathy, constipation
Dacarbazine	Alkylating agent	Hepatic metabolism[a]	Myelosuppression
CHOP			
Cyclophosphamide	Alkylating agent	Prodrug; CYP3A4/5, 2D6	Highly emetogenic Hemorrhagic cystitis
Doxorubicin	Anthracycline	Hepatic metabolism	Cardiomyopathy
Vincristine	Vinca alkaloid	CYP3A4/5	Neuropathy, constipation
Prednisone	Corticosteroid	100% oral bioavailability	Hyperglycemia, osteopenia

[a]See dose adjustments (Chapter 88).

is of historical significance because it was the first chemotherapy regimen to cure HL in the 1960s. However, significant toxicity, including sterility and secondary leukemia, led to the development of new regimens. A pivotal phase III trial comparing ABVD, MOPP, and ABVD-MOPP alternating in patients with stage III/IV HL documented a higher CR in the ABVD arms. A recent update of the data shows superior 18-year freedom from progression in the ABVD arms compared to MOPP though a survival advantage was not demonstrated.[12] ABVD is now considered standard therapy for initial treatment of stage III or IV HL. Further information on ABVD may be found in Table 97–5.

LO 4

Additional regimens such as Stanford V and BEACOPP were developed to improve outcomes in patients with advanced HL. Except in patients with high-risk disease (International Prognostic Score > 3) the Stanford V regimen has demonstrated similar response rates to ABVD reported for event-free survival, overall survival, and toxicity.[13] A dose-escalated regimen of BEACOPP (with colony-stimulating factor [CSF] support) was compared with a standard-dose BEACOPP and also COPP (cyclophosphamide substituted for mechlorethamine in MOPP) alternating with ABVD. The dose-escalated BEACOPP was superior to the other arms in both freedom from treatment failure and overall survival at 10 years.[14] However, the escalated BEACOPP regimen is associated with more toxicity including infertility and secondary leukemia. Currently, neither BEACOPP regimen is widely used in the United States but is considered for advanced HL with a high number of poor prognostic factors.

Despite the high success rate in treating HL, approximately 5% to 10% of patients will be refractory to initial treatment and 10% to 30% will relapse after initial response.[15] Patients relapsing after treatment should be offered additional therapy as durable responses have been reported. The duration of remission after chemotherapy remains a vital prognostic factor for likelihood of response to future treatment.[16] For healthy patients, the definitive therapy after relapse is high-dose chemotherapy with autologous stem cell transplantation (SCT).[17] This treatment offers a cure rate up to 50%.

LO 5

Several studies have reported the importance of giving conventional chemotherapy before SCT. The purpose of the initial treatment after relapse is to decrease the tumor bulk before SCT. The safety profile of autologous SCT continues to improve as refinements in supportive care advance. Current estimates of mortality from autologous SCT for HL are approximately 5%. Morbidity associated with preparative regimens in HL, aside from infectious and bleeding complications, includes pulmonary toxicity of bleomycin coupled with carmustine, inducing potentially fatal pulmonary pneumonitis.

Patients who are not candidates for autologous SCT may receive standard salvage chemotherapy, such as etoposide, methylprednisolone, cytarabine, and cisplatin (ESHAP) or dexamethasone, cytarabine, and cisplatin (DHAP). Other regimens such as GVD (gemcitabine, vinorelbine, and pegylated liposomal doxorubicin), IGEV (ifosfamide, gemcitabine, and vinorelbine), and GCD (gemcitabine, carboplatin, and dexamethasone) have also been effective. Single agents such as lenalidomide, bendamustine, and everolimus have also shown activity. Brentuximab vedotin is a monoclonal antibody that targets CD-30 and is linked to a microtubule-disrupting agent, monomethylauristatin E. This agent has demonstrated efficacy with sustained responses up to 3 years.[18] Programmed death 1 blocking monoclonal antibodies such as nivolumab and pembrolizumab have also shown benefit in patients with relapsed refractory disease. Clinical trials are ongoing to define the role of these agents.[19,20]

NON-HODGKIN LYMPHOMA

EPIDEMIOLOGY AND ETIOLOGY

Approximately 74,680 cases of NHL were estimated to be diagnosed in the United States in 2018, with an estimated 19,910 deaths. These figures represent a stabilization in the incidence of NHL since 1998 that follows a dramatic increase that nearly doubled the number of cases in the United States since 1950.[1,21] The increase may be related to the development of aggressive NHL in patients with HIV, although the overall increase is independent of HIV disease. The median age for diagnosis is 50 years, although children and young adults may also be affected. The etiology of certain aggressive NHL subtypes is related to specific

endemic geographic factors. Follicular or low-grade lymphoma is more common in the United States and Europe and is relatively uncommon elsewhere. Exposure to various causative agents, such as pathogens or occupational exposure, can be attributed to many different types of lymphoma and may be responsible for differences in regional lymphoma rates. Human T-cell leukemia virus I, human herpesvirus 8, hepatitis C, *Helicobacter pylori*, and EBV have all been implicated in inducing NHL.[22] The incidence of Burkitt NHL is 7 cases per 100,000 people in Africa compared with 0.1 per 100,000 in the United States. Malaria or EBV is thought to contribute to the chronic B-lymphocyte stimulation leading to malignant transformation in Burkitt NHL. Due to the pathogen-related induction of NHL, immunocompromised patients are at increased risk of NHL. Environmental factors have been identified as contributing to the development of NHL. Certain occupations such as wood and forestry workers, butchers, exterminators, grain millers, machinists, mechanics, painters, printers, and industrial workers have a higher prevalence of disease. Industrial chemicals such as pesticides, herbicides, organic chemicals (eg, benzene), solvents, and wood preservatives are also associated with NHL.

PATHOPHYSIOLOGY

LO 2

The pathophysiology of NHL is governed by numerous environmental and genetic events culminating with a monoclonal population of malignant lymphocytes. B cells represent the cells of origin in excess of 90% of cases. Figure 97–2 outlines normal B-cell maturation with accompanying cell-surface antigens. Evolving data are correlating chromosomal mutations with specific disease subtypes. Cytogenetic abnormalities involving translocations of antigen receptor genes are prevalent in NHL. These include T-cell receptor genes in T-cell lymphomas and immunoglobulin genes in B-cell lymphomas. The principal defect appears to be an error in assembly of the regulatory gene

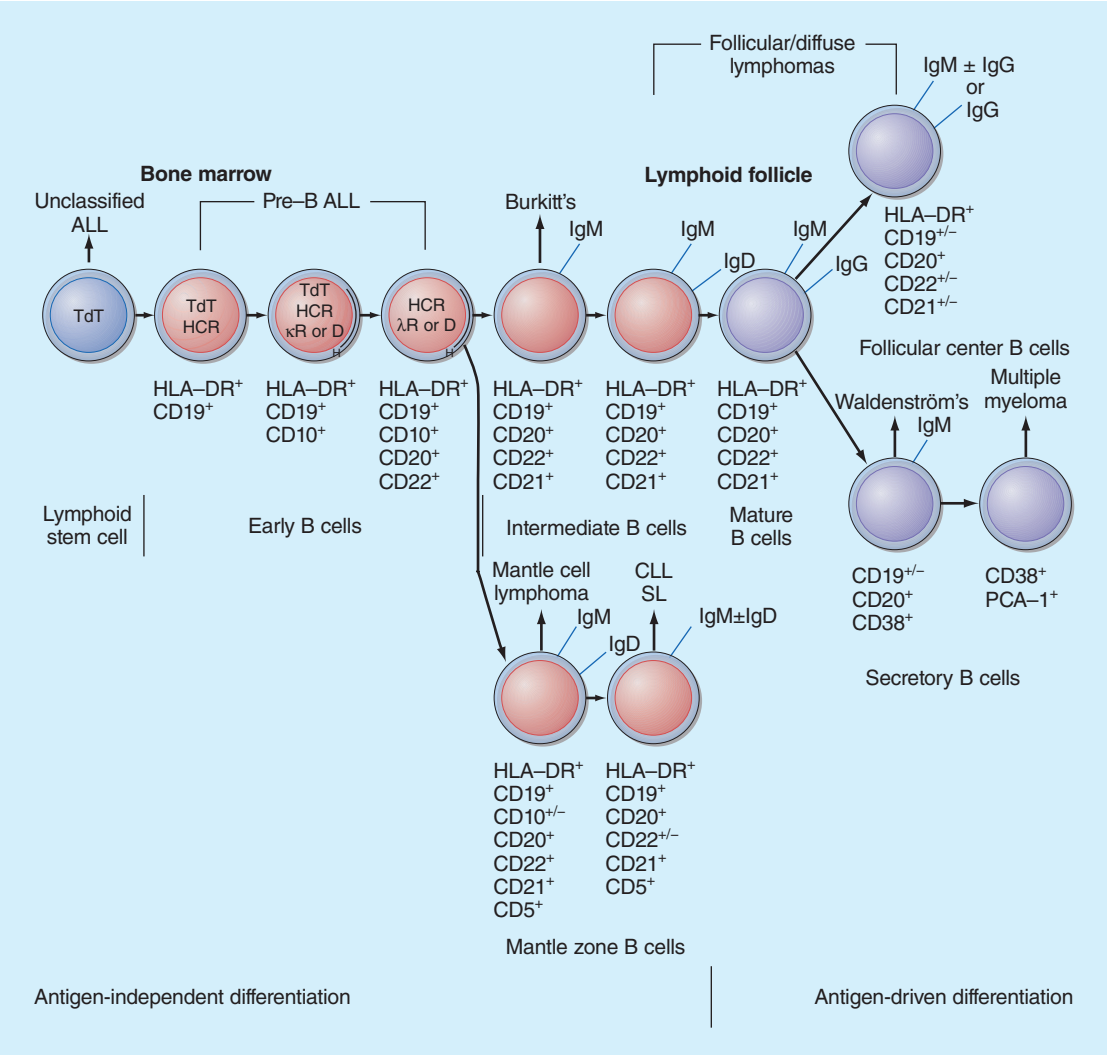

FIGURE 97–2. Pathway of normal B-cell differentiation and relationship to B-cell lymphocytes. (ALL, acute lymphoblastic leukemia; HCR, human chemokine receptor; HLA, human leukocyte antigen; Ig, immunoglobulin; TdT, terminal deoxynucleotidyl transferase.) (From Longo DL. Chapter 134. Malignancies of Lymphoid Cells. In: Kasper DL, Fauci AS, Hauser SL, Longo DL, Jameson J, Loscalzo J. eds. Harrison's Principles of Internal Medicine, 19e. New York, NY: McGraw-Hill; 2015.)

segment of an antigen receptor gene, resulting in inappropriate binding to an **oncogene**. This results in dysregulation of cell growth and proliferation, leading to the malignant clone of lymphocytes. Oncogenes identified in different lymphomatous diseases include *myc, bcl-1, bcl-2, bcl-3, NF-κB,* and *bcl-6*.[23] Classic translocations for NHL include t(8;14) in Burkitt lymphoma, t(14;18) in follicular lymphomas, t(11;14) mantle cell lymphoma, and t(11;18)/t(1;14) in mucosa-associated lymphoid tissue (MALT).

KEY CONCEPT Characterization of the **morphology** of lymphocytes, the reactivity of other cells in the lymph node, and architecture of the node are essential in obtaining a diagnosis and predicting disease course. The nodal presentation of NHL is divided into two main categories: follicular, corresponding to low-grade disease, and diffuse, corresponding to aggressive disease. A follicular disease pattern in the inspected lymph node is indicative of a more indolent or low-grade progression that has survival measured in years if left untreated. In contrast, a diffuse pattern of lymph node infiltration indicates highly aggressive disease, resulting in death within weeks to months if untreated. Follicular NHL is the most common indolent subtype, comprising 22% of NHL. Diffuse, large B-cell lymphoma (DLBCL) is the most common aggressive histology, comprising 31% of NHL. The cells of origin for follicular NHL tend to be more mature, nondividing lymphocytes, whereas aggressive NHL is derived from rapidly dividing lymphoid precursors. A unique feature of the biology of NHL is that follicular low-grade histologies can undergo further malignant transformation, transforming further into a DLBCL population. This syndrome, also possible as a transition from chronic lymphocytic leukemia to an aggressive lymphoma, is called Richter transformation. Richter transformation involves multiple genetic events, including abnormalities of chromosomes 11 and 12 and tumor suppressor genes.[24]

The classification of NHL has undergone several revisions as the histology, molecular biology, and clinical course have been more precisely defined. Classification schemes such as the Working Formulation categorize disease on aggressiveness into three categories: low grade–survival estimated in years without treatment, intermediate grade–survival estimated in months without treatment, and high grade–survival measured in days to weeks for untreated disease. This scheme is limited in clinical applicability because of the large number of distinct diseases that are not categorized by this classification. A more accepted classification system for lymphoid malignancies was proposed by the WHO. The WHO classification groups lymphomas based on cell of origin (B-cell, T-cell, NK-cell) as shown in Table 97–1. Further description of tumors is based on cell characteristics such as aggressiveness, cell size, and proliferation.[5]

LO 3

Prognostic factors present at diagnosis have been identified for NHL. Age, the presence of B symptoms, performance status, number of nodal and extranodal sites, lactate dehydrogenase (LDH) level, bulky disease (> 10 cm), advanced stage, and β_2-microglobulin concentration have been shown to be important prognostic features in NHL. Table 97–6 shows the International Prognostic Index (IPI), a predictive model for aggressive NHL to be treated with doxorubicin-containing chemotherapy regimens.[25] This index is used as a tool to identify patients who may benefit from a more intense treatment regimen. A similar model, the Follicular Lymphoma International Prognostic Index (FLIPI), is used to help guide treatment decisions in follicular lymphoma.[26]

Table 97–6

Negative Prognostic Factors for NHL

International Prognostic Index—Diffuse, Aggressive NHL

Criteria	Risk Group	Number of Criteria
Age ≥ 60 years		
Stage III/IV disease	Low	0–1
Extranodal disease > 1 site	Low-intermediate	2
ECOG performance status 2 or greater	High-intermediate	3
Serum LDH > 1 × normal limit	High	4–5

Follicular Lymphoma International Prognostic Index

Criteria	Risk Group	Number of Criteria
Age ≥ 60 years		
Stage III/IV disease	Low	0–1
Hemoglobin < 12.0 g/dL (120 g/L; 7.45 mmol/L)	Intermediate	2
Serum LDH > 1 × normal limit	High	≥ 3
Number of nodal sites ≥ 5[a]		

[a]The nodal map used in the Follicular Lymphoma International Prognostic Index is different than the nodal map used in conventional staging.

TREATMENT OF NHL

Desired Outcome

NHL treatment depends primarily on histologic subtype (follicular low grade versus diffuse aggressive) and staging (local stage I/II versus advanced stage III/IV) to guide treatment with observation, chemotherapy, radiation, or chemotherapy and radiation. The Lugano modification of the Ann Arbor staging system for HL is also used in NHL.

LO 6

Treatment goals depend on the specific subtype of NHL. For follicular low-grade NHL, the disease is considered to be incurable. Many patients with follicular lymphoma are older than 60 years of age, making allogeneic SCT impractical due to high treatment-related mortality for older patients.

KEY CONCEPT The treatment goals for low-grade NHL include:

- Observation of the disease until the patient exhibits obvious progression that limits functional capacity or is life threatening
- Treatment that induces remission with manageable toxicity
- Judicious selection of treatment to avoid long-term toxicity
- Prevention of infectious complications

The intent of treatment for patients with aggressive histologies is cure. Some histologic subtypes exhibit a highly aggressive clinical course and are not considered to be curable. These patients are still treated with curative-intent chemotherapy or may be considered for a clinical trial.

Nonpharmacologic Therapy

For patients with low-grade follicular NHL, deferring initial therapy until progression of disease is a standard approach. The median survival time is 6 to 10 years. Some patients may be asymptomatic for several years after diagnosis, making observation a reasonable approach. Radiation therapy has a limited role in NHL relative to HL. NHL is more often a

systemic disease, and radiation typically has been reserved for consolidation after chemotherapy in patients presenting with a large extranodal mass. However, ISRT without chemotherapy is a treatment option for patients with stage I/II follicular lymphoma.

For early-stage diffuse, aggressive NHL, combined-modality therapy was tested versus a longer course of chemotherapy.[27] Overall survival favored the CHOP–radiation arm for 5 years (82% vs 72%). There was a trend toward increased toxicity, particularly hematologic and cardiac toxicity, in the CHOP alone arm. The results of this trial have established combined-modality therapy as first-line treatment for early stage NHL.

Pharmacologic Therapy

▶ *Follicular Low-Grade NHL*

The management of low-grade lymphomas is an area of controversy, especially in patients presenting with early stage disease. Typical indications for treatment include cytopenias, recurrent infections, threatened end-organ function, disease progression over at least 6 months, or patient preference. In these patients, chemotherapy such as fludarabine or bendamustine is typically offered initially. The role of combination regimens is controversial as they have not been shown to improve overall survival compared to single agent chemotherapy. Rituximab, a chimeric monoclonal anibody that binds to CD20 on B lymphocytes, is an essential component of treatment of follicular lymphoma. Clinical trials have demonstrated improved patient outcomes with the combination of rituxan/chemotherapy versus chemotherapy alone for initial treatment of follicular lymphoma.[28] Rituximab is incorporated into most patients' treatment of follicular lymphoma. These regimens are detailed in Table 97–7. Additionally, rituximab was examined as maintenance therapy administered every 8 weeks for 2 years after rituximab-containing multiagent chemotherapy. Compared with observation, rituximab increased 3-year progression-free survival (PFS) (74.9 vs 57.6 months).[29]

Other strategies for treatment of low-grade lymphomas include the combination of monoclonal antibodies directed against CD20 with a radiopharmaceutical attached, a kinase inhibitor active against B-cells, an immunomodulatory agent, and a new monoclonal antibody against CD20. Ibritumomab-yttrium 90 is a monoclonal antibody targeting CD20 that delivers radioactive yttrium. It is indicated for the treatment of relapsed follicular lymphoma or as consolidation after response to initial chemotherapy. Idelalisib is a small molecule that inhibits PI3Kδ kinase found in B-cells, inducing apoptosis and inhibiting chemotaxis. It was approved based on a phase I study in patients who had failed multiple prior therapies. These heavily pretreated patients had an overall response rate of 45%.[30] Lenalidomide is an immunomodulatory agent that has shown promise when combined with rituximab for the treatment of follicular lymphoma.[31,32] Obinutuzumab is a type II anti-CD20 monoclonal antibody. It is currently being evaluated in combination with standard chemotherapy regimens versus rituximab with chemotherapy for the initial treatment of follicular lymphoma. The results have not fully matured; however, after approximately 3 years of follow-up, obinutuzumab containing regimens had a 35% improvement in progression-free survival.[33] High-dose chemotherapy is being evaluated for low-grade follicular NHL, but its role is limited to clinical trials.

Table 97–7

Chemotherapy Regimens for Low-Grade, Follicular NHL

Fludarabine/Rituximab
Fludarabine 25 mg/m^2 IV days 1–5 every 28 days
Rituximab 375 mg/m^2 IV, days 1 and 5 of weeks 1 and 26; single dose 72 hours before fludarabine cycles 2, 4, and 6

Bendamustine/Rituximab—Every 28 Days
Bendamustine 90 mg/m^2 IV days 1 and 2
Rituximab 375 mg/m^2 IV, day 1

R-CVP—Every 21 Days
Rituximab 375 mg/m^2 IV, day 1
Cyclophosphamide 750 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, day 1
Prednisone 40 mg/m^2 po daily, days 1–5

R-CHOP—Every 21 Days
Rituximab 375 mg/m^2 IV, day 1
Cyclophosphamide 750 mg/m^2 IV, day 1
Doxorubicin 50 mg/m^2 IV, day 1
Vincristine 1.4 mg/m^2 IV, day 1
Prednisone 100 mg/day po, days 1–5

IV, intravenous; po, oral.

▶ *Diffuse, Aggressive NHL*

LO 7

KEY CONCEPT The mainstay of therapy for diffuse, aggressive NHL, such as DLBCL, is anthracycline-based combination chemotherapy, generally consisting of four or more drugs. Therapy options for intermediate- and high-grade NHL generally are segregated between localized (stage I/II) and advanced (stage III/IV) disease. Combined-modality therapy with an abbreviated course of R-CHOP and local radiation is considered a standard of care for stage I/II disease.

The standard therapy for disseminated disease since the 1970s has been CHOP. This regimen conferred a response of 50% to 60%, with long-term survival of approximately 30%. The benefits of CHOP have been confirmed by multiple clinical trials including comparisons to regimens with more agents and varying schedules. None of these other options have improved on CHOP in patients with normal risk DLBCL.[34] There were no significant differences in response rate or overall survival between the groups and severe toxicity and death were higher in the advanced-generation treatment regimens relative to CHOP cementing CHOP as first-line chemotherapy in DLBCL.

LO 8

Rituximab is also routinely used to treat DLBCL. A study randomized patients 60 to 80 years of age with newly diagnosed disease to either CHOP for eight cycles or CHOP plus rituximab (R-CHOP) for eight cycles.[35] Two-year follow-up showed rituximab improved CR (76% vs 63%) and median event-free survival (57% vs 38%) and long-term follow-up confirmed benefit with an improvement in 10-year survival (43% vs 27.6%). Similar findings have been reported in younger patients, making R-CHOP first-line therapy for advanced-stage DLBCL (Table 97–8).

▶ *Special Populations*

There are histologic subtypes of diffuse, aggressive NHL which are less responsive to treatment with conventional regimens such as R-CHOP. Burkitt lymphoma, lymphoblastic lymphoma, mantle cell lymphoma, primary mediastinal large B-cell lymphoma, and primary CNS lymphoma are examples of disease that benefit from more intensive therapy. Regimens such as R-hyper-CVAD, which alternate cycles of rituximab, hyperfractionated cyclophosphamide, doxorubicin, vincristine, and dexamethasone with rituximab, high-dose cytarabine and methotrexate,[36,37] or EPOCH-R, which contains etoposide, prednisone, vincristine, cyclophosphamide, doxorubicin, and rituximab should be considered alternatives to R-CHOP.

Table 97–8

Treatment Regimens for Diffuse, Aggressive NHL

R-CHOP—Every 21 Days[a]
EPOCH-R—Every 21 Days
Rituximab 375 mg/m² IV, day 1
Etoposide 50 mg/m²/day CIVI, days 1–4
Prednisone 60 mg/m²/day po, days 1–5
Vincristine 0.4 mg/m²/day CIVI, days 1–4
Cyclophosphamide 750 mg/m² IV, day 5
Doxorubicin 10 mg/m²/day CIVI, days 1–4

R-CNOP-Rituximab—Every 21 Days[b]
Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 750 mg/m² IV, day 1
Mitoxantrone 10 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 1
Prednisone 100 mg/day po, days 1–5

R-Hyper-CVAD
Part A: The following drugs given on course 1, 3, 5, and 7
Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 300 mg/m² IV every 12 hours, days 1–3 (with Mesna)
Doxorubicin 50 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, days 1, 11
Dexamethasone 40 mg/day po, days 1–4 and 11–14
Methotrexate 15 mg intrathecal, day 2
Cytarabine 30 mg intrathecal, day 2
Hydrocortisone 15 mg intrathecal, day 2
Part B: The following drugs are given on courses 2, 4, 6, and 8
Rituximab 375 mg/m² IV, day 1
Methotrexate 1000 mg/m² IV over 24 hours, day 1
Cytarabine 3000 mg/m² IV every 12 hours, days 2 and 3
Leucovorin 25 mg IV × 1; then 25 mg po every 6 hours for seven doses
Methotrexate 15 mg intrathecal, day 2

Bendamustine/Rituximab—Every 28 Days[a]

ESHAP
Etoposide 40 mg/m² IV per day continuous infusion, days 1–4
Cisplatin 25 mg/m² IV per day continuous infusion, days 1–4
Cytarabine 2000 mg/m² IV × 1, day 5
Methylprednisone 250 mg IV every 12 hours, days 1–4

DHAP
Dexamethasone 40 mg po or IV daily, days 1–4
Cisplatin 100 mg/m² IV continuous infusion, day 1
Cytarabine 2000 mg/m² IV every 12 hours for two doses on day 2

ICE
Etoposide 100 mg/m² IV daily, days 1–3
Carboplatin AUC 5 (maximum dose, 800 mg) IV, day 2
Ifosfamide 5000 mg/m² IV continuous infusion × 1 on day 2 (with 100% replacement with Mesna)

[a]Refer to Table 97–8 for regimen.

[b]Data are limited, use only for patients who are unable to receive an anthracycline.

AUC, area under the curve; CIVI, continuous intravenous infusion; IV, intravenous; po, oral.

The presence of *C-Myc* gene rearrangement in addition to either *Bcl-2* or *Bcl-6* gene rearrangements is known as double-hit lymphoma (DHL) and can occur in patients with DLBCL or other high-grade lymphomas. These lymphomas are highly aggressive and have inferior response to R-CHOP.[38] Aggressive chemotherapy regimens such as R-hyper-CVAD and EPOCH-R have been shown to superior outcomes and should be used in the treatment of DHL.[39]

Patients with CNS NHL have disease that is poorly responsive to therapy because of inadequate penetration of standard doses of chemotherapy across the blood–brain barrier. High-dose methotrexate, ranging from 2500 to 8000 mg/m², is a mainstay of therapy. Treatment may also include intrathecal chemotherapy. Drugs that are commonly used intrathecally include methotrexate, cytarabine (conventional formulation and liposomal products), and corticosteroids.

The recognition of *H. pylori* colonization and MALT has spurred the more aggressive treatment of this organism with antibiotics. In patients with localized disease, aggressive, combination therapy for *H. pylori* has been shown to induce MALT remission. Patients with advanced disease may require chemotherapy with R-CHOP.

Patients with HIV-related lymphoma represent a therapeutic dilemma considering many have high-grade NHL. A common presentation includes extranodal disease, frequently in the GI tract, CNS, or bone marrow. Because of the aggressive nature of HIV-related lymphoma, aggressive chemotherapy regimens such as Hyper-CVAD and EPOCH are recommended. Antiretroviral therapy is important to improving patients' ability to tolerate chemotherapy and should be initiated before chemotherapy. The use of CSFs to promote white blood cell counts is also recommended. Rituximab should be added to chemotherapy for CD20 positive lymphomas in patients with an adequate CD4 count.

With more than half of patients with NHL expected to relapse, salvage therapy plays a major role in the attempt to treat recurrence. Multiple drug regimens such as ESHAP and DHAP can induce a CR, but long-term cure with these regimens is less than 10%. When salvage regimens are used, rituximab is frequently added to the regimen. Further salvage therapy can induce remissions with subsequent relapses; however, the chance for a CR is further diminished.

High-dose chemotherapy with autologous SCT has been studied as an alternative to standard dose regimens in the setting

Patient Encounter Part 2: Treatment Selection

Complete evaluation revealed stage IV diffuse large B-cell lymphoma that is positive for gene rearrangement in *c-Myc* and negative for *Bcl-2/Bcl-6* gene rearrangements. Therapy is scheduled to begin immediately.

What therapy (or therapies) is (are) most appropriate for this patient?

At this time, is this patient an appropriate candidate for stem cell transplant?

What other information (eg, laboratory studies, diagnostic tests) is needed prior to initiating chemotherapy?

Patient Encounter Part 3: Creating a Care Plan

Based on the information presented, create a care plan for this patient, including the goals of therapy, antineoplastic therapy plan, and necessary supportive care.

LO 5

of first relapse.[40] The best-studied indication for SCT is for patients with intermediate- or high-grade disease that fails to respond to first-line therapy. A 3- to 5-year survival of greater than 40% is achieved in patients who have good performance status and disease that demonstrates a significant response to one or two cycles of salvage chemotherapy. The procedure-related mortality rate has ranged from 5% to 10% in published reports. However, as with HL, with improvements in SCT techniques and better supportive care, the mortality rate continues to decline. The role of allogeneic SCT in this setting is limited because of donor availability, the older age of patients, and the high treatment-related morbidity and mortality. Outcomes between autologous and allogeneic transplant appear similar.

OUTCOME EVALUATION

Treatment response in lymphomas is measured using the response evaluation criteria in solid tumors (RECIST), a uniform criterion assessing tumor response developed by the National Cancer Institute. Lymphomas may have residual masses after completion of treatment, adding to the difficulty in establishing a definitive remission from treatment. Historically, imaging scans using positron emission tomography (PET) or computed tomography (CT) have been used to evaluate patient with lymphomas. Now, PET combined with CT (PET-CT) is recommended to evaluate patients with lymphoma for staging as well as for response assessment.[41]

Long-term follow-up monitors patients for continued disease remission with careful examination of the original areas of involvement and repeated follow-up imaging. Patients also require long-term monitoring for toxicities of their treatment.

Due to the high sensitivity to therapy of many lymphomas, most patients treated for lymphoma with chemotherapy or radiation notice a regression of palpable lymphadenopathy within days. This also necessitates implementation of tumor lysis syndrome precautions with aggressive intravenous hydration and allopurinol. Rasburicase should be considered for patients with moderate to high tumor burdens. Most chemotherapy treatments for lymphoma have a significant risk of infectious complications. Combination regimens for both HL and NHL are associated with rates of severe leukopenia and/or neutropenia ranging from 20% to 100% of patients. Consideration must be given to supportive care with prophylactic CSFs or antibiotics. Most chemotherapy regimens discussed in this section are highly emetogenic. Antiemetic regimens are available to control

Patient Care Process

Collect Information:

- Take a thorough medication history with particular attention to nonprescription or herbal medications.
- Review medical history with an emphasis on identifying causative factors of lymphoma and preexisting medical conditions that can affect chemotherapy.

Assess the Information:

- Evaluate home medications to identify any potential drug interactions with chemotherapy.
- Review findings of diagnostic tests including laboratory values, imaging results, pathology results, cancer diagnosis, and genetic profile of the malignancy.
- Determine the stage and prognostic index for the patient.
- Before initiation of treatment, assess patient for risk of tumor lysis syndrome.

Develop a Care Plan:

- Identify the optimal treatment regimen for the patient incorporating diagnosis, stage, and prognostic indicators (Tables 97–4, 97–7, 97–8)
- Verify chemotherapy regimen doses with a standardized reference and assess for dose adjustment based on height, weight, and body surface area and organ dysfunction (renal or hepatic).
- Assess appropriateness of supportive care for the chemotherapy regimens including need for prophylactic antiemetics and use of colony-stimulating factors.

Implement the Care Plan:

- Provide patient education regarding common toxicities associated with chemotherapy such as nausea/vomiting, mucositis, myelosuppression, and alopecia.
- For doxorubicin-containing regimens, maintain records of the cumulative doxorubicin dosage received by the patient to monitor for cardiac toxicity risk.
- For bleomycin-containing regimens, maintain records of the cumulative bleomycin dosage received by the patient to monitor for pulmonary fibrosis.
- Educate patients regarding the short- and long-term complications associated with radiation therapy.
- Provide contact numbers for patient in the event of a fever and a response plan if the patient is considered to be at risk for neutropenic fever.

Follow-up: Monitor and Evaluate:

- Schedule regulatory laboratory tests including complete blood count and blood chemistries to monitor for chemotherapy toxicities and tumor lysis syndrome.
- Use RECIST criteria to determine patient's response to therapy by reviewing PET-CT scan following completion of therapy.
- Develop a plan to monitor for long-term complications of chemotherapy such as cardiotoxicity and secondary malignancies.

chemotherapy-induced nausea and vomiting well for most standard-dose regimens.[42]

Advances in the treatment of lymphoma have increased the number of long-term survivors. Identification of long-term complications of lymphoma therapy is vital to patient follow-up and may influence treatment decisions in newly diagnosed patients. Outcomes associated with the treatment of HL make up the majority of data. However, advances in NHL treatment have provided more information regarding long-term toxicities. Two leading causes of death associated with lymphoma treatment are secondary malignancies and cardiovascular disease. The use of combined modality of irradiation with doxorubicin-based therapy has been reported to increase the risk of cardiac dysfunction. Treatment-related pulmonary toxicity, hypothyroidism, and infertility have been associated with lymphoma therapy as well. Lymphoma survivors have an increased risk for developing myelodysplasia, acute myelogenous leukemia, and various solid tumors.[43]

A limitation of rituximab is severe, potentially fatal infusion-related reactions. Deaths have been reported resulting from the profound hypotension and circulatory collapse, particularly with the first dose. The package labeling recommends premedication with acetaminophen and diphenhydramine before each infusion. The initial infusion should be given slowly, at 50 mg/hour and may be increased as tolerated to a maximum of 400 mg/hour. In the absence of infusion reactions, subsequent doses may be started at a higher rate and titrated more aggressively. Rituximab has also caused reactivation of hepatitis B. Patients at high risk for hepatitis B should be screened and monitored carefully for reactivation of hepatitis. If hepatitis occurs, rituximab should be discontinued, and patients should be treated appropriately. Other associated toxicities of rituximab include fever, chills, headache, asthenia, nausea, vomiting, angioedema, bronchospasm, and skin reactions. KEY CONCEPT Rituximab is an effective treatment option for patients with various forms of NHL as long as patients are monitored appropriately.[44]

Abbreviations Introduced in This Chapter

Bcl-1	Important in the regulation of mitosis
Bcl-2	A regulator of apoptosis
Bcl-3	A regulator of nuclear transcription factor
Bcl-6	Regulates cell differentiation
c-Myc	Regulator of gene transcription
ABVD	Doxorubicin, bleomycin, vinblastine, and dacarbazine
CHOP	Cyclophosphamide, doxorubicin, vincristine, and prednisone
CT	Computed tomography
CSFs	Colony-stimulating factors
CVP	Cyclophosphamide, vincristine, and prednisone
DHL	Double-hit lymphoma
EBV	Epstein-Barr virus
FLIPI	Follicular lymphoma international prognostic index
HL	Hodgkin lymphoma
IPI	International Prognostic Index
IPS	International Prognostic Score
LDH	Lactate dehydrogenase
MALT	Mucosa-associated lymphoid tissue
MOPP	Mechlorethamine, vincristine, procarbazine, and prednisone
NHL	Non-Hodgkin lymphoma
PET	Positron emission tomography
RECIST	Response evaluation criteria in solid tumors
RS	Reed-Sternberg
SCT	Stem cell transplantation

98 Hematopoietic Stem Cell Transplantation

Christina Bachmeier and Amber P. Lawson

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Explain the rationale for using hematopoietic stem cell transplant (HSCT) to treat cancer.
2. Compare the different types of HSCTs, specifically (a) the types of donors (ie, autologous and allogeneic), (b) the source of hematopoietic cells (ie, umbilical cord, peripheral blood progenitor cells, and bone marrow), and (c) the type of preparative regimen (ie, myeloablative and nonmyeloablative).
3. Develop a plan for monitoring and managing engraftment of hematopoiesis.
4. List the nonhematologic toxicity to high-dose chemotherapy used in myeloablative preparative regimens, specifically busulfan-induced seizures, hemorrhagic cystitis, gastrointestinal toxicities, and sinusoidal obstruction syndrome.
5. Explain graft-versus-host disease (GVHD).
6. Recommend a prophylactic and treatment regimen for GVHD.
7. Choose an appropriate regimen to minimize the risk of infectious complications in HSCT patients.
8. Evaluate the long-term health care of HSCT survivors.

INTRODUCTION

KEY CONCEPT

Hematopoietic stem cell transplantation (HSCT) is a procedure used primarily in the treatment of hematologic malignancies via high-dose chemotherapy and/or a graft-versus-tumor effect. HSCT may be either autologous, where a patient receives their own bone marrow, or allogeneic, where the patient receives bone marrow from a donor. As an alternative to bone marrow, hematopoietic stem cells may be obtained from the peripheral blood progenitor cells (PBPCs) or umbilical cord blood (UCB). Bone marrow and PBPCs contain pluripotent stem cells and postthymic lymphocytes, which are responsible for long-term hematopoietic reconstitution, called engraftment and immune recovery.[1]

LO 1

The rationale of an autologous transplant is to administer a **myeloablative preparative regimen** and eradicate the patient's malignancy. Collecting the bone marrow or PBPCs prior to administering high-dose chemotherapy essentially protects the collected PBPCs from the effects of chemotherapy and can restore hematopoiesis. Allogeneic transplants use donor PBPCs to rescue the patient after myeloablative chemotherapy with an added advantage of the donor cells generating an immunologic response toward the recipient's residual tumor, called the **graft-versus-tumor effect**. Unfortunately, **graft-versus-host disease** (GVHD) where the donor cells generate an immunologic response toward the recipient's normal tissue also occurs.

The type of HSCT performed depends on a number of factors, including the type and status of disease, availability of a compatible donor, patient age, performance status, and organ function. Examples of diseases treated with HSCT are listed in Table 98–1.

EPIDEMIOLOGY AND ETIOLOGY

In 2015, approximately 14,000 autologous HSCTs and 8000 allogeneic HSCTs were performed in the United States. The most common indications for HSCT were multiple myeloma (MM) and lymphoma; acute myeloid leukemia accounted for 70% of all allogeneic transplants. The annual number of transplants continues to steadily increase due to the use of alternative donors and the use of transplant expanding to older patients.[3]

The use of allogeneic PBPCs is increasing; from years 2007 through 2011, almost 80% of allogeneic HSCTs performed worldwide used PBPCs as the source of hematopoietic cells rather than bone marrow in adult patients.[3] Autologous PBPC use has increased and essentially has replaced bone marrow as a graft source in many transplant centers. From years 2007 through 2011, approximately 99% of autologous HSCTs in adults and 94% in children used PBPCs as the source of hematopoietic cells.[3]

PATHOPHYSIOLOGY

KEY CONCEPT

Autologous HSCT, or infusion of a patient's own hematopoietic cells, allows for the administration of higher doses of chemotherapy, radiation, or both to treat the malignancy or autoimmune disorder. In this setting, the hematopoietic cells "rescue" the recipient from otherwise dose-limiting hematopoietic toxicity, allowing higher doses of chemotherapy to be safely administered. Autologous HSCT is used to treat intermediate- and high-grade non-Hodgkin lymphoma (NHL), MM, autoimmune diseases, and relapsed or refractory Hodgkin lymphoma.[1,2] Patients do not benefit from an immunologic graft-versus-tumor effect while undergoing an autologous transplant;

Table 98–1

Diseases Commonly Treated with HSCT

	Autologous Graft	Allogeneic Graft
Cancers	Multiple myeloma Non-Hodgkin lymphoma Hodgkin disease Neuroblastoma Germ cell tumors	Acute myeloid leukemia Acute lymphoblastic leukemia Chronic myeloid leukemia Myelodysplastic syndrome Myeloproliferative disorders Non-Hodgkin lymphoma Hodgkin disease Chronic lymphocytic leukemia Multiple myeloma
Other Diseases	Autoimmune diseases Amyloidosis	Aplastic anemia Paroxysmal nocturnal hemoglobinuria Fanconi anemia Thalassemia major Sickle cell anemia Severe combined immunodeficiency Inborn errors of metabolism

instead, the administration of high-dose chemotherapy followed by an autologous stem cell transplant in chemotherapy-sensitive malignancies relies on the preparative regimen alone to eradicate the malignant disease. Autologous HSCT circumvents the need for histocompatible donors, is associated with a lower mortality rate, and is not restricted to younger patients.[3]

KEY CONCEPT **Allogeneic HSCT** involves the transplantation of hematopoietic cells obtained from a different person's (donor) bone marrow, peripheral blood, or umbilical cord blood to the recipient. Unless the donor and the recipient are identical twins (referred to as a *syngeneic HSCT*), they are dissimilar genetically. In allogeneic transplant, the donor and recipient share common cell surface antigens called human leukocyte antigens (HLA). These antigens are encoded by a group of genes called the major histocompatibility complex (MHC).[1]

The transplanted donor stem cells are immunologically active, and thus there is potential for bidirectional graft rejection. When host-versus-graft reactions occur, cytotoxic T cells and natural killer (NK) cells belonging to the host (recipient) recognize MHC antigens of the graft (donor hematopoietic stem cells) as foreign and this leads to a rejection response. When GVHD occurs, immunologically active cells in the graft recognize host MHC antigens and elicit an immune response. When host-versus-graft effects occur in allogeneic HSCT, they are referred to as *graft failure* or *rejection,* which results in ineffective hematopoiesis (ie, adequate absolute neutrophil count [ANC] and/or platelet counts were not obtained). Allogeneic HSCT is used to treat both nonmalignant conditions and hematologic malignancies such as acute and chronic leukemias.[1]

LO 2 For both allogeneic and autologous transplants, hematopoietic cells are infused after the administration of a combination of chemotherapy and/or radiation, termed the conditioning or preparative regimen. KEY CONCEPT A myeloablative preparative regimen involves the administration of sublethal doses of chemotherapy to the recipient to eradicate residual malignant disease. The recipient will not regain his or her own hematopoiesis and will be at risk for substantial life-threatening nonhematologic toxicity.[4] LO 2 For those undergoing an autologous HSCT, their hematopoietic cells must be harvested and stored before the myeloablative preparative regimen is administered. After the administration of the myeloablative preparative regimen, these hematopoietic cells serve as a rescue intervention to reestablish bone marrow function and avoid long-lasting, life-threatening bone marrow aplasia. In the setting of an allogeneic HSCT, the preparative regimen is designed to suppress the recipient's immunity, eradicate residual malignancy, or create space in the marrow compartment. Improved survival outcomes have been observed with both autologous and allogeneic HSCT when the hematologic malignancy is in complete remission at the time of HSCT.[3] At most HSCT centers, age younger than 65 years and normal renal, hepatic, pulmonary, and cardiac function are considered eligibility requirements for myeloablative allogeneic HSCT.

LO 2 The recognition of graft-versus-tumor effect, which likely is caused by cytotoxic T lymphocytes in the donor stem cells in those undergoing an allogeneic HSCT transplant, led to investigations with reduced intensity conditioning, in which less toxic preparative regimens are used in the hope of expanding the availability of HSCT to recipients whose medical condition or age prohibits use of myeloablative regimens. Reduced intensity regimens may still be myeloablative; purely nonmyeloablative regimens also have been introduced for certain disease states and are less toxic than myeloablative and reduced intensity regimens.

A myeloablative, or reduced intensity, or **nonmyeloablative preparative regimen** may be used for allogeneic HSCT; only myeloablative preparative regimens are used for autologous HSCT.

Histocompatibility

LO 2 **Histocompatibility** differences between the donor and the recipient necessitate immunosuppression after an allogeneic HSCT because considerable morbidity and mortality are associated with graft failure and GVHD. Rejection is least likely to occur with a syngeneic donor. In patients without a syngeneic donor, initial HLA typing is conducted on family members because the likelihood of complete histocompatibility between unrelated individuals is remote. Siblings are the most likely individuals to be histocompatible within a family; however, only 30% of patients will have an HLA-matched sibling donor. Having a matched-sibling donor is no longer a requirement for allogeneic HSCT because improved immunosuppressive regimens and the National Marrow Donor Program have allowed an increase in the use of unrelated or related matched or mismatched HSCTs. Establishment of the National Marrow Donor Program has helped to increase the pool of potential donors for allogeneic HSCT.[5] Through this program, an HLA-matched unrelated volunteer donor might be identified. Recipients of an unrelated graft are more likely to experience graft failure and acute GVHD relative to recipients of a matched-sibling donor. Due to the amount of patients without a matched donor, alternative strategies have been investigated such as mismatched unrelated donors, related haploidentical donors, and UCB stem cell products. Mismatched unrelated donors involve one or more HLA-locus mismatch and are high risk for GVHD. A related haploidentical donor refers to a complete half mismatch to the recipient (matched at 3 of 6 or 4 of 8 HLA loci); these donors are parents, children, or siblings. Haploidentical transplants are high risk for graft rejection and GVHD; however, recent advances including the use of posttransplant cyclophosphamide have led to an increase in the use of haploidentical donors for patients without an HLA-matched option.[6,7]

The degree of HLA mismatching is correlated with the risk of acute GVHD, graft rejection, and mortality. An optimal donor for transplantation will be an HLA match at the HLA-A, HLA-B,

HLA-C, and HLA-DRB1 loci (an 8/8 HLA match). There is an increase in the risk of GVHD and posttransplant mortality with each mismatch.[8] Determination of histocompatibility between potential donors and the patient is completed before allogeneic HSCT. Initially, HLA typing is performed using blood samples and compatibility for class I MHC antigens (ie, HLA-A, HLA-B, and HLA-C) is determined through serologic and DNA-based testing methods. In vitro reactivity between donor and recipient also can be assessed in mixed-lymphocyte culture, a test used to measure compatibility of the MHC class II antigens (ie, HLA-DR, HLA-DP, and HLA-DQ). Most clinical and research laboratories are also performing molecular DNA typing using polymerase chain reaction (PCR) methodology to determine the HLA allele sequence.[9]

Stem Cell Sources

KEY CONCEPT Bone marrow, PBPCs, and UCB can serve as the source of hematopoietic cells. The optimal cell source differs based on the donor and recipient characteristics.

LO 2

Hematopoietic stem cells are obtained from bone marrow or peripheral blood. The technique for harvesting hematopoietic cells depends on the anatomic source (ie, bone marrow or peripheral blood). A surgical procedure is necessary for obtaining bone marrow. Multiple aspirations of marrow are obtained from the anterior and posterior iliac crests until a volume with a sufficient number of hematopoietic stem cells is collected (ie, 600–1200 mL of bone marrow). The bone marrow then is processed to remove fat or marrow emboli and usually is infused intravenously into the patient similar to a blood transfusion.

The shift to the use of PBPCs over bone marrow for HSCT is primarily because of the more rapid engraftment and decreased health care resource use. For an autologous transplant, the harvest occurs before administering the preparative regimen; therefore, autologous hematopoietic cells must be cryopreserved and stored for future use.

Allogeneic cells are usually harvested just prior to the HSCT and administered to the recipient without cryopreservation; however, they are sometimes collected and cryopreserved as well. The bone marrow may need additional processing if the donor and recipient are ABO incompatible, which occurs in up to 30% of HSCTs. Red blood cells (RBCs) may need to be removed before infusion into the recipient to prevent immune-mediated hemolytic anemia and thrombotic microangiopathic syndromes.

Transplantation with PBPCs essentially has replaced bone marrow transplantation (BMT). PBPCs are obtained by administering a mobilizing agent(s) followed by apheresis, which is an outpatient procedure similar to hemodialysis. Hematopoietic growth factors (HGFs) alone or in combination with myelosuppressive chemotherapy are used for **mobilization** of autologous PBPCs with similar results.[10,11] HGFs are also used to mobilize donor PBPCs for allogeneic transplants, although chemotherapy is not used in this setting.

LO 2

UCB offers an alternative stem cell source to patients requiring an allogeneic transplant who do not have an acceptable matched related or unrelated donor. When allogeneic hematopoietic cells are obtained from UCB, the cord blood is obtained from a consenting donor in the delivery room after birth and delivery of the placenta. The UCB is processed, a sample is sent for HLA typing, and the cord blood is frozen and stored for future use. Numerous UCB registries exist, with the goal of providing alternative sources of allogeneic stem cells. UCB offers the advantage of being readily available, and has provided a stem cell source to a more diverse patient population, in addition to a low risk of GVHD.[12,13] Limitations include an increased risk of graft failure, delayed immune reconstitution leading to an increase in infections, and the inability to use donor-lymphocyte infusions in the event of relapse.[6,14] The prospective use of dual umbilical cord units and ex vivo expansion of umbilical cord units to obtain adequate engraftment are methods currently under exploration.

TREATMENT

Desired Outcome

KEY CONCEPT Engraftment is defined as the point at which a patient can maintain a sustained ANC of greater than 500 cells/mm^3 (0.5×10^9/L) and a sustained platelet count of 20,000/mm^3 (20×10^9/L) or more lasting 3 or more consecutive days without transfusions[15] and is the desired short-term outcome in a transplant. The desired long-term outcome with HSCT is to cure the patient of his or her underlying disease while minimizing the short- and long-term morbidity associated with HSCT.

Nonpharmacologic Therapy

▶ *Harvesting, Preparing, and Transplanting Autologous and Allogeneic Hematopoietic Cells*

Autologous Transplants The number of hematopoietic stem cells circulating in the peripheral blood is low and requires the use of mobilizing agents for successful apheresis. The HGFs granulocyte-macrophage colony-stimulating factor (sargramostim, Leukine) and granulocyte colony-stimulating factor (filgrastim, Neupogen; filgrastim-sndz, Zarxio) are used to mobilize stem cells from the bone marrow to the peripheral blood to collect an adequate number of PBPCs for transplantation. Filgrastim is the preferred agent as several studies have demonstrated superiority in PBPC mobilization and reduced toxicity compared with sargramostim. The use of pegylated granulocyte colony-stimulating factor (pegfilgrastim, Neulasta) for mobilization of PBPCs is more convenient due to less frequent dosing and is promising as a mobilization agent; however, further data are needed regarding graft composition, HSCT outcomes, and donor safety in allogeneic donations.[10]

The combination of chemotherapy with an HGF enhances PBPC mobilization relative to HGF alone.[1] In addition to treating the underlying malignancy, this approach lowers the risk of tumor cell contamination and the number of apheresis collections required, but there is a greater risk of thrombocytopenia, neutropenia, and hospitalization for neutropenic fever.[10] The HGF is initiated after completion of chemotherapy and is continued until apheresis is complete. Many centers monitor the number of cells that express the CD34 antigen (ie, CD34+ cells) to determine when to start apheresis. The CD34 antigen is expressed on almost all unipotent and multipotent colony-forming cells and on precursors of colony-forming cells, but not on mature peripheral blood cells. Apheresis is continued daily until the target number of PBPCs per kilogram of the recipient's weight is obtained. For adult recipients, the number of CD34+ cells correlates with time to engraftment. Lower yield of CD34+ cells is associated with administration of stem cell toxic drugs (eg, carmustine and melphalan) and intensive prior chemotherapy or radiotherapy, which should be avoided prior to transplant if possible.

LO 3

If patients are unable to obtain an adequate yield of CD34+ cells per kilogram after mobilization attempts fail, then allogeneic transplant may be considered as an alternative. Additionally, plerixafor (Mobozil) is approved by the Food and Drug Administration (FDA) for use in combination with granulocyte colony-stimulating factor to mobilize PBPCs for collection and

subsequent autologous transplantation in patients with NHL and MM. Plerixafor is an inhibitor of the CXCR4 chemokine receptor that results in more circulating PBPCs in the peripheral blood because of the inability of CXCR4 to assist in anchoring hematopoietic stem cells to the bone marrow matrix. Because administration of plerixafor with granulocyte colony-stimulating factor results in increased yield of CD34+ cells per kilogram compared to granulocyte colony-stimulating factor alone, this combination serves as an alternative mobilization strategy in patients deemed to be at risk for mobilization failure with conventional methods.[16]

Allogeneic Transplants The allogeneic donor first undergoes mobilization therapy with an HGF to increase the number of hematopoietic cells circulating in the peripheral blood. The most commonly used regimen to mobilize allogeneic donors is a 4- to 5-day course of filgrastim, 10 mcg/kg/day, administered subcutaneously followed by apheresis on the fourth or fifth days when peripheral blood levels of CD34+ cells peak. An adequate number of hematopoietic cells usually are obtained with one to two apheresis collections, with the optimal number of CD34+ collected being a minimum of 4–8 $\times$ 10^6 cells/kg of recipient body weight. Higher numbers of CD34+ cells are associated with more rapid neutrophil and platelet engraftment; patients who receive less than 2 $\times$ 10^6/kg CD34+ cells are at risk for delayed engraftment.[5] Hematopoietic stem cells obtained from the peripheral blood are processed like bone marrow–derived stem cells and may be infused immediately into the recipient or frozen for future use. Compared with bone marrow donation, allogeneic PBPC donation leads to a shorter time to neutrophil engraftment, shorter time to platelet engraftment and a decrease in platelet transfusions.[11] The donor may experience musculoskeletal pain, headache, and mild increases in hepatic enzyme or lactate dehydrogenase levels related to filgrastim administration. Hypocalcemia may also occur owing to citrate accumulation, which decreases ionized calcium concentrations during apheresis.

Allogeneic PBPC grafts contain approximately 10 times more T and B cells than bone marrow grafts. Historically, there has been significant concern that the greater T- and B-cell content of PBPCs could increase the risk of acute and/or chronic GVHD. No difference in acute GVHD or transplant-related mortality has been reported in patients receiving allogeneic PBPC transplants; however, in retrospective studies an increased risk of chronic GVHD has been observed.[17] In patients with a hematologic malignancy who have an HLA-matched sibling donor, a PBPC graft is optimal relative to bone marrow graft because the PBPC graft is associated with quicker neutrophil and platelet engraftment and potentially improved disease-free survival rates.[18] In patients receiving PBPC transplants from matched unrelated donors, an increased risk of chronic GVHD was reported; however, there was no difference in overall survival, relapse, acute GVHD, or mortality at 2 years. Numerous factors including risk of GVHD and relapse must be considered when selecting an optimal stem cell source for transplantation.[19]

T-Cell Depletion Immunocompetent T lymphocytes may be depleted from the donor bone marrow ex vivo before infusion (referred to as T-cell–depleted hematopoietic cells) into the recipient as a means of preventing GVHD. Depletion of T lymphocytes in donor hematopoietic cells is completed ex vivo using physical (eg, density-gradient fractionation) and/or immunologic (eg, antithymocyte globulin [ATG] antibodies) methods. Functional recovery of T cells in the recipient is delayed, and the risk of Epstein-Barr virus–associated lymphoproliferative disorders is higher with the use of T-cell–depleted bone marrow. The use of T-cell–depleted grafts reduces the incidence of GVHD, but graft failure and relapse are more common.[20] The use of donor lymphocyte infusion in patients who relapse after receiving a T-cell–depleted HSCT is being investigated.

LO 3

Engraftment After chemotherapy and radiation, pancytopenia lasts until the infused stem cells reestablish functional hematopoiesis. The median time to engraftment is a function of several factors, including the source of stem cells such as PBPCs, which can result in earlier engraftment than bone marrow. Myeloablative preparative regimens have significant regimen-related toxicity and morbidity and thus usually are limited to healthy, younger (ie, usually < 50 years) patients. Alternatively, nonmyeloablative transplants and reduced intensity preparative regimens are being used with the hope of curing more patients with cancer by increasing the availability of HSCT with less regimen-related toxicity and by using the graft-versus-tumor effect.[1]

A delicate balance exists between host and donor effector cells in the bone marrow environment. Residual host-versus-graft effects may lead to graft failure, which is also known as graft rejection. Graft failure is defined as the lack of functional hematopoiesis after HSCT and can occur early (ie, lack of initial hematopoietic recovery) or late (ie, in association with recurrence of the disease or reappearance of host cells after initial donor cell engraftment). Engraftment usually is evident within the first 30 days in patients undergoing an HSCT; however, rejection can occur after initial engraftment.

► *Graft-Versus-Tumor Effect*

A graft-versus-tumor effect caused by the donor lymphocytes occurs after transplant. This results in lower relapse rates in patients with GVHD relative to those who did not have GVHD; a higher rate of leukemia relapse after T-cell–depleted, autologous, or syngeneic HSCT; and the effectiveness of donor lymphocyte infusions in reinducing a remission in patients who relapsed after allogeneic HSCT. Rapid taper of immunosuppression in patients with residual disease may induce a graft-versus-tumor effect. In donor lymphocyte infusion, lymphocytes are collected from the peripheral blood of the donor and administered to the recipient. Eradication of the recurrent malignancy is caused by either specific targeting of the tumor antigens or GVHD, which may affect cancer cells preferentially. Patients with hematologic malignancies (eg, CML and acute myelogenous leukemia [AML]) and certain solid tumors (eg, renal cell carcinoma) appear to benefit from a graft-versus-tumor effect. These data gave rise to the use of nonmyeloablative preparative regimens.

Pharmacologic Therapy

► *Preparative Regimens for HSCT*

Examples of commonly used preparative regimens are included in Table 98–2.

Myeloablative Preparative Regimens Myeloablative conditioning refers to regimens of high-dose chemotherapy with or without radiation causing irreversible cytopenias that would lead to death without stem cell support.[4] In both autologous and allogeneic HSCT, infusion of stem cells circumvents this dose-limiting myelosuppression, maximizing the potential value of the steep dose–response curve to alkylating agents and radiation, suppressing the host immune system, and creating space in the marrow compartment to facilitate engraftment. The preparative

Table 98–2

Commonly Used Preparative Regimens for HSCT

Type of HSCT	Preparative Regimen	Dose and Schedule for Adults
Allogeneic	Myeloablative CY-TBI	CY 60 mg/kg/day IV on 2 consecutive days before TBI 10–16 Gy fractionated over 1–7 days (varies)
Allogeneic, autologous	Myeloablative BU-CY	Busulfan 1 mg/kg per dose po or 0.8 mg/kg per dose IV every 6 hours × 16 doses CY 60 mg/kg/day IV daily × 2 days after BU
Allogeneic	Myeloablative BU-FLU[a]	Busulfan 130 mg/m^2 IV daily × 4 days Fludarabine 40 mg/m^2 IV daily × 4 days
Autologous	Myeloablative BEAM (carmustine/etoposide/-cytarabine/melphalan)	Carmustine 300 mg/m^2 IV Etoposide 400–800 mg/m^2 IV given over 4 days Cytarabine 400–1600 mg/m^2 IV given over 4 days Melphalan 140 mg/m^2 IV
Allogeneic	Reduced intensity FLU-MEL	Fludarabine 25–30 mg/m^2 IV daily × 4–5 days Melphalan 100–180 mg/m^2 IV daily × 1 day
Allogeneic	Nonmyeloablative FLU-TBI	Fludarabine 25–30 mg/m^2/day IV daily × 3 days TBI 2 Gy × one dose

[a]Regimen may be considered myeloablative or reduced intensity dependent on busulfan AUC target.

BEAM, carmustine, etoposide, cytarabine, and melphalan; BU-CY, busulfan and cyclophosphamide; BU-FLU, busulfan and fludarabine; CY-TBI, cyclophosphamide–total-body irradiation; FLU-MEL, fludarabine and melphalan; IV, intravenous; po, oral; TBI, total-body irradiation.

Data from Gyurkocza B, Sandeaier BM. Conditioning regimens for hematopoietic cell transplantation: one size does not fit all. Blood. 2014;124:344–353.

regimen is designed to eradicate immunologically active host tissues (lymphoid tissue and macrophages) and to prevent or minimize the development of host-versus-graft reactions. Most allogeneic preparative regimens for the treatment of hematologic malignancies contain cyclophosphamide, radiation, or both. The combination of cyclophosphamide and total-body irradiation (TBI) was one of the first preparative regimens developed and is still used widely today. This regimen is immunosuppressive and has inherent activity against hematologic malignancies (eg, leukemias and lymphomas). TBI has the added advantage of being devoid of active metabolites that might interfere with the activity of donor hematopoietic cells. In addition, TBI eradicates residual malignant cells at sanctuary sites such as the central nervous system. Modifications of the cyclophosphamide–TBI preparative regimen include replacing TBI with other agents (eg, busulfan) or adding other chemotherapeutic or monoclonal agents to the existing regimen in hopes of minimizing long-term toxicities. In the case of a mismatched allogeneic HSCT with a substantially increased chance of graft rejection, ATG also may be added to the preparative regimen to further immunosuppress the recipient through T-cell depletion.

The optimal myeloablative preparative regimen remains elusive as no clinical trial has definitively shown superiority of one regimen. Busulfan–cyclophosphamide (BU-CY) is a chemotherapy-only option used to avoid the toxicities associated with TBI. Busulfan is an alkylating agent with activity in numerous hematologic malignancies. Intravenous busulfan with pharmacokinetic monitoring may improve outcomes when utilized with BU-CY compared to CY-TBI in AML patients although preparative regimens should be tailored to the primary disease and to the degree of HLA compatibility.[21]

Reduced Intensity and Nonmyeloablative Preparative Regimens A reduced intensity preparative regimen is composed of less toxic agents, lower doses of chemotherapy, and radiation, in the hope of being able to offer the benefit of an allogeneic HSCT to more patients with less toxicity. These regimens rely on the concept of a graft-versus-tumor effect. Due to the severe regimen-related toxicity of a myeloablative preparative regimen, the use of HSCT traditionally was limited to younger patients with minimal comorbidities.[22] Most patients diagnosed with cancer are elderly; therefore, myeloablative HSCT could not be offered to a substantial portion of cancer patients. The concept of donor immune response having a graft-versus-tumor effect gave rise to the theory of a strongly immunosuppressive, but not completely myeloablative, preparative regimen (ie, transplant may result in a state of chimerism in which the recipient and donor are coexisting). Reduced intensity is an intermediate category of reduced dose chemotherapy that may be considered myeloablative or nonmyeloablative. Fludarabine, a purine analog, is commonly used due to potent immunosuppressive effects in combination with lower dose alkylating agents (eg, busulfan, melphalan) or TBI.

Nonmyeloablative regimens cause minimal cytopenias and do not require stem cell support.[4] These preparative regimens

Patient Encounter Part 1

A 44-year-old woman is diagnosed with acute myeloid leukemia with complex cytogenetics. The patient achieved complete remission with induction chemotherapy and is now being evaluated for an allogeneic stem cell transplant. She has two siblings that underwent HLA typing at her first clinic visit and the results of the test will be available today. Her transplant preparative regimen will consist of cyclophosphamide and busulfan.

What nonhematologic toxicities are associated with the preparative regimen?

What type of preparative regimen is this patient receiving? How does this differ from other types of preparative regimens?

What are the implications for this patient if neither of her sisters are an HLA match?

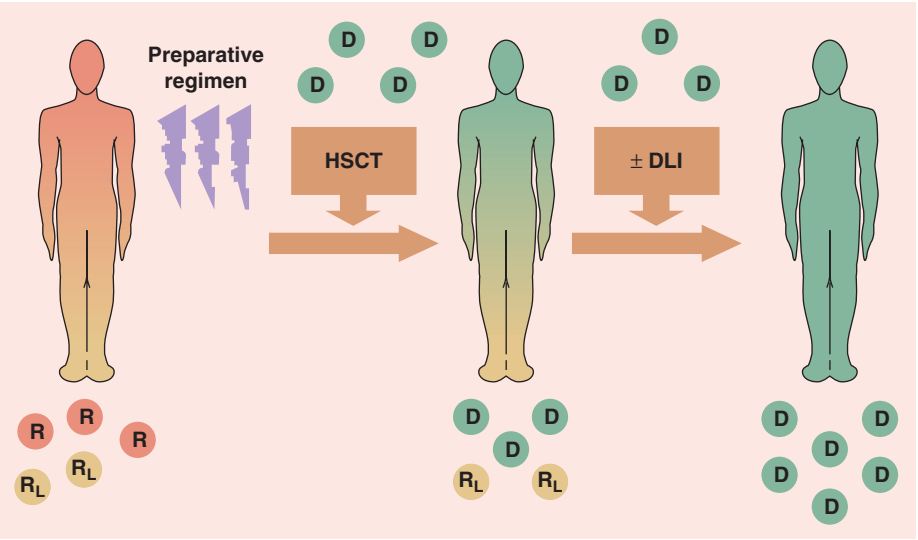

FIGURE 98–1. Schema for nonmyeloablative transplantation. Recipients (R) receive a nonmyeloablative preparative regimen and an allogeneic hematopoietic stem cell transplantation (HSCT). Initially, mixed chimerism is present with the coexistence of donor (D) cells and recipient-derived normal and leukemia or lymphoma (R_L) cells. Donor-derived T cells mediate a graft-versus-host hematopoietic effect that eradicates residual recipient-derived normal and malignant hematopoietic cells. Donor-lymphocyte infusions (DLIs) may be administered to enhance graft-versus-tumor effects. (Reprinted with permission from Champlin R, Khouri I, Anderlini P, et al. Nonmyeloablative preparative regimens for allogeneic hematopoietic transplantation. Blood Marrow Transplantation. 2001:27:S13–S22.)

allow for development of mixed chimerism (defined as 5%–95% peripheral donor T cells) between the host and recipient to allow for a graft-versus-tumor effect as the primary form of therapy (Figure 98–1). Chimerism is assessed within peripheral blood T cells and granulocytes and bone marrow using conventional (eg, using sex chromosomes for opposite-sex donors) and molecular (eg, variable number of tandem repeats) methods for same-sex donors.

The nonmyeloablative preparative regimen does not completely eliminate host normal and malignant cells. Donor cells eradicate residual host hematopoiesis, and the graft-versus-tumor effects generally occur after the development of full donor T-cell chimerism. After chimerism develops, donor-lymphocyte infusion can be administered safely in patients without GVHD to eradicate malignant cells. The risk of GVHD remains with nonmyeloablative transplant; the GVHD prophylaxis regimens are reviewed in the GVHD section below.

Reduced intensity preparative regimens have made HSCT available to patients who in the past were not healthy or young enough to receive a myeloablative preparative regimen.[22] The role of these regimens needs to be further defined, as although transplant-related mortality due to toxicity is reduced, relapse and GVHD are the major causes of treatment failure.

Toxicities and Management of Preparative Regimens Myelosuppression is a frequent dose-limiting toxicity for antineoplastics when administered in the conventional doses used to treat cancer. However, because myelosuppression is circumvented with hematopoietic rescue in the case of patients receiving HSCT, the dose-limiting toxicities of these myeloablative preparative regimens are nonhematologic and vary with the preparative regimen used. Most patients undergoing HSCT experience toxicities commonly associated with chemotherapy (eg, alopecia, mucositis, nausea and vomiting, and infertility), albeit these toxicities are magnified in the HSCT population.

LO 4

Busulfan Seizures Seizures have been reported in both adult and pediatric patients receiving high-dose busulfan for HSCT preparative regimens. Anticonvulsants are used to minimize the risk of seizures. Anticonvulsants are begun shortly before busulfan, with the loading dose completed at least 6 hours before the first busulfan dose. Oral loading and maintenance regimens generally are sufficient because target phenytoin concentrations of 10 to 20 mcg/mL (10–20 mg/L; 40–79 µmol/L) can be achieved by the peak time of seizure risk. Due to drug interactions and adverse effects, alternatives to phenytoin are being investigated. Benzodiazepines such as lorazepam or clonazepam and the second-generation antiepileptic drug levetiracetam have been used for seizure prophylaxis during high-dose busulfan therapy before HSCT.[23] Antiseizure medications usually are discontinued 24 to 48 hours after administration of the last dose of busulfan. Seizures still can occur despite the use of prophylactic anticonvulsants and usually do not result in permanent neurologic deficits.

Adaptive Dosing of Busulfan The considerable interpatient variability in the clearance of both oral and IV busulfan along with the identified concentration–effect relationships has led to the adaptive dosing of busulfan. Adjusting the oral busulfan dose to achieve a target concentration minimizes the toxicities of the BU-CY regimen, particularly hepatic sinusoidal obstruction syndrome (SOS; formerly referred to as veno-occlusive disease) while improving engraftment and relapse rates. Complete reviews of these relationships after oral busulfan administration are available elsewhere.[24] An IV busulfan product, Busulfex, was approved by the FDA in February 1999 in combination with cyclophosphamide as a preparative regimen before allogeneic HSCT for CML. In combination with either cyclophosphamide or fludarabine, the data available with busulfan suggest that therapeutic drug monitoring may be needed to optimize patient outcome with regards to efficacy and toxicity.[25]

LO 4 **Hemorrhagic Cystitis** High-dose cyclophosphamide causes moderate to severe hemorrhagic cystitis; acrolein, a metabolite of cyclophosphamide, is the putative bladder toxin. Preventive measures to lower the risk of hemorrhagic cystitis include vigorous hydration, continuous bladder irrigation, or concomitant use of the uroprotectant mesna. The American Society of Clinical Oncology (ASCO) Guidelines for the Use of Chemotherapy and Radiotherapy Protectants recommends the use of Mesna (2-mercaptoethane sulfonate) plus saline diuresis or forced saline diuresis to lower the incidence of urothelial toxicity with high-dose cyclophosphamide in the setting of HSCT.[26]

LO 4 **Chemotherapy-Induced Gastrointestinal Effects** Preparative regimens for myeloablative HSCT result in other end-organ toxicities such as renal failure and idiopathic pneumonia syndrome. In addition, recipients of myeloablative preparative regimens are at risk for severe gastrointestinal (GI) toxicity, specifically chemotherapy-induced nausea and vomiting (CINV), diarrhea, and mucositis. CINV can be caused by administration of highly emetogenic chemotherapy over several days, TBI, and poor control of CINV before HSCT. Thus, patients who are undergoing a myeloablative HSCT are at high risk for acute and delayed CINV in the peritransplant period, and the prevention and treatment of CINV should be addressed accordingly as per published clinical practice guidelines.[27]

Diarrhea is also an adverse effect experienced by a majority of patients undergoing HSCT. Chemotherapy-induced diarrhea occurs because of the effects of the preparative regimen, which results in inflammation and damage to the cells lining the GI tract. Diarrhea caused by the preparative regimen is usually apparent within the first week after the initiation of chemotherapy and/or radiation. Treatment strategies for chemotherapy-induced diarrhea include the administration of antidiarrheals after excluding infectious causes of diarrhea and the prevention of dehydration.

Virtually all patients receiving a myeloablative preparative regimen experience severe mucositis owing to its effects on rapidly dividing cells of the oral epithelium and subsequent inflammation of the oropharyngeal cavity. Routine oral care protocols are indicated to reduce the severity of mucositis, which may onset within the first week of HSCT and persist for up to approximately 2 weeks. Palifermin, a keratinocytic growth factor, may be considered for patients undergoing autologous HSCT with myeloablative TBI-based preparative regimens.[28] Patients may require parenteral opioid analgesics for pain relief owing to mucositis, and total parenteral nutrition may be necessary to prevent the development of nutritional deficiencies.

LO 4 **Sinusoidal Obstruction Syndrome** Hepatic SOS is a life-threatening complication that may occur secondary to preparative regimens or radiation. The pathogenesis of SOS is not understood completely, but several mechanisms have been proposed. The key event appears to be endothelial damage caused by the preparative regimen. The primary site of the toxic injury is the sinusoidal endothelial cells; the endothelial damage initiates the coagulation cascade, induces thrombosis of the hepatic venules, and eventually leads to fibrous obliteration of the affected venules.[29]

The clinical manifestations of SOS are hyperbilirubinemia, jaundice, fluid retention, weight gain, and right upper quadrant abdominal pain. To make a clinical diagnosis of SOS, these features must occur in the absence of other causes of posttransplant liver failure, including GVHD, viral hepatitis, fungal abscesses, or drug reactions. Most cases of SOS occur within 3 weeks of HSCT, and the clinical diagnosis can be confirmed histologically via liver biopsy.

Patients with mild SOS have an excellent prognosis, but those with more severe disease (ie, bilirubin > 20 mg/dL [342 μmol/L] or weight gain > 15%) have a high mortality rate. Pretransplant risk factors for SOS include a mismatched or unrelated graft, increased age, prior abdominal radiation or stem cell transplant, and increased transaminases before HSCT.[29] Interpatient variability in the metabolism and clearance of the chemotherapy (ie, busulfan and cyclophosphamide) used within the preparative regimen also may be associated with a poor outcome, although the relationships vary within the various preparative regimens. The association of SOS with busulfan concentrations is discussed in the section on adaptive dosing of busulfan. Use of ursodiol, unfractionated heparin, or low-molecular-weight heparin has been associated with a lower incidence of SOS in a limited number of small, randomized studies and may be recommended for SOS prophylaxis.[29]

The mainstay of treatment for established SOS is supportive care aimed at sodium restriction, increasing intravascular volume, decreasing extracellular fluid accumulation, and minimizing factors that contribute to or exacerbate hepatotoxicity and encephalopathy. Recombinant tissue plasminogen activator administered with or without heparin has been investigated for treatment of SOS, but the life-threatening risk of bleeding precludes any potential benefit.[29] Defibrotide, an oligonucleotide with antithrombotic, anti-ischemic, and anti-inflammatory activity, is FDA approved for the treatment of SOS in patients with renal or pulmonary dysfunction following HSCT, due to decreased mortality observed within this population in clinical trials.[29]

Myelosuppression and Hematopoietic Growth Factor Use HGFs may be administered to mobilize PBPCs before an HSCT, to hasten hematopoietic recovery during the period of aplasia after an autologous HSCT, and to stimulate hematopoietic recovery when the patient fails to engraft.[30]

Autologous HSCT is associated with profound aplasia owing to the myeloablative preparative regimen. Aplasia typically lasts 7 to 14 days after an autologous PBPC transplant. During this period of aplasia, patients are at high risk for complications such as bleeding and infection. HGFs exert their effects by stimulating the proliferation of committed progenitor cells and accelerating recovery on hematopoiesis. Once engraftment occurs, HGFs may be discontinued. The anatomic source of hematopoietic cells predicts the degree of benefit, with the greatest benefit reached when bone marrow is the graft source. With autologous PBPC transplant, the effect of HGF on neutrophil recovery is variable.

The use of HGF after allogeneic HSCT—whether from bone marrow or PBPC grafts—is controversial. The data with filgrastim after allogeneic HSCT have shown more rapid neutrophil but slower platelet engraftment in those receiving grafts from bone marrow or PBPCs.[30,31] The effects of post-HSCT filgrastim use on acute and chronic GVHD have been conflicting, with either no effect or increases in both the incidence of acute and chronic GVHD and treatment-related mortality.[31] Thus, there is little reason to treat allogeneic HSCT recipients with filgrastim as prophylaxis after HSCT and limited data exists with other HGFs in this setting.[30]

Graft Failure A delicate balance between host and donor effector cells in the bone marrow is necessary to ensure adequate engraftment because residual host-versus-graft effects may lead to graft rejection. The incidence of graft rejection is higher

Patient Encounter Part 2

The patient is excited to learn that her younger sister is an 8 of 8 HLA match and she will donate peripheral blood stem cells. Based on this information, her physician decides on a GVHD prophylaxis regimen consisting of tacrolimus and methotrexate. She has many questions on her risk of infection after HSCT, especially while on these immunosuppressive medications in the hospital setting.

What are the advantages and disadvantages of obtaining and infusing hematopoietic stem cells from a peripheral blood stem cell source as opposed to a bone marrow source?

When will this patient's calcineurin inhibitor start and why? What monitoring parameters are necessary for this medication to ensure safety and efficacy?

What infectious complications are of a concern for this patient during the early transplant period?

in patients with aplastic anemia and those undergoing HSCT with histoincompatible marrow or T-cell–depleted marrow.[1] Graft rejection is uncommon in leukemia patients receiving myeloablative preparative regimens with a histocompatible allogeneic donor.

Clinical Presentation and Diagnosis of Sinusoidal Obstructive Syndrome

General

- Sinusoidal obstructive syndrome (SOS) usually occurs within the first 3 weeks after HSCT.
- Busulfan, cyclophosphamide, pretransplant exposure to gemtuzumab, TBI-containing preparative regimens, and pretransplant abnormalities in liver function tests may increase the risk for SOS.

Symptoms

- Patients may complain of weight gain and abdominal pain.

Signs

- Fluid retention: Weight gain caused by ascites greater than 5% compared with pretransplant weight
- Hepatomegaly: May result in right upper quadrant pain
- Hepatic: Jaundice caused by hyperbilirubinemia defined as a bilirubin greater than 2 mg/dL (34.2 µmol/L)

Laboratory Tests

- Hepatic: Elevation of bilirubin, alkaline phosphatase, and γ-glutamyltransferase (GGT)
- Hematologic: Complete blood count with differential may reveal thrombocytopenia, elevated plasminogen activator-1 levels, decreased antithrombin III, protein C, and protein S

Other Diagnostic Tests

- Reversal of blood flow in portal and hepatic veins on Doppler ultrasonography
- Liver biopsy for pathologic review

Therapeutic options for the treatment of graft rejection or graft failure are limited. A second HSCT is the most definitive therapy, although the associated complications and toxicities may preclude its use. Graft rejection is best managed with immunosuppressants such as ATG. Primary graft failure occasionally can be treated successfully using HGFs, although patients who received purged autografts are less likely to respond.

▶ *Graft-Versus-Host Disease*

KEY CONCEPT GVHD is caused by the activation of donor lymphocytes, leading to immune damage to the skin, gut, and liver in the recipient. Immune-mediated destruction of tissues, a hallmark of GVHD, disrupts the integrity of protective mucosal barriers and thus provides an environment that favors the establishment of opportunistic infections. KEY CONCEPT An immunosuppressive regimen is administered to prevent GVHD in recipients of an allogeneic graft; this regimen is based on the type of preparative regimen and the source of the graft. The combination of GVHD and infectious complications are leading causes of mortality for allogeneic HSCT patients. GVHD is divided into two forms (ie, acute and chronic) based on clinical manifestations. Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge upon different clinical symptoms rather than the time of onset.[32,33]

Acute GVHD The degree of histocompatibility between donor and recipient is the most important factor associated with the development of acute GVHD. The pathophysiology for acute GVHD is a multistep phenomenon, including the development of an inflammatory milieu that results from host tissue damage induced by the preparative regimen; both recipient and donor antigen-presenting cells and inflammatory cytokines triggering activation of donor-derived T cells; and the activated donor T cells mediate cytotoxicity through a variety of mechanisms, which leads to tissue damage characteristic of acute GVHD.[33] LO 5

Despite prophylaxis, 20% to 80% of patients will develop acute GVHD.[34] Other factors that increase the risk of acute GVHD include increasing recipient or donor age (older than 20 years), female donor to a male recipient, and mismatches in minor histocompatibility antigens in HLA-matched transplants.[33] T-cell depletion or receipt of a UCB graft appears to lower the risk of acute GVHD.[1]

Clinical Presentation and Staging of Acute GVHD Acute GVHD targets the skin, liver, and GI tract; it must be distinguished accurately from other causes of skin, liver, or GI toxicity in HSCT patients. Other causes of toxicities affecting the skin, liver, or GI tract may include a drug reaction or an infectious process. A staging system based on clinical criteria is used to grade acute GVHD (Figure 98–2). The severity of organ involvement is scored on an ordinal scale from 0 (no symptoms) to IV (severe symptoms), and then an overall grade is established based on the number and extent of involved organs.

Immunosuppressive Prophylaxis of Acute GVHD GVHD is a leading cause of morbidity and mortality after allogeneic HSCT and thus, efforts have focused on preventing acute GVHD. The donor graft and preparative regimen influence the prophylactic regimen for acute GVHD, with two approaches having been taken by clinicians over time. One approach involves T-cell depletion, which was discussed more fully in the section on T-cell depletion earlier. The more common method is to use two-drug immunosuppressive therapy that typically consists of a calcineurin inhibitor (ie, cyclosporine or tacrolimus) with LO 6

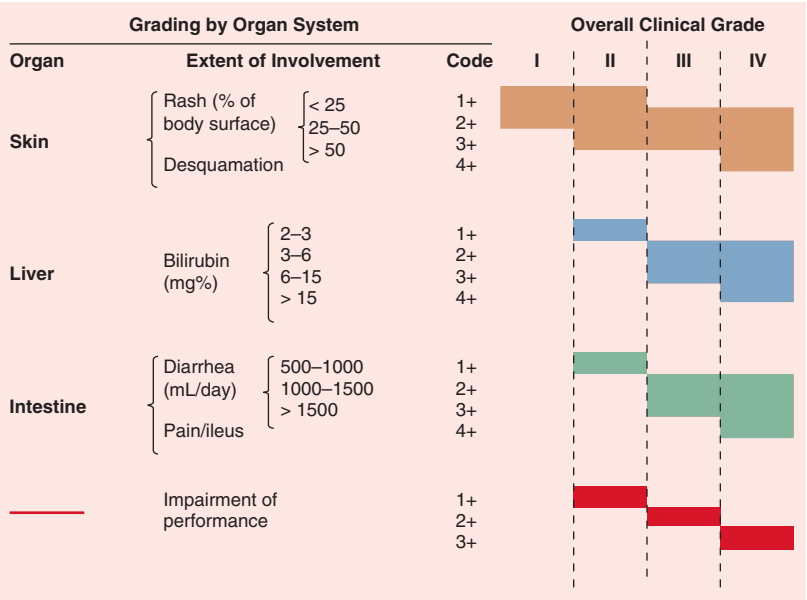

FIGURE 98–2. Staging system for graft-versus-host disease.

methotrexate after myeloablative HSCT. Prophylaxis of acute GVHD for preparative regimens may be varied based on regimen intensity and stem cell source; the role of additional agents such as cyclophosphamide, sirolimus, mycophenolate mofetil, and monoclonal antibodies is currently being studied in acute GVHD prophylaxis trials.[33]

The calcineurin inhibitors (ie, cyclosporine and tacrolimus) should be initiated before donor cell infusion (eg, day –1) when used for GVHD prophylaxis. This schedule is recommended because of the known mechanism of action of calcineurin inhibitors, which entails blocking the proliferation of cytotoxic T cells by inhibiting production of T helper cell–derived interleukin-2 (IL-2). Administering calcineurin inhibitors before the donor cell infusion allows inhibition of IL-2 secretion to occur before a rejection response has been initiated. Studies comparing cyclosporine and tacrolimus in combination with methotrexate have shown that tacrolimus administration is associated with a lower incidence of grade II to IV acute GVHD and a similar incidence of chronic GVHD but variable effects on overall survival.[35,36]

Adaptive Dosing of the Calcineurin Inhibitors Most HSCT centers have their own standardized approach to dose adjust the calcineurin inhibitors cyclosporine and tacrolimus to target concentration ranges. Cyclosporine and tacrolimus trough concentrations are associated with acute GVHD and nephrotoxicity. Cyclosporine trough concentrations usually are maintained between 150 and 400 ng/mL (125 and 333 nmol/L) in patients undergoing allogeneic HSCT. Tacrolimus trough concentrations are targeted to a range of 5 to 15 ng/mL (6.2–18.6 nmol/L).[33,37] Dosage adjustments to either calcineurin inhibitor also should be made for elevated serum creatinine regardless of their serum concentrations. Nephrotoxicity can occur despite low or normal concentrations of the calcineurin inhibitor cyclosporine and may be a consequence of other drug- or disease-related factors known to influence the development of nephrotoxicity (eg, genetic risk factors, concurrent use of other nephrotoxic agents, and sepsis). Careful monitoring for drug interactions via CYP 3A4 and P-glycoprotein is also warranted. The calcineurin inhibitor doses are adjusted based on serum drug levels and the calculated creatinine clearance. Common adverse effects to these agents include neurotoxicity, hypertension, hyperkalemia, hypomagnesemia, and/or nephrotoxicity (which may lead to an impaired clearance of methotrexate).

Clinical Presentation and Diagnosis of Acute Graft-Versus-Host Disease

General

- Patients may present with any or all of the following: Skin rash, GI complaints, or jaundice.
- Signs and symptoms present after engraftment when donor lymphoid elements begin to proliferate.

Symptoms

- Patients may complain of nausea, vomiting, bloody diarrhea, or itching from skin rash.

Signs

- Skin: Maculopapular skin rash on the face, truck, extremities, palms, soles, and ears which may progress to generalized total-body erythroderma, bullous formation, and skin desquamation
- GI: Ileus, malnutrition, dehydration and electrolyte abnormalities due to nausea, vomiting, and diarrhea
- Hepatic: Jaundice due to hyperbilirubinemia

Laboratory Tests

- Hepatic: Elevation of bilirubin, alkaline phosphatase, and hepatic transaminases
- GI: Send stool for bacterial, viral, and parasitic cultures to rule out infectious causes

Other Diagnostic Tests

- Biopsy of affected site for pathologic review

Tapering schedules for the calcineurin inhibitors after myeloablative HSCT vary widely. In patients without GVHD, the calcineurin inhibitor doses usually are stable for the first 3 months after HSCT and then are tapered slowly with the intent of discontinuing all immunosuppressive agents by 6 months after HSCT. By this time, immunologic tolerance has developed, and patients no longer require immunosuppressive therapy. There is a paucity of information regarding the optimal duration of GVHD prophylaxis after nonmyeloablative HSCT and immunosuppression taper schedules may be individualized based on GVHD and disease-specific factors.[33]

Treatment of Acute GVHD The most effective way to treat GVHD is to prevent its development. Corticosteroids, usually in combination with a calcineurin inhibitor, are the first-line therapy for treatment of established acute GVHD. Corticosteroids indirectly halt the progression of immune-mediated destruction of host tissues by blocking macrophage-derived IL-1 secretion. IL-1 is a primary stimulus for T helper cell–induced secretion of IL-2, which, in turn, is responsible for stimulating proliferation of cytotoxic T lymphocytes. The recommended dosage of methylprednisolone in this setting is 2 mg/kg/day; there is no advantage to higher corticosteroid doses (ie, 10 mg/kg/day).[34] A partial or complete response is seen in approximately 50% of patients treated with corticosteroids. Once a clinical improvement occurs, there is no consensus on the optimal method for tapering the corticosteroids. Patients with steroid-refractory acute GVHD have a poor prognosis, and a number of medications are being studied for salvage therapy.

Chronic GVHD Chronic GVHD is a major cause of nonrelapse mortality and morbidity in allogeneic HSCT recipients with up to 40% of patients requiring systemic therapy within 2 years of HSCT.[38] The clinical course of chronic GVHD is multifaceted, involving almost any organ in the body, and its symptoms resemble autoimmune and immunologic disorders (eg, scleroderma). Chronic GVHD symptoms usually present within 1 year after allogeneic HSCT and often are preceded by acute GVHD, although up to 10% of cases present later.[38] Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge on different clinical symptoms rather than the time of onset.[32] A consensus document regarding the diagnosis and scoring of chronic GVHD has been published that proposes a clinical scoring system to describe chronic GVHD as opposed to historical descriptions of chronic GVHD, which described the phenomenon as being "limited" versus "extensive" in nature.[32] The diagnosis of chronic GVHD requires distinction from acute GVHD; the presence of at least one diagnostic clinical sign of chronic GVHD or presence of at least one distinctive manifestation confirmed by pertinent biopsy or other relevant tests; and exclusion of other possible diagnoses.

Prevention and Treatment of Chronic GVHD Chronic GVHD is not a continuation of acute GVHD, and separate approaches are needed for its prevention and management. Prevention of chronic GVHD through prolonged use of immunosuppressive medications has been unsuccessful.[39] Thus, its prevention is focused on minimization of factors associated with higher rates of chronic GVHD. Several recipient, donor, and transplant factors are relevant. Recipient risk factors that are not modifiable include older age, certain diagnoses (eg, chronic myeloid leukemia), and lack of an HLA-matched donor. Modifiable factors that may lower the risk of chronic GVHD include selection of a younger donor, avoidance of a multiparous female donor, use of UCB or bone marrow grafts rather than PBPCs, and limitation of CD34+ and T-cell dose infused.[39] Development of acute GVHD is a major predictor for chronic GVHD, with 70% to 80% of those with grade II to IV acute GVHD developing chronic GVHD.[39]

Relative to no treatment, survival in those with chronic GVHD is improved by extended corticosteroid therapy; however, multiple long-term adverse effects are associated with corticosteroid use. The prednisone dosage is 1 mg/kg/day administered orally in divided doses for 30 days and then slowly converted to an alternate-day therapy. One to two months may pass before an improvement in clinical symptoms is noted, and therapy usually is continued for 9 to 12 months. Therapy can be tapered slowly after resolution of signs and symptoms of chronic GVHD. If a flare of chronic GVHD occurs during the tapering schedule or after therapy is discontinued, immunosuppressive therapy is restarted. Ibrutinib has been approved for treatment of chronic GVHD after failure of at least one treatment option. Other potential approaches for patients who are refractory to initial therapy include etanercept (Enbrel), infliximab (Remicade), mycophenolate mofetil (Cellcept), rituximab (Rituxan), extended use of calcineurin inhibitors, or extracorporeal photochemotherapy.[39] When immunosuppressive therapy is administered for long periods, the patient must be monitored closely for chronic toxicity. Cushingoid effects, aseptic necrosis of the joints, and diabetes can develop with long-term corticosteroid use. Other severe complications include a high incidence of infection with encapsulated organisms and atypical pathogens such as *Pneumocystis jiroveci*, cytomegalovirus (CMV), and varicella zoster virus (VZV).

▶ *Infectious Complications*

KEY CONCEPT Recipients of HSCT are at higher risk of bacterial, viral, and fungal infections and usually receive a prophylactic or preemptive regimen to minimize the morbidity and mortality associated with infectious complications. After myeloablative and nonmyeloablative HSCT, opportunistic infections are a major source of morbidity and mortality. There are three periods of infectious risks, preengraftment (from 15 days prior and to 45 days after HSCT), postengraftment (engraftment to day 100 post engraftment), and late (100 days after engraftment).

Patient Encounter Part 3

The patient is admitted for allogeneic HSCT with a preparative regimen consisting of busulfan and cyclophosphamide. Her hospital course was complicated for neutropenic fever and gastrointestinal toxicities. Neutrophil engraftment occurred on day +14 after HSCT, and the patient was discharged from the hospital on day +16 with minimal complaints. She presents to the transplant clinic on day +25 complaining of a skin rash covering 50% of her body surface including on her palms, arms, soles, and trunk. She also reports being persistently nauseous and having multiple stools throughout the day. After further evaluation, she is diagnosed with GVHD of the skin and intestinal tract.

What grade of GVHD is this patient likely experiencing and how should this be managed?

How should this patient be monitored for progression of GVHD?

From days 0 to 30 after HSCT, particularly for patients undergoing myeloablative HSCT, the primary pathogens are aerobic bacteria, *Candida* spp., and herpes simplex virus (HSV). Respiratory viruses such as respiratory syncytial virus (RSV), influenza, adenovirus, and parainfluenza virus are recognized increasingly as pathogens causing pneumonia, particularly during community outbreaks of infection with these organisms. Because of the need to administer chemotherapy, blood products, antibiotics, and other adjunctive medications, the placement of a semipermanent double- or triple-lumen central venous catheter is necessary before HSCT. However, the indwelling IV central catheters put HSCT recipients at increased risk for *Staphylococcus* infections.

The second period of infectious risk occurs after engraftment to posttransplant day 100. Bacterial infections are still of concern, but pathogens such as CMV, adenovirus, and *Aspergillus* spp. are common. A common manifestation of infection is interstitial pneumonitis (IP), which can be caused by CMV, adenovirus, *Aspergillus,* and *P. jiroveci*. Suppression of the immune system from acute GVHD and corticosteroids contributes to the risk of such infections during this period.[40]

During the late period (100 days after engraftment), the predominant organisms are the encapsulated bacteria (eg, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria meningitidis*), fungi, and VZV. The encapsulated organisms commonly cause sinopulmonary infections. The risk of infection during this late period is increased in patients with chronic GVHD as a result of prolonged immunosuppression.

Prevention and Treatment of Bacterial and Fungal Infections Between the time of administration of the preparative regimen and successful engraftment, allogeneic myeloablative HSCT patients undergo a period of pancytopenia that can last from 2 to 6 weeks. The risk of infection is also reduced by aggressive use of antibacterial, antifungal, and antiviral therapy both prophylactically and for the treatment of documented infection. The antibacterial prophylactic regimens vary substantially among HSCT centers. Some HSCT centers use a prophylactic fluoroquinolone (eg, levofloxacin) on admission for HSCT and then switch to a broad-spectrum IV antibiotic (eg, cefepime) when the patient experiences his or her first neutropenic fever. Although fluoroquinolones reduce the incidence of gram-negative bacteremia, they have not been shown to affect mortality; the possibility of developing clostridium difficile-associated diarrhea exists with fluoroquinolone use and infectious causes should be ruled out if diarrhea occurs. Concerns with fluoroquinolone use in the prophylactic setting during HSCT include the emergence of resistant organisms and an increased risk for streptococcal infection. Broad-spectrum IV antibiotics should be initiated immediately at the time of the first neutropenic fever under the treatment guidelines endorsed by the Infectious Disease Society of America for management of fever of unknown origin in the neutropenic host.[41]

Prevention of HSV and VZV Patients who are HSV antibody seropositive before HSCT are at high risk for reactivation of their HSV infection. Acyclovir is highly effective in preventing HSV reactivation, and thus, prophylactic acyclovir is used commonly in HSV-seropositive patients who are undergoing an allogeneic or autologous HSCT. In the setting of HSV prophylaxis, dosing regimens for prophylactic acyclovir vary widely.[40] Valacyclovir (Valtrex), a prodrug of acyclovir with improved bioavailability, may allow for adequate serum concentrations to prevent HSV in patients undergoing HSCT as well.

In those with a history of VZV infection, VZV disease occurs in 30% of allogeneic HSCT recipients.[42] The appropriate duration of VZV prophylaxis is controversial. Although VZV infections are reduced by prophylactic acyclovir administered from 1 to 2 months until 1 year after HSCT, the risk of VZV persists in those on continued immunosuppression.[40]

Prevention and Preemptive Therapy of CMV Disease After allogeneic HSCT, CMV disease is common and has high morbidity and mortality rates. Allogeneic patients are at greater risk than autologous recipients primarily because the latter more efficiently reconstitute their immune system after transplantation. Infection caused by CMV is usually asymptomatic and develops when CMV replication occurs. Replication occurs primarily in body fluids such as the blood (viremia), bronchoalveolar fluid, or urine (viruria). CMV disease is symptomatic and occurs when the virus invades an organ or tissue. Pneumonia and gastritis are the most common types of CMV disease after allogeneic HSCT. The presence of a CMV infection substantially increases the risk for developing invasive CMV disease. Strategies to prevent CMV infection have resulted in dramatic reductions in the incidence of CMV disease.

Primary CMV can be prevented with CMV seromatching, which includes transplanting PBPCs or bone marrow from CMV-seronegative donors and infusing CMV-negative blood products to CMV-negative recipients. Antivirals are important in those who are CMV seropositive or have a CMV-seropositive graft, with two available approaches to minimize the morbidity associated with CMV. The first is universal prophylaxis, in which ganciclovir is begun at the time of engraftment and is continued until approximately 100 days after engraftment. The second approach is called preemptive therapy, for which ganciclovir is selectively administered based on detection of CMV reactivation.

Preemptive therapy is the most commonly used strategy for preventing CMV disease after allogeneic HSCT because ganciclovir is used only in patients at highest risk for developing CMV disease. This approach minimizes administration of ganciclovir, thus lowering the risk of ganciclovir-induced neutropenia with its subsequent increased risk of invasive bacterial and fungal infections. Preemptive strategies typically use an induction course of ganciclovir for 7 to 14 days followed by a maintenance course until 2 or 3 weeks after the last positive antigenemia result or until 100 days after HSCT.[40] Oral valganciclovir (Valcyte) is an orally bioavailable prodrug of ganciclovir that is converted to ganciclovir in vivo after intestinal absorption and has been used for preemptive therapy. Foscarnet may be given as an alternative to ganciclovir to prevent CMV disease, although its use is complicated by nephrotoxicity and electrolyte wasting.

Fungal Infections

▶ *Prevention of Fungal Infections*

The widespread use of fluconazole prophylaxis since the early 1990s has led to a significant decline in the morbidity and mortality associated with invasive candidiasis in HSCT recipients. However, invasive aspergillosis (IA); zygomycetes; and fluconazole-resistant *Candida* spp., such as *Candida krusei* and *Candida glabrata,* have increased markedly in incidence.[43] Itraconazole, another azole antifungal agent, has better in vitro activity against fluconazole-resistant fungi (eg, *Aspergillus* and some *Candida* spp.) and is more effective than fluconazole for long-term prophylaxis of invasive fungal infections after allogeneic HSCT; however, itraconazole is used less often because of frequent GI side effects

and concern for potential drug interactions.[44] Posaconazole (Noxafil) is a triazole antifungal that has been approved by the FDA for prophylaxis against IA in HSCT patients with GVHD and is now the recommended prophylactic agent for this subset of HSCT patients on immunosuppression. Posaconazole oral suspension should be given with food for adequate absorption. The posaconazole tablet can be administered without regard to food. Micafungin (Mycamine), an agent of the newer class of antifungals known as the echinocandins, has been FDA approved for prophylaxis of *Candida* infections in patients undergoing HSCT.

▶ Risk Factors for Invasive Mold Infections

Invasive mold infections (eg, *Aspergillus* spp., *Fusarium* spp., *Zygomycetes*, and *Scedosporium* spp.) are an increasing cause of morbidity and death after allogeneic and autologous HSCT. It has been estimated that up to one-third of febrile neutropenic patients who do not respond to antibiotic therapy after 1 week are harboring a fungal infection.[41] In HSCT recipients, risk factors for invasive fungal infections include previous history of IA; recipient factors, including older age, CMV seropositivity, and type of stem cell transplant; treatment factors (eg, a fludarabine-based preparative regimen); transplant complications (eg, prolonged neutropenia, graft failure, and higher grade GVHD); and host factors (eg, diabetes, iron overload).[45] Infections with *Aspergillus* spp. remain the most common mold infections diagnosed in the HSCT population and optimal treatment must be promptly initiated if indicated.

▶ Treatment of Invasive Aspergillosis

Early diagnosis and initiation of appropriate therapy may reduce the high mortality rate of IA. Outcomes also depend on recovery of the recipient's immune system and reduction of immunosuppression. Diagnosis is difficult with the use of computed tomography scans and cultures. Research is ongoing to evaluate the benefit of using nonculture-based methods, such as galactomannan and (1,3)-β-D-glucan antigen detection, which are components of the fungal cell wall that can be detected by commercially available assays.

Practice guidelines are available for the treatment of invasive *Aspergillus* infections in immunocompromised patients.[46] Available mold-active agents include triazole antifungals (itraconazole, voriconazole, posaconazole, and isavuconazole), echinocandins (caspofungin, micafungin, and anidulafungin), and amphotericin B formulations.

The optimal duration of appropriate antifungal therapy for treating IA is individualized to the reconstitution of the patient's immune system and his or her response to antifungal treatment. Most clinicians continue aggressive antifungal therapy until the infection has stabilized radiographically and may continue with less aggressive "maintenance" therapy (eg, oral voriconazole) until immunosuppression is lessened or completed. In general, it is common to require several months of antifungal therapy to treat IA.

▶ Pneumocystis jiroveci

After allogeneic HSCT, prophylaxis for *P. jiroveci* (formerly *P. carinii*) pneumonia (PJP) is used because *Pneumocystis* is a serious infection with a high mortality rate if left untreated. Most centers use sulfamethoxazole/trimethoprim for 6 to 12 months after HSCT;[40] aerosolized or IV pentamidine and oral dapsone are alternatives for patients who are allergic to sulfa drugs or who do not tolerate sulfamethoxazole/trimethoprim. Because PJP most often occurs after engraftment, sulfamethoxazole/trimethoprim usually is begun after neutrophil recovery because of its myelosuppressive effects. Patients receiving prophylactic sulfamethoxazole/trimethoprim should be monitored closely for rash and unexplained neutropenia or thrombocytopenia. Sulfamethoxazole/trimethoprim usually is avoided on days of methotrexate administration because the sulfonamides can displace methotrexate from plasma binding sites and decrease renal methotrexate clearance, resulting in higher methotrexate concentrations. Autologous HSCT patients do not receive posttransplant immunosuppression, and thus, their risk of developing PJP is lower.[40] PJP prophylaxis is used often after autologous HSCT in patients with a hematologic malignancy.

▶ Issues of Survivorship After HSCT

The number of long-term HSCT survivors is increasing as 5-year disease-free survival rates improve. HSCT recipients—with either an autologous or an allogeneic graft—have a higher mortality rate than the general population.[47] KEY CONCEPT Long-term survivors of HSCT should be monitored closely, particularly for infections and secondary malignant neoplasms.

LO 8

Survivors of HSCT are at higher risk for secondary malignant neoplasms.[47] Long-term impairment of end-organ function, including the kidneys, liver, and lungs, may be caused by the preparative regimen, infectious complications, and/or posttransplant immunosuppression. Many HSCT recipients experience endocrine dysfunction, such as hypothyroidism from TBI, adrenal insufficiency from long-term corticosteroids to treat GVHD, and infertility from radiation and/or high doses of alkylating agents in myeloablative preparative regimens. Osteopenia has been found in more than half of HSCT recipients, most likely from gonadal dysfunction and/or corticosteroid administration.

Close monitoring of HSCT recipients for infections is necessary because recovery of immune function is slow, sometimes requiring more than 2 years, even in the absence of immunosuppressants.[47] Fevers should be assessed and treated rapidly to minimize the likelihood of a fatal infection. HSCT recipients—both autologous and allogeneic—lose protective antibodies to vaccine-preventable diseases; international guidelines have been published regarding recommendations for reimmunization of HSCT recipients.[40]

Survivors of HSCT should be monitored routinely for signs of relapse and, if an allogeneic graft was used, chronic GVHD. They should be advised regarding revaccination and obtaining prompt medical care for fevers or signs of infection. Routine evaluations of organ function (ie, renal, hepatic, thyroid, and ovarian) and osteopenia should occur and the appropriate management strategies initiated if necessary.

OUTCOME EVALUATION

Monitor for symptoms and signs of the disease that is being treated by HSCT to assess the effectiveness of the HSCT. For example, the monitoring plan for a patient with CML would be to monitor disease response by PCR of the *BCR-ABL* transcript. The actual clinical outcome monitored, along with the frequency of monitoring, is based on the underlying disease.

Monitor for nonhematologic toxicity of the preparative regimen during its administration. Monitor these symptoms at least daily, with more frequent monitoring if the patient is experiencing these nonhematologic effects. The goal is to prevent or minimize these adverse effects.

Patient Care Process

Collect Information:

- Obtain a current medication list and medication use history for prescription and nonprescription medications, herbal products, and dietary supplements. Review and update allergies and intolerances to medications and other substances.
- Review past medical history and/or interim medical history, physical assessment findings, and laboratory values.
- Interview patient to identify and discuss lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication access and/or adherence.

Assess the Information:

- Assess efficacy, safety, drug interactions, adherence, and access to current pharmacotherapy including any barriers to adherence.
- Analyze physical assessment and review of systems findings to determine if patient is exhibiting signs or symptoms of disease progression, infection, or noninfectious HSCT complications, including graft-versus-host disease where applicable.
- Evaluate clinical findings and assess need for medication adjustments to antimicrobials, immunosuppression, supportive care medications, immunizations, or home medications.
- Trend laboratory values (eg, renal function, hepatic function, electrolytes, hemogram with differential, lipid panel, drug levels) and compare with previous values to determine if medication adjustments are warranted.
- Review microbiology data (eg, cultures, fungal serologies, and viral surveillance studies), radiology findings, and other diagnostic tests to assess whether pharmacotherapeutic intervention is appropriate.

Develop a Care Plan:

- If patient is exhibiting a complication related to HSCT or medication therapy, determine if pharmacotherapeutic intervention is indicated.
- Select effective pharmacotherapeutic agents while minimizing drug interactions and overlapping adverse effects with current medication therapy.
- Adjust doses of medications according to prescribed guidelines for organ function, drug interactions, and adverse effects where applicable.

Implement the Care Plan:

- Determine whether the patient's insurance plan will require a prior authorization or if prescribed medication is on institution's formulary.
- Create a new medication list and educate patient on changes to current medications, administration, and how to manage and report adverse effects should they occur.
- Emphasize the importance of medication adherence post-HSCT and address any patient concerns to adherence.

Follow-up: Monitor and Evaluate:

- In the immediate post-HSCT period, follow up at least daily until engraftment and then at frequent intervals (eg, at least weekly) through first 3 months post-HSCT.
- Review medication adherence, vital signs, physical examination findings, laboratory data, monitorable drug levels, microbiology results, radiology data, and other tests related to organ function and disease assessment at each visit.
- Review post-HSCT timeline and make drug therapy modifications in consultation with health care team based on immune reconstitution, drug interactions, and adverse effects.

Abbreviations Introduced in This Chapter

AML	Acute myelogenous leukemia
ANC	Absolute neutrophil count
ASCO	American Society of Clinical Oncology
ATG	Antithymocyte globulin
BMT	Bone marrow transplantation
BU-CY	Busulfan–cyclophosphamide
CINV	Chemotherapy-induced nausea and vomiting
CML	Chronic myelogenous leukemia
CMV	Cytomegalovirus
CY-TBI	Cyclophosphamide–total-body irradiation
GVHD	Graft-versus-host disease
HGF	Hematopoietic growth factors
HLA	Human leukocyte antigen
HSCT	Hematopoietic stem cell transplant
IA	Invasive aspergillosis
IL-2	Interleukin-2
MHC	Minor histocompatibility
MM	Multiple myeloma
NHL	Non-Hodgkin lymphoma
NK	Natural killer
PBPC	Peripheral blood progenitor cells
PJP	Pneumocystis pneumonia
SOS	Sinusoidal obstruction syndrome
SCr	Serum creatinine
TBI	Total-body irradiation
UCB	Umbilical cord blood
VZV	Varicella zoster virus

99 Supportive Care in Oncology

Sarah Scarpace Peters

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Describe the impact of various supportive care interventions on the prognosis of patients with cancer.
2. Discuss the scientific basis for providing various supportive care interventions in the oncology patient population.
3. Identify patient-related and disease-related risk factors in defining a population for whom supportive care interventions would be of benefit.
4. Recognize typical presenting signs and symptoms of common complications and emergencies that require supportive care interventions.
5. Outline appropriate prevention and management strategies for various supportive care interventions.
6. Prepare a monitoring plan to evaluate the efficacy and toxicity of pharmacotherapy interventions for supportive care problems.

INTRODUCTION

Patients with cancer are at risk for serious adverse events that result from their treatment, the cancer, or both. The management of these complications is generally referred to as supportive care (or symptom management). Examples of treatment-related complications include chemotherapy-induced nausea and vomiting (CINV), myelosuppression, febrile neutropenia (FN), hemorrhagic cystitis, mucositis, and tumor lysis syndrome (TLS). Tumor or cancer-related complications include superior vena cava (SVC) obstruction, spinal cord compression, hypercalcemia, and brain metastases. In some cases, these events can be life threatening. SVC obstruction, spinal cord compression, TLS, and hypercalcemia have traditionally been defined as oncologic emergencies. Treatment- and disease-related complications in the oncology population require rapid assessment and supportive care interventions. The onset of oncologic emergencies may herald the onset of an undiagnosed malignancy or progression or relapse of a preexisting malignancy. Optimal management of patients with various oncologic emergencies and complications requiring supportive care interventions can significantly decrease morbidity and mortality in patients with cancer. This chapter provides an overview of these issues. First, an overview of the management of common side effects of treatment is given. Later, a summary of common oncologic emergencies is presented.

CHEMOTHERAPY-INDUCED TOXICITIES: NAUSEA/VOMITING

Nausea and vomiting are among the most commonly feared toxicities by patients undergoing chemotherapy.[1] KEY CONCEPT The optimal method of managing CINV is to provide adequate pharmacologic prophylaxis given a patient's risk level for emesis. Insufficient control during the first cycle of chemotherapy leads to more difficulty in controlling emesis for subsequent cycles.[2]

EPIDEMIOLOGY AND ETIOLOGY

Although it is widely known that chemotherapy causes nausea and vomiting, the rate of emesis varies depending on individual patient risk factors and drug therapy regimen. Therefore, cancer treatments are stratified into varying risk levels: high, moderate, low, and minimal. Agents with a "high" emetic risk cause emesis in more than 90% of cases if not given any prophylaxis. The rates of emesis for "moderate," "low," and "minimal" are 30% to 90%, 10% to 30%, and less than 10%, respectively. Table 99–1 lists the individual agents and their risk category.[3]

PATHOPHYSIOLOGY

LO 2

The pathophysiology of nausea and vomiting is described in Chapter 20. Specific to CINV, the key receptors include serotonin ($5\text{-}HT_3$) receptors (located in the chemoreceptor trigger zone, emetic center of the medulla, and gastrointestinal [GI] tract) and neurokinin-1 (NK1) receptors (located in the emetic center of the medulla). Serotonin plays an important role in the genesis of acute vomiting, occurring within the first 24 hours of chemotherapy, because some cancer drug therapies can stimulate a release of serotonin from enterochromaffin cells in the GI tract. Serotonin then activates the emetic response by binding to $5HT_3$ receptors in the emetic center. This short-lived release of serotonin likely explains why serotonin antagonists are more beneficial for preventing acute versus delayed vomiting.[4] Other sites that are targeted by antiemetics include dopamine, muscarinic (acetylcholine), histamine, and cannabinoid receptors.[5]

CLINICAL PRESENTATION AND DIAGNOSIS

CINV, although frequently discussed as one syndrome, includes two distinct clinical entities, including both nausea and vomiting. Nauseous patients may present with general GI upset and reflux and may report a sensation or desire to vomit without being able

Table 99–1

Emetogenic Potential of Selected Chemotherapy

Risk	Agent	Risk	Agent
High emetic risk (> 90% of patients will vomit without appropriate antiemetics)	AC combination (doxorubicin or epirubicin and cyclophosphamide) Carmustine > 250 mg/m^2 Carboplatin AUC ≥ 4 Cisplatin Crizotinib (oral) Cyclophosphamide > 1500 mg/m^2 Dacarbazine Doxorubicin ≥ 60 mg/m^2 Epirubicin > 90 mg/m^2 Etoposide (oral) Ifosfamide ≥ 2 g/m^2 Temozolomide >75 mg/m^2/day (oral)	Low emetic risk (10%–30%)	Ado-trastuzumab emtansine Afatinib (oral) Amifostine < 300 mg/m^2 Bexarotene Brentuximab Cabazitaxel Carfilzomib Capecitabine (oral) Dasatinib (oral) Docetaxel Doxorubicin (liposomal) Eribulin Erlotinib (oral) Etoposide 5-Fluorouracil Gemcitabine Ixabepilone Methotrexate > 50 mg/m^2 and < 250 mg/m^2 Mitomycin Mitoxantrone Paclitaxel Palbociclib (oral) Pemetrexed Sunitinib (oral) Topotecan Vorinostat
Moderate emetic risk (30%–90%)	Amifostine > 300 mg/m^2 Arsenic trioxide Azacitidine Bendamustine Busulfan > 4 mg/m^2 Carboplatin AUC < 4 Carmustine ≤ 250 mg/m^2 Cyclophosphamide ≤ 1500 mg/m^2 Cytarabine > 200 mg/m^2 Daunorubicin Doxorubicin < 60 mg/m^2 Epirubicin < 90 mg/m^2 Idarubicin Ifosfamide < 2 g/m^2 Irinotecan Methotrexate > 250 mg/m^2 Oxaliplatin	Minimal risk (< 10%)	Most other agents

Data from National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetic v.2.2017.

to do so.[5] In all cases, it is important that other etiologies of nausea and vomiting are ruled out before diagnosing chemotherapy as the cause.[6] Other causes of nausea and vomiting may include bowel obstruction, opioid intolerance, electrolyte imbalances, brain metastases, and vestibular dysfunction.[6]

TREATMENT

Desired Outcomes

The desired outcome is to completely prevent or minimize the severity of nausea, vomiting, and the use of breakthrough antiemetic medications. In clinical trials, a common end point is "complete response," defined as having no emesis and no breakthrough medication use within a defined period of time.[5] If patients experience nausea or emesis, the goal is to quickly relieve the episode and prevent future nausea or vomiting, whether in the next few days or for the next cycle of chemotherapy.[6]

General Approach to Treatment

Treatment-related factors and patient-related factors can help define a patient population at risk for developing CINV.[2] Treatment-related factors include those chemotherapy agents with high and moderate levels of emetogenicity, dose, and schedule (see Table 99–1 for a complete listing).[3] CINV is typically a cyclical occurrence. Although this section focuses on CINV, it can be helpful for practitioners to remember that patients undergoing concomitant radiation therapy and chemotherapy are at risk for more severe nausea and vomiting. Radiation (particularly total-body irradiation as part of a conditioning regimen for stem cell transplant) can cause a more cumulative (versus cyclical) nausea/vomiting phenomenon.[3]

LO 3

Specific patient-related factors such as female gender, age less than 50, history of motion sickness, pregnancy-induced nausea or vomiting, and poor emetic control in previous chemotherapy cycles increase the risk of emesis.[2] Interestingly, patients with a history of alcohol abuse have a reported decreased risk of emesis.[5] It is important to design an antiemetic regimen with consideration of these patient-specific risk factors.[6]A well-designed regimen includes a prophylactic regimen targeting the various phases of nausea/vomiting and a breakthrough antiemetic drug "as needed." Although many drugs are recommended as "breakthrough" drugs, choose a drug with a different mechanism of action compared with the drugs used for prophylaxis.[6]

▶ *Nonpharmacologic Therapy*

Nonpharmacologic therapy for nausea and vomiting can be useful adjuncts to drug therapy, particularly in the setting of anticipatory nausea and vomiting. Behavior therapies such as relaxation, guided imagery, and music therapy as well as acupuncture or acupressure may be useful in this setting.[6] Other general measures that can be taken include ensuring adequate

Clinical Presentation and Diagnosis of CINV

Acute Nausea/Vomiting

- Occurs within the first 24 hours after chemotherapy administration

Delayed Nausea/Vomiting

- Occurs between 24 hours and 5 days after chemotherapy administration

Anticipatory Nausea/Vomiting

- A learned, conditioned reflex response to a stimulus (sight, sound, smell) often associated with poor emetic control in a previous cycle of chemotherapy

Breakthrough Nausea/Vomiting

- Occurs despite prophylaxis with an appropriate antiemetic regimen

Differential Diagnosis

- Surgery, radiation
- Brain metastases
- Gastric outlet or bowel obstruction, constipation
- Hypercalcemia, hyperglycemia, hyponatremia, uremia
- Food poisoning or intolerance
- Other drugs (opioids)

Table 99–2

Recommended Therapy by Emetic Risk

Emetic Risk Category (Incidence of Emesis Without Antiemetics)	Antiemetic Regimens and Schedules
High (> 90%)	5-HT_3 serotonin receptor antagonist: day 1 Dexamethasone: days 1–4 Aprepitant: days 1–3 or fosaprepitant IV day 1 only Olanzapine: days 1–4
Moderate (30%–90%)	5-HT_3 serotonin receptor antagonist: day 1 Dexamethasone: day 1 *Or* 5-HT_3 serotonin receptor antagonist: day 1 Dexamethasone: days 1–3 for regimens with drugs known to cause delayed nausea/vomiting
Low (10%–30%)	Dexamethasone: day 1 *Or* 5-HT_3 serotonin receptor antagonist: day 1
Minimal (< 10%)	No routine prophylaxis. 5-HT3 receptor antagonists, others as needed

Data from American Society of Clinical Oncology. Antiemetics: Clinical Practice Guideline Update, 2017 and National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetics v.2.2017.

sleep before treatment, eating smaller meals, and avoiding spicy and greasy foods and foods with strong odors.[6]

▶ *Pharmacologic Therapy*

Nonprescription medications such as antacids, histamine-2 receptor blockers, and proton pump inhibitors can be helpful in reducing gastroesophageal reflux associated with some cancer treatments that may trigger or exacerbate CINV.[6] Nonprescription antihistamines marketed for nausea associated with motion sickness are not usually helpful in managing CINV.

LO 5

Four drug classes are highly effective in preventing CINV: corticosteroids (dexamethasone), serotonin receptor antagonists, NK1 receptor antagonists (aprepitant or fosaprepitant), and the thienobenzodiazepine, olanzapine.[3] Drugs with differing mechanisms of action are combined, depending on the emetic risk level of the chemotherapy regimen (Table 99–2).

Intravenous (IV) antiemetics are usually administered 30 minutes before chemotherapy, and oral antiemetics are administered 60 minutes before chemotherapy. Dexamethasone is the preferred agent to prevent CINV in the delayed setting (days 2–4 after chemotherapy administration) and is given at dose of 8 mg once daily for 3 to 4 days.[3,6] Recently, experts have modified recommendations and advise limiting the use of multi-day dexamethasone to only highly emetogenic risk chemotherapy and only for those moderately emetogenic regimens known to cause delayed nausea and vomiting (such as cyclophosphamide, doxorubicin, and oxaliplatin) due to concerns for toxicities related to dexamethasone.[3] In some cases, the serotonin antagonists may also be continued orally for 2 to 3 days after chemotherapy or be used in place of dexamethasone, though practice guidelines differ in their recommendations.[3,6] When oral aprepitant is used prechemotherapy, the aprepitant is continued as 80 mg orally once daily on days 2 and 3 of the chemotherapy cycle. No oral aprepitant is necessary when fosaprepitant 150 mg IV is given on day 1. Olanzapine is now a standard component of the antiemetic regimens for high emetic-risk chemotherapy at 10 mg by mouth once daily (5 mg by mouth once daily for elderly patients) for 4 days starting the day of chemotherapy, and an option to add to the antiemetic regimen for moderately emetogenic chemotherapy.[3,6] Concerns of QT prolongation have resulted in the IV formulation of dolasetron to be removed from the market and dosing of ondansetron has been reduced to 16 mg IV as the 32 mg IV was reported to extend the QT interval.[7]

The other classes of antiemetics are usually prescribed "as needed" for breakthrough nausea or vomiting. The dopamine antagonists prochlorperazine and metoclopramide are usually recommended because they antagonize a different receptor than the drugs already given for prophylaxis. Other medications, including serotonin receptor antagonists, cannabinoids, dexamethasone, scopolamine, or olanzapine, may be used as alternatives to dopamine antagonists for breakthrough nausea and vomiting.[3,6] Breakthrough medications should have different mechanisms of action than the medications a patient is taking to prevent nausea and vomiting. For those in any risk group who experience anticipatory nausea and vomiting, the addition of lorazepam for prophylaxis and breakthrough is recommended for its antiemetic and antianxiety properties, but not as a single-agent to prevent CINV.[3] Table 99–3 lists the doses of the antiemetic agents for prophylaxis and breakthrough use.

LO 5

A prophylactic antiemetic regimen for high emetic risk levels of IV chemotherapy should be with a four-drug combination using dexamethasone, (fos)aprepitant IV (or aprepitant, an oral agent), olanzapine, and 5-HT_3 antagonist to prevent both acute and delayed emesis.[3,6] Dexamethasone and olanzapine should be continued until day 4, and aprepitant is also administered on days 2

Table 99–3

Antiemetic Dosing

Antiemetic	Single Dose Administered Before Chemotherapy	Daily Schedule
5-HT$_3$ Serotonin Receptor Antagonists		
Dolasetron	By mouth: 100 mg	100 mg by mouth daily
Granisetron	By mouth: 2 mg IV: 1 mg or 0.01 mg/kg Topical: 34.3-mg patch (apply 24–48 hours before chemotherapy, leave on for 7 days)	1–2 mg by mouth daily or 1 mg by mouth two times a day
Ondansetron	By mouth: 16–24 mg IV: 8–16 mg	8 mg by mouth two times a day or 16 mg by mouth daily
Palonosetron	IV: 0.25 mg	
Others		
Aprepitant	By mouth: 125 mg	80 mg by mouth days 2 and 3
Fosaprepitant	IV: 150 mg × 1	None
Dexamethasone	By mouth or IV: 12 mg	8 mg by mouth days 2–4
Olanzapine	10 mg by mouth daily	10 mg by mouth daily

Data from American Society of Clinical Oncology. Antiemetics: Clinical Practice Guideline Update, 2017 and National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Antiemetics v.2.2017.

and 3 if the oral formulation is used.[3,6] A phase 3 trial of 241 patients comparing aprepitant, palonosetron, and dexamethasone to olanzapine with a palonosetron and dexamethasone for patients treated with highly emetogenic chemotherapy had similar rates of CINV control (87%–97% prevention of acute CINV, 73%–77% prevention of delayed CINV), though nausea was better controlled by the olanzapine-based regimen (69% overall vs 38% overall).[8]

LO 5

For moderately emetogenic regimens, acute emesis is still of major concern, but the incidence of delayed emesis is less. Therefore, dexamethasone plus a 5-HT$_3$ antagonist should be given on day 1. On days 2 to 3, choose to continue either the dexamethasone or the 5-HT$_3$ antagonist (dexamethasone preferred for regimens known to cause delayed CINV),[3,6] though one exception is when palonosetron is given as the 5-HT$_3$ antagonist on day 1. Because its half-life is long, no redosing is necessary on subsequent days. Aprepitant and fosaprepitant

Patient Encounter 1: CINV

A 73-year-old man with non–small cell lung cancer (NSCLC) presents today for initiation of chemotherapy with carboplatin AUC 5 and paclitaxel 175 mg/m^2.

What category of emetic risk should this dose regimen fall under?

What do you recommend for preventing nausea and vomiting in this patient?

150 mg IV are also approved by the Food and Drug Administration (FDA) for the prevention of CINV in the moderate setting. While an NK1 receptor antagonist is not routinely used for moderately emetogenic chemotherapy, if patients have clinical risk factors or if they experienced uncontrolled emesis with previous chemotherapy cycles, follow the suggest guidelines for "high-" emetogenic risk level.[6]

LO 5

For low emetic risk IV chemotherapy regimens, single-agent antiemetic prophylaxis with either dexamethasone or 5HT$_3$ antagonist is recommended 30 minutes before chemotherapy.[3,6] For minimal emetic risk groups, guidelines do not recommend routine prophylaxis with antiemetics; instead, patients should be provided with a drug to take as needed for nausea and vomiting.[3,6] Table 99–2 summarizes regimens for antiemetic prophylaxis for the different risk levels of IV chemotherapy.

Many oral anticancer agents are now available and are typically administered daily. For highly and moderately emetogenic oral anticancer therapy, an oral 5HT$_3$-antagonist is administered 60 minutes before each chemotherapy dose.[6] For low–minimal risk oral anticancer agents an "as needed" antiemetic agent may be given for any breakthrough nausea/vomiting.[6]

OUTCOME EVALUATION

It is often difficult to evaluate nausea and vomiting when chemotherapy is given as an outpatient. After drug administration, patients return home and may or may not report inadequate control of nausea or emesis. Subsequent chemotherapy cycles may also be poorly controlled, especially if patients do not state their experience with the previous cycle. To ameliorate this problem, patients' experiences with CINV should be assessed, particularly after the first and second cycles of chemotherapy. Patients should be asked about their previous emesis control with subsequent cycles of chemotherapy, and a prophylactic regimen may need to be adjusted. Patients should also be encouraged to self-report poor control of emesis while at home. Side effects of the antiemetic regimen should also be assessed and reported.

MUCOSITIS

Mucositis is the inflammation of the mucosal lining in the oral cavity and GI tract caused by damage from radiation or cytotoxic chemotherapy, often leading to ulcers.[9] Stomatitis is a related term that is specific to inflammation in the oral cavity and associated with targeted anticancer agents.[9] Both mucositis and stomatitis are common supportive care issues that deserve attention and are associated with many negative health consequences, including pain, inadequate nutritional intake, and risk for infection. Diagnosis is based on symptoms of pain, vomiting, diarrhea, and impact on appetite, all of which are surrogates for the inflammation and damage to the mucosal lining due to the impractical nature of a definitive diagnosis by invasive endoscopic biopsy.[10] Biomarkers are currently under investigation to better standardize the severity of mucosistis.[10] Patients with mucositis often require parenteral analgesics, nutrition supplementation, and anti-infectives to treat concomitant bacterial, fungal, or viral infections. Furthermore, mucositis is associated with economic consequences, primarily increased length of hospital stay, nutrition support, and infection management.[11,12] The use of evidence-based practice for prevention and treatment of mucositis can help improve patient outcomes.

LO 1

EPIDEMIOLOGY AND ETIOLOGY

The incidence of chemotherapy or radiation-induced mucositis depends mostly on the type of chemotherapy, the type and area of radiation, and the specific cancer. Studies have reported an incidence of about 85% in head and neck cancer patients receiving chemoradiation.[9] The World Health Organization estimates that approximately 75% of patients who are treated with high-dose chemotherapy for stem cell transplantation developed oral mucositis.[9] Specific chemotherapy agents associated with moderate–severe mucositis include taxanes, anthracyclines, platinum analogues, methotrexate, and the fluoropyrimidines.

PATHOPHYSIOLOGY

The classical concept of mucositis pathophysiology asserts that direct cytotoxicity from chemotherapy or radiation to basal epithelial cells results in ulcerative lesions caused by a lack of regeneration. These lesions are further complicated by trauma or microorganism growth. However, the most recent theory of mucositis pathophysiology is more detailed and involves a multistage, dynamic process that builds upon the historical model.[12] According to this theory, there are five stages of mucositis: initiation, primary damage response, signal amplification, ulceration, and healing. It is important to note that these stages do not occur sequentially and may be influenced by both the oral and gut microbiome as well as genetic polymorphisms in individual patients.[13] Prevention of mucositis or treatment in early stages results in the best outcomes for patients.

CLINICAL PRESENTATION AND DIAGNOSIS

LO 1 LO 4

Patients with mucositis may present along a continuum of mild, painless, erythematous ulcers to those that are painful and/or bleeding that may interfere with eating and swallowing or that may require treatment with hydration, antibiotics, and/or parenteral nutrition or opioid therapy in its most severe forms.[9,12] The severity of mucositis can be assessed with validated scales such as the Oral Mucositis Assessment Scale (OMAS)[14] or the Patient-Reported Oral Mucositis Symptom (PROMS) scale.[15]

Clinical Presentation and Diagnosis of Mucositis

- Painful, erythematous ulcers develop on the lips, cheeks, soft palate, floor of mouth, and throughout the entire gastrointestinal (GI) tract.
- Assess mucositis using validated scales, either oral mucositis assessment scale (OMAS) or Patient-Reported Oral Mucositis Symptom (PROMS) Scale.
- Symptoms appear within 5 to 7 days after chemotherapy and resolve in 2 to 3 weeks.
- Pain may affect ability to swallow and eat.
- The patient may have concomitant localized or systemic infection.
- Diarrhea is a symptom of mucositis in the lower GI tract; can lead to electrolyte imbalances.

TREATMENT

Nonpharmacologic Treatment

The goal of nonpharmacologic measures to prevent mucositis is to reduce the bacterial load. KEY CONCEPT The fundamental approach to lessen the severity of mucositis begins with basic, good oral hygiene (brushing with a soft-bristled toothbrush at least twice daily, flossing, bland rinses, and saliva substitutes) and maintaining optimal nutritional support.[9,12] Cryotherapy with ice chips is also helpful for patients at risk for mucositis who are receiving 5-FU–based chemotherapy.[9,12] Low-level laser therapy (in centers that have the resources to offer it) is also helpful to prevent mucositis in the hematopoietic cell transplant (HCT) setting.[9,12]

Pharmacologic Treatment

LO 5

In the setting of radiation therapy, amifostine, a free radical scavenger, at doses equal to or greater than 340 mg/m^2 intrarectal before each dose of radiation therapy for rectal cancer may be considered to prevent GI mucositis.[9,12] Gelclair, Caphasol, and Biotene are gels that provide a protective barrier between damaged oral mucosa and the environment, lessening pain and irritation and are also sometimes used as part of the overall treatment of patients with mucositis.[10]

While benzydamine mouthwash is recommended by practice guidelines, antimicrobial mouth washes and lozenges, sucralfate and chlorhexidine rinses, and "magic-mouthwash" compounded rinses are not generally recommended by clinical practice guidelines for mucositis prevention even though they are sometimes used in practice.[9,12] Ranitidine or omeprazole orally are recommended to prevent pain associated with mucositis and reflux following offending chemotherapy.[9,12] Additionally, octreotide at a dose of at least 100 mcg subcutaneously twice daily is recommended to treat mucositis-related diarrhea associated with high-dose stem cell transplantation if loperamide is ineffective.[9,12]

Unfortunately, little evidence is available to recommend specific treatments for mucositis. Pain assessment and appropriate management are important.[9,12] Pain management may be achieved with oral or intravenous opioids, topical anesthetic products, and compounded rinses that incorporate lidocaine.[9,12] In more severe cases in which infection of the oral mucosa is suspected, appropriate antimicrobial therapy is necessary to prevent systemic infection.[9,12]

Palifermin is FDA-approved for the prevention and treatment of mucositis in patients receiving high-dose chemotherapy as part of stem cell transplant or induction regimens for leukemia. Palifermin is administered as an IV bolus injection at a dosage of 60 mcg/kg/day for 3 consecutive days before and 3 consecutive days after myelotoxic therapy for a total of six doses. Administering palifermin within 24 hours of chemotherapy can result in an increased sensitivity of rapidly dividing epithelial cells to the cytotoxic agent. For this reason, palifermin should not be administered for 24 hours before, 24 hours after, or during the infusion of myelotoxic chemotherapy to avoid increasing the severity and the duration of oral mucositis.[9,12]

OUTCOME EVALUATION

The goal of therapy is to prevent or decrease the severity and duration of mucositis. Outcomes measured in clinical trials often assess the incidence, duration, and severity of mucositis with a given intervention intended to prevent or treat mucositis. Agents that are intended to palliate the symptoms of mucositis are usually assessed by measures in pain scales and the ability to eat or drink.

HEMATOLOGIC COMPLICATIONS: FEBRILE NEUTROPENIA (FN)

INTRODUCTION

LO 1

FN is a common adverse effect after administration of cytotoxic chemotherapy. The mortality rate in neutropenic patients caused by infectious complications currently remains between 5% and 10%; therefore, FN is considered a true oncologic emergency. Patients frequently require hospitalization for prompt administration of broad-spectrum antibiotics that are critical to avoid morbidity and mortality.

EPIDEMIOLOGY AND ETIOLOGY

The microorganisms responsible for infections in neutropenic patients have changed significantly in the last 50 years. From the 1960s through the mid-1980s, gram-negative organisms were the most common bacteria isolated. This pattern shifted to the gram-positive organisms in the late 1980s, which remain the most common isolates. Recent data indicate that gram-positive organisms account for up to 75% to 80% of all bloodstream infections in cancer patients while gram-negative species are more prevalent in nonbloodstream infections and particularly if there is deep tissue involvement.[16] The causes of this change are attributed to the widespread use of central venous catheters and more aggressive chemotherapy regimens as well as the use of prophylactic antibiotics with relatively poor gram-positive coverage (quinolones). Commonly isolated pathogens are shown in Table 99–4. Although gram-negative infections are less common, they cause the majority of infections in sites other than the blood and are particularly virulent.[16] It should be noted that isolates vary considerably among institutions; thus, attention to institutional isolation patterns is prudent.

Fungal infections caused by *Candida* spp. (especially *Candida albicans*) have emerged as significant pathogens, especially in patients with hematologic malignancies and those undergoing bone marrow transplantation (BMT).[16] In addition, *Aspergillus* spp. are important pathogens in patients with prolonged and severe neutropenia.[16]

Table 99–4

Commonly Isolated Pathogens in Patients with FN

Type of Organism	Comments
Bacteria	
Gram-positive organisms	Most common isolates in FN
Coagulase-negative *staphylococci* (ie, *Staphylococcus epidermidis)*	Between 70% and 90% resistant to methicillin; indolent course with low mortality
Staphylococcus aureus	Some centers report > 50% resistance to methicillin
Enterococcus spp.	Resistance to vancomycin ≥ 30%
Viridans streptococci	Increasing resistance to penicillin; result of fluoroquinolone prophylaxis; associated with mucositis
Gram-negative organisms	Infections rapidly fatal
Pseudomonas aeruginosa	High mortality rate; increasing resistance to quinolones
Escherichia coli	Increased incidence of β-lactamase–producing strains
Klebsiella spp	
Enterobacter spp.	Increased incidence of β-lactamase–producing strains
Fungi	Occur primarily after prolonged neutropenia (> 1 week)
Yeasts	
Candida albicans	Increasing incidence (~10%); high mortality rate
Non-*albicans Candida* (*Candida krusei, Candida glabrata*)	Resistant to fluconazole; high mortality rate
Molds	Resistant to fluconazole; high mortality
Aspergillus spp.	Pulmonary infection common
Fusarium spp.	Emerging pathogen
Scedosporium spp.	Emerging pathogen

FN, febrile neutropenia.

PATHOPHYSIOLOGY

The neutrophils are the primary defense mechanism against bacterial and fungal infection. Most infections in neutropenic patients are a result of organisms contained in endogenous flora, both on the skin and within the GI tract. These organisms are provided access to the bloodstream through breakdowns in host defense barriers (**mucositis**, use of central venous catheters).

Neutropenia is defined as an absolute neutrophil count (ANC) less than 500/μL (0.50×10^9/L) cells or an ANC less than 1000/μL (1.00×10^9/L) cells with a predicted decrease to less than 500/μL (0.50×10^9/L) cells over the next 48 hours. The ANC is calculated by multiplying the total WBC by the percentage of neutrophils (segmented neutrophils plus "bands"). Fever is defined as a single oral temperature greater than or equal to 38.3°C (101°F) or a temperature greater than or equal to 38.0°C (100.4°F) for at least 1 hour. The combination of these two factors defines FN.[17–19] The risk of infection during the period of neutropenia depends primarily on two factors:

- The duration of the neutropenia (time period of ANC < 500/μL [0.50×10^9/L] cells)
- The severity of the neutropenia (lowest ANC level reached [nadir])

LO 3

A multitude of other risk factors for FN have been identified[20] (Table 99–5). Many of these are also risk factors for poor outcome in patients who experience FN. Cancer drug therapy regimens are also categorized as being high risk (> 20% incidence of FN reported in clinical trials) or intermediate risk (10%–20% risk of FN reported in clinical trials). Similar to the approach to the

Patient Encounter 2: FN

A 63-year-old woman receiving treatment for metastatic breast cancer presents today, 8 days after chemotherapy, for follow-up and laboratory check. Relevant laboratory study results include WBC count, 0.7×10^3/mL (0.7×10^9/L); HgB 9.0 g/dL (90 g/L; 5.59 mmol/L)); HCT 26.6% (0.266); PLT, 6×10^3/mL (6×10^9/L); serum chemistries within normal limits except; SCr, 1.3 mg/dL (115 μmol/L); and estimated GFR 54 mL/min/1.73m^2. Vitals: T 98.2°F (36.8°C); P 71 beats/min; RR 18 breaths/min; BP 116/64 mm Hg. The patient has no known drug allergies.

What risk factors for FN does this patient have?

How would you approach this patient?

Table 99–5

Risk Factors for FN

Patient Related	Therapy Related
Age ≥ 60 years	History of extensive chemotherapy
Poor performance status	Planned full dose intensity of chemotherapy
Bone marrow involvement by tumor	High-dose chemotherapy (ie, stem cell transplant)
Poor nutritional status	> 20% incidence of FN reported in clinical trials with treatment regimen
Hematologic malignancy	10%–20% incidence of FN reported in clinical trials with treatment regimen plus presence of patient-specific risk factors
Elevated LDH	
Decreased hemoglobin level	
Baseline or first-cycle low neutrophil counts	
History of previous FN	
Renal or hepatic insufficiency	
Uncontrolled or advanced stage cancer	
MASCC Risk Index Score < 21	

FN, febrile neutropenia; LDH, lactate dehydrogenase; MASCC, Multinational Association for Supportive Care in Cancer.

Data from The National Comprehensive Cancer Network Clinical Practice Guidelines in Oncology: Prevention and Treatment of Cancer-Related Infections. V.2.2017. Available from: https://www.nccn.org/professionals/physician_gls/pdf/infections.pdf. Accessed August 29, 2017.

Table 99–6

MASCC Risk-Index for Identifying Low-Risk Patients with FN[a]

Characteristic	Score
Burden of illness[b]	
No symptoms	5
Mild symptoms	5
Moderate symptoms	3
No hypotension	5
No COPD	4
Solid tumor or hematologic malignancy without fungal infection	4
No dehydration	3
Outpatient onset of fever	3
Age < 60 years[c]	2

[a]Note: A risk-index score of ≥ 21 indicates that the patient is likely to be at low risk for complications and morbidity.

[b]Choose one symptom assessment.

[c]Does not apply to patients aged ≤ 16 years.

COPD, chronic obstructive pulmonary disease; FN, febrile neutropenia; MASCC, Multinational Association for Supportive Care in Cancer.

From Klastersky J, Paesmans M. The Multinational Association for Supportive Care in Cancer (MASCC) risk index score: 10 years of use for identifying low-risk febrile neutropenic cancer patients. Support Care Cancer. 2013;21(5):1487–1495.

prevention of CINV, it is important to consider both the regimen and patient-specific risk factors when determining whether a patient should receive prophylactic therapy for FN.

It is clear that patients with FN represent a heterogenous group. Some patients are at lower risk and could potentially be treated as outpatients, thereby avoiding the risk and cost of hospitalization. LO 3 The Multinational Association for Supportive Care in Cancer (MASCC) has validated a risk assessment tool that assigns a risk score to patients presenting with FN (Table 99–6).[20] Patients with a risk-index score greater than or equal to 21 are identified as low risk and are candidates for outpatient therapy (discussed under section Treatment).

PREVENTION

LO 5 Three primary modalities for preventing infection in patients who are expected to become neutropenic have been utilized, the first of which is the least expensive and simplest:

- Vigilant hand hygiene
- Prophylactic antibiotics
- Colony-stimulating factors (CSFs)

The advantages and disadvantages of these strategies are discussed individually in the following sections.

Hand Hygiene

As previously discussed, most infections in neutropenic patients are a result of endogenous flora; however, prevention of further acquisition of environmental pathogens is also important. Patients who are or will become neutropenic should practice careful handwashing and avoid contact with people who neglect hand hygiene. Although practice guidelines do not advocate for a "neutropenic diet" (ingestion of certain fresh fruits and vegetables as well as unprocessed dairy products) due to a lack of strong evidence that following such a diet will reduce the risk of infection-related morbidity and mortality, this is a common clinical advice given to patients.[18] Practitioners should also engage in vigilant hand hygiene after each patient encounter to limit the spread of infections between patients.[19]

Clinical Presentation and Diagnosis of FN[17–19]

General

- Only 50% of patients with FN have a clinically documented infection.
- Only 25% of patients with FN have a microbiologically documented infection.

Signs and Symptoms

- Fever is typically the only sign of infection, although septic patients may have chills.
- Infected catheter sites may be erythematous and tender to the touch.

Laboratory Tests

- CBC with differential
- Two blood cultures from each access site (peripheral and central), urinalysis, urine culture, chest x-ray, sputum cultures

Other Diagnostic Tests

- Detailed physical examination of the oral mucosa, sinuses, skin, catheter access sites, perineal area (no rectal examination because of the risk of bacteremia)

Prophylactic Antibiotics

Routine antibacterial prophylaxis is controversial and has been attempted primarily with sulfamethoxazole–trimethoprim (SMZ-TMP) and quinolones. SMZ-TMP offers improved prophylaxis against gram-positive organisms compared with quinolones; quinolones are more effective prophylaxis against gram-negative infections. The Infectious Diseases Society of America (IDSA), American Society of Clinical Oncology, and National Comprehensive Cancer Network guidelines recommend fluoroquinolone prophylaxis in patients who are at high risk for "prolonged and profound" neutropenia.[17–19] None of these expert groups recommend routine antibiotic prophylaxis for low-risk patients because of the lack of a clear benefit on mortality rates and concerns regarding increasing antibiotic resistance. One exception is that SMZ-TMP is recommended for prophylaxis of *Pneumocystis jiroveci* (formerly *Pneumocystis carinii*) pneumonitis (PCP) in all at-risk patients (ie, hematopoietic cell transplant recipients, AIDS), regardless of the presence of neutropenia.[17–19]

A recent systematic review of 109 trials involving over 13,000 patients demonstrated a significant reduction in the rates of fever, infection, and infection-related and all-cause-mortality when afebrile neutropenic chemotherapy patients were given fluoroquinolone or TMP-SMZ prophylaxis compared to placebo or no prophylaxis.[21] However, most of these studies were conducted in patients with hematologic malignancies (an inherently high-risk group). Although two additional randomized trials in patients with both solid tumors and hematologic malignancies demonstrated lower rates of FN, infection, and hospitalization with oral prophylactic levofloxacin compared with placebo,[22–23] both were significantly criticized for methodological concerns and theoretical concerns about drug resistance and effectiveness of early treatment in low-risk patients. NCCN, ASCO, and IDSA only recommend prophylactic levofloxacin for patients with expected duration of neutropenia (defined as an ANC < 1000/μL [1.00×10^9/L]) for more than 7 days because of the:

- Unknown long-term consequences on the development of resistant organisms
- Emergence of *Clostridium difficile* and methicillin-resistant *Staphylococcus aureus* (MRSA) from fluoroquinolone overuse
- Ability to treat lower-risk patients on an outpatient basis, reducing the need for prophylactic antibiotics[17–19]

Therefore, the use of prophylactic quinolones in patients who are at high risk for infection (ie, hematologic malignancies receiving high-dose chemotherapy for allogeneic stem cell transplant) is reasonable; however, use should not be routine for low-risk patients. If prophylactic quinolone use is adopted, changes in local patterns of resistance should be closely monitored.

Colony-Stimulating Factors

The CSFs stimulate the maturation and differentiation of neutrophil precursors. Four agents are currently approved for use in the United States (Table 99–7). The prophylactic use of these agents decreases days of hospitalization and use of empiric antibiotics by shortening the duration of severe neutropenia (defined as ANC < 500/μL [0.50×10^9/L]). There is little to no effect on the depth of neutrophil nadir. A meta-analysis found that the use of prophylactic granulocyte CSF (either filgrastim or pegfilgrastim) results in a 46% risk reduction of FN and a 48% risk reduction in infectious mortality, although absolute differences are small (3.3% vs 1.7%).[24] A more recent meta-analysis also found that a small (7%) but statistically significant reduction in the relative risk of all-cause mortality was found for patients treated with G-CSF prophylactically, with the benefit (11%) greater for patients receiving dose-dense regimens.[25] It is critical to note that patients who receive these agents may still experience FN despite the risk reduction. The primary limitation of the use of these agents is cost and in fact, ASCO recently identified inappropriate G-CSF use as one of the "Top 5" interventions clinicians can make to reduce cancer care costs without compromising patient care.[26] CSFs are recommended beginning with the first cycle (primary prophylaxis) of chemotherapy when the risk of FN is greater than or equal to 20%, regardless of whether the goal of therapy is curative or palliative.[27] This is the point where the use of CSFs is cost effective when balanced against the cost of hospitalization and antimicrobials.

Table 99–7

Overview of CSF

Agent	Effector Cell(s)	Dosage	Common Adverse Effects	Comments[a]
Filgrastim (G-CSF, Neupogen; filgrastim-sndz, Zarzio; tbo-filgrastim, Granix)	Neutrophil	5 mcg/kg/day SC or IV or round to 300- *or* 480-mcg vial size	Bone pain (~25%)	Begin 1–3 days after chemotherapy
Pegfilgrastim (Neulasta; Neulasta On-body Injector)	Neutrophil	6 mg SC once *or* Apply 1 device once	Bone pain (~25%)	Self-mediated clearance via neutrophils Once per cycle dosing Administer 1–3 days after chemotherapy
Sargramostim (Leukine GM-CSF)	Neutrophil, eosinophil, macrophage	250 mcg/m^2/day SC or IV or round to 250- *or* 500-mcg vial size	First dose effect (hypotension, flushing) Low-grade fever Bone pain Injection site skin reaction	Indicated for use after induction chemotherapy in older patients with AML Limited experience and lack of FDA approval for prevention of FN

[a]No renal or hepatic dose adjustments are required for any product listed in this table.

AML, acute myeloid leukemia; FDA, Food and Drug Administration; FN, febrile neutropenia; G-CSF, granulocyte colony-stimulating factor; GM-CSF, granulocyte-macrophage colony-stimulating factor; SC, subcutaneous.

Secondary prophylaxis refers to the subsequent prophylactic use of a CSF after a patient has had an episode of FN. This strategy should be used especially when the chemotherapy is being given in patients with the intention of cure (ie, Hodgkin lymphoma, early breast cancer). In this circumstance, administration of full doses of chemotherapy on time without delays has been shown to improve patient outcomes.[24,25]

Although generally well tolerated, CSFs may cause bone pain in around 25% of patients. This may be managed with acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs), although attention to the platelet count is warranted with the use of NSAIDs. Sargramostim in particular may result in low-grade fever and myalgias, perhaps as a result of its wider pattern of effector cell stimulation.[27]

TREATMENT

Desired Outcomes

Because rapid death may occur with certain infections in neutropenic patients, prompt and emergent treatment is indicated. The primary goal is to prevent morbidity and mortality during the neutropenic period. This is accomplished by effectively treating subclinical or established infections.

General Approach to Treatment

KEY CONCEPT A risk assessment should be performed at presentation of FN to identify low-risk patients for potential outpatient treatment (see Table 99–6). Patients who do not meet low-risk criteria should be hospitalized for parenteral administration of broad-spectrum antibacterials. The IDSA has published evidence-based guidelines for the management of FN (Figure 99–1).[17] The choice of initial antimicrobial agent(s) depends on the following factors:

- Presence of a central venous catheter
- Drug allergies
- Concurrent renal dysfunction or use of nephrotoxic agents
- Use of prophylactic antibiotics
- Institutional and/or community susceptibility patterns
- Cost

KEY CONCEPT The administration of empiric therapy should begin immediately after cultures are taken. Therapy should not be withheld until after culture results are obtained.

As illustrated in Figure 99–1, specific criteria exist for the addition of vancomycin for coverage of resistant gram-positive organisms or agents for coverage of fungal infections. Additional agents are necessary in the setting of continued fever or declining clinical status in neutropenic patients. In general, all empiric therapy is continued until recovery of the ANC to levels above 500 cells/μL (0.500×10^9/L) in patients with negative culture results. If a specific etiology is identified, appropriate therapy should generally be continued until 7 days after neutropenia resolves. Specific regimens with recommended dosages are summarized in Table 99–8.

▶ *Nonpharmacologic Therapy*

Prevention of infection is key. Handwashing is critical in the prevention of disease transmission.[17–19] It is also important to ensure that patients receive annual influenza vaccines and have had a pneumonia and meningococcal vaccine, and neutropenic patients should avoid individuals with active respiratory infections.[17–19] Indwelling catheters are often sources of infection; however, the IDSA acknowledges that catheters do not always need to be removed.[17] Catheters should be removed in the following circumstances: established tunnel infection (subcutaneous tunnel or periport infection, septic emboli, hypotension associated with catheter use, or a nonpatent catheter), recurrent infection, or no response to antibiotics within 2 or 3 days.[17] Wound debridement should also be performed upon catheter removal. In the setting of peripheral blood stem cell or bone marrow transplant, the Centers for Disease Control and Prevention recommends the use of high-efficiency particulate air (HEPA) filtration systems in patient rooms, and the NCCN suggests that HEPA filters are reasonable to be considered for other patients who experience prolonged neutropenia.[17] HEPA filters are likely to be most useful in preventing mold infections. Although several small studies have attempted to evaluate the effectiveness of isolation of neutropenic patients as a mechanism for infection prevention, no clear data are available to support this practice, nor are neutropenic diets, footwear exchange, and other dietary interventions.[18–19]

▶ *Pharmacologic Therapy*

There are two primary choices for the initial management of high-risk FN: monotherapy and dual therapy (see Figure 99–1). Both regimens have been shown to be equivalent in randomized studies and meta-analyses. Monotherapy avoids the nephrotoxicity of the aminoglycosides and is potentially less expensive but lacks significant gram-positive coverage and may increase selection of resistant organisms. Dual therapy provides synergistic activity, decreased resistance, and dual coverage of *Pseudomonas aeruginosa* but also lacks gram-positive coverage and requires therapeutic monitoring for aminoglycosides. The choice between monotherapy and dual therapy is usually provider and institution preference, although dual therapy may be preferred in an acutely symptomatic patient (eg, hypotensive).

Vancomycin adds broad-spectrum gram-positive coverage; however, the increasing emergence of vancomycin-resistant organisms (ie, *Enterococcus* spp.) prompts conservative use of this medication. Vancomycin should only be included as part of the initial therapy if the following are present:

- Severe mucositis
- Soft tissue infection
- Quinolone or TMP-SMX prophylaxis
- Hypotension or septic shock
- Colonization with resistant gram-positive organisms (ie, MRSA)
- Evidence of central venous catheter infection[17]

Vancomycin may be added to the empiric regimen after 3 to 5 days in persistently febrile patients or if cultures reveal gram-positive organisms. Vancomycin should be changed if the gram-positive organism is susceptible to other antibacterials or discontinued in patients with persistent fever after 3 days with negative culture results. Linezolid, quinupristin–dalfopristin, tigecycline, and daptomycin may be used in cases of vancomycin-resistant organisms or if vancomycin is not an option because of drug allergy or intolerance.[17]

Empiric antifungal agents are typically added in persistently febrile patients after 5 to 7 days, especially if continued neutropenia is expected. Amphotericin B has historically been the drug of choice because of its broad-spectrum activity against both yeast (*Candida* spp.) and mold (*Aspergillus* spp.) infections. Because frequent toxicity (nephrotoxicity, infusion reactions) limits the use of amphotericin B, less toxic alternatives have been studied. Lipid formulations of amphotericin provide decreased toxicity,

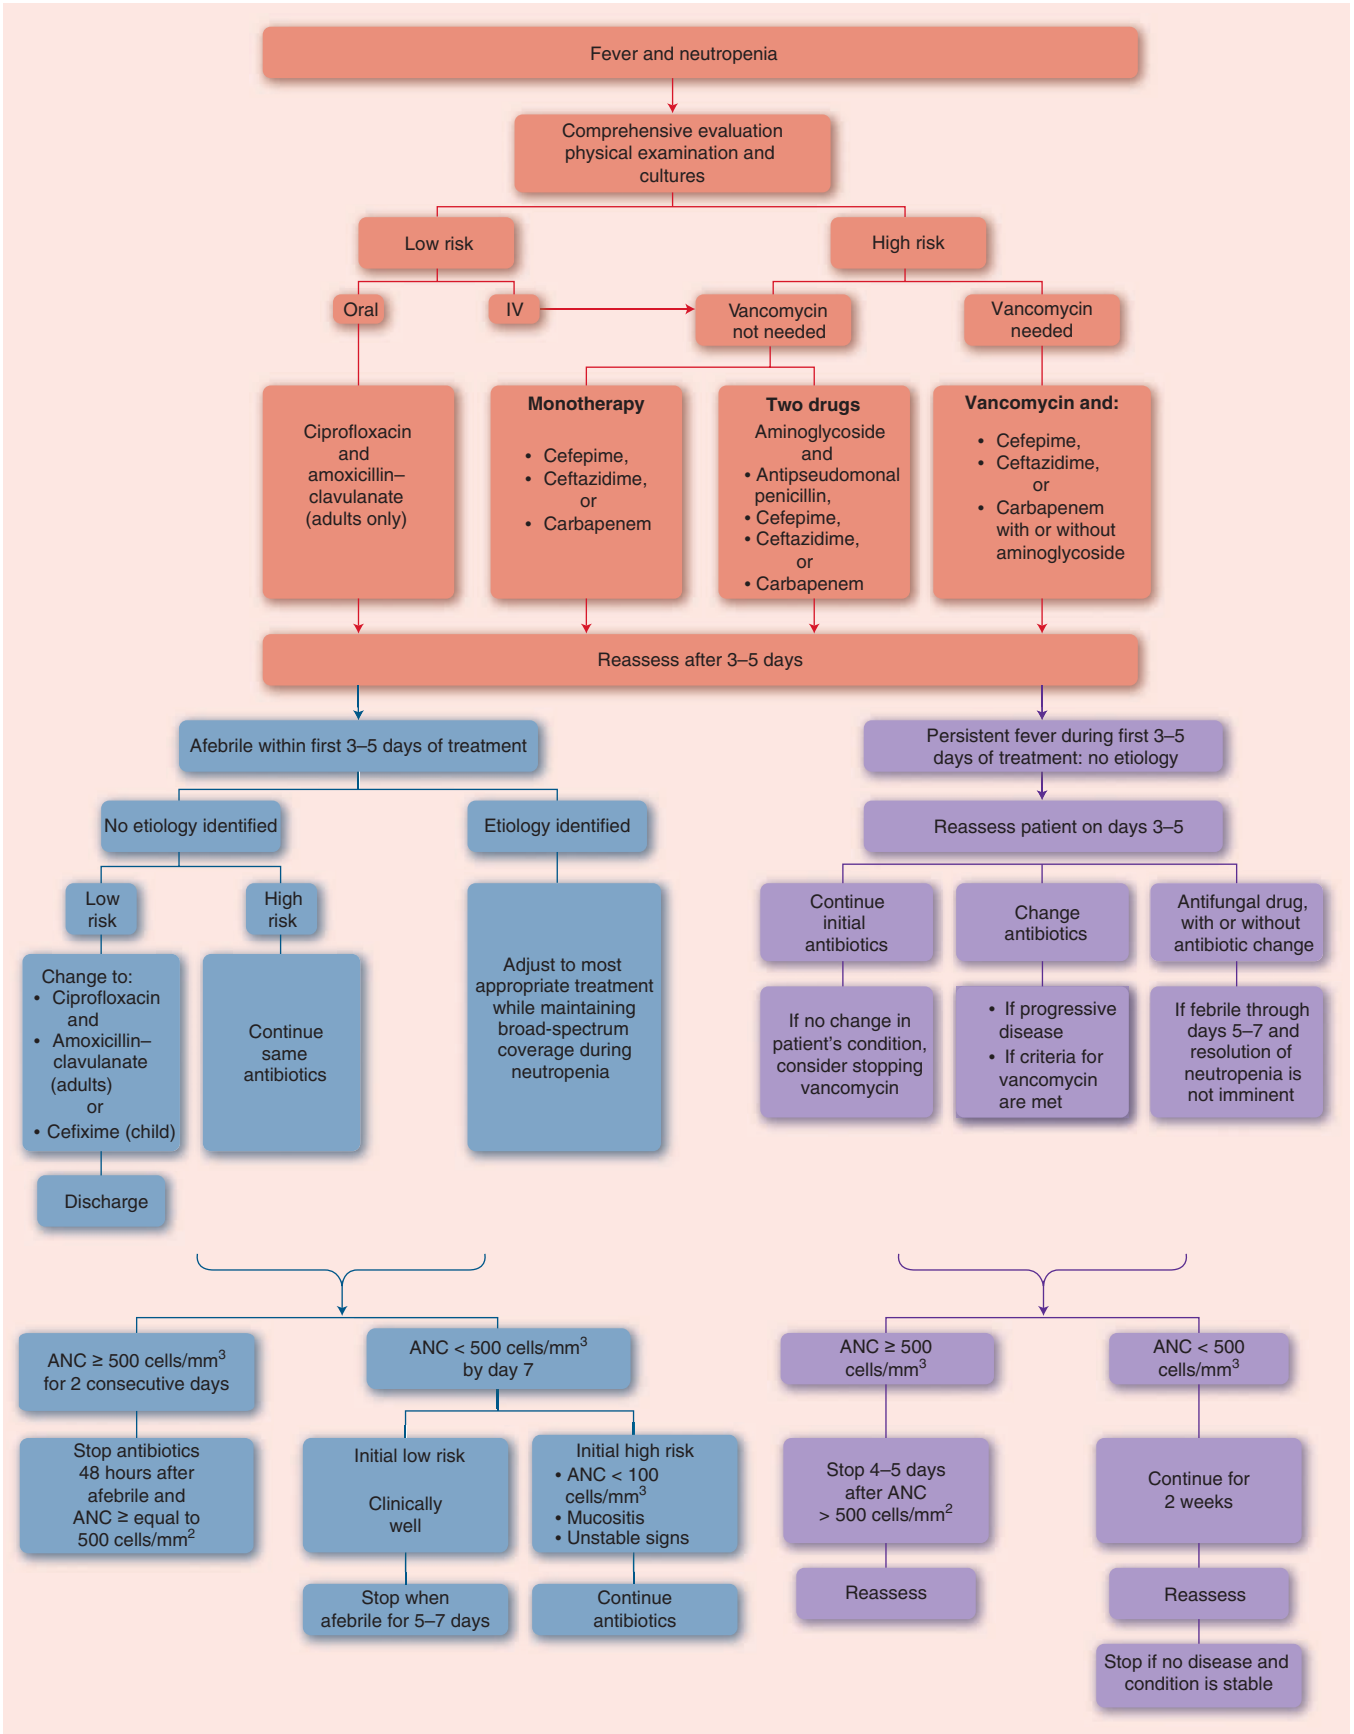

FIGURE 99–1. Management of febrile episodes in neutropenic cancer patients. (ANC, absolute neutrophil count.)

Table 99–8

Dosing Guidelines for Empiric Antimicrobial Agents in FN

Regimen Type	Agents and Dosing[a]	Comments
Antibacterial		
β-Lactam monotherapy	Cefepime 2 g IV every 8 hours Ceftazidime 2 g IV every 8 hours Imipenem 500 mg IV every 6 hours Meropenem 1 g IV every 8 hours Piperacillin–tazobactam 4.5 g IV every 6 hours	Although piperacillin–tazobactam is not recommended in the IDSA guidelines, recent data demonstrate equivalence to other monotherapy and dual therapy regimens. All these agents require renal dose adjustment, and none requires adjustment in hepatic dysfunction. All except meropenem require adjustment during dialysis.
Dual therapy with antipseudomonal β-lactam plus aminoglycoside	Cefepime, ceftazidime, imipenem, meropenem, piperacillin–tazobactam (above dosages), ticarcillin–clavulanic acid 3.1 g IV every 6 hours and gentamicin or tobramycin	Gentamicin or tobramycin 2 mg/kg loading dose followed by doses adjusted by serum concentrations; once-daily dosing of aminoglycosides may be used. Both gentamicin and tobramycin require renal dose adjustment but are dosed based on serum levels. Neither gentamicin nor tobramycin requires hepatic dose adjustment.
Empiric regimens containing vancomycin	Cefepime, ceftazidime, imipenem, meropenem (above dosages) and vancomycin 0.5–1 g every 6–12 hours with or without aminoglycoside	Vancomycin dosages may be adjusted based on serum levels and are adjusted for renal disease and dialysis. No dose adjustment is recommended for hepatic dysfunction.
Dual therapy containing fluoroquinolone	Ciprofloxacin 400 mg IV every 8 hours and piperacillin–tazobactam or ceftazidime (above dosages)	Cannot be used in patients who receive fluoroquinolone prophylaxis. Dose adjusted in renal disease and dialysis but not for hepatic dysfunction.
Low-risk po regimen	Ciprofloxacin 750 mg po every 12 hours and amoxicillin–clavulanate 500–875 mg po every 12 hours	For patients with MASCC scores ≥ 21 not receiving fluoroquinolone prophylaxis. Amoxicillin–clavulanate is adjusted in renal disease and dialysis but not hepatic dysfunction.
Antifungal		
Amphotericin B deoxycholate	0.5–1 mg/kg IV daily	Premedication with acetaminophen and diphenhydramine; 500 mL normal saline boluses before and after. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Liposomal amphotericin B	3 mg/kg IV daily	Lower incidence of nephrotoxicity and infusion reactions; more expensive. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis.
Caspofungin	70 mg/kg IV loading dose on day 1 followed by 50 mg/kg IV daily	Dosage adjustment in hepatic dysfunction but not for renal disease or dialysis.
Voriconazole	6 mg/kg IV loading dose every 12 hours on day 1 followed by 4 mg/kg po or IV every 12 hours	Dosage adjustment in hepatic dysfunction; IV formulation contraindicated if creatinine clearance < 50 mL/min (0.83 mL/s); multiple drug interactions.
Posaconazole	Prophylactic: 200 mg po three times a day with food 300 mg IV twice a day on day 1, then 300 mg IV daily Salvage: 200 mg po four times a day with food; then 400 mg po two times a day when stable	Not FDA-approved for primary or salvage therapy for invasive fungal infections but used clinically; no dose adjustments required for renal or hepatic dysfunction or during dialysis.

[a]Dosing for adult patients; adjust doses for renal dysfunction.

AML, acute myeloid leukemia; FDA, Food and Drug Administration; IDSA, Infectious Diseases Society of America; IV, intravenous; MDS; myelodysplastic syndrome; NCCN, National Comprehensive Cancer Network; po, oral.

and liposomal amphotericin B (AmBisome) has been shown to be equivalent to conventional amphotericin B as empiric therapy but is significantly more expensive. Caspofungin is equivalent with less toxicity compared with liposomal amphotericin B in a randomized trial and is FDA-approved for this indication.[17,19] Voriconazole is equivalent to liposomal amphotericin in mortality, but response was improved in those receiving liposomal amphotericin. Voriconazole does not have an indication, but it is sometimes used. Itraconazole has also been used in some institutions, but its use is complicated by poor bioavailability of oral preparations and numerous drug interactions. Posaconazole is FDA-approved for the prevention of invasive *Aspergillus* and *Candida* infections in patients at high-risk due to being severely immunocompromised (ie, prolonged neutropenia; hematopoietic stem cell transplant patients with graft-versus-host-disease). The oral suspension of posaconazole is also approved for the treatment of local oropharyngeal Candidiasis. It is not FDA-approved as primary or salvage therapy for the treatment of invasive fungal infections but it is approved by the European Union for invasive aspergillosis and other fungal infections that are refractory to standard antifungal agents.

As stated earlier, low-risk patients fulfilling the MASCC criteria (see Table 99–6) may be treated empirically as an outpatient with a regimen combining amoxicillin–clavulanic acid

and ciprofloxacin. Ciprofloxacin and clindamycin are reasonable alternatives for penicillin-allergic patients.

The CSFs should not routinely be used for treatment of FN in conjunction with antimicrobial therapy.[17,19] However, the use of CSFs in certain high-risk patients with hypotension, documented fungal infection, pneumonia, or sepsis is reasonable. A meta-analysis demonstrated that hospitalization and neutrophil recovery are shortened and infection-related mortality is marginally improved with CSF prophylaxis in high-risk patients.[24] As with prophylactic use of these agents, cost considerations limit their use to high-risk patients.

OUTCOME EVALUATION

The success of the treatment of FN depends on the adequate recovery of the ANC and either optimal antimicrobial coverage of identified organisms or empiric coverage of unidentified organisms. Monitor the complete blood count (CBC) with differential and T_{max} (maximum temperature during previous 24 hours) daily. Assess renal and hepatic function at least twice weekly, especially in patients receiving nephrotoxic agents. Vital signs should be taken every 4 hours. Follow up on blood and urine culture results daily because many cultures do not become positive for several days. Assess the patient daily for pain that may indicate an infectious source. Conduct daily physical examination of common sites of infection. Repeat cultures and chest x-ray in persistently febrile patients and culture developing sources of infection (ie, stool cultures for diarrhea).

CARDIOVASCULAR COMPLICATIONS: SUPERIOR VENA CAVA SYNDROME (SVCS)

INTRODUCTION

Superior vena cava syndrome (SVCS) is a relatively rare complication that may occur in patients with cancer. SVCS is rarely immediately life threatening except in patients with airway compromise and/or laryngeal or cerebral edema. However, rapid recognition of typical presenting symptoms facilitates referral for tissue diagnosis (if unknown) and treatment.

EPIDEMIOLOGY AND ETIOLOGY

SVCS occurs in around 15,000 patients per year, 90% of which are caused by malignancy. Specific cancers most commonly associated with SVCS are listed in Table 99–9. Lung cancer is the most frequent cause, of which small cell lung cancer (SCLC) is the most frequent subtype associated with SVCS. This is thought to be because of its predilection for the central and perihilar areas of the lung. Interestingly, right-sided lung cancers are four times more likely than left-sided lesions to cause SVCS. Mediastinal masses from lymphomas are the second most common cause.

The most common nonmalignant etiology of SVCS is catheter-related thrombosis, primarily caused by the increasing use of central access devices. Other causes include benign teratoma, tuberculosis, silicosis, and sarcoidosis.

Table 99–9

Tumors Most Commonly Associated with SVCS

Cause	Frequency (%)
Non–small cell lung cancer	50
Small cell lung cancer	22
Lymphoma	12
Metastatic cancer (especially breast)	9
Germ cell tumor	3
Thymoma	2
Mesothelioma	1

Data from Wilson LD, Detterbeck FC, Yahalom J. Superior vena cava syndrome with malignant causes. N Engl J Med. 2007;356(8):1862–1869.

Clinical Presentation and Diagnosis of SVCS[28]

General

- Presentation depends on the degree of SVCS obstruction.
- Almost complete obstruction is necessary to demonstrate symptoms.

Signs and Symptoms

- Most common: swelling of face, neck, and upper extremity edema; dyspnea; cough; dilated upper extremity veins; orthopnea
- Less common: hoarseness, dysphagia, dizziness, headache, lethargy, chest pain
- Patients with elevated ICP may have mental status changes
- Patients with airway obstruction may have shortness of breath

Diagnostic Tests

- Tissue biopsy to determine underlying malignancy (if unknown), chest x-ray, CT scan, bronchoscopy, mediastinoscopy

PATHOPHYSIOLOGY

The SVC is the primary drainage vein for blood return from the head, neck, and upper extremities. It is a relatively thin-walled vein that is particularly vulnerable to obstruction from adjacent tumor invasion or thrombosis. The obstruction leads to elevated venous pressure, although collateral veins partially compensate. This is one reason for the relatively slow onset of the classic symptoms of SVCS. In fact, 75% of patients have signs and symptoms for more than 1 week before seeking medical attention.[28]

CLINICAL PRESENTATION AND DIAGNOSIS TREATMENT

Desired Outcomes

KEY CONCEPT The primary goal of treatment of SVCS is to relieve the obstruction of the SVC by treating the underlying malignancy. In the case of SVCS caused by thrombosis, the goal is to eliminate the thrombus and prevent further clot formation. Resolution of the obstruction will rapidly relieve symptoms and restore normal SVC function. The final goal of therapy is to avoid potentially fatal complications of SVCS such as cerebral edema from rapid increases in intracranial pressure (ICP) and intracranial thrombosis or bleeding.

General Approach to Treatment

Because the majority of SVCS is not immediately life threatening, a tissue diagnosis (if malignancy is unknown) to specifically identify the cancer origin is critical because treatment approaches vary considerably according to tumor histology. Thus, therapy can typically be withheld until a definitive tissue diagnosis is established. While biopsy results are pending, supportive measures such as head elevation, diuretics, corticosteroids, and supplemental oxygen may be used.

▶ *Nonpharmacologic Therapy*

Radiation therapy is the treatment of choice for chemotherapy-resistant tumors such as non–small cell lung cancer (NSCLC) or in chemotherapy-refractory patients with SVCS. Between 70% and 90% of patients experience relief of symptoms. Radiation therapy may also be combined with chemotherapy for chemotherapy-sensitive tumors such as SCLC and lymphoma. In the rare emergency situations of airway obstruction or elevated ICP, empiric radiotherapy before tissue diagnosis should be used. In most patients, symptoms resolve within 1 to 3 weeks.

Surgical options for the management of SVCS include stent placement and surgical bypass. SVC stenting may provide longer-term relief of symptoms than radiotherapy, so it is often used in the palliative care setting when chemotherapy has failed.[28] One disadvantage of SVC stenting is the need for anticoagulation, especially in patients at high risk for thrombosis. The role of surgical bypass is limited to patients with complete SVC obstruction or patients who are refractory to chemotherapy and radiotherapy; thus, it is rarely indicated.

▶ *Pharmacologic Therapy*

LO 5 Cytotoxic chemotherapy is the treatment of choice for chemotherapy-sensitive tumors such as SCLC and lymphoma. As indicated earlier, chemotherapy may also be combined with radiotherapy, especially in patients with lymphoma who have bulky mediastinal lymphadenopathy.

Corticosteroids play a key role in the management of SVCS, particularly in cases of lymphoma, because these tumors inherently respond to corticosteroid therapy. They are also helpful in the setting of respiratory compromise. Corticosteroids benefit patients who are receiving radiation therapy by reduction of local radiation-induced inflammation and patients with increased ICP. Dexamethasone 4 mg IV or by mouth every 6 hours is a frequently used regimen. The dosage should be tapered upon completion of radiation therapy or resolution of symptoms.

The role of diuretics in the management of SVCS is controversial. Although patients may derive symptomatic relief from edema, complications such as dehydration and reduced venous blood flow may exacerbate the condition. If diuretics are used, furosemide is most frequently used with diligent monitoring of the patient's fluid status and blood pressure.

In the case of thrombosis-related SVCS, anticoagulation is controversial because there is a lack of survival benefit. However, thrombolytics (ie, alteplase) and anticoagulation with heparin and warfarin may be beneficial in patients with thrombosis caused by indwelling catheters if used within 7 days of onset of symptoms, although catheter removal may be required.[28]

OUTCOME EVALUATION

The major measure of outcome of treatment of SVCS is the relief of symptoms, regardless of the therapy used.

NEUROLOGIC COMPLICATIONS: SPINAL CORD COMPRESSION

INTRODUCTION

Although not typically life threatening, spinal cord compression is a true oncologic emergency because delays in treatment by mere hours may lead to permanent neurologic dysfunction. Practitioners must quickly recognize the signs and symptoms of this condition to facilitate rapid management strategies.

EPIDEMIOLOGY AND ETIOLOGY

LO 1 Around 20,000 cancer patients experience spinal cord compression in the United States every year, most of which involves the thoracic spine (~70%). Cancers that inherently metastasize to the bone (ie, breast, prostate, and lung) are the most frequent underlying malignancies associated with this complication. Most spinal cord compression occurs in patients with a known malignancy; however, 20% to 25% of cases occur as the initial presentation of cancer, especially in patients with non-Hodgkin lymphoma, multiple myeloma, and lung cancer.[29] Recently, predictive models have been developed to predict survival from SCC from myeloma and NSCLC.[30,31]

PATHOPHYSIOLOGY

The spinal cord emerges from the brain stem at the base of the skull and terminates at the second lumbar vertebra. The thoracic spine is most vulnerable to cord compression because of natural kyphosis and because the width of the thoracic spinal canal is the smallest

Clinical Presentation and Diagnosis of Spinal Cord Compression

General

- Once neurologic deficits appear, progression to irreversible paralysis may occur within hours to days.
- Around 30% to 50% of patients present with multiple sites of spinal involvement.

Signs and Symptoms

- Back pain is present in more than 90% of patients.
- Initially localized and increases in intensity over several weeks
- Aggravated by movement, supine positioning, coughing, sneezing, neck flexion, straight leg raise, Valsalva maneuver, palpation of spine
- Sensory deficit
- Cervical spine compression: quadriplegia
- Thoracic spine compression: paraplegia
- Upper lumbar spine compression: bowel and bladder dysfunction (constipation and urinary retention) and abnormal extensor plantar reflexes
- Weakness

Diagnostic Tests

- MRI with gadolinium enhancement is the gold standard.
- X-rays may be helpful to identify bone abnormalities.

among the vertebrae. Most spinal cord compression is caused by adjacent vertebral metastases that compress the spinal cord or from pathologic compression fracture of the vertebra. This results in significant edema and inflammation in the affected area.

Patients with spinal cord compression are in acute, severe back and/or neck pain and may present to the emergency department for evaluation. Diagnosis is made based on symptoms and imaging studies that show fractured vertebrae.

TREATMENT

Desired Outcomes

KEY CONCEPT Because patients with cancer and spinal metastases are generally incurable, the primary goal of treatment of spinal cord compression is palliation. The most important prognostic factor for patients presenting with spinal cord compression is the degree of underlying neurologic dysfunction. Only around 10% of patients who present with paralysis are able to ambulate after treatment.[29] Therefore, the goals of treatment are recovery of normal neurologic function, local tumor control, pain control, and stabilization of the spine. Therapeutic options depend primarily on the following factors:

- Underlying malignancy
- Prior therapies
- Stability of the spine at presentation
- Overall patient prognosis

▶ *Nonpharmacologic Therapy*

Radiation therapy at 20 Gy in five daily fractions or 30 Gy in 10 daily fractions is generally considered to be the treatment of choice for most patients. Exceptions to this include patients with prior radiation to the treatment site and patients with inherently radio-resistant tumors (ie, melanoma, renal cell carcinoma). The radiation field should include two vertebral bodies above and below the involved area.

Surgery for spinal cord compression typically involves either laminectomy for posterior lesions or decompression with fixation. Surgery is the treatment of choice for the following patients: (a) patients with unstable spine requiring stabilization, (b) immediately impending sphincter dysfunction requiring rapid spinal decompression, (c) patients who do not respond to or have received their maximum dose of radiotherapy, and (d) direct compression of the spinal cord caused by spinal bony fragments.[29] Surgery followed by radiation therapy may be superior to radiotherapy alone in terms of increased ambulation time after treatment, maintenance of continence, and rates of nonambulatory patients becoming ambulatory.[32] Surgery is also useful for establishing a tissue diagnosis in cases of unknown malignancy. Overall, the risks and benefits of surgery must be weighed against the expected prognosis of the patient in light of the significant rehabilitation required after surgery.

▶ *Pharmacologic Therapy*

LO 5 Corticosteroids play a vital role in the management of spinal cord compression. Dexamethasone is most frequently used to reduce edema, inhibit inflammation, and delay the onset of neurologic complications. Dexamethasone has been shown to improve ambulation in combination with radiation compared with radiation alone.[29] Significant controversy exists regarding the optimal dosing of dexamethasone though both the UK and Canadian guidelines recommend 16 mg orally or IV immediately, followed by a short course of 8 mg by mouth or intravenously twice daily. Higher doses may be used in cases of rapidly progressing symptoms, but adverse effects, including GI bleeding and psychosis, are more severe. Steroids should be continued during radiation therapy and then tapered appropriately.

LO 5 Pain management is also of critical importance in patients with spinal cord compression. Although dexamethasone will provide some benefit, opioid analgesics should also be used and titrated rapidly to achieve adequate pain control.

Clinical Presentation and Diagnosis of Brain Metastasis

General

- Almost all patients with brain metastases are symptomatic.
- New cerebral neurologic symptoms in a cancer patient should initiate evaluation for brain metastases.
- Other causes of brain lesions, including hemorrhage, infection, and infarct, should be ruled out.

Signs and Symptoms

- Mental status changes (most common): loss of consciousness, irritability, confusion
- Hemiparesis, aphasia, papilledema, weakness, seizure, nausea, and vomiting
- Headache: may be of gradual onset or sudden in the case of hemorrhage

Diagnostic Tests

- MRI with contrast enhancement is the gold standard.
- CT scans may be used in patients with pacemakers, but may miss small metastases.

OUTCOME EVALUATION

Patients who receive definitive treatment with radiation and/or surgery generally derive benefit within days.

COMPLICATIONS OF BRAIN METASTASES

INTRODUCTION

Brain metastases are among the most feared complications of cancer and generally carry a poor prognosis. One serious consequence of brain metastases is elevated ICP, which can rapidly lead to fatal intracranial herniation and death. Rapid identification of the signs and symptoms of brain metastases is critical to improve long-term outcome and avoid mortality. The signs and symptoms of brain metastasis can be confused with common psychological distress or other neurologic problems (eg, headaches) that may go unrecognized. It is important that patients who are suspected to have brain metastasis are quickly referred for appropriate management.[33]

EPIDEMIOLOGY AND ETIOLOGY

Brain metastasis is the most common neurologic complication seen in patients with cancer. Approximately 170,000 patients develop brain metastases in the United States each year.[33] Many malignancies are frequently associated with brain metastases (Table 99–10). Although melanoma is the tumor type most likely

Table 99–10

Cancers Most Frequently Associated with Brain Metastases

Type of Cancer	Frequency (%)
Lung cancer	18–64
Breast cancer	2–21
Melanoma	4–16
Colorectal cancer	2–11
Hematologic malignancies (ie, leukemia)	~10 (primarily caused by leptomeningeal spread)

Data from Lin X, DeAngelis LM. Treatment of brain metastases. J Clin Oncol. 2015;33(30):3475–3484.

to metastasize to the brain, brain metastases caused by lung and breast cancer are seen more often because they are among the most common cancers. In addition, brain metastases may be diagnosed at the same time as the primary malignancy in around 20% of cases.[33] Around 80% of brain metastases occur in the cerebral hemispheres, 15% in the cerebellum, and 5% in the brain stem.

PATHOPHYSIOLOGY

A delicate balance of normal pressure is maintained in the brain and spinal cord by brain, blood, and cerebrospinal fluid. Because the brain is contained within a confined space (skull), any foreign mass contained within that space causes adverse sequelae. This results in either destruction or displacement of normal brain tissue with associated edema. Most brain metastases occur through hematogenous spread of the primary tumor and around 80% of patients have multiple sites of metastases within the brain.

TREATMENT

Desired Outcomes

Therapeutic modalities used for the management of brain metastases may be divided into symptomatic management and definitive management. KEY CONCEPT The goals of treatment of brain metastases are to manage symptoms by reducing cerebral edema, treat the underlying malignancy both locally and systemically, and improve survival.

General Approach to Treatment

Patients with brain metastases have a poor prognosis. Untreated patients generally have a median survival of 1 month. Recent advances in drug therapy and radiation/stereotactic radiosurgery now yield median survival times as long as 13.5 months in some patients with solitary brain lesions and good performance status.[33] The choice of treatment depends primarily on the status of the patient's underlying malignancy and the number and sites of brain metastases. The primary definitive treatments for brain metastases are surgery and radiation therapy. Pharmacologic modalities such as corticosteroids and antiepileptics are primarily used to control symptoms, although cytotoxic chemotherapy plays a limited role in the management. Monoclonal antibodies have a large molecular size and therefore would not be expected to cross the blood-brain-barrier (BBB); however, BBB permeability may be enhanced due to physical disruption from the brain metastasis itself and some of the targeted oral therapies have better BBB penetration.[33]

LO 5

▶ *Nonpharmacologic Therapy*

LO 5

Radiation therapy is the treatment of choice for most patients with brain metastases. Most patients receive whole-brain radiation (WBRT) because the majority of brain metastases are multifocal. Another method known as stereotactic radiosurgery provides intense focal radiation, typically using a **linear accelerator** or **gamma knife**, in patients who cannot tolerate surgery or have lesions that are surgically inaccessible (ie, brain stem). Stereotactic radiosurgery is also often used for selected patients with up to three lesions that are each less than 4 cm.[33] WBRT can cause long-term problems with memory and cognitive function but this risk is less than that seen with declines due to brain disease and thus the benefits of WBRT outweigh the risks in appropriate patients.[33] Because brain metastases can occur in up to 50% of patients with small cell lung cancer, prophylactic cranial irradiation (PCI) is recommended in patients with limited stage disease with good performance status who at least partially respond to chemotherapy to both prevent the development of brain metastases and to prolong survival; there is conflicting evidence on the role of PCI in extensive stage SCLC though generally many patients will be offered treatment.[34] Although other cancers can metastasize to the brain, the benefits of routine prophylactic cranial irradiation have only been demonstrated in studies conducted in patients with small cell lung cancer.[34] In fact, a recent meta-analysis reported that prophylactic cranial irradiation may reduce overall survival when used in NSCLC patients even though it reduced brain metastases in these patients.[35]

LO 5

Surgery plays a key role in the management of patients with brain metastases, particularly in patients whose systemic disease is well controlled and in patients with solitary lesions. Surgery may also benefit patients with multiple metastatic sites who have a single dominant lesion with current or impending neurologic sequelae.

▶ *Pharmacologic Therapy*

LO 5

Corticosteroids are a mainstay in the management of brain metastases. They reduce edema that typically surrounds sites of metastases thereby reducing ICP. A loading dose of dexamethasone 10 mg to 24 mg IV followed by 4 mg by mouth or IV every 6 hours or 8 mg by mouth twice daily is typically used. Symptom relief may occur shortly after the loading dose, although the maximum benefit may not be seen for several days (after definitive therapy).[36]

LO 5

Mannitol is an agent that may be used in patients with impending cerebral herniation. Mannitol is an osmotic diuretic that shifts brain osmolarity from the brain to the blood. Doses of 100 g (1–2 g/kg) as an IV bolus should be used. Repeated doses are typically not recommended because mannitol may diffuse into brain tissue, leading to rebound increased ICP.[36]

Around 20% patients with brain metastases may present with seizures and require anticonvulsant therapy. Phenytoin is the most frequently used agent with a loading dose of 15 mg/kg followed by 300 mg by mouth daily (titrated to therapeutic levels between 10 and 20 mcg/mL [40 and 79 μmol/L]). Diazepam 5 mg IV may be used for rapid control of persistent seizures. Prophylactic anticonvulsants have frequently been used; however, a systematic review did not support their use.[37] Thus, because adverse effects and drug interactions are common, the routine use of prophylactic anticonvulsants is not recommended.

OUTCOME EVALUATION

The success of therapy is based on the ability to decrease symptoms, treat the underlying sites of disease within the brain, and prolong survival.

UROLOGIC COMPLICATIONS: HEMORRHAGIC CYSTITIS

INTRODUCTION

LO 1

Hemorrhagic cystitis is defined as acute or insidious bleeding from the lining of the bladder. Although therapy with certain medications is the most common cause, it is also the most preventable. Once it occurs, hemorrhagic cystitis causes significant morbidity and mortality rates between 2% and 4%. This section focuses on preventive strategies for chemotherapeutic causes of hemorrhagic cystitis.

EPIDEMIOLOGY AND ETIOLOGY

Numerous etiologies have been linked to hemorrhagic cystitis (Table 99–11).[38] Of these, the oxazaphosphorine alkylating agents (cyclophosphamide and ifosfamide) are most frequently implicated. Hemorrhagic cystitis is the dose-limiting toxicity of ifosfamide and predisposes patients with bladder cancer. Incidence rates vary considerably but generally range between 20% and 25% with high-dose (300 mg/m^2 or more) cyclophosphamide in the absence of prophylactic measures and even more commonly with ifosfamide.[38] Chronic, low-dose oral cyclophosphamide as typically used in autoimmune disorders and chronic lymphocytic leukemia is infrequently associated with hemorrhagic cystitis. Cystitis occurs in 80% of patients treated with intravesicle bacillus Calmette-Guerin (BCG) for bladder cancer, with 20% also experiencing hematuria.[38]

Around 20% patients receiving pelvic irradiation may experience hemorrhagic cystitis, especially with concurrent cyclophosphamide. Notably, this toxicity can present acutely or long after treatment with radiation has ended (up to 15 years).[38] Viral infections commonly associated with this condition most frequently occur in bone marrow transplant recipients who may also receive cyclophosphamide.

PATHOPHYSIOLOGY

Cyclophosphamide- or ifosfamide-induced damage to the bladder wall is primarily caused by their shared metabolite known as acrolein. Acrolein causes sloughing and inflammation of the bladder lining, leading to bleeding and hemorrhage. This is most common when urine output is low because higher concentrations of acrolein come into contact with the bladder urothelium for longer periods of time. Radiation treatment directly damages the protective glycosaminoglycan layer of the bladder epithelium.[38]

Table 99–11

Primary Causes of Hemorrhagic Cystitis

Pharmacologic	Nonpharmacologic
Cyclophosphamide	Pelvic irradiation
Chronic low doses	Viral infection
High doses used in BMT	CMV
Ifosfamide	Papovavirus
Intravesicular thiotepa	Herpes simplex virus
Chronic oral busulfan	Adenovirus
Anabolic steroids	

BMT, bone marrow transplantation; CMV, cytomegalovirus.

Data from Payne H, Adamson A, Bahl A, et al. Chemical- and radiation-induced hemorrhagic cystitis: current treatments and challenges. BJU Int. 2013;112(7):885–897.

Clinical Presentation and Diagnosis of Hemorrhagic Cystitis

General

- Presentation may be mild (microscopic hematuria) or severe (massive hemorrhage) and develops during or shortly after chemotherapy infusion.
- Presentation may be delayed when associated with pelvic radiation.

Signs and Symptoms

- Suprapubic pain and cramping, urinary urgency and frequency, dysuria and burning, hematuria
- Urinary retention leading to hydronephrosis and renal failure may occur if large blood clots obstruct the ureters or bladder outlet.

Laboratory Tests

- Urine dipsticks for blood
- Urinalysis reveals more than three RBCs per high-power field: microscopic hematuria
- CBC with differential, prothrombin time or international normalized ratio, activated partial thromboplastin time, blood urea nitrogen, creatinine

PREVENTION

KEY CONCEPT The use of effective prevention strategies can decrease the incidence of hemorrhagic cystitis to fewer than 5% in patients receiving cyclophosphamide or ifosfamide. Three methods are used to reduce the risk: administration of Mesna (2-mercaptoethane sulfonate), hyperhydration, and bladder irrigation with catheterization. Mesna is the primary method used with ifosfamide; all three strategies are used with cyclophosphamide.

LO 3

Mesna is a thiol compound that is rapidly oxidized in the bloodstream after administration to dimesna, which is inactive. However, after being filtered through the kidneys, dimesna is reduced back to Mesna, which binds to acrolein, leading to its inactivation and excretion. ASCO has published evidence-based guidelines for the dosing and administration of Mesna (Table 99–12).[39] The dose of oral Mesna must be double the IV dose because of its oral bioavailability between 40% and 50%. Because the half-life of Mesna (~1.2 hours) is much shorter than that of ifosfamide or cyclophosphamide, prolonged administration of Mesna beyond the end of the chemotherapy infusion is critical (Figure 99–2). Patients should receive at least 2 L of IV fluids beginning 12 to 24 hours before and ending 24 to 48 hours after the last dose of chemotherapy.[38,39]

Hyperhydration with normal saline at 3 L/m^2/day with IV furosemide to maintain urine output greater than 100 mL/hour has also been used with cyclophosphamide. Continuous bladder

Table 99–12

ASCO Guidelines for the Use of Mesna with Ifosfamide and High-Dose Cyclophosphamide

Chemotherapy Schedule	Dosing Schedule for Mesna	Comments
Low-dose ifosfamide < 2 g/m²/day	Oral: 100% of total daily dose of ifosfamide given 20% IV: 15 minutes before and 40% po 2 and 6 hours after start of ifosfamide	Available in 400-mg tablets Peak urinary thiol concentrations with oral Mesna is at 3 hours If patient vomits within 2 hours of administration, repeat dose po or IV
Standard-dose ifosfamide equal to 2.5 g/m²/day	Bolus: 60% of total daily dose of ifosfamide given IV in 20% increments 15 minutes before and 4 and 8 hours after start of ifosfamide Infusion: 60% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% by continuous infusion during and for 12–24 hours after end of ifosfamide	Peak urinary thiol concentrations with IV Mesna is at 1 hour Compatible with ifosfamide and cyclophosphamide by Y-site administration or when admixed in the same bag
High-dose ifosfamide > 2.5 g/m²/day	Lack of evidence for dosing, but higher doses for longer duration recommended based on longer half-life of ifosfamide at high doses	
Standard-dose cyclophosphamide	Use of Mesna is not routinely necessary	
High-dose cyclophosphamide (BMT)	Bolus: 40% of cyclophosphamide dose given IV at hours 0, 3, 6, and 9 after cyclophosphamide Infusion: 100% of cyclophosphamide dose given by continuous infusion until 24 hours after cyclophosphamide	Should be combined with saline diuresis (1.5 L/m²/day of normal saline)

ASCO, American Society of Clinical Oncology; BMT, bone marrow transplantation; IV, intravenous; Mesna, 2-mercaptoethane sulfonate; po, oral.

Data from Hensley ML, Hagerty KL, Kewalramani T, et al. American Society of Clinical Oncology 2008 clinical practice guideline update: use of chemotherapy and radiation therapy protectants. J Clin Oncol. 2009;27(1):127–145.

irrigation by catheterization uses normal saline at 250 to 1000 mL/hour to flush acrolein from the bladder. Mesna is equivalent to both strategies in patients receiving high-dose cyclophosphamide and avoids the discomfort and infection risk with catheterization and the intensity of hyperhydration. Thus, mesna is the preventive method of choice.[38,39]

TREATMENT

Desired Outcomes

If hemorrhagic cystitis occurs, the goals of treatment are to decrease exposure to the offending etiology, establish and maintain urine outflow, avoid obstruction and renal compromise,

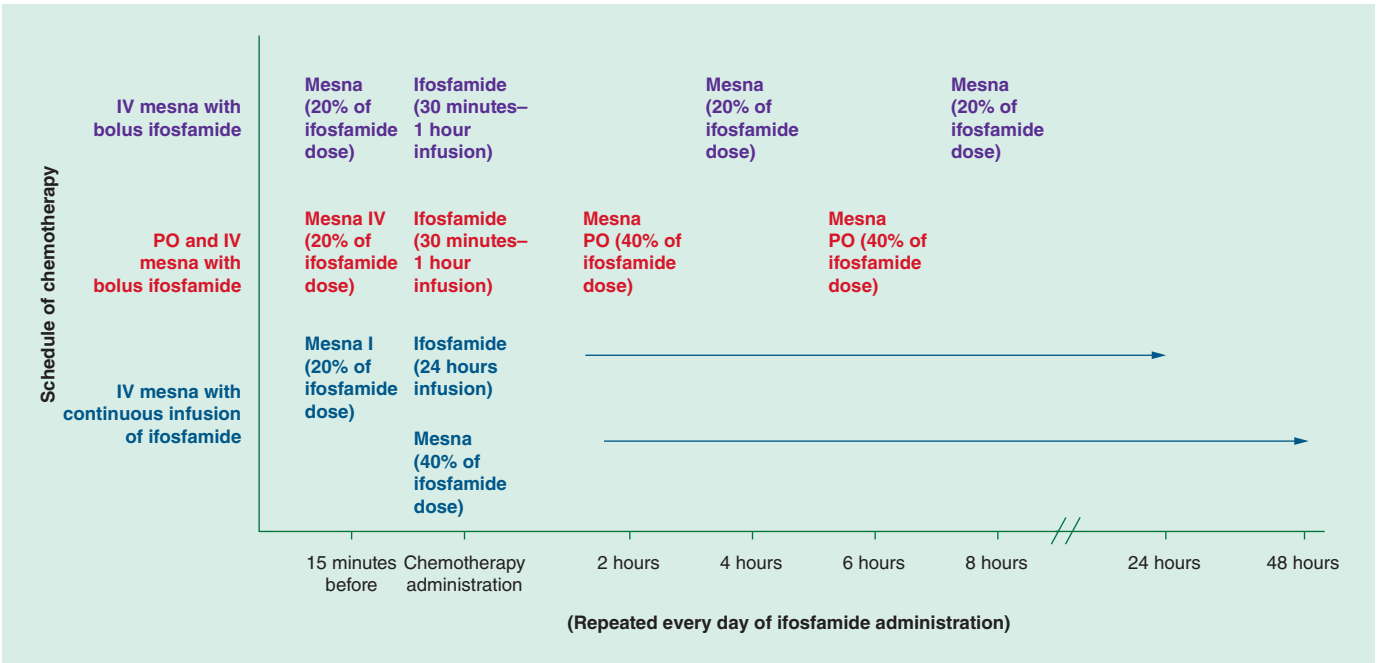

FIGURE 99–2. Examples of mesna (2-mercaptoethane sulfonate) administration with ifosfamide. (IV, intravenous; po, oral.)

and maintain blood and plasma volume. Restoration of normal bladder function is the ultimate goal following acute treatment.

General Approach to Treatment

The treatment of hemorrhagic cystitis first involves discontinuation of the offending agent. Agents such as anticoagulants and inhibitors of platelet function should also be discontinued. IV fluids should be aggressively administered to irrigate the bladder. Blood and platelet transfusions may be necessary to maintain normal hematologic values. Pain should be managed with opioid analgesics. Local intravesicular therapies may be necessary if hematuria does not resolve[38] (Figure 99–3).

▶ *Nonpharmacologic Therapy*

A large-diameter, multihole urethral catheter should be inserted to facilitate saline lavage and evacuation of blood clots. Surgical removal of blood clots under anesthesia may be required if saline lavage is ineffective. Active bleeding from isolated areas may be cauterized with an electrode or laser. In severe cases that are unresponsive to local or systemic pharmacologic intervention, urinary diversion with percutaneous nephrostomy or surgical removal of the bladder may be required.[38]

▶ *Pharmacologic Therapy*

LOS

A number of local or systemic agents are used in the treatment of hemorrhagic cystitis.[38] Local (direct instillation into the bladder), one-time administration of hemostatic agents such as alum, prostaglandins, silver nitrate, and formalin may be used; however, general anesthesia is required, especially with formalin, because of pain. Aluminum toxicity has been noted with alum irrigation, particularly in children. Systemic agents, including estrogens, vasopressin, aminocaproic acid, and hyperbaric oxygen (HBO), may be used in patients who are refractory to local therapy, although they introduce the risk of systemic side effects. HBO is particularly useful for radiation- and cyclophosphamide-induced cystitis. These agents should be continued until bleeding stops.

Antispasmodic agents such as oxybutynin 5 mg by mouth two to three times daily may be used for bladder spasms. In patients with refractory pain, opioid analgesics should be titrated to adequate pain control.[38] In very severe cases refractory to medical therapy, surgical procedures may be warranted.[38]

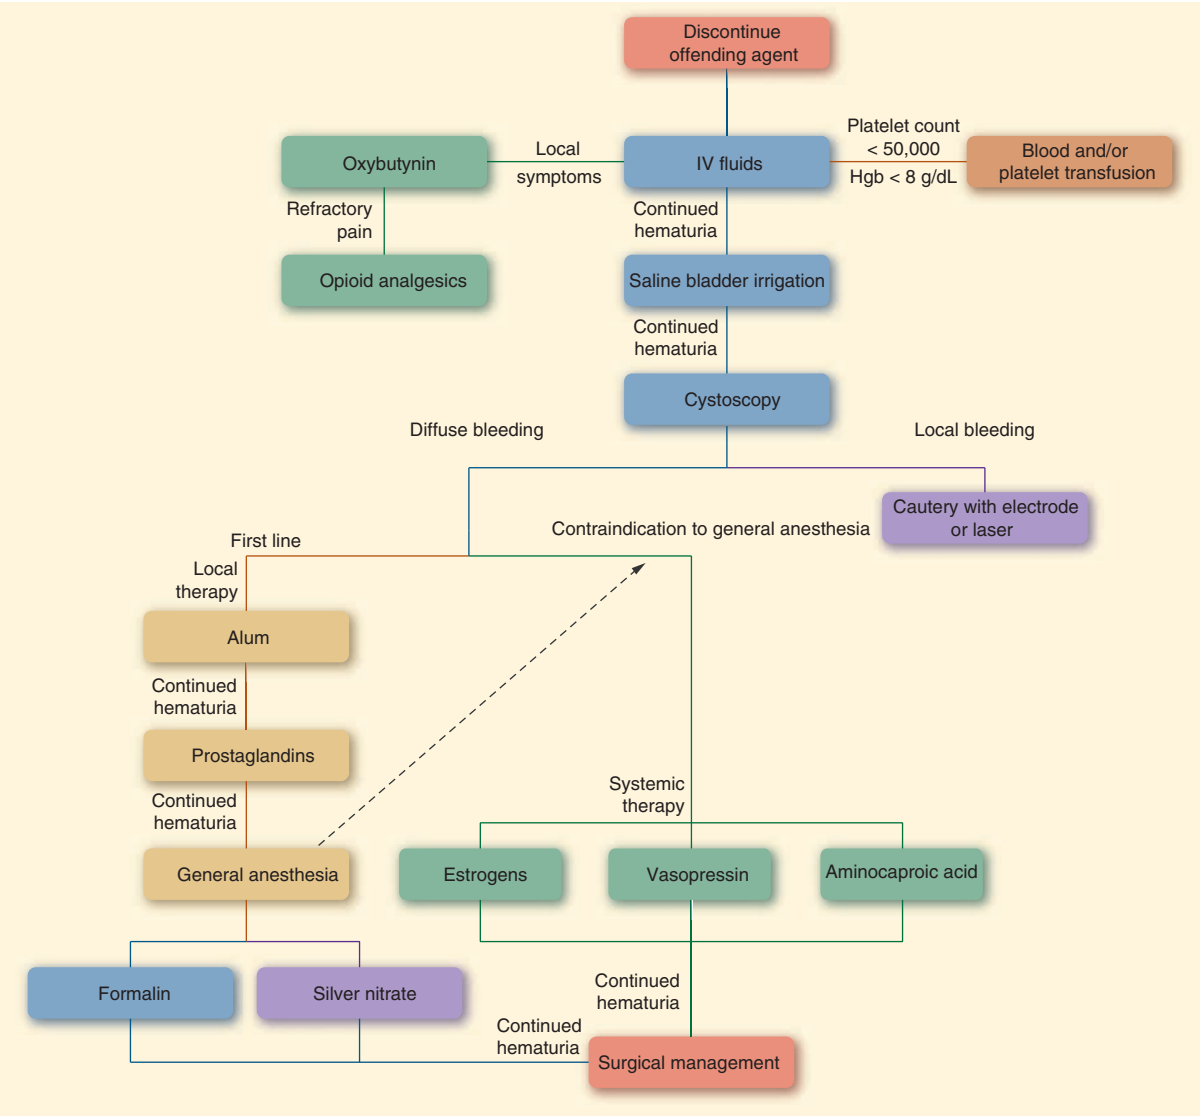

FIGURE 99–3. Treatment of hemorrhagic cystitis.

OUTCOME EVALUATION

The goal of treatment is resolution of bladder symptoms and appropriate pain management.

Monitor the patient for resolution of hematuria after each successive therapeutic intervention. The frequency of monitoring is based on the severity of hemorrhaging. Monitor urinary output and serum chemistries (including sodium, potassium, chloride, blood urea nitrogen [BUN], and serum creatinine) daily for renal dysfunction. Check the CBC at least daily to monitor hemoglobin and platelet count.

METABOLIC COMPLICATIONS: HYPERCALCEMIA OF MALIGNANCY

INTRODUCTION

Hypercalcemia is the most common metabolic abnormality experienced by patients with cancer. A small percentage of undiagnosed patients present with hypercalcemia. Once hypercalcemia occurs, it is associated with a very poor prognosis because of the frequent association with advanced or metastatic disease.[40]

EPIDEMIOLOGY AND ETIOLOGY

LO 3

Hypercalcemia occurs in 10% to 30% of patients with cancer during the course of their disease. The most common tumor types associated with hypercalcemia are breast cancer; squamous cell carcinomas of the head, neck, and lung; and renal cancer. Hematologic malignancies such as multiple myeloma and, rarely, lymphomas are other underlying malignancies associated with hypercalcemia.

PATHOPHYSIOLOGY

Around 99% of calcium is contained in the bones; the other 1% resides in the extracellular fluid. Of this extracellular calcium, approximately 40% is bound to albumin, and the remainder is in the ionized, physiologically active form. Normal calcium levels are maintained by three primary factors: parathyroid hormone (PTH), 1,25-dihydroxyvitamin D, and calcitonin. PTH increases renal tubular calcium resorption and promotes bone resorption. The active form of vitamin D, 1,25-dihydroxyvitamin D, regulates absorption of calcium from the GI t ract. Calcitonin serves as an inhibitory factor by suppressing osteoclast activity and stimulating calcium deposition into the bones.[40]

The delicate balance maintained by these factors is altered in patients with cancer by two principal mechanisms: tumor production of humoral factors that alter calcium metabolism in the absence of bone metastasis (humoral hypercalcemia) and by local osteolytic activity from bone metastases.[40] Humoral hypercalcemia causes around 80% of all hypercalcemia cases and is primarily mediated by systemic secretion of PTH-related protein (PTHrP). This protein mimics the action of endogenous PTH on bones. Local osteolytic activity causes 20% to 30% of hypercalcemia cases, although local osteolytic activity may also have a humoral component. Local production of various factors such as PTHrP, transforming growth factor-β, interleukin-1, and interleukin-6, and tumor necrosis factor-α promote RANK ligand expression on osteoblasts. RANK ligand signaling to the RANK receptor on osteoclasts causes osteoclast maturation and activation, leading to bone resorption.[40] Thus, these metastatic tumors perpetuate their own growth through this mechanism. Calcium is also released by the osteolytic activity, resulting in hypercalcemia.[40] Of note, multiple myeloma, breast, and lung cancer patients tend to develop osteolytic lesions and are at increased risk for hypercalcemia, whereas prostate cancer patients tend to develop osteoblastic lesions and are more at risk for hypocalcemia. A third and less common mechanism is production of 1,25-dihydroxyvitamin D by tumor cells (usually lymphoma), which increases GI absorption of calcium and enhances osteoclastic bone resorption.

TREATMENT

Desired Outcomes

KEY CONCEPT The primary goal of treatment for hypercalcemia is to control the underlying malignancy. Therapies directed at lowering the calcium level are temporary measures that are useful until anticancer therapy begins to work. The goals of calcium-lowering

Clinical Presentation and Diagnosis of Hypercalcemia[40]

General

- Presence of symptoms depends not only on the calcium level but the rapidity of onset.
- Normal calcium level is 8.5 to 10.5 mg/dL (2.13–2.63 mmol/L) (varies by laboratory).
- Serum calcium level *must* be corrected for albumin level using the following formula:

Corrected calcium (mg/dL) = Serum calcium + 0.8 (4 – Serum albumin) for serum calcium expressed in mg/dL and albumin in g/dL.

or

Corrected calcium (mmol/L) = Serum calcium + 0.02 (40 – serum albumin) for serum calcium expressed in mmol/L and albumin in g/L.

Signs and Symptoms

- Five primary organ systems may be affected:
  - GI: lack of appetite, nausea, vomiting, constipation
  - Musculoskeletal: weakness, bone pain, fatigue, ataxia
  - CNS: confusion, headache, lethargy, seizures, coma
  - Genitourinary: polydipsia, polyuria, renal failure
  - Cardiac: Bradycardia, ECG abnormalities, arrhythmias

Laboratory Tests

- Elevated corrected serum calcium level (≥ 10.5 mg/dL [2.63 mmol/L]), low serum albumin, low to normal serum phosphate
- Patient may have elevated blood urea nitrogen and serum creatinine.
- Elevated alkaline phosphatase may indicate bone destruction.
- ECG may indicate prolonged PR interval, shortened QT interval, widened T wave.

Other Diagnostic Tests

- Rule out other causes of hypercalcemia, including primary hyperparathyroidism, hyperthyroidism, vitamin D intoxication, chronic renal failure.

therapy are to (a) lower the corrected calcium to normal levels, (b) regain fluid and electrolyte balance, (c) relieve symptoms, and (d) prevent life-threatening complications.[40] Hypercalcemia is often indicative of a progressing cancer, with survival rates ranging from 2 months to 4.5 months.[40]

General Approach to Treatment

Therapeutic options for the treatment of hypercalcemia should be directed toward the level of corrected serum calcium and the presence of symptoms (Figure 99–4). Hypercalcemia may be classified as mild (corrected calcium equal to 10.5–11.9 mg/dL [2.63–2.98 mmol/L]), moderate (12–13.9 mg/dL [3.00–3.49 mmol/L]), and severe (> 14 mg/dL [3.50 mmol/L] or more).[40] Adequate treatment of mild or asymptomatic hypercalcemia may be achieved on an outpatient basis with nonpharmacologic measures. Moderate to severe or symptomatic hypercalcemia almost always requires pharmacologic intervention. Ultimately, effective treatment of the patient's underlying malignancy is the most important factor for the long-term prevention and management of hypercalcemia.[40]

▶ *Nonpharmacologic Therapy*

LOS

Calciuric therapy in the form of hydration is a key component in the treatment of hypercalcemia, regardless of severity or presence of symptoms.[40] Mild or asymptomatic patients may be encouraged to increase their oral fluid intake (3–4 L/day). Patients with moderate to severe or symptomatic hypercalcemia should receive normal saline at 200 to 500 mL/hour according to their dehydration and cardiovascular status. Patients should be encouraged to ambulate as much as possible because immobility enhances bone resorption. Although calcium should be discontinued from parenteral feeding solutions, oral calcium supplementation minimally contributes to hypercalcemia unless it is mediated by vitamin D. In these cases, oral calcium should be discontinued. Finally, agents that may contribute to hypercalcemia (thiazide diuretics, vitamin D, lithium) or decrease renal function (NSAIDs) should be discontinued. Dialysis may be used in refractory cases or patients who cannot tolerate aggressive saline hydration.[40]

Patient Encounter 3: Hypercalcemia of Malignancy

A 79-year-old man with stage IV moderately differentiated adenocarcinoma with features suggestive of a combined hepatocellular cholangiocarcinoma. The patient feels well but is fatigued and has a headache. He presents today to discuss treatment options for his disease. Relevant laboratory test results today are: calcium, 11.1 mg/dL (2.78 mmol/L) and albumin, 3.2 g/dL (32 g/L).

What is this patient's corrected calcium level?

How would you approach this patient's hypercalcemia?

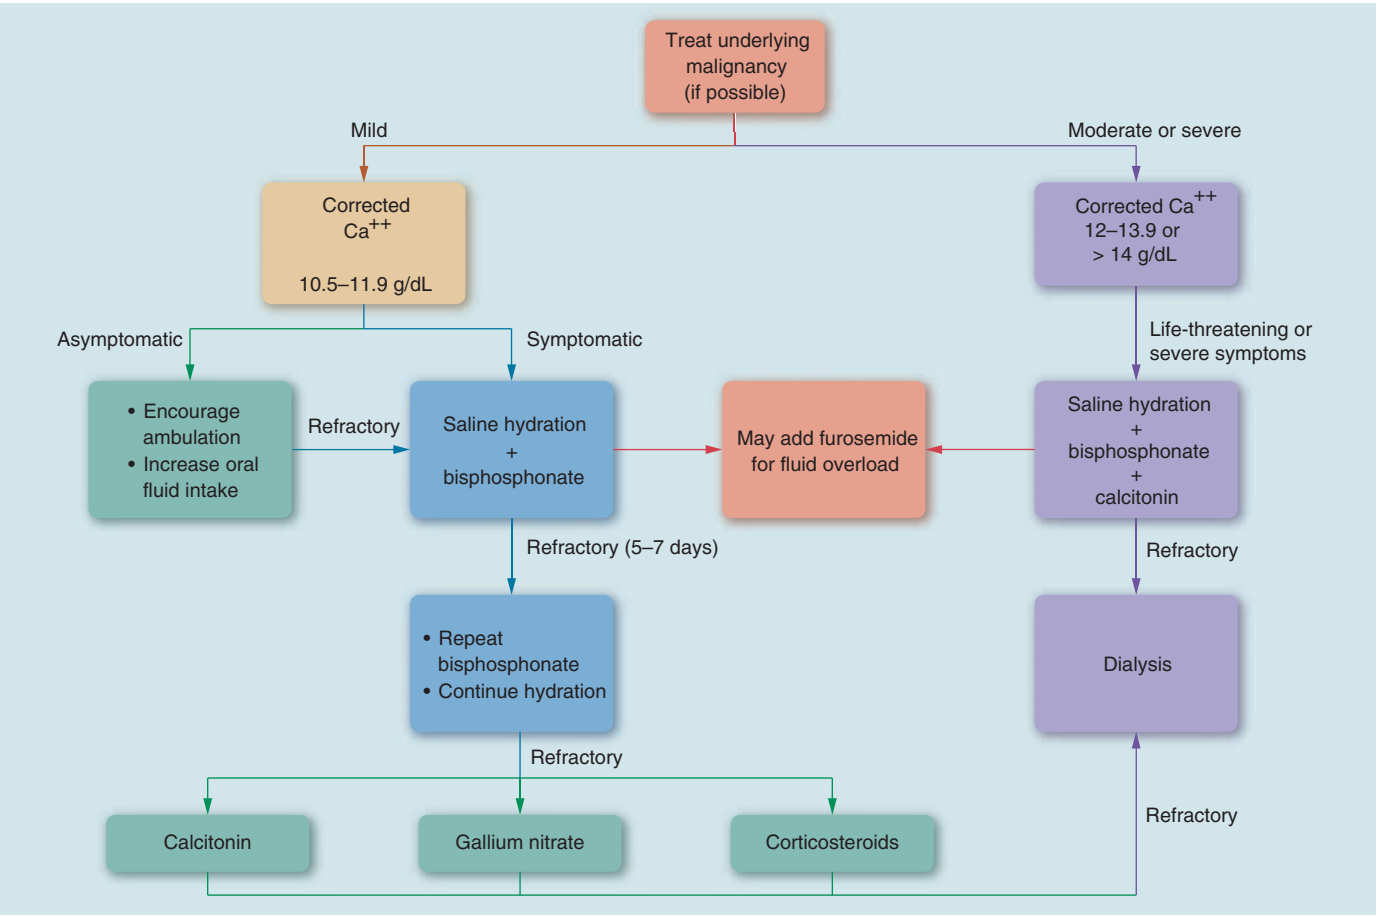

FIGURE 99–4. Treatment algorithm for the hypercalcemia of malignancy.

Table 99–13

Treatment Options for Hypercalcemia of Malignancy

	Agent	Dosage	Onset	Duration of Action	Reduction in Serum Calcium Concentration	Comments
Calciuric therapy	IV normal saline furosemide	200–500 mL/hour 20–40 mg IV	24–48 hours 4 hours	2–3 days 2–3 days	0.5–2 mg/dL (0.13–0.50 mmol/L)	Avoid fluid overload, monitor electrolytes Monitor for hypokalemia, dehydration
Antiresorptive therapy	Pamidronate	60–90 mg IV over 2–24 hours[a]	24–72 hours	3–4 weeks	> 1 mg/dL (0.25 mmol/L)	Nadir not seen until after 4–7 days; may cause fever, renal dysfunction
	Zoledronic acid	4 mg IV over 15 minutes	24–48 hours	4+ weeks	> 1 mg/dL (0.25 mmol/L)	
	Corticosteroids	Prednisone (or equivalent) 50–100 mg/day	5–7 days	3–4 days	0.5–3 mg/dL (0.13–0.75 mmol/L)	Monitor for hyperglycemia, insomnia, immunosuppression
	Calcitonin	4–8 IU/kg SC or IM every 6–12 hours	2–4 hours	1–3 days	2–3 mg/dL (0.50–0.75 mmol/L)	Salmon-derived formulation preferred; 1-unit test dose recommended; can be given in renal failure; may cause flushing, nausea
	Gallium nitrate	100–200 mg/m^2 CIV daily for 5 days	24–48 hours			Do not administer if creatinine > 2.5 mg/dL (221 µmol/L); may cause renal failure
	Denosumab	120 mg SQ days 1, 8, 15, and 29 the first month, then day 1 only every 4 weeks	48–96 hours	4+ weeks	> 1 mg/dL (0.25 mmol/L)	Not renally cleared, may be used in patients with renal dysfunction, but reduce dose as increased risk of hypocalcemia in renally impaired

[a]60 mg of pamidronate may be used in smaller patients or in patients with mild hypercalcemia or renal dysfunction. May use longer infusion time in patients with renal dysfunction.

CIV, continuous intravenous infusion; IM, intramuscular; IV, intravenous; SC, subcutaneous.

Data from Body JJ, Niepal D, Tonini G. Hypercalcemia and hypocalcemia: finding the balance. Support Care Cancer. 2017;25(95):1639–1649.

▶ *Pharmacologic Therapy*

Multiple pharmacologic interventions are available for the treatment of hypercalcemia (Table 99–13). Furosemide 20 to 40 mg/day may be added to hydration after rehydration has been achieved to avoid fluid overload and enhance renal excretion of calcium. Although effective in relieving symptoms, hydration and diuretics are temporary measures that are useful until the onset of antiresorptive therapy; thus, hydration and antiresorptive therapy should be initiated simultaneously.[40]

LOS

The antiresorptive therapy of choice for hypercalcemia of malignancy is a bisphosphonate. Because of poor oral bioavailability, only IV agents should be used. Pamidronate and zoledronic acid are most commonly used and are potent inhibitors of osteoclast activity.[39] The bisphosphonates should be administered at diagnosis of hypercalcemia because of their delayed onset of action.

Calcitonin is the drug of choice in cases of emergent hypercalcemia (patients with life-threatening electrocardiographic [ECG] changes, arrhythmias, or central nervous system [CNS] effects) because of its rapid onset of action. Calcitonin inhibits osteoclast activity and decreases renal tubular calcium resorption. However, calcitonin does not yield sustained effects and bisphosphonates are usually necessary as well. Corticosteroids are useful in patients with steroid-responsive malignancies, such as lymphomas or multiple myeloma, and may delay tachyphylaxis to calcitonin. Gallium nitrate is another treatment option, although the 5-day administration regimen and risk of nephrotoxicity limit its use. Denosumab, a RANKL inhibitor, is FDA-approved for hypercalcemia refractory to bisphosphonates at 120 mg subcutaneously days 1, 8, 15, and 29 then monthly thereafter.

OUTCOME EVALUATION

The long-term success of therapy for hypercalcemia is determined primarily by the success of treatment of the underlying malignancy. The goal of treatment is to reduce serum calcium levels to normal range and to relieve patient symptoms and life-threatening complications if present.

METABOLIC COMPLICATIONS: TLS

INTRODUCTION

Although not as common as hypercalcemia, TLS may cause significant morbidity and mortality if adequate prophylaxis and treatment are not instituted. TLS is the result of rapid destruction of malignant cells with subsequent release of intracellular contents into the circulation.

Table 99–14

Risk Factors for TLS

Disease Related
High risk
Acute lymphoblastic leukemia
High-grade non-Hodgkin lymphoma (ie, Burkitt lymphoma)
Intermediate risk
Chronic lymphocytic leukemia (especially bulky lymphadenopathy)
Acute myeloid leukemia (especially WBC count > 50,000 × 10^3/μL [50 × 10^9/L])
Multiple myeloma
Low risk
Low- and intermediate-grade non-Hodgkin lymphoma
Hodgkin disease
Chronic myeloid leukemia (blast crisis)
Rare
Breast cancer
Small cell lung cancer
Testicular cancer
Patient Related
Decreased urinary output, dehydration, or renal failure
Previous or current nephrotoxin exposure
Preexisting hyperuricemia
Acidic urine
WBC count > 50,000 10^3/μL (50 × 10^9/L)
LDH levels > 1500 IU/L (25.0 μkat/L)
High tumor sensitivity to treatment modalities

LDH, lactate dehydrogenase; WBC, white blood cell.

EPIDEMIOLOGY AND ETIOLOGY

LO 3

The overall incidence of TLS is unknown but has been linked to a number of patient- and tumor-related risk factors (Table 99–14).[41] TLS typically occurs in malignancies with high tumor burden or high proliferative rates. Because of this, children are most frequently affected because they frequently have aggressive malignancies. TLS is typically induced by cancer treatment modalities, including chemotherapy, hormonal therapy, radiation, biologic therapy, or corticosteroids, although some patients may present spontaneously before treatment.[41]

PATHOPHYSIOLOGY

Patients with TLS experience a wide range of metabolic abnormalities. The massive cell lysis that occurs leads to the release of intracellular electrolytes, resulting in hyperuricemia, hyperkalemia, and hyperphosphatemia. High concentrations of phosphate bind to calcium, leading to hypocalcemia and calcium phosphate precipitation in the renal tubule. Purine nucleic acids are also released, which are subsequently metabolized to uric acid through multiple enzyme-mediated steps (Figure 99–5). Uric acid is poorly soluble at urinary acidic pH, leading to crystallization in the renal tubule. The precipitation of uric acid and calcium phosphate leads to metabolic acidosis, facilitating further uric acid crystallization. Acute renal failure may be the end result.[41]

TREATMENT

Desired Outcomes

KEY CONCEPT The primary goals of management of TLS are (a) prevention of renal failure and (b) prevention of electrolyte imbalances. Thus, the best treatment for TLS is prophylaxis to enable delivery of cytotoxic therapy for the underlying malignancy. For patients who present with or develop TLS despite prophylaxis, treatment goals include (a) decreasing uric acid levels, (b) correcting electrolyte imbalances, and (c) preventing compromised renal function. These goals should be achieved in a cost-effective manner.

General Approach to Treatment

LO 5

Prevention of TLS is generally achieved by increasing the urine output and preventing accumulation of uric acid. Prophylactic strategies should begin immediately upon presentation, preferably 48 hours prior to cytotoxic therapy. Treatment modalities for established TLS primarily increase uric acid solubility, maintain electrolyte balance, and support renal output.[41]

▶ *Nonpharmacologic Therapy*

LO 5

Vigorous IV hydration with dextrose 5% in water with half normal saline at 3 L/m^2/day to maintain a urine output greater than or equal to 100 mL/m^2/hour is necessary unless the patient presents with acute renal dysfunction. Alkalinization

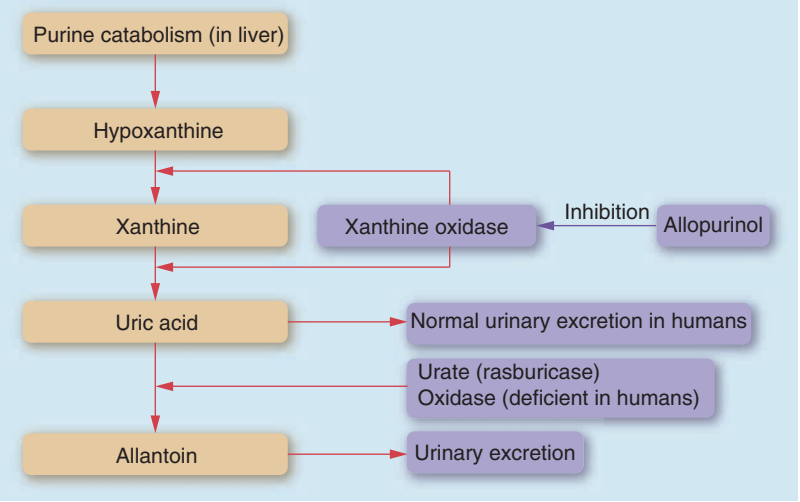

FIGURE 99–5. The role of allopurinol and rasburicase in the enzymatic degradation of purine nucleic acids.

Clinical Presentation and Diagnosis of TLS[41]

General

- Patients present primarily with laboratory abnormalities.
- Normal uric acid is equal to 2 to 8 mg/dL (119–476 µmol/L).
- Most often occurs within 12 to 72 hours of initiation of cytotoxic therapy

Signs and Symptoms

- Most patients are asymptomatic.
- Patients may develop edema, fluid overload, and oliguria, which may progress to anuria with acute renal failure.
- Some patients with hyperuricemia may have nausea, vomiting, and lethargy.
- Hyperkalemia: lethargy, muscle weakness, paresthesia, ECG changes, bradycardia
- Hypocalcemia: muscle cramps, tetany, irritability, paresthesias, arrhythmias

Laboratory Tests (Adults)

- Serum uric acid level greater than 8 mg/dL (476 µmol/L)
- Serum potassium greater than 6 mEq/L (6 mmol/L)
- Serum phosphorus greater than 4.5 mg/dL (1.45 mmol/L)
- Serum calcium less than 7 mg/dL (1.75 mmol/L)
- Elevated blood urea nitrogen and creatinine once renal dysfunction develops

or

- A change of greater than 25% from baseline in the above laboratory values

of the urine to a pH greater than or equal to 7.0 with 50 to 100 mEq/L (50–100 mmol/L) of sodium bicarbonate has been used to promote uric acid solubility for excretion. This measure is controversial because xanthine and hypoxanthine are less soluble at alkaline pH, potentially leading to crystallization, especially during and after allopurinol therapy (see Figure 99–5).[41] Medications that increase serum potassium (angiotensin-converting enzyme inhibitors, spironolactone) or block tubular resorption of uric acid (probenecid, thiazides) should be discontinued. Nephrotoxic agents such as amphotericin B or aminoglycosides should also be avoided. Hemodialysis may be required in patients who develop anuria or uncontrolled hyperkalemia, hyperphosphatemia, hypocalcemia, acidosis, or volume overload.[41]

▶ *Pharmacologic Therapy*

LO 2

Allopurinol is an xanthine oxidase inhibitor that is used for prevention only because it has no effect on preexisting elevated uric acid. Rasburicase is a recombinant form of urate oxidase that is useful for both prevention and treatment, but is expensive (Figure 99–6, Table 99–15). Although the approved dose is 0.2 mg/kg/day for 5 days, recent studies using abbreviated courses (1–3 days) and/or lower doses (0.05–0.1 mg/kg/day) may be equally efficacious with significantly reduced cost.[39] Because uric acid levels generally fall within 4 hours of the first dose, one dose may be administered with frequent, serial monitoring of the uric acid level for repeat dosing if necessary (see Figure 99–6). Of note, rasburicase continues to break down uric acid in blood samples drawn

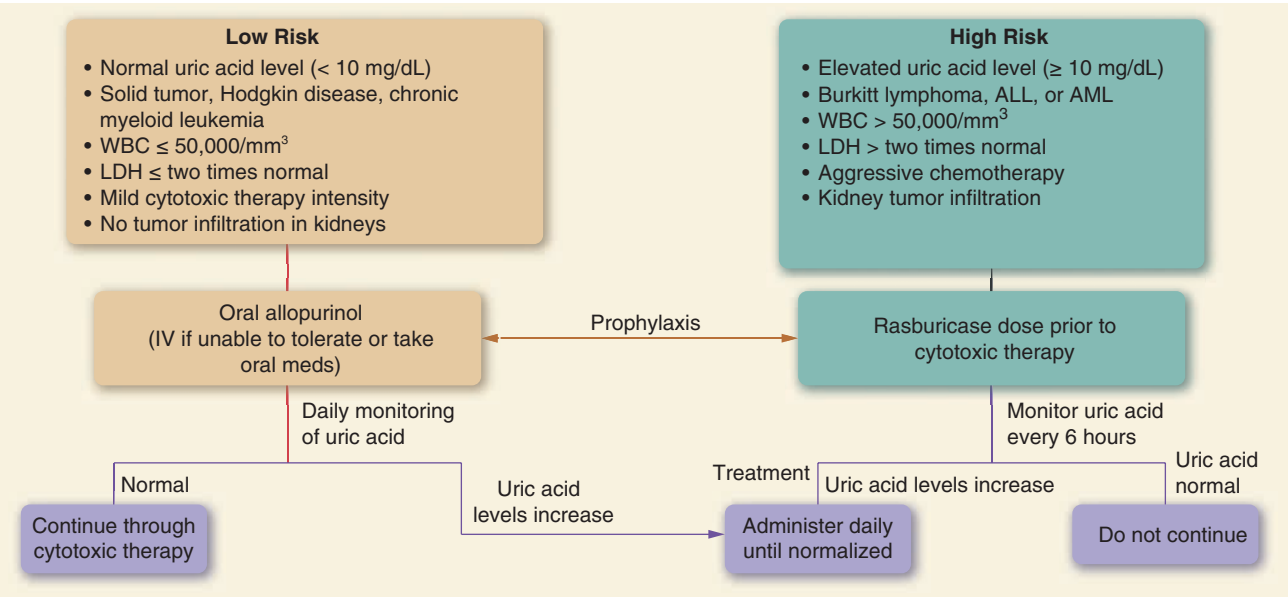

FIGURE 99–6. Prophylaxis and treatment of hyperuricemia associated with tumor lysis syndrome. (ALL, acute lymphoblastic leukemia; AML, acute myelogenous leukemia; IV, intravenous; LDH, lactate dehydrogenase; WBC, white blood cell.)

Table 99–15

Comparison of Allopurinol and Rasburicase in TLS

Drug	Dosing	AWP	Comments
Oral allopurinol (Zyloprim)	Adult: 600–800 mg/day in two to three divided doses Pediatric: 10 mg/kg/day or 200–300 mg/m^2/day	$1.80/day	Adjust dose for renal impairment Avoid drug interactions (mercaptopurine) Monitor for skin rash
IV allopurinol (Aloprim)	Adult: 200–400 mg/m^2/day Pediatric: 200 mg/m^2/day	$4680/day	As above Reserve for patients who cannot tolerate or take oral medications Maximum dose = 600 mg/day
Rasburicase (Elitek)	0.2 mg/kg/day for up to 5 days	$2809/day	Lower doses and abbreviated schedules may be used to decrease cost (0.05–0.1 mg/kg/day) May rarely cause nausea and vomiting Contraindicated in patients with G6PD deficiency → hemolytic anemia Rare cases of hypersensitivity and antibody formation

[a]Normalized for 70-kg patient or body surface area = 1.73 m^2; all costs are estimated and may vary.

AWP, average wholesale price; G6PD, glucose-6-phosphate dehydrogenase; po, oral.

From Wilson FP, Berns JS. Tumor lysis syndrome: new challenges and recent advances. Adv Chronic Kidney Dis. 2014;21(1):18–26. Accessed from RedBook Online ®, Truven Health Analytics/Micromedex. Subscription required for access. Accessed August 30, 2017.

from patients. This can be avoided by immediately placing the sample in an ice bath for processing to avoid falsely lowered uric acid levels.[41]

Electrolyte disturbances that develop in patients with TLS should be aggressively managed to avoid renal failure and cardiac sequelae. One exception pertains to the use of IV calcium for hypocalcemia. Adding calcium may cause further calcium phosphate precipitation in the presence of hyperphosphatemia and should be used cautiously.

OUTCOME EVALUATION

The most successful outcome in TLS is prevention. If the condition is not able to be prevented, the goal of treating established TLS is to avoid renal failure and quickly return electrolytes to normal.

Patient Care Process

Collect Information:

- Review patient history of chemotherapy regimens and concurrent medications.
  - Determine patient allergies, especially to antibiotics, antifungals, and antivirals.
- Evaluate risk of chemotherapy complications using appropriate NCCN practice guideline if available.
- Evaluate patient-specific risk factors.
- Review laboratory values, including WBC, electrolytes, hepatic and renal function, performance status, and vital signs.

Assess the Information:

- Determine complications (nausea, vomiting, febrile neutropenia, etc) to previous cycles of chemotherapy and risk with current cycle.
- Assess individual and treatment-related risk factors for chemotherapy complications.
  - Determine insurance coverage for supportive care interventions, availability of appropriate storage conditions.

Develop a Care Plan:

- Communicate treatment goals of symptomatic management to the patient.
- Provide patient with education regarding appropriate use of supportive therapies and potential adverse effects.
- Educate patient about nonpharmacologic interventions to manage chemotherapy complications.

Counsel patients regarding risk factors, symptoms to call their health care providers, and symptoms requiring a visit to the emergency room.

Implement the Care Plan:

- Initiate patient-specific supportive care therapy for managing chemotherapy complications.
- Coordinate follow-up with interprofessional team.

LO 6

Follow-up: Monitor and Evaluate:

- Review laboratory values, including WBC, electrolytes, hepatic and renal function, performance status, and vital signs.
  - Determine efficacy and adverse effects of supportive cancer intervention and determine if modifications in the treatment plan are required.
- Assess the patient for any new signs or symptoms of chemotherapy complications. Evaluate the patient for adverse drug reactions, drug allergies, and interactions. Have all medications been dose adjusted for renal or hepatic dysfunction?

Abbreviations Introduced in This Chapter

ANC	Absolute neutrophil count
AWP	Average wholesale price
BMT	Bone marrow transplantation
BUN	Blood urea nitrogen
CIV	Continuous intravenous infusion
CSF	Colony-stimulating factor
G6PD	Glucose-6-phosphate dehydrogenase
ICP	Intracranial pressure
IV	Intravenous
LDH	Lactate dehydrogenase
NSAID	Nonsteroidal anti-inflammatory drug
NSCLC	Non–small cell lung cancer
PCP	*Pneumocystis jiroveci* pneumonitis (formerly *Pneumocystis carinii*)
PTHrP	Parathyroid hormone–related protein
SCLC	Small cell lung cancer
SVCS	Superior vena cava syndrome

100 Parenteral Nutrition

Melissa R. Pleva and Michael D. Kraft

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

LO

1. List appropriate indications for parenteral nutrition (PN) in adult patients.
2. Describe the components of PN and their role in nutrition support therapy.
3. List key elements of nutrition assessment and factors considered in assessing an adult patient's nutritional status and nutritional requirements.
4. List important recommendations to improve PN safety.
5. Explain important pharmaceutical and compounding concerns with PN admixtures.
6. Develop a plan to design, initiate, and adjust a PN formulation for an adult patient based on patient-specific factors.
7. Describe the etiology and risk factors for PN macronutrient-associated complications in adult patients receiving PN.
8. Describe the etiology and risk factors for refeeding syndrome, as well as measures to prevent refeeding syndrome.
9. Design a plan to assess the efficacy and monitor for safety, as well as fluid, electrolyte, vitamin, and trace element abnormalities in adult patients receiving PN.

INTRODUCTION

Malnutrition in hospitalized patients is associated with significant complications (eg, increased infection risk, poor wound healing, prolonged hospital stays, increased mortality), especially in surgical and critically ill patients.[1] Maintaining adequate nutritional status, especially during periods of illness and metabolic stress, is an essential part of patient care. *Nutrition support therapy* refers to the administration of nutrients via the oral, enteral, or parenteral route for therapeutic purposes.[1]

KEY CONCEPT Parenteral nutrition (PN), also called total parenteral nutrition (TPN), is the intravenous (IV) administration of fluids, macronutrients, electrolytes, vitamins, and trace elements for the purpose of weight maintenance or gain, to preserve or replete lean body mass and visceral proteins, and to support anabolism and nitrogen balance when the oral or enteral route is not feasible or adequate. PN is a potentially lifesaving therapy in patients with intestinal failure but can be associated with significant complications.

Desired Outcomes and Goals

The goals of nutrition support therapy include:

- Correction or avoidance of nutritional deficiencies
- Weight maintenance (or weight gain in malnourished patients and growing children)
- Preservation or repletion of lean body mass and visceral proteins
- Support of anabolism and nitrogen balance and improvement of healing
- Correction or avoidance of fluid, electrolyte, vitamin, and trace element abnormalities
- Improving clinical outcomes

Indications for PN Therapy

PN can be a lifesaving therapy in patients with intestinal failure, but the oral or enteral route is preferred when providing nutrition support therapy. Compared with PN, enteral nutrition is associated with a lower risk of hyperglycemia and fewer infectious complications (eg, pneumonia, intraabdominal abscess, catheter-related infections).[1–3] However, if used appropriately, PN can be safe and effective and can improve nutrient delivery. Indications for PN are listed in Table 100–1.[1,2,4] PN should be reserved for patients with altered intestinal function or absorption or when the gastrointestinal (GI) tract cannot be used. The anticipated duration of adequate PN therapy should be at least 5 to 7 days because shorter durations are unlikely to have a beneficial effect on a patient's clinical and nutritional outcomes.[1,2]

LO 1

PN COMPONENTS

LO 2

PN should provide a *balanced* nutrition formula, including macronutrients, micronutrients, fluids, and electrolytes. Macronutrients, including amino acids, dextrose, and injectable lipid emulsions (ILE; also known as IV lipid emulsion or IV fat emulsion), are important sources of structural and energy-yielding substrates. In a balanced PN formulation for adult patients, total daily calories are typically provided as 10% to 20% from amino acids, 50% to 60% from dextrose, and 15% to 30% from ILE. Amino acids may provide more than 20% of

Table 100–1

Indications for Parenteral Nutrition in Adults[1,2,4]

- Bowel obstruction
  - Physical or mechanical (eg, tumor compressing intestinal lumen)
  - Functional (eg, ileus, colonic pseudo-obstruction)
- Major small bowel resection (eg, short-bowel syndrome)
  - Adult patients with < 100 cm of small bowel distal to the ligament of Treitz without a colon
  - Adult patients with < 50 cm of small bowel if the colon is intact
- Diffuse peritonitis
- Intestinal fistulas if EN cannot be provided above or below the fistula
- Pancreatitis—if patients have failed EN beyond the ligament of Treitz or cannot receive EN (eg, because of intestinal obstruction)
- Severe intractable vomiting or diarrhea
- Preoperative nutrition support in patients with moderate to severe malnutrition who cannot tolerate EN and in whom surgery can be delayed safely for at least 7 days

the total daily calories in patients with conditions that increase protein requirements (eg, severe thermal injury, healing wounds, cachexia, treatment with continuous renal replacement therapy, hypocaloric feeding). Electrolytes and micronutrients, including vitamins and trace elements, are required to support essential biochemical reactions and maintain cellular homeostasis. Patients require individual adjustments of PN components based on their nutritional status, nutritional requirements, underlying disease state(s), degree of metabolic stress, clinical status, and organ functions.

LO 2

Macronutrients

▶ *Amino Acids*

LO 2

Amino acids, the building blocks of proteins, are an essential component of PN admixtures. KEY CONCEPT Amino acids are provided to preserve or replete lean body mass and visceral proteins, to promote protein anabolism and wound healing. Amino acids also provide a source of energy, providing 4 kcal/g (17 kJ/g).

Patient Encounter Part 1

RK is a 64-year-old woman with a history of hypertension and colon cancer, status post colon resection and colostomy, followed by chemotherapy, and subsequent colon reanastomosis. She was admitted approximately 2 weeks ago with signs and symptoms consistent with a bowel obstruction. She was taken to the OR for an **exploratory laparotomy** and found with multiple adhesions causing small bowel obstructions in two locations. She underwent a small bowel resection (jejunum) and extensive lysis of adhesions, and was discharged 8 days ago. RK is readmitted with foul-smelling drainage from her surgical incision × 2 days along with nausea, decreased appetite, and decreased oral intake (~30% of estimated energy requirements) for the past 2 to 3 days. Since her diagnosis of colon cancer, she has had weight loss, poor oral intake, and malnutrition. Most recently, she reports an unintentional weight loss of about 12 lb (5.5 kg) over the past 4 to 5 weeks.

Past Medical History

- Hypertension × 10 years
- Colon cancer diagnosed 2 years ago, status post colectomy, chemotherapy, and reanastomosis
- Malnutrition since diagnosis of colon cancer

Past Surgical History

- Colon resection with colostomy, colostomy takedown with reanastomosis 2 years ago
- Exploratory laparotomy with small bowel resection and lysis of adhesions due to small bowel obstruction (> 100 cm of small intestine remaining, ileocecal valve intact, part of the colon remaining)

Family History

- Mother and father: Hypertension
- Grandmother: Chronic constipation

Social History

- 30 pack-year smoking history, quit 2 years ago; patient reports only occasional alcohol; no recreational drugs

Medications Prior to Admission

- Hydrochlorothiazide 50 mg orally daily
- Docusate 100 mg orally twice daily
- Metformin 500 mg orally twice daily

Allergies

- NKDA

Physical Examination

- Ht 157 cm (~5′2″); actual body wt 53 kg (116 lb); ideal body wt 50 kg (110 lb); T 37.2°C (99.0°F); HR 83 beats/min; BP 138/82 mm Hg; RR 14 breaths/min; alert and oriented × 3; mucous membranes and skin appear cool and dry; lungs clear

Abdomen: Soft, tender around incision, faint bowel sounds, drainage of apparent enteric contents from surgical incision

Physical examination otherwise unremarkable

Diagnoses

Likely enterocutaneous fistula, probably from small bowel/jejunum (most recent surgery/small bowel resection), mild dehydration, and malnutrition

Plan

The patient was admitted to the hospital (non-ICU) for evaluation of a possible enterocutaneous fistula. The team performed a fistulogram and confirmed presence of an enterocutaneous fistula apparently originating in the proximal- to mid-jejunum. Given the patient's recent surgery, surgical intervention was deemed to not be an appropriate option at this time. A drain was placed into the fistula to control drainage and quantify output; the fistula drained approximately 600 mL in the first 24 hours. Against medical orders, the patient drank approximately 1 L of water, and the following day her fistula drained approximately 1500 mL of fluid. It is now hospital day #2.

Is PN therapy indicated in this patient? Why or why not?

Parenteral crystalline amino acid solutions are supplied by various manufacturers in various concentrations (eg, 7%, 8%, 8.5%, 10%, 15%, and others). Different formulations are tailored for specific age groups and disease states. Specialized formulations for patients with acute kidney injury contain higher proportions of essential amino acids. Formulations for patients with hepatic encephalopathy contain higher amounts of branched-chain and lower amounts of aromatic amino acids. These specialized formulations have not been clearly shown to improve patient outcomes and are not routinely used in clinical practice. Crystalline amino acid solutions have an acidic pH (pH ≈ 5–7) and may contain inherent electrolytes (eg, sodium, potassium, acetate, phosphate).

▶ *Dextrose*

LO 2

KEY CONCEPT Dextrose (D-glucose) is the major energy source, and it is vital for cellular metabolism, body protein preservation, and cellular growth. The central nervous system, red blood cells, and the renal medulla depend primarily on dextrose as a source of energy.

Typically, a 70% (70 g/100 mL) parenteral dextrose (hydrous dextrose) stock solution is used in PN compounding. Hydrous dextrose provides 3.4 kcal/g (14.2 kJ/g). A dextrose infusion rate of 2 mg/kg/min in adult patients is typically sufficient to suppress gluconeogenesis and spare proteins from being used for energy.[5] Dextrose infusion rate in hospitalized adult patients should not exceed 4 to 5 mg/kg per minute when PN is infused over 24 hours.[6,7] Use adjusted body weight (AdjBW), rather than actual weight, in obese patients when calculating the dextrose infusion rate.

▶ *Lipid Injectable Emulsions*

LO 2

KEY CONCEPT Injectable lipid emulsions (ILE) are provided to prevent or treat **essential fatty acid deficiency** (EFAD) and as an energy source. ILE particles consist of a triglyceride (TG) core surrounded by a layer of egg phospholipids (PL) (emulsifiers). These particles carry a negative charge on their surface that creates repulsive electrostatic forces between droplets and maintains the stability of the emulsion. Glycerol is added to adjust the tonicity, and water is the solvent. The negative charges on the surface of lipid particles can be disrupted by cations, especially divalent cations (eg, calcium, magnesium) and trivalent cations (eg, iron), and extreme pH changes, particularly acidic pH.[8] **Creaming**, **coalescence**, and **oiling out** are signs of a destabilized ILE. If there is any apparent disruption to ILE, it should *not* be infused into a patient.

ILEs differ in their concentration (10%, 20%, and 30%), caloric density by volume, natural source of fats/triglycerides, and ratio of phospholipids to triglycerides (PL:TG ratio). **Table 100–2** shows a comparison of standard commercially available ILEs in the United States. Most standard ILEs in the United States contain long-chain triglycerides derived from soybean oil. Because of the addition of PL emulsifiers and glycerol, the caloric density of ILEs by weight is approximately 10 kcal/g (42 kJ/g; dietary fat is ~9 kcal/g [38 kJ/g]). Compared with the 10% ILE, 20% and 30% ILEs have a lower PL:TG ratio and lower PL content, and this translates to better plasma clearance compared to the 10% ILE.[9] The 30% ILE is only approved by the Food and Drug Administration (FDA) for infusion in a total nutrient admixture (TNA) and should neither be infused directly into patients nor via Y-site injection.

More recently, the FDA approved two additional ILE products for use in adult patients in the United States: SMOFLipid and Clinolipid (Table 100–2). SMOFLipid is a combination of soybean oil, medium-chain triglycerides (MCTs), olive oil, and fish oil (30%/30%/25%/15%, respectively). Clinolipid is a mixture of refined olive and soybean oil (80%/20%, respectively), but this product is not yet on the market in the United States. Both alternative combinations of oil sources result in a reduced amount of omega-6 fatty acids and SMOFLipid has a higher concentration of omega-3 fatty acids. This may have a positive impact on inflammation and immune function, but significant data demonstrating improved clinical outcomes are lacking.[10] The optimal role of these ILE products in patient care is not yet known.

ILE particles are hydrolyzed in the bloodstream by **lipoprotein lipase** to release free fatty acids and glycerol. Fatty acids are taken up into adipose tissue for storage (triglycerides), oxidized to energy in various tissues (eg, skeletal muscles), or recycled in the liver to make lipoproteins.

The essential fatty acids that cannot be produced endogenously in humans are linoleic acid (C18:2 n-6) and α-linolenic acid (C18:3 n-3) (long-chain fatty acids). Arachidonic acid (C20:4 n-6) is also essential but can be synthesized in vivo from linoleic acid. Adult patients should receive a minimum of 2% to 4% of total daily calories as linoleic acid and 0.25% to 0.5% of total daily calories as α-linolenic acid to prevent essential fatty acid deficiency.[7] This can be achieved by providing a minimum of ~100 g (500 mL of 20%) of soybean oil-based ILE per week (in a single dose, or divided doses) for most adult patients. The typical daily dose of ILE in adults is about 0.5 to 1 g/kg/day (or ~15–30% of total daily calories). The maximum dose is 2.5 g/kg/day[7] or 60% of total daily calories, although doses this high are rarely used in practice and should be avoided to prevent complications.

Biochemical evidence of essential fatty acid deficiency (eg, decreased serum linoleic acid, α-linolenic acid, and arachidonic acid concentrations; elevated mead acid concentrations; elevated triene-to-tetraene ratio) can develop in well-nourished adult patients within about 2 to 4 weeks of receiving PN without ILE, and clinical manifestations (eg, dry skin, skin **desquamation**, hair loss, hepatomegaly, anemia, **thrombocytopenia**, poor wound healing) may begin to appear after an additional 1 to 2 weeks.[11]

Complications and safety concerns related to the administration of ILE include severe hypertriglyceridemia, infection, **anaphylactic** reactions, and infusion-related reactions. Patients with a history of hypertriglyceridemia, acute kidney injury, chronic kidney disease, hepatic dysfunction, severe metabolic stress, or **pancreatitis** (particularly if caused by hypertriglyceridemia) may have reduced lipid clearance and be at risk of developing hypertriglyceridemia. ILE should be temporarily withheld in adult patients with serum triglyceride concentrations exceeding 400 mg/dL (4.52 mmol/L).

ILEs support the growth of bacterial and fungal pathogens; bacterial growth is slower in TNAs than in ILE alone due to the acidic pH of amino acid solutions and higher osmolarity of PN formulations.[7,12,13] Because of this, the Centers for Disease Control and Prevention (CDC) recommends that TNA infusions be completed within 24 hours of initiation. Recent guidelines suggest that ILE infusion should be completed ideally within 12 hours if administered from the original manufacturer container (within 24 hours if 12 hours are not feasible for medical reasons), but completed within 12 hours if repackaged/transferred to another container and infused separately from a 2-in-1 PN admixture (although repackaging/transfer to another container was not recommended).[14]

Patients with an allergy to eggs, soybean, or legumes may develop cross-allergic reactions to ILE. Additionally, patients with an allergy or hypersensitivity to fish, olives, or other ingredients may develop cross-allergic reactions to SMOFLipid. Rarely, infusion-related adverse effects may occur with rapid infusion, including fever, chills, headache, palpitations, dyspnea,

Table 100–2

Comparison of Lipid Injectable Emulsion Products Approved in the United States

Brand Names	Intralipid			Nutrilipid	Liposyn III			SMOFLipid	Clinolipid
Oil source(s)	Soybean oil			Soybean oil	Soybean oil			Soybean oil (30%) MCT (30%) Olive oil (25%) Fish oil (15%)	Olive oil (80%) Soybean oil (20%)
Concentration	10%	20%	30%[a]	20%	10%	20%	30%[a]	20%	20%
Linoleic acid[b] (%)	44–62			48–58	54.5			14–25	13.8–22
α-Linolenic acid[c] (%)	4–11			4–11	8.3			1.5–3.5	0.5–4.2
Phospholipids (egg yolk) (%)	1.2			1.2	1.2	1.2	1.8	1.2	1.2

[a]Only approved for compounding in a 3-in-1 admixture, not for direct patient administration

[b]Omega-6 (ω-6) fatty acid

[c]Omega-3 (ω-3) fatty acid

[d]One kcal/mL is equivalent to 4.19 kJ/mL.

[e]One mOsm/kg is equivalent to mmol/kg.

PL, phospholipid; TG, triglyceride.

LO 2

Table 100–3

Approximate Daily Maintenance Electrolyte Requirements for Adults[7,14]

Electrolyte	Approximate Daily Maintenance Requirements[a]	Electrolyte Salts Used in PN	Maximum Suggested Concentration in PN
Sodium	1–2 mEq/kg (mmol/kg)	Chloride, acetate, phosphate	154 mEq/L (mmol/L, equivalent to normal saline)
Potassium	1–2 mEq/kg (mmol/kg)	Chloride, acetate, phosphate	120 mEq/L (mmol/L) (central PN)
Phosphorus	20–40 mmol (~10–15 mmol per 1000 kcal [2.4–3.6 mmol per 1000kJ])	Sodium phosphate, potassium phosphate	See text section on calcium–phosphate solubility Maximum calcium + magnesium = 20 mEq/L in 3-in-1 admixture
Calcium	10–15 mEq (5–7.5 mmol)	Gluconate	
Magnesium	8–20 mEq (4–10 mmol)	Sulfate	20 mEq/L (10 mmol/L)[b]
Chloride	[c]	Sodium, potassium	Linked to limitations of sodium and potassium. Usual ratio of chloride to acetate ~1:1 to 1.5:1
Acetate	[c]	Sodium, potassium	
Conversions	1 mmol potassium phosphate = 1.47 mEq potassium 1 mmol sodium phosphate = 1.33 mEq sodium 1 gram of calcium gluconate = 4.65 mEq (2.32 mmol) calcium 1 gram of magnesium sulfate = 8.1 mEq (4 mmol) magnesium		

[a]Electrolyte requirements are adjusted based on serum electrolyte concentrations and vary depending on kidney function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, and medication therapy that affect electrolyte losses or retention.

[b]For 3-in-1 formulations only.

[c]As needed to maintain acid–base balance; linked to amounts of sodium and potassium provided (as chloride and acetate salts).

chest tightness, and nausea. Extending the ILE infusion time can minimize infusion-related adverse events and improves ILE clearance. The maximum recommended infusion rate of ILE is 0.11 g/kg/hour.[7]

► *Fluid*

KEY CONCEPT PN should not be used to treat acute fluid abnormalities. PN should be adjusted to provide maintenance fluid requirements and to minimize worsening of underlying fluid disturbances, taking into account other fluids the patient is receiving. Daily maintenance fluid requirements for adults can be estimated with the following equation:

LO 2

$$\text{Total daily maintenance fluid requirements} = 1500\ \text{mL} + (20\ \text{mL/kg} \times [\text{Wt (kg)} - 20])^*$$

For patients with significant fluid deficits, it is safer and more cost effective to correct fluid abnormalities using standard IV fluids (eg, 0.9% sodium chloride in water, dextrose 5% and 0.45% sodium chloride in water +/– 20 milliequivalents (mEq)/L (mmol/L) of potassium chloride, lactated Ringer's solution). Minimizing PN fluid volume may be indicated in patients with fluid overload, patients with oliguric or anuric acute kidney injury, or those with congestive heart failure or symptomatic pleural effusion. It is reasonable to provide total daily fluid requirements (maintenance requirements and replacement for GI or other abnormal losses) in the PN admixture in patients who require long-term PN if stability and compatibility limits are maintained with dilution of the PN admixture.

*For patients > 60 years old, use 15 mL/kg for every kilogram above 20 kg.

Micronutrients

KEY CONCEPT Electrolytes, vitamins, and trace elements are essential for numerous biochemical and metabolic functions and should be added to PN daily unless otherwise not indicated.

► *Electrolytes*

KEY CONCEPT Electrolytes are essential for many metabolic and homeostatic functions, including enzymatic and biochemical reactions, maintenance of cell membrane structure and function, neurotransmission, hormone function, muscle contraction, cardiovascular function, bone composition, and fluid homeostasis. The causes of electrolyte abnormalities in patients receiving PN may be multifactorial, including altered absorption and distribution; excessive or inadequate intake; altered hormonal, neurologic, and homeostatic mechanisms; altered excretion and losses via the GI tract (eg, gastric, diarrhea, ostomy, enterocutaneous fistula) and kidneys; changes in fluid status and fluid shifts; and medication therapies. PN should not be used to treat acute electrolyte abnormalities but should be adjusted to meet maintenance requirements and to minimize worsening of underlying electrolyte disturbances.

LO 2

Electrolytes that are included routinely in PN admixtures include sodium, potassium, phosphorus (as phosphate), calcium, magnesium, chloride, and acetate. Always assess the patient's kidney function when determining electrolyte doses in PN admixtures. Typical daily electrolyte maintenance requirements for adults with normal kidney function are listed in Table 100–3.[7,15] For additional details regarding management of fluid, electrolyte, and acid–base disorders, refer to Chapters 27 and 28.

LO 2

LO 5 **Calcium–Phosphate Solubility** The FDA published a safety alert in response to two deaths from microvascular pulmonary emboli associated with calcium–phosphate precipitation in PN.[16] Because calcium and phosphate can bind and precipitate in solution, caution must be exercised when mixing these two electrolytes in PN admixtures. Several factors can affect calcium–phosphate solubility, including:

- *Amino acid brand and concentration:* Primary factor that affects pH of the PN admixture. The pH of amino acid stock solutions may vary between commercial products. In general, the higher the final amino acid concentration, the lower the pH of the final admixture (ie, closer to pH of the amino acid solution). Phosphates can also bind with amino acids, leaving fewer phosphates available to bind with calcium.
- *pH:* Largely affected by the amino acid brand and concentration, to a lesser extent by the dextrose concentration; the lower the solution pH, the less chance for calcium–phosphate precipitation. Monobasic phosphates predominate at low pH, leaving fewer free dibasic phosphates for precipitation with divalent calcium; monobasic calcium phosphate is more soluble than dibasic calcium phosphate.
- *Calcium salt:* Calcium gluconate is the preferred calcium salt in PN because it has a lower dissociation constant in solution with less free calcium available at a given time to bind phosphate.
- *Time:* The longer calcium and phosphate are in solution, the more calcium and phosphate will dissociate over time and increase the risk for calcium–phosphate precipitation.
- *Temperature:* As temperature increases, more calcium and phosphate dissociate and increase the risk of calcium–phosphate precipitation.
- *Order of mixing:* Calcium and phosphate should not be added simultaneously or consecutively when compounding PN admixtures (eg, add phosphate first, then add other PN components, and then add calcium near the end of compounding). The volume in the PN admixture at the time calcium is added (not necessarily the final volume) must be used to determine the maximum calcium that can be added.

When compounding PN admixtures, use calcium–phosphate solubility curves (based on the specific brand and final concentration of amino acids and dextrose) to determine safe and appropriate calcium and phosphate concentration limits.

Acetate Acetate is converted to bicarbonate at a 1:1 molar ratio. Bicarbonate should *never* be added to or co-infused with PN admixtures. This can lead to the release of carbon dioxide and result in the formation of insoluble calcium or magnesium carbonate salts.

► *Vitamins*

LO 2 Water-soluble and fat-soluble vitamins in the parenteral multivitamin products are essential cofactors for numerous biochemical reactions and metabolic processes. Parenteral multivitamins are added daily to the PN admixture. Water-soluble vitamins, with the exception of vitamin B_{12}, are generally readily excreted and not stored in the body in significant amounts. Deficiencies of water-soluble vitamins can occur rapidly in the absence of adequate vitamin supplementation in PN. Severe refractory lactic acidosis and deaths were reported in patients who received PN without added thiamine. Thiamine is an essential cofactor in carbohydrate metabolism (via the tricarboxylic acid cycle). Deficiency of thiamine pyrophosphate prevents the formation of acetyl-CoA from pyruvate, which is instead converted to lactate via anaerobic metabolism, resulting in lactic acidosis. Parenteral multivitamin products contain 150 mcg of vitamin K in accordance with FDA recommendations. A parenteral adult multivitamin formulation is available without vitamin K, but standard compounding of PN formulations should include a product that contains vitamin K unless otherwise indicated.

► *Trace Elements*

LO 2 Trace elements are essential cofactors for numerous biochemical processes. Trace elements added routinely to PN include zinc, selenium, copper, manganese, and chromium (Table 100–4). Various individual and multi-ingredient parenteral trace element formulations can be added to PN admixtures. Trace element supplementation in PN should be individualized, especially for long-term PN-dependent patients, rather than using a fixed dose of multi-trace element products.[17] Zinc is important for wound healing. Patients with high-output enterocutaneous fistulas, diarrhea, burns, and large open wounds may require additional zinc supplementation. Patients may lose as much as 12 to 17 mg zinc per liter of GI output; however, 12 mg/day may be adequate to maintain positive zinc balance in these patients.[18] Patients with chronic severe diarrhea, malabsorption, high-output enterocutaneous fistula, or short-bowel syndrome may also have increased selenium losses and may require additional selenium supplementation. Chromium is a cofactor for glucose metabolism, and patients with chromium deficiency may exhibit glucose intolerance; however, chromium deficiency is a rare cause of hyperglycemia. Patients who are chronically dependent on PN may accumulate chromium and manganese, resulting in high serum levels because these are known contaminants of parenteral products that are used in the making of PN, and manganese content of multitrace element products is higher than the recommended daily dose.[7,17] Patients with cholestasis (serum direct bilirubin concentrations that exceed 2 mg/dL [34.2 μmol/L]) should have manganese and possibly copper

LO 2 **Table 100–4**

Approximate Daily Maintenance Trace Element Requirements for Adults[7,a]

Zinc (Zn)	Selenium (Se)	Copper (Cu)	Manganese (Mn)	Chromium (Cr)
2.5–5 mg	20–60 mcg	0.3–0.5 mg	0.06–0.1 mg	10–15 mcg

[a]Requirements may vary based on patients' kidney function, liver function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, serum levels, and medication therapy. Contamination of some PN ingredients with trace elements (eg, chromium, manganese) can contribute significantly to the total amount the patient receives. Monitor serum trace element levels in patients receiving long-term PN therapy.

LO 2

restricted to avoid accumulation and possible toxicity because both elements undergo biliary elimination. However, copper deficiency resulting in anemia, pancytopenia, and death has occurred in PN-dependent patients when copper was omitted from the PN admixture. Because copper deficiency has been reported to occur anywhere between 6 weeks and 12 months after copper elimination from PN,[19] serum copper concentrations must be regularly monitored (eg, every 6–12 weeks) when copper is omitted from PN admixtures. Trace element status should initially be monitored approximately every 3 months in patients at risk for trace element deficiency or accumulation. When stable, serum trace element concentrations can be monitored every 6 to 12 months. These levels should always be interpreted by a knowledgeable nutrition support professional, in context of the clinical stability of the patient and combined with a clinical assessment of signs and symptoms of deficiency or toxicity.

PN Additives

In general, additives in PN admixtures should be avoided or minimized to limit the risk of incompatibilities and potential safety risks. Some medications are compatible with PN admixtures and appropriate for administration over a prolonged infusion time (eg, 12–24 hours), and it may be reasonable to add these to PN admixtures when indicated.

▶ *Regular Insulin*

Regular insulin may be added to PN admixtures for glycemic control. The dose depends on the patient's clinical condition, severity of hyperglycemia, predisposing factors for hyperglycemia, renal function, and daily insulin requirements. Generally, after the patient is receiving his or her goal dextrose dose in PN, about 50% to 70% of the total insulin units administered over the previous 24 hours as sliding scale or continuous infusion can be added to the next PN admixture. In patients with diabetes, typical IV insulin doses in the PN admixture to maintain euglycemia range from 0.05 to 0.2 unit of insulin per gram of dextrose in PN. Caution should be used when insulin is added to PN to avoid hypoglycemia, especially when reversible causes of hyperglycemia have resolved (eg, stress, acute pancreatitis, corticosteroids therapy) or more than one form of insulin therapy is used concurrently. Adding insulin to PN (vs a continuous IV infusion) does not provide the flexibility of frequent titration. Other forms of insulin should not be added to PN admixtures because they are not a true solution (eg, NPH insulin) and/or their pharmacokinetics/duration of action may not be appropriate for infusion over a prolonged time.

▶ *Histamine-2 Receptor Antagonists*

Intravenous histamine-2 receptor antagonists (eg, ranitidine, famotidine) are compatible with PN admixtures and can be added when indicated.

▶ *Parenteral Iron*

Chronic PN-dependent patients are at risk for iron-deficiency due to underlying clinical conditions and the lack of regular iron supplementation in PN. Parenteral iron dextran should be used with caution due to its infusion-related adverse effects. Iron dextran is compatible with 2-in-1 PN formulations, but is not commonly added to PN admixtures due to incompatibility with ILE. Other parenteral iron formulations (eg, iron sucrose, ferric gluconate) should NOT be added to PN admixtures due to a lack of compatibility data.

▶ *Other Additives*

Other nonnutrient additives should only be included in PN admixtures if there are data supporting physicochemical compatibility and stability and if there are clinical data demonstrating the efficacy and safety of use when administered in the manner of PN administration (ie, continuous infusion over ~12–24 hours).[14]

NUTRITION ASSESSMENT AND NUTRIENT REQUIREMENTS

LO 3

A nutrition assessment is used to determine a patient's nutritional status, identify patients with malnutrition, identify risk factors for nutrition-related problems, identify or rule out specific nutrient deficiencies, and determine nutrient requirements.[1] A complete description of nutrition assessment is beyond the scope of this chapter, and a nutrition assessment should be completed by a health care professional with appropriate training and expertise (eg, dietitian, nutrition-certified pharmacist or nurse, physician). Briefly, key components of a nutrition assessment include:[1,20]

LO 3

- Patient history
- Anthropometric measurements including height, weight, ideal body weight (IBW), body mass index (BMI = weight [kg]/height [m^2]), and recent weight changes (intentional or unintentional) (refer to Chapter 102 for additional information)
- Physical examination of the musculoskeletal system (eg, biceps, triceps, quadriceps, temporalis, deltoid, and interosseous muscles) for loss of muscle mass or decreased grip strength, and examination of the skin and mucous membranes for abnormalities (eg, dry or flaky skin, bruising, edema, ascites, poorly healing wounds) and loss of subcutaneous fat
- Changes in eating habits, GI function, and associated GI symptoms
- Presence and severity of underlying and concurrent disease(s)
- Serum visceral protein concentrations (eg, albumin, prealbumin). Hypoalbuminemia at baseline or before hospitalization may indicate malnutrition, and severe hypoalbuminemia may be associated with poor outcomes. Serum albumin (half-life ~20 days) and prealbumin (half-life ~2 days) are negative acute phase proteins and therefore are neither sensitive nor specific indicators of nutritional status and protein stores in patients under metabolic stress or with evidence of inflammatory response. Measuring C-reactive protein (CRP), white blood cell count, and blood glucose levels may help assess inflammatory response. Synthesis and distribution of albumin and prealbumin may be altered, and serum concentrations are affected by nonnutritional factors, including hydration status, kidney function, and liver function.
- Biochemical evidence of vitamins, trace elements, and iron studies if clinical suspicion and minimal to no inflammation
- Functional assessment including handgrip strength

A diagnosis of malnutrition is made by identifying at least two of the following six characteristics:[20]

- Insufficient energy intake
- Weight loss
- Loss of muscle mass

- Loss of subcutaneous fat
- Localized or generalized fluid accumulation that may sometimes mask weight loss
- Diminished functional status as measure by hand grip strength

Using these criteria in combination with an assessment of inflammatory status, malnutrition may be defined as:[20]

- Without inflammation: Starvation-related malnutrition (pure chronic starvation, anorexia nervosa)
- Mild to moderate inflammation: Chronic disease-related malnutrition (organ failure, pancreatic cancer, rheumatoid arthritis, sarcopenic obesity)
- Marked inflammation: Acute disease or injury-related malnutrition (major infection, burns, trauma, closed head injury)

After performing a nutrition assessment, estimate the patient's daily energy and protein requirements (Table 100–5).[1,2,7,21,22] Indirect calorimetry involves measuring the volumes of oxygen consumption (VO_2) and carbon dioxide production (VCO_2) to determine the resting metabolic rate (RMR) or resting energy expenditure (REE) and respiratory quotient (RQ = VCO_2/VO_2). The REE or RMR is the amount of calories required during 24 hours by the body in a nonactive state and is approximately 10% higher than the basal energy expenditure (BEE, metabolic activity required to maintain life) as it adjusts for the thermic effect of food and awake state. Critically ill patients may have variable energy expenditure (EE), and indirect calorimetry is a valuable tool in assessing EE in these patients. Indirect calorimetry requires specific equipment and trained personnel and therefore is not feasible in all settings.

More than 200 equations and derivations have been developed to predict EE for adults. The Harris-Benedict, Penn State, and Mifflin-St. Jeor equations are some of the most widely used, and they take into account several variables including a patient's sex, weight, height, age, and mechanical ventilation data to determine the REE (Table 100–5). A "stress" or "injury" factor is sometimes applied to estimate the daily total EE (TEE), although there is debate about the appropriateness and validity of this approach. Alternatively, EE can be estimated based on EE per body weight. However, dry weight or hospital

LO 3

Table 100–5

Estimating Daily Nutritional Requirements in Adults[1,2,7,20–22]

Determining Energy Expenditure	
Penn State equations (for critically ill, mechanically ventilated, nonobese adult patients)	RMR = (0.85 × BEE[a]) + (33 × V_E) + (175 × T_{max}) – 6433 RMR = (0.96 × BMR[b]) + (31 × V_E) + (167 × T_{max}) – 6212
Mifflin-St. Jeor equations (for nonobese and obese, noncritically ill adult patients)	Men: BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) + 5 Women: BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) – 161
Harris-Benedict equations (historical, not currently recommended for use in acute setting)	Men: BEE = 66.42 + (13.75 × Wt) + (5 × Ht) – (6.78 × Age) Women: BEE = 655.1 + (9.65 × Wt) + (1.85 × Ht) – (4.68 × Age) Energy expenditure then multiplied by a stress factor. To estimate the TEE: Bed rest ≈ 1.2 × BEE Ambulatory ≈ 1.3 × BEE Anabolic ≈ 1.5 × BEE Energy requirements should also be increased ~12% with each degree of fever above 37°C (98.6°F).
Energy expenditure per body weight (ie, kcal/kg)[c]	Range of ~20–30 kcal/kg/day, possibly up to 35 kcal/kg/day Maintenance ~20–25 kcal/kg/day Repletion, postoperative wound healing, critical illness, sepsis, severe trauma, severe burns ~25–30 kcal/kg/day, possibly up to 35 kcal/kg/day

Determining Amino Acid Requirements Patient Clinical Condition	Daily Amino Acid Requirements[d] (g/kg)
Maintenance or nonstressed	0.8–1
Repletion	1.3–2
Trauma, burns, sepsis, critical illness, wound healing	1.5–2
Hepatic failure with encephalopathy	0.8–1
Acute kidney injury, predialysis	0.8–1
Acute kidney injury receiving IHD	1.2–1.5
Chronic kidney disease receiving CAPD	1.2–1.5
Acute kidney disease receiving CRRT	1.5–2.5

[a]BEE calculated using the Harris-Benedict equation.

[b]BMR calculated using Mifflin-St. Jeor equation.

[c]One kcal/kg is equivalent to 4.184 kJ/kg.

[d]Amino acid requirements are based on actual body weight for normal body sized or malnourished adult patients and on ideal body weight (IBW) for obese patients.

BMR, basal metabolic rate; CAPD, continuous ambulatory peritoneal dialysis; CRRT, continuous renal replacement therapy; Ht, height (cm); IHD, intermittent hemodialysis; RMR, resting metabolic rate; TEE, total energy expenditure; T_{max}, maximum body temperature in degrees Celsius; V_E, minute ventilation in liters per minute; Wt, weight (kg).

admission weight should be used, and this estimation may not be appropriate in obese or elderly patients. There is debate over the best method to estimate energy requirements for obese patients. Indirect calorimetry would be the preferred method but may not always be available. Several equations have been developed to estimate EE in obese patients. Although there is no consensus on the weight used to estimate EE in obese patients, it is reasonable to use an AdjBW in obese patients to avoid overfeeding. AdjBW can be calculated with 25% to 50% of the difference between the actual weight and IBW added to the IBW. Using a 25% difference in calculating the AdjBW further avoids overfeeding when estimating energy requirements:

$$\text{AdjBW} = \text{IBW} + (0.25 \times [\text{Actual weight} - \text{IBW}])$$

Hypocaloric feeding is another approach for nutrient dosing in obese critically ill patients (discussed below).

Amino acid requirements are based on the patient's nutritional status, clinical condition(s), kidney function, and liver function. Amino acids are needed in adequate amounts to facilitate anabolism, restore lean body mass, and promote wound healing while avoiding adverse effects from excessive amino acid loading (eg, azotemia). No evidence-based data are available confirming the optimal body weight (actual, ideal, or adjusted) to use for dosing amino acids in adult patients. It is suggested to dose amino acids based on actual body weight for normal body sized or malnourished adult patients (ie, when actual weight is at or below IBW) and based on IBW or AdjBW for obese patients.

Hypocaloric nutrition support is an approach to dosing nutrition therapy for obese patients (BMI ≥ 30 kg/m^2). Hypocaloric feeding involves providing high doses of protein (≥ 2–2.5 g/kg IBW/day) to support anabolism with lower amounts of total calories (~11–14 kcal/kg [~46–59 kJ/kg] actual weight/day or ~22–25 kcal/kg [~92–105 kJ/kg] IBW/day) with primary goals to promote net protein anabolism and avoid hyperglycemia or exacerbation of metabolic stress in critically ill patients.[2,21] Other benefits could include avoiding fat weight gain or promoting fat weight loss. Most data with hypocaloric feeding are in critically ill adult patients, but this approach has been used in other patients. Hypocaloric feeding should not be used in patients with kidney or liver failure. The optimal safe duration of hypocaloric feeding is unknown.

Permissive underfeeding refers to providing a lower calorie nutrition support regimen to critically ill adult patients for a short period of time during the initial phase of high metabolic stress. The aims of permissive underfeeding are to avoid the burden of caloric intake on worsening metabolic stress and the negative effects of carbohydrate loading and associated hyperglycemia, increased carbon dioxide production, and fat accumulation. Typically, a permissive underfeeding PN regimen provides about 60% to 80% of daily energy requirements. Because the optimal amount of calories for critically ill patients is not well defined, strong clinical evidence to support the use of permissive underfeeding is also lacking. Severe or prolonged underfeeding should be avoided because it can result in energy deficit to the patient with the consequences of increased infectious complications with negative outcomes.

PARENTERAL NUTRITION SAFETY

Serious and sometimes fatal adverse events have occurred with inappropriate use of PN. Shortages of key PN components have also presented challenges to meet nutritional needs of patients requiring PN therapy. The American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.) has published several key PN safety documents, including comprehensive safe practice guidelines,[7] PN safety recommendations,[23] and revised guidelines that address PN ordering, order review, compounding, labeling, and dispensing.[14] A.S.P.E.N. has also provided guidance for managing shortages of PN components. These are essential resources for health care professionals for the safe and efficacious use of PN therapy, and they represent the standards of practice as related to PN prescribing, compounding, stability, compatibility, labeling, administration, and quality assurance. There are several key points and recommendations in these documents to improve the safety of the PN use process, including:

LO 4

- Adopting published guidelines and literature
- Developing standardized processes for PN prescribing, order verification, compounding, labeling, dispensing, administering, and monitoring
- Developing PN-specific policies and procedures
- Develop education and competency assessments at least annually for all health care professionals involved in the PN use process
- Optimizing electronic health records (EHR) and clinical decision support for PN orders
- Build, test, and heed clinical decision support warnings in EHR systems and in automated compounding devices
- Avoiding use of handwritten PN orders and eliminating transcription of PN orders
- Matching templates between ordering/EHR, compounding software/automated compounding devices, and PN labels
- PN use process and development of policies, procedures, education, and competencies should include health care professionals with expertise in nutrition support, preferably from multiple disciplines.

Although application of these guidelines is voluntary, health care professionals who are involved in prescribing, compounding, dispensing, administering, and monitoring PN therapy should review and apply them to their practice.

PREPARING THE PN PRESCRIPTION: ADMINISTRATION, COMPOUNDING, AND PHARMACEUTICAL ISSUES

LO 5

After performing a nutrition assessment and estimating nutritional requirements, determine the optimal route to provide nutrition support therapy (eg, oral, enteral, or parenteral). If PN is indicated, venous access for PN infusion must be obtained. Finally, formulate a PN prescription and administer PN according to safety guidelines.

Route of PN Administration: Peripheral Versus Central Vein Infusion

KEY CONCEPT PN can be administered via a smaller peripheral vein or via a larger central vein (Figure 100–1). Peripheral PN (PPN) is generally reserved for short-term administration (up to 7 days) when central venous access is not available. PN formulations are hyperosmolar, and PN infusion via a peripheral vein can cause thrombophlebitis. Factors that increase the risk of **phlebitis** include high solution osmolarity, extreme pH, rapid infusion rate, vein properties, catheter properties (eg, diameter, material), and infusion time via the same vein.[23] The osmolarity of PPN admixtures should be limited to ≤ 900 milliosmoles (mOsm)/L to minimize the risk of phlebitis. The approximate osmolarity

LO 5

LO 5

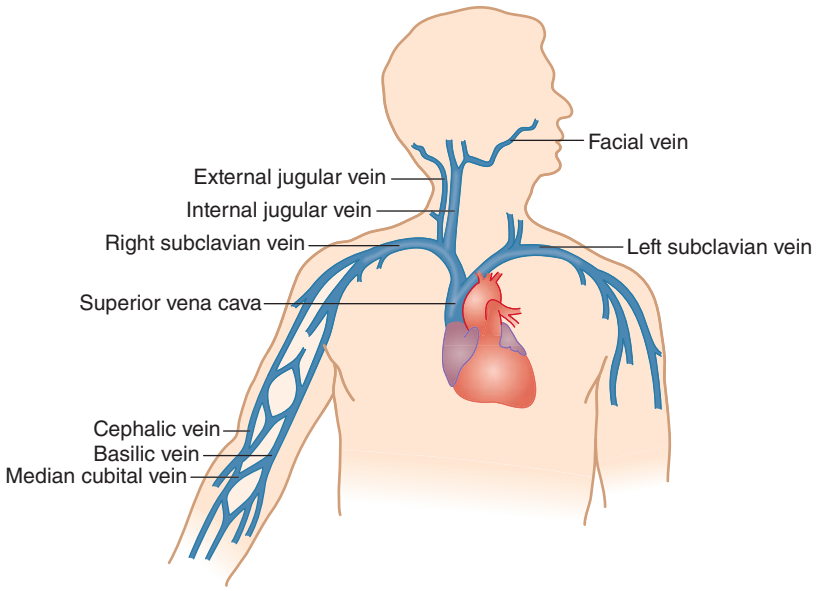

FIGURE 100–1. Selected vascular anatomy. (Reprinted with permission from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. Nutrition Support Core Curriculum: A Case-Based Approach—The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition; 2007:300–322.)

of a PN admixture can be calculated from the osmolarity of the individual components:

- Amino acids ~10 mOsm/g (or 100 mOsm/L% final concentration in PN)
- Dextrose ~5 mOsm/g (or 50 mOsm/L% final concentration in PN)
- Sodium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Potassium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Calcium gluconate = 1.4 mOsm/mEq (2.8 mOsm/mmol)
- Magnesium sulfate = 1 mOsm/mEq (2 mOsm/mmol)

LO 5 PPN admixtures should be co-infused with ILE when using 2-in-1 PN because the iso-osmolarity and near-neutral pH of ILE may decrease the risk of phlebitis (Table 100–2). Infectious and mechanical complications may be lower with PPN compared with central venous PN administration. However, because of the risk of phlebitis, severe soft tissue damage if extravasation occurs, and osmolarity limit, PPN admixtures have low macronutrient concentrations and therefore usually require large fluid volumes to meet a patient's nutritional requirements. Given these limitations, every effort should be made to obtain central venous access and initiate central PN in patients who have an appropriate indication (Table 100–1).

LO 5 *Central PN* refers to the administration of PN via a large central vein, and the catheter tip must be positioned in the superior vena cava (Figure 100–2). Central PN allows the infusion of a highly concentrated, hyperosmolar nutrient admixture. The typical osmolarity of a central PN admixture is about 1500 to 2000 mOsm/L. Central veins have much higher blood flow and the PN admixture is diluted rapidly on infusion, so phlebitis is usually not a concern. Patients who require PN therapy for longer periods of time (> 7 days) should receive central PN. Central PN requires placement of a central venous catheter and an x-ray to confirm placement of the catheter tip. A commonly used central catheter for PN infusion is a peripherally inserted central venous catheter (PICC), which is inserted into a peripheral vein but the catheter tip is placed in the superior vena cava (Figure 100–3). Central venous catheter placement may be associated with complications, including **pneumothorax**, arterial injury, **air embolus**, venous thrombosis, infection, **chylothorax**, and **brachial plexus** injury.[1,24]

Types of PN Formulations: 3-in-1 Versus 2-in-1

LO 5 KEY CONCEPT PN admixtures can be prepared by mixing all components into one bag, or ILE may be infused separately (via a Y-site infusion or through a separate IV catheter or lumen). When all components are mixed together, it is referred to as a 3-in-1 admixture or TNA.[25] When dextrose, amino acids,

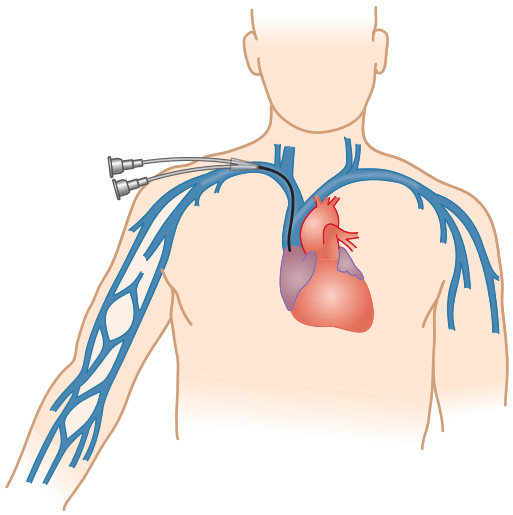

FIGURE 100–2. Percutaneous nontunneled catheter. (Reprinted with permission from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. FIGURE 100–3. Peripherally inserted central venous catheter. (Reprinted with permission from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. Nutrition Support Core Curriculum: A Case-Based Approach—The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition; 2007:300–322.)

and all other PN components are mixed together without ILE, this is referred to as a 2-in-1 PN admixture. There are various advantages and disadvantages to using either TNA or 2-in-1 PN admixtures (Table 100–6). With a 2-in-1 PN admixture, ILE can be infused separately on a daily or intermittent basis. When ILE is mixed in the PN, the TNA becomes an emulsion with respect to physical and chemical characteristics. The final concentration of ILE in a 3-in-1 admixture should be greater than or equal to 2% (20 g/L) to prevent compromising the stability of the emulsion.[24] Electrolyte, dextrose, and amino acid concentrations may also be more limited in a 3-in-1 admixture.

LO 4 LO 5 The FDA has provided recommendations for safe infusion of PN admixtures containing calcium and phosphate:

- A 0.22-μm air-eliminating in-line filter should be used for infusion of non–ILE-containing PN.
- A 1.2-μm in-line filter should be used for the infusion of a TNA because it can remove large and unstable fat droplets and particulate matter.[25] (A 0.22-μm filter cannot be used on the TNA or ILE infusion line because the average size of ILE particles is ~0.3 to 0.5 μm.)[26]

LO 4 Medications should not be admixed or coinfused with PN unless necessary, and it should only be done if reasonable and safe (based on toxicity profile, pharmacokinetic, and pharmacodynamic considerations).[23] *Always* consult compatibility data before adding a medication to or coinfusing with a PN admixture. Many IV medications have limited compatibility with 3-in-1 formulations but may be coinfused with a 2-in-1 formulation.[27,28] Some medications can be coinfused at the Y-site, few medications can be mixed directly into the PN admixture or coinfused with ILE, and some cannot be mixed or coinfused with the PN admixture.[27,28]

Standardized, Commercially Available (Premixed) PN Formulations

A standardized, commercially available PN formulation is a product available from a manufacturer that requires fewer compounding steps before administration.[29] These products usually contain amino acids and dextrose in a two-chamber bag, with or without electrolytes. Vitamins and trace elements must be manually added. ILE can be added to create a TNA or infused separately. Potential advantages of standardized commercial PN products include improvements in safety (both decreased compounding errors and microbiologic contamination) and reduced costs.[29] The safety advantages are logically related to fewer manual manipulations of the system, but clinical trial data are lacking. Cost advantages have been demonstrated in some trials, with others finding no difference or increased costs. Limitations with the use of these products in the United States include relatively low amino acid concentrations, only 1- and 2-L volumes, limited

LO 5

Table 100–6

Potential Advantages and Disadvantages of Using 3-in-1 (TNA) or 2-in-1 PN Admixtures

	3-in-1 (TNA)	2-in-1
Advantages	Simplified regimen for patient Increased patient compliance at home Decreased labor (less nursing time) Decreased supply and equipment costs Decreased risk of contamination (less manipulation; all components aseptically compounded) Inhibited bacterial growth vs separate ILE Minimize infusion-related reactions from ILE and possibly improved lipid clearance (if infused over > 12 hours) Decreased vein irritation (with PPN)	Improved stability compared with TNA Increased number of compatible medications Decreased bacterial growth (in dextrose–amino acid component) compared with TNA Easier visual inspection Can use 0.22-μm bacterial retention filter
Disadvantages	Decreased stability compared to 2-in-1 PN Cannot use 0.22-μm bacterial retention filter; must use 1.2-μm filter Increased bacterial growth compared with 2-in-1 PN Visual inspection is difficult Limited compatibility with medications	Increased labor and costs (if ILE infused separately) Increased vein irritation with PPN, especially if not coinfused with ILE

ILE, IV lipid emulsion; PN, parenteral nutrition; PPN, peripheral parenteral nutrition; TNA, total nutrient admixture.

Patient Encounter Part 2

It is now hospital day #3. Given that RK has malnutrition, an enterocutaneous fistula originating from the jejunum with high output (> 500 mL/day, increased when the patient drank water), and had recent abdominal surgery, the surgery team decided to manage RK conservatively: control fistula drainage, nothing oral status, and begin parenteral nutrition (PN) support today. A peripherally inserted central catheter (PICC) was placed for PN therapy.

Laboratory Data

Na = 134 mEq/L (mmol/L), K = 3.2 mEq/L (mmol/L), Cl = 91 mEq/L (mmol/L), HCO_3 = 24 mEq/L (mmol/L), BUN = 6 mg/dL (2.1 mmol/L), serum creatinine = 0.4 mg/dL (35 µmol/L), blood glucose = 91 mg/dL (5.1 mmol/L), total Ca = 8.4 mg/dL (2.10 mmol/L)], ionized Ca = 2.38 mEq/L (1.19 mmol/L), Mg = 1.5 mg/dL (0.62 mmol/L), phosphorus = 2.5 mg/dL (0.81 mmol/L), TG = 129 mg/dL (1.46 mmol/L), albumin = 2.9 g/dL (29 g/L), WBC count = 8,300/mm^3 (8.3 × 10^9/L), hemoglobin = 11.4 mg/dL (114 g/L or 7.08 mmol/L), hematocrit = 35.1% (0.35), and platelets = 204,000/mm^3 (204 × 10^9/L)

Determine appropriate nutritional goals for RK (calorie and protein requirements).

What other patient data should be collected to help formulate a PN prescription?

variability in electrolyte content, and no formulations available for neonates and infants. These limitations may make standardized commercial PN admixtures less appropriate for some patients (eg, critically ill, obese, those with organ dysfunction or who require fluid restriction).

Formulating a PN Admixture and Regimen

After completing a full nutrition assessment; estimating the patient's daily fluid, energy, and protein requirements (Table 100–5); and determining if PN is indicated (Table 100–1), develop an appropriate PN prescription.

Initiating PN

LO 6 LO 7

Exercise caution when initiating PN to avoid hyperglycemia and fluid and electrolyte abnormalities. After determining the goal daily PN volume, initiate PN at a lower infusion rate (eg, ~50% of goal for anywhere from ~6 to 24 hours) on day 1 with no more than 150 to 200 g of dextrose per day (or a maximum initial dextrose infusion rate of ~2 mg/kg per minute). Then increase PN to goal over the following ~24 hours, provided that glycemic control is maintained and the patient does not experience significant fluid or electrolyte abnormalities. Monitor electrolytes daily and correct as needed. Advance PN more slowly and cautiously in patients with severe malnutrition and monitor for refeeding syndrome (see Complications of PN).

Patient Encounter Part 3

The surgical team asks for your recommendations for PN therapy for RK.

Develop a plan for a complete and balanced PN prescription for amino acids (including fluid, total calories, dextrose, amino acids, ILE, electrolytes, vitamins, trace elements, and any additives) and explain the rationale supporting your PN formulation and plan.

How should this PN admixture be initiated and titrated to goal?

Would you recommend any other treatments before initiating PN? (Hint: Is this patient at risk for refeeding syndrome?)

Cycling PN

PN should be administered over 24 hours in most hospitalized patients to minimize glucose, fluid, and electrolyte abnormalities. However, administering PN via an infusion over less than 24 hours, or *cycling PN*, may be advantageous in certain patients and situations. Cycling PN typically involves administering the same PN volume over a goal infusion time, usually over 12 to 18 hours, rather than over 24 hours. Begin with PN infusion over 24 hours; then taper the PN infusion to the goal cycle over 2 to 4 days (eg, 24 hours, then 18–20 hours the next day, then 14–16 hours the next day, and then 12 hours the next day). A longer goal cycle may limit adverse effects related to rate of fluid and dextrose administration (hyper- and hypoglycemia). Titrate the PN infusion rate up over 1 to 2 hours to peak rate to avoid hyperglycemia and taper down over 1 to 2 hours at the end of the cycle to avoid reactive hypoglycemia. Most home infusion pumps can be programmed to cycle a given PN volume automatically over a given time. However, the clinician may have to develop an appropriate PN cycle if the infusion pump cannot be programmed for an automatic cycle.

LO 6

Cyclic PN has the following potential advantages:

- It may improve the quality of life of patients receiving home PN by allowing the patient time off of PN to engage in normal activities of daily living.
- While data are limited, it may help prevent and alleviate PN-associated liver disease by avoiding continuous compulsive nutrient overload on the liver.[30]

Concerns with cycling PN include hyperglycemia with high infusion rates, reactive hypoglycemia when PN infusion is stopped, and fluid and electrolyte abnormalities. Random capillary blood glucose concentrations should be checked ~2 hours after reaching goal rate, 15 to 60 minutes after PN stops, and intermittently during the PN cycle as needed for glycemic control. During cyclic PN infusion, the potassium infusion rate should not exceed 10 mEq/h (mmol/h) if the patient is not on a cardiac monitor. If nocturnal cyclic PN infusion interferes with patient's sleep pattern by causing overdiuresis, the PN cycle can be extended over a longer infusion time or PN can be infused during other times of the day that are most convenient to the patient.

Transition to Oral or Enteral Nutrition

The goal is to transition the patient to enteral or oral nutrition and taper off PN as soon as indicated. After initiation of enteral or oral nutrition, monitor the patient for glucose, fluid, and electrolyte abnormalities. When oral nutrition intake is inconsistent, perform calorie counts to determine the adequacy of nutrition via the oral route. When the patient is tolerating more than 50% of total estimated daily calorie and protein requirements via the oral or enteral route, decrease PN by about 50%.

PN can be stopped when the patient is tolerating at least 75% of total daily calorie and protein requirements via the oral or enteral route, assuming that intestinal absorption is maintained.

COMPLICATIONS OF PN

KEY CONCEPT PN therapy is associated with significant complications, both with short- and long-term therapy (Table 100–7). Many complications are related to overfeeding (Table 100–8).

Hyperglycemia

LO 7

Hyperglycemia is one of the most common complications associated with PN therapy. The rate of dextrose oxidation may be reduced in patients with stress and hypermetabolism, patients with diabetes or acute pancreatitis, and patients receiving certain medications (eg, corticosteroids, vasopressors, octreotide, and tacrolimus).[31,32] Uncontrolled hyperglycemia can lead to fluid and electrolyte disturbances, hyperglycemic hyperosmolar nonketotic syndrome, hypertriglyceridemia, and an increased risk of infection.[33] Hyperglycemia in critically ill patients may be more a reflection of illness severity than from dextrose infusions, provided that the patient is not being overfed with dextrose.[34] Critical illness is associated with increased endogenous glucose production (caused by increased glycogenolysis and gluconeogenesis) and insulin resistance. Therefore, critically ill patients have lower tolerance for dextrose infusion compared with nonstressed patients. A portion of daily calories (~20% to 30%) can be administered via ILE to help decrease hyperglycemia, provided that the patient does not have hypertriglyceridemia. Overfeeding (with dextrose and with total calories) must always be avoided. Most recent data suggests that moderate glucose control is indicated in critically ill patients (eg, capillary glucose concentrations between ~140 and 180 mg per dL [7.8 and 10.0 mmol/L]).[35] Refer to the section on "PN Additives: Regular Insulin" regarding management of hyperglycemia with insulin.

Hypoglycemia

LO 7

Hypoglycemia can occur in patients when PN is interrupted suddenly (reactive hypoglycemia), especially when patients are treated with insulin or as a result of insulin overdosing in PN.[1] It is essential to prevent hypoglycemia and, if it occurs, identify and treat it promptly. Reactive hypoglycemia typically is rare and usually can be avoided by tapering PN over 1 to 2 hours before discontinuation rather than abruptly stopping the infusion (especially if the patient is receiving insulin in PN or if the patient is not receiving oral or enteral nutrition). Reactive hypoglycemia generally occurs within 15 to 60 minutes after stopping PN (especially in neonatal patients), although it can occur later than this after discontinuing PN.[1] Capillary blood glucose concentrations should be monitored about 15 to 60 minutes after stopping PN infusion to detect any potential hypoglycemia. If PN is interrupted abruptly (eg, because of lost IV access), infusing an IV solution containing dextrose 10% in water at the same rate as PN should prevent hypoglycemia. In patients with poor venous access, reduce the PN infusion rate by 50% for 1 hour before discontinuing. Another alternative to prevent reactive hypoglycemia is to provide a glucose source via the oral or sublingual route when feasible.

LO 7

Table 100–7

Complications Associated with Parenteral Nutrition

Short Term	Long Term

LO 7

Table 100–8

Consequences of Overfeeding

Source of Overfeeding	Consequences
Dextrose	Hyperglycemia, hypertriglyceridemia, hepatic steatosis, hypercapnia; hyperglycemia may cause fluid and electrolyte disturbances and increased infection risk
IV lipid emulsions	Hypertriglyceridemia, hyperlipidemia, hepatic steatosis
Amino acids	Azotemia
Total calories	Hepatic steatosis, cholestasis, hypercapnia

Hyperlipidemia/Hypertriglyceridemia

Patients receiving ILE may be at risk for hyperlipidemia and hypertriglyceridemia. Hyperlipidemia in patients receiving PN may lead to a reduction in pulmonary gas diffusion and pulmonary vascular resistance.[36] Severe hypertriglyceridemia (especially serum triglyceride concentrations exceeding 1000 mg/dL or 11.30 mmol/L) can precipitate acute pancreatitis.[37] Hypertriglyceridemia may develop as a result of increased fatty acid synthesis caused by hyperglycemia, impaired ILE clearance, in patients with history of hyperlipidemia, obesity, diabetes, alcoholism, kidney failure, liver failure, multiorgan failure, sepsis, or pancreatitis, or as a result of medications (eg, propofol, corticosteroids, cyclosporine, and sirolimus).[38,39] Hyperglycemia is probably one of the most common causes of hypertriglyceridemia in patients receiving PN.

LO 7

A higher PL:TG ratio has been proposed to cause the appearance of the abnormal lipoprotein X particles in the blood.[9,38] Lipoprotein X may compete with ILE particles for metabolism by lipoprotein lipase. It is preferred to use ILE with a lower PL:TG ratio, especially in patients with hypertriglyceridemia, because they have improved clearance compared with emulsions with a higher PL:TG ratio (Table 100–2).[9,38]

Monitor serum triglyceride concentrations regularly during PN therapy (Table 100–8). If a patient develops hypertriglyceridemia, identify and correct the underlying cause(s) if possible. Prolonging the infusion of ILE may improve lipid clearance. If a patient is receiving propofol, ILE should be withheld and the triglyceride load and calories from the 10% ILE in propofol should be taken into account (Table 100–2). ILE should be held when the serum is lipemic or when serum triglyceride concentrations are greater than 400 mg/dL (4.52 mmol/L). When this occurs, restart ILE when the serum triglyceride concentration is approximately 200 to 400 mg/dL (2.26 to 4.52 mmol/L) (or less) and administer only

two to three times per week to prevent EFAD. Avoid completely holding ILE for more than 3 to 4 weeks due to risk of EFAD.

Hypercapnia

LO 7 Hypercapnia can develop as a result of overfeeding with dextrose and/or total calories.[1,40] Excess carbon dioxide production and retention can lead to acute respiratory acidosis. Excess carbon dioxide will also stimulate an increase in respiratory rate, and this increase in respiratory workload could cause respiratory insufficiency that may require mechanical ventilation. Reducing total calorie and dextrose intake would result in resolution of hypercapnia if due to overfeeding.

Liver Complications

The incidence of liver complications associated with PN ranges from approximately 7% to 84%, and end-stage liver disease historically developed in as many as 15% to 40% of adult patients on long-term PN (likely lower in current practice with avoidance of overfeeding).[38] Patients may develop a mild increase in liver transaminases within 1 to 2 weeks of initiating PN, but this generally resolves as PN continues, provided overfeeding is avoided. Severe liver complications include hepatic **steatosis**, **steatohepatitis**, cholestasis, and **cholelithiasis**.[38]

LO 7 Hepatic steatosis is usually a result of excessive administration of carbohydrates or fats, but deficiencies of carnitine, choline, and essential fatty acids also may contribute. Hepatic steatosis can be minimized or reversed by avoiding overfeeding, especially from dextrose and ILE.[38] Cholestasis is a common and potentially LO 7 serious complication in PN-dependent patients. Factors that predispose PN patients to cholestasis include overfeeding, bowel rest, long duration of PN, short-bowel syndrome, bacterial overgrowth and translocation, and sepsis.[38] Patients may exhibit increased liver transaminase, alkaline phosphatase and gamma-glutamyl transferase concentrations, and mainly increased bilirubin concentrations with jaundice. The most sensitive marker of cholestasis is increased serum conjugated bilirubin concentration of greater than 2 mg/dL (34.2 μmol/L).[38] Cholestasis generally is reversible if PN is discontinued before permanent liver damage occurs. Serum liver function tests may take up to 3 months to return to normal after discontinuing PN. Steps to prevent cholestasis associated with PN include early enteral or oral feedings, using a balanced PN formulation, avoiding overfeeding, using cyclic PN infusion, and treating and avoiding sepsis.[38] Limiting soy-based ILE infusion to one or two times weekly at a dose adequate to prevent essential fatty acid deficiency may also decrease serum bilirubin concentrations and improve cholestasis.[41] Pharmacologic treatments include ursodeoxycholic acid (ursodiol), which may improve bile flow and reduce the signs and symptoms of cholestasis. Ursodiol is only available in an oral dosage form, and absorption may be limited in patients with intestinal resections.

LO 7 Cholelithiasis can develop as a result of decreased gallbladder contractility, especially in the absence of enteral or oral intake. Lack of intestinal stimulation reduces secretion of cholecystokinin, a peptide hormone secreted in the duodenum that induces gallbladder contractility and emptying. The best prevention of cholelithiasis is early initiation of enteral or oral feeding.

Monitor liver function tests, including serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, total bilirubin, conjugated bilirubin, unconjugated bilirubin, and γ-glutamyl transferase at the initiation of PN therapy and regularly thereafter during PN therapy. The frequency of monitoring liver function tests depends on the presence or absence of liver disease, ranging from once weekly in the acute setting to monthly or less frequently in stable home PN patients.

Manganese Toxicity

LO 7 Manganese accumulation can occur in patients with cholestasis or in patients receiving long-term PN therapy. Neurotoxicity is the most common manifestation (headache, somnolence, weakness, confusion, tremor, muscle rigidity, altered gait, and masklike face [a Parkinson-like syndrome]), but liver toxicity also may occur.[38] Periodically monitor blood manganese concentrations in patients on long-term PN. Patients with cholestasis receiving PN may require restriction of manganese in PN to prevent accumulation and possible toxicity.

Metabolic Bone Disease

LO 7 Metabolic bone disease (MBD) is a condition of bone demineralization leading to **osteomalacia**, **osteopenia**, or **osteoporosis** in patients receiving long-term PN. MBD may occur in as many as 40% to 100% of patients receiving long-term PN.[38] Often patients are asymptomatic, although symptoms can include bone pain, back pain, and fractures. Patients often have increased serum alkaline phosphatase concentrations, low to normal parathyroid hormone (PTH) concentrations, normal 25-hydroxyvitamin D and low 1,25 dihydroxyvitamin D concentrations, hypercalcemia or hypocalcemia, and hypercalcuria.[42] Because patients may be asymptomatic, diagnosis can be incidental. Radiographic techniques commonly used in diagnosing bone disease include quantitative computed tomography (CT) and bone mineral density.[42]

LO 7 Factors that can predispose patients to developing MBD include deficiencies of phosphorus, calcium, and vitamin D; aluminum toxicity; amino acids and hyperosmolar dextrose infusions; chronic metabolic acidosis; corticosteroid therapy; and lack of mobility.[38,42] Calcium deficiency (caused by decreased intake or increased urinary excretion) is one of the major causes of MBD in patients receiving PN. Provide adequate calcium and phosphate with PN to improve bone mineralization and help to prevent MBD. Administration of amino acids and chronic metabolic acidosis also appears to play an important role.

Aluminum toxicity appears to play a role in the development of MBD in patients on long-term PN, possibly by impairing calcium bone fixation, inhibiting the conversion of 25-hydroxyvitamin D to the active 1,25-dihydroxyvitamin D, and/or reducing PTH secretion.[38,42] The FDA issued a rule specifying acceptable LO 4 aluminum concentrations in large-volume parenterals,[43] LO 7 indicating that products contain no more than 25 mcg/L (0.93 μmol/L) of aluminum and defined a safe upper limit for parenteral aluminum intake at less than 4 to 5 mcg/kg/day. Pharmacies should use products with the lowest labeled aluminum content for the making of PN. Patients who are chronically dependent on PN should have their serum aluminum concentrations routinely monitored or whenever MBD is suspected or diagnosed.

Encourage patients on long-term PN to engage in regular low-intensity exercise. Yearly bone density measurements also should be performed on patients on long-term PN and when MBD is suspected.

Refeeding Syndrome

Refeeding syndrome describes the metabolic derangements that occur during nutritional repletion of patients who are starved, underweight, or severely malnourished.[44] Hypophosphatemia and hypokalemia (along with associated complications) are

the classic signs and symptoms, but refeeding syndrome encompasses a constellation of fluid and electrolyte abnormalities affecting neurologic, cardiac, hematologic, neuromuscular, and pulmonary systems. The most severe cases of refeeding syndrome have resulted in cardiac failure, seizures, coma, and death.[44] The reintroduction of energy substrates, especially carbohydrates, increases metabolism and utilization of glucose as the predominant fuel source. This increases insulin secretion and demand for phosphorylated intermediates of glycolysis (eg, ATP and **2,3-diphosphoglycerate** [2,3-DPG]), inhibits fat metabolism, and causes an intracellular shift of phosphorus, potassium, and magnesium. These changes, in combination with preexisting low total body stores of phosphorus, potassium, and magnesium and enhanced cellular uptake of phosphorus during anabolic refeeding, result in hypophosphatemia, hypokalemia, and hypomagnesemia. Vitamin deficiencies (eg, thiamine) also may exist or be precipitated during refeeding. High carbohydrate intake increases the demand for thiamine, which can precipitate thiamine deficiency and cause lactic acidosis and neurologic abnormalities,[44] as well as myocardial dysfunction and congestive heart failure. Other metabolic alterations that may occur include expansion of the extracellular water compartment and fluid intolerance.

LO 8

The primary goal is preventing refeeding syndrome when initiating PN in high-risk patients (eg, prolonged lack of adequate nutritional intake, significant weight loss, or moderate to severe malnutrition). When initiating nutrition support, the rule of thumb to prevent refeeding syndrome is to "start low and go slow." Initiate PN cautiously (eg, ~25%–33% of estimated nutritional or dextrose requirements, or ~20 kcal/hour [84 kJ/hour]) and gradually increase to goal over 3 to 5 days.[44,45] Correct electrolyte abnormalities before initiating PN and provide supplemental phosphate, potassium, and magnesium in and/or outside of PN. Doses of IV phosphate up to 0.64 to 1 mmol/kg may be used to treat severe hypophosphatemia (in patients with normal kidney function), and doses can be repeated as needed until serum phosphorus concentration has normalized.[46] Provide supplemental oral or IV thiamine 100 mg/day for about 1 week in addition to the standard multivitamin in PN. Assess patients for fluid balance, signs of edema, fluid overload, and weight gain, and consider minimizing fluid and sodium intake during the first few days of PN.[44] Monitor patients closely for signs and symptoms of refeeding syndrome until they are tolerating PN at goal for a few days:

LO 8

- Vital signs, mental status, and neurologic and neuromuscular function at least every 4 to 8 hours
- Pulse oximetry and any electrocardiographic changes when indicated
- Serum laboratory values (including sodium, potassium, phosphorus, and magnesium) at least once a day

If a patient develops severe hypophosphatemia and/or other signs or symptoms of refeeding syndrome, decrease nutritional intake (eg, back to the amount provided on day 1, or ~20 kcal/hr [84 kJ/hr]) and gradually increase back to goal over 3 to 5 days.[45]

Infectious Complications

Patients receiving central PN are at increased risk of developing infectious complications caused by bacterial and fungal pathogens.[1,47] Earlier studies found that patients without malnutrition who receive early PN (eg, within 48 hours of ICU admission) may have a higher incidence of infectious complications than patients who do not receive PN or receive late PN initiation (eg, > 7 days after ICU admission).[2,3,48] However, more recent studies have not demonstrated this same risk (potentially due to avoiding overfeeding, improvements in catheter care, glycemic control, and other aspects of ICU care).[49,50] Strict aseptic techniques must be used when placing the catheter along with continuous care of the catheter and infusion site. Catheter-related bloodstream infections are a common complication in long-term PN patients, often requiring hospital admission for parenteral antimicrobial therapy and/or removal of the catheter. Contamination of the PN admixture is possible but rare if protocols are followed for aseptic preparation of PN admixtures.

Mechanical Complications

Mechanical complications of PN are related to venous catheter placement and the equipment used to administer PN. A central venous catheter must be placed by a trained professional, and risks associated with placement include pneumothorax, arterial puncture, bleeding, hematoma formation, venous thrombosis, and air embolism.[1] Over time, the venous catheter may require replacement. Problems with the equipment include malfunctions of the infusion pump, IV tubing sets, and filters.

MONITORING PN THERAPY

KEY CONCEPT When initiating PN, patients should have important baseline laboratory values checked to assess electrolyte status, organ function, and nutritional status. Thereafter, these and other nutritional parameters should be monitored routinely or as indicated. Random capillary blood glucose concentrations also should be monitored every 6 to 8 hours when initiating PN, and regular insulin should be administered to control blood glucose concentrations as needed (**Table 100–9**).

SUMMARY AND CONCLUSION

PN is an effective and potentially lifesaving therapy for patients who cannot receive adequate oral or enteral nutrition. The PN use process and PN orders are complex, and there are a number of significant safety concerns with PN ordering and order review, compounding, and administration. PN therapy can be associated with significant adverse effects and metabolic, infectious, and mechanical complications. Health care professionals must take appropriate steps to optimize the safety of PN therapy and the PN use process to minimize the risk of adverse effects and complications, and patients must be monitored closely while receiving PN to optimize outcomes.

Patient Encounter Part 4

The surgical team plans to initiate PN for RK per your recommendations. Laboratory data were listed previously.

What monitoring parameters related to PN therapy should you follow in RK after initiating PN? List monitoring parameters and frequency.

What potential complications of PN should you monitor for in RK?

What special considerations must be made when developing a plan for nutrition support therapy and a PN formulation for patients with severe malnutrition?

LO 9

Table 100–9

Suggested Frequency of Monitoring Parameters in Hospitalized Patients Receiving PN

Parameters	Initial	Daily (Unstable)	2–3 × Weekly (Stable)	Weekly	As Indicated
BUN, creatinine	X	X	X		
Sodium, potassium, chloride, bicarbonate	X	X	X		
Glucose	X	X	X		
Calcium, phosphorus, magnesium albumin, AST, ALT, LDH, alkaline phosphatase, total bilirubin	X	X	X		
Conjugated bilirubin	X			X	X
Prealbumin[a]	X				X
Triglycerides	X			X	X
RBC count, hemoglobin, hematocrit, WBC count ± differential, platelets, PTT	X				X
PT or INR				X	X
Nitrogen balance					X
Zinc, selenium, chromium, copper, manganese, iron					X
TIBC, ferritin					X
Vitamin concentrations					X
Blood cultures					X
Body weight	X	X	X		

[a]Only recommended/indicated in the absence of inflammatory response.

ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; INR, international normalized ratio; LDH, lactate dehydrogenase; PT, prothrombin time; PTT, partial thromboplastin time; RBC, red blood cell; TIBC, total iron-binding capacity; WBC, white blood cell.

Patient Care Process: Parenteral Nutrition

Collect Information:

- Perform a medication history for use of prescription and nonprescription medications and dietary supplements. Identify allergies to medications and other substances.
- Review the medical history and physical assessment findings.
- Review diet/nutritional intake history (or perform this history if not available).
- Identify lifestyle habits, preferences and beliefs, health goals, and socioeconomic factors that affect medication and food access and other aspects of care.

Assess the Information:

- Determine whether the patient is taking any substance that could adversely affect nutritional status, nutrient intake, or interact with prescribed medications or specialized nutrition support.
- Review relevant laboratory tests pertinent to nutrition status and fluid/electrolyte balance (eg, electrolytes, lipids, liver panel, renal function, A1C, basic metabolic profile, complete blood count).
- Determine whether the patient is at risk of refeeding syndrome or short- or long-term complications of parenteral nutrition (PN).
- Determine or assess appropriateness of the patient's macronutrient goals.
- Assess the efficacy, safety, and patient adherence of current pharmacotherapy and specialized nutrition support.
- Identify any significant adverse drug effects or drug–drug or drug–nutrient interactions.

Develop a Care Plan:

- If patient is at risk for refeeding, develop a plan for preventing refeeding while initiating and advancing PN.
- Develop an initial, and subsequently a goal, PN formulation that is appropriate, safe, and pharmaceutically stable/compatible.
- Once stabilized on goal nutrition regimen, determine monitoring plan appropriate for the patient's current clinical status.
- Develop cycle regimen for PN if patient has an indication for cycling PN.
- If patient is unable to take oral medications, determine which medications can be given via alternate routes or identify other medication changes needed to address comorbid conditions.

Implement the Care Plan:

- Educate the patient about changes in drug and nutrition therapy, medication administration, potential adverse effects, and how to manage and report adverse effects that occur.
- Review the patient's practices and technique for self-administration of PN (including sterile technique) if patient will self-manage at home.

(*Continued*)

Patient Care Process: Parenteral Nutrition (*Continued*)

- Address any patient concerns about PN and its management.
- Determine whether the patient has insurance coverage for home PN if indicated.

Follow-up: Monitor and Evaluate:

- Follow up at regular intervals (frequency as appropriate for clinical status and stability of PN regimen) with laboratory monitoring.
- Review PN adherence, administration technique, any changes in oral or enteral nutrition intake, and gastrointestinal function (indication for PN).
- Review physical examination, lab tests, and results of other diagnostic tests to assess for short- and long-term complications of PN.

Abbreviations Introduced in This Chapter

AdjBW	Adjusted body weight
ALT	Alanine aminotransferase
A.S.P.E.N.	American Society for Parenteral and Enteral Nutrition
AST	Aspartate aminotransferase
ATP	Adenosine triphosphate
CT	Computed tomography
2,3-DPG	2,3-Diphosphoglycerate
FDA	Food and Drug Administration
GI	Gastrointestinal
IBW	Ideal body weight
ILE	Lipid injectable emulsion
kcal	Kilocalorie(s)
kJ	Kilojoule(s)
LDH	Lactate dehydrogenase
MBD	Metabolic bone disease
mEq	Milliequivalents
mmol	Millimoles
mOsm	Milliosmoles
PL	Phospholipid(s)
PN	Parenteral nutrition
PPN	Peripheral parenteral nutrition
PTH	Parathyroid hormone
TG	Triglyceride
TNA	Total nutrient admixture
TPN	Total parenteral nutrition

101 Enteral Nutrition

Sarah J. Miller

LEARNING OBJECTIVES

LO

Upon completion of the chapter, the reader will be able to:

1. Discuss how gut structure and function impact choice of feeding route and outcome of feeding.
2. Estimate kilocalorie and protein requirements of an enteral feeding candidate and design an enteral nutrition (EN) regimen to meet these.
3. Evaluate patient-specific parameters to determine whether EN is appropriate.
4. Compare clinical efficacy, complications, and costs of EN versus parenteral nutrition (PN).
5. Formulate a monitoring plan for an EN patient.
6. Select appropriate medication administration techniques for an EN patient.

INTRODUCTION

Enteral nutrition (EN) is broadly defined as delivery of nutrients via the gastrointestinal (GI) tract. The terms *enteral nutrition* and *tube feedings* are often used synonymously. Formulas for EN usually are delivered in the form of commercially prepared liquid preparations, although some products are produced as powders for reconstitution, and a few patients may be appropriate for delivering specific blenderized foods down their feeding tubes.[1] Nonvolitional feedings in patients who cannot meet nutritional requirements by oral intake include EN and **parenteral nutrition** (PN), which are collectively known as *specialized nutrition support* (SNS).

Several organizations have issued clinical guidelines on the use of EN. These include the American Society for Parenteral and Enteral Nutrition (ASPEN), European Society for Clinical Nutrition and Metabolism (ESPEN), and a Canadian team known as Critical Care Nutrition.[2–5] ASPEN and the Society for Critical Care Medicine (SCCM) have jointly issued guidelines for SNS in critically ill patients.[6]

GI TRACT STRUCTURE AND FUNCTION

Anatomy and Absorptive Function

With normal volitional feeding, food is ingested via the mouth. There, the process of breaking down complex foodstuffs into simpler forms that can be absorbed by the small bowel begins. Solid food is chewed in the mouth, and enzymes begin digestion. Presence of food in specific regions of the GI tract triggers release for many enzymes and GI hormones. Food is swallowed and passes through the esophagus and the esophageal sphincter to the stomach, where additional digestive enzymes and acids further break it down. The stomach also mixes and grinds.

The food, now in a liquid form known as *chyme*, passes through the pyloric sphincter into the duodenum, where stomach acid is neutralized. The food then passes from the duodenum into the jejunum, where most absorption of digested carbohydrate and protein occurs. Most fat absorption occurs within the jejunum and ileum, the final segment of the small bowel. In the small bowel, breakdown of carbohydrate, protein, and fat occurs both within the lumen and at the intestinal mucosal membrane surface. The absorptive units on the intestinal mucosal membrane are infoldings known as *villi*. These villi are made up of epithelial cells called *enterocytes*. Projections from these enterocytes called *microvilli* increase surface area of the small bowel and make up the *brush-border membrane*.

Digestive substances secreted by the pancreas play a role in food breakdown. Large amounts of sodium bicarbonate neutralize stomach acid. Digestive substances flow from the pancreas through the pancreatic duct. The pancreatic duct typically joins the hepatic duct to become the common bile duct that empties through the sphincter of Oddi into the duodenum. Bile salts secreted by the liver help emulsify fat and facilitate fat absorption. Bile flows through bile ducts into the hepatic duct and common bile duct. Bile is stored in the gallbladder until needed to aid fat digestion, at which time it empties through the cystic duct to the common bile duct to the duodenum. Pathways through which carbohydrate, protein, and fat are digested and absorbed through the small bowel are illustrated in **Figure 101–1**.

Remaining undigested food passes from the ileum through the ileocecal valve to the colon. A major role of the colon is fluid absorption. Some water and sodium absorption is facilitated by short-chain fatty acids (SFCAs) formed from digestion of certain dietary fibers by colonic bacterial enzymes.

Gut Immune Function

The gut plays significant immune roles. The distal small bowel and colon host many bacteria and their endotoxins, and it is important that these organisms not gain access to internal systems of the body. This function is known globally as the *gut barrier function*.[7] Normal flora of the gut comprise one component. Normal flora, particularly some anaerobes, help to prevent overgrowth of potential pathogens. A second component involves mechanical factors. These include a mucus layer that prevents adherence of bacteria. Peristalsis of the small bowel prevents stasis of bacteria. **Gut-associated lymphoid tissue** (GALT), prominent in the small bowel, serves as a local immune

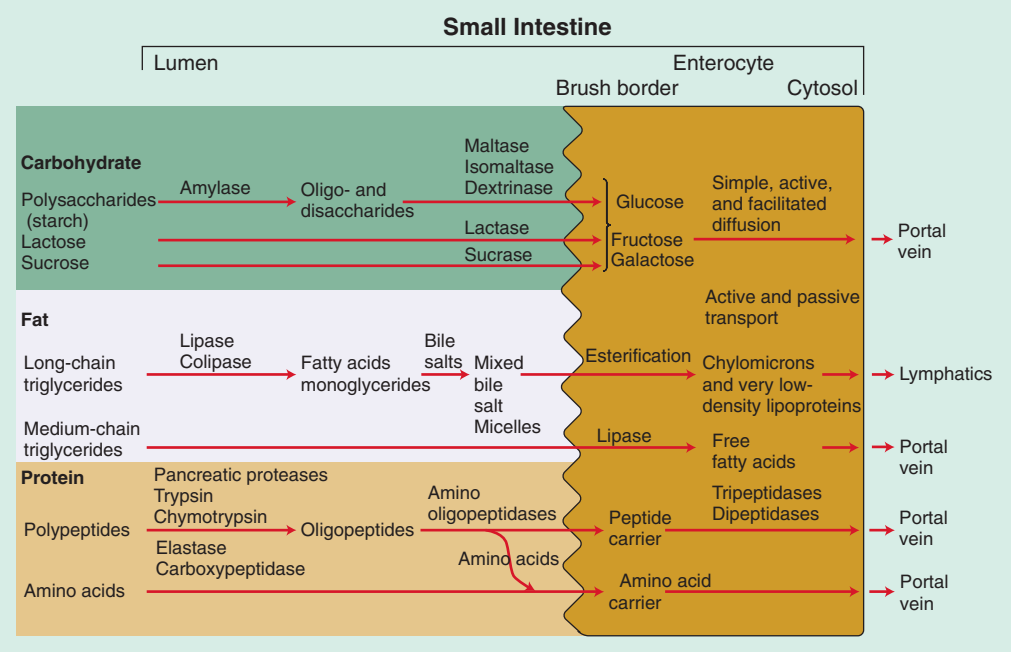

FIGURE 101–1. Schematic of carbohydrate, fat, and protein digestion. (From Kumpf VJ, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014:2428.)

system. Secretory immunoglobulin A produced at the mucosal surface in response to food prevents bacteria from invading the surface.

PATIENT SELECTION

In general, KEY CONCEPT EN is the preferred route if the gut can be used safely in patients who cannot meet nutritional requirements by oral intake. If the gut functions, EN is usually preferred over PN. The timing of SNS (either EN or PN) is controversial, but definitive guidelines for these therapies state that SNS should be started when intake has been inadequate for 7 to 14 days or if inadequate oral intake is anticipated for at least 7 to 14 days.[2] Previously well-nourished patients can better afford not being fed for longer periods than previously poorly nourished patients. Patients in the intensive care unit (ICU) probably benefit from early EN started within 24 to 48 hours of admission to the ICU.[4,6] Ethical questions come into play when consideration is given to starting (or stopping) EN in seemingly futile situations. Methods for assessing nutritional status and designing SNS regimens are covered in Chapter 100. Generally, nonobese hospitalized patients require 20 to 35 total kcal/kg of body weight/day (84–147 kJ/kg body weight/day) and 1.2 to 2 g protein/kg of body weight/day. Obese patients are often fed hypocaloric, high protein diets; guidelines state to start feedings at 1.2 g protein per kg of actual body weight (or 2–2.5 g per kg of ideal body weight) and no more than 14 kcal/kg actual body weight (59 kJ/kg actual body weight).[8]

LO 1

LO 2

Indications

Many potential indications for EN exist (Table 101–1). PN was used extensively in the past for many of these conditions. Advances in EN technology now allow many patients with these conditions to receive EN. EN is administered in both institutional and home settings.

Table 101–1

Potential Indications for EN

Neoplastic Disease
Chemotherapy
Radiation therapy
Upper GI tumors
Cancer cachexia

Organ Dysfunction
Liver disease/failure
Kidney insufficiency/failure
Cardiac cachexia
ARDS/ALI
Bronchopulmonary dysplasia
Congenital heart disease
Organ transplantation

Hypermetabolic States
Closed head injury
Burns
Trauma
Postoperative major surgery
Sepsis

GI Disease
Inflammatory bowel disease
Short-bowel syndrome
Esophageal motility disorder
Pancreatitis
Fistulas
Gastroesophageal reflux disease (severe)
Esophageal or intestinal atresia

Neurologic Impairment
Comatose state
Cerebrovascular accident
Demyelinating disease
Severe depression
Cerebral palsy

Other Indications
AIDS
Anorexia nervosa
Complications during pregnancy
Failure-to-thrive
Geriatric patients with multiple chronic diseases
Extreme prematurity
Inborn errors of metabolism
Cystic fibrosis

AIDS, acquired immune deficiency syndrome; ALI, acute lung injury; ARDS, acute respiratory distress syndrome.

From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014.

Table 101–2

Contraindications and Precautions for EN

Severe hemorrhagic pancreatitis
Severe necrotizing pancreatitis
Necrotizing enterocolitis
Diffuse peritonitis
Small bowel obstruction
Paralytic ileus
Severe hemodynamic instability
Enterocutaneous fistulae
Severe diarrhea
Severe malabsorption
Severe GI hemorrhage
Intractable vomiting
Uncorrectable coagulopathy
Bowel ischemia

Contraindications and Precautions

LO 3

EN should be avoided or used with caution in certain conditions (Table 101–2). It is possible to use EN in some patients with these conditions depending on severity of illness, location of abnormality, and experience of practitioners delivering care. Feeding in the setting of hemodynamic instability is controversial; the 2016 ASPEN/SCCM critical care guidelines recommend withholding feedings in hypotension or when vasopressors are being initiated or escalated.[6]

Enteral Versus Parenteral Feeding

With advent of the technique of PN by large central vein in the late 1960s, this modality quickly became popular. PN was incorporated quickly into care of patients such as critically ill patients. The relative ease of PN administration, along with the perception that critically ill patients had prolonged high-energy expenditures, led to complications of overfeeding. Dextrose overfeeding led to hyperglycemia, carbon dioxide overproduction leading to delays in weaning from mechanical ventilation, and liver abnormalities owing to hepatic steatosis.

LO 4

The pendulum began to swing toward EN in the late 1980s and early 1990s as clinical studies showed better clinical outcomes with EN compared to PN. Some potential advantages of EN over PN are included here. First, EN is expected to preserve the gut barrier function better than PN. This could prevent translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation, thus preventing infections. Some studies support that KEY CONCEPT EN is associated with fewer infectious complications than PN. EN is cited frequently as having a better overall safety profile than PN. Whereas PN is associated with more severe complications, such as pneumothorax and catheter sepsis, EN is associated with more nuisance complications, such as GI side effects. Another frequently cited advantage of EN over PN is that EN is less expensive. EN formulas typically are cheaper and less labor intensive to prepare than PN, although some specialty EN formulas approach the cost of PN formulas. Depending on the method of feeding tube placement, EN costs can mount if the tube must be placed by a radiologist or gastroenterologist rather than a bedside nurse.

Arguments in support of EN over PN have been questioned. Part of this questioning relates to the question of whether EN is beneficial compared with PN or whether PN as previously administered might have been detrimental. Overfeeding and hyperglycemia occur easily with PN, and the potential harm of hyperglycemia, especially in critical care populations, has been demonstrated, although the exact range optimal for glycemic control in ICU patients remains controversial and may differ for various subpopulations of the critically ill. Parenteral nutrition as it was historically delivered led to an increased risk of infection and perhaps caused more harm than good in many instances unless patients were severely malnourished.[9] Whether EN truly prevents infections and improves clinical outcomes or whether PN is detrimental continues to be debated and probably depends on the specific patient population. At present, EN is preferred by most experts over PN when the gut is functional. In Europe (more so than in North America), PN has been used to supplement EN during the first week of intensive care therapy when EN is not yet being tolerated at full rates.[3] This approach is currently discouraged by American and Canadian ICU guidelines.[4,6] Randomized controlled trials relating to EN versus PN and deliberate (permissive) underfeeding (setting caloric goals below what would be considered necessary to achieve energy balance) have yielded disparate results.[10-16]

ROUTES OF ACCESS[17]

There are several access sites for EN (Figure 101–2). The tip of the feeding tube can end up in the stomach, duodenum, or jejunum. Both advantages and disadvantages exist for each EN route (Table 101–3). Tube sizes vary from about 8 to 24 French (Fr).

Gastric Feeding

Gastric feedings are commonly used. They require an intact gag reflex and normal gastric emptying for safety and success. Certain patients, such as those who have suffered head trauma, may not empty their stomachs efficiently and therefore may not be good candidates for gastric feedings. In these patients, it may be impossible to achieve a gastric tube feeding rate to provide adequate nutrients. Pooling of formula in the stomach could increase risk of aspirating feeding formula into the lungs.

The nasogastric (NG) route is used most commonly for short-term enteral access. The major advantage of this route is that the tube can be placed quickly and inexpensively by the nurse at the bedside.

Gastrostomy tubes, in which an incision is made directly through the abdominal wall, are indicated for patients who can tolerate gastric feedings but in whom long-term feedings are anticipated. The most commonly placed gastrostomy tubes are either placed percutaneously by interventional radiology or are percutaneous endoscopic gastrostomy (PEG) tubes placed endoscopically. Gastrostomy tubes also can be placed laparoscopically or during an open procedure by a surgeon. Placement of a gastrostomy tube either endoscopically or surgically is more expensive than bedside orogastric (OG) or NG placement but can result in placement of a larger bore tube.

Postpyloric Feedings

KEY CONCEPT For patients intolerant of gastric feedings or in whom the risk of aspiration is high, feedings delivered with the tip of the tube in the jejunum are preferred. This bypasses the problem of poor gastric emptying and adds another barrier (pyloric sphincter) through which tube feedings must traverse before aspiration into the lungs. However, postpyloric feedings do not preclude the possibility of aspiration. Many patients with this complication aspirate their own nasopharyngeal secretions.

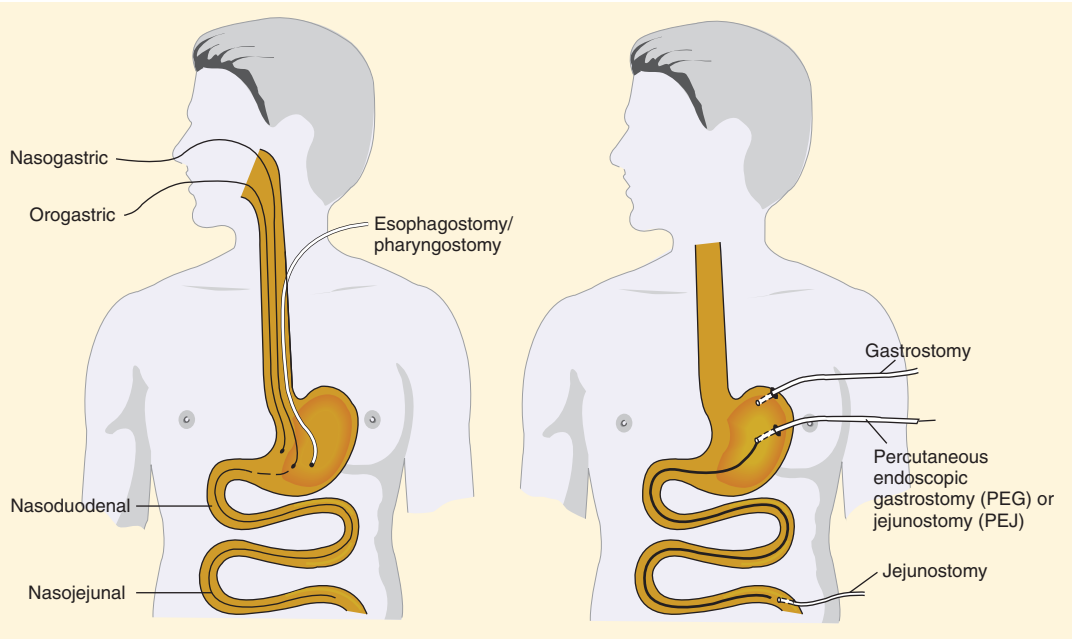

FIGURE 101–2. Access sites for tube feeding. (From Kumpf VJ, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014:2431.)

Table 101–3

Options and Considerations in the Selection of Enteral Access

Access	EN Duration/Patient Characteristics	Tube Placement Options	Advantages	Disadvantages
Nasogastric or orogastric	Short term Intact gag reflex Normal gastric emptying	Manually at bedside	Ease of placement Allows for all methods of administration Inexpensive Multiple commercially available tubes and sizes	Potential tube displacement Potential increased aspiration risk
Nasoduodenal or nasojejunal	Short term Impaired gastric motility or emptying High risk of GER or aspiration	Manually at bedside Fluoroscopically Endoscopically	Potential reduced aspiration risk Allows for early post injury or postoperative feeding Multiple commercially available tubes and sizes	Manual transpyloric passage requires greater skill Potential tube displacement or clogging Bolus or intermittent feeding not tolerated
Gastrostomy	Long term Normal gastric emptying	Surgically Endoscopically Radiologically Laparoscopically	Allows for all methods of administration Low-profile buttons available Large-bore tubes less likely to clog Multiple commercially available tubes and sizes	Attendant risks associated with each type of procedure Potential increased aspiration risk Risk of stoma site complications
Jejunostomy	Long term Impaired gastric motility or gastric emptying High risk of GER or aspiration	Surgically Endoscopically Radiologically Laparoscopically	Allows for early post injury or postoperative feeding Potential reduced aspiration risk Multiple commercially available tubes and sizes Low-profile buttons available	Attendant risks associated with each type of procedure Bolus or intermittent feeding not tolerated Risk of stoma site complications

EN, enteral nutrition; GER, gastroesophageal reflux.

From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014.

Nasoduodenal (ND) and nasojejunal (NJ) feeding tubes can be placed by trained, experienced nurses at the bedside. This is still a relatively inexpensive method of placement. Bedside electromagnetic transmitter devices (eg, CORTRAK, Corpak Medsystems) may be helpful in achieving postpyloric tube placement. In some institutions, ND or NJ placements are done in radiology by a radiologist using fluoroscopy to visualize tube advancement, increasing the cost of EN therapy. NJ tubes generally are preferred over ND tubes; placement of the tube tip distal to the **ligament of Treitz** may reduce risk of aspiration. Alternatively, during a laparotomy, the surgeon can place an ND or NJ tube.

Surgically placed jejunostomy tubes are placed through an incision in the abdominal wall. These tubes are sometimes placed during laparotomy following abdominal trauma. Alternatively, jejunal access can be obtained by placing a jejunal extension through a PEG tube; the resulting tube is sometimes referred to as a *PEGJ tube* or *G-J tube*. Another option is to place a **percutaneous endoscopic jejunostomy** (PEJ) tube directly; this is more technically difficult than PEG placement and is not available in most institutions.

METHODS OF DELIVERY

Enteral feedings are delivered by several different methods. Continuous infusion must be used when duodenal or jejunal feedings are administered; intermittent feedings directly into the small bowel generally result in GI intolerance. For gastric feedings, bolus or intermittent feedings could be administered instead of continuous feedings. Each method has advantages and disadvantages.

In hospitals, EN is delivered most commonly as a continuous infusion at a constant rate regulated by an infusion pump. A variation of continuous infusion is cyclic feeding, in which a constant rate is maintained over a certain number of hours daily; this method of administration is used commonly in long-term care or home settings. Sometimes EN is administered overnight. Continuous feedings are often started at a low rate and titrated up every few hours as the patient tolerates. Ideally the patient will reach goal rate of feeding within 1 to 2 days.

Intermittent feedings are used commonly in long-term care or home settings. Patients frequently are started with continuous feedings; transitioned to intermittent feedings given several times a day over about 30 to 45 minutes for each feeding; and eventually changed to bolus feedings administered over less than 10 minutes per feeding. Intermittent feedings may be administered by gravity flow adjusted with a roller clamp, although some institutions may use an infusion pump. Bolus feedings can be administered using a 60-mL syringe, although sometimes an infusion set and pump may be used. Intermittent and bolus feedings often are given in amounts of 240 to 480 mL per feeding, corresponding to one to two cans of formula.

Some institutions now have volume-based feeding protocols instead of rate-based. In these protocols, nurses are given the latitude to increase the rate after the feeding has been held such that the prescribed volume is administered over a 24-hour period.

EN FORMULAS

One advantage of EN over PN is the availability in the United States of certain nutrients in some EN formulations (eg, glutamine, medium-chain triglycerides [MCT]) that are not available for parenteral use. Many EN formulas are marketed commercially. Hospitals and long-term care facilities limit formularies of EN formulas, stocking only a limited number of products.

Polymeric Versus Oligomeric Formulas

A major criterion for categorizing EN products is whether macronutrients (particularly protein) are more intact (polymeric) or present in simpler forms (oligomeric). KEY CONCEPT Standard EN formulas are polymeric; these are appropriate for most patients. Oligomeric formulas should be reserved for patients with GI dysfunction.

Polymeric formulas typically contain intact proteins (most commonly casein and soy protein). They have low osmolality of 300 to 500 mOsm/kg (mmol/kg). These usually supply essential vitamins and minerals in amounts similar to the adequate intakes (AI) or Recommended Dietary Allowances (RDA) when the formula is delivered in amounts adequate to meet macronutrient requirements. The AI or RDA of a nutrient is the amount of that nutrient that must be consistently consumed by individuals to meet the needs of most of the population for that nutrient. Most modern formulas are lactose- and gluten-free. Products designed for use as oral supplements generally are polymeric and often have sucrose or other simple sugars added to improve taste.

Oligomeric formulas are also known as *chemically defined formulas*. These can be subcategorized based on whether the formula contains all free amino acids (elemental formulas) or peptides (peptide based) as the protein source. Some formulas contain a combination of free amino acids and small peptides. Dipeptides and tripeptides are absorbed more efficiently than free amino acids. Oligomeric formulas may be better tolerated than polymeric formulas for patients with defects in GI function and may be particularly useful with severe pancreatic dysfunction or significantly decreased GI surface area. However, adaptation of the bowel is better when intact nutrients are supplied to patients with short-bowel syndrome, so those patients should be transitioned to intact nutrients as soon as possible.

Oligomeric formulas typically are more expensive than polymeric formulas and have higher osmolality. However, osmolality of these products usually does not exceed 700 mOsm/kg (mmol/kg), a value less than that of many oral medications or a regular diet. Sometimes enteral feedings are diluted to deliver extra water required by the patient; this practice generally is discouraged because of potential risk of formula contamination. Instead, it is better to give extra water as boluses through the tube. If medications are administered through the feeding tube, generous amounts of water should be used to flush the tube before and after each medication; this practice helps provide extra fluid and prevent problems with tube occlusion.

Oligomeric formulas are less palatable than polymeric formulas and are not designed for use as oral supplements. Many oligomeric formulas provide some fat calories as MCT, a fat source that is more readily absorbed and metabolized than long-chain triglycerides (LCTs) typically found in polymeric formulas. The MCTs do not require bile salts or pancreatic enzymes for absorption. Some elemental formulas contain a low proportion of fat (< 10% of total calories), which makes them useful in certain situations where fat needs to be restricted. The carbohydrate source in oligomeric formulas is less complex than in polymeric formulas, consisting of oligosaccharides rather than hydrolyzed starch.

Fiber Content

Another distinguishing factor of enteral formulas is whether or not they contain fiber. Both soluble and insoluble fibers may be included. Insoluble fiber exerts an effect on gut motility by drawing water into the intestine and decreasing transit time, thus preventing constipation. Soluble fiber can help to lower

blood cholesterol levels, regulate blood sugar, and prolong gastric emptying. Soluble fiber may also help control diarrhea. Cellulose gum is an example source of insoluble fiber. Oat fiber and guar gum provide primarily soluble fiber. Soy fiber not only provides primarily insoluble fiber but also some soluble fiber and is the most commonly used fiber source in tube feeding products. Fiber has been useful for regulating gut motility in some but not all clinical studies; it certainly can be useful in selected patients.[18] Some patients may experience GI discomfort secondary to gas production with introduction of fiber.

Fructooligosaccharides (FOS) are a form of soluble fiber that pass through the stomach and small bowel undigested and are fermented by colonic bacteria to the SCFAs butyrate, propionate, and acetate. The SCFAs serve as a fuel source for **colonocytes** and also serve other important functions.[19] The FOS are thus **prebiotics** that serve as fermentable substrates for normal flora of the colon. The SCFAs are not added directly to EN products because they would be absorbed completely before reaching the colon; rather, FOS are added, allowing bacterial degradation to form SCFAs. Products containing FOS are often avoided postoperatively due to increased gas, bloating, and abdominal distention with these products.

Caloric Density

Enteral feeding formulas can be categorized based on caloric density. Standard caloric density is 1 to 1.3 kcal/mL (4.2–5.4 kJ/mL). More calorically dense formulas containing 1.5 to 2 kcal/mL (6.3–8.4 kJ/mL) are available and have higher osmolality. Fluid-overloaded patients may benefit from more calorically dense formulas. As caloric content of a formula increases, the amount of free water decreases.

Protein Content

Protein content is an important factor in choosing an EN formula. Standard protein content in EN formulas is up to about 20% of total calories as protein. High-protein formulas containing 25% or more of total calories as protein are available for highly stressed patients with elevated protein needs. Low-nitrogen formulas containing less than 10% of total calories as protein for use in patients requiring protein restriction are also available. A wide range of protein is available, from about 35 to 95 g/L.

Carbohydrate Content

Common carbohydrate sources in tube feeding products include maltodextrin, corn syrup solids, and hydrolyzed cornstarch. Products containing simple sugars (often those intended for oral use) tend to be higher in osmolality.

Fat Content

Both MCTs and LCTs are used in tube feeding products. Corn, soy, sunflower, and safflower oils are standard sources of fat, providing mainly ω-6 polyunsaturated fatty acids (PUFAs). Some EN products contain higher quantities of ω-3 PUFAs from sources such as fish oil (ie, docosahexaenoic acid [DHA] and eicosapentaenoic acid [EPA]). Other formulas contain higher quantities of monounsaturated fatty acids (MUFAs) from canola oil and high-oleic safflower or sunflower oils. The essential fatty acid (EFA) content (mainly linoleic acid) of EN formulas is important because EFA deficiency can be induced if at least 1% to 4% of total calories are not supplied as EFAs. MCT oil does not contain EFAs.

Vitamin, Mineral, and Electrolyte Content

Most EN products contain vitamins and minerals, including major electrolytes, in amounts adequate to deliver the RDA or AI when a standard volume of formula is delivered daily. Some specialty formulas (eg, renal formulas) may have altered amounts of certain micronutrients.

Specialty Formulas

Specialty formulas designed for use in specific clinical situations generally are more expensive than standard polymeric formulas. KEY CONCEPT Robust clinical trial data supporting use of specialty formulas in niche populations typically remain lacking in terms of improved patient outcomes. Manufacturers' websites should be consulted for the most current information on content of enteral formulas as changes do occur.

▶ *Stress and Trauma Formulas*

Historically, formulas aimed specifically for highly stressed, critically ill patients were enriched with branched-chain amino acids (BCAAs). The rationale was that skeletal muscle BCAAs are preferentially used for energy in critical illness. Provision of BCAAs might limit breakdown of muscle in these patients. Clinical data failed to support or refute benefit of these formulas unequivocally in terms of clinical outcomes.[4]

The newer generation of enteral feeding formulas marketed for use in these populations covers a broad spectrum of characteristics (**Table 101–4**). Whereas some are polymeric, others are oligomeric to address malabsorption that may accompany high stress. Some formulas marketed for use in critical illness are calorically dense (1.5–2 kcal/mL [6.3–8.4 kJ/mL]) to address fluid restrictions seen in this population, and others are less calorically dense. Most products contain generous amounts of protein to address requirements of highly stressed patients (**nonprotein kilocalorie to nitrogen ratios** typically between 75:1 and 125:1 [nonprotein energy to nitrogen ratio between about 300 and 500 kJ/g N]). Many products contain ingredients purported to increase immune function; the term *immunonutrition* is sometimes attached to these products.

Immune-enhancing ingredients present in some enteral feeding products include arginine, glutamine, ω-3 fatty acids, nucleic acids, and antioxidants. Few products contain all of these (see Table 101–4). Arginine is an important substrate for nitric oxide (NO) synthesis, and small amounts of NO have beneficial effects on immune function under certain conditions. Arginine has been purported to have a positive influence on lymphocyte and macrophage function. Glutamine is considered to be conditionally essential in critical illness and is a preferred fuel source for enterocytes. Supplementation with glutamine, either parenterally or enterally, may help maintain integrity of gut mucosa, preventing translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation. However, glutamine supplementation remains controversial.[4,6,20,21] The ω-3 fatty acids, primarily from fish oils, are included in many immunonutrition products. Metabolites of ω-6 fatty acids include mediators such as prostaglandins, leukotrienes, and thromboxanes that are primarily proinflammatory and increase coagulation. Conversely, mediators produced from ω-3 fatty acids are less proinflammatory and decrease coagulation. Limited data support nucleic acids as immunomodulators. Quantities of antioxidants (particularly vitamin C, vitamin E, and β-carotene) higher than traditionally found in standard enteral formulas are added to some immunonutrition formulas to protect

Table 101–4

Selected Enteral Feeding Formulas Marketed for Use in Critical Illness, High-Stress, Pulmonary Disease and Ventilator-Dependent, or Trauma Patients[a]

Product Name/Manufacturer	kcal/mL	Protein (g/L)	Protein (g/1000 kcal)	Enriched Ingredients[b]
Peptamen 1.5/Nestle	1.5	68	46	MCT
Nutren 2.0/Nestle	2	84	42	MCT

Perative/Abbott	1.3	67	52	MCT, arginine
Vital AF 1.2 Cal/Abbott	1.2	75	63	MCT, ω-3 fatty acids

[a]One kcal is equivalent to 4.186 kJ.

[b]Formula considered enriched if following criteria met: arginine > 8.5 g/1500 kcal (6279 kJ); glutamine > 9 g/1500 kcal (6279 kJ); MCT > 30% of total fat; and ω-3 fatty acid ratio of ω-6 to ω-3 ≤ 2:1 or > 1.5 g/L ω-3 fatty acids.

[c]Low fat product.

MCT, medium-chain triglycerides.

body systems, including the immune system, from damage by oxygen-free radicals. KEY CONCEPT Use of enteral immunonutrition in certain clinical settings is widely accepted. Commercial immunonutrition products and/or specific ingredients found in these products have generally been found to have no benefit in terms of mortality rates.[4,22,23] However, infection rates, length of stay, and length of time on a ventilator may be decreased with these products. The 2016 ASPEN/SCCM ICU Guidelines support use of these formulas in traumatic brain injury and surgical ICU patients but not in medical ICU patients.[6] The best timing (initiation and duration) of delivery remains to be determined.

► *Pulmonary Formulas*

Enteral feeding formulas designed for use in patients with chronic obstructive pulmonary disease or receiving mechanical ventilation contain higher amounts of fat (40% to 55% of total kilocalories) than most formulas. The rationale for high fat content is that burning of fat for energy is associated with less carbon dioxide production compared with burning of carbohydrate. Less carbon dioxide production theoretically would be advantageous in patients with retention of this substance and might facilitate weaning from mechanical ventilation. Because part of the market targeted by the manufacturers of these products comprises mechanically ventilated patients, these products are included in Table 101–4. Carbon dioxide retention owing to carbohydrate administration was a problem previously when feeding was overzealous. However, at conservative calorie levels, standard enteral formulas usually can be given without fear of excess carbon dioxide production.

One formula, Oxepa (Nestle), has been studied specifically in critically ill patients with acute respiratory distress syndrome (ARDS), acute lung injury (ALI), and sepsis. This formula contains high quantities of the ω-3 fatty acids (EPA) and γ-linolenic acid (GLA). GLA is metabolized to a prostaglandin with vasodilatory properties. EPA is converted to prostaglandins and leukotrienes that are less proinflammatory than those derived from ω-6 fatty acids. This formula contains large quantities of antioxidants. Whereas the Canadian guidelines state that use of this formula should be considered in ALI and ARDS, the 2016 ASPEN/SCCM critical care guidelines do not endorse use of the product.[4,6]

► *Diabetic Formulas*

Similar to pulmonary formulas, formulas designed for patients with diabetes or stress-induced hyperglycemia are relatively high in fat and low in carbohydrates (Table 101–5). These formulas typically contain fiber (primarily soluble) because it plays some role in glycemic control. They also may contain fructose and MUFAs. Data support improved blood sugar control with use of these formulas in patients with diabetes.[24] Whether or not a diabetic EN formula is chosen, avoidance of overfeeding and maintenance of good glycemic control with insulin or other hypoglycemic medications are important in this population.

► *Renal Formulas*

Products designed for use in renal failure have high caloric density (1.8–2 kcal/mL [7.5–8.4 kJ/mL]) to decrease administered fluid (Table 101–6). The products vary in amounts of nutrients such as protein, potassium, phosphorus, and magnesium. Products low in protein (20–35 g/L) may be appropriate in chronic renal

Table 101–5

Selected Enteral Feeding Formulas Marketed for Use in Diabetes and Stress-Induced Hyperglycemia[a]

Product Name/Manufacturer	kcal/mL	% kcal as Fat	% kcal as Carbohydrate	Fiber (g/L)
Glytrol/Nestle	1	43	40	15
Glucerna 1.0 Cal/Abbott	1	49	34	14
Glucerna 1.2 Cal/Abbott	1.2	45	38	16
Glucerna 1.5 Cal/Abbott	1.5	45	35	16
Diabetisourse AC/Nestle	1.2	53	33	15

[a]1 kcal is equivalent to 4.186 kJ.

failure patients not yet receiving dialysis. On the other hand, removal of nitrogen by dialysis, coupled with the hypercatabolic, hypermetabolic condition seen in many acute renal failure patients, makes use of higher protein formulas (80–90 g/L) appropriate in these situations. Potassium, phosphorus, and magnesium contents of EN formulas designed for use in renal failure tend to be lower than standard formulas because these renally excreted electrolytes accumulate during renal failure.

Historically, elemental formulas designed for renal failure were enriched with essential amino acids (EAAs) and contained lesser amounts of nonessential amino acids (NEAAs) than standard formulas. Theoretically, EAAs could combine with urea nitrogen in the synthesis of NEAAs, leading to a decrease in blood urea nitrogen (BUN). The only situation in which such formulas may be appropriate is in patients with chronic renal failure who are not candidates for dialysis. Even in this setting, use of these products should be limited to no more than 2 or 3 weeks.[2] These formulas have been supplanted largely by polymeric formulas with protein content similar to standard EN formulas. Many dialysis patients tolerate standard, high-protein EN formulas, although electrolytes must be monitored closely.

▶ *Hepatic Formulas*

Specialized formulas for patients with hepatic insufficiency are limited in number. These are enriched with BCAAs while containing a reduced quantity of aromatic amino acids (AAAs) and methionine compared with standard formulas. These changes address high levels of AAAs and low levels of BCAAs found in the blood of patients with hepatic insufficiency. Theoretically, these products might help patients with hepatic encephalopathy (HE). Improvement in mortality attributable to these products has not been consistent.[2]

The ASPEN/SCCM guidelines for the ICU recommend against the use of protein restriction to reduce risk of development of HE.[6] These guidelines recommend use of standard EN formulas for ICU patients with acute or chronic liver disease. An example of a specialized hepatic formula is Hepatic-Aid II (Hormel Health Labs), a product supplied as a powder for reconstitution that requires vitamin, mineral, and electrolyte supplementation. A second product is NutriHep (Nestle), supplied as a liquid formula containing the recommended amounts of key vitamins, minerals, and electrolytes.

▶ *Wound Healing Formulas*

Tube feeding and oral supplement formulas designed for use in patients with wounds or decubitus ulcers typically supply high amounts of protein and calories. The antioxidant vitamins A, C, and E are frequently also found in high quantities as is zinc.

▶ *Modular Components*

Single nutrient components are frequently administered through feeding tubes to augment the composition of the EN formula. Protein modules are probably the most commonly used. These may be supplied as a liquid product or as a powder that must be reconstituted with water. Another modular component is fiber. These components are typically given as a bolus through the feeding tube rather than being added to the feeding formula.

Table 101–6

Selected Enteral Feeding Products Designed for Use in Renal Failure

Product Name/Manufacturer	Protein g/L	Protein (g/1000 kcal[a])	Characteristics
Nepro with Carb Steady/Abbott	81	45	Complete formula[b] for patients on dialysis
Novasource Renal/Nestle	91	46	Complete formula for patients with CKD or AKI on dialysis
Suplena with Carb Steady/Abbott	45	25	Complete formula with low amounts of protein for patients not on dialysis
Renacal/Nestle	34	17	For patients with AKI and severe electrolyte restriction not on dialysis

[a]1 kcal is equivalent to 4.186 kJ.

[b]Complete formula—contains all nutrients in amounts sufficient to meet needs of most patients in a volume equal to or less than that usually administered.

AKI, acute kidney injury; CKD, chronic kidney disease.

Patient Encounter Part 1

LT is a thin 50-year-old woman with a history of smoking, chronic obstructive pulmonary disease, and an eating disorder. Her sister reports that the patient has been on another of her "weird" diets and has lost about 15 pounds (6.8 kg) in the last couple of months. She is admitted with sepsis with a suspected pulmonary source. She requires mechanical ventilation and exhibits prerenal azotemia. She receives a 30 mL/kg bolus of normal saline as part of the sepsis protocol and is started on vasopressor therapy and antibiotics. She is started on propofol for sedation while on the ventilator.

LT responds somewhat slowly to the sepsis protocol and on day 3 is still requiring both norepinephrine and vasopressin for blood pressure support. The dietitian assesses her nutritional needs. Her dry weight is 55 kg, height is 66 inches (168 cm), body mass index is 20 kg/m^2.

Is there any concern regarding starting EN at this time?

If EN is not appropriate at this time, should PN be initiated?

MONITORING AND COMPLICATIONS

Although complications of EN generally are considered less serious than those of PN, some complications nevertheless can be dangerous or can lead to impaired delivery of desired nutrient load. Complications can be divided into four categories: GI, technical, infectious, and metabolic. The first three categories, along with common causes, are listed in Table 101–7. Patients on EN must be monitored for prevention of complications (Table 101–8). Monitoring of many parameters can become less frequent as patient condition stabilizes. Monitoring for efficacy of EN is also important.

LOS

GI Complications

KEY CONCEPT GI complications are the most common complications of EN limiting the amount of feeding that patients receive. Although diarrhea frequently is blamed on feeding formula or method of EN administration, other possible causes usually exist (see Table 101–7). In the inpatient setting, patients receiving EN frequently are very sick. Along these lines, *Clostridium difficile* colitis must be considered as a possible cause of diarrhea, especially in patients receiving antimicrobial therapy or proton pump inhibitors.[25] Antibiotic therapy is a major cause of diarrhea in acutely ill patients, including those receiving EN. A medication-related cause of diarrhea is the sorbitol content of medications.[26] Large quantities of sorbitol present in oral liquid medications can cause diarrhea. Unfortunately, sorbitol content of many medications is not listed on their labeling, and manufacturers frequently reformulate preparations to contain varying amounts of excipients, such as sorbitol.

Determining the cause of diarrhea is important to determine how to address the problem. Whereas *C. difficile* colitis should be treated with an appropriate antibiotic, medication-related diarrhea can be addressed by removal of the offending agent. Likewise, diarrhea secondary to malabsorption sometimes can be addressed by changing to an oligomeric EN formula. Antiperistaltic agents (eg, loperamide) may be useful in some noninfectious diarrhea.

On the other hand, constipation may occur in patients receiving EN, especially the elderly. Increased provision of fluid or fiber may be useful. Constipation may be drug related, in which case discontinuation or replacement of the offending drug may be beneficial.

Impaired gastric emptying is seen commonly in EN patients receiving gastric feedings and may be associated with nausea and vomiting. Impaired emptying may be related to disease process (eg, diabetic gastroparesis or sequelae to head injury) or to drug

Table 101–7

Complications of Tube Feeding

Complication	Causes
GI	
Diarrhea	Drug related Antibiotic-induced bacterial overgrowth Hyperosmolar medications administered via feeding tubes Antacids containing magnesium Malabsorption Hypoalbuminemia or gut mucosal atrophy Pancreatic insufficiency Inadequate GI tract surface area Rapid GI tract transit Radiation enteritis Tube feeding related Rapid formula administration Formula hyperosmolality Low residue (fiber) content Lactose intolerance Bacterial contamination
Nausea and vomiting	Gastric dysmotility (surgery, anticholinergic drugs, diabetic gastroparesis) Rapid infusion of hyperosmolar formula
Constipation	Dehydration Drug induced (anticholinergics) Inactivity Low residue (fiber) content Obstruction or fecal impaction
Abdominal distention or cramping	Too rapid formula administration
Technical	
Occluded feeding tube lumen	Insoluble complexation of enteral formula and medication(s) Inadequate flushing of feeding tube Undissolved feeding formula
Tube displacement	Self-extubation Vomiting or coughing Inadequate fixation (jejunostomy)
Aspiration	Improper patient position Gastroparesis or atony causing regurgitation Feeding tube malpositioned Compromised lower esophageal sphincter Diminished gag reflex
Peristomal excoriation	Improper skin and tube care GI tract secretions leaking peristomally
Infectious	
Aspiration pneumonia	Same as technical—aspiration comments Prolonged use of large-bore polyvinylchloride tube

Table 101–8

Suggested Monitoring for Patients on Enteral Nutrition

Parameter	During Initiation of EN Therapy	During Stable EN Therapy
Vital signs	Every 4–6 hours	As needed with suspected change (ie, fever)
Clinical assessment		
Weight	Daily	Weekly
Total intake/output	Daily	As needed with suspected changed in intake/output
Tube-feeding intake	Daily	Daily
Enterostomy tube site assessment	Daily	Daily
GI tolerance		
Stool frequency/volume	Daily	Daily
Abdomen assessment	Daily	Daily
Nausea or vomiting	Daily	Daily
Gastric residual volumes	Every 4–8 hours (varies)	As needed when delayed gastric emptying suspected
Tube placement	Prior to starting; then ongoing	Ongoing
Laboratory		
Electrolytes, blood urea nitrogen/serum creatinine, glucose	Daily	Every 1–3 months
Calcium, magnesium, phosphorus	3–7 times/week	Every 1–3 months
Liver function tests	Weekly	Every 1–3 months
Trace elements, vitamins	If deficiency/toxicity is suspected	If deficiency/toxicity is suspected

EN, enteral nutrition.

From Kumpf VS, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York, NY: McGraw-Hill, 2014.

therapy, most notably narcotics. Gastric residual checks frequently are measured in patients receiving gastric feedings (see Table 101–8). The 2016 ASPEN/SCCM critical care guidelines recommend against routine gastric residual check and suggest that, if such checks are performed, feedings should not be held for residual volumes less than 500 mL in absence of other signs of intolerance.[6] Approaches to the patient with delayed gastric emptying might include changing to a formula containing less fat because dietary fat is associated with slower gastric emptying. Metoclopramide often is given to patients receiving gastric feedings to facilitate gastric emptying. Erythromycin is an alternative that may be useful, although it is associated with drug–drug interactions. Patients with poor gastric emptying may be at higher risk of aspirating feedings into their lungs and should be considered for transition to postpyloric feedings. Postpyloric feedings may help relieve EN-related nausea and vomiting and are preferred for patients without an intact gag reflex. An important practice to help prevent aspiration is elevation of the head of the bed to at least 30 degrees during continuous feedings as well as during and for 30 to 60 minutes after intermittent and bolus feedings.

Technical Complications

Technical or mechanical complications are encountered frequently in EN patients. Tube occlusion most commonly is related to formula occlusion or medication administration through the tube. KEY CONCEPT An important practice to help prevent medication-related occlusion is adequate water flushing of the tube before, between, and after each medication administration. If intermittent feedings are used, water flushing after each feeding is recommended. Clearing of occlusions using water or pancreatic enzymes plus sodium bicarbonate can be attempted, and special devices and kits are available.[5,27]

Tube displacement is a potentially significant complication. This may be seen in an agitated patient pulling at the tube, or the tube tip may migrate spontaneously. If the tip of the tube is positioned in the tracheobronchial tree and feeding is delivered to this area, pneumonia, pneumothorax, and other problems could potentially occur. Location of the tip of a blindly placed feeding tube (eg, NG) should be confirmed initially by chest radiograph after placement and before use. For ongoing assessment of tube placement, auscultation and measurement of aspirate pH can be utilized.

Endoscopic and surgical feeding tubes can cause erosion of the exit site due to leakage of gastric or intestinal contents onto the skin. This complication must be addressed by good wound care and repair or replacement of the access device. Similarly, NG, ND, and NJ tubes can be complicated by nasopharyngeal irritation or necrosis. This is one reason why such tubes should be considered for short-term use only.

Infectious Complications

Infectious complications of EN include aspiration pneumonia and infections related to delivery of contaminated EN formula. Although GI infections owing to industrial contamination of enteral formulas have been reported uncommonly, formulas are more commonly seeded with organisms during the processes of transferring from can to delivery bag with ready-to-use formulas and during the process of reconstitution with powdered formulas. So-called closed systems of delivery, wherein the formulas come from the manufacturer premixed in a delivery bag, should help decrease possibility of formula contamination. Practice recommendations from ASPEN state that tap water may be inappropriate for formula reconstitution, medication dilution, tube flushing, and additional water provision in patients requiring EN.[5]

Metabolic Complications

Metabolic complications of EN most commonly include disorders of fluid and electrolyte homeostasis and hyperglycemia. More severely ill patients require more frequent monitoring (see Table 101–8). Both dehydration and fluid overload can occur. Careful monitoring of fluid inputs and outputs as well as body weight is important. Dehydration may be caused by either excessive fluid losses or inadequate fluid intake. The trend in the ratio of BUN to serum creatinine can be useful in helping monitor fluid status; a ratio greater than 15:1 (60:1 for SI mmol/L:mmol/L) may be an indicator of dehydration; high ratios may also be a result of high protein provision by the feeding. Attention should be paid to free-water content of EN formulas. Free-water content varies from about 70% to 85%; percentage-free water typically drops as caloric density of the formula rises. If dehydration develops, switching to a less calorically dense formula or using larger water flushes is appropriate. Fluid overload is reflected by increases

in weight, lower extremity edema, and pulmonary rales and particularly may be a problem in patients with renal or cardiac insufficiency. Use of a more calorically dense EN formula may be helpful, and diuretic therapy may be necessary. Fluid imbalances often are associated with abnormalities of sodium homeostasis that should be addressed in concert with fluid imbalance.

Hypokalemia, hypomagnesemia, and hypophosphatemia are some of the most common electrolyte abnormalities in sick, hospitalized patients. These can occur in context of the refeeding syndrome, which may be seen in chronically malnourished patients aggressively started on feeding. Careful monitoring of electrolytes, coupled with a feeding regimen increased gradually to goal rate over a period of several days, should help protect at-risk patients from this complication. Hypokalemia and hypomagnesemia also are associated with excessive losses through the GI tract or urine and are associated with various medications, including diuretics. Repletion may be accomplished enterally in nonsymptomatic patients or parenterally if the patient is symptomatic or the abnormality is severe. Enteral repletion with magnesium and phosphate can cause diarrhea. Hyperkalemia, hypermagnesemia, and hyperphosphatemia are less common and usually are associated with renal insufficiency. Hyperkalemia also is associated with medications, including potassium-sparing diuretics, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers.

Although hyperglycemia is less common with EN than PN, it can occur. Many severely ill patients (eg, septic, highly stressed) receiving EN have a metabolic milieu promoting hyperglycemia. For ICU patients with hyperglycemia receiving continuous EN, an IV insulin drip may be the most effective way to achieve good glycemic control. Scheduled intermediate or long-acting insulin plus nutritional and correctional regular or rapid acting insulin can be utilized after stabilization on the feeding regimen or for patients in whom insulin drips are not feasible.[28] Administration of a higher fat, lower carbohydrate EN formula may be useful in selected patients.

Monitoring for Efficacy and Outcome Evaluation

A useful physical measurement of EN efficacy in the long-term patient is body weight. Depending on the clinical situation, the goal may be weight gain, weight maintenance, or weight loss. Whereas day-to-day fluctuations in weight generally reflect fluid changes, week-to-week variations are more useful in determining if caloric provision is appropriate.

The amount of EN actually administered is often less than the amount ordered owing to interruptions in therapy. It is imperative to monitor volume of feedings actually received and to make adjustments in rates or amounts of EN as necessary.

Biochemical markers have been used historically to help interpret EN adequacy. Use of visceral proteins such as albumin or prealbumin is limited by the effects of inflammation on serum levels of these biomarkers.[29] In the acute phase of illness characterized by a proinflammatory state, proteins known as *acute-phase reactants* are preferentially synthesized. One of these measured clinically is C-reactive protein (CRP). In some patients with significant illness, prealbumin may not rise, even though the patient is receiving appropriate EN, until CRP begins to fall. Collection of urine to measure nitrogen balance can help analyze adequacy of caloric and protein provision.

In patients with wounds (eg, decubitus ulcers, surgical wounds), a goal of therapy is to facilitate wound healing. Monitoring status of the wound becomes part of ongoing nutritional assessment. In debilitated patients, particularly on long-term EN, measures of functional status such as grip strength and ability to perform activities of daily living become important components of nutritional assessment.

MEDICATION ADMINISTRATION IN PATIENTS RECEIVING EN

Medication Administration Through Feeding Tubes

If a patient receiving EN is alert and can swallow oral medications, then medications should be given by mouth. Many patients are not able to receive medications by this route, and the feeding tube may be considered as a delivery route. Effects of medication administration through feeding tubes on the delivery of both the drug and the EN formula nutrients have been inadequately studied.[30]

KEY CONCEPT Compatibility of medication with EN formula is of concern when administering medications through feeding tubes. An important technical complication of EN is tube occlusion, related most commonly to medication administration. Not only must compatibility of medication and EN formula be considered, but interactions between medications and the feeding tube itself must be considered. Strict protocols for flushing the tube before, between, and after administration of medications are important.[5] The best fluid for flushing is warm water. At least 15 mL of water should be used as a flush before and after medication administration through a feeding tube. Medications should be administered one at a time sequentially rather than being mixed together for simultaneous administration down the tube; ideally 15 mL of water should be used as a flush between medications. This should help prevent interactions between drugs within the tube itself that could lead to occlusion.

LO 6

Different dosage forms present unique challenges for administration through feeding tubes. Certain solid dosage forms should not be crushed because crushing would alter release characteristics.[31] For example, controlled-release, extended-release, and sustained-release preparations should not be crushed, nor should sublingual dosage forms. Enteric-coated dosage forms generally are designed to protect acid-labile medications from stomach acid; when these dosage forms reach the small bowel with its higher pH, the drug is released into an environment in which it is more stable. Alternatively, enteric-coated dosage forms protect the stomach from medications that could cause irritation. Thus, crushing the enteric coating defeats the purpose of the dosage form and could lead to decreased efficacy or increased adverse events.

Medications available commercially as compressed tablets can be crushed for administration through tubes. After crushing, the fine powder should be mixed with 10 to 30 mL of fluid

Patient Encounter Part 2

On day 4, vasopressor requirements are minimal and enteral feeding is infusing at a low rate via nasogastric tube. Propofol is changed to dexmedetomidine on day 5.

How does propofol affect the initial EN prescription?

What is refeeding syndrome and is this patient at risk? If so, how can it be prevented?

Design an enteral feeding regimen, including choice of formula, titration schedule, and goal rate, appropriate for this patient at this time.

(usually warm water) for administration. A powdered dosage form inside a hard-gelatin capsule can be poured out and mixed with water for administration through tubes. Soft-gelatin capsules can be dissolved in warm water. Some enteric-coated and delayed-release microencapsulated products can be opened and individually coated particles administered through the tube without crushing if the tube has a large enough diameter.

If a liquid dosage form of a medication exists, it would seem rational to use this for administration through a feeding tube. This may decrease potential for tube clogging but may, in some instances, decrease tolerability of medication administration. Sorbitol is an excipient found in many liquid medications in amounts sufficient to cause diarrhea.

Another potential problem with administration of liquid medications through feeding tubes is high osmolality of some products. Dilution of hypertonic medications with 30 to 60 mL of water or administration of smaller dosages more frequently may help prevent diarrhea. Although administration of IV medications through feeding tubes may be entertained, these dosage forms frequently are hypertonic and contain problematic excipients when given via the GI tract.

It is generally not recommended to mix medications directly into EN formula because physical incompatibilities might lead to tube occlusion. Limited data currently available indicate that acidic syrups and elixirs may be most harmful, causing physical incompatibility when admixed with EN formulas. It would seem logical that medications considered absorbed better in the fasted state either should be given between feedings on an intermittent feeding schedule or feedings should be held before and after medication administration. However, not all studies have supported this idea, therefore this issue deserves further study.

Location of feeding tube tip is important when considering medication administration. This is particularly true if the medication acts locally in the GI tract. For example, sucralfate and antacids act locally in the stomach; therefore, administration through a duodenal or jejunal tube is illogical. Likewise, for medications requiring acid for best absorption, administration directly into the duodenum or jejunum may result in suboptimal absorption. Absorption of drugs when administered directly into the small bowel, especially the jejunum, is a topic where more research would be useful.

Problem Medications

▶ *Phenytoin*

Certain medications present challenges when administered through feeding tubes. The medication studied most thoroughly is phenytoin. Most studies have shown significant decreases in phenytoin absorption when administered enterally to patients receiving EN. Several mechanisms have been proposed. Liberal dilution of phenytoin suspension before its administration down the tube may improve delivery. Many institutions hold tube feedings for 1 or 2 hours before and after administration of phenytoin, although some EN patients subjected to this routine still require high dosages to achieve therapeutic serum concentrations. Holding feeding around medication administration can make meeting nutritional requirements difficult with continuous feedings, especially if phenytoin is administered several times daily. Diligent monitoring of serum concentrations is necessary for the patient on EN receiving this medication. In some cases, use of IV phenytoin or another anticonvulsant may be prudent.

Patient Encounter Part 3

LT is extubated on day 13. Concern regarding her swallowing strength leads to a speech pathology consult. On day 14 an order to advance oral diet as tolerated is written following the speech pathology assessment.

How should the transition from EN to oral feedings be accomplished?

▶ *Warfarin*

EN formulas contain vitamin K, which can antagonize the pharmacologic activity of warfarin. Vitamin K content of EN formulas has been adjusted down over several decades, resulting in products that contain amounts of vitamin K unlikely to affect anticoagulation by warfarin significantly. However, inadequate warfarin anticoagulation in EN patients receiving formulas containing minimal vitamin K has been reported. A component of certain tube feedings, perhaps protein, may bind warfarin and result in suboptimal activity, as might the feeding tube itself. One small study indicated a better response in terms of the international normalized ratio (INR) when feedings were held for 1 hour before and after warfarin compared with administration of the drug without holding feedings.[32] When tube feedings are started, changed, or discontinued, INR should be monitored closely. Alternatively, a different oral anticoagulant may be considered to avoid the potential interaction with warfarin, especially for short-term tube feedings in hospitalized patients.

▶ *Fluoroquinolones*

Absorption of antimicrobial agents such as fluoroquinolones and tetracyclines that can be bound by divalent and trivalent cations potentially could be compromised by administration with EN formulas containing these cations. Fluoroquinolones (eg, levofloxacin and ciprofloxacin) have been best studied in this regard, and results of studies are not consistent.[33] Some institutions hold tube feedings for 1 to 2 hours or more before and after enteral dosages of fluoroquinolones. Not all fluoroquinolones are affected by the interaction, suggesting that a mechanism other than chelation by divalent cations may also be significant. Because ciprofloxacin absorption has been shown to be decreased with jejunal administration, this drug probably should not be given by jejunal tube.

SUMMARY AND CONCLUSION

EN is an important method of feeding patients who cannot or should not eat enough to meet nutrient requirements for a prolonged time. When the GI tract can be used safely, EN is preferred over PN. Various types of enteral access devices are available. Whereas tubes inserted through the nose often are adequate for patients expected to receive EN for a short time, devices that are more permanent are preferred for longer-term patients. Choice of whether to feed into the stomach or postpylorically is patient specific. Although numerous EN formulas are available, many products are very similar, making a limited formulary feasible. Data supporting many specialized types of EN formulas are limited. Although complications of EN tend to be less serious than those of PN, adverse effects encountered can be significant, and ongoing monitoring is necessary. Although medications can be administered through feeding tubes, various factors must be taken into account in each individual patient.

Patient Care Process

Collect Information:

- Based on patient's disease states and severity, estimate the amount of time until adequate oral intake resumes (Table 101–1).
- Are there any contraindications or precautions regarding use of EN (Table 101–2)? When the GI tract is nonfunctional, either PN or no SNS is indicated.
- If inadequate intake has occurred or is anticipated for 7 to 14 days, start SNS. The threshold for starting SNS is lower for previously malnourished patients. Critically ill patients at high nutritional risk should generally be started on EN within 24 to 48 hours of ICU admission.
- Choose the appropriate type of enteral access device based on expected duration of use and whether any condition exists which precludes gastric feeding (Table 101–3).
- Choose method of feeding administration (eg, intermittent or continuous) based on feeding location (ie, gastric versus postpyloric) and other patient factors.

Assess the Information:

- Are medications being administered down the feeding tube? If so, assess the appropriateness of this route.

Develop a Care Plan:

- Start tube feeding at full strength and increase rate as tolerated to goal that will meet patient's nutritional requirements.
- Develop plan to include monitoring at appropriate intervals for metabolic, GI, technical, or infectious complications (Table 101–8).
- Develop monitoring plan for adequacy of nutritional regimen. This may include serial weights, intakes and outputs, and a measure of functional status.

Implement the Care Plan:

- If patient is to be discharged home on EN, educate patient or caregiver on enteral access device care, feeding delivery, troubleshooting, and complications to observe for and who should be contacted when complications occur (Table 101–7).

Follow-up: Monitor and Evaluate:

- Adjust formula, rate of administration, and/or route of administration if intolerance develops or nutritional goals (eg, weight loss, weight maintenance, weight gain, maintenance of muscle mass, slowing of functional decline) are not met.

Abbreviations Introduced in This Chapter

AAA	Aromatic amino acid(s)
AI	Adequate intake
AKI	Acute kidney injury
ALI	Acute lung injury
ARDS	Acute respiratory distress syndrome
ASPEN	American Society for Parenteral and Enteral Nutrition
BCAA	Branched-chain amino acid(s)
BUN	Blood urea nitrogen
CRP	C-Reactive protein
DHA	Docosahexaenoic acid
EAA	Essential amino acid(s)
EFA	Essential fatty acid(s)
EN	Enteral nutrition
EPA	Eicosapentaenoic acid
ESPEN	European Society for Clinical Nutrition and Metabolism
FOS	Fructooligosaccharide
Fr	French
GALT	Gut-associated lymphoid tissue
GI	Gastrointestinal
GLA	γ-Linolenic acid
HE	Hepatic encephalopathy
IBD	Inflammatory bowel disease
ICU	Intensive care unit
INR	International normalized ratio
LCT	Long-chain triglyceride
MCT	Medium-chain triglyceride
MUFA	Monounsaturated fatty acid
ND	Nasoduodenal
NEAA	Nonessential amino acid
NG	Nasogastric
NJ	Nasojejunal
NO	Nitric oxide
OG	Orogastric
PEG	Percutaneous endoscopic gastrostomy
PEJ	Percutaneous endoscopic jejunostomy
PN	Parenteral nutrition
PUFA	Polyunsaturated fatty acid
RDA	Recommended Dietary Allowance
SCFA	Short-chain fatty acid
SCCM	Society for Critical Care Medicine
SNS	Specialized nutrition support

102 Overweight and Obesity

April Smith

LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Explain the underlying causes of overweight and obesity.
2. Identify parameters used to diagnose obesity and indicate the severity of disease.
3. Identify desired therapeutic goals for patients with obesity.
4. Recommend appropriate nonpharmacologic and pharmacologic therapeutic interventions for overweight or obese patients.
5. Implement a monitoring plan that will assess both the efficacy and safety of therapy initiated.
6. Educate patients about the disease state and associated risks, comprehensive lifestyle interventions, drug therapy, and surgical options necessary for effective treatment.

INTRODUCTION

Overweight and obesity are terms used to describe weight measurements greater than what is considered healthy for a given height.[1] KEY CONCEPT **Body mass index** (BMI), waist circumference (WC), comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients. BMI should be used to identify adults at increased risk for cardiovascular disease (CVD) and other obesity-related disorders. Evaluation of the patient's risk status involves not only calculation of the BMI but also the measurement of WC. KEY CONCEPT The presence of comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose) requires identification and aggressive management for overall effective treatment of the overweight or obese patient to reduce their risk of mortality.[2] Obesity contributes to some of the leading causes of preventable death including hypertension, dyslipidemia, diabetes mellitus, CVD, stroke, sleep apnea, gallbladder disease, osteoarthritis, and certain cancers.[2] Obesity is officially recognized as a disease by the American Medical Association with a pathophysiological basis for metabolic and biochemical dysfunctions.

ETIOLOGY AND EPIDEMIOLOGY

Obesity is a multifactorial, complex disease that occurs because of an interaction between genotype and the environment. Although the etiology is not completely known, it involves overlapping silos of social, behavioral, hormonal, and genetic influence.[3] The majority of overweight or obese individuals are adults, but overweight or obesity is also prevalent in children between 2 and 19 years of age. Just over 1/3rd of US adults 20 years of age and older are currently considered obese. The prevalence of obesity in men and women of various racial and ethnic origins differs. Thirty-six percent of non-Hispanic white adults are obese, whereas approximately 40% of Hispanics and 50% of non-Hispanic blacks are obese.[4]

Thirty-two percent of children and adolescents aged 2 to 19 years are overweight or obese. Overweight children typically become overweight adults, but most obese adults were not overweight as children.[2,5,6,7] Psychosocial functioning also may be hindered because obese patients may be at risk for discrimination as well as higher risk of low self-esteem and depression.[2]

PATHOPHYSIOLOGY

The key factor in the development of overweight and obesity is the imbalance that occurs between energy intake and energy expenditure. The extent of obesity is determined by the length of time this imbalance has been present. The hormone leptin, released from adipose tissue, is generally thought to play a major role in long-term weight homeostasis.[8] Leptin increases signaling to the hypothalamus as fat stores rise[9] (**Figure 102–1**). In the setting of obesity, leptin levels remain high, but eating behavior does not seem to be impaired, which is thought to be due in part to leptin resistance. Energy intake is affected by environmental influences and various gut hormones, whereas genetic composition and metabolism affect energy expenditure.[8]

Energy Intake

Food intake is regulated by various receptor systems that comprise the gut-brain axis. Gut peptides travel via the vagus nerve or pass directly through the blood brain barrier to affect the appetite control centers in the hypothalamus (Figure 102–1). There are two groups of neurons in the arcuate nucleus (ARC) of the hypothalamus that send signals to higher brain centers and ultimately drive eating behavior. When neuropeptide Y or agouti-related peptide (NPY/AgRP) neurons in the ARC are stimulated by gut peptides such as ghrelin, eating ensues. When pro-opiomelanocortin or cocaine-amphetamine-regulated transcript (POMC/CART) neurons in the ARC are stimulated by various gut peptides or leptin, eating is halted. Stimulation of the following receptors increases and decreases food intake, respectively.

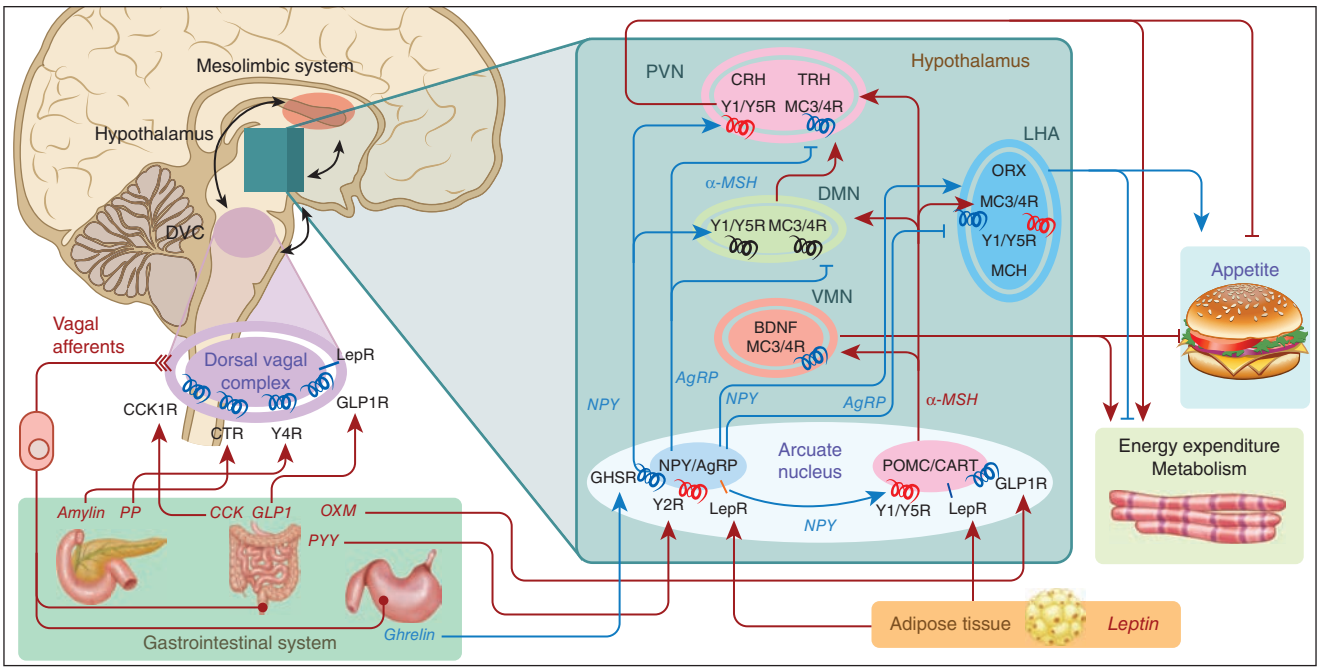

FIGURE 102–1. Central regulation of appetite and energy homoeostasis. The hypothalamus is the major site of integration of anorexigenic and orexigenic signaling. Peripheral satiety hormones, such as ghrelin from the stomach and leptin from adipose tissue, primarily bind and activate their cognate receptors directly in the hypothalamus, particularly in the arcuate nucleus, or in the dorsal vagal complex in the medulla, which communicates with the hypothalamus. Among the neurons in the arcuate nucleus there exist two populations of neurons: those expressing the orexigenic neuropeptide y (NPY) or agouti-related peptide (AgRP); and those expressing the anorexigenic pro-opiomelanocortin (POMC) and cocaine- and amphetamine-regulated transcript (CART). Several satiety hormones induce their anorectic effects by either inhibiting the activity of NPY/AgRP neurons or activating POMC/CART neurons. These neurons in the arcuate nucleus project to second-order neurons in other hypothalamic nuclei, including the paraventricular nucleus (PVN), dorsomedial nucleus (DMN), ventromedial nucleus (VMN), and lateral hypothalamic area (LHA). These second-order hypothalamic neurons express anorexigenic neuropeptides (corticotropin-releasing hormone [CRH], thyrotropin-releasing hormone [TRH], brain-derived neurotrophic factor [BDNF]) and orexigenic neuropeptides (orexin [ORX], melanin-concentrating hormone [MCH]), which modulate appetite and energy homeostasis. Furthermore, the regulation of energy balance involves an integration of signaling from the hypothalamus, brainstem, and reward pathways of the mesolimbic system. Symbols: blue receptor = activating; red receptor = inhibiting; blue arrow = appetite-stimulating; red arrow = appetite-suppressing. (From Kim GW, Lin JE, Blomain ES, et al. Antiobesity pharmacotherapy: new drugs and emerging targets. Clin Pharmacol Ther. 2014;95(1):53–66.)

▶ *Increase Food Intake*

- Serotonin 1A subtype (5-HT_{1A})
- Noradrenergic α_2
- Cannabinoid 1 (CB1)
- NPY/AgRP
- Melanin-concentrating hormone (MCH)
- Orexin

▶ *Decrease Food Intake*

- Serotonin 2C subtype (5-HT_{2C})
- Noradrenergic α_1 or β_2
- Histamine subtypes 1 and 3
- Dopamine 1 and 2
- CART/POMC
- α-melanocyte-stimulating hormone (α-MSH)

Targeting of this endogenous circuitry is a primary trait shared by many of the newer antiobesity medications on the market as well as those currently in development.

Energy Expenditure

A person's metabolic rate is the primary determinant of energy expenditure. The metabolic rate is enhanced immediately after food consumption and is directly related to the amount and type of food consumed.[10] After a period of weight loss, total energy expenditure is reduced.[10] Physical inactivity and/or endocrine-related disorders (eg, hypothyroidism and Cushing syndrome) may lower the metabolic rate, further contributing to the development of overweight and obesity.

LO 1

CLINICAL PRESENTATION AND DIAGNOSIS

LO 2

KEY CONCEPT BMI, WC, body fat percentage, comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients. Any interaction between a patient and a health care provider presents an opportunity to evaluate the patient's height and weight and calculate their BMI. These parameters should be measured no less than annually. The BMI is calculated using the measured weight in kilograms divided by the height in meters squared (kg/m^2) for all adult patients, regardless of gender, and is used to classify overweight or obesity. The greater the BMI in overweight and obese individuals, the greater the risk

LO 2

Table 102–1

BMI Classification

Adult	
Underweight	< 18.5 kg/m^2
Normal weight	18.5–24.9 kg/m^2
Overweight	25–29.9 kg/m^2
Obesity (Class 1)	30–34.9 kg/m^2
Obesity (Class 2)	35–39.9 kg/m^2
Extreme obesity (Class 3)	≥ 40 kg/m^2
Children (Only for Those > 2 Years of Age[a])	
Underweight	< 5th percentile
Healthy weight	5th–84th percentile
Overweight	85th–94th percentile
Obesity	≥ 95th percentile

[a]Weight for height values should be plotted and monitored over time for children < 2 years of age.

From Refs. 2 and 12.

of CVD, type 2 diabetes mellitus, and all-cause mortality.[11] The BMI distribution changes with age for children just as height and weight. Percentiles specific for age and gender are used to classify pediatric patients as overweight and obese as well as healthy and underweight. BMI is classified according to Table 102–1. WC should also be determined no less than annually for adult patients by placing a measuring tape at the top of the right iliac crest and proceeding around the abdomen, ensuring that the tape is tight but not constricting the skin. The value is measured after normal expiration. High-risk WC is defined as greater than 40 inches (102 cm) in men and greater than 35 inches (89 cm) in women.[13] Measurement of WC is not recommended for children and adolescents because reference values identifying risk are unavailable.[13] After obtaining patient-appropriate parameters, further assess the adult patient for the presence of obesity-related comorbidities and cardiovascular risk factors. KEY CONCEPT The presence of obesity-related comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors requires identification and aggressive management for overall effective treatment of the overweight or obese patient. A patient is at very high absolute risk of a cardiovascular event if diagnosed with CVD, type 2 diabetes mellitus, or sleep apnea or if three or more of the following risk factors exist: cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, decreased high-density lipoprotein cholesterol, or impaired fasting glucose.[2] Aggressive disease management should be initiated and not limited to weight loss.

TREATMENT

Desired Outcome

KEY CONCEPT The treatment goals for overweight and obesity are to prevent additional weight gain, reduce and maintain a lower body weight, and control related risks. A 5% to 10% weight loss has been shown to improve obesity-related comorbidities such as hypertension, hyperlipidemia, and type 2 diabetes mellitus and thus serves as the initial goal for obesity treatment strategies.[11] A sustained 5% weight loss will likely reduce triglyceride and blood glucose values as well as risk for the development of type 2 diabetes mellitus.[11] Greater reductions in weight will reduce blood pressure and improve both low-density and high-density lipoprotein cholesterol. KEY CONCEPT Weight loss is indicated for patients with a BMI of 25 to 29.9 kg/m^2 with one or more indicators of increased CVD risk (eg, elevated WC, prediabetes or type 2 diabetes, hypertension, dyslipidemia, current cigarette smoker) or for any patient with a BMI of 30 kg/m^2 or greater. Weight loss should occur at a rate of 0.45 to 0.9 kg (1–2 lbs) per week, meeting the initial weight loss goal within the first 6 months of therapy. If the patient achieves a 5% to 10% loss in weight, weight loss maintenance strategies should be considered. KEY CONCEPT Weight maintenance occurs after successful achievement of weight loss.

For children or adolescents, a BMI below the 85th percentile is warranted, but is difficult to assess in frequent or short time periods. Serial weight measurements may better quantify energy balance. Goals are most likely accomplished through adaptation of lifelong healthy lifestyle habits. In doing so, weight loss or maintenance can be attained for some children. Others may need to incorporate changes that result in a negative energy balance or energy input less than energy output.[12–14]

General Approach to Treatment

KEY CONCEPT Treatment of obesity includes comprehensive lifestyle intervention (caloric-restricted diet, increased physical activity, and behavioral therapy to facilitate compliance with diet and exercise), pharmacologic treatment, surgical intervention, or a combination of modalities. Before initiating therapy, secondary causes of obesity (eg, hypothyroidism and Cushing syndrome) must be considered. Current treatment with medications that increase weight should be determined and, if present, alternative therapies should be suggested.[15,16] Table 102–2 provides a list of drugs commonly associated with weight gain. Therapy implemented to minimize associated risk(s) may not enhance

Table 102–2

Drugs Contributing to Weight Gain

- Anticonvulsants/mood stabilizers
  - Carbamazepine
  - Gabapentin
  - Pregabalin
  - Valproic acid
  - Lithium
- Antidepressants
  - Monoamine oxidase inhibitors (phenelzine)
  - Presynaptic α-2 antagonist (mirtazapine)
  - Selective serotonin reuptake inhibitors (citalopram, escitalopram, fluvoxamine)
  - Serotonin and norepinephrine reuptake inhibitors (duloxetine)
  - Tricyclics (amitriptyline, imipramine)
- Antidiabetics
  - Insulin
  - Meglintinides
  - Sulfonylureas (glipizide, glyburide)
  - Thiazolidinediones
- Antipsychotics
  - Atypical (clozapine, olanzapine, paliperidone, risperidone)
  - Conventional (haloperidol)
- Others
  - Antihistamines
  - Some nonselective β-blockers
  - Corticosteroids
  - Hormonal contraceptives (depot injections)

From Refs. 15 and 16.

weight loss, but weight loss will positively address risk factors. Weight loss therapy should not be initiated in pregnant or lactating patients, decompensated psychiatric patients, or patients in whom reduced caloric intake can exacerbate an acute, serious illness.[2]

The treatment of pediatric obesity is a comprehensive strategy combined of four main pillars; regulating quality and quantity of food intake, encouraging at least 60 minutes of physical activity daily while also limiting screen time to less than 1–2 hours per day, sleep regulation, and pharmacotherapy for those who qualify.[12,15]

Nonpharmacologic Therapy

Weight loss therapy requires the creation of an energy deficit. This may be achieved through daily caloric restriction and increased physical activity. Comprehensive lifestyle intervention and behavior modification is foundational to weight loss and should be recommended for all overweight or obese patients, even when adjunctive therapy with medications, devices, or bariatric surgery has been implemented.[11] Table 102–3 indicates which treatment options may be appropriate according to BMI category.[13,17]

▶ *Reduced-Calorie Diet*

LO 4

Techniques to reduce dietary energy intake include adoption of a target energy intake less than that required for energy balance. This can usually be accomplished by reducing the energy intake by 500 kcal/day (2093 kJ/day) or greater from current intake. Recommend total intake of 1200 to 1500 or 1500 to 1800 kcals/day (5023–6279 or 6279–7534 kJ/day) for women and men, respectively. The choice of calorie-restricted diet is based on patient preference and current health status. A variety of diets, including but not limited to, high protein, low carbohydrate, low fat, Mediterranean and American Heart Association (AHA) Step-1 diet, can result in weight loss if reduction in dietary intake is achieved.[11] The AHA Step-1 diet restricts daily calories to a range of 1000 to 1200 kcal (4186–5023 kJ/day) for women weighing less than 75 kg (165 lbs) and 1400 to 1600 kcal (5860–6697 kJ/day) for all others. This daily limit should be considered after assessing a patient's normal daily caloric intake and ensuring that the initial caloric restriction does not exceed 500 to 1000 kcal (2093–4186 kJ/day). For example, a male patient who consumes 3000 kcal (12,557 kJ/day) should not reduce his daily caloric intake to less than 2000 kcal (8372 kJ/day) when initially implementing a dietary program. Further reduction to the target of 1600 kcal (6697 kJ/day) can be attempted when the patient has reduced calories successfully, as initially recommended, for a period agreeable to the practitioner and the patient.[2] Diets too restrictive in calorie reduction are successful initially, but fail in the long term because compliance is difficult to sustain.[18] Therefore, this less aggressive approach promotes gradual weight loss and weight maintenance. Consultation with a dietician is recommended when implementing a healthy meal plan tailored to the individual's nutritional needs.

Pediatric patients should be encouraged to consume three servings of protein daily, three servings of dairy daily, four to six servings of fruits and vegetables daily (majority from vegetables), avoid fast food, restrict dessert to special occasions only, and allowing the child to leave food on their plate if they feel full.[12]

▶ *Increased Physical Activity*

LO 4

Although diet and exercise contribute to weight loss, combining a reduced-calorie diet with increased physical activity results in greater weight loss compared with either therapy alone.[13] In addition, physical activity can help prevent weight regain and reduce related cardiovascular risks.[11] Slow titration of both the amount and intensity of aerobic physical activity is recommended for most patients.[2] A program that incorporates walking daily is a viable option for most patients. Suggest starting with 10 minutes of physical activity 3 days/week and titrate up to 30 minutes most days as tolerated for optimal weight maintenance.[2,11] Pediatric patients should engage in at least 60 minutes of moderate to vigorous activity daily and limit nonacademic sedentary time.[12]

LO 3 LO 4

▶ *Behavioral*

Eliminating barriers through behavior modification is necessary to gain maximal benefit from both dietary modification and exercise. Successful behavioral therapy includes regular self-monitoring of food intake, physical activity, and weight.[11,13]

LO 3 LO 4

Targeted behaviors should be recommended to pediatric patients and their families because healthy habits help prevent excessive weight gain. These include, but are not limited to:[12,14]

- Limit the consumption of sugar-sweetened beverages.
- Limit the amount of screen time (television, computer, etc) to 2 hours or less per day.
- Limit the number meals eaten at restaurants, especially those serving fast food.
- Limit portion size when preparing and serving meals.

Pharmacologic Therapy

KEY CONCEPT Pharmacotherapy in addition to comprehensive lifestyle intervention can be considered for patients with a BMI of 30 kg/m^2 or greater, or a BMI of 27 kg/m^2 or greater with other obesity-related co-morbidities. Obesity is a chronic

Table 102–3

Indications for Obesity Treatment by BMI Category

	BMI Category				
Treatment	25–26.9	27–29.9	30–34.9	35–39.9	> 40
Bariatric Surgery	No	No	Gastric banding with comorbidity	With comorbidity	Yes
Devices	No	No	Balloon	Aspire Assist Balloon vBloc[a] with comorbidity	Aspire Assist vBloc
Pharmacotherapy	No	With comorbidity	Yes	Yes	Yes
Lifestyle Modification (diet, activity, behavior)	Yes	Yes	Yes	Yes	Yes

[a]vBloc = vagal nerve block therapy

From Refs. 13 and 17.

disease that needs chronic treatment. There is no other chronic disease where therapy is withdrawn after a definitive time point. KEY CONCEPT Weight will likely be regained if lifestyle changes and/or therapeutic interventions are not continued indefinitely. Five drugs are approved for long-term use (at least 2 years) in promoting weight loss and preventing weight regain. If 4% to 5% weight loss is not achieved after 12 weeks of target dose therapy, the drug should be discontinued. Pharmacotherapy is not appropriate for women who are pregnant or lactating. Orlistat is the only agent approved for adolescent patients and is FDA approved for patients greater than 12 years of age.[19] All other pharmacotherapeutic agents are only approved for patients greater than 18 years of age. Table 102–4 summarizes currently available pharmacotherapeutic agents for weight management.

Table 102–4

Pharmacotherapy for the Treatment of Obesity

Drug	Dose	Side Effects	Warnings and Contraindications	Relative Monthly Cash Price
Phentermine (Adipex P, Lomaira)	8–37.5 mg daily (given in 1–3 divided doses)	Restlessness, tremor, palpitations or tachycardia, hypertension, cardiac valvulopathy pulmonary hypertension	Tolerance develops after a few weeks Do not discontinue abruptly from max dose (seizure possible), avoid alcohol, hypokalemia if used with diuretics, avoid in hepatic dysfunction, take in morning to avoid insomnia History of drug abuse, cardiovascular disease, hyperthyroidism, glaucoma, administration of a monoamine oxidase inhibitor within 14 days	~$50
Phentermine/ Topiramate (Qsymia) Risk Evaluation and Mitigation Strategy (REMS) Program—pregnancy warning; cleft palate	3.75/23 mg daily × 14 days, 7.5/46 mg × 12 weeks Titrate up to 11.25/69 mg × 14 days then 15/92 mg daily if first 12 weeks successful Max dose 7.5/46 mg for CrCL < 50 mL/min (0.84 mL/s)	Constipation, paresthesias, xerostomia, blurred vision, impaired cognition, headache, kidney stones, increased upper respiratory tract infection, tachycardia, metabolic acidosis	Do not discontinue abruptly from max dose, avoid alcohol, hypokalemia if used with diuretics, avoid in hepatic dysfunction, take in morning to avoid insomnia Glaucoma, hyperthyroidism, administration of a monoamine oxidase inhibitor within 14 days	~$200–250
Bupropion/ Naltrexone (Contrave)	8/90 mg ER tab titrate up by 1 tab each week over 4 weeks to 32/360 mg given twice daily Limit to 1 tab twice a day for moderate–severe renal, and 1 tab daily for hepatic dysfunction	Nausea, vomiting, constipation, headache, dizziness, tachycardia, hypertension, insomnia, mood disturbances—report suicidal ideation immediately	Don't take with high-fat meals, **potential drug interactions:** other serotonergic drugs, antipsychotics, clopidogrel, antiretrovirals Seizure disorder, uncontrolled hypertension, history of eating disorder, **chronic opioid use**, administration of a monoamine oxidase inhibitor within 14 days	~$250–300
Lorcaserin (Belviq, Belviq XR)	10 mg twice daily or 20 mg XR daily	Valvular heart disease, cognitive impairment/psychiatric disturbances, priapism, headache, dizziness, increased upper respiratory tract infection, nausea, constipation	Avoid if CrCL < 30 mL/min (0.50 mL/s), **drug–drug interactions with other serotonergic drugs**	~$250–300
Liraglutide 3 mg (Saxenda) REMS: Thyroid C-cell tumors, acute pancreatitis	0.6 mg subcutaneously daily, increase by 0.6 mg each week up to 3 mg	Nausea, vomiting, diarrhea, constipation, headache, dizziness, dyspepsia (delayed gastric emptying), increased heart rate, acute pancreatitis, cholelithiasis	↓ Sulfonylurea dose by 50% and do NOT use with insulin Personal or family history of medullary thyroid cancer or endocrine neoplasia type 2	~$100–1300
Orlistat (Xenical—prescription) (Alli—OTC)	Xenical 120 mg three times daily with meals Alli 60 mg three times daily with meals	Abdominal pain fecal urgency, leakage, incontinence flatulence, steatorrhea	Take a multivitamin containing vitamins A,D,E, and K Cholestasis, malabsorption syndromes	~$700–750 ~$50–100

From Refs. 19–26.

▶ *Agents for Long-Term Use*

Orlistat Orlistat promotes and maintains weight loss by acting locally in the GI tract. It inhibits pancreatic and gastric lipases, as well as triglyceride hydrolysis. As a result, undigested triglycerides are not absorbed, causing a caloric deficit and weight loss.[19] Two different orlistat products are available; prescription strength (Xenical 120 mg) and over the counter strength (Alli 60 mg) and both are taken with each meal. Initiate orlistat with a well-balanced but reduced-caloric meal containing no more than 30% of calories from fat. Orlistat may be taken during or up to 1 hour after the meal. If a meal is missed or contains little fat, the dose of orlistat may be omitted. Doses above 360 mg/day provide no greater benefit and thus are not recommended.[19] LO 4

Prescription strength orlistat in combination with diet, exercise, and behavior modification resulted in a significant reduction in BMI and WC in adolescents. In addition, orlistat-treated subjects exhibited minimal weight increase after 1 year.[19]

The safety and efficacy of orlistat have not been determined beyond 4 years of use. Orlistat's product label contains liver injury warning. Signs and symptoms of liver injury include itching, yellowing of the eyes or skin, dark urine, decreased appetite and light-colored stools. Orlistat should be stopped if the patient complains of these signs and symptoms. In addition, liver function tests should be assessed.[27] LO 5 LO 6

Orlistat reduces the absorption of some fat-soluble vitamins. Daily intake of a multivitamin containing fat-soluble vitamins is recommended. Because the absorption of vitamin K may be reduced in patients receiving orlistat therapy, closer monitoring of coagulation status should occur in patients also taking warfarin.[19] Simultaneous administration of orlistat and some other medications may cause reduced absorption of the other medication and put the patient at increased risk of clinical adverse effects. Patients should take levothyroxine 4 hours before or after the orlistat dose and be monitored for changes in thyroid function. Administration of orlistat in conjunction with cyclosporine can result in decreased cyclosporine plasma levels. Cyclosporine should be taken 2 hours before or after the dose of orlistat and cyclosporine levels should be monitored more frequently.[19] LO 5 LO 6

Lorcaserin Lorcaserin, a 5-HT_{2C} agonist, promotes satiety and decreases food consumption, however, the mechanism is unknown. Its use with other serotonin promoting drugs such as triptans, monoamine oxidase inhibitors (MAOI), selective serotonin reuptake inhibitors (SSRIs), serotonin-norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs), bupropion, lithium, antipsychotics, St. John's wort, and dextromethorphan is extremely cautioned due to the potential for serotonin syndrome.

Almost 30% of diabetic patients taking lorcaserin experienced hypoglycemia. Blood glucose should be monitored closely in patients taking an antidiabetic medication and lorcaserin.[21]

Initiate lorcaserin 10 mg twice daily or 20 mg once daily of the extended release version in addition to a calorie-restricted diet and increased physical activity. Doses greater than 20 mg daily are not recommended and may result in the development of euphoria, altered mood, and hallucinations. Due to the potential for psychic dependence and abuse, lorcaserin is a federally controlled substance (CIV) in the United States.[21] LO 5 LO 6

Phentermine-topiramate Phentermine-topiramate is an extended-release combination product. Phentermine decreases food intake by increasing norepinephrine and dopamine release in the central nervous system (CNS) which suppresses appetite. Topiramate is an antiepileptic drug whose exact mechanism of action is unknown. It is thought to increase satiety and suppress appetite through multiple pathways.[22]

Phentermine-topiramate use is associated with increased heart rate. Monitor resting heart rate frequently and have patients report the presence of palpitations. Topiramate can increase a patient's risk for suicidal thoughts and behaviors and alter mood. Patients should be monitored for worsening depression, thoughts of suicide, and unusual mood or behavior. Topiramate is contraindicated in patients with glaucoma or hyperthyroidism. Cognitive impairment is also associated with use of phentermine-topiramate; patients should proceed with caution when operating hazardous machinery including driving a car until the extent of impairment is known. An increase in serum creatinine and decrease in both potassium and bicarbonate have been reported.[22]

Because topiramate is a known teratogen, use of phentermine-topiramate during pregnancy is contraindicated. All women of childbearing potential should have a documented negative pregnancy result before this drug is initiated and monthly while on therapy.

Coadministration of phentermine-topiramate and MAOI could result in a hypertensive crisis. Do not initiate phentermine-topiramate within 14 days of MAOI discontinuation. Phentermine-topiramate used in patients taking an oral contraceptive may cause irregular bleeding but not an increased risk of pregnancy. Advise patients to continue the oral contraceptives even if spotting occurs. LO 5 LO 6

Initiate phentermine-topiramate at a dose of 3.75 mg/23 mg daily and titrate to max dose as per Table 102–4. Discontinue drug or increase the dose of phentermine-topiramate if a 3% weight loss is not achieved in 12 weeks. If the decision is made to increase the dose, recommend 11.25 mg/69 mg daily for 14 days then increase to 15 mg/92 mg daily. Discontinue drug if a 5% weight loss is not achieved after 12 weeks at the highest drug dose. Due to the potential for drug abuse, phentermine-topiramate is a federally controlled substance (CIV).[22] Gradually discontinue the 15 mg/92 mg dose to prevent possible seizures from abrupt withdrawal.

Naltrexone-bupropion Naltrexone-bupropion is an extended-release combination product. The exact mechanisms by which this opioid antagonist/antidepressant combination product decreases food intake and weight are not fully known but involve two separate areas of the brain (hypothalamus and mesolimbic dopamine circuit).[23] LO 6

Patients taking this product should be monitored for emergence or worsening of suicidal thoughts and behaviors and neuropsychiatric reactions. Bupropion inhibits CYP2D6 and can therefore increase the concentration of antidepressants, antipsychotics, and β-blockers. When taken with a CYP2B6 inhibitor (eg, clopidogrel), the concentration of bupropion increases. Reduce maximum daily dose by half in these patients. CYP2B6 inducers may reduce bupropion efficacy.[23] LO 5 LO 6

Each extended release tablet contains 8 mg of naltrexone and 90 mg of bupropion. Patients should be advised to not cut, crush, or chew tablets. Patients should also avoid taking naltrexone-bupropion with high-fat meals to minimize the risk of enhanced bupropion absorption and subsequent seizure occurrence. To further reduce the risk of seizures, the dose must be titrated slowly as suggested in Table 102–4.

Liraglutide 3 mg Liraglutide is an injectable analog of GLP-1 with a sequence that is 97% homologous with endogenously produced GLP-1.[20] When liraglutide stimulates GLP-1 receptors

in the brain, signals of satiety are received and gastric emptying is delayed. A 50% dose reduction of sulfonylureas is recommended with concomitant administration of liraglutide 3 mg in patients with type 2 diabetes. Liraglutide 3 mg was not studied in patients currently using insulin; therefore, this combination should be avoided. Acute pancreatitis occurs in 0.3% of patients taking liraglutide.[20]

Liraglutide is administered subcutaneously at a starting dose of 0.6 mg daily and increased to a target dose of 3 mg as suggested in Table 102–4. The dose increase may be delayed by 1 week if the patient is experiencing intolerable gastrointestinal adverse effects.

► *Agents for Short-Term Use*

LO 4 LO 5 LO 6

Agents for short-term use are indicated as an adjunct to lifestyle modifications for no more than 12 weeks use.[22,28,29] They are structurally related to amphetamine and work to suppress appetite. They can cause CNS stimulation and carry a potential for abuse. They should also not be used concurrently or within 14 days of an MAOI. These agents are cheaper than chronic obesity medications, but often have more risky side effect profiles.

Phentermine An average weight loss of 3.6 kg (7.9 lbs) was demonstrated for patients treated with phentermine compared with placebo.[24]

Common adverse reactions seen with phentermine use include heart palpitations, tachycardia, elevated blood pressure, stimulation, restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, dry mouth, constipation, and diarrhea. Avoid phentermine in patients with CVD, hypertension, hyperthyroidism, and agitated states. Because phentermine is related to the amphetamines, the potential for abuse is high.[24] Alcohol is not recommended for patients prescribed phentermine.[24]

LO 5 LO 6

Phentermine is available as an immediate- and a sustained-release product. In conjunction with a healthy lifestyle, 30 to 37.5 mg of phentermine is administered once daily, typically before breakfast or 1 to 2 hours after the morning meal. The dosage should be individualized; some patients may be managed adequately at 15 to 18.75 mg/day, but a dose of 18.75 mg twice daily may be used to minimize side effects, excluding insomnia. To lessen the risk of insomnia, dosing phentermine in the evening should be avoided.[24] A lower dose, 8 mg tablet, is given three times daily prior to meals.

Diethylpropion and Phendimetrazine These older sympathomimetic amines exhibit pharmacologic activity similar to amphetamines, resulting in CNS stimulation and appetite suppression.

Use of diethylpropion for a period longer than 12 weeks is associated with an increased risk for development of pulmonary hypertension.[28] When used as directed, reported common CNS adverse effects of these amphetamine derivatives included restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, anxiety, tachycardia, palpitations, dry mouth, constipation, mydriasis, and blurred vision.[28,29] In addition, diethylpropion can decrease the seizure threshold.[28] These agents are contraindicated in patients with pulmonary hypertension, advanced arteriosclerosis, severe hypertension, hyperthyroidism, agitated states, or glaucoma. Because these medications are related to the amphetamines, the potential for abuse is high.[28]

Use of diethylpropion and phendimetrazine should be avoided in patients receiving or having received an MAOI within the preceding 14 days to prevent hypertensive crisis. Combination with other anorectic agents should be avoided.[28,29]

Patient Encounter 1, Part 1

A 44-year-old woman presents to your weight loss clinic for an initial evaluation. She reports that her glucose and blood pressure were elevated upon screening while attending a community health fair. She followed up with her primary care provider who recommended weight loss. The patient has gained 25 pounds (11.4 kg) since her last check up 2 years ago. She is not currently following any specific diet. She admits to eating fast food 2 to 3 days per week. The patient is recently divorced (1 year ago) and does not enjoy cooking for one. This patient is currently part of a walking group where she walks 20 minutes per day roughly 5 days per week. The patient does not smoke and consumes one glass of wine at least 4 nights per week. Her BMI is 33.1 kg/m^2 and her waist circumference is 39 inches (99 cm).

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does she have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

LO 4

Diethylpropion is available as both an immediate- and a controlled-release product. In conjunction with a reduced-calorie diet and/or exercise, dose diethylpropion (immediate release) 25 mg three times a day before meals or 75 mg (controlled release) once a day, usually midmorning.[28] Dose phendimetrazine extended release (105 mg) in the morning, 30 to 60 minutes before the morning meal or 35 mg immediate release 2 to 3 times per day prior to meals. Phendimetrazine is a federally controlled substance (CIII).[29]

Surgical Intervention

LO 6

KEY CONCEPT Weight loss (bariatric) surgery is warranted when other treatment attempts have failed in severely obese patients (BMI ≥ 40 kg/m^2, or ≥ 35 kg/m^2 with obesity-related comorbidities).[2,13] Several surgical techniques exist; however, three are currently recognized as contemporary procedures: **gastric bypass**, which induces weight loss through both malabsorptive and restriction, **sleeve gastrectomy**, and **laparoscopic adjustable gastric banding (LAGB)**, which achieve weight loss through restriction of food intake only.[30] Currently, the sleeve gastrectomy is the most commonly performed bariatric surgery procedure.[31]

Surgical options for obesity provide the most effective and sustainable weight loss results and may produce a loss of two-thirds of **excess body weight** after 2 years.[2] Additionally, very favorable outcomes for obesity-related comorbid conditions are observed.[32] Risk versus benefit must be considered as complications are inherent to any surgical procedure, but the overall likelihood of major complications is less than 4%. Possible short-term complications include pulmonary embolism, wound infection, and anastomotic leak. The overall risk of mortality from bariatric surgery is about 0.1%. Several studies have compared mortality in obese patients who have underwent bariatric surgery to those who have not and consistently found reduced mortality rates in the surgical population.[32]

Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Persistent lower back pain, occasional heartburn, depression, insomnia

FH: Father alive and 68 years of age; mother also alive (age 65) with history of obesity

SH: (–) Tobacco, (+) alcohol

Meds: Hydrocodone/acetaminophen 5/325 one tablet orally at bedtime, pantoprazole 40 mg orally each day, citalopram 20 mg orally each day, and quetiapine 12.5 mg orally at bedtime for sleep

ROS: (+) Heartburn; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

PE:

VS: BP 147/88 mm Hg, P 92 beats/min, RR 16 breaths/min, T 98.6°F (37.0°C)

Weight: Wt 193 lbs (87.7 kg); Ht 64" (163 cm)

Cardiovascular: Normal S_1S_2; no murmurs, rubs, gallops

Abdominal: Obese, soft, nontender, nondistended; (+) bowel sounds

Extremities: (–) Edema

Labs: Glucose (118 mg/dL[6.5 mmol/L]) and HbA1C (6.0% [0.06 or 42 mmol/mol Hgb]).

ECG: Normal; no evidence of past ischemia

Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?

What nonpharmacologic and pharmacologic treatments are available for the patient?

Would you recommend any changes to her current medication regimen to assist with her weight loss?

If you elected to start her on a pharmacotherapeutic agent for weight loss, what would you need to monitor and when would you recommend the patient come back for follow-up?

LO 6 Bariatric surgery is an alternative offered to adolescents because it results in substantial weight loss and medical health improvement.[33] Adolescent patients should be managed by a multidisciplinary team that can provide psychosocial, nutritional, and exercise support.[34] LO 6 Both adult and pediatric surgical patients must understand and commit to a substantial change in eating and activity patterns to maintain long-term weight reduction.

Postoperatively, healthcare providers should also make considerations for medication management as these procedures may alter drug and nutrient absorption.[35]

- If safe to do so for individual medications, crush tablets, open capsules, or use liquid formulations to replace sizeable pills until appropriate to restart solid foods (likely variable per program).
- Avoid nonsteroidal anti-inflammatory drugs (NSAIDs), diuretics, oral bisphosphonates, and potentially extended- or delayed-release products for malabsorptive procedures.
- Certain micronutrient supplements may be indicated depending on procedure type (eg, fat soluble vitamins, iron, vitamin B12).
- Nonoral routes of administration may be considered if available.

▶ *Devices*

Weight loss devices require a minimally invasive outpatient procedure since most of them are endoscopically placed.[17] There are currently three types of devices approved for use in adult patients by the FDA, vagal nerve blocking stimulators (vBloc), gastric balloons, and gastric emptying systems. Indications for use are dependent on BMI category and/or presence of obesity-related comorbidities (see Table 102–3) and some are only approved for short-term therapy (6 months).[13,17] Devices are associated with an overall equal to or greater weight loss profile compared to pharmacotherapy, but are not quite as effective as bariatric surgery.[17] Devices are associated with some similar adverse effects but an overall lesser serious complication rate compared to bariatric surgery.[17]

Vagal Nerve Block Stimulator The vBloc system contains a pacemaker-like device that is implanted under the skin and connects to electrodes that are attached to the vagus nerve.[36] It blocks hunger signals sent from the stomach to the brain along the vagus nerve. The vBloc system is not appropriate for patients with hepatic cirrhosis or those who have another electronic medical device already implanted.

Gastric Balloons Three medical-grade silicone gastric balloons are currently available for endoscopic placement and inflation in the stomach: Reshape, Orbera, and Obalon. The balloon reduces the amount of food that a patient can consume by taking up significant space in the stomach. After 6 months, balloons must be removed. Most common adverse events are nausea/vomiting, abdominal pain, and gastric ulcers.

Reduced Calorie Absorption System The AspireAssist device works by removing roughly one-third of the food consumed from the stomach before it reaches the intestinal

Patient Encounter 2, Part 1

A 41-year-old white man presents to your CVD risk reduction clinic. The patient currently denies chest pain, shortness of breath, dizziness, and lightheadedness. Upon review of previous progress notes, you discover that the patient's blood pressure has been elevated during the past three office visits. As a computer programmer, he finds himself sitting more than engaging in physical activity. He frequently eats fast food for lunch. Evenings are spent watching TV. He claims that his knee arthritis limits his exercise ability. The patient's BMI is 45 kg/m^2 and waist circumference is 47 inches (119 cm). He presents to the clinic today seeking recommendation for additional weight loss and says he is willing to make changes to better his health. He claims to have lost about 10 pounds (4.5 kg) since starting on Victoza for his diabetes.

What classification of overweight and obesity is appropriate for this patient?

Does this patient have a high-risk waist circumference?

Does he have other risk factors that may contribute to morbidity or mortality?

What are the treatment goals for the patient?

What additional information do you need to know before creating a treatment plan for this patient?

Patient Encounter 2, Part 2: Medical History, Physical Examination, and Diagnostic Tests

PMH: Occasional headache, Type 2 diabetes mellitus, hypertension, osteoarthritis of the left knee

FH: Father alive and 78 years of age; mother also alive and 77 years of age

SH: Drinks alcohol occasionally (socially) but denies any alcohol-related problems; distant history of substance abuse, mostly cocaine, but has been sober for 20 years

Meds: Lisinopril/hydrochlorothiazide 10/25 mg orally daily, aspirin 81 mg orally daily, metformin 1000 mg orally twice a day, Victoza 1.8 mg subcutaneously daily, atorvastatin 20 mg orally daily, Excedrin migraine 2 tabs orally as needed for headache, acetaminophen 650 mg orally four times a day as needed for knee pain

ROS: (–) Heartburn, regurgitation; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

VS: BP 134/92 mm Hg, P 92 beats/min, RR 15 breaths/min, T 98.7°F (37.1°C)

Weight: 289 lbs (131.3 kg)

Height: 68″ (173 cm)

Waist circumference: 47″ (119 cm)

10-year CVD risk: 7%

PE:

General: Well developed, in no acute distress

HEENT: Conjunctiva clear

CV: Regular rhythm, no S_3 or S_4 noted

Lungs: Clear to auscultation (CTA) bilaterally

Abd: Obese, soft, nontender, nondistended; (+) bowel sounds

Neuro: Normal gait, normal speech

Ext: (–) Edema

Labs:

Na: 142 mEq/L (mmol/L); **K:** 4.6 mEq/L (mmol/L); **Cl:** 107 mEq/L (mmol/L); **CO_2:** 23 mEq/L (mmol/L); **BUN:** 18 mg/dL (6.4 mmol/L); **Creatinine:** 0.9 mg/dL (80 µmol/L); **glucose:** 72 mg/dL (4.0 mmol/L) **HbA1C:** 6.9% (0.069; 52 mmol/mol Hgb)

TC: 213 mg/dL (5.51 mmol/L); **LDL:** 110 mg/dL (2.84 mmol/L); **HDL:** 30 mg/dL (0.78 mmol/L); **TG:** 152 mg/dL (1.72 mmol/L)

AST: 24 U/L (0.40 µkat/L); **ALT:** 30 U/L (0.50 µkat/L)

What would be the optimal treatment strategy for this patient?

tract; effectively reducing the calories absorbed from food.[17] A tube is placed into the stomach and connects to a small button on the outside of the abdomen. Roughly 20 to 30 minutes after a meal, the patient connects the tube to a handheld device that then pumps food out of the stomach and into the toilet. The most common adverse effects are abdominal discomfort and button site irritation.

OUTCOME EVALUATION

LO 5

Successful management of overweight and obesity is determined by the ability the treatment plan has to (a) prevent weight gain, (b) reduce and maintain a lower body weight, and (c) decrease the risk of obesity-related comorbidities. Obesity management may encompass more than weight loss or maintenance in the presence

Patient Care Process

Collect and Assess Information:

- Measure weight and height.
- Calculate and classify BMI.
- Medical history, current medications, and laboratory data for secondary causes of weight gain
- CVD risks and obesity-related comorbidities
- Current lifestyle and history of weight gain/loss
- Need to lose weight (candidates include obese patients or overweight patients with at least one indicator of increased CVD risk)
- Readiness to make lifestyle changes
- Weight loss goals

Develop and Implement a Care Plan:

- Comprehensive lifestyle intervention strategies (restricted caloric-diet, increased physical activity and behavioral therapy)
- Determine eligibility for obesity pharmacotherapy and, if so, verify if insurance coverage exists for the patient or if they qualify for any manufacturer offered discount cards
- If patient is already receiving an antiobesity medication, assess efficacy, safety, adherence, and potential drug, interactions.
- Manage CVD risk factors such as hypertension, dyslipidemia, etc.
- Encourage self-weighing, at least weekly, for better weight loss and maintenance over time.

Follow-Up: Monitor and Evaluate:

- In 2 weeks, assess weight, blood pressure, heart rate, and adherence with comprehensive lifestyle intervention. Assess weight monitoring log.
- Reassess patient in person, ideally monthly.
- Once weight loss is achieved, continue contact with the patient monthly. Address small weight gains and continued adherence with comprehensive lifestyle intervention.

of other conditions such as hypertension, type 2 diabetes mellitus, hyperlipidemia, CVD, sleep apnea, hypothyroidism, osteoarthritis, gallbladder disease, gout, or cancer. Measure blood pressure and heart rate before implementation of any therapy and assess basic metabolic panel, liver function tests, complete blood count, fasting lipid profile, thyroid function tests, and other laboratory studies at baseline and as clinically indicated. Additionally, obtain an electrocardiogram if recent results are unknown.[2]

LO3 LO5 When considering various approaches to behavioral therapy for weight loss, in-person, high-intensity (defined as a minimum of 14 sessions within 6 months) behavioral therapy is the most effective. During each session, assess compliance with comprehensive lifestyle intervention, as well as measure weight, blood pressure, and heart rate. Measure WC intermittently. Identify presence of adverse drug reactions or drug interactions if weight loss medications have been initiated.[2,13]

When the patient has achieved the recommended weight loss, he or she then enters the weight maintenance phase, which includes continued contact for education (no less than monthly), guidance, and risk factor assessment. Self-weighing, at least weekly, is associated with better weight maintenance over time. Counsel patient to address small weight gains before they become larger.[11]

LO3 LO5 If weight loss is not attained, further assess why the goals of therapy are unmet. Direct the interaction toward determining the motivation to lose weight, balance between caloric intake and physical activity, adherence to behavioral therapy, and determination of psychological stressors present.[2] Refer patient to a nutrition professional or for evaluation for bariatric surgery if eligibility criteria are met. If adjunctive pharmacotherapy has not been initiated, consider antiobesity drugs approved for long-term use.[26]

Abbreviations Introduced in This Chapter

ALT	Alanine aminotransferase
AST	Aspartate transaminase
BMI	Body mass index
CB1	Cannabinoid receptor
CNS	Central nervous system
CVD	Cardiovascular disease
FDA	Food and Drug Administration
5-HT_{1A}	Serotonin 1A subtype
5-HT_{2C}	Serotonin 2C subtype
GI	Gastrointestinal
MAOI	Monoamine oxidase inhibitor

Appendix A: Conversion Factors and Anthropometrics*

CONVERSION FACTORS

SI Units

SI (*le Systéme International d'Unités*) units are used in many countries to express clinical laboratory and serum drug concentration data.* Instead of using units of mass (eg, micrograms), the SI system uses moles (mol) to represent the amount of a substance. A molar solution contains 1 mole (the molecular weight of the substance in grams) of the solute in 1 L of solution. The following formula is used to convert units of mass to moles (mcg/mL to μmol/L or, by substitution of terms, mg/mL to mmol/L or ng/mL to nmol/L).

► *Micromoles per Liter*

$$\text{Micromoles per liter } (\mu\text{mol/L}) = \frac{\text{drug concentration (mcg/mL)} \times 1000}{\text{molecular weight of drug (g/mol)}}$$

► *Milliequivalents*

An equivalent weight of a substance is the weight that will combine with or replace 1 g of hydrogen; a milliequivalent is 1/1000 of an equivalent weight.

Milliequivalents per Liter

$$\text{Milliequivalents per liter (mEq/L)} = \frac{\text{weight of salt (g)} \times \text{valence of ion} \times 1000}{\text{molecular weight of salt}}$$

$$\text{Weight of salt (g)} = \frac{\text{mEq/L} \times \text{molecular weight of salt}}{\text{valence of ion} \times 1000}$$

Approximate Milliequivalents: Weight Conversions for Selected Ions

Salt	mEq/g Salt	mg Salt/mEq
Calcium carbonate ($CaCO_3$)	20.0	50.0
Calcium chloride ($CaCl_2 \cdot 2H_2O$)	13.6	73.5
Calcium gluceptate ($Ca[C_7H_{13}O_8]_2$)	4.1	245.2
Calcium gluconate ($Ca[C_6H_{11}O_7]_2 \cdot H_2O$)	4.5	224.1
Calcium lactate ($Ca[C_3H_5O_3]_2 \cdot 5H_2O$)	6.5	154.1
Magnesium gluconate ($Mg[C_6H_{11}O_7]_2 \cdot H_2O$)	4.6	216.3
Magnesium oxide (MgO)	49.6	20.2
Magnesium sulfate ($MgSO_4$)	16.6	60.2
Magnesium sulfate ($MgSO_4 \cdot 7H_2O$)	8.1	123.2
Potassium acetate ($K[C_2H_3O_2]$)	10.2	98.1
Potassium chloride (KCl)	13.4	74.6
Potassium citrate ($K_3[C_6H_5O_7] \cdot H_2O$)	9.2	108.1
Potassium iodide (KI)	6.0	166.0
Sodium acetate ($Na[C_2H_3O_2]$)	12.2	82.0
Sodium acetate ($Na[C_2H_3O_2] \cdot 3H_2O$)	7.3	136.1
Sodium bicarbonate ($NaHCO_3$)	11.9	84.0
Sodium chloride (NaCl)	17.1	58.4
Sodium citrate ($Na_3[C_6H_5O_7] \cdot 2H_2O$)	10.2	98.0
Sodium iodide (NaI)	6.7	149.9
Sodium lactate ($Na[C_3H_5O_3]$)	8.9	112.1
Zinc sulfate ($ZnSO_4 \cdot 7H_2O$)	7.0	143.8

Valences and Atomic/Molecular Weights of Selected Ions

Substance	Electrolyte	Valence	Atomic/Molecular Weight
Calcium	Ca^{2+}	2	40.1
Chloride	Cl^-	1	35.5
Magnesium	Mg^{2+}	2	24.3
Phosphate	HPO_4^{2-} (80%)	1.8	96.0[a]
(pH = 7.4)	$H_2PO_4^-$ (20%)		97.0
Potassium	K^+	1	39.1
Sodium	Na^+	1	23.0
Sulfate	SO_4^-	2	96.0[a]

[a]The atomic/molecular weight of phosphorus is only 31; that of sulfur is only 32.1.

*This appendix contains information from Appendices 1 and 2 of Smith KM, Riche DM, Henyan NN (eds.). Clinical Drug Data, 11th ed. New York: McGraw-Hill, 2010:1239–1246; With permission.

Anion Gap

The anion gap is the concentration of plasma anions not routinely measured by laboratory screening. It is useful in the evaluation of acid–base disorders. The anion gap is greater with increased plasma concentrations of endogenous species (eg, phosphate, sulfate, lactate, and ketoacids) or exogenous species (eg, salicylate, penicillin, ethylene glycol, ethanol, and methanol). The formulas for calculating the anion gap are as follows:

$$\text{Anion gap} = (Na^+ + K^+) - (Cl^- + HCO_3^-)$$

or

$$\text{Anion gap} = Na^+ - (Cl^- + HCO_3^-)$$

where the expected normal value for the first equation is 11 to 20 mmol/L and for the second equation is 7 to 16 mmol/L. Note that there is a variation in the upper and lower limits of the normal range.

Temperature

Fahrenheit to Celsius: (°F – 32) × 5/9 = °C
Celsius to Fahrenheit: (°C × 9/5) + 32 = °F
Celsius to Kelvin: °C + 273 = °K

Weights and Measures

▶ *Metric Weight Equivalents*

1 kilogram (kg) = 1000 grams
1 gram (g) = 1000 milligrams
1 milligram (mg) = 0.001 gram
1 microgram (mcg, μg) = 0.001 milligram
1 nanogram (ng) = 0.001 microgram
1 picogram (pg) = 0.001 nanogram
1 femtogram (fg) = 0.001 picogram

▶ *Metric Volume Equivalents*

1 liter (L) = 1000 milliliters
1 deciliter (dL) = 100 milliliters
1 milliliter (mL) = 0.001 liter
1 microliter (μL) = 0.001 milliliter
1 nanoliter (nL) = 0.001 microliter
1 picoliter (pL) = 0.001 nanoliter
1 femtoliter (fL) = 0.001 picoliter

▶ *Apothecary Weight Equivalents*

1 scruple (℈) = 20 grains (gr)
60 grains (gr) = 1 dram (ʒ)
8 drams (ʒ) = 1 ounce (℥)
1 ounce (℥) = 480 grains (gr)
12 ounces (℥) = 1 pound (lb)

▶ *Apothecary Volume Equivalents*

60 minims (m) = 1 fluidram (fl ʒ)
8 fluidrams (fl ʒ) = 1 fluid ounce (fl ℥)
1 fluid ounce (fl ℥) = 480 minims (m)
16 fluid ounces (fl ℥) = 1 pint (pt)

▶ *Avoirdupois Equivalents*

1 ounce (oz) = 437.5 grains
16 ounces (oz) = 1 pound (lb)

▶ *Weight/Volume Equivalents*

1 mg/dL = 10 mcg/mL
1 mg/dL = 1 mg%
1 ppm = 1 mg/L

▶ *Conversion Equivalents*

1 gram (g) = 15.43 grains (gr)
1 grain (gr) = 64.8 milligrams (mg)
1 ounce (℥) = 31.1 grams (g)
1 ounce (oz) = 28.35 grams (g)
1 pound (lb) = 453.6 grams (g)
1 kilogram (kg) = 2.2 pounds (lb)
1 milliliter (mL) = 16.23 minims (m)
1 minim (m) = 0.06 milliliter (mL)
1 fluid ounce (fl oz) = 29.57 milliliters (mL)
1 pint (pt) = 473.2 milliliters (mL)
1 US gallon = 3.78 liters (L)
1 Canadian gallon = 4.55 liters (L)
0.1 milligram = 1/650 grain
0.12 milligram = 1/540 grain
0.15 milligram = 1/430 grain
0.2 milligram = 1/320 grain
0.3 milligram = 1/220 grain
0.4 milligram = 1/160 grain
0.5 milligram = 1/130 grain
0.6 milligram = 1/110 grain
0.8 milligram = 1/80 grain
1 milligram = 1/65 grain

▶ *Metric Length Conversion Equivalents*

2.54 cm = 1 inch
30.48 cm = 1 foot
1 m = 3.28 feet
1.6 km = 1 mile

ANTHROPOMETRICS

Creatinine Clearance Formulas

▶ *Formulas for Estimating Creatinine Clearance in Patients with Stable Renal Function*

Cockcroft-Gault Formula

Adults (age 18 years and older)[1]:

$$\text{CrCl (men)} = \frac{(140 - \text{age}) \times \text{weight}}{\text{SCr} \times 72}$$

CrCl (women) = 0.85 × above value*

*Some studies suggest that the predictive accuracy of this formula for women is better *without* the correction factor of 0.85.

where CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or μmol/L divided by 88.4]), age is in years, and weight is in kilograms.

Traub-Johnson Formula

Children (age 1–18 years)[2]:

$$\text{CrCl} = \frac{0.48 \times \text{height} \times \text{BSA}}{\text{SCr} \times 1.73}$$

where BSA is body surface area (in m^2), CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or μmol/L divided by 88.4]), and height is in centimeters.

▶ *Formula for Estimating Creatinine Clearance from a Measured Urine Collection*

$$\text{CrCl (mL/min)} = \frac{U \times V}{P \times T}$$

where U is the concentration of creatinine in a urine specimen in mg/dL, V is the volume of urine in mL, P is the concentration of creatinine in serum at the midpoint of the urine collection period in mg/dL, and T is the time of the urine collection period in minutes (eg, 6 hours = 360 minutes; 24 hours = 1440 minutes). Procedures for obtaining urine specimens should stress the importance of complete urine collection during the collection time period.

▶ *IDMS-Traceable MDRD Equation (Used for Creatinine Methods with Calibration Traceable to IDMS)*

For creatinine in mg/dL:

$$X = 175 \times \text{creatinine}^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

For creatinine in μmol/L:

$$X = 175 \times (\text{creatinine}/88.4)^{-1.154} \times \text{age}^{-0.203} \times \text{constant}$$

where X is the glomerular filtration rate, constant for white men is 1 and for women is 0.742, and constant for African Americans is 1.212.

Ideal Body Weight

IBW is the weight expected for a non-obese person of a given height. The IBW formulas below and various life insurance tables can be used to estimate IBW. Dosing methods described in the literature may use IBW as a method in dosing obese patients.

Adults (age 18 years and older)[3]:

IBW (men) = 50 + (2.3 × height in inches over 5 ft)
IBW (women) = 45.5 + (2.3 × height in inches over 5 ft)

where IBW is in kilograms.

Children (age 1–18 years)[2] under 5-feet tall:

$$\text{IBW} = \frac{\text{height}^2 \times 1.65}{1000}$$

where IBW is in kilograms and height is in centimeters.

Children (age 1–18 years) 5 feet or taller:

IBW (males) = 39 + (2.27 × height in inches over 5 ft)
IBW (females) = 42.2 + (2.27 × height in inches over 5 ft)

where IBW is in kilograms.

Appendix B: Common Medical Abbreviations

These are the abbreviations used commonly in medical practice both in verbal communication and in the medical record.

A&O	alert and oriented
A&O×3	awake (or alert) and oriented to person, place, and time
A&O×4	awake (or alert) and oriented to person, place, time, and situation
A&P	active and present; anterior and posterior; assessment and plans; auscultation and percussion
A&W	alive and well
A1c	hemoglobin A1c
AA	aplastic anemia; Alcoholics Anonymous
AAA	abdominal aortic aneurysm
AAO	awake, alert, and oriented
AAO×3	awake and orientated to time, place, and person
ABC	absolute band counts; absolute basophil count; apnea, bradycardia, and cytology; aspiration, biopsy, and cytology; artificial beta cells
Abd	abdomen
ABG	arterial blood gases
ABO	blood group system (A, AB, B, and O)
ABP	arterial blood pressure
ABW	actual body weight
ABx	antibiotics
AC	before meals (*ante cibos*)
ACE	angiotensin-converting enzyme
ACE-I	angiotensin-converting enzyme inhibitor
ACLS	advanced cardiac life support
ACS	acute coronary syndromes
ACTH	adrenocorticotropic hormone
AD	Alzheimer disease; right ear (*auris dextra*)
ADA	American Diabetes Association; adenosine deaminase
ADE	adverse drug effect (or event)
ADH	antidiuretic hormone
ADHD	attention-deficit hyperactivity disorder
ADL	activities of daily living
ADR	adverse drug reaction
AF	atrial fibrillation
AFB	acid-fast bacillus; aortofemoral bypass; aspirated foreign body
AFEB	afebrile
AI	aortic insufficiency
AIDS	acquired immune deficiency syndrome
AKA	above-knee amputation; alcoholic ketoacidosis; all known allergies; also known as
AKI	acute kidney injury
ALFT	abnormal liver function test
ALL	acute lymphoblastic leukemia; acute lymphocytic leukemia
ALP	alkaline phosphatase
ALS	amyotrophic lateral sclerosis
ALT	alanine transaminase (SGPT); alanine aminotransferase
AMA	against medical advice; American Medical Association; antimitochondrial antibody
AMI	acute myocardial infarction
AML	acute myelogenous leukemia
Amp	ampule
ANA	antinuclear antibody
ANC	absolute neutrophil count
ANLL	acute nonlymphocytic leukemia
AODM	adult-onset diabetes mellitus
AOM	acute otitis media
AP	anteroposterior
APAP	acetaminophen (acetyl-*p*-aminophenol)
aPTT	activated partial thromboplastin time
ARB	angiotensin receptor blocker
ARC	AIDS-related complex
ARD	acute respiratory disease; adult respiratory disease; antibiotic removal device; aphakic retinal detachment
ARDS	adult respiratory distress syndrome
ARF	acute renal failure; acute respiratory failure; acute rheumatic fever
AROM	active range of motion
AS	left ear (*auris sinistra*)
ASA	aspirin (acetylsalicylic acid)
ASCVD	arteriosclerotic cardiovascular disease
ASD	atrial septal defect
ASH	asymmetric septal hypertrophy
ASHD	arteriosclerotic heart disease
AST	aspartate transaminase (SGOT); aspartate aminotransferase
ATG	antithymocyte globulin
ATN	acute tubular necrosis
AU	each ear (*auris uterque*)
AV	arteriovenous; atrioventricular; auditory visual
AVR	aortic valve replacement
BBB	bundle branch block; blood–brain barrier
BC	blood culture
BCOP	Board Certified Oncology Pharmacist
BCP	birth control pill
BCPP	Board Certified Psychiatric Pharmacist
BCPS	Board Certified Pharmacotherapy Specialist
BE	barium enema

BG	blood glucose
bid	twice daily (*bis in die*)
BKA	below-knee amputation
BM	bone marrow; bowel movement; an isoenzyme of creatine phosphokinase
BMC	bone marrow cells
BMD	bone mineral density
BMI	body mass index
BMP	basic metabolic panel
BMR	basal metabolic rate
BMT	bone marrow transplantation
BP	blood pressure
BPD	bronchopulmonary dysplasia
BPH	benign prostatic hyperplasia
bpm	beats per minute
BR	bed rest
BS	bowel sounds; breath sounds; blood sugar
BSA	body surface area
BUN	blood urea nitrogen
Bx	biopsy
C&S	culture and sensitivity
CA	cancer; calcium
CABG	coronary artery bypass grafting
CAD	coronary artery disease
CAH	chronic active hepatitis
CAM	complementary and alternative medicine
CAPD	continuous ambulatory peritoneal dialysis
CBC	complete blood count
CBD	common bile duct
CBG	capillary blood gas; corticosteroid-binding globulin
CC	chief complaint
CCA	calcium channel antagonist
CCB	calcium channel blocker
CCE	clubbing, cyanosis, edema
CCK	cholecystokinin
CCU	coronary care unit
CF	cystic fibrosis
CFS	chronic fatigue syndrome
CFU	colony-forming unit
CHD	coronary heart disease
CHF	congestive heart failure; chronic heart failure
CHO	carbohydrate
CI	cardiac index
CIWA	Clinical Institute Withdrawal Assessment
CK	creatine kinase
CKD	chronic kidney disease
CLL	chronic lymphocytic leukemia
CM	costal margin
CMG	cystometrogram
CML	chronic myelogenous leukemia
CMV	cytomegalovirus
CN	cranial nerve
CNS	central nervous system
C/O	complains of
CO	cardiac output; carbon monoxide
COLD	chronic obstructive lung disease
COPD	chronic obstructive pulmonary disease
CP	chest pain; cerebral palsy
CPAP	continuous positive airway pressure
CPK	creatine phosphokinase (BB, MB, and MM are isoenzymes)
CPP	cerebral perfusion pressure
CPR	cardiopulmonary resuscitation
CrCl	creatinine clearance
CRF	chronic renal failure; corticotropin-releasing factor
CRH	corticotropin-releasing hormone
CRI	chronic renal insufficiency; catheter-related infection
CRNA	Certified Registered Nurse Anesthetist
CRNP	Certified Registered Nurse Practitioner
CRP	C-reactive protein
CRTT	Certified Respiratory Therapy Technician
CSF	cerebrospinal fluid; colony-stimulating factor
CT	computed tomography; chest tube
cTnI	cardiac troponin I
CTZ	chemoreceptor trigger zone
CV	cardiovascular
CVA	cerebrovascular accident
CVC	central venous catheter
CVP	central venous pressure
Cx	culture; cervix
CXR	chest x-ray
CYP	cytochrome P450
D&C	dilatation and curettage
D_5W	5% dextrose in water
DBP	diastolic blood pressure
D/C	discontinue; discharge
DCC	direct-current cardioversion
DI	diabetes insipidus
DIC	disseminated intravascular coagulation
Diff	differential
DJD	degenerative joint disease
DKA	diabetic ketoacidosis
dL	deciliter
DM	diabetes mellitus
DNA	deoxyribonucleic acid
DNR	do not resuscitate
DO	Doctor of Osteopathy
DOA	dead on arrival; date of admission; duration of action
DOB	date of birth
DOE	dyspnea on exertion
DOT	directly observed therapy
DPGN	diffuse proliferative glomerulonephritis
DPI	dry powder inhaler
DRE	digital rectal examination
DRG	diagnosis-related group
DS	double strength
d/t	due to
DTP	diphtheria–tetanus–pertussis
DTR	deep tendon reflex
DVT	deep vein thrombosis
Dx	diagnosis
EBV	Epstein-Barr virus
EC	enteric coated
ECF	extracellular fluid
ECG	electrocardiogram
ECHO	echocardiogram
ECT	electroconvulsive therapy
ED	emergency department
EEG	electroencephalogram
EENT	eyes, ears, nose, throat
EF	ejection fraction
EGD	esophagogastroduodenoscopy
EIA	enzyme immunoassay
ECG	electrocardiogram
EMG	electromyogram
EMT	Emergency Medical Technician
Endo	endotracheal, endoscopy
EOMI	extraocular movements (or muscles) intact
EPO	erythropoietin
EPS	extrapyramidal symptoms
ER	emergency room
ERCP	endoscopic retrograde cholangiopancreatography
ERT	estrogen replacement therapy
ESKD	end-stage kidney disease
ESLD	end-stage liver disease

ESR	erythrocyte sedimentation rate
ESRD	end-stage renal disease
ET	endotracheal
EtOH	ethanol
FB	finger breadth; foreign body
FBS	fasting blood sugar
FDA	Food and Drug Administration
FEF	forced expiratory flow rate
FEV_1	forced expiratory volume in 1 second
FFP	fresh-frozen plasma
FH	family history
FiO_2	fraction of inspired oxygen
FOBT	fecal occult blood test
FPG	fasting plasma glucose
FPIA	fluorescence polarization immunoassay
FSH	follicle-stimulating hormone
FTA	fluorescent treponemal antibody
FT_4	free thyroxine
F/U	follow-up
FUO	fever of unknown origin
Fx	fracture
g	gram
G-CSF	granulocyte colony-stimulating factor
G6PD	glucose-6-phosphate dehydrogenase
GB	gallbladder
GBS	group B *Streptococcus*; Guillain-Barré syndrome
GC	gonococcus
GDM	gestational diabetes mellitus
GE	gastroesophageal; gastroenterology
GERD	gastroesophageal reflux disease
GFR	glomerular filtration rate
GGT	γ-glutamyl transferase
GGTP	γ-glutamyl transpeptidase
GI	gastrointestinal
GM-CSF	granulocyte-macrophage colony-stimulating factor
GN	glomerulonephritis; graduate nurse
gr	grain
GT	gastrostomy tube
gtt	drops (*guttae*)
GTT	glucose tolerance test
GU	genitourinary
GVHD	graft-versus-host disease
GVL	graft-versus-leukemia
Gyn	gynecology
H&H, H/H	hemoglobin and hematocrit
H&P	history and physical examination
HA	headache
HAART	highly active antiretroviral therapy
HAMD	Hamilton Rating Scale for Depression
HAV	hepatitis A virus
Hb, hgb	hemoglobin
HbAlc	glycosylated hemoglobin (hemoglobin Alc)
HBIG	hepatitis B immune globulin
HBP	high blood pressure
HBsAg	hepatitis B surface antigen
HBV	hepatitis B virus
HC	hydrocortisone, home care
HCG	human chorionic gonadotropin
HCO_3	bicarbonate
Hct	hematocrit
HCTZ	hydrochlorothiazide
HCV	hepatitis C virus
HD	Hodgkin disease; hemodialysis
HDL	high-density lipoprotein
HEENT	head, eyes, ears, nose, and throat
HF	heart failure
HFA	hydrofluoroalkane
H flu	*Hemophilus influenzae*
HGH	human growth hormone
HH	hiatal hernia
Hib	*Hemophilus influenzae* type b
HIT	heparin-induced thrombocytopenia
HIV	human immunodeficiency virus
HJR	hepatojugular reflux
HLA	human leukocyte antigen; human lymphocyte antigen
HMG-CoA	hydroxy-methylglutaryl coenzyme A
H/O	history of
HOB	head of bed
HPA	hypothalamic–pituitary axis
hpf	high-power field
HPI	history of present illness
HR	heart rate
H_2RA	H_2 receptor antagonist
HRSD	Hamilton Rating Scale for Depression
HRT	hormone-replacement therapy
HS	at bedtime (*hora somni*)
HSV	herpes simplex virus
HTN	hypertension
Hx	history
I&D	incision and drainage
I&O, I/O	intake and output
IBD	inflammatory bowel disease
IBW	ideal body weight
ICD	implantable cardioverter defibrillator
ICP	intracranial pressure
ICS	intercostal space; inhaled corticosteroid
ICU	intensive care unit
ID	identification; infectious disease
IDDM	insulin-dependent diabetes mellitus
IFN	interferon
Ig	immunoglobulin
IgA	immunoglobulin A
IgD	immunoglobulin D
IHD	ischemic heart disease
IJ	internal jugular
IM	intramuscular; infectious mononucleosis
INH	isoniazid
INR	international normalized ratio
IOP	intraocular pressure
IP	intraperitoneal
IPG	impedance plethysmography
IPN	interstitial pneumonia
IRB	institutional review board
ISA	intrinsic sympathomimetic activity
ISH	isolated systolic hypertension
IT	intrathecal
ITP	idiopathic thrombocytopenic purpura
IU	international units (this can be dangerous abbreviation because it may be read as "IV" for "intravenous")
IUD	intrauterine device
IV	intravenous; Roman numeral four; symbol for class 4 controlled substances
IVC	inferior vena cava; intravenous cholangiogram
IVDA	intravenous drug abuse
IVDU	injection drug use; intravenous drug use
IVF	intravenous fluids
IVIG	intravenous immunoglobulin
IVP	intravenous pyelogram; intravenous push
JODM	juvenile-onset diabetes mellitus
JRA	juvenile rheumatoid arthritis
JVD	jugular venous distension
JVP	jugular venous pressure
K	potassium
kcal	kilocalorie

KCl	potassium chloride
KOH	potassium hydroxide
KUB	kidney, ureter, and bladder
KVO	keep vein open
L	liter
LABA	long-acting beta agonist
LAD	left anterior descending; left axis deviation
LAO	left anterior oblique
LBBB	left bundle branch block
LBP	low-back pain
LDH	lactate dehydrogenase
LDL	low-density lipoprotein
LE	lower extremity
LES	lower esophageal sphincter
LFT	liver function test
LHRH	luteinizing hormone-releasing hormone
LLE	left lower extremity
LLL	left lower lobe
LLQ	left lower quadrant (abdomen)
LMD	local medical doctor
LMP	last menstrual period
LMWH	low-molecular-weight heparin
LOS	length of stay
LP	lumbar puncture
LPN	Licensed Practical Nurse
LPT	Licensed Physical Therapist
LR	lactated Ringer's
LS	lumbosacral
LT_4	levothyroxine
LUE	left upper extremity
LUL	left upper lobe
LUQ	left upper quadrant
LUTS	lower urinary tract symptoms
LVH	left ventricular hypertrophy
MAP	mean arterial pressure
MAR	medication administration record
MB-CK	a creatine kinase isoenzyme
mcg	microgram
MCH	mean corpuscular hemoglobin
MCHC	mean corpuscular hemoglobin concentration
MCV	mean corpuscular volume
MD	Medical Doctor
MDI	metered-dose inhaler
MDRD	modification of diet in renal disease
MEFR	maximum expiratory flow rate
mEq	milliequivalent
mg	milligram
MHC	major histocompatibility complex
MI	myocardial infarction; mitral insufficiency
MIC	minimum inhibitory concentration
mL	milliliter
MM	multiple myeloma; an isoenzyme of creatine phosphokinase
MMR	measles–mumps–rubella; midline malignant reticulosis
MOM	milk of magnesia
MPV	mean platelet volume
m/r/g	murmur/rub/gallop
MRI	magnetic resonance imaging
MRSA	methicillin-resistant *Staphylococcus aureus*
MRSE	methicillin-resistant *Staphylococcus epidermitis*
MS	mental status; mitral stenosis; musculoskeletal; multiple sclerosis; morphine sulfate
MSE	mental status exam
MSW	Master of Social Work
MTD	maximum tolerated dose
MTX	methotrexate
MVA	motor vehicle accident
MVI	multivitamin
MVR	mitral valve replacement; mitral valve regurgitation
MVS	mitral valve stenosis; motor, vascular, and sensory
N&V	nausea and vomiting
NAD	no acute (or apparent) distress
N/C	noncontributory; nasal cannula
NG	nasogastric
NGT	nasogastric tube; normal glucose tolerance
NIDDM	non–insulin-dependent diabetes mellitus
NIH	National Institutes of Health
NKA	no known allergies
NKDA	no known drug allergies
NHDA	nonketotic hyperosmolar acidosis
NL	normal
NOS	not otherwise specified
NPN	nonprotein nitrogen
NPO	nothing by mouth (*nil per os*)
NS	normal saline solution (0.9% sodium chloride solution); neurosurgery
NSAID	nonsteroidal anti-inflammatory drug
NSR	normal sinus rhythm
NSS	normal saline solution
NTG	nitroglycerin
NT/ND	nontender, nondistended
NVD	nausea/vomiting/diarrhea; neck vein distension; neovascularization of the disk; neurovesicle dysfunction; nonvalvular disease
N&V	nausea and vomiting
NYHA	New York Heart Association
O&P	ova and parasites
OA	osteoarthritis
OB	obstetrics
OCD	obsessive-compulsive disorder
OD	right eye (*oculus dexter*)
OGTT	oral glucose tolerance test
OPV	oral poliovirus vaccine
OR	operating room
OR×1	oriented to time
OR×2	oriented to time and place
OR×3	oriented to time, place, and person
OS	left eye (*oculus sinister*)
OSA	obstructive sleep apnea
OT	occupational therapy
OTC	over the counter
OU	each eye (*oculus uterque*)
P	pulse; plan; percussion; pressure
P&A	percussion and auscultation
P&T	peak and trough
PA	physician assistant; posteroanterior; pulmonary artery
PAC	premature atrial contraction
$Paco_2$	arterial carbon dioxide tension
Pao_2	arterial oxygen tension
PAOP	pulmonary artery occlusion pressure
PC	after meals (*post cibum*)
PCA	patient-controlled analgesia
PCI	percutaneous coronary intervention
PCKD	polycystic kidney disease
PCN	penicillin
PCP	*Pneumocystis carinii* pneumonia (also known as *Pneumocystis jirovecii* pneumonia); pneumocystis pneumonia; primary care physician; phencyclidine
PCWP	pulmonary capillary wedge pressure
PDE	paroxysmal dyspnea on exertion
PE	physical examination; pulmonary embolism
PEEP	positive end-expiratory pressure

PEFR	peak expiratory flow rate
PEG	percutaneous endoscopic gastrostomy; polyethylene glycol
Peg-IFN	pegylated interferon
PERL	pupils equal, reactive to light
PERRLA	pupils equal, round, and reactive to light and accommodation
PERRRLA	pupils equal, round, regular, and reactive to light and accommodation
PET	positron emission tomography
PFT	pulmonary function test
pH	hydrogen ion concentration
PH	past history; personal history; pinhole; poor health; pubic hair; public health
PHx	past history
PharmD	Doctor of Pharmacy
PID	pelvic inflammatory disease
PJD	*Pneumocystis jirovecii* pneumonia (also known as *Pneumocystis carinii* pneumonia)
PKU	phenylketonuria
PMH	past medical history
PMI	past medical illness; point of maximal impulse
PMN	polymorphonuclear leukocyte
PMS	premenstrual syndrome
PND	paroxysmal nocturnal dyspnea
Po	by mouth (*per os*)
Po_2	partial pressure of oxygen
POAG	primary open-angle glaucoma
POD	postoperative day
PPBG	postprandial blood glucose
ppd	packs per day
PPI	proton pump inhibitor
PPN	peripheral parenteral nutrition
PR	per rectum
PRBC	packed red blood cell
PRERLA	pupils round, equal, reactive to light and accommodation
PRN	when necessary, as needed (*pro re nata*)
PSA	prostate-specific antigen
PSH	past surgical history
PST	paroxysmal supraventricular tachycardia
PSVT	paroxysmal supraventricular tachycardia
PT	prothrombin time; physical therapy; patient
PTA	prior to admission; percutaneous transluminal angioplasty
PTCA	percutaneous transluminal coronary angioplasty
PTE	pulmonary thromboembolism
PTH	parathyroid hormone
PTSD	posttraumatic stress disorder
PTT	partial thromboplastin time
PUD	peptic ulcer disease
PVC	premature ventricular contraction
PVD	peripheral vascular disease
PVR	peripheral vascular resistance
PVT	paroxysmal ventricular tachycardia
q	every (*quaque*)
QA	quality assurance
qday	every day (*quaque die*)
QI	quality improvement
qid	four times daily (*quater in die*)
QNS	quantity not sufficient
qod	every other day
QOL	quality of life
QS	quantity sufficient
QTc	corrected QT interval
R&M	routine and microscopic
R&R	rate and rhythm
RA	rheumatoid arthritis; right atrium
RAAS	renin–angiotensin–aldosterone system
RBC	red blood cell
RCA	right coronary artery
RCM	right costal margin
RDA	recommended daily allowance
RDS	respiratory distress syndrome
RDW	red blood cell distribution width
REM	rapid eye movement; recent event memory
RES	reticuloendothelial system
RF	rheumatoid factor; renal failure; rheumatic fever
Rh	rhesus factor in blood
RHD	rheumatic heart disease
RLE	right lower extremity
RLL	right lower lobe
RLQ	right lower quadrant
RML	right middle lobe
RN	Registered Nurse
RNA	ribonucleic acid
R/O	rule out
ROM	range of motion
ROS	review of systems
RPh	Registered Pharmacist
RR	respiratory rate; recovery room
RRR	regular rate and rhythm
RRT	Registered Respiratory Therapist
RSV	respiratory syncytial virus
RT	radiation therapy
RUE	right upper extremity
RUL	right upper lobe
RUQ	right upper quadrant
RVH	right ventricular hypertrophy
S_1	first heart sound
S_2	second heart sound
S_3	third heart sound (ventricular gallop)
S_4	fourth heart sound (atrial gallop)
SA	sinoatrial
SABA	short-acting beta agonist
SAD	seasonal affective disorder
SAH	subarachnoid hemorrhage
Sao_2	arterial oxygen percent saturation
SBE	subacute bacterial endocarditis
SBFT	small bowel follow-through
SBGM	self-blood glucose monitoring
SBO	small bowel obstruction
SBP	systolic blood pressure
SC	subcutaneous; subclavian
SCr	serum creatinine
SEM	systolic ejection murmur
SG	specific gravity
SGOT (AST)	serum glutamic oxaloacetic transaminase (aspartate transaminase)
SGPT (ALT)	serum glutamic pyruvic transaminase (alanine transaminase)
SH	social history
SIADH	syndrome of inappropriate antidiuretic hormone secretion
SIDS	sudden infant death syndrome
SJS	Stevens-Johnson syndrome
SL	sublingual
SLE	systemic lupus erythematosus
SMA-6	sequential multiple analyzer for sodium, potassium, CO_2, chloride, glucose, and BUN
SMA-7	sequential multiple analyzer for sodium, potassium, CO_2, chloride, glucose, BUN, and creatinine

SMA-12	sequential multiple analyzer for glucose, BUN, uric acid, calcium, phosphorous, total protein, albumin, cholesterol, total bilirubin, alkaline phosphatase, SGOT, and LDH
SMA-23	includes the entire SMA-12 plus sodium, potassium, CO_2, chloride, direct bilirubin, triglyceride, SGPT, indirect bilirubin, R fraction, and BUN/creatinine ratio
SMBG	self-monitoring of blood glucose
SNF	skilled nursing facility
SNS	sympathetic nervous system
SOB	shortness of breath; see order book; side of bed
S/P	status post
SPF	sun protection factor
SQ	subcutaneous
SSKI	saturated solution of potassium iodide
SSRI	selective serotonin reuptake inhibitor
STAT	immediately; at once
STEMI	ST-segment elevated myocardial infarction
STD	sexually transmitted disease
SV	stroke volume
SVC	superior vena cava
SVRI	systemic vascular resistance index
SVR	supraventricular rhythm; systemic vascular resistance
SVT	supraventricular tachycardia
SW	social worker
Sx	signs
T	temperature
T_3	triiodothyroxine
T_4	thyroxine
T&A	tonsillectomy and adenoidectomy
T&C	type and crossmatch
TB	tuberculosis
TBG	thyroid-binding globulin
TBI	total-body irradiation; traumatic brain injury
TBW	total body weight
T bili	total bilirubin
TCA	tricyclic antidepressant
TCN	tetracycline
Tdap	tetanus, diphtheria, acellular pertussis vaccine
TEE	transesophageal echocardiogram
TFT	thyroid function test
TG	triglyceride
TIA	transient ischemic attack
TIBC	total iron-binding capacity
tid	three times daily (*ter in die*)
TLC	therapeutic lifestyle changes
TMJ	Temporomandibular joint
TMP-SMX	trimethoprim–sulfamethoxazole
TNTC	too numerous to count
TOD	target organ damage
TPN	total parenteral nutrition
TPR	temperature, pulse, respiration
T PROT	total protein
TSH	thyroid-stimulating hormone
TURP	transurethral resection of the prostate
Tx	treat, treatment
UA	urinalysis, uric acid
UC	ulcerative colitis
UE	upper extremity
UFH	unfractionated heparin
UGI	upper gastrointestinal
UOQ	upper outer quadrant
UPT	urine pregnancy test
URI	upper respiratory infection
USP	United States Pharmacopeia
UTI	urinary tract infection
UV	ultraviolet
VF	ventricular fibrillation
VLDL	very low-density lipoprotein
VO	verbal order
VOD	veno-occlusive disease
V_A/Q	ventilation–perfusion
VRE	vancomycin-resistant Enterococcus
VS	vital signs
VSS	vital signs stable
VT	ventricular tachycardia
VTE	venous thromboembolism
WA	while awake
WBC	white blood cell (count)
W/C	wheelchair
WDWN	well-developed, well-nourished
WHO	World Health Organization
WNL	within normal limits
W/U	workup
yo	year old
y	year

Appendix C: Glossary

2,3-Diphosphoglycerate: A compound in red blood cells that affects oxygen binding to and release from hemoglobin.

Ablation: Destruction of part or all of an organ or structure.

Abscess: Purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs.

Acanthosis nigricans: Increased thickness and hyperpigmentation of the outer cell layers of the skin; typically observed at areas of flexure.

Acaricide: A chemical that kills mites and ticks.

Acetylcholine: Neurotransmitter at synapses in the ganglia of the visceral motor system and a variety of sites within the central nervous system.

Achalasia: Disorder in which the esophageal sphincter is impaired, preventing normal swallowing and often causing reflux of contents and a feeling that something is caught in the throat.

Achlorhydria: Absence of free hydrochloric acid in the stomach.

Acinar cells: Cells in the pancreas responsible for the synthesis, secretion, and storage of certain digestive enzymes.

Action potential: A rapid change in the polarity of the voltage of a cell membrane from negative to positive and back to negative; a wave of electrical discharge that travels across a cell membrane.

Acute coronary syndromes: Ischemic chest discomfort at rest most often accompanied by ST-segment elevation, ST-segment depression, or T-wave inversion on the 12-lead electrocardiogram; caused by plaque rupture and partial or complete occlusion of the coronary artery by thrombus. Acute coronary syndromes include myocardial infarction and unstable angina.

Acute respiratory distress syndrome: Diffuse inflammatory condition of the lung resulting in damage of alveoli, surfactant production, innate immune system response, and dysregulation of hemostasis in the pulmonary tract.

Addiction: A primary, chronic, neurobiologic disease, with genetic, psychosocial, and environmental factors influencing its development and manifestations. Characterized by behaviors such as impaired control over substance use, compulsive use, continued use despite harm, and craving.

Adenoma: A non-malignant tumor of the epithelial tissue that is characterized by glandular structures.

Adenomatous polyposis coli: A gene associated with familial adenomatous polyposis, an inherited disorder characterized by the development of myriad polyps in the colon, often occurring in adolescents and young adults ages 15 to 25.

Adjuvant chemotherapy: Treatment given after primary surgical treatment and designed to eliminate any remaining cancer cells that are undetectable, with the goal of improving survival.

Adrenalectomy: Surgical removal of an adrenal gland.

Adverse drug reaction: Any unexpected, unintended, undesired, or excessive response to a medication that requires discontinuing the medication; requires changing the medication; requires modifying the dose (except for minor dosage adjustments); necessitates admission to the hospital; prolongs stay in a health care facility; necessitates supportive treatment; significantly complicates diagnosis; negatively affects prognosis; or results in temporary or permanent harm, disability, or death.

Aeroallergen: Airborne substance that causes an allergic response.

Afterload: The force against which a ventricle contracts that is contributed to by the vascular resistance, especially of the arteries, and by the physical characteristics (mass and viscosity) of the blood.

Ageism: Discrimination against aged persons.

Air embolus: An obstruction in a small blood vessel caused by air that is introduced into a blood vessel and carried through the circulation until it lodges in a smaller vessel.

Akathisia: Motor or subjective feelings of restlessness, often characterized by the urge to move limbs and inability to sit still.

Akinesia: Lack of movement.

Allodynia: Pain that results from a stimulus that does not normally cause pain.

Allogeneic: A transplant taking cells from one person and donating them to another.

Allogeneic hematopoietic stem cell transplant (HSCT): A procedure in which a patient receives hematopoietic stem cells from a genetically similar donor.

Allograft: Tissue or organ transplanted from a donor of the same species but different genetic makeup; recipient's immune system must be suppressed to prevent rejection of the graft.

Allograft survival: After the transplant procedure, when the transplanted organ continues to have some degree of function, from excellent to poor.

Allorecognition: Recognition of the foreign antigens present on the transplanted organ or the donor's antigen presenting cells.

Alopecia: Hair loss.

Ambulatory esophageal reflux monitoring: A telemetry capsule containing a tiny camera is swallowed, or a transnasal catheter is inserted to determine how often reflux is occurring as well as the incidence of abnormal esophageal acid exposure. The telemetry capsule provides about 48 hours of data, whereas the transnasal catheter provides about 24 hours of data.

Amenorrhea: The absence or discontinuation of regular menstrual periods. Abnormal cessation or absence of menses.

Ampulla of Vater: Dilation of the duodenal wall at the opening of the fused pancreatic and common bile ducts.

Amylin: A 37-amino acid polypeptide hormone that is secreted from the β-cells of the pancreas in response to nutrients. Mechanisms of action include slowing gastric emptying, suppressing postmeal glucagon secretion, and suppressing appetite.

Amyloid: Any of a group of chemically diverse proteins that are composed of linear non-branching aggregated fibrils.

Anaerobic: Living in the absence of oxygen.

Anaphylactic/anaphylaxis: Immediate, severe, potentially fatal hypersensitivity reaction induced by an antigen.

Anaphylactoid: An anaphylactic-like reaction, similar in signs and symptoms but not mediated by IgE. The drug causing this reaction produces direct release of inflammatory mediators by a pharmacological effect.

Anastomosis: The connection of two hollow organs to restore continuity after resection. A surgical connection made between two blood vessels.

Androgen deprivation therapy: Agents such as LHRH agonists, GnRH antagonist, and antiandrogens that are used to suppress testosterone levels to that consistent with medical castration (testosterone levels < 50 ng/mL).

Anergy: A reduction or lack of an immune response to a specific antigen.

Aneurysm: A blood-filled bulge which forms in the wall of a weakened blood vessel; if ruptured, may result in bleeding, shock, and/or other negative health outcome including mortality.

Angioedema: Swelling similar to urticaria (hives), but the swelling occurs beneath the skin instead of on the surface. It is characterized by deep swelling around the eyes and lips and sometimes of the hands and feet. If it proceeds rapidly, it can lead to airway obstruction and suffocation, and should therefore be treated as a medical emergency.

Angiogenesis: The formation of new blood vessels. Increased blood flow to deliver nutrients is required for tumor growth.

Angiography: Examination of the blood vessels using x-rays after injection of a radiopaque substance.

Anosmia: Loss of smell.

Anovulatory cycle: A menstrual cycle where ovaries fail to produce, mature, or release egg.

Anterior circulation: Blood supply to the anterior section of the brain supplied by the internal carotid arteries, anterior cerebral artery, and middle cerebral artery.

Anterograde amnesia: Inability to create new memories or recall the recent past.

Anticitrullinated protein antibodies: Autoantibodies directed against cyclic citrullinated peptide, a circular peptide (a ring of amino acids) containing the amino acid citrulline.

Anticoagulant: Any substance that inhibits, suppresses, or delays the formation of blood clots. These substances occur naturally and regulate the clotting cascade. Several anticoagulants have been identified in a variety of animal tissues and have been commercially developed for medicinal use.

Antiprotease: A substance that inhibits the enzymatic activity of a protease.

Aortic dissection: A serious condition in which there is a tear in the wall of the aorta.

Aortic stenosis: A condition in which the aortic valve becomes thickened or calcified leading to a narrowing of the aortic valve opening and restriction of blood flow from the left ventricle.

Aphakic: The absence of a lens in the eye.

Aphasia: Impairment of language affecting the ability to speak and to understand speech.

Aphthous ulcer: A small superficial area of ulceration within the gastrointestinal mucosa, typically found in the oral cavity.

Aplasia cutis: Congenital absence of skin, commonly affecting the scalp.

Apoptosis: Programmed cell death as signaled by the nuclei in normally functioning cells when age or state of cell health and condition dictates. A genetically directed process of cell self-destruction or programed cell death.

Arcuate scotoma: An arc-shaped area of blindness in the field of vision.

Arteriovenous malformation: A tangle of blood vessels, usually in the brain, that results in abnormal connections between arteries and veins; if ruptured, may result in hemorrhage.

Arthrocentesis: Puncture and aspiration of a joint. Certain drugs can be injected into the joint space for a local effect.

Articular: Related to the joints of the body.

Ascites: Accumulation of fluid within the peritoneal cavity.

Asterixis: Involuntary jerking movements, especially in the hands, best demonstrated by having the patient extend their arms in front of them, flex the hands upward, where a subsequent "flapping" can be seen; occurs primarily with various metabolic and toxic encephalopathic conditions, such as hepatic encephalopathy.

Astringent: A substance that causes tissues to constrict, resulting in a drying effect of the skin.

Atelectasis: Decreased or absent air in a partial or entire lung, with resulting loss of lung volume.

Atherosclerosis: Accumulation of lipids, inflammatory cells, and cellular debris in the subendothelial space of the arterial wall.

Atherosclerotic cardiovascular disease: Disease in which plaque builds up in vessels.

Atresia: Congenital absence of a normal opening or normally patent lumen.

Atrophic urethritis: Thinning and inflammation of the vaginal walls secondary to decline in estrogen, experienced by almost 50% of postmenopausal women.

Attenuated: Loss of intensity or virulence.

Aura: Visual, but sometimes sensory, motor, or verbal disturbance, usually occurring before a migraine or seizure.

Auspitz sign: Pinpoint bleeding that occurs when a psoriasis scale or lesion is peeled off of the skin.

Autologous: A transplant using one's own stem cells.

Autologous hematopoietic stem cell transplant (HSCT): A procedure in which hematopoietic stem cells are removed, stored, and then infused into the same patient.

Autoreceptor: Transmitter receptors on or near presynaptic terminals which are sensitive to the transmitter(s) released by the terminal itself.

Avolition: Inability to initiate and persist in goal-directed activities.

Azoospermic: Having no living spermatozoa in the semen, or failure of spermatogenesis.

Bacteremia: Presence of bacteria in the blood.

Barium enema: A diagnostic test using an x-ray to view the lower gastrointestinal tract (colon and rectum) after rectal administration of barium sulfate, a chalky liquid contrast medium.

Barrett esophagus: A change of the normal squamous epithelium of the distal esophagus to a metaplastic, columnar-lined epithelium, usually caused by prolonged exposure of the esophageal mucosa to gastric acid. The condition is associated with an increased risk of developing esophageal cancer.

Basal ganglia: Cluster of nerve cells deep in the brain that coordinate normal movement.

Bence–Jones proteins: Light chained immunoglobulins found in the urine.

β-Hydroxybutyric acid: A ketone body that is elevated in ketosis, is synthesized in the liver from acetyl-CoA, and can be used as an energy source by the brain when blood glucose is low.

β-Lactam allergy: Allergy to the β-lactam family, namely penicillins and cephalosporins, but may also include carbapenems.

β_2 microglobulin: A low molecular weight protein that may be elevated in multiple myeloma.

Bilateral salpingo-oophorectomy: Surgical removal of both ovaries and fallopian tubes.

Bile acids: The organic acids in bile. Bile is the yellowish-brown or green fluid secreted by the liver and discharged into the duodenum where it aids in the emulsification of fats, increases peristalsis, and retards putrefaction.

Biliary sludge: A deposit of tiny stones or crystals made up of cholesterol, calcium bilirubinate, and other calcium salts. The cholesterol and calcium bilirubinate crystals in biliary sludge can lead to gallstone formation.

Biopsy: The removal of cells or tissue for examination.

Bladder hypotonicity: Low elastic tension of the bladder.

Blast: An immature cell.

Blastospores: An asexual reproductive sphore formed by budding, often seen with yeast.

Blood urea nitrogen (BUN): A waste product in the blood produced from the breakdown of dietary proteins. The kidneys filter blood to remove urea and maintain homeostasis; a decline in kidney function results in an increase in BUN.

Body mass index: A calculation utilized to correct weight changes for height and is a direct calculation regardless of gender. It is the result of the weight in kilograms divided by the height in meters squared. If nonmetric measurements are used, it is the result of the weight in pounds multiplied by 703 and then that quantity divided by the product of height in inches squared.

Bouchard nodes: Hard, bony enlargement of the proximal interphalangeal (middle) joint of a finger or toe.

Boutonniere deformity: Joint deformity associated with rheumatoid arthritis that presents as flexion of the proximal interphalangeal joints with hyperextension of the distal interphalangeal joints.

Brachial plexus: Collection of nerves that arises from the spine at the base of the neck from nerves that supply parts of the shoulder, arm, forearm, and hand.

Brachytherapy: A form of radiotherapy where a sealed radiation source is placed inside or next to the area requiring treatment.

Bradycardia: Slower than normal heart rate.

Bronchiectasis: Chronic dilation of bronchi or bronchioles as a result of inflammatory disease or obstruction associated with heavy sputum.

Bullectomy: Surgical removal of one or more bullae (air spaces in the lung measuring more than one centimeter in diameter in the distended state).

Burst suppression: Electroencephalography pattern characterized by electrical brain activity alternating with periods of no activity.

Calcitonin: A hormone produced by the parafollicular cells of the thyroid gland; involved in helping to regulate levels of calcium and phosphate in the blood.

Calculi: An abnormal concretion (or stone) usually found in hollow organs or their passages (eg, kidney stone).

Capillary leak: Loss of intravascular volume into the interstitial space within the body.

Carcinogenesis: Production or origin of cancer.

Carcinoma: A malignant growth that arises from epithelium, found in skin or the lining of body organs. Carcinomas tend to infiltrate into adjacent tissue and spread to distant organs.

Carcinomatosis: Condition of having widespread dissemination of carcinoma (cancer) in the body.

Cardiac cachexia: Physical wasting with loss of weight and muscle mass caused by cardiac disease; a wasting syndrome that causes weakness and a loss of weight, fat, and muscle.

Cardiac index: Cardiac output normalized for body surface area (cardiac index = cardiac output/body surface area).

Cardiac output: The volume of blood ejected from the left side of the heart per unit of time:

Cardiac output (L/min) = Stroke volume (L) × heart rate (1/min)

Cardiac remodeling: Genome expression resulting in molecular, cellular and interstitial changes and manifested clinically as changes in size, shape, and function of the heart resulting from cardiac load or injury.

Cardiomyopathy: Diseases of the heart muscle in which the heart muscle becomes enlarged, thick, or rigid.

Carotid bruit: Abnormal sound heard when auscultating a carotid artery caused by turbulent blood flow, usually due to the presence of atherosclerotic plaques.

Carotids: The two main arteries in the neck.

Castration resistant prostate cancer: Prostate cancer that continues to progress despite suppression of typical hormonal growth signals (ie, despite androgen deprivation that achieves castration levels of testosterone).

Cataplexy: A sudden loss of muscle control with retention of clear consciousness that follows a strong emotional stimulus (eg, elation, surprise, or anger) and is a characteristic symptom of narcolepsy.

Catheterization: Insertion of a tubular medical device into canals, vessels, passageways, or body cavities to permit injection or withdrawal of fluids or to keep a passage open.

Causalgia: Persistent burning pain, allodynia, and hyperpathia following a traumatic nerve lesion.

Cavitary lesions: Gas or fluid filled areas of the lung in the center of a nodule observed through radiographic investigation.

CD4 and CD8: Protein markers predominantly found on the surface of T cells.

Cell-mediated immunity: An immune response that involves activation of phagocytes, antigen-specific cytotoxic T-lymphocytes, and the release of various cytokines in response to an antigen. Can be independent of antibody action.

Central pain: Pain that results from a lesion or dysfunction in the central nervous system.

Cervicitis: Inflammation of the cervix.

Chemokines: Any of a group of cytokines produced by various cells that stimulate chemotaxis in white blood cells.

Chemoprevention: Clinical application of pharmacologic agents to reduce the risk of developing certain malignancies. Use of drugs, vitamins, or other agents to reduce the risk of or delay the development or recurrence of cancer.

Chemoreceptor trigger zone: Located in the area postrema of the fourth ventricle of the brain. It is exposed to cerebrospinal fluid and blood and is easily stimulated by circulating toxins to induce nausea and vomiting.

Chemosis: Edema of the bulbar conjunctiva.

Cheyne–Stokes respiration: Pattern of breathing with gradual increase in depth (and sometimes in rate) to a maximum, followed by a decrease resulting in apnea; the cycles ordinarily are 30 seconds to 2 minutes in duration, with 5 to 30 seconds of apnea.

Chimeric: An individual, organ, or substance composed of substances with different genetic origins.
Chloasma: Melasma characterized by irregularly shaped brown patches on the face and other areas of the skin, often seen during pregnancy or associated with the use of oral contraceptives.
Chlorpromazine equivalents: Approximate dose equivalent of a first-generation antipsychotic to 100 mg of chlorpromazine (relative potency).
Cholecystitis: Inflammation of the gallbladder.
Cholelithiasis: Formation of stones in the gallbladder (gallstones).
Cholestasis: Reduced or lack of flow of bile, or obstruction of bile flow.
Cholesteatoma: A mass of keratinized epithelial cells and cholesterol resembling a tumor that forms in the middle ear or mastoid region.
Chorea: A type of dyskinesia with rhythmic dance-like movement.
Chronotropic: An effect that influences the rate of rhythmic movements (eg, heart rate).
Chvostek sign: Elicited by tapping on the proximal distribution of the facial nerve (adjacent to the ear). This will produce a brief spasm of the upper lip, eye, nose, or face in hypocalcemic patients.
Chylothorax: The presence of lymphatic fluid (chyle) in the pleural cavity.
Circadian rhythm: 24-hour cycles of behavior and physiology that are generated by endogenous biological clocks (pacemakers).
Cirrhosis: Hepatic fibrosis and regenerative nodules that have destroyed the architecture of the liver, scarring the liver tissues. Progressive scarring of the liver resulting in non-functional hepatocytes.
Clonal expansion: An immunologic response in which lymphocytes stimulated by antigen proliferate and amplify the population of relevant cells.
Closed comedo: A plugged hair follicle of sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Also referred to as a "whitehead."
Clotting cascade: A series of enzymatic reactions by clotting factors leading to the formation of a blood clot. The clotting cascade is initiated by several thrombogenic substances. Each reaction in the cascade is triggered by the preceding one and the effect is amplified by positive feedback loops.
Clotting factor: Plasma proteins found in the blood that are essential to the formation of blood clots. Clotting factors circulate in inactive forms but are activated by their predecessor in the clotting cascade or a thrombogenic substance. Each clotting factor is designated by a Roman numeral (eg, factor VII) and by the letter "a" when activated (eg, factor VIIa).
Clubbing: Proliferation of soft tissues, especially in the nail bed, which results in thickening and widening of finger and toe extremities.
Coalescence: Fusion of smaller lipid emulsion particles forming larger particles, resulting in destabilization of the emulsion.
Cocoon immunization: Vaccine strategy to protect an infant from disease by vaccinating those with expected close contact.
Cognitive deficit: An impairment in the mental process that affects the way a person interacts with their environment.
Collateral damage: Bacterial resistance to an antimicrobial that occurs when the antimicrobial is being used to treat a separate bacterial infection.
Colonocyte: Cell lining the colonic surface.
Colonoscopy: Visual examination of the colon using a lighted, lens-equipped, flexible tube (colonoscope) inserted into the rectum.
Colony-forming units: The number of microorganisms that form colonies when cultured and is indicative of the number of viable microorganisms in a sample.
Comedolytic: An agent that is able to break up or destroy a comedo.
Comorbidities: Multiple disease states occurring concurrently in one patient.
Complete response: In cancer, disappearance of all targeted lesions.
Complex regimen: Taking medications 3 or more times per day, or 12 or more doses per day.
Computed tomography: Radiography in which a three-dimensional image of a body structure is constructed by computer from a series of plane cross-sectional images made along an axis.
Concreteness: Inability to think in abstract terms. It may be a primary developmental defect or secondary to organic mental disorder or schizophrenia.
Congenital adrenal hyperplasia: A rare inherited condition resulting from a deficiency in cortisol and aldosterone synthesis with resulting excess androgen production. The clinical presentation depends on the variant of the condition but typically manifests as abnormalities in sexual development and/or adrenal insufficiency.
Conidia: Non-motile spores produced by fungi.
Conjunctival injection: Erythema of the conjunctiva.
Conjunctivitis: Inflammation of the conjunctiva.
Conjunctivitis medicamentosa: A drug-induced form of allergic conjunctivitis resulting from overuse of topical ocular vasoconstrictors.
Consolidation: Treatment that is given after cancer has disappeared following the initial therapy. Consolidation therapy is used to kill any cancer cells that may be left in the body.
Contiguous: Spread of infection via direct invasion of adjacent structures.
Continuous positive airway pressure (CPAP): A technique of assisting breathing by maintaining the air pressure in the lungs and air passages constant and above atmospheric pressure throughout the breathing cycle.
Cor pulmonale: Right-sided heart failure caused by lung disease.
Corneal arcus: Accumulation of lipid on the cornea.
Coronary artery bypass graft surgery: Surgical intervention to improve coronary blood flow by removing a vein from the leg and attaching one end to the aorta and the other end to the coronary artery distal to the atherosclerotic plaque. Alternatively, an artery from the inside of the chest wall may be used to bypass the coronary occlusion.
Cosyntropin: A synthetic version of adrenocorticotropic hormone.
Counterirritant: A substance that elicits a superficial inflammatory response with the objective of reducing inflammation in deeper, adjacent structures.
C-peptide: A peptide which is made when proinsulin is split into insulin and C-peptide. They split before proinsulin is released from endocytic vesicles within the pancreas, one C-peptide for each insulin molecule. C-peptide is the abbreviation for "connecting peptide." It is used to determine if a patient has type 1 or type 2 diabetes mellitus.
Creaming: Aggregation of lipid emulsion particles that then migrate to the surface of the emulsion can be reversed with mild agitation.
Creatinine: A waste product in the blood produced from the breakdown of protein by-products generated by muscle in the body or ingested in the diet. The kidneys filter blood to remove creatinine and maintain homeostasis; a decline in kidney function results in an increase in creatinine.

Crepitus: A grating sound or sensation typically produced by friction between bone-on-cartilage or bone-on-bone contact. It is also a crackling chest sound that is heard in pneumonia.

Cross-allergenicity: Sensitivity to one drug with activity to a different drug with a similar chemical structure.

Crypt abscess: Neutrophilic infiltration of the intestinal glands (crypts of Lieberkühn); a characteristic finding in patients with ulcerative colitis.

Cutis laxa: Hypereflacidity of the skin with loss of elasticity.

Cyanosis: A dark blue or purple discoloration of the skin and mucous membranes due to deficient oxygenation of the blood.

Cyclooxygenase: An enzyme that catalyzes the conversion of arachidonic acid to prostaglandins and consists of two isoforms, generally abbreviated COX-1 and COX-2.

Cystitis: Inflammation of urinary bladder.

Cystocele: Herniation of the urinary bladder into the vagina. Herniation is abnormal protrusion of an organ through a defect or natural opening.

Cytokines: Regulatory proteins, such as interleukins and lymphokines, are released by cells of the immune system and act as intercellular mediators in the generation of an immune response. Soluble glycoproteins released by the immune system which act through specific receptors to regulate immune responses.

Cytomegalovirus (CMV) disease: This is the term used when patients who are already infected with CMV present with the classically associated symptoms that resemble a viral infection and may include fever, malaise, arthralgias, and others.

Cytomegalovirus (CMV) infection: This is the term used when a patient has anti-CMV antibodies in the blood, when CMV antigens are detected in infected cells, or when the virus is isolated from a culture.

Debridement: Removal of necrotic tissue to promote wound healing and reduce risk of further infection.

Delayed peak response: The effects of medication take longer than expected to initiate.

Delirium: Transient brain syndrome presenting as disordered attention, cognition, psychomotor behavior, and perception.

Delirium tremens (DTs): Symptom of alcohol withdrawal characterized by hallucinations, delirium, severe agitation, fever, elevations of blood pressure and heart rate, and possible cardiac arrhythmias.

Dematiaceous: Darkly pigmented colored spores or fungal hyphae.

Dennie-Morgan line: A line or fold below the lower eyelids; associated with atopy.

Dermatophyte: Any microscopic fungus that grows on the skin, scalp, and nails.

Desensitization: The process of giving a medication in a controlled and gradual manner, which allows the person to tolerate it temporarily without an allergic reaction.

Desquamation: Peeling or shedding of the epidermis (superficial layer of the skin) in scales or flakes.

Diabetes insipidus: An uncommon disorder that occurs when the kidneys pass an abnormally large volume of urine (3–20 quarts/day of urine versus the typical 1–2 quarts/day) that is dilute and odorless ("insipid"). Unrelated to diabetes mellitus, although both conditions cause frequent urination and constant thirst. Individuals with diabetes insipidus have normal blood glucose levels; however, their kidneys cannot balance fluid in the body.

Diabetic ketoacidosis: A reversible but life-threatening short-term complication primarily seen in patients with type 1 diabetes caused by the relative or absolute lack of insulin that results in marked ketosis and acidosis.

Dialysate: The physiologic solution used during dialysis to remove excess fluids and waste products from the blood.

Dialysis: The process of removing fluid and waste products from the blood across a semi-permeable membrane to maintain fluid, electrolyte, and acid–base balance in patients with kidney failure.

Diaphoresis: Sweating or profuse perspiration, generally as a symptom of a disease or an adverse drug effect.

Diarthrodial joint: A freely moveable joint (eg, knee, shoulder). Contrast with amphiarthrodial joint (a slightly movable joint; eg, vertebral joint) and synarthrodial joint (an unmovable joint; eg, fibrous joint).

Dilated cardiomyopathy: Ability of the heart to pump blood is decreased because the left ventricle is enlarged and weakened.

Diphasic dyskinesia: The motor fluctuations occur while the plasma levodopa concentrations are rising and when they are falling. In each dosing interval the patient may experience improvement, dyskinesia, and improvement (IDI) or dyskinesia, improvement, dyskinesia (DID).

Direct current cardioversion: The process of administering a synchronized electrical shock to the chest, the purpose of which is to simultaneously depolarize all of the myocardial cells, resulting in restoration of normal sinus rhythm.

Directly observed treatment: Method to increase adherence to medications when a patient is observed taking the medication by a health care worker.

Disease-free survival: Period of time from the end of treatment that the patient survives without signs or symptoms of the disease.

Disease progression: In cancer, at least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment.

Disseminated erythrosquamous papules: Widespread or whole body red, scaly psoriatic lesions.

Disseminated intravascular coagulation (DIC): A thrombotic and hemorrhagic disorder marked by uncontrolled systemic coagulation resulting in thrombosis, which may lead to generalized bleeding due to the depletion of clotting factors and increased fibrinolysis.

DNA mismatch repair (dMMR) genes: Genes that control an intrinsic intracellular mechanism which corrects nucleotide insertion errors made during DNA replication, by excising the mismatched base pairs that escaped correction by the proofreading activities of DNA polymerases and replacing the mismatched bases with the correct ones.

Door-to-needle time: Time from arrival in hospital to drug administration in appropriate patients.

Dose density: The total amount of drug given in a fixed unit of time (usually 1 week), thus is a function of dose and frequency of administration.

D-test: Double disk diffusion microbiological testing which indicates the presence or absence of macrolide-induced resistance to clindamycin.

Ductus arteriosus: Shunt connecting the pulmonary artery to the aortic arch that allows blood from the right ventricle to bypass fetal lungs.

Duodenal enterocyte: Cells lining the duodenum, which is the first of three parts of the small intestine.

Dysarthria: Speech disorder due to weakness or incoordination of speech muscles; speech is slow, weak, and imprecise.

Dysentery: A number of disorders marked by inflammation of the intestines, especially of the colon, and attended by pain in the abdomen, tenesmus, and frequently stools containing blood and mucus.

Dysesthesia: An unpleasant abnormal sensation.

Dyskinesia: Abnormal involuntary movements (dystonia, chorea, and akathisia).

Dyslipidemia: Elevation of the total cholesterol, low density lipoprotein cholesterol or triglyceride concentrations, or a decrease in high density lipoprotein cholesterol concentration in the blood.

Dysmenorrhea: Crampy pelvic pain occurring with or just prior to menses. "Primary" dysmenorrhea implies pain in the setting of normal pelvic anatomy, while "secondary" dysmenorrhea is secondary to underlying pelvic pathology.

Dyspareunia: Pain during or after sexual intercourse.

Dyspepsia: Upper abdominal symptoms that may include pain or discomfort, bloating, feeling of fullness despite little food intake, unusual fullness after meals, nausea, loss of appetite, heartburn, regurgitation of food or acid, and belching.

Dysphagia: Painful or difficult swallowing, accompanied by a sensation of food being stuck in passage.

Dysphonia: Impairment of the voice or difficulty speaking.

Dyspnea: Difficult or labored breathing.

Dystonia: A type of dyskinesia. The movement is slow and twisting. It may be associated with painful muscle contractions or spasms.

Ebstein anomaly: Congenital heart defect in which the opening of the tricuspid valve is displaced towards the apex of the right ventricle.

Eburnation: A condition in which bone or cartilage becomes hardened and denser.

Ecchymosis: Passage of blood from ruptured blood vessels into subcutaneous tissue causing purple discoloration of the skin.

Eclampsia: Seizures associated with high blood pressure.

Ectopic pregnancy: Presence of a fertilized ovum outside of the uterine cavity.

Effector cells: Cells that become active in response to initiation of the immune response.

Ejection fraction: The fraction of the volume present at the end of diastole that is pushed into the aorta during systole.

Electroconvulsive therapy: Administration of electric current to the brain through electrodes placed on the head to induce seizure activity in the brain; used in the treatment of certain mental disorders.

Electroencephalography: The recording of brain waves via electrodes placed on the scalp or cortex.

Embolism: The sudden blockage of a vessel caused by a blood clot or foreign material which has been brought to the site by the flow of blood.

Embolization: The process by which a blood clot or foreign material dislodges from its site of origin, flows in the blood, and blocks a distant vessel.

Empiric: A strategy or treatment administered without definitive evidence of the cause, ie, often at the onset of symptoms or radiological findings.

Endometritis: Inflammation of the endometrium.

Endophthalmitis: Inflammation of intraocular fluid (vitreous and aqueous), usually due to infection.

Endoscopy: Visual inspection of the inside of hollow organs with an endoscope, mainly for diagnostic purposes; refers to procedures such as gastroscopy, duodenoscopy, colonoscopy, and sigmoidoscopy.

Endothelial cell: A single layer of cells surrounding the lumen of arteries.

Endovascular: Procedures involving insertion of a catheter containing medications or instruments into a blood vessel for the treatment of vascular disease.

End-stage liver disease: Liver failure that is usually accompanied by complications such as ascites or hepatic encephalopathy.

Enthesitis: Inflammation of the sites where tendons, ligaments, or fascia attach to bone.

Enuresis: Involuntary discharge of urine.

Eosinophilic asthma: Sub-phenotype of asthma with elevated tissue and sputum eosinophils, thickening of the basement membrane zone, and corticosteroid responsiveness. Criteria that have been used for medications to treat eosinophilic asthma include blood eosinophil count ≥ 150 cells/μL (0.150×10^9/L) or > 300 cells/μL (0.3×10^9/L) (400 cells/μL [0.4×10^9/L] for reslizumab) in the past year, sputum eosinophil count ≥ 3% (0.03), and exhaled nitric oxide concentration ≥ 50 ppb.

Epilepsy: A neurological disorder characterized by recurring motor, sensory, or psychic malfunction with or without loss of consciousness or convulsive seizures.

Epistaxis: Nasal hemorrhage with blood drainage through the nostrils; a nosebleed.

Erosive esophagitis: A severe form of gastroesophageal reflux disease (GERD) in which the mucous membrane lining the esophagus is inflamed with areas of erosion resulting from abnormal reflux of gastric acid.

Erythema nodosum: Inflammation of the fat cells under the skin resulting in termer red nodules or lumps.

Erythematous: Flushing of the skin caused by dilation of capillaries. Erythema is often a sign of inflammation and infection.

Erythrodermic psoriasis: Generalized erythema covering nearly the entire body surface area. Fever and malaise are common and, while quite rare, can be severe and even fatal; it is usually associated with a worsening of other forms of psoriasis.

Erythropoiesis stimulating agents: Agents developed by recombinant DNA technology that have the same biological activity as endogenous erythropoietin to stimulate erythropoiesis (red blood cell production) in the bone marrow.

Erythropoietin: A hormone primarily produced by the progenitor cells of the kidney that stimulates red blood cell production in the bone marrow. Lack of this hormone leads to anemia.

Esophageal manometry: Measurement of pressures and muscle contractions in the esophagus.

Esophageal stricture: Narrowing of the esophageal lumen resulting chronic inflammation and formation of scar tissue.

Esophageal varices: Dilated blood vessels in the esophagus.

Essential fatty acid deficiency: Deficiency of linoleic acid, linolenic acid, and/or arachidonic acid, characterized by hair loss, thinning of skin, and skin desquamation. Long-chain fatty acids include trienes (containing three double-bonds [eg, 5,8,11-eicosatrienoic acid [or Mead acid], trienoic acids]) and tetraenes (containing four double-bonds [eg, arachidonic acid]). Biochemical evidence of essential fatty acid deficiency includes a triene:tetraene greater than 0.2 and low linoleic or arachidonic acid plasma concentrations.

Exanthem: Eruption of the skin.

Excess body weight: Calculated as the difference between actual and ideal body weight.

Exfoliative dermatitis: Severe inflammation and peeling of the entire skin surface due to a reaction to certain drugs.

Exploratory laparotomy: Surgical incision into the abdominal cavity, performed to examine the abdominal organs and cavity in search of an abnormality and diagnosis.

External beam radiotherapy (EBRT): An external source of radiation is pointed at a particular part of the body.

Extraabdominal: Outside of the abdominal cavity.

Extraction ratio: Fraction of the drug entering the liver in the blood which is irreversibly removed.

Extrapyramidal symptoms (EPS): Adverse drug effects of medications such as phenothiazines. EPS include dystonia (involuntary muscle contractions), tardive dyskinesia (repetitive, involuntary movements), and akathisia (motor restlessness or anxiety).

Extravasation: Movement of fluid from inside a blood vessel into the surrounding tissues.

Facultative: An optional biological condition, not required for growth or survival.

Felty syndrome: An extra-articular manifestation of rheumatoid arthritis associated with splenomegaly and neutropenia.

Ferritin: A protein in the body that binds to iron; most of the iron stored in the body is bound to ferritin.

Festination: Walking with short, rapid, shuffling steps.

Fibrin: An insoluble protein that is one of the principal ingredients of a blood clot. Fibrin strands bind to one another to form a fibrin mesh. The fibrin mesh often traps platelets and other blood cells.

Fibrinolysis: A normal ongoing process that dissolves fibrin and results in the removal of small blood clots; hydrolysis of fibrin.

Fibroadenoma: A benign neoplasm which commonly occurs in breast tissue and is derived from glandular epithelium.

Fibrosis: Development of fibrous connective tissue in response to injury or damage.

Fluorescence in situ hybridization (FISH): A laboratory technique used to look at genes or chromosomes in cells and tissues. Pieces of DNA that contain a fluorescent dye are made in the laboratory and added to cells or tissues on a glass slide. When these pieces of DNA bind to specific genes or areas of chromosomes on the slide, they light up when viewed under a microscope with a special light.

Fistula: Abnormal connection between two internal organs (eg, arteriovenous fistula is a connection between an artery and a vein), or between an internal organ and the exterior or skin (eg, enterocutaneous fistula is a connection between the intestine and the skin).

Fistulogram: X-ray photograph (or radiograph) taken after injection of a contrast material or radiopaque material (material that will not allow passage of x-rays and will be visible in an x-ray photograph [or radiograph]).

Flexural psoriasis: Flexural psoriasis is characterized by lesions found in skin folds. These lesions tend to be erythematous plaques and are often found in the axillary, genital, perineal, intergluteal, and inframammary regions. While shiny, smooth, and deep red in color there may be skin fissures and the absence of the silvery scales.

Flight of ideas: A nearly continuous flow of rapid speech and thought that jumps from topic to topic, usually loosely connected.

Floppy iris syndrome: A syndrome of pupillary constriction, flaccid iris, and iris prolapse which can result in intraoperative complications during cataract surgery; associated with use of an α_1 adrenergic antagonist (eg, tamsulosin).

Flow cytometry: A method of measuring the number of cells in a sample, the percentage of live cells in a sample, and certain characteristics of cells, such as size, shape, and the presence of tumor markers on the cell surface. The cells are stained with a light-sensitive dye, placed in a fluid, and passed in a stream before a laser or other type of light. The measurements are based on how the light-sensitive dye reacts to the light.

Foam cell: Lipid-laden white blood cell.

Focal seizures: Seizures that start in a small area of the brain. They may stay localized or spread to involve larger areas or the entire brain.

Forced expiratory volume in the first second (FEV_1): The volume of air that a patient can forcibly exhale in the first second of forced exhalation after taking a maximal breath.

Forced vital capacity: The maximum volume of air that can be forcibly exhaled after taking a maximal breath.

Fraction of exhaled nitric oxide (FeNO): A noninvasive test that, when elevated, is an indicator of inflammation in the airways and likely responsiveness to inhaled corticosteroids.

Fragility fracture: A fracture resulting from a fall from standing height or less amount of trauma.

Frailty: Excess demand imposed upon reduced capacity; a common biological syndrome in the elderly.

Frank-Starling mechanism: Increase in stroke volume in response to an increase in volume of blood filling the heart (ie, end diastolic volume) when all other factors remain constant.

Freezing: A sudden but temporary inability to move.

Fremitus: Vibrations through the chest wall that may be detected through touch (tactile) or heard (vocal) through a stethoscope with certain spoken words (eg, "ninety-nine").

French scale: Scale used to measure external diameter of a feeding tube.

Fructooligosaccharide: Soluble fiber that is fermented by colonic bacteria to short-chain fatty acids (SCFAs).

Gadolinium: An intravenous contrast agent used with magnetic resonance imaging.

Gallstone (cholelithiasis): A solid formation in the gallbladder or bile duct composed of cholesterol and bile salts.

γ-Aminobutyric acid (GABA): An inhibitory neurotransmitter.

Gamma knife: A type of radiosurgery (radiation therapy) machine that acts by focusing low-dosage gamma radiation from many sources on a precise target.

Gastric bypass: A surgical procedure for weight loss that elicits its effectiveness through malabsorption and gastric volume limitation. The procedure involves full partitioning of the proximal gastric segment into a jejunal loop.

Gastritis: Inflammation of stomach lining.

Gastroparesis: A form of autonomic neuropathy involving nerves of the stomach. It may include nausea, vomiting, feeling full, bloating and lack of appetite. It may cause wide fluctuations in blood sugars due to insulin action and nutrient delivery not occurring at the same time.

Gastrostomy: Operative placement of a new opening into the stomach usually associated with feeding tube placement.

Generalized seizures: A seizure where the entire cerebral cortex is involved from the onset of the seizure.

Geniculate nucleus: The portion of the brain that processes visual information from the optic nerve and relays it to the cerebral cortex.

Genotype: The genetic constitution of an individual.

Geriatric syndrome: Age-specific presentations or differential diagnoses, including visual and hearing impairment, malnutrition and weight loss, urinary incontinence, gait impairment and falls, osteoporosis, dementia, delirium, sleep problems, and pressure ulcers; commonly seen conditions in older patients.

Gleason score: System of histological grading used in prostate cancer. Individual scores range from 2 to 5. The two highest scores from each sample are combined for a total score (up to 10). Higher scores indicate higher grade and more aggressive tumor.

Glomerular filtration rate (GFR): The volume of plasma that is filtered by the glomeruli per unit time, usually expressed as mL/min or mL/min/1.73 m^2 (and in some areas in SI units of mL/s or mL/s/m^2), which adjusts the value for body surface area. This is the primary index used to describe overall renal function.

Glomerulonephritis: Glomerular lesions that are characterized by inflammation of the capillary loops of the glomerulus. These lesions are generally caused by immunologic, vascular, or idiopathic diseases and lead to high blood pressure and possible loss of kidney function.

Glucagon: Hormone involved in carbohydrate metabolism that is produced by the pancreas and released when glucose levels in the blood are low. When blood glucose levels decrease, the liver converts stored glycogen into glucose, which is released into the bloodstream. The action of glucagon is opposite of insulin.

Gluconeogenesis: Formation of glucose from precursors other than carbohydrates especially by the liver and kidney using amino acids from proteins, glycerol from fats, or lactate produced by muscle during anaerobic glycolysis.

Glucosuria: Presence of glucose in the urine.

Glutamate: An excitatory amino acid found in the central nervous system.

Glycogenolysis: The process by which glycogen is broken down to glucose in body tissues.

Goiter: An enlargement of the thyroid gland, causing a swelling in the front part of the neck.

Gonioscopy: Examination of the anterior chamber angle. A gonioprism or Goldman lens is used to perform gonioscopic evaluation.

Graft-versus-host disease: A condition that results from donor immune cells attacking the normal tissue of a hematopoietic stem cell transplant recipient.

Graft-versus-tumor effect: An immune response directed at a patient's malignant cells that is the result of donor immune cell activation.

Grandiosity: Exaggerated sense of self-importance, ideas, plans, or abilities.

Granuloma: Organized collection of macrophages designed to wall off a foreign body or infectious pathogen that cannot be eliminated.

Gummatous: A small, soft swelling that is characteristic of the late stages of syphilis and generally occurs in the connective tissue of the liver, brain, testes, and heart.

Gut-associated lymphoid tissue: Lymphoid tissue, including Peyer patches, found in the gut that are important for providing localized immunity to pathogens.

Guttate psoriasis: Characterized by a heavy or light sprinkling of teardrop-like, salmon-pink papules covered with a fine scale. These lesions are found primarily on the trunk and proximal extremities.

Gynecomastia: Excessive development of the breasts in males.

HACEK: Group of fastidious gram-negative bacteria consisting of *Haemophilus* spp., *Aggregatibacter actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella kingae*.

Hashimoto Disease: Condition in which the immune system attacks the thyroid gland; may result in hypothyroidism. Symptoms may include fatigue, weight gain, pale or puffy face, feeling cold, joint and muscle pain, constipation, dry and thinning hair, heavy menstrual flow or irregular periods, depression, a slowed heart rate, and problems getting pregnant and maintaining pregnancy. It occurs more commonly in women than in men.

Health literacy: Degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.

Heberden nodes: Hard, bony enlargement of the distal interphalangeal (terminal) joint of a finger or toe.

Hematemesis: Vomiting blood from gastric or esophageal bleeding; in cirrhosis this is caused by variceal bleeding.

Hematochezia: Passage of stool that is bright red or maroon, usually because of bleeding from the lower gastrointestinal tract.

Hematogenous: Spread of infection via the blood stream.

Hematoma: A localized swelling in an organ or soft tissue that is filled with clotted or partially clotted blood resulting from a break in a blood vessel wall.

Hemiparesis: Weakness on one side of the body.

Hemisensory deficit: Loss of sensation on one side of the body.

Hemithorax: A single side of the trunk between the neck and the abdomen in which the heart and lungs are situated.

Hemoptysis: The expectoration of blood or blood-tinged sputum from the larynx, trachea, bronchi, or lungs.

Heparin-induced thrombocytopenia: A clinical syndrome of IgG antibody production against the heparin-platelet factor 4 complex occurring in approximately 1% to 5% of patients exposed to either heparin or low-molecular weight heparin. Results in excess production of thrombin, platelet aggregation, and thrombocytopenia (due to platelet clumping), often leading to venous and arterial thrombosis, amputation of extremities, and death.

Hepatic encephalopathy: Confusion and disorientation experienced by patients with advanced liver disease due to accumulation of ammonia in the bloodstream.

Hepatic steatosis: Accumulation of fat in the liver.

Hepatocellular carcinoma: Cancer of the liver.

Hepatorenal syndrome: Acute kidney injury occurring in individuals with disease of the liver or biliary tract due to decreased renal blood flow and conditions that damage both organs.

Hepatotoxicity: Toxicity to the liver causing damage to liver cells.

Herd immunity: The resistance to the spread of a contagious disease within a population, if a sufficiently high proportion of the people are immune to the disease, such as through vaccination.

Herniation: Abnormal protrusion of an organ or other structure through a defect or natural opening in a covering, membrane, muscle, or bone (eg, protrusion of the brain through the cranial wall).

Hesitancy: A decrease in the force of the stream of urine usually the result of an obstruction or stricture between the bladder and the external urethral orifice.

Heteroreceptor: A site on a neuron that binds a neurotransmitter other than that released by the neuron.

Heterotopic: Placing a transplanted organ into an abnormal anatomic location.

Heterozygous: Having different alleles at a gene locus.

Hiatal hernia: Protrusion of a portion of the stomach through the esophageal hiatus of the diaphragm.

Hirsutism: Excessive body and facial hair, especially in the female.

Histocompatibility: State of having antigenic similarities that prevent donor hematopoietic stem cells from being rejected by the recipient.

Homeostenosis: Impaired capability to withstand stressors and decreased ability to maintain physiological and psychosocial homeostasis; a state commonly found in elderly.

Homozygous: Having identical alleles at a gene locus.
Hormone receptor-positive: Expression of estrogen and/or progesterone receptors in breast cancer cells.
Hot flashes: A feeling of warmth that is commonly accompanied by skin flushing and mild to severe perspiration.
Human epidermal growth factor receptor type 2 (HER2)-positive: Tumor positivity is defined by immunohistochemistry (3+ when > 10% of the cells harbor complete membrane staining) and FISH (fluorescence in situ hybridization) (if the number of HER2 gene copies is > 6 or the HER2/chromosome 17 ratio is > 2).
Human leukocyte antigens (HLA): Groups of genes found on the major histocompatibility complex that contain cell-surface antigen presenting proteins. The body uses HLA to distinguish between self cells and non-self cells.
Humoral: Relating to the body fluids, especially with regard to immune responses involving antibodies in body fluids as distinct from cells.
Hydrocephalus: A condition marked by accumulation of cerebral spinal fluid in the brain resulting in increased pressure inside the skull.
Hydronephrosis: Swelling of the renal pelvis and calyces of the kidney due to a back-up of urine due to obstruction.
Hyperalgesia: An exaggerated intensity of pain sensation.
Hypercalcemia: Excessive amount of calcium in the blood.
Hypercalciuria: Excessive amount of calcium in the urine.
Hypercapnia: Excessive carbon dioxide in the bloodstream, typically caused by inadequate respiration.
Hypercoagulable state: A disorder or state of excessive or frequent thrombus formation; also known as thrombophilia.
Hyperemesis gravidarum: A rare disorder of severe and persistent nausea and vomiting during pregnancy that can result in dehydration, malnutrition, weight loss, and hospitalization.
Hyperglycemic hyperosmolar nonketotic syndrome: Severe increase in serum glucose concentration without the production of ketones, leading to an increase in serum osmolality and symptoms such as increased thirst, increased urination, weakness, fatigue, confusion, and in severe cases convulsions and/or coma.
Hyperopia: Farsightedness.
Hyperpigmentation: A common darkening of the skin which occurs when an excess of melanin forms deposits in the skin.
Hypertrichosis: Excessive growth of hair.
Hyphae: A long, branching multicellular filamentous form of a fungus.
Hypocretin: A wake-promoting hypothalamic neuropeptide whose deficiency is involved in the pathophysiology of narcolepsy.
Hypogammaglobulinemia: Reduced levels of antibodies.
Hypogonadism: A medical condition resulting from or characterized by abnormally decreased functional activity of the gonads, with retardation of growth and sexual development. Associated with testosterone deficiency resulting from either testicular or pituitary/hypothalamic diseases. Presenting symptoms differ according to the timing of disease onset in relation to puberty.
Hypomimia: Lack of facial expression. Often termed masked face.
Hypophonia: Decreased voice volume.
Hypopituitarism: A clinical disorder characterized by complete or partial deficiency in pituitary hormone production.
Hypoxemia: Deficiency of oxygen in the blood.
Hypoxia: Deficiency of oxygen in body tissues.
Hysterectomy: An operation to remove a woman's uterus.
Immune reconstitution inflammatory syndrome (IRIS): A paradoxical clinical worsening of a known infection or the appearance of a new condition after initiating antiretroviral therapy in HIV-infected patients (or recovery from immunosuppression in non-HIV infected patients).
Immunoassay: A blood test for antibodies to antigens that worsen asthma, such as pollen, mold, or dust mites.
Immunogenicity: Ability of a substance to provoke an immune response.
Immunoglobulin G index: The ratio of immunoglobulin G to protein in the serum or cerebrospinal fluid.
Immunophenotyping: A process used to identify cells, based on the types of antigens or markers on the surface of the cell. This process is used to diagnose specific types of leukemia and lymphoma by comparing the cancer cells to normal cells of the immune system.
Immunotherapy: A type of biological therapy that uses substances to stimulate or suppress the immune system to help the body fight cancer, infection, and other diseases.
Implantable cardioverter-defibrillator: A device implanted into the heart transvenously with a generator implanted subcutaneously in the pectoral area that provides internal electrical cardioversion of ventricular tachycardia or defibrillation of ventricular fibrillation.
Incretin effect: A greater insulin stimulatory effect after an oral glucose load than that caused by an intravenous glucose infusion. The majority of the effect is thought to be due to glucose-dependent insulinotropic peptide (GIP) and glucagon like peptide-1 (GLP-1). Patients with type 2 diabetes have a significant reduction of the incretin effect, implying that these patients either have decreased concentration of the incretin hormones, or a resistance to their effects. GLP-1 concentrations are reduced in patients with type 2 diabetes in response to a meal, while GIP concentrations are either normal or increased, suggesting a resistance to the actions of GIP, thus making GLP-1 a more logical target for therapeutic intervention.
Induction: The first treatment given for a disease. It is often part of a standard set of treatments, such as surgery followed by chemotherapy and radiation.
Infantile spasms (West syndrome): A seizure syndrome in infants younger than 1 year. It is characterized by a specific electroencephalogram pattern and spasms or jitters.
Inotropic: Relating to or influencing the force of muscular contractions.
In-stent restenosis: Complex process following stent implantation resulting in smooth muscle cell proliferation within an implanted stent, renarrowing of the arterial lumen, and recurrent ischemia.
Insulin resistance: A decreased response to insulin found before or early in the diagnosis of type 2 diabetes mellitus.
International normalized ratio (INR): The ratio of the patient's clotting time to the clinical laboratory's mean reference value; normalized by raising it to the international sensitivity index (ISI) power to account for differences in thromboplastin reagents. Therefore, INR = (patient's prothrombin time/laboratory's mean normal prothrombin time)^{ISI}.
Interstitial nephritis: An acute inflammation of the kidney, often due to drugs; patients commonly present with fever, rash, and peripheral eosinophilia.
Intraabdominal: Within the abdominal cavity.
Intraarticular: Administered to or occurring in the space within joints.
Intraperitoneal: Within the peritoneal cavity.
Intravesicular: Situated or occurring within the bladder.

Intussusception: The prolapse of part of the intestine into the lumen of an immediately adjoining part. Blood supply to the telescoped region can be compromised leading to necrosis.
Iontophoresis: Introduction of a medication into tissue through use of an electric current.
Ipsilateral: Occurring on the same side.
Ischemia: Deficient supply of blood to a part(s) of the body.
Ischemic penumbra: Ischemic but still viable cerebral tissue. Typically a rim of mild to moderately ischemic tissue in between normally perfused tissue and the area of evolving infarction; may remain viable for several hours.
Jejunal entercocyte: Cells lining the jejunum, a section of the small intestine connecting the duodenum to the ileum.
Jejunostomy: Operative placement of a new opening into the jejunum, usually associated with feeding tube placement.
Jugular venous distention: Assessed with the patient laying at a 45 degree angle, and demonstrating a measurement of the right internal jugular vein that is more than 4 cm above the sternal angle; suggests systemic venous congestion and volume overload.
Juvenile myoclonic epilepsy: An epilepsy syndrome that typically occurs during teenage years and consists of generalized tonic-seizures and myoclonic jerks. Absence seizures may also occur with this syndrome.
Keratinization: The sloughing of epithelial cells in the hair follicle.
Keratinocytes: The predominant cell type in the outermost layer of the skin.
Keratitis: Infection of the cornea.
Keratoconjunctivitis sicca: An eye disease caused by eye dryness, which results from either decreased tear production or increased tear film evaporation. Also known as dry eye syndrome.
Kernicterus: Form of brain damage caused by excessive jaundice.
Ketosis: An abnormal increase of ketone bodies present in conditions of reduced or disturbed carbohydrate metabolism.
Korotkoff sounds: The noise heard over an artery by auscultation when pressure over the artery is reduced below the systolic arterial pressure.
Kyphosis: Abnormal curvature of the spine resulting in protrusion of the upper back; hunchback.
Lactose intolerance: The inability to digest lactose, a sugar found in milk products, resulting in diarrhea, bloating, and gas after ingestion.
Lagophthalmos: Poor closure of the upper eyelid.
Lamina cribrosa: A series of perforated sheets of connective tissue that the optic nerve passes through as it exits the eye.
Laminectomy: A surgical operation to remove the back of one or more vertebrae.
Laparoscopic: Abdominal exploration or surgery employing a type of endoscope called laparoscope.
Laparoscopic adjustable gastric banding: A surgical procedure for weight loss that elicits its effectiveness through gastric volume limitation. The procedure involves inserting a silicone band lined with an inflatable donut-shaped balloon around the neck of the stomach to be filled with isotonic liquid.
Laparotomy: Surgical opening of the abdominal cavity.
Left shift: An increase in the number of immature neutrophils (also referred to as bands). A left shift usually indicates infection or inflammation. The term originated in the days in which lab reports were written by hand and the bands were written on the left-hand side of the lab report. Also known as bandemia.
Lennox–Gastaut syndrome: An epilepsy syndrome that often appears early in life that consists of a distinct electroencephalogram pattern, mild to severe developmental delay, and multiple seizure types.
Lesch–Nyhan syndrome: A rare inherited gene mutation that results in accumulation of abnormally high uric acid levels.
Leukocytoclastic vasculitis: Acute cutaneous vasculitis characterized by purpura (especially of the legs) and histologically by exudation of neutrophils and sometimes fibrin around dermal venules, with extravasation of red blood cells.
Leukopenia: A condition where the number of circulating white blood cells are abnormally low due to decreased production of new cells, possibly in conjunction with medication toxicities.
Lewy bodies: Abnormal deposits of a protein called alpha-synuclein inside some nerve cells.
Lhermitte sign: Tingling or shock-like sensation passing down the arms or trunk when the neck is flexed.
Libido: Sexual drive or desire.
Ligament of Treitz: Landmark in the proximal portion of the jejunum beyond which it is preferred that postpyloric feedings be delivered to minimize aspiration.
Linea nigra: Dark vertical line that appears on the abdomen during pregnancy.
Linear accelerator: A device in which charged particles are accelerated in a straight line by successive impulses from a series of electric fields.
Lipophilic: Having affinity for fatty substances.
Lipoprotein lipase: Enzyme located in the capillary endothelium involved in the breakdown of intravenous lipid emulsion particles.
Livedo reticularis: Purple mottling of the skin.
Lower esophageal sphincter: A manometrically defined zone of the distal esophagus with an elevated basal resting pressure that prevents the reflux of gastric material from the stomach. It relaxes on swallowing to permit the free passage of food into the stomach.
Lymphangitis: Inflammation of lymphatic channels.
Lymphatic: The network of vessels carrying tissue fluids.
Lymphedema: Swelling, primarily in the appendages, caused by a blockage or disruption in the lymphatic system.
Lymphoproliferative: Of or related to the growth of lymphoid tissue.
Magnetic resonance imaging: A form of medical imaging that measures the response of the atomic nuclei of body tissues to high-frequency radio waves when placed in a strong magnetic field, and that produces images of the internal organs.
Major malformation: A defect that has either cosmetic or functional significance to the patient.
Maltodextrin: Easily digestible partially hydrolyzed starch.
Marcocytosis: Enlargement of red blood cells with near-constant hemoglobin concentration.
Mastalgia: Tenderness of the breasts.
Mastodynia: Pain in the breast.
Matrix metalloproteinases: Any of a group of enzymes, normally located in the extracellular space of tissue, that function to break down proteins (eg, collagen) and require zinc or calcium atoms as cofactors for enzymatic activity. Responsible for the degradation of connective tissue.
Meatal stenosis: Narrowing in the opening of the urethra.
Meconium: First intestinal discharge ("stool") of a newborn infant, usually green in color and consisting of epithelial cells, mucus, and bile.
Medication-assisted treatment: The use of medications with counseling and other behavioral therapies for the treatment of substance use disorders.
Melasma: Patchy skin pigmentation or dark skin discoloration, often seen during pregnancy.

Melena: Abnormally dark black, tarry feces containing blood (usually from gastrointestinal bleeding).
Menarche: The first menstrual cycle.
Meninges: Membranes surrounding the brain and spinal cord.
Meningismus: Symptoms similar to meningitis (nuchal rigidity, photophobia, and headache) but not caused by meningitis.
Mesial temporal lobe epilepsy: A common epilepsy syndrome manifested by seizures arising from the mesial temporal lobe of the brain, and is often associated with an anatomical change, described as hippocampal sclerosis.
Mesocortical pathway: A neural pathway that connects the ventral tegmentum to the cortex, particularly the frontal lobes. It is one of the major dopamine pathways in the brain.
Mesothelioma: A benign or malignant tumor affecting the lining of the chest or abdomen. Commonly caused by exposure to asbestos fibers.
Metabolic acidosis: A condition in the blood and tissues that is a consequence of an accumulation of lactic acid resulting from tissue hypoxia and anaerobic metabolism. It may also be caused by a decrease in the concentration of alkaline compounds (typically bicarbonate).
Metabolic syndrome: Constellation of cardiovascular risk factors related to hypertension, abdominal obesity, dyslipidemia, and insulin resistance diagnosed by the presence of at least three of the following criteria: increased waist circumference, elevated triglyceride concentrations, decreased high density lipoprotein (HDL) cholesterol or active treatment to raise HDL cholesterol, elevated blood pressure or active treatment with antihypertensive therapy, or elevated fasting glucose or active treatment for diabetes.
Metastasis: Cancer that has spread from the original site of the tumor.
Methemoglobinemia: A condition caused by elevated levels of methemoglobin in red blood cells, resulting in enhanced oxygen affinity in heme sites and reduced oxygen delivery to tissues; leads to hypoxia, cyanosis, shortness of breath, mental status changes, and dizziness. In severe cases, it can lead to seizures, coma, or death.
Microalbuminuria: Urinary excretion of small but abnormal amounts of albumin. Confirmed spot urine albumin to creatinine ratio of 30 to 300 mg/g (3.4–34 mg/mmol creatinine) is consistent with microalbuminuria. Considered an early sign of chronic kidney disease.
Microcytosis: A condition in which the erythrocytes are smaller than normal.
Micrognathia: Abnormal smallness of the jaws.
Micrographia: Small handwriting.
Microsatellite instability (MSI): The condition of genetic hypermutability that results from impaired DNA mismatch repair (MMR). The presence of MSI represents phenotypic evidence that MMR is not functioning normally.
Microvascular: Pertaining to the smaller vessels of the circulatory system such as capillaries, venules, and arterioles.
Microvascular pulmonary emboli: An obstruction in the small blood vessels in the lung caused by material (eg, blood clot, fat, air, foreign body) that is carried through the circulation until it lodges in another small vessel.
Micturition: Act of passing urine.
Minimum inhibitory concentration: The lowest concentration of a drug that visually inhibits the growth of a microorganism.
Minor malformation: Defect that has neither cosmetic nor functional significance to the patient.
Mixed mood features: Symptoms of mania and depression occurring simultaneously or in close juxtaposition. Criteria are either met for a manic/hypomanic episode and there are also at least three symptoms of depression, or criteria are met for a depressive episode with at least three manic/hypomanic symptoms.
Mobilization: A process by which medication(s) are used to promote the release of hematopoietic stem cells from the bone marrow to the peripheral blood for the purpose of collecting a sufficient amount of hematopoietic stem cells for a hematopoietic stem cell transplant.
Moebius syndrome: Rare congenital neurological disorder which is characterized by facial paralysis and affects eye movement.
Monoamine neurotransmitters: Serotonin, norepinephrine, dopamine.
Monoparesis: Slight or incomplete paralysis affecting a single extremity or part of one.
Monosodium urate: A crystallized form of uric acid that can deposit in joints leading to an inflammatory reaction and the signs and symptoms of gout.
Morphology: Structure and form of a cell.
Mucositis: Inflammatory, erosive, and/or ulcerative process inside the mouth, which is usually caused by radiation or chemotherapy.
Multiparity: Condition of having given birth to multiple children.
Muscularis mucosa: The thin layer of smooth muscle found in most parts of the gastrointestinal tract.
Mydriasis: Pupil dilation.
Myelin: A protein and phospholipid sheath that surrounds the axons of certain neurons. Myelinated nerves conduct impulses more rapidly than nonmyelinated nerves.
Myeloablative preparative regimen: Chemotherapy regimens with or without radiation that cause irreversible cytopenias without hematopoietic stem cell support.
Myelodysplastic syndrome: A type of cancer in which the bone marrow does not make enough healthy blood cells (white blood cells, red blood cells, and platelets) and there are abnormal cells in the blood and/or bone marrow.
Myelopathy: A neurologic deficit related to the spinal cord.
Myelosuppression: Reduction in white blood cells, red blood cells, and platelets.
Myocardial infarction: The formation of an infarct, an area of tissue death, due to a local lack of oxygen. Myocardial cell death secondary to prolonged ischemia.
Myocarditis: Inflammation of the heart muscle.
Myoglobinuria: The presence of myoglobin in urine.
Myonecrosis: Necrotic damage to muscle tissue.
Myopathy: Any disease of the muscle causing weakness, pain, and tenderness.
Myringotomy: A surgical incision made in the tympanic membrane to relieve pressure and drain fluid from the middle ear.
Myxedema: Hypothyroidism characterized by a relatively hard edema of subcutaneous tissue, with increased content of proteoglycans in the fluid; characterized by somnolence, slow mentation, dryness and loss of hair, increased fluid in body cavities such as the pericardial sac, subnormal temperature, hoarseness, muscle weakness, and slow return of a muscle to the neutral position after a tendon jerk.
Nail psoriasis: Characterized by pitting, onycholysis, hyperkeratosis, and an oil-drop sign.

Nasal scotoma: An area of blindness in the nasal portion of peripheral vision.
Nasolacrimal occlusion: The closing of the tear duct to decrease systemic absorption of a drug.
Natriuresis: Excretion of sodium in the urine.
Necrotizing enterocolitis: Medical condition seen in premature infants, where portions of the bowel undergo necrosis.
Nelson syndrome: A condition characterized by the aggressive growth of a pituitary tumor and hyperpigmentation of the skin.
Neoadjuvant therapy: Treatment given before the primary modality to downsize the tumor.
Nephrolithiasis: A condition marked by the presence of renal calculi (stones) in the kidney or urinary system.
Nephron: The working unit of the kidney that filters blood to remove fluid, toxins, and drugs. Each kidney contains approximately 1 million nephrons.
Nephrostomy: An artificial opening created between the kidney and the skin which allows for the urinary diversion directly from the upper part of the urinary system (renal pelvis).
Neuritic plaques: Extracellular deposits of amyloid beta with concentration markedly increased in the hippocampus, amygdala, and cerebral cortex. The plaque is thought to be formed through a cascade involving the formation of abnormally folded amyloid beta from amyloid precursor protein.
Neuritis: Inflammation of a nerve.
Neurofibrillary tangles: Aggregates of hyperphosphorylated tau protein which can disrupt cellular function and lead to cellular degeneration and death.
Neuropathic pain: Pain resulting from a lesion or dysfunction of the nervous system.
Neuropathy: An abnormal and usually degenerative state of the nervous system or nerves. Damage to the small and large nerves due to glycation end products, lack of blood and nutrients to the nerves, or chemical imbalances.
Neurotransmitters: Chemicals in the brain that allow the passage of a message between neurons or nerve cells.
Neutralizing antibodies: Antibodies that develop in response to a therapeutic agent that decrease the efficacy of the agent.
Nidus: A place in which something is formed or deposited; often used to refer to the site in which bacteria have lodged and multiply.
Nociception: Encoding and processing of noxious stimuli to the nervous system.
Nociceptors: Receptors for pain caused by injury from physical stimuli (mechanical, electrical, or thermal) or chemical stimuli (toxins); located in the skin, muscles, or in the walls of the viscera.
Nocturia: Urination that occurs during sleep, causing patients to awaken overnight.
Nocturnal polysomnography: Electrophysiologic assessment of human sleep minimally composed of electroencephalogram, electrooculogram, and electromyogram that allows determination of sleep stage, breathing events, and muscle movements.
Nodule: An abnormal small swelling or aggregation of cells in the body. When seen with rheumatoid arthritis, nodules are subcutaneous knobs over bony prominences or extensor surfaces.
Non-rapid eye movement (REM) sleep: A state of usually dreamless sleep that occurs regularly during a normal period of sleep with intervening periods of REM sleep and that consists of four distinct substages and low levels of autonomic physiological activity.
Nonbacterial thrombotic endocarditis: Endocarditis which consists of a sterile or noninfectious vegetation that has developed on the heart valve and may be visible on imaging tests.
Nonmyeloablative preparative regimen: Chemotherapy or chemotherapy/radiation regimens that cause minimal cytopenias and do not require hematopoietic stem cell support for hematopoietic cell recovery.
Nonpolyposis: Absence of polyps.
Nonprotein kilocalorie to nitrogen ratio: Numerical value derived from dividing kilocalories from carbohydrate plus fat by the number of grams of nitrogen in the diet (1 g of nitrogen represent about 6.25 g of protein).
Non–ST-segment elevation myocardial infarction: A type of myocardial infarction that is limited to the sub-endocardial myocardium and is smaller and less extensive than an ST-segment elevation myocardial infarction.
Noradrenergic: Neurons or receptors whose primary neurotransmitter is norepinephrine.
Nuchal rigidity: Inability to flex the neck forward due to neck muscle rigidity.
Nuclear factor kappa B (NF kappa B): Regulates cytokine production.
Nulliparity: Condition of not having given birth to a child.
Nystagmus: Rapid, involuntary movements of the eyes.
Odynophagia: Pain on swallowing solid food and fluids, which is often due to esophageal disease.
Off time: The time when the patient has poor control of their symptoms.
Off-label use: Use of a medication outside the scope of its approved, labeled use.
Oiling out: Continued coalescence of lipid emulsion particles, resulting in irreversible separation of the emulsion (also called "breaking" or "cracking" of the emulsion).
Oligoclonal immunoglobulin G bands: Small discrete bands in the gamma globulin region of fluid electrophoresis.
Oligohydramnios: Decreased amniotic fluid.
Oliguria: Reduced urine output; usually defined as less than 400 mL in 24 hours or less than 0.5 mL/kg/hour.
Omentumectomy: Excision of the double fold of peritoneum attached to the stomach and connecting it with abdominal viscera (omentum).
On time: The time when patient has good control of their symptoms.
Oncogenes: Genes found in the chromosomes of tumor cells whose activation is associated with the initial and continuing conversion of normal cells into cancer cells. Genes that cause transformation of normal cells into cancer cells by promoting uncontrolled cell growth and multiplication leading to tumor formation.
Open comedo: A plugged hair follicle of sebum, keratinocytes, and bacteria that protrudes from the surface of the skin and appears black or brown in color. Also referred to as a "blackhead."
Opsonization: The process by which an antigen is altered so as to become more readily and more efficiently engulfed by phagocytes.
Optic neuritis: Usually monocular central visual acuity loss and ocular/periorbital pain caused by demyelination of the optic nerve.
Oral glucose tolerance test: Used to measure the body's response to glucose; may be used to screen for type 2 diabetes and gestational diabetes.
Orchiectomy: Surgical removal of the testes.
Organification: Binding of iodine to tyrosine residues of thyroglobulin.
Orthopnea: Difficulty in breathing that occurs when lying down and is relieved upon changing to an upright position.

Orthostasis: Characterized by a drop in blood pressure when standing up from sitting or lying down, often causing lightheadedness and dizziness.

Orthostatic hypotension: Occurs when a person's systolic or diastolic blood pressure falls at least 20 mm Hg or 10 mm Hg, respectively, when a person suddenly changes from a lying or a sitting position to a standing position.

Orthotopic: Placing a transplanted organ into the normal anatomic location.

Osmolality: A measure of the number of osmotically active particles per unit solution, independent of the weight or nature of the particle.

Osmolar gap: The difference between the measured serum osmolality and the calculated serum osmolality.

Osteoblasts: Cells that secrete the matrix for bone formation.

Osteoclasts: Cells involved in bone resorption.

Osteomalacia: Softening of the bones.

Osteonecrosis: Death of bone tissue.

Osteopenia: Reduced bone density or mass.

Osteophytes: Bony outgrowths (also called bone spurs) into the joint space.

Osteoporosis: Disease of the bones characterized by a loss of bone tissue, resulting in brittle, weak bones that are susceptible to fracture (porous bones).

Ostomy: Surgical operation where part of the abdominal wall is opened and part of the intestine is connected to the opening for intestinal draining (eg, colostomy, ileostomy).

Otalgia: Ear pain or earache.

Ototoxicity: Damage to the hearing or balance functions of the ear by drugs or chemicals.

Ovulation: Periodic ripening and rupture of mature follicle and the discharge of ovum from the cortex of the ovary.

Palliative care: Pharmacologic and nonpharmacologic therapy to prevent or treat, as early as possible, the symptoms and side effects of the disease and treatment psychological, social, and spiritual problems too; with an overall goal of improving quality of life.

Palpable cord: The presence of an induration (cord) that is palpable, sometimes nodular, along the course of/or within the affected vein. Persistence of this cord when the extremity is raised suggests the presence of thrombus.

Pancolitis: Inflammation that involves the majority of the colon in patients with inflammatory bowel disease; often used interchangeably with extensive disease.

Pancreatic pseudocyst: A cyst-like space not lined by epithelium and contained within the pancreas.

Pancreatitis: Inflammation of the pancreas.

Panhypopituitarism: A clinical disorder characterized by complete deficiency in pituitary hormone production.

Pannus: Inflamed synovial tissue that invades and destroys articular structures. A sheet of inflammatory granulation tissue that invades the joint in rheumatoid arthritis after spreading from the synovial membrane. It eventually leads to fibrous ankylosis.

Papilledema: Swelling of the optic disc caused by increased intracranial pressure.

Paracentesis: Removal of ascitic fluid from the peritoneal space.

Paracentral scotoma: Blind spots near the center of the visual field.

Parasomnia: Undesirable physical or behavioral phenomena that occur predominantly during sleep. The most common parasomnias include sleepwalking, sleep talking, bruxism, enuresis, and REM sleep behavior disorder.

Parenchyma: The functional tissue of an organ as distinguished from connective and supporting tissue.

Parenteral nutrition: Delivery of nutrients via the intravenous route.

Paresthesia: An abnormal sensation, typically tingling or pricking ("pins and needles"), caused chiefly by pressure on or damage to peripheral nerves.

Partial response: In cancer, at least a 30% decrease in the sum of the longest diameter of target lesions from baseline.

Peak expiratory flow (PEF): The maximum flow rate of air leaving the lungs upon forced exhalation. Individualized best measurements are established for each patient using a handheld peak flow meter.

Pelvic inflammatory disease: Inflammation of the endometrium, uterine tubes, and pelvic peritoneum; often due to a sexually transmitted infection.

Percutaneous coronary intervention: A minimally invasive procedure whereby access to the coronary arteries is obtained through either the femoral or radial artery up the aorta to the coronary ostia. Contrast media is used to visualize the coronary artery stenosis using a coronary angiogram. A guidewire is used to cross the stenosis and a small balloon is inflated to break up atherosclerotic plaque and restore coronary artery blood flow. A stent is often deployed at the site to prevent acute closure and restenosis of the coronary artery. Newer stents are coated with antiproliferative drugs, such as paclitaxel, sirolimus, zotarolimus, or everolimus, which further reduce the risk of restenosis of the coronary artery.

Percutaneous endoscopic gastrostomy: Gastric feeding tube placed via endoscopic technique.

Percutaneous endoscopic jejunostomy: Jejunal feeding tube placed via endoscopic technique.

Performance status: An attempt to quantify cancer patients' general well-being and activities of daily life.

Pericarditis: Inflammation of the pericardial sac that surrounds the heart and the roots of the great blood vessels.

Perihilar: Just above the middle of the mediastinal surface and behind the cardiac impression of the lung.

Perimetry: Measurement of the field of vision.

Peripheral artery disease: Atherosclerosis of the peripheral arteries.

Peripheral vascular resistance: The sum of resistance to blood flow by systemic blood vessels.

Peritonitis: Acute inflammatory response of the peritoneal lining to microorganisms, chemicals, irradiation, or foreign-body injury.

Phagocytosis: The process of engulfing and ingesting an antigen by phagocytes.

Pharmacogenomics: The study of inherited genetic variations that dictate different drug responses. Pharmacogenomics explores the ways such variations can be used to predict responses to investigational products and plays an increasingly important role in drug discovery.

Phenotype: The visible or observable properties of an organism that are produced by the interaction of the genotype and the environment.

Pheochromocytoma: A tumor arising from chromaffin cells, most commonly found in the adrenal medulla. The tumor causes the adrenal medulla to hypersecrete epinephrine and norepinephrine resulting in hypertension and other signs and symptoms of excessive sympathetic nervous system activity. The tumor is usually benign but may occasionally be cancerous.

Phlebitis: Inflammation of a blood vessel (eg, vein).

Photochemotherapy: The use of psoralens in addition to ultraviolet rays for patients with a significant amount of body surface area affected (> 10%).
Photodynamic therapy: Treatment with drugs that become active when exposed to light.
Photophobia: Intolerance to bright light.
Phototherapy: The use of ultraviolet rays for patients with a significant amount of body surface area affected (> 10%).
Physical dependence: A state of adaptation that is manifested by a drug-class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist.
Pilosebaceous unit: A hair follicle and the surrounding sebaceous glands.
Plaque psoriasis: The most common form of psoriasis and manifests as well-defined, sharply demarcated, erythematous plaques typically covered with silvery scales. These plaques are irregular, round to oval in shape, and are almost always found on the scalp, trunk, buttocks, and limbs.
Plasma cell: Antibody producing cells.
Pleocytosis: Increased cell count, particularly an increase in white blood cells count in a bodily fluid, such as cerebral spinal fluid.
Pleuritis: Inflammation of the lining (pleura) around the lungs.
Pneumatic otoscopy: A diagnostic technique involving visualization of the tympanic membrane for transparency, position, and color, and its response to positive and negative air pressure to assess mobility.
Pneumothorax: A condition that occurs when air leaks into the space between chest wall and lung. The air pocket exerts pressure against the lung causing it, or a portion of it, to "collapse." Often referred to as a collapsed lung.
Polycystic ovary syndrome: Condition in which women have many small cysts on their ovaries that can lead to hormone imbalances and irregular periods.
Polycythemia: An abnormal increase in the number of erythrocytes in the blood.
Polycythemia vera: A hematologic cancer that is slow-growing in which the bone marrow produces excess red blood cells.
Polydipsia: Excessive thirst.
Polymerase chain reaction: A laboratory method used to make many copies of a specific DNA sequence.
Polyphagia: Eating excessively large amounts of food at a meal.
Polypharmacy: Taking multiple medications concurrently.
Polyps: Any growth or mass protruding from a mucous membrane.
Polyuria: Excessive excretion of urine resulting in profuse micturition.
Posterior circulation: Blood supply to the posterior section of the brain through the vertebral, basilar, and posterior cerebral arteries (ie, brainstem, cerebellum, occipital lobe).
Prader–Willi syndrome: A genetic disorder characterized by short stature, mental retardation, low muscle tone, abnormally small hands and feet, hypogonadism, and excessive eating leading to extreme obesity.
Prebiotic: Substance that can be used to nourish beneficial microbes in the gut.
Prediabetes: An asymptomatic but abnormal state that precedes the development of clinically evident diabetes.
Preemptive: Therapy administered prior to evidence of active disease (fever, radiological findings) but based on a positive biomarker or microbiological test.
Preload: The stretched condition of the heart muscle at the end of diastole just before contraction; volume in the left ventricle at the end of diastole estimated by the pulmonary artery occlusion pressure (also known as the pulmonary artery wedge pressure or pulmonary capillary wedge pressure).
Priapism: A prolonged, painful erection lasting more than 4 hours. Considered a medical emergency.
Primary amenorrhea: Absence of menses by age 15 in the presence of normal secondary sexual development or within 5 years of thelarche (if occurs before age 10).
Probiotics: Dietary supplements containing potentially beneficial bacteria that promote health by stimulating optimal mucosal immune responses.
Proctitis: Inflammation confined to the rectum in patients with inflammatory bowel disease.
Proctosigmoiditis: Inflammation involving the sigmoid colon and rectum in patients with inflammatory bowel disease.
Prodrome: A symptom indicating the onset of a disease.
Progenitor: A primitive cell.
Prognostic factors: Biological or clinical markers associated with survival independent of therapy.
Progression-free survival: The length of time during and after the treatment of a disease, such as cancer, that a patient lives with the disease but it does not get worse. In a clinical trial, measuring the progression-free survival is one way to see how well a new treatment works.
Prolapse: The dropping, falling, sinking, or sliding of an organ from its normal position or location in the body.
Prophylaxis: Therapy administered in the absence of active disease (fever, radiological findings) or a positive biomarker or microbiological test.
Proptosis: Forward displacement of the eyeball.
Prostaglandin: Any of a large group of biologically active, carbon-20, unsaturated fatty acids that are produced by the metabolism of arachidonic acid through the cyclooxygenase pathway.
Prostate specific antigen (PSA): Protein produced by columnar secretory cells in the prostate that plays a role in the liquefaction of seminal fluid. Serum PSA levels greater than 10 ng/mL are associated with prostate cancer.
Prostatectomy: An operation to remove the prostate gland and tissues surrounding it.
Proctitis: Inflammation of the rectum.
Prostatic hyperplasia: Benign enlargement of the prostate gland.
Prostatism: A syndrome associated with outlet obstruction at the bladder neck, and most commonly caused by benign prostatic hypertrophy.
Protease: Any of numerous enzymes that catalyze the breakdown of proteins.
Protectant: An agent that forms an occlusive barrier between the skin and surrounding moisture.
Proteinuria: The presence of measurable amounts of protein in the urine, which is often indicative of glomerular or tubular damage in the kidney.
Proteoglycan: Any one of a class of glycoproteins of high molecular weight that are found in the extracellular matrix of connective tissue. They are made up mostly of carbohydrate consisting of various polysaccharide side chains linked to a protein and resemble polysaccharides rather than proteins with regard to their properties.
Proteosome: An enzyme complex that degrades intracellular proteins.

Prothrombin time: A measure of coagulation representing the amount of time required to form a blood clot after the addition of thromboplastin to the blood sample; also known as Quick test.

Prothrombotic state: A state of high coagulation of the blood.

Protooncogenes: Normal genes that are present in all normal cells and regulate cell function and replication, and through some genetic alteration caused by carcinogens, change into oncogenes.

Pruritus: Localized or generalized itching due to irritation of sensory nerve endings.

Pseudohyphae: Chains of easily disrupted fungal cells; not a true hypha.

Pseudophakic: Presence of a lens after cataract extraction.

Pseudopolyp: An area of hypertrophied gastrointestinal mucosa that resembles a polyp and contains non-malignant cells.

Psoralens: Compounds that act as photosensitizing compounds.

Psoriatic arthritis: Inflammatory arthropathy associated with psoriasis. This condition is characterized by stiffness, pain, swelling, and tenderness around the joints and ligaments.

Pulmonary artery catheter: An invasive device used to measure hemodynamic parameters directly, including cardiac output and pulmonary artery occlusion pressure; calculated parameters include stroke volume and systemic vascular resistance.

Pulmonary artery occlusion pressure: A hemodynamic measurement obtained via catheter placed into the pulmonary artery used to evaluate patient volume status within the left ventricle.

Pulmonary embolus: An obstruction of the pulmonary artery or one of its branches by material that originated elsewhere in the body. The embolic material is often either thrombus, air, tumor, or adipose tissue.

Pulmonary hypertension: An elevation in the pulmonary arterial pressure that can lead to right ventricular failure and heart failure symptoms.

Pulse oximetry: A noninvasive method of measuring arterial oxygen saturation. A pulse oximeter is a small device placed on a finger or earlobe that reads reflected light from capillary blood and estimates oxygen saturation.

Pulsus paradoxus: A large fall in systolic blood pressure and pulse volume during inspiration or an abnormal variation in pulse volume during respiration in which the pulse becomes weaker with inspiration and stronger with expiration.

Punding: Stereotyped behavior with repetitive movement or actions. An adverse reaction to dopaminergic therapy.

Purified protein derivative: An extract of Mycobacterium tuberculosis used for intradermal injection to determine if a patient has been previously exposed based on immune response.

Purkinje fibers: Specialized myocardial fibers that conduct impulses from the atrioventricular node to the ventricles.

Purpura: A small hemorrhage of the skin, mucous membrane, or serosal surface.

Purulent: Containing, consisting of, or being pus.

Pustular psoriasis: Collection of neutrophils is great enough to be seen clinically. May be generalized or localized. Often characterized by widespread sterile pustules and erythema.

Pyuria: Presence of pus in urine when voided.

Quality indicators: A list of indicators used by long-term care facility administrators and government overseers to identify potential problems in patient care.

Quality of life: Perceived physical and mental health over time.

Radon: A chemically inert, radioactive gaseous element produced by the decay of radium.

Rales: Abnormal rattling or cracking sounds heard when listening to breath sounds through a stethoscope; caused by air passing through fluid in the bronchioles; sign of pulmonary edema.

Rapid cycling: Four or more mood episodes (major depressive, manic, or hypomanic) within 1 year.

Rapid eye movement (REM) sleep: A state of sleep that recurs cyclically several times during a normal period of sleep and that is characterized by increased neuronal activity of the forebrain and midbrain, by depressed muscle tone, and especially in humans by dreaming, rapid eye movements, and vascular congestion of the sex organs.

Receptor editing: A process that occurs during the maturation of B cells, which are part of the adaptive immune system. This process forms part of central tolerance to attempt to change the specificity of the antigen receptor of self-reactive immature B-cells, to rescue them from programmed cell death, called apoptosis.

Rectal prolapse: Externally visible sinking of the rectum through the anal sphincter.

Recurrence: A relapse that occurs after a clear-cut recovery.

Regurgitation: The effortless and nonprojectile passage of refluxed gastric contents into the pharynx or mouth.

Relapse: The return of symptoms, satisfying the full syndrome criteria, after a patient has responded, but prior to recovery.

Remission: Patient has no or minimal symptoms of disease. In the case of cancer, in partial remission, some but not all signs and symptoms of cancer have disappeared. In complete remission, all signs and symptoms of cancer have disappeared, although cancer still may be in the body.

Renin-angiotensin-aldosterone system: The hormonal system controlled mainly by the kidneys and adrenal glands that regulates blood pressure, blood volume, and electrolyte balance.

Resistance-associated substitution: Resistance to a drug resulting in decrease antiviral activity caused by an amino acid change in the viral protein.

Respiratory disturbance index: A summary measure that quantifies the number of apneas, hypopneas, and respiratory effort-related arousals per hour of sleep.

Response: A predefined reduction of symptoms from baseline that generally results in significant functional improvement.

Response inhibition: Ability to stay on task or the ability to think before acting.

Reticulocytes: Immature blood cells that mature into erythrocytes.

Retinopathy: Occurs when the microvasculature nerve layer that provides blood and nutrients to the retina is damaged, and can cause blindness.

Retrograde ejaculation: Semen flows to the bladder instead of the urethra.

Retrograde pyelography: Injection of a radiocontrast agent into the ureters to visualize the ureter and kidney with fluoroscopy or radiography.

Reverse transcriptase: Enzyme that catalyzes the formation of DNA from an RNA template in reverse transcription.

Rhabdomyolysis: Destruction of skeletal muscle.

Rheumatic fever: A rare, acute immune-mediated disease that occurs mainly in children and young adults that is characterized by fever, arthritis, and inflammation of the pericardium and heart valves; it is associated with untreated or undertreated group A streptococcal disease.

Rheumatoid factors: Antibodies reactive with the Fc region of IgG.

Rhonchi: Abnormal, rumbling sounds heard on auscultation of an obstructed airway. They are more prominent during expiration and may clear somewhat on coughing.
Rubefacient: A substance that produces redness of the skin.
Salicylism: A toxic syndrome caused by excessive doses of acetylsalicylic acid (aspirin), salicylic acid, or any other salicylate product. Signs and symptoms may include severe headache, nausea, vomiting, tinnitus (ringing in the ears), confusion, increased pulse, and increased respiratory rate.
Scleritis: Inflammation of the outer layer of the eyeball (sclera).
Scotoma: A spot in the visual field in which vision is absent or deficient.
Secondary amenorrhea: Absence of menses for 3 cycles or 6 months in a previously menstruating woman.
Seizure: A sudden electrical disturbance of the cerebral cortex, when a population of neurons fires rapidly and repetitively for seconds to minutes, and electrical discharges are excessively rapid, rhythmic, and synchronous.
Sentinel lymph node: The first lymph node to which cancer is likely to spread from the primary tumor.
Septic emboli: A detached, traveling intravascular mass of infected tissue. An infected emboli containing the causative organism that breaks off from a vegetation or cardiac foci, which then travels to various areas of the body resulting in significant complications.
Sequestra: A fragment of dead bone detached from healthy bone.
Seropositive: Showing a positive reaction to a test on blood serum for a disease.
Severe myoclonic epilepsy of infancy: Resistant epilepsy that occurs in the first year of life of previously healthy children.
Sialorrhea: Drooling.
Sigmoidoscopy: Visual inspection of the sigmoid colon and rectum with a flexible tube called a sigmoidoscope.
Sleep apnea: The temporary stoppage of breathing during sleep; can be caused by narrowing of the airways resulting from swelling of soft tissue.
Sleep latency: The amount of time it takes to fall asleep.
Sleeve gastrectomy: A surgical treatment for weight loss that involves constructing a small gastric "sleeve" but cutting vertically and removing up to 90% of the stomach.
Slit-lamp biomicroscope: An instrument that allows for the microscopic examination of the cornea, anterior chamber lens, and posterior chamber.
Source control: Removal of primary source of infection through surgery, drainage, or removal of infected material.
Spasticity: Feelings of stiffness and involuntary muscle contractions or sudden movements.
Spirometry: Measurement by means of a spirometer of the air entering and leaving the lungs.
Sputum smear: Microscopic examination on a glass slide of material produced from the lungs usually collected through coughing.
Stable disease: In cancer, neither sufficient shrinkage to qualify for partial response nor sufficient increase to qualify for progressive disease.
Status epilepticus: Continuous seizure activity lasting more than 5 minutes or two or more seizures without complete recovery of consciousness.
Steatohepatitis: A severe form of liver disease caused by fat deposition in the liver, characterized by hepatic inflammation that may rapidly progress to liver fibrosis and cirrhosis.
Steatorrhea: Passage of fat in large amounts in the feces, due to failure to digest and absorb it.
Steatosis: Infiltration of liver cells with fat.
Stent retriever: Thrombectomy devices used to trap a thrombus between the arterial wall and stent to allow rapid restoration of blood flow. The stent is pulled back to remove the thrombus.
Stenting: Placement of a stent (a metal or plastic tube) to allow blood flow through an artery.
Stevens–Johnson syndrome: A severe expression of erythema multiforme (also known as erythema multiforme major). It typically involves the skin and the mucous membranes, with the potential for severe morbidity and even death.
Stimulant: Any amphetamine or amphetamine-like substance (methylphenidate) that causes an increase in dopaminergic and norepinephrine activity in the brain resulting in lessening of hyperactivity, impulsiveness, and/or inattentiveness.
Stomatitis: Inflammation of mucous membranes in the mouth.
Stricture: An abnormal narrowing of a body passage, especially a tube or a canal.
Stroke volume: The amount of blood ejected from the heart during systole.
ST-segment elevation myocardial infarction: A type of myocardial infarction that typically results in an injury that transects the thickness of the myocardial wall.
Subchondral: Situated beneath and supporting cartilage.
Substance use disorder: The recurrent use of a substance and the pathological pattern of behaviors that result from substance use, including significant impairment in health, disability, or failure to meet obligations at home, work, or school.
Substantia nigra: The area in the brainstem with highly pigmented cells that make dopamine.
Subtrochanteric: Below the trochanter (the bony protrusion at the end of the femur where the hip and thigh muscles attach).
Suspending agent: An additive used in the compounding of oral liquid medications to suspend drug particles throughout a liquid and enables resuspension of particles by agitation (eg, shaking well).
Swan neck deformity: Joint deformity associated with rheumatoid arthritis that presents as flexion of the distal interphalangeal joints with hyperextension of the proximal interphalangeal joints.
Sympathomimetics: Drugs that mimic the effects of stimulating adrenergic sympathetic nerves.
Synechia: Adhesions or abnormal attachment of the iris to another structure. Peripheral anterior synechia refers to occurrence of synechia with the trabecular meshwork.
Synergism: Combination of agents (eg, bacteria, drugs) increasing the activity or severity greater than the sum of the individual effects.
Synovitis: Inflammation of the synovial membrane, often in combination with pain and swelling of the affected joint.
Synovium: The membrane lining the internal surfaces of joints.
Systemic inflammatory response syndrome: A complex pathophysiologic response to an insult such as infection, trauma, burns, pancreatitis, and/or other injuries.
T2-weighted magnetic resonance imaging: A setting of the magnetic resonance imaging machine that shows water and similar fluids such as cerebrospinal fluid as a bright signal.
Tachycardia: An abnormally rapid heart rate.
Tachyphylaxis: Rapidly diminishing response to successive doses of a drug, rendering it less effective.
Tachypnea: Faster than normal respiratory rate.
Tachypneic: Rapid breathing indicated by a rate of greater than 20 breaths per minute.
Tachysystole: More than five contractions in 10 minutes, averaged over a 30-minute window.

Tangentiality: Abandoning one's ideational objective in pursuit of thoughts peripheral to the original goal. Used to describe a thought and speech pattern wherein the individual never gets to the point or answers the question.

Tardive dyskinesia: A chronic disorder of the nervous system characterized by involuntary jerky or writhing movements of the face, tongue, jaws, trunk, and limbs, usually developing as a late occurring side effect of prolonged treatment with antipsychotic drugs.

Targeted therapy: A type of treatment that uses drugs or other substances to identify and attack specific types of cancer cells with less harm to normal cells.

Tendinosis: Tendon degeneration without accompanying inflammation.

Tenesmus: Difficulty with bowel evacuation despite the urgency to defecate.

Teratogenic: Causing malformation in the development of the embryo or fetus.

Terminal secretions: The noise produced by the oscillatory movements of secretions in the upper airways in association with the inspiratory and expiratory phases of respiration. It is also known as "death rattle".

Tetany: A condition marked by intermittent muscular spasms, caused by malfunction of the parathyroid glands and a consequent deficiency of calcium.

Thelarche: Onset of breast development.

Third spacing: Fluid moving from the intravascular space into the interstitial or "third" space or into a body cavity.

Thought-blocking: Speech is halted, often in mid-sentence, and then picked up later, usually at another point in the thought process.

Thrombin: An enzyme formed from prothrombin which converts fibrinogen to fibrin and also activates platelets. It is the principal driving force in the clotting cascade.

Thrombocytopenia: A condition whereby the number of circulating platelets are abnormally low due to decreased production of new cells, possibly secondary to medication toxicities.

Thrombocytosis: Increased number of platelets in the blood.

Thrombogenesis: The process of forming a blood clot.

Thrombolysis: The process of enzymatically dissolving or breaking apart a blood clot.

Thrombolytic: An enzyme that dissolves or breaks apart blood clots.

Thrombophlebitis: Inflammation of a blood vessel (eg, vein) associated with the stimulations of clotting and formation of a thrombus (or blood clot).

Thromboplastin: A substance that triggers the coagulation cascade. Tissue factor is a naturally occurring thromboplastin and is used in the prothrombin time test.

Thrombosis: A condition in which blood changes from a liquid to a solid state and produces a blood clot.

Thrombotic thrombocytopenic purpura: Condition characterized by formation of small clots within the circulation resulting in the consumption of platelets and a low platelet count.

Thrombus: Blood clot attached to the vessel wall and consisting of platelets, fibrin, and clotting factors. A thrombus may partially or completely occlude the lumen of a blood vessel compromising blood flow and oxygen delivery to distal tissue.

Thyroglobulin: A thyroid hormone-containing protein, usually stored in the colloid within the thyroid follicles.

Thyroid peroxidase: Enzyme that catalyzes the organification and coupling steps of thyroid hormone synthesis.

Thyroiditis: Inflammation of the thyroid gland.

Thyrotoxicosis: A syndrome caused by elevated levels of thyroid hormone. Thyrotoxicosis is often caused by hyperthyroidism, a condition in which the thyroid gland produces excessive levels of thyroid hormone.

Tocolytic: Medication used to stop premature labor.

Tonometry: A method by which the cornea is indented or flattened by an instrument. The pressure required to achieve corneal indentation or flattening is a measure of intraocular pressure.

Tophi: Collections of monosodium urate crystals that develop in tissues and generally appear as firm nodules under the skin.

Topoisomerase-I: Enzymes that cut one of the two strands of double-stranded DNA, relax the strand, and reanneal the strand.

Torsade de pointes: Very rapid ventricular tachycardia characterized by a gradually changing QRS complex in the electrocardiogram; may change into ventricular fibrillation.

Total abdominal hysterectomy and bilateral salpingo-oophorectomy: Surgical removal of the uterus, fallopian tubes, and ovaries which results in immediate menopause.

Toxic epidermal necrolysis: A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.

Toxoid: Bacterial toxin which has been inactivated.

Transcranial magnetic stimulation: A technique that involves the use of electrical coils on the head to generate a brief magnetic field which reaches the cerebral cortex.

Transesophageal echocardiogram: Procedure (Doppler ultrasound) used to generate an image of the heart via sound waves, via a probe introduced into the esophagus (rather than the traditional transthoracic view) to obtain a better image of the left atrium.

Transferrin saturation: The ratio of serum iron and total iron-binding capacity, multiplied by 100.

Translocation: Movement of viable bacteria from gastrointestinal tract into other areas of the body.

Transmural: Existing or occurring across the entire wall of an organ or blood vessel.

Transsphenoidal pituitary microsurgery: Surgery through the nasal cavity to access the pituitary gland through the sphenoid bone.

Transthoracic echocardiogram: A Doppler ultrasound to visualize the heart through placing the device on the patient's chest or abdomen; views may be limited by the size of the vegetation or patient's body habitus.

Traveler's diarrhea: An acute infectious diarrhea that afflicts travelers during or immediately upon return and is due to ingestion of contaminated food or beverages resulting in diarrhea and other gastrointestinal symptoms.

Trigeminal neuralgia: A disorder of the fifth cranial (trigeminal) nerve characterized by excruciating paroxysms of pain in the face.

Troponins T or I: Proteins found predominately in the myocardium. Troponin I and T are released into the blood from the myocytes at the time of myocardial cell necrosis secondary to infarction. These biochemical markers become elevated and are used in the diagnosis of myocardial infarction.

Trousseau sign: Elicited by inflating a blood pressure cuff on the patient's upper arm, whereby hypocalcemic patients will experience tetany of the wrist and hand as evidenced by thumb adduction, wrist flexion, and metacarpophalangeal joint flexion.

Trypsin: A proteolytic enzyme formed in the small intestine from trypsinogen by the action of enteropeptidase, which once activated hydrolyzes peptides, amides, and esters.

Tuberoeruptive xanthomas: Small yellow-red raised papules usually presenting on the elbows, knees, back, and buttocks.

Tubulointerstitial: Involving the tubules or interstitial tissue of the kidneys.

Tumor lysis syndrome: A syndrome resulting from cytotoxic therapy, occurring generally in aggressive, rapidly proliferating lymphoproliferative disorders. It is characterized by combinations of hyperuricemia, lactic acidosis, hyperkalemia, hyperphosphatemia, and hypocalcemia.

Tumor suppressor genes: A gene that suppresses growth of cancer cells.

Tympanocentesis: Puncture of the tympanic membrane with a needle to aspirate middle ear fluid.

Tympanostomy tube: Small plastic or metal tube surgically inserted in the eardrum to keep the middle ear aerated and improve hearing in patients with chronic middle ear effusion.

Uhthoff phenomenon: Acute worsening of multiple sclerosis symptoms on exposure to heat because high body temperatures may exceed the capacitance of the demyelinated nerve and conduction may fail.

Ultrasound: An imaging method that uses high-frequency sound waves to produce images of structures within the body.

Unknown-onset seizures: Seizures where the onset (ie, focal or generalized) cannot be determined.

Unstable angina: Pathogenically similar to non-ST segment myocardial infarction but without muscle damage, therefore troponins are not elevated.

Uremia: A condition that results from accumulation of metabolic waste products and endogenous toxins in the body resulting from impaired kidney function. Symptoms of uremia include nausea, vomiting, weakness, loss of appetite, and mental confusion.

Urethral stricture: Narrowing of the urethra.

Urgency: A compelling desire to void, which is difficult to defer.

Uricosuric: Pertaining to, characterized by, or promoting renal excretion of uric acid.

Urticaria: Itchy, raised, swollen areas on the skin, also known as hives.

Uterine tachysystole: Uterine hyperstimulation with frequent contractions, hypertonus and non-reassuring fetal heart rate pattern.

Uveitis: An inflammation of the uvea. Uveal structures include the iris, the ciliary body, and the choroid.

Valsalva maneuver: A forceful attempt at exhalation while keeping the mouth and nose closed.

Valvular heart disease: Damage or defects in one or more of the heart valves, disrupting blood flow into and out of the heart. The most common valves affected are the aortic and mitral valves. Valvular stenosis is a narrowing of the valve opening restricting the forward flow of blood. Valvular regurgitation or insufficiency occurs when there is inadequate closure of the valve leaflets leading to blood "leaking" backward.

Vasculitis: Inflammation of the walls of blood vessels.

Vasomotor symptoms: Menopausal symptoms that include both hot flashes (flushes) and night sweats for which women most commonly seek therapy.

Vasopressors: Medications that cause constriction of blood vessels, increase in vascular resistance, and increase in blood pressure.

Vegetation: Infectious mass comprised of protein, cellular components, and microorganisms attached to the endocardial surface of a heart valve which may be visualized on an echocardiogram.

Ventilation/perfusion ratio (V_A/Q): A comparison of the proportion of lung tissue being ventilated by inhaled air to the rate of oxygenation of pulmonary blood.

Ventricular depolarization: Change in the membrane potential of a ventricular myocyte, resulting in loss of polarization. Under normal conditions, depolarization of ventricular myocytes is followed by ventricular contraction.

Vertigo: Sensation of spinning or feeling out of balance.

Vesicants: Chemotherapy drugs that cause significant tissue damage if extravasation occurs.

Virilization: Production or acquisition of virilism, which is masculine characteristics.

Viscoelastic testing: Point-of-care testing devices utilizing thromboelastography principles to evaluate clot formation and dissolution.

Volvulus: Twisting of the intestine causing obstruction and possible necrosis.

Vulvovaginal atrophy: Thinning of vaginal tissue due to a lack of estrogen stimulation.

Wernicke syndrome: Neurologic condition caused by thiamine deficiency and characterized by mental confusion, ataxia, and ophthalmoplegia.

Wheeze: A high-pitched whistling sound caused by air moving through narrowed airways. Wheezes are usually heard at the end of expiration but may be heard during inspiration and expiration in acute severe asthma.

White coat hypertension: A persistently elevated average office blood pressure of greater than 140/90 mm Hg and an average awake ambulatory reading of less than 135/85 mm Hg.

Wild-type virus: The phenotype of naturally occurring, nonmutated strain of the HIV virus.

Wilson disease: A disorder of copper metabolism, characterized by cirrhosis of the liver and neurological manifestations.

Xanthomas: Firm raised nodules composed of lipid-containing histocytes.

Xerostomia: Unusual dryness of the mouth.

ZAP-70 expression: An intracellular tyrosine kinase found in CLL B-cells.

Zymogen: An inactive protein precursor of an enzyme that is converted into an active form.

Appendix D: Prescription Writing Principles

Kim Hawkins, Jill Isaacs, Emily Knezevich, and Jon Knezevich

According to the International Monetary Systems (IMS) Health Report, 4 billion prescriptions were written and dispensed in the United States in 2016. Seventy-seven percent of those were digital prescriptions.[1] This reflects a need for prescribers and dispensers to fully understand prescriptive privileges and rational prescribing.[2] The following outlines principles of pharmacotherapy, including general considerations of prescribing, rational prescribing of medications, types of prescription orders, safe prescribing practices including the importance of handwriting and electronic prescribing, adverse event reporting, and medication education.

It is essential that the prescriber and dispenser familiarize themselves with professional guidelines, state laws, and federal laws. In addition, they must understand the components of rational prescribing. Table D–1 provides key elements a prescriber should understand as well as useful resources.

TYPES OF PRESCRIPTION ORDERS

Prescription orders can be provided in a variety of ways by authorized prescribers. Outpatient prescriptions may be written, verbally authorized by phone, faxed, or provided via electronic means. All outpatient prescriptions are subject to federal regulations and contain the same basic components. Laws and regulations for outpatient prescription requirements can vary from state to state, so prescribers should be knowledgeable of all applicable laws. The basic components of a prescription are listed below as well as numbered in Figure D–1.[3]

1. Prescriber information: name, address, and phone number
2. Prescriber's signature and prescriptive authority number or Drug Enforcement Administration (DEA) number (if applicable)
3. Patient information: full name and address, and weight and age if appropriate
4. Date the prescription was written
5. Superscription (Rx symbol), meaning "you take" or "recipe"
6. Inscription: medication being prescribed (name of medication, strength, and dose)
7. Signa, sig, or signature: directions to the patient (eg, take one tablet daily)
8. Subscription: dispensing instructions to the pharmacist (number, quantity, or volume to dispense)
9. Number of refills allowed
10. Generic substitution requirement: "DAW (dispense as written)" or "no substitution" if brand name medication only is desired

Further regulations are in place for prescriptions written for controlled substances. In addition to the above elements, prescriptions for controlled substances must also include the patient's full name and address as well as the full name, address, and DEA number of the prescriber. Stricter regulations exist for schedule II-controlled substances compared with schedules III and V. Schedule II prescriptions must be written and can only be provided orally in an emergency situation. However, with advancements in security capabilities of electronic medical records (EMR), the DEA amended this to provide an option to issue schedule II prescriptions electronically. Federal and state rules must be followed. In cases where federal and state laws conflict, the stricter law must be adhered to.[4] Refills are prohibited with schedule II prescriptions.[5] Schedule III and IV prescriptions may be refilled up to five times within 6 months of when the prescription was issued.

Orders listed in the medical record for hospitalized patients are not considered prescriptions and are not subject to the same requirements. Typically medical record orders include:

- Patient identifiers including name, account number
- Prescriber name
- Medication name, dose, route, and frequency of administration
- Date and time of order
- Prescriber signature
- If the order was given verbally, the person reducing the order to writing must sign the order and the ordering provider countersign.

Electronic prescribing has become common practice because of government incentives aimed at moving health records to electronic databases with the goal of improving health care processes.[6] Principles discussed previously in regard to requirements of a prescription hold true for electronic orders; however, additional considerations must be taken to ensure safe prescribing habits. A brief list of potential barriers and benefits is summarized in Table D–2.

Electronic prescribing is no longer a projection of the future but instead is becoming the norm. With appropriate use of this technology, patients are provided with safer and more efficient care.

Omission of any of the above-discussed elements on a prescription order can be considered erroneous and poses a danger to patient care. Responsibility lies with the prescriber as well as the pharmacist dispensing the medication to ensure prescriptions are accurate and appropriate for each patient.

Table D–1

Pharmacotherapy Principles

Pharmacotherapy Principle	Description	Online Resources
Prescriptive privileges	Dictated by federal and state law Scope of practice and formularies vary by profession. Physicians, nurse practitioners, physician assistants, and dentists all have varying scopes of practice, which may include formularies or supervising prescribers. Each provider must become familiar with his or her profession's scope of practice. Pharmacology courses in program of study and continuing education required	
	Prescribing legend drugs requires board examination and National Provider Identifier (NPI)	https://nppes.cms.hhs.gov/NPPES/Welcome.do
	Prescribing controlled substances requires DEA registration number	http://www.justice.gov/dea/
Rational prescribing	Ensure necessity of medication Obtain pertinent history • Health history: comorbidities or contraindications (ie, pregnancy, hepatic failure, or renal failure) • Medication history: prior and current prescription, OTC, or herbal use; drug allergies or sensitivities; compliance issues • Family and social history	
	Select correct medication • It is important to know the following components of each medication when prescribing or dispensing: • Pharmacokinetics • Pharmacodynamics • Drug interactions • Drug-disease interactions • Interdisciplinary collaboration when necessary	http://www.jointcommission.org/

DEA, Drug Enforcement Administration; OTC, over the counter.

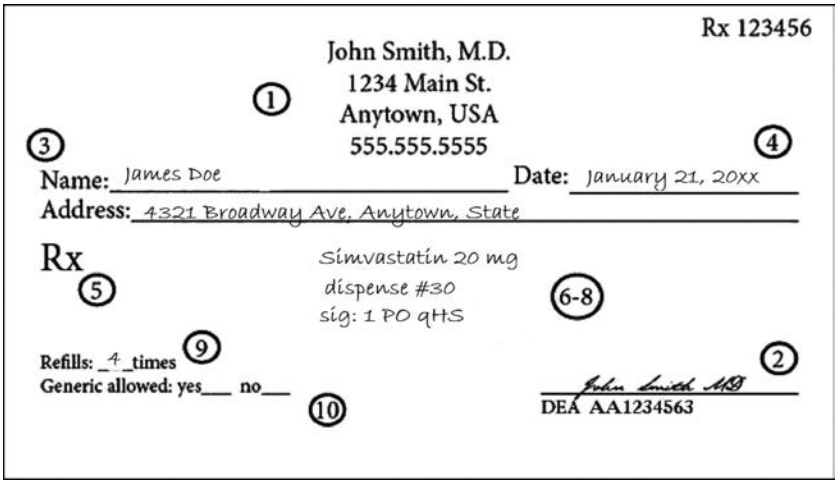

FIGURE D–1. Example of a prescription.

Table D–2

Electronic Prescribing[7-9]

Benefits	Barriers
Reduce medication errors	Cost of software programs
Reduce adverse drug events	Lack of financial benefit seen immediately
Improves efficiency	Lack of software standardization
Improved recognition of drug–drug and drug–disease interactions	Indirect costs: training personnel, reduced patient visits during training period
Improved recognition of medication allergy cross-sensitivity	Clinician resistance: worry of worsening relationship with patient, negative impact on workflow, and fears of restrictions on prescribing habits
Enhanced prescriber knowledge of patient adherence	
Enhanced prescriber knowledge of insurance coverage for medications	

SAFE PRESCRIBING PRACTICES

Safe prescribing should be a priority of all healthcare providers. To avoid inappropriate use of medications, prescribers should take careful consideration in writing clear and descriptive prescriptions. This ensures appropriate communication among the interdisciplinary health care team.

A thorough understanding of the medication prescribed, including its expected risks and benefits, should be realized by the prescriber ensuring appropriate drug selection. Providers must also be able to recognize and avoid common errors related to prescription writing. These errors include sound-alike/look-alike medications and inappropriate use of shorthand language and abbreviations. The Joint Commission, as well as the Institute for Safe Medication Practices (ISMP), has collected common examples of these errors seen during the ordering process. Common examples are described in Tables D–3 and D–4.

Table D–3

Sound-Alike/Look-Alike Medications[10,a]

Medication Name	Misinterpreted Medication Name
acetoHEXAMIDE	aceta**ZOLAMIDE**
chlordiazePOXIDE	chlorpro**MAZINE**
CISplatin	**CARBO**platin
ePHEDrine	**EPINEPH**rine
hydrALAZINE	hydr**OXY**zine
LORazepam	**ALPRAZ**olam
NIFEdipine	ni**CAR**dipine
RABEprazole	**ARIP**iprazole
risperiDONE	r**OPINIR**ole
sulfADIAZINE	sulfa**SALA**zine
valACYclovir	val**GAN**ciclovir
Zantac	Xanax

[a]For additional information, please see http://www.ismp.org/tools/confuseddrugnames.pdf.

Table D–4

Error-Prone Abbreviations[10,a]

Abbreviation	Anticipated Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as "mg"	Use "mcg"
IJ	Injection	Mistaken as "IV" or "intrajugular"	Use "injection"
q.d. or QD	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "i"	Use "daily"
U	Units	May appear as a µ or 0	Use "units"
IU	International Units	IV (intravenous)	Use "units"
bid, tid, qid	Twice daily, three times daily, four times daily	Depending on handwriting, may be misinterpreted a number of ways	Write out the words "twice daily," etc
biw, tiw, qiw	Twice weekly, three times weekly, four times weekly	Two times per day, three times per day, four times per day	Write out the words "twice weekly," etc
Dose Designation	**Anticipated Meaning**	**Misinterpretation**	**Correction**
Trailing zero after decimal point (eg, 4.0 mg)	4 mg	Mistaken as 40 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
No leading zero before a decimal point (eg, .8 mg)	0.8 mg	Mistaken as 8 mg if the decimal point is NOT seen	Use zero before a decimal point when the dose is less than a whole unit
Large doses without properly placed commas (eg, 100,000 units;1000000 units)	100,000 units 1,000,000 units	100,000 has been mistaken as 10,000 or 1,000,000; 1,000,000 has been mistaken as 100,000	Use commas for dosing units at or above 1000 or use words such as 100 "thousand" or 1 "million" to improve readability
Drug Name Abbreviation	**Anticipated Meaning**	**Misinterpretation**	**Correction**
AZT	Zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
MS, MSO_4	Morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
PCA	Procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
Stemmed Drug Names	**Anticipated Meaning**	**Misinterpretation**	**Correction**
"Nitro" drip	Nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
"IV Vanc"	Intravenous vancomycin	Mistaken as Invanz	Use complete drug name
Symbol	**Anticipated Meaning**	**Misinterpretation**	**Correction**
×3d	For 3 days	Mistaken as three doses	Use "for 3 days"
&	And	Mistaken as "2"	Use "and"
°	Hour	Mistaken as a zero (eg, q2° seen as q 20)	Use "hr," "h," or "hour"

[a]For additional information, please see https://www.ismp.org/Tools/errorproneabbreviations.pdf.

Other commonly used medical abbreviations used in prescription writing can be found in Appendix B: Common Medical Abbreviations.

Adverse Event Reporting

Adverse events may occur related to inappropriate prescribing, dispensing, or administering medications. Inappropriate prescribing may be avoided by ensuring care is taken to determine all pertinent patient-related issues are discussed during the encounter. Additionally, appropriate interdisciplinary care where multiple health care providers are evaluating and treating the patient's problem may help avoid adverse events from occurring. Inappropriate dispensing and administration may be avoided through use of clear order entry that undergoes multiple checks by a variety of providers before a prescription reaches the patient. Movement to electronic prescribing has helped eliminate many issues with misinterpreting handwritten orders; however, should they still be encountered, providers should take care to very legibly write prescriptions. If any questions remain upon receipt of a questionable order, verification should occur with the writing provider by the dispensing pharmacist. If adverse events related to medication use are determined, the health care provider who discovers the event is responsible for reporting it. The Food and Drug Administration's reporting system for such adverse events is MedWatch https://www.accessdata.fda.gov/scripts/medwatch/index.cfm?action=reporting.home.[11] This online database archives medication-related adverse events, and providers are able to report errors seen in clinical practice.

Medication Education

After a prescription has been written, counseling patients on newly prescribed therapies is an essential responsibility of the prescriber and pharmacist. The patient should be made aware of the rationale for drug use, the dose, route, and frequency at which they should administer the medication and expectations of the prescribed drug. Expectations should include risks and benefits to avoid patient confusion about side effects or efficacy measures. Thorough discussion with the patient about the selected medication therapy may identify contraindications previously unknown or a patient history of failure or success with the selected agent in the past.

CONCLUSION

Multiple principles must be exercised for appropriate drug delivery from the bedside to the patient. As a health care provider, understanding these processes helps to ensure safe medication prescribing.

Common Laboratory Tests

The following table is an alphabetical listing of some common laboratory tests and their reference ranges for adults as measured in plasma or serum (unless otherwise indicated). Reference values differ among laboratories, so readers should refer to the published reference ranges used in each institution. For some tests, both the Système International Units and Conventional Units are reported.

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Acid phosphatase			
Male	2–12 U/L	16.7	33–200 nkat/L
Female	0.3–9.2 U/L	16.7	5–154 nkat/L
Activated partial thromboplastin time (aPTT)	25–40 seconds		
Adrenocorticotropic hormone (ACTH)	15–80 pg/mL or ng/L	0.2202	3.3–17.6 pmol/L
Alanine aminotransferase (ALT, SGPT)	7–53 U/L	0.01667	0.12–0.88 µkat/L
Albumin	3.5–5.0 g/dL	10	35–50 g/L
Albumin:creatinine ratio (urine)		0.113	
Normal	< 30 mg/g creatinine		< 3.4 mg/mmol creatinine
Microalbuminuria	30–300 mg/g creatinine		3.4–34 mg/mmol creatinine
Proteinuria	> 300 mg/g creatinine		> 34 mg/mmol creatinine
or	or		
Normal			
Male	< 18 mg/g creatinine	0.113	< 2.0 mg/mmol creatinine
Female	< 25 mg/g creatinine	0.113	< 2.8 mg/mmol creatinine
Microalbuminuria			
Male	18–180 mg/g creatinine	0.113	2.0–20 mg/mmol creatinine
Female	25–250 mg/g creatinine	0.113	2.8–28 mg/mmol creatinine
Proteinuria			
Male	> 180 mg/g creatinine	0.113	> 20 mg/mmol creatinine
Female	> 250 mg/mmol creatinine	0.113	> 28 mg/mmol creatinine
Alcohol			
See under Ethanol			
Aldosterone			
Supine	< 16 ng/dL	27.7	< 444 pmol/L
Upright	< 31 ng/dL	27.7	< 860 pmol/L
Alkaline phosphatase			
10–15 years	130–550 IU/L	0.01667	2.17–9.17 µkat/L
16–20 years	70–260 IU/L	0.01667	1.17–4.33 µkat/L
> 20 years	38–126 IU/L	0.01667	0.63–2.10 µkat/L
α-Fetoprotein (AFP)	< 15 ng/mL	1	< 15 mcg/L
α-1-Antitrypsin	80–200 mg/dL	0.01	0.8–2.0 g/L
Amikacin, therapeutic			
Peak	15–30 mg/L	1.71	25.6–51.3 µmol/L
Trough	≤ 8 mg/L	1.71	≤ 13.7 µmol/L
Amitriptyline	80–200 ng/mL or mcg/L	3.605	288–721 nmol/L
Ammonia (plasma)	15–56 mcg/dL	0.5872	9–33 µmol/L
Amylase	25–115 U/L	0.01667	0.42–1.92 µkat/L
Androstenedione	50–250 ng/dL	0.0349	1.7–8.7 nmol/L
Angiotensin-converting enzyme	15–70 units/L	16.67	250–1167 nkat/L
Anion gap	7–16 mEq/L	1	7–16 mmol/L
Anti–double-stranded DNA (anti-ds DNA)	Negative		
Anti-HAV	Negative		
Anti-HBc	Negative		
Anti-HBs	Negative		
Anti-HCV	Negative		
Anti-Sm antibody	Negative		
Antinuclear antibody (ANA)	Negative		
Apolipoprotein A-1			
Male	95–175 mg/dL	0.01	0.95–1.75 g/L
Female	100–200 mg/dL	0.01	1.0–2.0 g/L
Apolipoprotein B			
Male	50–110 mg/dL	0.01	0.5–1.10 g/L
Female	50–105 mg/dL	0.01	0.5–1.05 g/L
Aspartate aminotransferase (AST, SGOT)	11–47 IU/L	0.01667	0.18–0.78 µkat/L
β_2-Microglobulin	< 0.2 mg/dL	10	< 2 mg/L
Bicarbonate	22–26 mEq/L	1	22–26 mmol/L
Bilirubin			
Total	0.3–1.1 mg/dL	17.1	5.1–18.8 µmol/L
Direct	0–0.3 mg/dL	17.1	0–5.1 µmol/L
Indirect	0.1–1.0 mg/dL	17.1	1.7–17.1 µmol/L
Bleeding time	3–7 minutes	60	180–420 seconds
Blood gases (arterial)			
pH	7.35–7.45	1	7.35–7.45
PO_2	80–105 mm Hg	0.133	10.6–14.0 kPa
PCO_2	35–45 mm Hg	0.133	4.7–6.0 kPa
HCO_3	22–26 mEq/L	1	22–26 mmol/L
O_2 saturation	≥ 95%	0.01	≥ 0.95
Blood urea nitrogen (BUN)	8–25 mg/dL	0.357	2.9–8.9 mmol/L
B-type natriuretic peptide (BNP)	0–99 pg/mL	1	0–99 ng/L
		0.289	0–29 pmol/L
B-type natriuretic peptide, N-terminal fragment (NT-proBNP)	0–299 pg/mL	1	0–299 ng/L
		0.118	0–35 pmol/L
BUN-to-creatinine ratio	10:1–20:1		40:1–100:1
C-peptide	0.51–2.70 ng/mL	331	170–894 pmol/L
		0.331	0.17–0.89 nmol/L
C-reactive protein	< 0.8 mg/dL	10	< 8 mg/L
CA-125	< 35 units/mL	1	< 35 kU/L
CA 15–3	< 30 units/mL	1	< 30 kU/L
CA 19–9	< 37 units/mL	1	< 37 kU/L
CA 27.29	< 38 units/mL	1	< 38 kU/L
Calcium			
Total	8.6–10.3 mg/dL	0.25	2.15–2.58 mmol/L
	4.3–5.16 mEq/L	0.50	2.15–2.58 mmol/L
Ionized	4.5–5.1 mg/dL	0.25	1.13–1.28 mmol/L

(*Continued*)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
	2.26–2.56 mEq/L	0.50	1.13–1.28 mmol/L
Carbamazepine, therapeutic	4–12 mg/L	4.23	17–51 µmol/L
Carboxyhemoglobin (nonsmoker)	< 2%	0.01	< 0.02

Complement component 3 (C3)	70–160 mg/dL	0.01	0.70–1.60 g/L
Complement component 4 (C4)	20–40 mg/dL	0.01	0.20–0.40 g/L
Copper	70–150 mcg/dL	0.157	11–24 µmol/L
Cortisol (fasting, morning)	5–25 mcg/dL	27.6	138–690 nmol/L
Creatine kinase			
Male	30–200 IU/L	0.01667	0.50–3.33 µkat/L
Female	20–170 IU/L	0.01667	0.33–2.83 µkat/L
MB fraction	0–7 IU/L	0.01667	0.0–0.12 µkat/L
Creatinine clearance (CrCl)	85–135 mL/min/1.73 m^2	0.00963	0.82–1.30 mL/s/m^2
		0.01667	1.41–2.25 mL/s/1.73 m^2
Creatinine			
Male 4–20 years	0.2–1.0 mg/dL	88.4	18–88 µmol/L
Female 4–20 years	0.2–1.0 mg/dL	88.4	18–88 µmol/L
Male (adults)	0.7–1.3 mg/dL	88.4	62–115 µmol/L
Female (adults)	0.6–1.1 mg/dL	88.4	53–97 µmol/L
Cyclosporine			
Renal, cardiac, liver, or pancreatic transplant	100–400 ng/mL or mcg/L	0.832	83–333 nmol/L
Cryptococcal antigen	Negative		
D-dimers	< 250 ng/mL	1	< 250 mcg/L
Desipramine	75–300 ng/mL or mcg/L	3.75	281–1125 nmol/L
Dexamethasone suppression test (DST) (overnight), 8:00 am cortisol	< 5 mcg/dL	27.6	< 138 nmol/L
DHEAS (dehydroepiandrosterone sulfate)			
Male	170–670 mcg/dL	0.0272	4.6–18.2 µmol/L
Female			
Premenopausal	50–540 mcg/dL	0.0272	1.4–14.7 µmol/L
Postmenopausal	30–260 mcg/dL	0.0272	0.8–7.1 µmol/L
Digoxin, therapeutic (heart failure)	0.5–0.8 ng/mL or mcg/L	1.28	0.6–1.0 nmol/L
Therapeutic (atrial fibrillation)	0.8–2.0 ng/mL or mcg/L	1.28	1.0–2.6 nmol/L
Erythrocyte count (blood)			
See under red blood cell (RBC) count			
Erythrocyte sedimentation rate (ESR)			
Westergren			
Male	0–20 mm/h		
Female	0–30 mm/h		
Wintrobe			
Male	0–9 mm/h		
Female	0–15 mm/h		
Erythropoietin	2–25 mIU/mL	1	2–25 IU/L
Estradiol			
Male	10–36 pg/mL	3.67	37–132 pmol/L
Female	34–170 pg/mL	3.67	125–624 pmol/L
Ethanol, legal intoxication (depends on location)	≥ 50–100 mg/dL	0.217	≥10.9–21.7 mmol/L
	≥ 0.05–0.1%	217	≥10.9–21.7 mmol/L
Ethosuximide, therapeutic	40–100 mg/L or mcg/mL	7.08	283–708 µmol/L
Factor VIII or factor IX			
Severe hemophilia	< 1 IU/dL	0.01	< 0.01 IU/mL
Moderate hemophilia	1–5 IU/dL	0.01	0.01–0.05 IU/mL
Mild hemophilia	> 5 IU/dL	0.01	> 0.05 IU/mL
Usual adult levels	60 to 140 IU/dL	0.01	0.60–1.40 IU/mL
Ferritin			
Male	20–250 ng/mL	1	20–250 mcg/L
		2.25	45–562 pmol/L
Female	10–150 ng/mL	1	10–150 mcg/L
		2.25	22–337 pmol/L
Fibrin degradation products (FDP)	2–10 mg/L		
Fibrinogen	200–400 mg/dL	0.01	2.0–4.0 g/L
Folate (plasma)	3.1–12.4 ng/mL	2.266	7.0–28.1 nmol/L
Folate (RBC)	125–600 ng/mL	2.266	283–1,360 nmol/L
Follicle-stimulating hormone (FSH)			
Male	1–7 mIU/mL	1	1–7 IU/L
Female			
Follicular phase	1–9 mIU/mL	1	1–9 IU/L
Midcycle	6–26 mIU/mL	1	6–26 IU/L
Luteal phase	1–9 mIU/mL	1	1–9 IU/L
Postmenopausal	30–118 mIU/mL	1	30–118 IU/L
Free thyroxine index (FT_4I)	6.5–12.5		
Gamma glutamyltransferase (GGT)	0–30 U/L	0.01667	0–0.50 µkat/L
Gastrin (fasting)	0–130 pg/mL	1	0–130 ng/L
Gentamicin, therapeutic (traditional dosing)			
Peak	4–10 mg/L	2.09	8.4–21 µmol/L
Trough	≤ 2 mg/L	2.09	≤ 4.2 µmol/L
Globulin	2.3–3.5 g/dL	10	23–35 g/L
Glucose (fasting, plasma)	65–109 mg/dL	0.0555	3.6–6.0 mmol/L
Glucose, 2-hour postprandial blood (PPBG)	< 140 mg/dL	0.0555	< 7.8 mmol/L
Granulocyte count	1.8–6.6 × 10^3/mm^3	10^6	1.8–6.6 × 10^9/L

(Continued on back inside cover)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Growth hormone (fasting)			
Male	< 5 ng/mL	1	< 5 mcg/L
Female	< 10 ng/mL	1	< 10 mcg/L
Haptoglobin	60–270 mg/dL	0.01	0.6–2.7 g/L
Hepatitis B surface antigen, extracellular form (HBeAg)	Negative		
Hepatitis B surface antigen (HbsAg)	Negative		
Hepatitis B virus (HBV) DNA	Negative		
Hematocrit			
Male	40.7%–50.3%	0.01	0.407–0.503
Female	36.1%–44.3%	0.01	0.361–0.443
Hemoglobin (blood)			
Male	13.8–17.2 g/dL	10	138–172 g/L
		0.621	8.56–10.68 mmol/L
Female	12.1–15.1 g/dL	10	121–151 g/L
		0.621	7.51–9.36 mmol/L
Hemoglobin A1c	4.0%–6.0%	0.01	0.04–0.06
		[a]	20–42 mmol/mol hemoglobin
Heparin			
Via protamine titration method	0.2–0.4 units/mL		
Via antifactor Xa assay	0.3–0.7 units/mL		
High-density lipoprotein (HDL) cholesterol	> 35 mg/dL	0.0259	> 0.91 mmol/L
Homocysteine	3.3–10.4 µmol/L		
Ibuprofen			
Therapeutic	10–50 mcg/mL	4.85	49–243 µmol/L
Toxic	≥ 100 mcg/mL	4.85	≥ 485 µmol/L
Imipramine, therapeutic	100–300 ng/mL or mcg/L	3.57	357–1071 nmol/L
Immunoglobulin A (IgA)	85–385 mg/dL	0.01	0.85–3.85 g/L
Immunoglobulin G (IgG)	565–1765 mg/dL	0.01	5.65–17.65 g/L
Immunoglobulin M (IgM)	53–375 mg/dL	0.01	0.53–3.75 g/L
Insulin (fasting)	2–20 µU/mL or mU/L	7.175	14.3–143.5 pmol/L
International normalized ratio (INR), therapeutic	2.0–3.0 (2.5–3.5 for some indications)		
Iron			
Male	45–160 mcg/dL	0.179	8.1–28.6 µmol/L
Female	30–160 mcg/dL	0.179	5.4–28.6 µmol/L
Iron-binding capacity (total)	220–420 mcg/dL	0.179	39.4–75.2 µmol/L
Iron saturation	15%–50%	0.01	0.15–0.50
Itraconazole			
Trough, therapeutic	0.5–1 mcg/mL or mg/L	1.42	0.7–1.4 µmol/L
Lactate (plasma)	0.7–2.1 mEq/L	1	0.7–2.1 mmol/L
	6.3–18.9 mg/dL	0.111	0.7–2.1 mmol/L
Lactate dehydrogenase (LDH)	100–250 IU/L	0.01667	1.67–4.17 µkat/L
Lead	< 25 mcg/dL	0.0483	< 1.21 µmol/L
Leukocyte count	3.8–9.8 × 10^3/mm^3	10^6	3.8–9.8 × 10^9/L
Lidocaine, therapeutic	1.5–6.0 mcg/mL or mg/L	4.27	6.4–25.6 µmol/L
Lipase	< 100 IU/L	0.01667	1.67 µkat/L
Lithium, therapeutic	0.5–1.25 mEq/L	1	0.5–1.25 mmol/L
Low-density lipoprotein (LDL) cholesterol			
Target for very high-risk patients	< 70 mg/dL	0.0259	< 1.81 mmol/L
Desirable LDL level and target for high-risk patients (optimal)	< 100 mg/dL	0.0259	< 2.59 mmol/L
Above desirable	100–129 mg/dL	0.0259	2.59–3.34 mmol/L
Borderline high risk	130–159 mg/dL	0.0259	3.36–4.11 mmol/L
High risk	160–189 mg/dL	0.0259	4.14–4.89 mmol/L
Very high risk	≥ 190 mg/dL	0.0259	≥ 4.91 mmol/L
Luteinizing hormone (LH)			
Male	1–8 mIU/mL	1	1–8 IU/L
Female			
Follicular phase	1–12 mIU/mL	1	1–12 IU/L
Midcycle	16–104 mIU/mL	1	16–104 IU/L
Luteal phase	1–12 mIU/mL	1	1–12 IU/L
Postmenopausal	16–66 mIU/mL	1	16–66 IU/L
Lymphocyte count	1.2–3.3 × 10^3/mm^3	10^6	1.2–3.3 × 10^9/L
Magnesium	1.3–2.2 mEq/L	0.5	0.65–1.10 mmol/L
	1.58–2.68 mg/dL	0.411	0.65–1.10 mmol/L
Mean corpuscular volume (MCV)	80.0–97.6 $µm^3$	1	80.0–97.6 fL
Mononuclear cell count	0.2–0.7 × 10^3/mm^3	10^6	0.2–0.7 × 10^9/L
Nortriptyline, therapeutic	50–150 ng/mL or mcg/L	3.797	190–570 nmol/L
Osmolality (serum)	275–300 mOsm/kg	1	275–300 mmol/kg
Osmolality (urine)	250–900 mOsm/kg	1	250–900 mmol/kg
Parathyroid hormone (PTH), intact	10–60 pg/mL or ng/L	0.107	1.1–6.4 pmol/L
PTH, N-terminal	8–24 pg/mL or ng/L		
PTH, C-terminal	50–330 pg/mL or ng/L		
Phenobarbital, therapeutic	15–40 mcg/mL or mg/L	4.31	65–172 µmol/L
Phenytoin, therapeutic (total concentration)	10–20 mcg/mL or mg/L	3.96	40–79 µmol/L
Phosphate	2.5–4.5 mg/dL	0.323	0.81–1.45 mmol/L
Platelet count	140–440 × 10^3/mm^3	10^6	140–440 × 10^9/L
Potassium (plasma)	3.3–4.9 mEq/L	1	3.3–4.9 mmol/L
Prealbumin (adult)	19.5–35.8 mg/dL	10	195–358 mg/L
Primidone, therapeutic	5–12 mcg/mL or mg/L	4.58	23–55 µmol/L
Procainamide, therapeutic	4–10 mcg/mL or mg/L	4.25	17–42 µmol/L
Progesterone			
Male	13–97 ng/dL	0.0318	0.4–3.1 nmol/L
Female			
Follicular phase	15–70 ng/dL	0.0318	0.5–2.2 nmol/L
Luteal phase	200–2500 ng/dL	0.0318	6.4–79.5 nmol/L
Prolactin	< 20 ng/mL	1	< 20 mcg/L
		43.5	< 870 pmol/L
Prostate-specific antigen (PSA)	< 4 ng/mL	1	< 4 mcg/L
Protein, total	6.0–8.0 g/dL	10	60–80 g/L
Prothrombin time (PT)	10–12 seconds		
Quinidine, therapeutic	2–5 mcg/mL or mg/L	3.08	6.2–15.4 µmol/L
Radioactive iodine uptake (RAIU)	< 6% in 2 hours		
Red blood cell (RBC) count (blood)			
Male	4–6.2 × 10^6/mm^3	10^6	4–6.2 × 10^{12}/L
Female	4–6.2 × 10^6/mm^3	10^6	4–6.2 × 10^{12}/L
Pregnant			
Trimester 1	4–5 × 10^6/mm^3	10^6	4–5 × 10^{12}/L
Trimester 2	3.2–4.5 × 10^6/mm^3	10^6	3.2–4.5 × 10^{12}/L
Trimester 3	3–4.9 × 10^6/mm^3	10^6	3–4.9 × 10^{12}/L
Postpartum	3.2–5 × 10^6/mm^3	10^6	3.2–5 × 10^{12}/L

(*Continued*)

Laboratory Test	Conventional Units	Conversion Factor	Système International Units
Red blood cell distribution width (RDW)	11.5%–14.5%	0.01	0.115–0.145
Reticulocyte count			
Male	0.5%–1.5% of total RBC count	0.01	0.005–0.015
Female	0.5%–2.5% of total RBC count	0.01	0.005–0.025
Retinol-binding protein (RBP)	2.7–7.6 mg/dL	10	27–76 mg/L
Rheumatoid factor (RF) titer	Negative		
Salicylate, therapeutic	150–300 mcg/mL or mg/L	0.00724	1.09–2.17 mmol/L
	15–30 mg/dL	0.0724	1.09–2.17 mmol/L
Sirolimus (renal transplant)	4–20 ng/mL	1	4–20 mcg/L
		1.094	4–22 nmol/L
Sodium	135–145 mEq/L	1	135–145 mmol/L
Tacrolimus			
Renal, cardiac, liver, or pancreatic transplant	5–20 ng/mL	1	5–20 mcg/L
		1.24	6.2–24.8 nmol/L
Testosterone (total)			
Men	300–950 ng/dL	0.0347	10.4–33.0 nmol/L
Women	20–80 ng/dL	0.0347	0.7–2.8 nmol/L
Testosterone (free)			
Men	9–30 ng/dL	0.0347	0.31–1.04 nmol/L
Women	0.3–1.9 ng/dL	0.0347	0.01–0.07 nmol/L
Theophylline			
Therapeutic	5–15 mcg/mL or mg/L	5.55	28–83 µmol/L
Toxic	20 mcg/mL or mg/L or more	5.55	111 µmol/L or more
Thiocyanate	Toxic level unclear; units are mcg/mL or mg/L	17.2	µmol/L
Thrombin time	20–24 seconds		
Thyroglobulin	< 42 ng/mL	1	< 42 mcg/L
Thyroglobulin antibodies	Negative		
Thyroxine-binding globulin (TBG)	1.2–2.5 mg/dL	10	12–25 mcg/L
Thyroid-stimulating hormone (TSH)	0.35–6.20 µIU/mL	1	0.35–6.20 mIU/L
TSH receptor antibodies (TSHRab)	0–1 units/mL		0–1 kU/L
Thyroxine (T_4)			
Total	4.5–12.0 mcg/dL	12.87	58–154 nmol/L
Free	0.7–1.9 ng/dL	12.87	9.0–24.5 pmol/L
Thyroxine index, free (FT_4I)	6.5–12.5		
TIBC—see Iron binding capacity (total)			
Tobramycin, therapeutic			
Peak	4–10 mcg/mL or mg/L	2.14	8.6–21.4 µmol/L
Trough	≤ 2 mcg/mL or mg/L	2.14	≤ 4.3 µmol/L
Transferrin	200–430 mg/dL	0.01	2.0–4.3 g/L
Transferrin saturation	30%–50%	0.01	0.30–0.50
Triglycerides (fasting)	< 160 mg/dL	0.0113	< 1.81 mmol/L
Triiodothyronine (T_3)	45–132 ng/dL	0.0154	0.69–2.03 nmol/L
Triiodothyronine (T_3) resin uptake	25%–35%		
Uric acid	3–8 mg/dL	59.48	178–476 µmol/L
Urinalysis (urine)			
pH	4.8–8.0		
Specific gravity	1.005–1.030		
Protein	Negative		
Glucose	Negative		
Ketones	Negative		
RBC	1–2 per low-power field		
WBC	< 5 per low-power field		
Valproic acid, therapeutic	50–100 mcg/mL or mg/L	6.93	346–693 µmol/L
Vancomycin, therapeutic			
Peak	20–40 mcg/mL or mg/L	0.690	14–28 µmol/L
Trough	10–20 mcg/mL or mg/L	0.690	7–14 µmol/L
Trough for central nervous system infections	15–20 mcg/mL or mg/L	0.690	10–14 µmol/L
Vitamin A (retinol)	30–95 mcg/dL	0.0349	1.05–3.32 µmol/L
Vitamin B_{12}	180–1000 pg/mL	0.738	133–738 pmol/L
Vitamin D_3, 1,25-dihydroxy	20–76 pg/mL	2.4	48–182 pmol/L
Vitamin D_3, 25-hydroxy	10–50 ng/mL	2.496	25–125 nmol/L
Vitamin E (*α*-tocopherol)	0.5–2.0 mg/dL	23.22	12–46 µmol/L
WBC count	4–10 × 10^3/mm^3	10^6	4–10 × 10^9/L
WBC differential (peripheral blood)			
Polymorphonuclear neutrophils (PMNs)	50%–65%	0.01	0.50–0.65
Bands	0%–5%	0.01	0–0.05
Eosinophils	0%–3%	0.01	0–0.03
Basophils	1%–3%	0.01	0.01–0.03
Lymphocytes	25%–35%	0.01	0.25–0.35
Monocytes	2%–6%	0.01	0.02–0.06
WBC differential (bone marrow)			
PMNs	3%–11%	0.01	0.03–0.11
Bands	9%–15%	0.01	0.09–0.15
Metamyelocytes	9%–25%	0.01	0.09–0.25
Myelocytes	8%–16%	0.01	0.08–0.16
Promyelocytes	1%–8%	0.01	0.01–0.08
Myeloblasts	0%–5%	0.01	0–0.05
Eosinophils	1%–5%	0.01	0.01–0.05
Basophils	0%–1%	0.01	0–0.01
Lymphocytes	11%–23%	0.01	0.11–0.23
Monocytes	0%–1%	0.01	0–0.01
Zinc	60–150 mcg/dL	0.153	9.2–23.0 µmol/L

[a]Hemoglobin A1c (mmol/mol hemoglobin) = (Hemoglobin A1c (%) – 2.15) × 10.929.
