So, how can C/PHNs influence policies that affect the clients and communities they serve? And, how do we influence policymakers to hear our concerns and act on them? Using persuasion, through either written or oral methods, to influence government is known as **lobbying**. While personal stories may call attention to your issue, effective lobbying requires more substance. Seasoned advocates developed ground rules by which to be effective. Some call them the “ten commandments of lobbying.” However these steps are named, advocates adhere to the basic ideas inherent in the following:

- **Honesty is the best policy.** Being known as someone who has integrity is a lasting virtue. Never mislead a legislator about the importance of an issue or the position of the opposition as it is difficult to regain credibility once lost. Do not speak beyond your level of expertise. If you do not know the answer, say so. If you promise to get the answer, then do so. Do not promise what you cannot deliver.
- **Start early.** Planning always takes longer than you think it will. Your interests are not everyone's interests, and convincing others they should be involved always involves time. If you are planning policy change at the state or federal level, it is vital to know the legislative process and the critical time lines.
- **Know what you want and be prepared.** Understand the role politics plays in getting what you want and how policymakers may respond to your issue. Targeting your story to the goals, emotions, and interests of the legislator is important and may result in a positive outcome. It is crucial to understand the role funding may have on your policy issue.

- **KISS** (Keep it simple, stupid). Be able to articulate your issues in a clear and concise manner. Do not confuse possible supporters with complicated arguments. Key issues should be concise and clear and on one page, no more than two.
- **No permanent enemies, no permanent friends.** Political affiliation does not always determine what interests a person has or whether they are likely to support your issue. It behooves you to speak with everyone. Respectful disagreement keeps the door open for future agreement and compromise. Remember, an opponent on one issue may be an ally on another. Always be polite and professional.
- **Know your opponents.** Understand all sides of the issue prior to approaching a policymaker. Be prepared to answer questions and provide data on both sides of the issue.
- **Make an “ask”:** Be *clear* about what you are asking the legislator for—to carry legislation or to vote no or yes on specific legislation. Asking your legislator to vote a certain way is perfectly legitimate, and if you don't ask, the opposition will. Ask for much more than you think you can get. When negotiating, this allows you to give up something without hurting your priorities or your bottom line. In politics, rarely does anyone get all they want, but priority setting is a key.
- **There is strength in numbers.** The more groups involved, the more likely you are to be successful. Any opportunity for networking is an opportunity to enlarge your coalition. Including disparate groups means you may have accessed conflicting political persuasions. Additionally, it is useful to have groups who can speak with those who are not viewed as “friends.” Cross-fertilization of groups is politically expedient but understands that next time you or they may be in opposition.
- **Know your legislators and work at the local level.** Legislators are interested in their constituents—these are the people who elected them to office and who will keep them in office. To be noticed by policymakers, sharing information with them about their constituents is the surest way to capture their attention. Information sharing should occur on issues both in the community where you live and in the one where you work.
- **Thank you.** Everyone loves to be told, “Job well done.” To maintain your coalitions, always recognize the work of others. Spreading the credit is like sowing seeds: the wider the spread, the more bountiful the crop.

Common methods of making contact with legislators are by e-mail, over phone, or in person. Often, your first contact will be a staff member. This person is the gatekeeper and your interaction may determine the level of communication you have with your legislator. It is important to organize

your thoughts and carefully craft a pitch that ends with an “Ask” or how you want the legislator to take action (Kostas-Polston et al., 2015, p. 12).

- If you plan to make contact in person, prepare a “one-pager,” with your contact information and credentials listed, along with brief bulleted points on the subject of interest that includes current statistics and research (p. 13).
- If you meet with a legislator, it is important to remember that they are not allowed to discuss campaign contributions in their legislative offices. Finally, it is important for those new to advocacy to understand that the thing with the most critical influence on policy is *money*.

Nurses, even with the passage of the recent health care reform legislation, must become even more actively involved in the process of influencing policy. How many nurses understand that the nurse practice acts, or portions thereof, under which they work are developed by legislators or special interest groups who don't have a background in health care? How many nurses know who their legislators are at either the state or federal level? How many nurses have written their legislators about pending health care legislation or legislation that affects nursing?

## Political Action Committees

- Financial resources are essential to effective advocacy. One reason why nurses are less politically active can be tied to a lack of money.
  - As mentioned earlier, the ANA has a PAC that supports federal candidates on a nonpartisan basis. Candidates must demonstrate an interest in and willingness to vote for nursing issues or issues that nurses support.
  - To participate in the PAC, you must be a member of the ANA (this also allows your family to contribute to the PAC). By contributing to the ANA-PAC, one maximizes his/her contribution by joining with other nurses. Power in numbers increases our influence with those candidates we choose to endorse.

During the 2016 election cycle, the ANA-PAC contributed just over \$200,000 to federal candidates who supported nurses and nursing issues. While this is a large amount of money, it is significantly less than the \$1.2 million that the American Medical Association's PAC contributed during the same time frame ([U.S. FEC, n.d.](#)). Because nursing organizations do not have as much money as other health care groups (e.g., hospitals, physicians, insurance companies, and health care plans), there is less opportunity to employ lobbyists and contribute to supportive candidates. This often means nurses have less influence than other groups.

- Another way to influence policy is to make contributions to your personal legislator. This will keep you on his/her mailing list and may lead to invitations to local legislative activities. It also lets your legislator know you are interested in whether he/she remains in office. Being in regular contact with your legislators provides an avenue for introducing legislation that impacts nursing or important community issues, and when you call to ask for a vote “for” or “against” an issue, the legislator may be more likely to entertain your request.
- Lobbyists may work for PACs or independently represent various special interests or groups. Professional organizations or other **special interest groups** (individuals who share a common interest and work politically to make their goals a reality) may retain paid lobbyists.

Lobbyists are professionals who know the rules governing the state or federal political process, have or develop relationships with policymakers, provide guidance for members of the organizations employing them on how to impact public policy decisions, and work behind the scenes to influence policy discussions and outcomes. States and the federal government have laws and regulations that determine the legal actions of lobbyists as well as

the organizations that employ those ([Mason et al., 2016](#); [Milstead, 2016](#)). However, some lobbyists are former legislators or staff members who “take lucrative jobs representing the very industries” they formerly regulated, and this “revolving door” lobbying is disconcerting to most citizens as they are often seen as selling their access to current key legislators ([LaPira & Thomas, 2014](#), p. 4).

## Volunteering

Money is *not* the only way to build a relationship with your legislator. Being involved in local and state elections can take many forms. Volunteering your time can be just as important (Box 13-9). Candidates develop position papers to tell their constituents where they stand on key campaign concerns. Nurses have the expertise to assist legislators in developing position papers and setting policy agendas for health care issues, including the social determinants of health. Legislators and legislative candidates also need people to assist in everyday tasks such as phone banking, stuffing mailers, answering phones, putting up flyers and campaign posters, and walking door to door to spread support.

### BOX 13-9 PERSPECTIVES

#### **A Volunteer's Viewpoint on Campaigning for an RN**

A registered nurse (RN) who had been through what I called the women's legislative career ladder—School Board, City Council, and the County Board of Supervisors—was now poised to run for the state legislature. Because we had had numerous contacts and I believed she would make a good state legislator and a voice for nursing and health care, I volunteered to work in her campaign office. I primarily answered the phones on the evenings I worked, but I met the office staff—many of them were much younger than me. And, even once, she came in while I was there. I talked with the staff about some of my experiences as a lobbyist, and they shared their experiences; many of them were fresh out of college.

She was successful in her run for office, and whenever I needed to meet with her or her staff, I was shown right in. I was also asked my opinion about the hiring of certain staff. Her staff knew me by name—many of them did not work on her campaign, but they were told about me by those campaign staff who were still around. After 3 years in office, she was appointed chairperson of a key committee, and I maintained access to her committee consultants and to her when necessary. We were able to work together quite successfully, and although we didn't always agree on every

policy issue, I think the weeks I put in volunteering 3 years earlier really paid off for the clients and the issues I was representing.

Lydia, professional lobbyist

- *Relationships* are critical in policy development and in affecting public policy. As demonstrated earlier, being a friend can reap huge benefits when health care policy is on the line. Voting, for instance, is vital—RNs represent a substantial block of potential voters (Nickitas et al., 2016).
- Joining your local and state professional organizations is imperative to having the voice of nursing heard at all levels.

You can become more actively involved by writing legislators about the health care issues that impact the communities, both where you live and work. It is also vital to understand the importance of critically timing those communications. Effective communications with legislators should be tied to times when the issues are being heard in policy committee—thus, you must know when your issue is scheduled to be discussed in committee. For example, it is prudent to send letters on your issue—via fax or regular mail—close to the time of the committee hearing. Holding a press conference or getting other media coverage when the bill is introduced, or on the day it will be heard in committee, is quite effective in drawing attention to your issue. Writing letters to the editor of your local newspaper on health issues and writing articles for various publications are also effective methods of persuading others to back your issue.

- Other methods for influencing health policy or nursing issues include applying for positions on boards and commissions; each local area has advisory committees for their locally elected officials at the city and county level.
  - The state board of RNs needs nurses willing to sit on their board or to serve on various advisory committees and task forces.
  - At your state capitols, there are usually vacancies on policy committees, or legislators may be looking for new staff. And, who better to serve in this capacity than a nurse! Serve your patients and communities by *running for office!*

# SUMMARY

This chapter briefly reviewed health outcomes in the United States.

- Health outcomes for Americans do not compare well with peer countries, particularly considering the high cost of the US health care system; this is largely due to system issues and not addressing the SDOH.
- Health policy guides health care and governmental actions related to the SDOH; C/PHNs can use policy in their practice to improve the health of the communities with which they work.
- Policy competence as it relates to local, state, and federal health policy—and how nurses are impacted by these policies—is an essential skill for C/PHNs.
- An understanding of how a bill becomes a law helps inform policy process, implementation, and evaluation.
- Frameworks such as the rational and Kingdon provide guidance in health policy analysis.
- Policy analysis as a call for activism can be used to support social justice in public health, professional advocacy, and the C/PHN's role in health care reform, PACs, and volunteerism.
- Current US health policy includes the ACA within community and public health practice, value-based purchasing, and accountable care organizations.

# ACTIVE LEARNING EXERCISES

1. Using “Utilize Legal and Regulatory Actions” (1 of the 10 essential public health services; see [Box 2-2](#) ), describe a legislative bill related to health at either your state or the federal level and where the bill is in the legislative process. Identify who is sponsoring the bill, who is opposing it, and why. Determine the population that will be affected most by the bill if it passes and in what ways they will be affected. Discuss what you, as a C/PHN, could do to be involved in this bill and then develop a political action plan to support or oppose the bill. E-mail your legislator regarding your position.
2. Who are your state legislators? What are the critical health issues in your state, and how have your legislators responded to the issues? How have your state legislators voted on policies to advance the nursing profession?
3. Attend a meeting of a professional organization, board of directors, government agency, or council when a health policy or health care issue is on the agenda. Analyze the positions of the major interest groups involved and describe to what extent economics comes into the discussion. Describe who controls the discussion and why. Compare your findings with classmates.
4. Are nurses the most qualified group to articulate national health care issues? If so, why? If not, why not?
5. Pick a policy issue and take a position related to political action and advocacy. What stance does your nursing professional organization have on this issue?

## **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Discuss characteristics all families have in common.
2. Identify the stages of the family life cycle and the developmental tasks of a family.
3. Discuss how a family's culture influences its values, behaviors, and roles.
4. Describe the functions of a family.
5. Analyze the role of the community health nurse in promoting the health of the family.
6. Describe the components of the nursing process as they apply to enhancing family health.
7. Identify the steps in a successful family health intervention.
8. Describe useful activities and actions when intervening on family health visits.
9. List at least six specific safety measures the community/public health nurse should take when traveling to a home or making a home visit.
10. Describe the effect of family health on individual health.
11. Describe individual and group characteristics of a healthy family.
12. List the five basic principles the public health nurse should follow when assessing family health.

13. Discuss the two foci of family health visits: education and health promotion.
14. Describe the three types of evaluations that are necessary after family health interventions.

# INTRODUCTION

Community health nurses are intimately involved with families. The family plays a critical role in the health of its members. Health habits such as preventative care, diet, exercise, and physical activity are developed through your experiences in a family. Health beliefs, genetic influences, and care of the ill family member all take place within the family environment. The community/public health nurse (C/PHN) is in a unique position to influence and promote **family health**. Families should be considered at every point of nursing care.

The definition of family varies by organization, discipline, and individual. Family theorists suggest that a family consists of two or more individuals who share a residence or live near one another; possess some common emotional bond; engage in interrelated social positions, roles, and tasks; and share cultural ties and a sense of affection and belonging (Kaakinen, Coehlo, Steele, Tabacco, & Robinson, 2018).

Today's C/PHN needs to understand and work with many types of families, each of which has unique health needs. For example, a young, single mother seeks help in caring for her infant. A 67-year-old provides care for his mother, who was recently discharged from the hospital after a stroke. A family from Haiti needs instruction on the purchase and preparation of food for the kidney dialysis diet their father has been given. The effectiveness of C/PHN depends on knowing how to work with all kinds of families.

This chapter draws from various theories to strengthen the student's understanding and appreciation of families as clients. This information will promote the effectiveness of interventions with families at the primary, secondary, and tertiary levels of prevention (Box 14-1).

## **BOX 14-1 Levels of Prevention Pyramid**

### **A Home Visit to an Infant With**

**Gastroesophageal Reflux SITUATION: A young single mother with a new infant (Patrick) asks for help with her baby at a well-baby visit as the baby is spitting up after feeding. The baby is**

## diagnosed with gastroesophageal reflux. The mother was referred to a PHN for a home visit.

**GOAL:** Using the three levels of prevention, avoid negative health conditions, and promptly diagnose, treat, and/or restore the fullest possible potential.

Tertiary Prevention		
Rehabilitation	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Monitor infant's reflux.</li> <li>Work closely with the provider to ensure follow-up for concerns.</li> <li>Be alert for any complication.</li> </ul>	<ul style="list-style-type: none"> <li>The family continues to see provider for well visits.</li> <li>Encourage more frequent feedings (feed Patrick half as much, twice as often).</li> <li>Keep baby upright for 30 minutes after feeding.</li> </ul>	<ul style="list-style-type: none"> <li>Educate and follow up to assure that infant immunization schedule begins on time and continues through childhood.</li> <li>Baby maintains weight and developmental milestones.</li> </ul>

Secondary Prevention	
Early Diagnosis	Prompt Treatment
<ul style="list-style-type: none"> <li>Parents discuss feeding with provider and when to introduce solids.</li> <li>Baby has irritability after eating and refuses to eat.</li> <li>Baby has not gained weight.</li> </ul>	<ul style="list-style-type: none"> <li>The child has projectile vomiting; yellow, green, or coffee ground spit; blood in spit.</li> <li>Parents use feeding techniques to minimize infant reflux.</li> </ul>

Primary Prevention	
Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Address infant feeding.</li> <li>Discuss anticipatory guidance.</li> </ul>	<ul style="list-style-type: none"> <li>Baby continues to gain weight.</li> <li>Milestones for development are obtained.</li> <li>Review immunization schedule.</li> </ul>

The family is the basic element of a community and a population. A **family** refers to a group of individuals whose behaviors, actions, health conditions, and interrelationships impact the health of the group and the individuals (Kaakinen et al., 2018). As discussed in Chapter 1, a community is a set of people in families that share a common purpose with a sense of belonging and place (Kaakinen et al., 2018). A **population** encompasses the total number of persons in families within communities at a specific geographic location (Kaakinen et al., 2018). Based on the above definitions, the family's positive experience when accessing health services improves the health for the community that leads to a healthier population.

Families need to have equal access to optimal health care, social services, and community resources in a supportive and healthy environment. For example, immunization programs exist for infants and children. Pregnant women can attend childbirth education classes and receive medical care throughout the entire pregnancy from their health care providers (Mutch, 2016). Growing families can access parenting classes and support groups for

help with developmental crises and in the management of chronic illness (Lee et al., 2017). Older adults have senior centers for a myriad of social and recreational activities as well as numerous services and activities offered at senior discounts (Frost, Beattie, Bhanu, Walters, & Ben-Shlomo, 2019). All these clients have one point in common—they are members of families. Clearly, the health of the family influences the health and wellness of the population.

Within the family, the interactions are unique because a family member can knowingly or unknowingly influence another. The health of one family member can influence other members' perspective(s) about health or their social value system. The emotional state of a family member can be the deciding factor in another family member's choice for a career or the schools you attended. The impact can be as mundane as the type of meals eaten. Will the meal include chicken if the dinner guests include vegetarian parents? Family members clearly influence each other and the entire family. This makes for a unique unit of service.

Just as each family is unique, so too are their homes. A public health nurse may feel comfort in some families' homes and not in others. A **home** is a structure or building where families live (e.g., mobile homes, high-rise inner-city apartments, rural cabins, cardboard boxes, farm labor camps). It can be daunting for students to enter a home that is a small and cluttered apartment, a sparsely furnished single room, or a makeshift structure in disrepair. Each home brings its own set of unique challenges and strengths that can influence the way the public health nurse perceives and interacts with the community to promote health, prevent illnesses, and reduce risk.

Public health nurses rely on the nursing process when working with families, the “core unit of service,” to promote health and wellness, prevent illness, and improve the overall health of the population. The delivery of care occurs in various community settings (i.e., homes, work settings, classrooms, clinics and outpatient departments, neighborhood centers, and homeless shelters). Although caring for the family, as a unit of service, is an effective way to treat the population in the communities, practice does not always match a family nursing theory. The problem, in part, is that health care services are often tailored to an individual and not a family and/or a community. Third-party payer and reimbursement policies impose limits to the kinds of services funded. Public health agencies often organize services around individuals. The government requires that public health agencies structure disease statistics or service categories on an individual instead of aggregated data on a family.

Family-level problem-solving techniques are used to deal with health issues including health promotion, pregnancy and childbirth, acute life-threatening illness, chronic illness, substance abuse, domestic violence, and terminal illness (Beck, Le, Henry-Okafor, & Shah, 2017; Coker, Martin,

Simpson, & Lafortune, 2019; De Grubb, Levine, & Zoorob, 2017; Dyess-Nugent, 2018). The first step is a detailed family assessment that emphasizes internal and external influences (Salmond & Echevarria, 2017; Shajani & Snell, 2019). This creates a database from which a family diagnosis is generated, an essential step before planning, implementation, and evaluation of services.

The novice public health nurse must be able to practice within the nursing process. Moreover, when public health nurses address the health needs of the core unit of service, the family, the nurses are treating the health needs of the communities and the population (Association of Public Health Nurses [APHN], 2016a, 2016b). Public health nurses are legally the leaders in using the accessible health care services to prevent illnesses and promote health in families (APHN, 2016a, 2016b; Salmond & Echevarria, 2017). Family health is the cornerstone for community and population health, making the family the focus of health care and related services. Therefore, the health of the *family* is addressed through the nursing process that involves assessing, diagnosing, planning, implementing, and evaluating the family.

# FAMILY HEALTH AND FAMILY HEALTH NURSING

Throughout history, the family has been the most basic unit. One of the first steps for nurses is to explore how a family influences the care that they provide and how they interact with the family. Most of us were raised in families and spent a good portion of our lives within families. Our first experiences with others are influenced by our families of origin. [Feetham \(2018\)](#) asserts that the way we interact with families actually comes from how we define family. So we come to our nursing practice with ideas about families based on our own experiences.

- The United States Census Bureau ([Pemberton, 2015](#)) views family as people living together and related by birth, adoption, or marriage.
- [Kaakinen et al. \(2018, p. 5\)](#) define family as “two or more individuals who depend on one another for emotional, physical, and economical support.”
- [Kaakinen et al. \(2018, p. 5\)](#) define family health as a “dynamic changing state of wellbeing, which includes the biological, psychological, spiritual, sociological, and culture factors of individual members and the whole family system.”

Family health is concerned with how well the family functions together as a unit. It involves not only the health of the members and how they relate to other members but also how well they relate to and cope with the community, outside the family. In fact, family health, like individual health, ranges along a continuum from wellness to illness. A family may be at one point on that continuum now and at a much different point 6 months from now. Family health refers to the health status of a given family at a given point in time ([Kaakinen et al., 2018](#)).

**Family health nursing** is how public health nurses care for individuals within the family or for the family as the client (family as context) or for the family as a system ([Fig. 14-1](#)). There are multiple ways that community health nurses can approach families. Some nurses view family nursing as part of other specialties such as public health nursing, maternal child nursing, or behavioral health nursing. However, some nurses view family nursing as its own distinct specialty, rich with its own body of literature and research. Each of these approaches with families has its own distinct set of beliefs.

**FIGURE 14-1** Community/public health nurses work with families and individual family members.

Nurses work with individuals within families every day. Most often, the individual is the recipient of care. While assessing the needs of the individual, the nurse needs to include the family in the assessment, as the family is the pivotal provider of care. How does the family assist the individual family member or hinder his or her progress? What are their available resources (physically, emotionally, and spiritually)?

Nurses working with families as a system view the family as part of a larger suprasystem that includes many subsystems. The family becomes greater than the sum of all of its parts. Any change within the family system affects all of the family members (Shajani & Snell, 2019).

When visualizing a family as a system, it may help to compare it to a mobile. Think of all the pieces suspended freely by a string. If you pull lightly on one piece, all the pieces move, just as a change in one member's health affects the entire family. Can you think of some examples of this in your own family?

# FAMILY CHARACTERISTICS AND DYNAMICS

Several observations can be made about families. First, each family is unique, with its own distinct set of strengths. As a nurse you want to look first at the family's strengths. When you approach the door of a house to begin your visit with a family, you cannot be sure of what they will be like. You will have to gather information about the family in order to provide the best nursing care possible. Starting with their strengths will assure your success.

Families share universal characteristics with every other family (Box 14-2). For instance, families in every culture throughout history have engaged in similar functions: families have produced children, physically cared for their members, protected their health, encouraged their education or training, given emotional support and acceptance, and provided supportive and nurturing care during illness. These characteristics provide an important key to understanding each family's uniqueness. No matter how many families a nurse may visit over the course of a year, each one will have universal features; it is important for PHNs to know each family's unique set of characteristics and their effects on family health.

## Box 14-2 Universal Characteristics of Family Life

- Every family is a small social system.
  - Families are interdependent.
  - Families maintain boundaries.
  - Families exchange energy with their environments.
  - Families adapt.
  - Families are goal oriented (providing love, security, and a sense of belonging).
- Every family moves through stages in its life cycle.
- Every family has its own cultural values and rules.
- Family members share certain values that affect their behavior.
- Certain roles are defined for family members.
- A family's culture influences its distribution and use of power.
- Every family has certain basic functions:
  - Providing affection

- Providing security
- Instilling identity
- Promoting affiliation
- Providing socialization
- Establishing controls
- Every family has structure.

Source: [Duvall and Miller \(1985\)](#).

## Family Stage of Development

Many of the characteristics and defined developmental stages of individual growth also apply to families. For example, families change continuously. Families grow and develop as the individuals within them mature and adapt to changes. A family's composition, set of roles, and interpersonal relationships change with time. Families vary with each stage of the **family life cycle**. See [Box 14-3](#) for some questions to ask yourself about your own family.

### BOX 14-3 What Do *You* Think?

#### Questions for Self-Evaluation

1. What are your first memories of family?
2. What is your definition of family?
3. How would you describe your own family?
4. Who do you now include as family members?

As [Duvall and Miller \(1985\)](#) first pointed out, no two children come to precisely the same family. Consider the following example of how families change over time. The Garcia family, a young married couple, begins their family by getting to know each other, learning more about their new roles, and developing a satisfying marriage. They have difficulty getting pregnant, so they decide to adopt a baby. Their baby, Rosa, changes the family and their roles as parents. Thus new roles are added (father, mother, and daughter). Within 2 years they become pregnant and Luis is born. This once again changes the family. Both family size and a reorganization of family occurred. The children entered school; Mrs. Garcia went back to work, and soon, Rosa was leaving for college. The Garcia family, like every family, is moving through a predictable and sequential pattern of stages known as the family life cycle.

PHNs who are knowledgeable about this cycle can provide anticipatory guidance to families. For instance, nurses can help prepare the family for having children. The nurse can help the soon-to-be parents to anticipate the responsibility and costs of raising her child by helping them calculate child care needs. The nurse can assist the family in figuring out the monthly costs of breast-feeding versus buying formula, disposable versus cloth diapers, and the clothing, equipment, and medical costs of infant care.

To progress through the stages of the life cycle, a family must carry out its basic functions and the developmental tasks associated with those

functions. Often, how we define family will determine how the family functions are filled. Unlike developmental tasks, which are specific to each age level, family developmental tasks are ongoing throughout the life cycle. The manner and degree to which each function is carried out varies depending on how well members accomplish individual developmental tasks and meet the demand of a particular stage (Kaakinen et al., 2018).

Some functions require greater emphasis at certain stages. Socialization, for example, consumes much of a family's time during the early years of child development. Duvall and Miller (1985) described these activities as “stage critical” family developmental tasks that must be completed before moving onto the next stage. Sample community health nursing actions with the family at different stages are presented in Table 14-1.

Stage of the Family Life Cycle	Developmental Tasks	Role of the Community Health Nurse
Forming a partnership	Establishing a mutually satisfying relationship	Interact with family where they are at
Childbearing	Adjusting to pregnancy and the promise of parenthood Fitting into the kin network Having and adjusting to infants and encouraging their development Establishing a satisfying home for both parents and infant(s)	Assist them in developing strong relationships
Preschool-age children	Adapting to the critical needs and interests of preschool children in stimulating, growth-promoting ways Coping with energy depletion and lack of privacy as parents	Assist in preparing for family expansion through education and anticipatory guidance
School-age children	Fitting into the community of school-age families in constructive ways Encouraging children's educational achievement	Encourage time for each other as adults in a relationship separate from parenting role
Teenage children	Balancing freedom with responsibility as teenagers mature and emancipate themselves Establishing outside interests and careers as growing parents	Provide anticipatory guidance for the school-aged children as they grow into adulthood
Launching children	Releasing young adults into work, military service, college, marriage, etc., with appropriate rituals and assistance Maintaining a supportive home base	Provide anticipatory guidance for the contracting family as children leave home
Middle-aged parents	Rebuilding the relationship Maintaining kin ties with older and younger generations	Prepare adults for grandparenting role
Aging family members	Adjusting to retirement Coping with bereavement and living alone Closing the family home or adapting it to aging	Assist aging adults with emotional and financial security, as they approach retirement Prepare the aging adults with ways to cope with the losses of old age, including changes in space, work, health, status, and loss of friends and family members

Source: Duvall and Miller (1985).

## **Family Values and Their Effect on Behavior**

Every family has its own set of values and rules for operation (McGoldrick, Garcia-Preto, & Carter, 2016). Like all cultural values, many family values remain outside the conscious awareness of family members. These values, often not verbalized, become powerful determinants of what the family believes, feels, thinks, and does. Family values include those beliefs transmitted by previous generations, religious influences, immediate social pressures, and the larger society. Values become an integral part of a family's life and are difficult to change (Box 14-4).

### **BOX 14-4 Cultural Values Cultural values such as the following shape most decisions and choices in our lives:**

- Education
- Sex roles
- Health care
- Courtship/marriage
- Lifestyle
- Childrearing

## Family Roles

**Roles**, the assigned or assumed parts that members play during day-to-day family living, are bestowed and defined by the family (Kaakinen et al., 2018). Families distribute among their members all the responsibilities and tasks necessary to conduct family living.

Family members may play several roles at the same time. This can be taxing. A single parent often takes on the role of both father and mother but may distribute responsibilities and tasks more widely. A grandmother or a child may assume responsibility for some chores and thereby relieve some of the demands on the single parent. Among families, there is great variation in expectations for each role and in the degree of flexibility in divisions of roles. An example may be specific tasks given to girls versus boys within the family. Girls may be given child care or kitchen responsibilities and boys given yard tasks.

Many families enjoy the fellowship of organized religious or cultural groups. This fellowship can be a source of support or comfort, as well as an additional role function for the family members. Family members can also participate in roles outside the family. These may involve local or regional politics, community improvement, volunteerism for nonprofit groups, or other groups outside the home that the community may offer. These diverse role relationships should enrich and energize the participants. The community health nurse may work with families to help them achieve a balance of activities that promote family health.

Power is the possession of control, authority, or influence over others—assuming patterns in each family. In some families, power is concentrated primarily in one member; in other families, it is distributed on a more egalitarian basis (McGoldrick et al., 2016).

The traditional patriarchal family, in which the father holds absolute authority over the other members, is rare in American society. However, the pattern of husband as head of the household and dominant member of the family is still frequently seen. The dominant power, whether male or female, holds the majority of the decision-making power, particularly over more important family matters such as employment, finances, and health care. With changing societal influences, however, the present trend among American families is toward egalitarian power distribution.

## Family Social Class and Economic Status

As a community health nurse, it is important for your assessment to include social class of families you are visiting. Social class often shapes a family's access and choices to work, educational, and health care opportunities (McGoldrick et al., 2016). Their overall health is often determined by their class position. The biggest predictor of health is your level of wealth (Penman-Aguilar et al., 2016). How healthy we are and how long we live are often related to our social standing. The neighborhoods families choose to live in, and the schools their children attend, are often determined by social class. These decisions/choices have lifelong implications and shape the history of families. See [Chapter 23](#) for more on social determinants of health and the socioeconomic gradient.

Most people who experience homelessness are single adults. In 2017:

- 184,661 people in families were homeless.
- 57,971 families with children were homeless.
- This represents one third (33%) of the total homeless population.
- 16,938 people in families with children who were counted in unsheltered locations (living on the streets, in cars, or in another place not meant for human habitation) ([National Alliance to End Homelessness, 2018](#)).

Families who are homeless are not necessarily incomeless. They may include working parents who just are not making enough money to pay for housing. On average, a homeless family household consisted of three people. Homeless families present the C/PHN with unique challenges. Primarily, the family is in crisis and often not able to provide for their most basic needs. When families are unable to meet these needs, they are unable to address other concerns such as medical appointments, healthy eating and exercise, and other preventative actions that nurses typically recommend.

Children who experience homelessness have higher risks of emotional and behavioral problems, serious health problems, school mobility, repeating a grade, and being expelled or dropping out of school and have lower academic performance ([National Alliance to End Homelessness, 2018](#)).

Community health nurses should be aware of this and focus on first assisting the family in getting their essential needs met. They should also acknowledge that the behaviors seen in children may be the direct result of the situation that the family finds itself in. A C/PHN's knowledge of the resources available in the community is an important first step in providing the family with the help to deal with the crisis and assisting in the provision of ongoing shelter, food, health, employment, and schooling needs. See

Chapter 26 for more on homeless populations. You can check your state rates at <https://endhomelessness.org/homelessness-in-america/homelessness-statistics/state-of-homelessness-2020/>

## Family Composition

Globally, families—in all varied forms—are the basic social unit (Shajani & Snell, 2019). The meaning of family among the Hmong of northern Laos may include hundreds of people who make up a clan. In Mexico, families remain close, are large, and extend into multiple generations. In Germany and Japan, families are small and tend to the needs of their elders at home.

In the United States, where families come from many cultural groups, many variations coexist within communities. Families come in many shapes and sizes (Fig. 14-2).

**FIGURE 14-2** Families exist in many forms.

It is a privilege to gain entry into a family's home. This is a uniquely private space belonging to the family. The people who are members of this household interact, care for one another, and bond in ways that may never be fully understood by anyone outside the family. Therefore, being granted entrance into this system gives the community health nurse an opportunity to work with the family that few other professionals experience. Each type of household requires recognition and acceptance by community health nurses, who must help families achieve optimal health.

### *Traditional Versus Contemporary Families*

Traditional families are those that are likely most familiar to us:

- The nuclear family—husband, wife, and children living together in the same household. In nuclear families, the workload distribution between the two adults can vary. Both adults may work outside the home; one

adult may work outside the home, whereas the other stays at home and assumes primary responsibilities for the household; or partners may alternate, constantly renegotiating work and domestic responsibilities.

- A nuclear dyad family consists of two adults living together who have no children or who have grown children living outside the home.
- A single adult family is one in which one adult is living alone by choice or because of separation from a spouse or children or both. Separation may be the result of divorce, death, or distance from children.

Half of American adults are married today, which is drastically different than 72% in 1960 ([Pew Research Center, 2017](#)). Couples are putting off marriage as they get their careers started and begin working on their futures. In 2016, the median age for marriage among men was 29.5 and for women 27.4, which is roughly 7 years more than in 1960 ([Pew Research Center, 2017](#)). In 2017, 65% of children under the age of 17 years old lived with two-parent families which is up slightly from 64% in 2014 ([ChildStats.gov, 2019](#)).

Sometimes, in close-knit ethnic communities, families form a kin network, in which several nuclear families live in the same household or near one another and share goods and services. They may own and operate a family business, sharing work and child care responsibilities, income and expenses, and even meals. Variations of this trend are increasing among all groups as children postpone leaving home because of economic conditions, educational plans, or student loans. This is the most popular living arrangement for young adults today ([Vespa, 2017](#)).

The number of young adults who continue to live with their parents is on the rise. A third of young adults aged 18 to 34 lived with their parents, and more young adults lived in their parents' home than with a spouse in 2016 ([Vespa, 2017](#)).

Families in America today do not look the way they did several years ago.

- The traditional nuclear family has been a fundamental part of our cultural heritage shared by many Americans and reinforced by religion, education, and other influential social institutions. The “ideal” family was historically considered a nuclear family including a mom, dad, and children. By thinking of this as the ideal family, any variation was often treated as deviant and abnormal. This view can leave families and family members, who do not fit this description, feeling isolated and alone.
- Families are changing for a variety of reasons; Americans are putting off previously expected milestones, families are getting smaller, and life expectancy is getting longer. There is an increase in single-parent

adoptions; an increase in lesbian, gay, bisexual, transgender, or queer (LGBTQ) couples and families; and high divorce and remarriage rates.

- The role of women in the family is changing, they are marrying at older ages, and children are being born outside of marriage. Families should no longer be defined as “what” they are but rather “who” they are (Feetham, 2018).
- McGoldrick *et al.* (2016) fosters the importance of putting a positive spin on the families that make up our world. The nurse is in a unique position to assess families in a strength-based model rather than viewing certain families as deviant.

As society struggles with what they consider to be the ideal family, the media portrays them in various forms, showing that society is beginning to accept more contemporary definitions of family.

- Television shows such as *Gilmore Girls*, *Blackish*, *Modern Family*, and *The Fosters* are all examples of the ways that television is changing along with family structures. The days of *Leave it to Beaver* type shows are becoming less common. People want to see characters like themselves, going through similar experiences, on the shows that they watch.
- Another way that families are impacted by media is through social media. It can be a positive or negative influence on the family and its members. In a study done by Valdermorose-San-Emeterio, Sanz-Arazu, & Ponce-de-Leon-Elizondo (2017), it was discovered that children who report more digital leisure time as one of their favorite leisurely practices had less family cohesion. Digital leisure time can be considered playing video games, social networking, and scanning the Internet. Since these activities are becoming more commonplace, the public health nurse should consider these factors when working with families. See Chapter 10.

One of the positive aspects of social media is its use in promoting health care resources to families. Nurses can use messaging and other platforms to reach patients who otherwise may be limited by distance or transportation issues. Families turn to online resources for many reasons and health care questions are no exception. With the high usage of social media, families and its members are likely to use it for health access and information (Schroeder, 2017). Nurses can play a role in using them to communicate and teach families with current and evidence-based information.

## *Families Experiencing Divorce, Remarriage, and Blending*

Divorce, remarriage, and blending of families can result in distinct emotional responses and developmental issues among family members, as shown in Table 14-2.

Phase	Emotional Responses	Developmental Issues
Divorce	<ul style="list-style-type: none"> <li>Continue working on emotional recovery by overcoming hurt, anger, or guilt</li> </ul>	<ul style="list-style-type: none"> <li>Giving up fantasies of reunion</li> <li>Staying connected with extended families</li> <li>Rebuild and strengthen own social network</li> </ul>
Postdivorce	<ul style="list-style-type: none"> <li>Separate feelings about ex-spouse from parenting role</li> <li>Prepare self for possibility of changes in custody as child(ren) get older; be open to their needs</li> <li>Risk developing a new intimate relationship</li> </ul>	<ul style="list-style-type: none"> <li>Make flexible and generous visitation arrangements for child(ren) and noncustodial parent and extended family members</li> <li>Deal with possibilities of changing custody arrangements as child(ren) get older</li> <li>Deal with child(ren)'s reaction to parents establishing relationships with new partners</li> </ul>
Meeting new people	<ul style="list-style-type: none"> <li>Allowing for the possibility of developing a new intimate relationship</li> </ul>	<ul style="list-style-type: none"> <li>Dealing with child(ren)'s and ex-family members' reactions to a parent "dating"</li> </ul>
Entering a new relationship	<ul style="list-style-type: none"> <li>Completing an "emotional recovery" from past divorce</li> <li>Accepting one's fears about developing a new relationship</li> <li>Working on feeling good about what the future may bring</li> </ul>	<ul style="list-style-type: none"> <li>Recovery from loss of marriage is adequate</li> <li>Discovering what you want from a new relationship</li> <li>Working on openness in a new relationship</li> </ul>
Planning a new marriage	<ul style="list-style-type: none"> <li>Accepting one's fears about the ambiguity and complexity of entering a new relationship such as:                             <ul style="list-style-type: none"> <li>New roles and responsibilities</li> <li>Boundaries: space, time, and authority</li> <li>Affective issues: guilt, loyalty, conflicts, and unresolvable past hurts</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Recommitment to marriage and forming a new family unit</li> <li>Dealing with stepchild(ren) as custodial or noncustodial parent</li> <li>Planning to help child(ren) deal with fears, loyalty conflicts, and memberships in two systems</li> <li>Realignment of relationships with ex-family to include new spouse and child(ren)</li> </ul>
Remarriage and blending families	<ul style="list-style-type: none"> <li>Final resolution of attachment to previous spouse</li> <li>Acceptance of new family unit with different boundaries</li> </ul>	<ul style="list-style-type: none"> <li>Restructuring family boundaries to allow for new spouse of stepparent</li> <li>Realignment of relationships to allow intermingling of systems</li> <li>Expanding relationships to include all new family members</li> <li>Sharing family memories and histories to enrich members' lives</li> </ul>

Source: McGoldrick *et al.* (2016).

## *Divorce*

Divorce does not just affect the involved couple; it changes the entire family structure and each family member's life course. Demographics play a role in divorce with those who are less educated and earning a lower income. Approximately 850,000 marriages in the United States end in divorce and even more parents who are never married break up, which also greatly impacts the family (Dissing, Dich, Nybo-Andersen, Lund, & Rod, 2017). As divorce becomes more acceptable, couples are making this choice for a variety of reasons. These can vary from marital dissatisfaction, infidelity, finances, and many other factors. Something new to consider in this day and age is the effect of social media on couples. It is now easier than ever to form emotional relationships online. Through various online platforms, couples

are able to reconnect with old friends and even make new ones. Social media boundaries are important for couples to discuss and agree on. These virtual relationships can become part of a family's daily lives and can lead to infidelity and even divorce (Abassi & Alghamdi, 2017).

Divorce affects all members of the family in a different way, since each is at a different stage in life. Each member is going through unique adjustments and transitions as they cope with their new normal.

- For children, it may require coping with a new geographic location and a new school, as well as adjusting to changes in the mental and physical health of family members.
- In addition to the normal growth and developmental changes, children from divorced families may face an absent father or mother, interparental conflict, economic distress, parental adjustment, multiple life stressors, and short-term crises.
- New schools mean that children must find new friends and social groups, proving themselves once again and trying to gain acceptance in a completely new social setting. Their previous sense of security and comfort at home is forever changed. These adjustments take time and C/PHN can provide support for the children involved (Table 14-2).
- The frequency of divorce does appear to be stabilizing in America today; the number of children living with unmarried parents has remained unchanged in the 21st century (Kaakinen et al., 2018).

## *Remarriage and Blending*

The United States Census Bureau uses the term “blended families” to describe families who bring nonbiological children into a new marriage. In this structure, single parents marry and raise the children from each of the previous relationships together. If this is the result of divorce or death, this can be an especially painful transition (Table 14-2).

- They may be custodial parents who have the children except during planned visits with the noncustodial parent, or they may share custody, so that the children live in the blended arrangement only part time or possibly live in two separate blended homes.
- The family may include children from the couple, in addition to the children brought into the relationship. Not all divorced adults stay single; most remarry or cohabit with another adult, who may or may not have children. This new couple may have children from their union, or adopt, creating an even more complex family.
- Merged or blended families require considerable adjustment and relearning of roles, tasks, communication patterns, and relationships.

- Traditional nuclear families have well-established roles and stages that members go through, but this is not true for blended families, which leads to the complexity of the family dynamics and structure (Kaakinen et al., 2018).
- We all come to new relationships with our own history from the past.

Since this emerging family pattern is becoming more prominent, it is very possible that the C/PHN is familiar with this pattern or lives in such a family. In the blended family, there isn't a definitive and common definition of who makes up the family among its members (Kaakinen et al., 2018). This is something for the nurse to keep in mind as the family is assessed. The data on blended families can be challenging to track since the United States Census information is done only every 10 years. The American Community Survey done in 2017 found that 3,927,266 households included stepchildren (U.S. Census, 2017). Some of the challenges that blended families face are merging traditions, adjustment to change, sibling rivalry, change in discipline styles, and managing age differences (Guzzo, Hemez, Anderson, Manning, & Brown, 2019). This adds to the complexity of the dynamics and health of families.

Nursing skills that are needed when working with divorced or blended families include the ability to listen and be empathetic, as well as a nonjudgmental attitude. The nurse should meet the family where they are at and provide resources that the family may need. Resources may include support groups, reading materials, or interventions available in the community. Communication among all parents and family members should be encouraged. Peer support groups for children and adolescents and support from within the schools should be used, if available, or started if they do not exist. The school nurse could be a rich resource for families also. The community health nurse can have a significant role in community-wide planning if services are needed but unavailable.

### *Single-Parent Families*

One of the most common contemporary family structures is the single-parent family, mostly headed by women. These families are created in several ways. Sometimes single women choose to adopt or have children without being married, and some become single parents through divorce. Depending on how single-parent families come about, there can be loss and grief to deal with. Family strength and security is important for the family members regardless of the situation.

- In 2016, the birth rate for unmarried women was 42.4 births per 1,000 aged 15 to 44, which is down 2% from 2015 (Martin, Hamilton, Osterman, Driscoll, & Drake, 2018).

- The percentage of all births to unmarried women was 39.8% in 2016, a 1% decline from 2015 and the lowest level since 2007 (Martin et al., 2018).

Nonmarital birth rates declined from 2015 to 2016 for women in age groups under 35, with the rate for teenagers ages 15 to 19 dropping 8% (to 18.5 per 1,000 in 2016).

- The rate for females aged 15 to 17 was at an all-time low (8.6).
- Conversely, rates rose for all age groups aged 35 and over, reaching historic peaks for women aged 35 to 39 (35.6) and 40 to 44 (10.0) (Martin, Hailton, Osterman, & Driscoll, 2019).

This is thought to be the result of two trends; the increased financial independence of women and the tightening of the job market for men. Although Kaakinen et al. (2018) mentions that the wage gap between men and women still exists, women are better able to support themselves than in the past.

Over time, this form of family has become more accepted by society. It is important for C/PHNs to view the strengths of single-parent families. Building on their current strengths can be most helpful in terms of meeting the challenges that they may face. These challenges will typically result from one parent being solely responsible for the financial income, caregiving, and support for the family. The needs of the family will depend on their stage in the family cycle and experiences that brought them into the single-parent family. Nurses with their connections in the community can assist these families through advocacy and collaboration.

### *Families Headed by an Adolescent Parent or Parents*

Statistics indicate that teenagers are increasingly the heads of single-parent families; some of these teen heads of households become pregnant in junior high or high school. The birth rate among teens 15 to 19 years old has continued a steady decline, but teen birth rates in the United States remain the highest among those in developed countries (Guttmacher Institute, 2015).

- The birth rate for women aged 15 to 19 in the United States in 2016 was 20.3 births per 1,000 women, down 9% from 2015 (22.3) and another record low.
- The number of births to teenagers aged 15 to 19 was 209,809 in 2016, also down 9% from 229,715 in 2015.
- The 2016 birth rates for teenagers aged 15 to 17 and 18 to 19 were 8.8 and 37.5 births per 1,000 women, respectively, down 11% and 8% from 2015 to record lows for both groups (Martin et al., 2018).

Teenagers are still developing physically, mentally, and emotionally and are not prepared to take on parenthood without help. Consideration should be given to helping the mother on her life course as well as the baby. The mother needs support and structure so that she may support her child. Home visitation programs such as the Nurse Family Partnership are able to provide this stability for both mom and baby if available in the community.

Specific factors related to teen birth rates are low education and low-income levels of a teen's family, few opportunities in a teen's community for positive youth involvement, neighborhood racial segregation, neighborhood physical disorder (e.g., graffiti, abandoned vehicles, litter, alcohol containers, cigarette butts, glass on the ground), and neighborhood-level income inequality, and teens in child welfare systems are at increased risk of teen pregnancy and birth than other groups. For example, young women living in foster care are more than twice as likely to become pregnant than those not in foster care (CDC, 2019). Teenagers also lack availability to contraceptives and the education to use them properly. They may be afraid to ask for resources and fear judgment which adds to risk of pregnancy and unsafe sex practices.

Housing is another significant issue that affects teen mothers. A study conducted by SmithBattle (2018a), which started in 1988 and continues today, found that housing is a concern that needs to be addressed when assessing teen moms. Housing was especially a concern for black moms who grew up in poverty. Compared to their white counterparts, they lived in various situations that increased toxic stress associated with discriminatory housing policies (SmithBattle, 2018a). Children raised without safe and secure housing struggle in other aspects of their lives. It is also difficult for teen moms to become productive members of society if they do not have a home to call their own.

Teen fathers are often left out of the loop for services that communities provide for the teen mother and infants, and there is a lack of research in the literature on the experiences and roles of teen fathers (Ngweso, Peterson, & Quenlivan, 2017). However, it has been established that partner involvement contributes positively to the outcomes in pregnancy (SmithBattle, Phengnum, Shagavah, & Okawa, 2019).

- A father who is emotionally supportive of the mother and provides child care and financial support directly and indirectly affects the wellbeing of his child.
- Children with absent fathers are at increased risk for behavioral difficulties and poor academic performance. Longitudinal research found lower birth weights and lower cognitive and behavioral scores at age 2 and poorer health for children of adolescent fathers when compared with those of adult fathers.

- [Ngweso et al. \(2017\)](#) found that teen fathers feel unprepared and uninvolved in the birth and decision-making process. It would benefit teen moms, babies, fathers, and the community if we were to involve teen fathers in the preparation and education of birth and early parenting.
- There are home visiting programs that include the father in the visits and activities ([Nurse Family Partnership, 2019](#)). This encourages a sense of inclusion and promotes healthy family relationships. Teens often feel misunderstood; and this is even more true in the case of teen pregnancy. See [Chapter 4](#) for research demonstrating the effectiveness of NFP.

The implications for the role of the C/PHN are greatest with the adolescent parent population. For example, nurses work with young teens through schools, clinics, or home visiting programs to ensure healthy pregnancies and teach parenting skills to the parents and grandparents.

- Nurses can also ensure that the infant receives immunizations and primary care health services, reaches age-appropriate milestones, and can provide family planning information to the new parents.
- Teen mothers experience high levels of psychological distress, and one of the recommendations given by [SmithBattle and Freed \(2016\)](#) is to be proactive and screen for distress in pregnant and parenting teens.
- Teens may have trauma in their backgrounds that may not have been addressed. They may feel stigmatized and this can prevent them from reaching out for help. If C/PHNs focus on the teen mothers' strengths and aspirations to prevent childhood trauma, which they themselves may have experienced, they will be in a unique position to help these families ([SmithBattle, 2018b](#)).
- On a broader scale, C/PHNs should collaborate with other professionals to make sure that the community has resources for all levels of prevention, with a focus on primary prevention.

### *Families Headed by a Cohabiting Couple*

Cohabiting couples' ages can range from young adults to elderly couples. The couples may be heterosexual or LGBTQ; they may or may not share a sexual relationship. In some instances, these couples have their own biologic or adopted children. Cohabitation has increased for all race groups of unmarried mothers in America over the last decade ([Pew Research, 2018](#)). There is a wide class gap in marriage in America. Marriage is [more prevalent](#) and [more durable](#) among better educated, higher-income Americans. It should come as no surprise, then, to find an education gap between married and cohabiting parents. Married mothers and fathers are over four times more

likely to hold a bachelor's or advanced degree than cohabiting biological parents (Reeves & Krause, 2017).

Young adults may put off marriage to complete their education, work on their careers, or simply experiment with different living experiences. Since many have delayed marriage, it has become more likely that couples will live together prior to marriage. Living together does not necessarily mean that marriage is imminent though. Raley (2016) explains that nearly two thirds of married couples lived together prior to marriage and that couples who cohabitate are less likely to marry and are more likely to break up within the first 3 years (Raley, 2016). Elderly couples may choose to cohabitate after losing a spouse or experiencing loneliness but not wanting to go through a legal marriage. Similar to the other families mentioned in this chapter, cohabiting couples have become an accepted family structure in America.

## *LGBTQ Families*

Although the exact number of LGBTQ families is not known, this emerging family type is increasing. The United States Census estimates close to 900,000 same-sex households. Romero (2017) states that 1.1 million LGBTQ individuals are married to a same-sex partner. There are over 10.7 million American adults identifying themselves as LGBTQ, and 2 to 3.7 million children report having a LGBTQ parent. Almost one half of LGBTQ women and about one fifth of LGBTQ men are raising a child. Foster and adopted children are often being raised by LGBTQ couples, and over 25% of same-sex couples are raising siblings, grandchildren, or other related/nonrelated children (Jones, 2015).

*Healthy People 2030* addresses lesbian, gay, bisexual, and transgender Health. This speaks to the importance of understanding the discrimination and oppression that LGBTQ families have faced. Although much progress has been made in accepting people with values and beliefs different from those of the mainstream, LGBTQ still face health-related challenges and disparities (U.S. Department of Health and Human Services, 2020).

These families have many of the same hopes regarding parenting that any family may have. In addition, they experience the stress that accompanies being stigmatized by much of a society.

- Lack of acceptance from their families and communities may have negative implications on their own family.
- Out and Equal: Workplace Advocates (2019) reports that one in four of LGBTQ participants surveyed has experienced workplace discrimination. Other markers of discrimination (e.g., rejected by family/friend; been a subject of jokes/slurs; threatened or physically attacked; poor service at business, hotel, restaurant) have shown

decreases from the past year to current year; this indicates that some progress has occurred. Healthy People 2030 addresses reduction in bullying as an objective for this population ([USDHHS, 2020](#)).

- Annual family income is lower (39% vs. 38% earning <\$30,000; 20% vs. 34% earning <\$75,000) for LGBTQ families than for the overall US population.

The nurse can become a valued resource for the family. Through education and anticipatory guidance, the nurse can assist the family to successfully navigate the developmental stages of their children as well as the varied issues faced by families. The nurse can work with parents to anticipate what questions to expect from their children about their family.

### *Families With Older Adults*

Aging is something that begins the day we are born; however, it is not focused on until a person turns 65 or older or begins to experience declining health. It is often thought of as something negative rather than a normal process. Elderly individuals are the fastest-growing segment of the population and their value is often overlooked. Since Americans are getting older and families are getting smaller, there is an increase in elderly and a decrease in adult children to care for them. However, family relationships remain strong and last longer than ever due to the increase in life expectancy ([Kaakinen et al., 2018](#)).

- In 2010, 40 million people in the United States were over the age of 65 years or 11% of the total population. This is projected to double by 2030 ([AgingStats.gov, 2015](#)).
- Many older adults live independently well into their eighties and maintain healthy contacts with family and friends.
- Others feel isolated because of chronic health problems that limit mobility, thereby reducing or eliminating the ability to interact or contribute meaningfully in society. Relationships in later life are affected by several factors: retirement status, health, mental health, and caregiving roles ([Eliopoulos, 2018](#)).
- The way that individual members of the family react to these factors will affect how the rest of the family copes. This is where the nurse can help.

The community health nurse needs to understand the complex dynamics of such situations and offer support and encouragement as family members work through chronic health problems. Adult children may become caregivers as their parents become older which is a change in the family dynamic for nurses to keep in mind. Often, a nurse serves an entire community of elders in a senior apartment complex, an assisted living center,

or a mobile home community, for whom maintaining wellness is the focus. Keeping physically active, eating healthy meals, receiving appropriate medical care and immunizations, and establishing and maintaining social contacts are some of the tasks elders should focus on to stay healthy well into old age. The community health nurse can intervene by advocating for the individual medical and social needs for the elderly.

### *Foster Families*

Many children are removed from their families because of maltreatment due to abuse, violence, or neglect. When this occurs, children are often placed with foster families. On September 30, 2016, there were an estimated 437,465 children in foster care, more than a quarter (32%) were in relative homes, and nearly half (45%) were in nonrelative foster family homes ([childwelfare.gov](http://childwelfare.gov), 2018).

- Foster families take a variety of forms, but all foster families have formal training to accept unrelated children into their homes on a temporary basis, while the children's parents receive the help necessary to reunify the original family.
- Although this arrangement is not ideal, most foster families provide safe and loving homes for these children in transition.
- Roughly half (55%) had a case goal of reunification with their parents or primary caretakers, and a little over half (51%) of the children who left foster care in 2016 were discharged to be reunited with their parents or primary caretakers.
- Close to half of the children (45% who left foster care in 2016 were in care for <1 year. ([childwelfare.gov](http://childwelfare.gov), 2018).

Often, foster children have emotional and physical health problems, and they may never have experienced the positive structure that foster families provide. Consideration should be given to the loss that typically present in foster situations. The losses may include biological parents losing their children, foster parents unable to have biological children, and foster children losing biological parents ([Turney & Wildeman, 2016](#)). These problems, which can cause stress and grief for everyone involved, are typically ones that the community health nurse may help to alleviate.

### *Implications of Family Composition Diversity for Community/public Health Nurses*

The variety of family structures raises three important issues for consideration:

- First, C/PHNs can no longer hold to a myth that idealizes the traditional nuclear family. They must be prepared to work with and accept all types of families. Unless the C/PHN can accept the full array of family lifestyles and address the special needs of each, it is questionable that they will be able to fully help the family and may even create additional difficulties.
- Second, the structure of an individual's family may change several times over a lifetime. A girl may be born into a nuclear family and then become part of a single-parent family when her parents are divorced. As she matures, she may become a single adult living alone and then become a part of a cohabitating couple. Still later, she may marry and have children in a nuclear family. After the death of her husband as a senior citizen, she may have a relationship outside of marriage and choose not to remarry. For the individual, each family form involves changes in roles, interaction patterns, socialization processes, and links with external resources. The community health nurse must learn to address clients' needs throughout these life changes equipping people with the skills needed to deal with the inevitability of changing structures.
- Finally, each type of family structure creates different issues and problems that, in turn, influence a family's ability to perform basic functions. [Shajani and Snell \(2019\)](#) discuss the need for nurses to identify and develop strengths with families in planning nursing care. This should be a community health nurse's starting point. What are the family strengths? How does the family see their strengths? All families have strengths, although sometimes these are not easily recognized. It is important for the nurse to identify these with the family's collaboration ([Box 14-5](#)).

## **BOX 14-5 Questions the Nurse May Ask the Family**

### **1. What are your strengths as a family?**

2. If you had to tell me your three most favorite things about your family, what would they be?
3. Name one quality about your mother that you really respect. About your father? Your partner? Your child?
4. What is your best memory of your family?

The family is the basic unit of a community and a population. Maintaining the health of family transitions into the health of both the community and the population. Caring for family impacts the health of the

community, which in turn affects the health of the population ([APHN, 2016a, 2016b](#); [Kub, Kulbok, Miner, & Merrill, 2017](#)). This interdependence is evident even within the family because one family member can positively or negatively impact other family members and the family unit itself. As a result, public health nurses must first understand what constitutes a “healthy family” so that they can use the nursing process with family-level problem-solving techniques for health prevention and promotion within the family and subsequently the community and the population.

## Traits Associated With Healthy Family Functioning

A family is a health aggregate from the interrelationships of the family members. The health of the family is affected by each family member and all family members collectively. A healthy family promotes each family member's growth and resistance to illnesses so that the family's health can sustain members during times of crisis such as serious illness, emotional dilemmas, divorce, or death of a family member (Gladding, 2019; Kaakinen, et al., 2018). Conversely, a family with underdeveloped coping skills or a limited capacity for problem-solving, self-management, or self-care is often unable to promote the potential of its members or assist them in times of need.

Adherence to cultural practices and family standards for family health can influence each member's health. Many families comply with cultural norms when deciding about utilizing preventative health care, adhering to immunization recommendations, completing routine health assessments, or investing in family planning (Spector, 2017). In turn, these cultural norms dictate how family members will participate in their health care. This interlacing can either obstruct or facilitate the health of the family and the family members.

The description of “normal” family health is challenging given the heterogeneity and subjectivity of the data related to family health. However, there are some standards that characterize a healthy family. Major family strengths have emerged for family functioning and coping with crisis—family pride, family support, cohesion, adaptability, communication, religious orientation, and social support (Nichols & Davis, 2019). Specific topics have been used to characterize a healthy family (Kaakinen, et al., 2018):

- Communicates and listens
- Has a balance of interaction among members
- Exhibits a sense of shared responsibilities
- Teaches a sense of right and wrong
- Abounds in rituals and traditions
- Respects the privacy of each member
- Admits to problems and seeks help

From this information, six signs have persisted about a healthy family—maintaining a spiritual foundation, making the family a top priority, asking for and giving respect, communicating and listening, valuing service to others, and expecting and offering acceptance (Clark-Jones, 2018; Parachin,

1997). While using these signs to guide and understand family-oriented interventions (Clark-Jones, 2018), six important characteristics have consistently emerged (Kaakinen et al., 2018):

1. A facilitative process of interaction exists among family members.
2. Individual member development is enhanced.
3. Role relationships are structured effectively.
4. Active attempts are made to cope with problems.
5. There is a healthy home environment and lifestyle.
6. Regular links are established with the broader community.

### *Healthy Communication Among Family Members*

- Healthy families communicate in patterns that are regular, varied, and supportive (Fig. 14-3). Adults talk and engage with adults, children with children, and adults with children; it is through communications that families find ways to adapt to changes as they seek family stability (Denham, Eggenberger, Young, & Krumwiede, 2016).

**FIGURE 14-3** Good communication promotes healthy families.

Healthy families discuss problems, confront each other when angry, share ideas and concerns, and write or call each other when separated. They communicate through nonverbal means. This level of family communication sensitizes family members to one another. They watch for cues and verify messages to ensure understanding, which intensifies the family's recognition and dealing with conflict. Thus, a communicative family knows to share and collaborate with each other.

Furthermore, family members use communication to demonstrate affection and acceptance, to promote identity and fellowship, and to guide

behavior through socialization and social ethics. Importantly, effective communication patterns are associated with a family that promotes the health and development of each family member.

### *Enhancement of Family Members' Development*

Healthy families respond to the needs of family members and provide the freedom and support necessary to promote each member's growth. This family tolerates differences of opinion or lifestyle because each member has the right to be an individual, and the family respects this right. A healthy family encourages freedom and autonomy for each of its members because it contributes to the family's stability (Kaakinen et al., 2018).

Freedom and autonomy are supported even if the patterns of promoting family members' development vary from family to family. As a result, family members will experience increased competence, self-reliance, social skills, intellectual growth, and overall capacity for self-management among family members (Kaakinen et al., 2018; Salem et al., 2017; Shajani & Snell, 2019).

### *Effective Structuring of Family Role Relationships*

In healthy families, role relationships are structured to meet the family's changing needs over time (Kaakinen et al., 2018). In a stable society, families establish members' roles and tasks to maintain workable patterns throughout the life of the family. There is high role consistency because family members experience little to no external pressure or the need to change their role(s).

In a technologically advanced society, most families establish roles for the changing family needs that are created by external forces. The degree of role consistency is highly influenced by the permanency of the external forces on the family members' roles and expected tasks. Finally, changing life cycle stages require alterations in the structure of relationships. With each stage, family members change in their developmental needs so that the family must adapt their roles, tasks, and controls in a healthy family (Kaakinen et al., 2018; Salem et al., 2017).

### *Active Coping Effort*

Healthy families actively attempt to cope with life's problems and issues. When faced with a challenge, the family assumes responsibility for coping and seeks to meet the demands of the situation (Gladding, 2019; Kaakinen et al., 2018; Nichols & Davis, 2019).

Family members may pursue treatment opportunities for other family members in order to maintain the health of the family. The collective support of family members may be essential for a family member to acquire any type

of assistance outside the family. Clearly, the healthy family recognizes the need for assistance, accepts help, and pursues opportunities to eliminate or decrease the stressors that affect it ([Gladding, 2019](#); [Salem et al., 2017](#)).

Even if most healthy families are dealing with less dramatic, day-to-day changes, the healthy families remain receptive to innovation, new ideas, and creative and energetic ways to solve problems. Moreover, healthy families actively seek and use a variety of resources to solve problems, which may be internal or external within the family.

### *Healthy Environment and Lifestyle*

Another sign of a healthy family is a healthy home environment and lifestyle. Healthy families maintain safe and hygienic living conditions for their members. Steps are taken to minimize the risk of damage to any family member while maximizing the potential for health within the family.

A healthy family lifestyle encourages family members to find balance or harmony in their lives so that the family will have sufficient energies for daily living. A balanced and varied family diet is nutritious and appealing. Adequate physical activity helps to maintain a healthy weight while promoting cardiac health. Family members seek out and use health care services and demonstrate adherence to recommended regimens. The emotional climate of a healthy family is positive and supportive of growth. Contributing to this healthful emotional climate is a strong sense of shared values, often combined with a strong moral ethical orientation. When the home environment makes family members feel welcomed, they express their individuality in simple ways ([Gladding, 2019](#)).

### *Regular Links With the Broader Community*

Healthy families maintain dynamic ties with the broader community. They participate regularly in external groups and activities. They use external resources suited to family needs.

Healthy families also show an interest in current events and attempt to understand significant social, economic, and political issues. The families are exposed to a wider range of alternatives and a variety of contacts, which can increase options for finding resources and strengthen coping skills. Public health nurses need to assess and encourage family's involvement within the broader community as it facilitates a relationship between the family and the community ([Kaakinen et al., 2018](#)).

# FAMILY HEALTH NURSING: PREPARING FOR THE HOME VISIT

Because the nurse encounters most family members in their homes and neighborhoods, the focus of this section is on the home visit (Fig. 14-4). However, some nurses encounter families in other settings in the community, including on the streets, in homeless shelters, and in the homes of relatives or friends. For more on family health nursing in nonhome community settings, see Box 14-6. Regardless of the family's location, the family is the client; the family is the unit of service in public health nursing (Kaakinen et al., 2018).

**FIGURE 14-4** Family health assessments are foundational to the community/public health nurse's work with families.

**BOX 14-6 Working With Families in Nonhome Community Settings** There is a variety of nonhome settings or public places for visits to accommodate the family's schedules and routines provided the family member is comfortable with

**the nonhome setting. A visit may occur during a lunch break, after work/school, in a day care or senior center, or public setting. Be mindful of maintaining a confidential atmosphere.**

Visiting a family member in public places can enhance the family assessment. The nurse can assess an individual's ability to function outside the home setting. It decreases the potential of issues in the home impacting the individual's response(s) to the questions. The family member may feel comfortable talking about problems and issues related to the home environment from other family members such as parents.

In the unique setting of the patient's home, the nurse is permitted into the most intimate of spaces that human beings have. The key to this privilege is trust. Family members must have a certain amount of trust to let a stranger and representative of a governmental agency into their home. Family members believe that you are there to help enhance their ability to function as a healthy family with internal and external resources. In the same manner, the nurse must have a certain amount of trust to enter the family's home. Once the door closes, the nurse enters the client's world where they are the experts, and the nurse is the guest, a stranger. Nevertheless, you are trusting that the family welcomes your visit and is ready to work with you for healthier outcomes.

To be best prepared to enter a client's home, you must have an understanding of the skills of observation and communication, the components of the home visit, the various purposes for the home visit, and how to maintain your own personal safety while making the home visit. These topics are covered below. For general guidelines on public health nursing practice when the family is the client, see [Box 14-7](#).

**BOX 14-7 Public Health Nursing Practice Guidelines for Working With Families** The family is the unit of service in public health nursing ([Kaakinen et al., 2018](#)). The nurse assesses the family

**to determine what services are needed to move the family to a state of health, which can be determined by using five guidelines for practice.**

**Work With the Family Collectively** The family is a group of several persons living together with a collective personality, collective interests, and a collective set of needs. The family functions collectively as a single entity with common attributes and activities so that all family members are involved in the nurse–client interactions ([Gladding, 2019](#); [Shajani & Snell, 2019](#)).

**Start at the Family's Present Level of Functioning** The C/PHN begins by conducting a detailed family assessment to ascertain the needs and health level of each family member. The nurse can also recognize patterns of behaviors to determine collective interests, concerns, problems, risks, and priorities.

**Adapt the Nursing Intervention to the Family's Stage of Development** Every family engages in the same basic functioning but not the same approaches to accomplish these functions within the family's development. A young family meets the family members' affiliation needs by establishing mutually satisfying relationships and meaningful communication patterns. The bonds of a family in the later

**stages of development change due to some family members becoming part of another family unit or family member(s) dying (Box 14-8). With this assessment, the nurse recognizes the family's appropriate level of functioning, determines the problems/risks, and implements the tailored interventions needed to move the family to a state of health (Kaakinen et al., 2018; Shajani & Snell, 2019).**

**Recognize the Validity of Family Structure Variations C/PHNs work with families from communities with varying family structures and individualized patterns of family functioning. The nurse must learn to understand and accept variations in family structure to address the needs of the families. Two principles guide this acceptance and understanding (Kaakinen et al., 2018; Sperry, 2019; Shajani & Snell, 2019):**

1. *Principle One*—Each family is unique in its combination of structures, composition, roles, and behaviors. This uniqueness is valid, while family functions effectively and demonstrates the characteristics of a healthy family.
2. *Principle Two*—Families are constantly changing throughout the life cycle, which leads to a family to adapt to its circumstances.

There may be a change in the family structure and the family members' roles due to internal and external environmental issues from the addition, loss, or alteration of persons related to the family. It is the C/PHN's responsibility to help the family to cope with these changes with a nonjudgmental and acceptance manner about the family structure. A nurse personally may find it difficult to work with same-sex couples or respect same-sex marriages because this lifestyle conflicts with the nurse's personal set of values. As a professional, however, it is the nurse's responsibility to help promote the collective health of that family because all families are

unique groups, each with its own set of needs that are best served through unbiased care.

**Empower Families Throughout the family visit, the public health nurse realizes that the ultimate goal is to assist the family in becoming independent of services (Kaakinen et al., 2018; Salem et al., 2017; Sperry, 2019). This positive outcome is accomplished via the working nurse–family relationship, which can be guided by four suggestions:**

- The current functioning of the family has worked for the family before meeting you.
- Before doing “something” for a family, consider who did this “something” before you.
- Find family strengths even in the most challenging and compromised family situation.
- Think about your ability to manage, cope, or function as well as the family members if you were in a similar situation.

With an **asset-based approach**, the nurse collaborates with the family to discern the family's strengths and positive potentiality embedded in the family weaknesses so that independence from the agency's services reflects a positive outcome (Marshall & Easton, 2018). Regrettably, too often, C/PHNs perceive family weaknesses as *needs* or *problems*, which can undermine any hope of a therapeutic relationship between nurse and family as well as the use of an asset-based approach. It is the nurse's job to recognize the strengths in families and to help families recognize them and understand their potential for self-efficacy (Kaakinen et al., 2018; Shajani & Snell, 2019). The asset-based approach fosters a positive self-image, promotes self-confidence and self-efficacy, and often helps a family feel better able to address other problems as they arise (Marshall & Easton, 2018). Furthermore, C/PHNs need to ensure that whatever assistance they offer/provide to a family will promote the family's independence and self-efficacy.

The C/PHN should be able to say, at the least, that the family is managing as best as possible so that the assessment can explore all aspects of family functioning, positive and negative. It also emphasizes the positive outcomes, indicating to the family that they are important to the nurse—creating a collaborative relationship.

One helpful communication technique is **strengthening**, which involves verbally listing the positive aspects of an otherwise negative situation in a natural and conversational manner (Gladding, 2019). This strengthening technique empowers the family through positivism instead of negativity that may be viewed by the family as condescending or punitive. Strengthening also facilitates the use of the nurse as a resource and guide (Shajani & Snell, 2019).

Through empowerment, the family can meet the needs of each family member and the demands made by systems outside the family unit. Of course, all behaviors must first be assessed in terms of promoting the family functioning before deemed a strength. Some behaviors that are considered as strengths are related to basic family functions, family developmental tasks, and characteristics of family health. Thus, it is the context in which the behavior exists that makes it a strength, not the behavior alone.

## **BOX 14-8 STORIES FROM THE FIELD**

**Factoring in the Ravina Family's Stage of Development** The Ravinas, a couple in their early 70s, recently moved to a retirement complex. They had received nursing visits after Mrs. Ravina's stroke 3 years earlier but requested service now because Mr. Ravina was feeling “poorly” all the time. He thought that perhaps his diet and lack of activity might be the cause and hoped the nurse might have some helpful suggestions. The couple had eagerly awaited Mr. Ravina's retirement from teaching, with plans to be lazy, travel, visit all their children, and do all those things they never had time to do when they were young. Now, neither of them seemed to have enough energy or the capacity to enjoy their new life. The move from their home of 28 years had been difficult: they

**were still trying to find space in the tiny apartment for their cherished books and mementos, although they had given many items away.**

Ronald Bell, a C/PHN, recognized that the Ravinas were experiencing a situational crisis (leaving their home of 28 years) and a developmental crisis (aging and entering retirement) and may perhaps have some underlying health problems. Many of the Ravinas' expectations for this new life stage were unrealistic; they had not adequately prepared themselves for the adjustments that the loss of their home and retirement would demand. Through discussion, Ronald was able to help the Ravina family understand their situation and express their feelings. He completed physical assessments on the Ravinas and encouraged regular follow-up with their health care provider. He also helped them join a support group of retired persons who were experiencing some of the same difficulties. Because this nurse was able to help the Ravina family through their crisis in a supportive and nonjudgmental manner, he found them receptive later to discussing preparation for the inevitable loss and bereavement that would occur when one of them died. He was adapting his nursing intervention to this family's stage of development.

1. *What concerns might the C/PHN have in this situation?*
2. *What strategies might the C/PHN employ for this situation?*

## Skills Used During the Home Visit

Many skills are needed when assessing, diagnosing, planning, implementing, and evaluating families in their home at a variety of functional levels. Expert interviewing skills and effective communication techniques are essential for effective family intervention (see [Chapter 10](#)). It is equally important to enhance these established techniques with your relational skills (e.g., intuition, openness, nurturing, and compassion) ([Stastny, Keens, & Alkon, 2016](#)). A trusting relationship is the key to a productive home health visit and effective use of nursing skills ([Healthy Families America, 2019](#)). Through home visits nurses can assist families in promoting nurturing relationships leading to stronger family-centered healthy development ([Healthy Families America, 2019](#)). The following paragraphs describe special skills required when making home visits.

### *Acute Observational Skills*

You will be using your acute observational skills to assess both the family and the environment, which are equally important for a detailed assessment. This refers to the ability to take note of every detail (physical and nonphysical) that is directly and indirectly related to the family, the environment, the visit, and the entire process. Throughout the visit, the nurse focuses on the family members' concerns and the purpose of the visit, while being observant about the neighborhood, travel safety, home environmental conditions, number of household members, client demeanor, and body language, as well as other nonverbal cues. All this information contributes to understanding the family, identifying patterns, and recognizing how to navigate the neighborhood. Addresses on referrals may be incorrect, incomplete, or generally dubious. Confirm with the referring agency to identify any anomalies and environmental conditions of the neighborhood.

### *Observation of Home and Neighborhood Environmental Conditions*

Conditions in the neighborhood and home environments reveal important information that can guide diagnosing, planning, and intervention with families. While traveling to and arriving at the family home, you have been gathering information about the neighborhood conditions and the physical appearance of the apartment or house. Observing the home environment conditions provides an assessment about the resources and barriers encountered by the family. The external environment may contradict the family's values, resources, and goals. They may have little control over the neighborhood or the building in which they live, especially if they are

renting. While these external factors may influence the behavior of the family, they may not define the behavior.

### *Observation of Body Language and Other Nonverbal Cues*

You gather data as soon as you knock on the door or ring the doorbell, greet the people in the doorway, and enter the home (Box 14-9). Observations of previsit nonverbal cues and body language contribute to your initial opinions and perceptions about the family. Also, *all* family members (present or absent) are doing the same with you (Box 14-10). Thus, you need to be aware of all family members; acknowledge and greet them. Inquire about those who are absent. Make this a habit on all visits. Each family member has opinions and health care needs, even if you only see certain members of the family on each visit.

#### **BOX 14-9 STORIES FROM THE FIELD**

**A Home Visit to James Cutler and Brian Hoag**  
James Cutler and Brian Hoag have a 6-year monogamous relationship. A same-sex couple, they worked with an attorney to privately adopt a child. The arrangements were completed and their 2-week-old son, Adrian, arrived in their home last week. Helen Jeffers, a public health nurse, receives a referral from the county hospital where Adrian was born. The request is for an assessment of the home situation and parenting skills. At the hospital, the baby tested positive for cocaine with APGAR scores of 6 and 8 and had some initial difficulty sucking. Birth weight was 2,900 g. Discharge weight, at 3 days, was 2,850 g. At her first home visit, Helen finds a neat and orderly two-bedroom condominium that is well equipped with baby

**supplies. The infant has gained 200 g and is being well cared for by two fatigued parents whose previous contact with infants was limited. James and Brian have many questions and are anxious learners. Helen plans with the couple to make weekly home visits to assess infant growth and development, provide support, and answer questions. She suggests a neighborhood parenting class and finding a reliable babysitter. She also helps James and Brian develop an infant care work schedule. After 6 weeks of intervention, Adrian is thriving. Helen closes the case to home visits, feeling confident that the parents' goal of becoming knowledgeable and confident has been achieved.**

- 1. As the C/PHN, identify the family life cycle and developmental tasks of this family.*
- 2. How can the C/PHN support this family in health promotion and education?*

## **BOX 14-10 PERSPECTIVES**

**A C/PHN Nursing Instructor's Viewpoint on Home Visits—How Your Knock Helps Families Open the Door** This question may seem trite, but how do you knock on the door when you visit a family? Do you use the “I don't want to be here,

**and if they don't hear the knock I can quickly and quietly leave” type of knock that even Superman can't hear? Or do you knock like, “I'm a bill collector and *you better* open this door!” During this knock, the entire family may be running out the back door or through a window! The preferred knock is loud enough to be heard, yet friendly and nonthreatening. If necessary, practice “your knock” until you can create this beneficial combination.**

With some families, it is helpful to call toward the door as you knock or ring the bell with, “Mrs. Smith, this is Jenny from the Health Department—remember I was coming by today,” or “Ms. Jiminez, it's the student public health nurse, Terry De Leon, and I brought some pamphlets for you,” or “Hello, it's James from the neighborhood clinic; we planned to meet today.” Using such a greeting allows the family to know who is at the door and choose to open the door if they want. It will get you into more homes than the “quiet-as-a-mouse” or “bill-collector” knocks.

—Alice K., PHN

Be observant of the family's nonverbal cues such as body language and demeanor because they provide information that must not be overlooked. Opening statements such as “You seem anxious today,” or “Did I come at a bad time? You seem distracted,” will encourage family members to express what is on their minds, which otherwise might not be indicated or addressed. Through their facial expressions, hand gestures, subtle glances, eye movement, and body language, detailed information will be generated to address both direct and indirect concerns of the family. Overlooking the body language makes it easy to continue with *your* agenda instead of the *family member's* agenda, although the family is distracted by another, more pressing issue.

### *Nonverbal Communication*

It is equally important to be aware of your body language that can tell the family a great deal about how you feel being in their home, dealing with the family members, and completing the home visit. Suggestive behaviors like fidgeting with car keys during the entire visit or appearing to be in a hurry or

rushed can be perceived as nervousness, anxious, or not wanting to be in the current situation. Minimal eye contact or continuously looking at your paperwork may be viewed as rudeness, unprofessionalism, and unknowledgeable about the family and/or the purpose of the visit. Your “fear” can be implied from the refusal to sit on any of the furniture or a shocked expression from a roach or mouse scampering across the floor. Your behavior impacts the family's trust in you, subsequent visits, and interventions.

## Components of the Family Health Visit

The components of the family health visits align with the nursing process. Previsit preparation steps encompass assessment, diagnosing, and planning, which are necessary for implementation or completion of the actual family health visit. The documentation and planning for the next visit (or evaluation) terminates one visit and prepares the nurse for the next action needed.

### *Previsit Preparation*

Public health nurses identify preliminary family diagnoses and design a plan for the initial family health visit based on a referral to the agency. A **referral** is a request for service from another agency or person. They are the source of new cases and need timely responses. This request can be a form letter or the transfer of information from the originating agency to the receiving agency. Referrals may be formal (from physicians or complementary agencies) or informal (verbal or telephone referrals from friends or relatives who believe that someone needs help). Some examples include:

- Labor and delivery hospital units request service for low-birth-weight babies and teen mothers.
- Social service agencies request a home assessment for a child being returned to parents after previous removal.
- A homeless shelter might be seeking services for homeless or transient persons showing signs of uncontrolled diabetes.
- A battered woman's shelter needs services to treat emotional issues of a mother and her children who are running from an abusive husband and father.
- A woman in a city 500 miles away requests that a nurse check on an elderly relative who lives alone in the community and has recently exhibited slurred speech and/or has been homebound.

Follow-up visits are based on the family's needs and agency protocol. Public health nurses must be equipped with the appropriate tools to establish a physical place to work:

- Access to a telephone, the Internet, and other necessary resources
  - Educational material (pamphlets, brochures, and related Web information)
  - Charting tools
  - Any other supplies required for home visits
- **Resource directory**, which is a list of resources for the broader community, or a nurse-made directory of resources created over years of

working with people in the community

- A nursing bag or carryall tote (issued by agency or devised by the nurse) for medical supplies
  - Specialized supplies depending on the visit (a tote for each type of visit)
  - Basic supplies to treat basic needs of a new mother and her infant or an elderly man with hypertension

Once the nurse is prepared, the family is contacted to schedule a visit. The referral ideally contains a correct telephone number for the family, a relative, or a neighbor. The nurse needs to extract as much information as possible from the referral so that the preparation can be exact and specific for the health visit. This sets the stage for a detailed assessment, appropriate family diagnosing, and family-oriented care planning (Arbaje et al., 2018). If the referral does not contain this information, an unannounced visit is scheduled. During this visit, it is important to get a contact number for the family. When calling for the first time, you, the C/PHN, will:

1. Introduce yourself
2. Explain the reason for the call
3. Give the reason why the family was referred
4. Indicate what the visit consists of
5. Determine when a visit would be convenient for the family and you
6. Get explicit directions to where the family is staying (the referral may have a different address, or the family did not mention that they are staying elsewhere)
7. Repeat the date and time of the scheduled visit

The nurse's intention(s) may be questioned with some people becoming defensive or suspicious. A new young mother may wonder, "Why is this nurse visiting me so close to my time in the hospital? Did I say or do something wrong with my baby when I was in the hospital?" The C/PHN will explain that:

- The visit is a follow-up one to see if the move from the hospital to home is okay.
- The visit is an opportunity for her to ask questions that she might have about her new baby since her return home. It is also a chance to learn more about handling her baby in the home if needed.
- The visit is a service provided by the agency to all mothers.
- The visit is paid for by taxes or donations, or by the client's health maintenance organization (if applicable). There is no direct cost to her or the family.

Following logical steps in the previsit preparation enhances the nurse's confidence in her or his ability to intuitively recognize patterns and/or trends from the referral information for preliminary diagnoses to guide preliminary care planning.

## *Making the Visit*

It is recommended to call the family to remind them of the scheduled meeting and your arrival time prior to the scheduled visit. State the purpose of the visit and the anticipated length of time needed. Once you arrive, the following guidelines for initial contact should be used (Kaakinen et al., 2018):

1. Engage the family in a manner to build a supportive and trusting relationship (Box 14-11).
  - a. Introduce yourself to the family.
  - b. Explain the value of the nursing services provided by the agency.
  - c. Spend the first few minutes of the visit establishing cordiality and getting acquainted (a mutual discovery or “feeling out” time).
  - d. Become acquainted with all family and household members if you are making a home visit.
  - e. Encourage each person to speak for himself.

**BOX 14-11 Developing a Trusting Relationship with the Stevenson Family**  
The public health nurse, David Dow, made an initial home visit after referral by an outpatient physician who was concerned about possible child abuse. The physician suspected abuse after seeing bruises on the arm of a baby boy (Eugene) who was in the emergency room for treatment of a laceration on the forehead. Alice Stevenson, the mother, claimed that the laceration resulted from Eugene falling off a table when she was changing him. She also explained that the bruise happened when Phillip (Eugene's older brother)

was playing too rough. David began the visit by stating that he was simply following up on the emergency room visit and wanted to see how Eugene was progressing. David made no mention of child abuse. He simply observed Alice and the children closely to learn more about the family's background and used the strengthening technique to create a trusting relationship interaction. Due to David's supportive demeanor, Alice agreed to further visits, and at one of the visits, Alice confessed that her ring cut Eugene's forehead when she slapped him. "I could not get him to stop crying, no matter what I did," she whimpered. "I just could not endure it any longer." She also confessed that the bruises happened when she, not Phillip, grabbed Eugene roughly to stop him from pulling and touching things he should not. David learned that Alice's husband abandoned her while she was still pregnant with Eugene. David realized that Alice would be particularly vulnerable to any criticism, so he

**concentrated on her strengths such as managing the home, dressing the children, and reading to little Eugene. During subsequent visits, Alice and David were able to discuss her feelings frankly and work toward improving the health of the Stevenson family. Alice started counseling and attended a support group for single parents counseling.**

2. Use acute observational skills.
  - a. Use your “sixth sense” or intuition as a guide regarding family responses, questions they ask, and your personal safety (trust your feelings).
  - b. Be sensitive to verbal and nonverbal cues.
  - c. Be accepting and listen carefully.
  - d. Be cognizant of possible internal and external stressors and effect on mental status of family.
  - e. Be aware of your own personality—balance talking and listening—and be aware of your nonverbal behaviors.
3. Help the family focus on issues and move toward the desired goals.
  - a. Be adaptable and flexible (you may be planning a prenatal visit, but the woman delivered her baby the day after you made the appointment, and now there is a newborn).
  - b. Be aware that most clients are not extremely ill and have higher levels of wellness than are generally seen in acute care settings.
  - c. Be prepared to develop a sustained continuity of care by actively collaborating with the family in addressing their issues.
4. Near the end of the visit, review the important points and emphasize the family strengths.
5. Plan with the family for the next visit.

The length of the visit varies depending on its purpose and can influence the C/PHN–family relationship.

#### **Less than a 20-minute visit**

- Not enough time for a thorough assessment, but ideal for
  - Dropping off supplies
  - Relaying information about a referral
  - Stopping by at the family's request, for instance

### **More than a 60-minute visit**

- Avoid; not a productive way to provide nursing services.
- Any lengthy assessments should be conducted over two visits.
- Disruptive to the family with the potential for unwanted outcomes.
  - Families have routines that are important to them.
  - The family may feel that nothing of value occurred during a visit.
  - The family may not continue to make themselves available for future visits. This becomes a balancing act for the family and the nurse, and you may want to work at picking up on nonverbal cues.
- May reflect the nurse's hesitation in trusting the family to understand and/or follow the instructions and feedback.
- Limits the family's ability to seek out community resources for community-based health care.

Remember, the outcome of better health for family members must be demonstrated in order to support and validate the value, as well as justify the cost of public health nursing services.

## *Concluding and Documenting the Visit*

The current home visit concludes after planning for the follow-up visit with the family. You will say goodbye and pack up any paperwork, materials, and supplies used for this visit in your car. Before leaving this community, you need to get ready for the next home visit on your schedule. By arriving prepared at the next home, you demonstrate respect for the family's time, efficiency, and professionalism (Arbaje et al., 2018).

Documentation or charting of each home visit used to be typically completed as soon as the nurse returned to the agency. Today, it is recommended that charting happens *immediately* at the end of the home visit (not upon arrival at the next one) on an agency-provided device (laptop, smartphone, or tablet) linked to electronic charting forms and records (Arbaje et al., 2018). For the most part, most agencies expect the charting to be completed as soon as practically possible in that workday.

Agencies use a variety of forms that assist the nurse to document fully and succinctly. Some forms use a checklist format that contains code numbers, letters, or checkmarks on developmental or disease-specific care

plans. A four-paged postpartum visit and newborn assessment may consist of two narrative forms to chart the expectations for the mother and baby plus two forms for the head-to-toe assessment of the newborn. There is a place to document parent teaching within the expected parameters and for listing other professionals' involvement with the family. Other forms may focus on chronic illness common in the agency's clientele (e.g., alcoholism, chronic obstructive pulmonary disease, communicable diseases diabetes, HIV/AIDS, hypertension).

## **Focus of the Family Health Visit**

The focus of family health visits depends on the agency's mission and resources or services and the needs of the families. Some agencies provide education, recreational activities, and support groups for families of persons with Alzheimer's disease, asthma, or diabetes. Other agencies provide services to address issues related to immigration, poverty, and/or homelessness (Beck et al., 2017; de Grubb et al., 2017; Lee et al., 2017). In general, family health visits are designed to educate, provide anticipatory guidance, and focus on health promotion or prevention.

### *Family Education and Anticipatory Guidance*

Local health departments distribute their services based on the broader community's needs. The health department may contract with health care providers to treat a community with a high rate of teen pregnancies and high-risk infants through home or clinic visits to all teens and women with high-risk pregnancies and their newborns after delivery (Tachibana et al., 2019). The treatment involves teaching prenatal, postpartum, and newborn care and providing anticipatory guidance to promote regular health care provider visits for the infant, immunizations, and safety awareness. The health department may address the needs of another community with a significant number of older adults or migrant workers who need to learn how to manage a chronic illness, enhance their nutrition, and practice safety measures to prevent injuries and falls (Coker et al., 2019; Frost et al., 2019).

### *Family Promotion and Illness Prevention*

Family members can be taught health promotion activities for healthy living even within the limitations of chronic illnesses. These activities may include screening for hypertension and elevated cholesterol, performing a physical assessment, teaching about nutrition and safety, and promoting immunization.

Immunizations protect the health of all individuals and the larger community. Although such services are not brought into the home, it remains the C/PHN's responsibility to provide information about immunizations, teach the importance of following an immunization schedule, and follow up with the family during home visits. A focus on population health shifts care to the needs of the community and strengthens the focus on aggregate health promotion strategies that optimize personal health (APHN, 2016a, 2016b). Adding social determinants of health also contributes to the ultimate goal of creating “social, physical, and economic environments that promote attaining

the full potential for health and wellbeing for all” (USDHHS, 2020, para. 4; see [Box 14-12](#)).

## **BOX 14-12 HEALTHY PEOPLE 2030**

### **Selected Goals and Objectives Related to Family Health**

#### **Family Planning**

##### **Core Objectives**

FP-01	Reduce the proportion of unintended pregnancies
FP-02	Reduce the proportion of pregnancies conceived within 18 months of a previous birth
FP-03	Reduce pregnancies in adolescents
FP-04	Increase the proportion of adolescents who have never had sex
FP-05	Increase the proportion of adolescent females who used effective birth control the last time they had sex
FP-06	Increase the proportion of adolescent males who used a condom the last time they had sex
FP-07	Increase the proportion of adolescents who use birth control the first time they have sex
FP-08	Increase the proportion of adolescents who get formal sex education before age 18 years
FP-09	Increase the proportion of women who get needed publicly funded birth control services and support
FP-10	Increase the proportion of women at risk for unintended pregnancy who use effective birth control
FP-11	Increase the proportion of adolescent females at risk for unintended pregnancy who use birth control

##### **Developmental Objectives**

FP-D01	Increase the proportion of publicly funded clinics that offer the full range of reversible birth control
--------	--

#### **Adolescent Health**

##### **Core Objectives**

AH-01	Increase the proportion of adolescents who had a preventative health care visit in the past year
AH-02	Increase the proportion of adolescents who speak privately with a provider at a preventive medical visit
AH-03	Increase the proportion of adolescents who have an adult they can talk to about serious problems
AH-04	Increase the proportion of students participating in the School Breakfast Program
AH-05	Increase the proportion of 4th-graders with reading skills at or above the proficient level
AD-06	Increase the proportion of 4th-graders with math skills at or above the proficient level
AH-07	Reduce chronic school absence among early adolescent
AH-08	Increase the proportion of high school students who graduate in 4 years

##### **Developmental Objectives**

IVP-D03	Reduce the number of young adults who report 3 or more adverse childhood experiences
EH-D01	Increase the proportion of schools with policies and practices that promote health and safety

#### **Maternal, Infant, and Child Health**

##### **Core Objectives**

##### **Morbidity and Mortality**

MICH-01	Reduce the rate of fetal deaths at 20 or more weeks of gestation
MICH-02	reduce the rate of infant deaths

##### **Infant Care**

MICH-14	Increase the proportion of infants who are put to sleep on their backs
MICH-15	Increase the proportion of infants who are breastfeed exclusively through age 6 months

### **Health Services**

MICH-08	Increase the proportion of pregnant women who receive early and adequate prenatal care
MICH-19	Increase the proportion of children and adolescents who receive care in a medical home
MICH-20	Increase the proportion of children and adolescents with special health care needs who have a system of care

### **Developmental Objectives**

MICH-D01	Increase the proportion of women who get screened for postpartum depression
----------	---

C/PHNs provide health promotion services during a family health visit in any setting. During prenatal classes, the C/PHN teaches couples about the expected changes during pregnancy and provides anticipatory guidance for safe infant care and postpartum care (Mutch, 2016). The C/PHN screens older adults for hypertension or elevated cholesterol at the senior center, educates family members attending Alcoholics Anonymous, or provides mental and health assessments for homeless persons in shelters.

## Personal Safety During the Home Visit

Being streetwise is essential when interacting and traveling throughout communities. Continuation of personal safety must be considered while maintaining respect for the families, a trusting relationship, and professionalism.

### *Traveling to and in the Neighborhood*

When leaving your “base of operation,” make sure you have all the necessary supplies, materials, and paperwork for the scheduled home visits. To ensure safety and promote coordination with your agency, always inform your agency about your planned itinerary and all contact information (your mobile phone number and telephone numbers of families scheduled to visit) so that the agency can promptly reach you (Arbaje et al., 2018). Traveling safely in a community can mean different things to different people.

Traveling in an agency or private car requires

- A full gas tank
- Addresses for families you are visiting, city/county map, or GPS
- A cell phone

Using public transportation requires

- Change/bus card or smartphone app for each bus trip
- A current bus schedule
- Knowledge of the exit at the bus stop closest to your family's home
- Knowledge of the bus stop for the return trip to agency or to the next home visit
- A cell phone

You should *always* call ahead to the family and give them an estimated time of your arrival. Be “streetwise” when walking in neighborhoods. A C/PHN understands the value of safety measures used by expert nurses, following these measures for personal safety, and not challenging them. Another focus of concern is the perceived risk to self when making a home visit. Feeling and being safe can relate to the nurse's perception of a situation, views on risk-taking, awareness of the traveling conditions (e.g., the time and/or the setting), and coping process. What one person sees as a risk, another sees as a challenge or an opportunity, and another may see nothing. We each perceive risks differently based on knowledge, experience, and personality.

## *Arriving at the Home*

Make sure you are at the right house. Do not go into the home until you are assured that the family you are intending to visit does live there and is home. You are scheduled to visit 16-year-old Jennifer and her 5-day-old infant, Marcus. A 50-year-old man answers the door when you knock. Give your name and ask if Jennifer can come to the door because you are here to see her. Do not enter the house even if he invites you in to wait for Jennifer. Smile and let him know that you are comfortable waiting for Jennifer at the door. Remain outside the house and go inside *only after* you talk to Jennifer at the door. This precaution ensures that the family members you want to visit are in the house and that this is the right address.

## *Dealing With Challenging Situations*

Due to the nature of the home setting, you may encounter unexpected and challenging situations, including family conflict, family members under the influence, and the presence of strangers.

## *Friction Between Family Members*

During a home visit, two or more family members may begin to argue or physically fight. You should immediately terminate the visit and inform the family what will take place regarding the home visit. Follow these steps:

1. Inform the family that the visit is now terminated.
2. Calmly let the family know that such distraction takes away from the purpose of the visit.
3. Inform the family that you will return at another convenient time.
4. Calmly and quickly remove yourself from the home.

When two or more family members are physically fighting, never intervene, try to stop the fight, serve as a referee, or assist an adult family member. You may be the next victim. Once you are out of the house, call 911, if necessary, from your cell phone. Once you are safe, rely on your acute observation skills to recall the altercation. This data may provide significant information about the family's structure, process, and health. Depending on your assessment and processing of the information, it may be appropriate to discuss the altercation and the friction in the family at a later visit.

## *Family Members Under the Influence*

If the focus of the visit is on two family members, but a third member's behavior suggests the use of drugs or alcohol, use your judgment as to the best action to take. It is important for you to assess the situation and proceed accordingly within the parameters of guidelines provided by your agency or your school. If the intoxicated or high person goes to another room and

remains quiet/calm, it might be appropriate to continue the visit. You might want to discuss your observations with the two family members. If the intoxicated or high person remains in another room but interrupts the visit by being abusive or distracting, it is best to terminate the visit. Let the two family members know that you want to reschedule when the intoxicated or high family member is not under the influence or is not present. Never put yourself in the middle of a situation that could deteriorate rapidly and compromise your safety.

### *The Presence of Strangers*

In some families, it is common to have extended family members, neighbors, and friends present in the home. This may be the norm for the family but not for the nurse because it is a different setting from her or his experience. The nurse may have to weave your way past five teenage boys sitting on the front stoop in order to enter the home and step over three men sleeping on the living room floor in the small apartment of a teenage mother and her infant. Children may be riding their tricycles inside the house during a teaching visit to two young parents who do not seem fazed by the commotion. These situations may not be indicative of danger, but they can make you feel vulnerable and uncomfortable, while distracting you from the purpose of the visit. Always rely on your observation skills; inquire about the people you observe in the periphery of the home visit; ask about their relationship to the family and if they should be included in the visit. The family may suggest that you ignore these people or say they are transient family members. It may be important to learn who they are, if they have unmet health care needs, or if their presence influences the health of the family you are visiting.

# APPLYING THE NURSING PROCESS TO FAMILY HEALTH

The nursing process (assessing, diagnosing, planning, implementing, and evaluating nursing care) includes steps used to deliver care to families and aggregates in community health settings. These steps are, interestingly, the same ones used to care for clients in acute care settings and in the extensive clinic system. The difference in implementing this process in family health nursing is the context (the home), the client focus (the family), and the consideration of external variables not typically encountered in other contexts. In public health nursing, addressing the health needs of the core unit of service (in this case, the family) should always transition to addressing the health needs of the community and the population. The context and application of each step are tailored to the needs of the population by focusing on the core unit of service (APHN, 2016a, 2016b).

The nursing process commences on the first visit when the public health nurse performs an initial assessment (Box 14-13). Subsequent visits entail the nurse and the family working collectively to reach the targeted goals.

## **BOX 14-13 C/PHN Use of the Nursing Process**

### **Family Health**

- Family assessment refers to a detailed collection of information from the C/PHN's observations about the family and external environment that includes verbal cues, nonverbal cues, and what is observed as well as what is not observed (certain barriers to health care may be invisible, camouflaged as another issue, or understated).
- During the family diagnosis process, the C/PHN recognizes patterns, behaviors, constraints of health (positive and negative), and/or seen/unseen routines from the collected information during the assessment (Swartz, 2018). This step involves identifying issues, risks, concerns, and problems that can negatively and positively alter the health of the family. During the family planning of care step, targeted outcomes and goals are identified based on the patterns of unhealthy/healthy behavior and relationships.

- A plan of care is created. It includes interventions, strategies, and interactions, which involves family resources and external services to promote the health of the family.
- Implementation of family care plan involves the C/PHN collaborating with the family, community resources, and external services to organize and complete the plan of care. The family is educated about the resources and how to use them to address the health problems and promote the family health. It is equally important to include seen/unseen cultural and social issues in completing the interventions and strategies.

Finally, the evaluation step is where the entire nursing process is reviewed to determine if (1) the targeted outcomes and goals were achieved, (2) the process was a positive experience for the family, (3) new and current relationships with internal and external resources will maintain and strengthen the efforts for the family health, and (4) the family feels comfortable in participating in their care. With this understanding of the nursing process, the novice public health nurse is ready to prepare to work with families in the community (Swartz, 2018).

## Preliminary Considerations

Before implementing the nursing process, the nurse must establish (1) a conceptual framework, (2) a clearly defined set of data collection categories, and (3) a method of measuring a family's functional level.

### *Conceptual Frameworks*

A **conceptual framework** is a set of concepts integrated into a meaningful explanation (Hosseini Shokouh et al., 2017). Three conceptual frameworks are used in public health nursing: the interactional, structural–functional, and developmental (Hill & Hansen, 1960; Raingruber, 2017; Shajani & Snell, 2019).

Theories structured on the **interactional framework** focuses on the family's internal environment, their relationships. The family is a unit of interacting personalities with emphasis on communication, roles, conflict, coping patterns, and decision-making processes (Raingruber, 2017; Shajani & Snell, 2019).

The **structural–functional framework** creates a structure that focuses on the family's internal and external environments. The family is a social system with a specific structure that exists in an external environment defined by interactions with other social systems (e.g., other families, church, work, and the health care system). The family structure is used to process, analyze, and understand how the family functions in the external environment (Raingruber, 2017; Shajani & Snell, 2019).

The theories based on the **developmental framework** incorporate elements from both interactional and structural–functional frameworks. For a life cycle perspective, one examines the changing roles and tasks as family members progress through life cycle stages within the environment. Internal relationships elucidate the development of the family. External environmental influences highlight how the family is structured, functions as a social system, and interacts with other social systems. This framework gives context to the family development within the environment (2018; Raingruber, 2017; Shajani & Snell, 2019).

Even though these three core frameworks are the basis for theories and conceptual models used by C/PHNs, these frameworks are the foundations for various methods of family assessment. Their concepts have been combined to design family assessments, diagnosing process, and intervention models.

### *Data Collection Categories*

The conceptual framework gives the nurse a format to group the data about the family into specific categories in order to organize the collected data. This data may be useful for assessing, diagnosing, care planning, and serving as a guide for subsequent visits in which to obtain additional information. For an example of a data collection tool that lists 12 assessment categories in which data are grouped for three data sets (family strengths and self-care capabilities, family stresses and problems, and family resources), see [thePoint](#)<sup>®</sup> (Edelman & Kudzma, 2017).

### *Methods of Measuring a Family's Functioning*

Family function includes the relationships, interactions, and structural properties within the family system in which communication, conflict, cohesion, adaptability, and organization are assessed. The C/PHN will evaluate the strengths, resources, and protective factors of a family including any underlying behaviors that might create unsafe conditions.

## **Family Health Assessment**

A thorough family health assessment relies on the public health nurse's commitment to understand the family, to determine the value of the referred information, and to process any prior opinions about the family in order to promote family health. See [Box 14-14](#) for guidelines that can help the C/PHN conduct a detailed family assessment and organize data. See [Box 14-15](#) for an application-oriented exercise in conducting a family assessment.

### **BOX 14-14 STORIES FROM THE FIELD**

#### **Assessing the Beck Family's Nutritional Status**

**A public health nurse had an initial contact with Mr. and Mrs. Beck and their youngest child at the well-baby clinic. The 9-month-old child was over the 95th percentile for weight and at the 40th percentile for height. The nurse also noted that both parents were obese. The nurse asked about the family's eating patterns, the baby in particular, and suggested a home visit to determine whether the Becks were interested in family nursing. The nurse explained the purpose of home visits (to assess all family members, coping patterns, eating patterns, and food purchasing choices) and the importance of including all family members and asked for a time that would be good for the family as a whole. The nurse explained that each person should be involved and committed to the agreed-upon goals and that, like a team of oarsmen, the family has to pull together to accomplish the purpose of the visits. To help the**

**Beck family improve its nutritional status, the nurse might suggest a session of brainstorming to uncover many causes of poor nutrition. More brainstorming might also lead to more solutions and plans for action. On each visit, the nurse views the Becks as a group so that group responses and actions would be expected. Evaluation of outcomes will be based on what the family did collectively. The Becks were interested, and a home visit date was made.**

- 1. What developmental stages appear to have been achieved?*
- 2. What is your plan of action for this family over the next three visits?*
- 3. What are the goals for this family (immediate, midrange, and long-term)?*

## **BOX 14-15 STORIES FROM THE FIELD**

**A Family Assessment for Lorenzo You are a C/PHN assigned to a small suburb in Chicago. Your new client is Lorenzo, a 103-year-old White American male. He is being released from the geriatric ICU of Uptown Hospital after being treated for severe pneumonia, three episodes of delirium, and 2-degree bedsores. He resides in his own house in the center of Othertrackside. The local hospital is the only medical facility with a geriatric unit in a 75-mile radius that will accept Medicare clients.**

His respiratory complications started 4 weeks ago. He experienced SOB and pain with breathing after working in his garden 3+ hours at 43°F temperature while it was raining. The frequency and severity of

the respiratory problems resulted in Lorenzo significantly decreasing his activities while increasing his time in the bed. When he was rushed to the hospital, due to severe chest pains and arrhythmia, his neighbor Adam, a 97-year-old African American male, expressed to the admitted nurse, “Please fix him Ms. Nurse. He has just been lying in bed staring at the ceiling for a while now. Even at bedtime, it was like sleeping next to a dead person; he didn't even roll around or sit up. He even didn't speak to his sister and brother when they made their occasional visit or any of the neighbors who stopped by to check on us.” The nurse later discovered that Lorenzo and Adam are in a 50+ year intimate relationship.

Your job is to facilitate Lorenzo's return to his home from Uptown Hospital, assist him in regaining his preillness level of activity, and address issues affecting his mental health. The teaching over your scheduled visits will include but not limited to the following:

- Signs and symptoms warranting follow-up
- Medication and administration
- Nutrition and fluid consumption
- Bladder, bowel, skin, and mental health care
- ADLs and IADLs
- Physical activity/endurance
- Safety/injury prevention
- Altered significant other/family/neighbor processes
- Community resources

Consider the following questions:

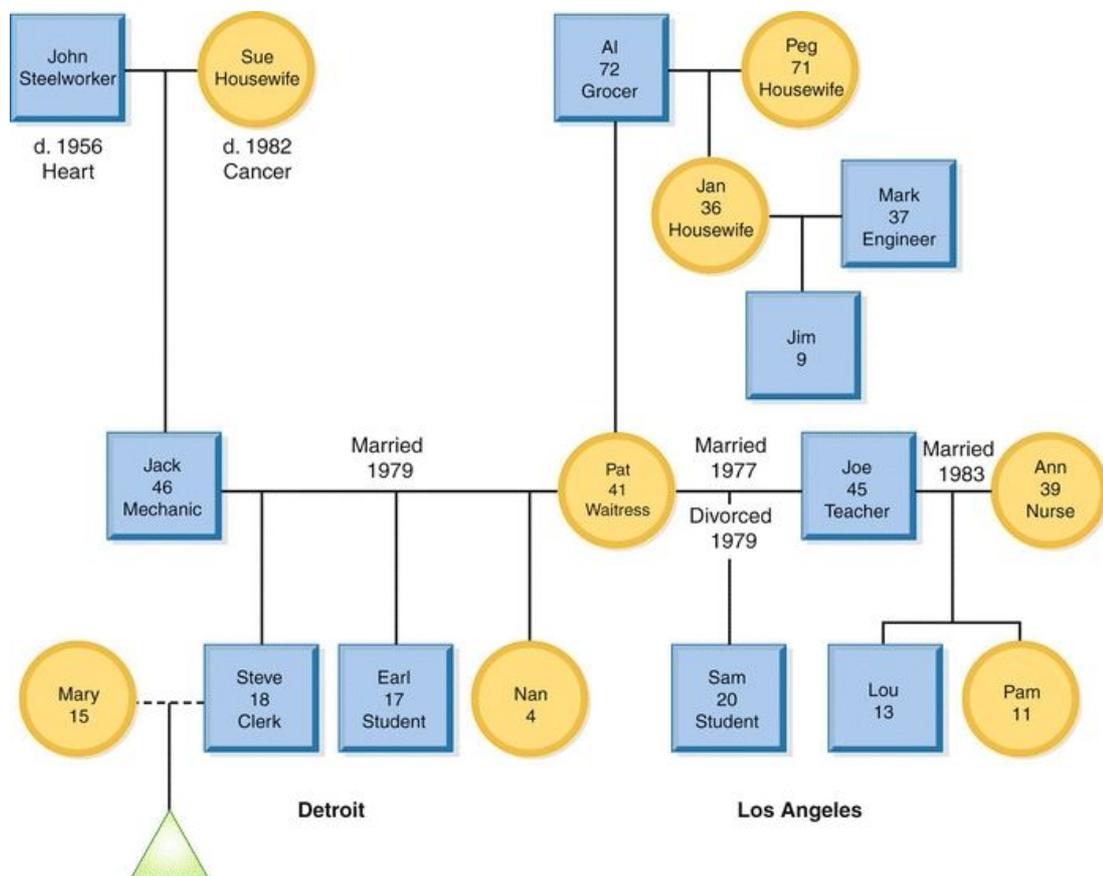

1. *How will you empower the family to avoid Lorenzo's isolation (self-imposed and socially constructed), risky behavior, and potential for noncompliance with his treatment?*
2. *How would you prioritize Lorenzo's issues, both medical and psychosocial?*
3. *As the public health nurse, what interventions can you utilize to achieve the indicated goals without offending, embarrassing, alienating, and/or “outing” the core family system?*

## *Assessment Methods*

Assessment methods generate information about selected aspects of family structure and function, while matching the purpose for assessment. An informal approach consists of the nurse's acute observational skills and occasional questioning to confirm the observations and determine the next direction to take. A formal approach entails the use of specific questions and

assessment tools to assess each family member in terms of health data, family history, physical data, family's development, or potential health problems not detected by family members.

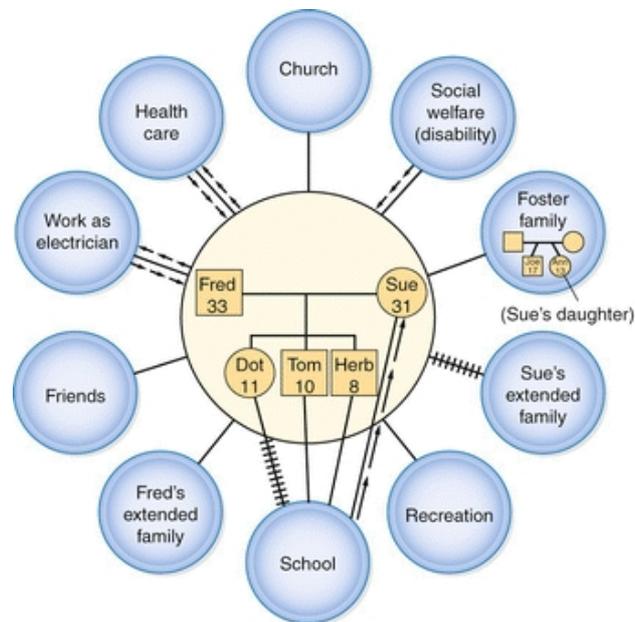

The **genogram** (Fig. 14-5) diagrams the family's genealogy, relationships, and complex family patterns. The PHN can formulate hypotheses about a family over a significant period of time and across generations (de Souza, Bellato, de Araujo, & de Almeida, 2016). Completing the genogram with the family encourages family expression, which can reveal family behavior and problems. The genogram has been useful in linking health outcomes to preventive strategies based on potential health risks and guiding clinical and public health interventions (Centers for Disease Control and Prevention [CDC], 2018).

**FIGURE 14-5** A genogram.

The **eco-map** (Fig. 14-6) shows the connections between a family and the other systems in the ecologic environment. It visually depicts dynamic family–environment interactions (de Souza et al., 2016). A central circle represents the family or family member with smaller peripheral circles indicative of people and systems significantly relating to the central circle.

Connecting lines between the central circle and smaller ones depict the strength of relationships.

**FIGURE 14-6** An eco-map of a family's relationship to its environment.

For consistency and ease of documentation, public health nursing agencies usually develop their own tools, often in the form of questionnaires, checklists, flow sheets, or interview guides (Chapman et al., 2017; Pontin et al., 2019) to fit organizational needs (for examples of family assessment tools, visit [thePoint](#)). One type of family assessment tool uses questions based on characteristics of healthy families and follows a checklist format that is useful to observe family growth or decline over a span of time. The novice C/PHN can use this tool to gather data and to document how the nurse's rapport develops with the family and the PHN's comfort level.

Another type of family assessment tool has an open-ended format that allows the nurse to create an informative document while limiting subjective observations. A self-care assessment guide examines a family member's ability to provide self-care by measuring the family's stressors and self-care practices. This tool is used adjunctively, especially with families from various cultural groups. Videotaping is a method used to assess family interactions for structured observations and analyses of life-changing events. Using it with other tools enhances the breadth of data collection.

### *Guidelines for Family Health Assessment*

There are five guidelines to use since a family health assessment results in a voluminous amount of data. These guidelines emphasize the family as the core service unit and will strengthen your ability to work collaboratively with the family—promoting a trusting relationship.

### *Focus on the Family as a Total Unit*

The family is a single core unit of service, and it is the family's aggregated behavior that is being assessed (APHN, 2016a, 2016b; Shajani & Snell, 2019). The C/PHN ensures that the information is typical of the entire family.

Getting families to share their stories can be a health promotion tool by creating meaning for individuals and the family. The story can tell nurses what is important to the family to help develop interventions. Nurses can begin by asking the family who are you from rather than where are you from? Practice telling and listening to family stories with someone (Driessnack, 2017).

When assessing the communication patterns of two family members, the nurse is also thinking about how other family members communicate among themselves and with the two being assessed. After analyzing the data, the nurse may decide that the family, as a whole, communicates well and supportively even if one family member does not. The nurse documents this deviation and considers it in the care planning.

### *Ask Goal-Directed Questions*

Goal-directed questions are the cornerstone of a detailed assessment (Sperry, 2019; Shajani & Snell, 2019). They facilitate the C/PHN in determining a family's level of health, making family diagnoses, and crafting a care plan. These relevant questions yield relevant and comprehensive data that goes beyond the family dynamics at the moment (Sperry, 2019). Examples of goal-directed questions include the following:

- Does this family recognize when a change needs to be made?
- How does the family react when a change is forced on the family?
- If a problem arises from the change, such as the baby having diarrhea or constantly crying, will the family be responsible for dealing with the problem?
- Is there a family member who knows how to solve the problem, and will this person be willing to accept outside assistance?

Thus, you watch everyone closely for signs of the family's response(s) to change and the ability to problem-solve any problems resulting from the change. Another more open-ended format or approach is to use assessment categories to stimulate questions to explore family support systems for a specific category.

## *Collect Data Over Time*

You want to take your time to accumulate observations, make notes, identify both major and minor issues, and observe the interactions of all family members (Sperry, 2019; Shajani & Snell, 2019).

Timeliness also helps to develop a trusting and supportive relationship with the family since assessment can occur during any family activity such as mealtime. The family needs to feel comfortable with you, the observing nurse. Even if the C/PHN feels welcomed and comfortable at the initial home visit, it may take the family several visits to reciprocate that level of comfort.

## *Combine Quantitative With Qualitative Data*

Both qualitative and quantitative data are collected when appraising a family's health and are used to create a database for planning care. Asking if family members engage in some type of behaviors is qualitative, and asking how often the family engages in the behaviors is quantitative.

One type of assessment tool evaluates a family's ability to enhance individuality by rating the family's behavior on a scale of 0 (never) to 4 (most of the time), which provides a way to compare the family's development over several home visits. The difference between the present and previous scores assists the C/PHN in executing the intervention(s). For this reason, it is useful to conduct periodic assessments when a case is reopened or every 3 to 6 months if it is kept open for an extended period.

## *Exercise Professional Judgment*

The content of a family assessment is driven by the nurse's professional judgment with the assessment tools guiding the nurse's observations and quantifying the nurse's decisions (McDowell & Boyd, 2018; Sperry, 2019).

The nurse may observe that a family makes good use of a community agency, but the decision that using this external resource contributes to the family's health results from a professional judgment. An assessment tool is only a tool, and its value should never be interpreted as an absolute and irrevocable statement about a family's health status.

As a professional, the C/PHN knows that the completion of an assessment tool should occur at the end of the home visit(s). The C/PHN may review the assessment tool before entering a family's home or keep it in a folder for easy reference or note during the visit. However, the assessment tool is not completed in the presence of the family. Even with an eco-map or genogram, the C/PHN uses professional judgment to determine when the family is ready.

## Family Health Diagnosis

The family diagnosing process moves the data from assessment to care planning, implementation, and evaluation. This process is an expected standard of practice for public health nurses (APHN, 2016a, 2016b). The C/PHN uses observational skills and clinical reasoning to understand the patterns in the data.

Specifically, the C/PHN identifies patterns of behavior, barriers preventing the family from being healthy, and internal relationships with the external environment (APHN, 2016a, 2016b). Next, the nurse prioritizes the information while taking the best action(s) for the desired outcome or goal (Kaakinen et al., 2018). The diagnosing process can occur as follows (Kaakinen, et al., 2018):

1. Identify the family health problems.
  - a. Determine what family members are directly and indirectly related to the problem.
  - b. Determine what factors from the external environment are related to the problem.
  - c. Describe the problem as it impacts the identified family members and external environment.
  - d. Indicate the risks that are associated with the problem(s).
  - e. Prioritize the problems along with their risks with an emphasis on the problems that are overlapping and/or have overlapping risks.
2. Indicate the factors from the family (family unit and family members) and the external environment that are associated with the health problems.
3. Determine the measurements (quantitative and qualitative data) that confirm or verify the health problems.

The diagnosing process is an ongoing one with two major goals: improve the family health and give them the tools for health promotion. It should be completed several times, especially with a lot of assessment data so that the nurse can craft a plan of care to move the family toward a state of health.

## Family Health Planning and Implementation

A formal care plan occurs after identifying the main concerns, problems, and risks. The nurse and the family collaborate to identify the problem(s), to suggest interventions, and to discuss the plan of action (Fiese, Celano, Deater-Deckard, Jouriles, & Whisman, 2018; Stastny et al., 2016; Shajani & Snell, 2019).

If there is no agreement, the data should be reviewed and discussed with family members to reach a mutual understanding about the best interventions and how to put them into action. The family needs to believe in the plan of action or the nurse will be limited in her or his efforts to prevent identified problems and/or risks while promoting the family's health (Shajani & Snell, 2019). Once family members are ready to learn ways to improve their health status, then the nurse determines the best teaching approach to use and tailors interventions to the specific family needs and functional capability (Sperry, 2019; Shajani & Snell, 2019). If the family's level of functioning does not enable them to use anticipatory guidance and teaching, then the nurse can serve as a counselor.

Planning for subsequent visits assures that the nurse is totally prepared for the next encounter with the family, assuring a successful family visit. This planning ensures that the family transitions toward a healthy outcome in the visit. Planning commences during the first home visit as the nurse collects data so that subsequent visits can be individualized and tailored to meet the family's needs, especially since this information is not available from a paper referral. Consequently, planning for the next visit will affect the nurse's continued success with the family.

Implementation includes making referrals and contacting appropriate resources.

### *Making Referrals*

The nurse makes a referral so that the family can have access to services that might be beyond the agency's resources. The referral reflects the nurse's knowledge of resources within the community, which includes the eligibility requirements and availability of services, provided by official, voluntary, religious, and neighborhood organizations (Kaakinen et al., 2018; McDowell & Boyd, 2018). The nurse must also be aware of any updates or changes to the information about these organizations. Therefore, C/PHNs need to network with colleagues on a regular basis in order to remain up-to-date with community services for family referrals (APHN, 2016a, 2016b; Kaakinen et al., 2018).

## *Contacting Resources*

Public health nurses know how to access key personnel in agencies, which can eliminate some of the red tapes involved in obtaining services, while giving family members pointers on procuring needed services. When C/PHNs seek informal services for families, the nurse establishes a relationship with the agency's staff that can help nurses secure services for the family over time. This rapport can also be used to connect with other agencies, which increases the nurse's database of services.

## Family Health Evaluation

Evaluation represents the final step in the nursing process and involves appraising the work with the family and preparing for the next visit. A formal evaluation concludes with the documenting of the outcomes, which facilitates the nurse in making appropriate referrals and contacting key resources to meet the needs of family.

The components of the evaluation are the structure–process, the outcome, and the nurse's self-evaluation. Each one contributes to determining what made the visit a success and what made it less than successful by evaluating if the outcomes were achieved and if they can be advanced to the next level of family health. The nurse must be prepared to determine if a change is needed in the structure–process, the nurse's level of preparedness, or the nurse's behavior in order to promote health in the family, the community, and eventually the population.

### *Structure–Process Evaluation*

The structure–process evaluation should be completed first as it refers to the organization of the visit and how it proceeded (see [Chapter 12](#)). The nurse identifies where the organization or the flow of the assessment needs to be changed or modified in order to avoid distractions in the next visit.

Specifically, the nurse will analyze the available resources, number of persons present, timing of home visit(s), environmental factors, or materials/supplies used as well as the use of observational skills, people's attitudes, and reliance on standards of assessment and analysis. Every aspect must be used in the evaluation in order to effectively and thoroughly modify subsequent visits.

### *Outcome Evaluation*

The outcome evaluation facilitates the nurse in deciding if the anticipated outcomes were achieved and what made them possible. This **outcome evaluation**, a formal appraisal process, happens with documentation of the home visits. The effectiveness of any achieved outcomes is determined with standards and/or agency-driven criteria.

The standards are the Nursing Outcomes Classification (NOC) System, the Nursing Intervention Classification (NIC) System, and the Omaha System (see [Chapter 15](#)). The agency-driven criteria may be the successful achievement of the indicated expectations for each client category or visit type. Evaluating the outcomes with the agency-driven criteria may be more exact if the effectiveness is demonstrated by small changes over time in the

family dynamics as noted on a visit-by-visit basis instead of cumulatively as represented in the standards. Therefore, the nurse must use professional judgment to determine the success or failure of the family to achieve certain outcomes at the conclusion of agency services, with the family included in the decision process.

### *Self-Evaluation*

The self-evaluation encompasses the nurse appraising the ability to facilitate the desired outcome during the home visit(s), the level of being prepared, the thoroughness in data collection, the degree of preparedness for subsequent home visits, and the pros and cons of completed home visits. In other words, this self-evaluation affords the community/public health nurse the opportunity to recognize her or his strengths and failings with internal measures to improve practice (Edelman & Kudzma, 2017).

In some agencies, routine peer evaluations are conducted to recognize strengths and/or weaknesses not indicated in a self-evaluation. The peer evaluation can be completed by an agency staff nurse who makes a family visit with the community/public health nurse and provides feedback based on her or his observations. This might be helpful when working with a family that has not made progress toward the desired outcomes or to a family you have not been able to reach (Sperry, 2019). Peer consultation can also assist the C/PHN in becoming better prepared or more focused in order to improve the interaction(s) with families from different cultures or in difficult situations (Spector, 2017).

# SUMMARY

- Because today the family is recognized as an important unit of service, an effective C/PHN must understand family theory and characteristics. Family health and individual health strongly influence each other, and family health affects community health.
- Although every family on the globe is unique in terms of its needs and strengths, each family is at the same time alike because of certain shared universal characteristics: every family is a small social system, has its own cultural values and rules, has structure, has certain basic functions, and moves through stages in its life cycle.
- The C/PHN needs to understand the different needs of various family patterns. Whereas the single adolescent parent needs the community health nurse's knowledge of family developmental theory, more complex interaction patterns and living arrangements are created by divorce, remarriage, the blending of families, and the unique relationships these arrangements create. Gay and lesbian families with children may also have special needs, calling for a sensitive understanding of society's reaction to their family.
- The essential starting point in the community health nurse's work is to accept the family's definition of who their family is and listen to the family's ideas. The nurse and the family become partners in providing health care, with the nurse beginning the work assessing the family's strengths, which will begin to build a positive relationship between the nurse and the family. The family unit remains the focus of service in public health nursing because each family member strongly influences the other, which affects the community health.
- Healthy families demonstrate six important characteristics. The characteristics of a healthy family provide one assessment framework that public health nurses can use.
- Making family health visits is a unique role for nurses and is one of the activities common to most public health nurses.
- The nurse's preparation for the visit facilitates (1) an orderly and organized flow for the visit and (2) the nurse becoming acquainted with the family, which is indispensable for the comprehensive execution of the nursing process and development of a trusting relationship.
- For a comprehensive assessment, C/PHNs employ acute observational skills, good verbal and nonverbal communication, assessment skills, and intuition to guide them safely in the community and with the families they visit.

- The family is a total unit or single entity, and the nurse must consciously recall this point through the home visits and every stage of the nursing process, especially during assessment.
- To systematically assess a family's health, the nurse needs a conceptual framework, categories for data collection, and a measure of the family's level of functioning.
- The main broad categories of a family health visit are previsit preparation, conduct of the visit, postvisit documentation, and preparation or planning for the next visit. Each step contributes to the success of the subsequent one.
- There are specific precautions for safety that a nurse must follow if using a personal or agency car or public transportation or walking to visit families. Safety must be considered in a family's home even if it means terminating the visit and rescheduling.
- The nurse empowers the family by establishing a verbal or written contract with the family so that the family members (1) understand their personal roles and responsibilities in the relationship and (2) feel confidence in making independent decisions about their own health.
- The C/PHN makes referrals to other agencies on behalf of the family in order to provide all the services that a family needs; therefore, the C/PHN needs to know how and where to locate official and voluntary services within their community.

# ACTIVE LEARNING EXERCISES

1. Analyze two families you know well (other than your own) and answer the following questions:  
If the major breadwinner in this family was unable to work or lost his or her job, how would the family most likely respond immediately and in the long term?  
What are the strengths of the family?  
How could a nurse most effectively intervene in this situation?
2. Talk with members of a blended family, and discuss with each member his or her relationships with stepchildren, stepparents, or siblings. What strengths can they identify in their family? How has this helped them adapt to their blended family?
3. Listen to two to three stories on Story Corp <https://storycorps.org/>. What did you learn? Are there themes that you recognize among the stories?
4. Construct an eco-map of your family and ask a peer to do the same, which can be completed face-to-face or online (i.e., Google Docs). Compare the eco-maps. Assess the balance between your family and the resources in its environment. How does your eco-map compare with that of your peer? What changes are needed in each family system? Are you able to influence the changes that are needed?
5. Using “Build a Diverse and Skilled Workforce” (1 of the 10 essential public health services; see [Box 2-2](#) ), watch one of the two YouTube videos, A Day in the Life of a Public Health Nurse (<https://www.youtube.com/watch?v=n8FvhaMvcDQ>) or A Day in the Life-Mary (Public Health Nursing) <https://www.youtube.com/watch?v=fGj5wncmuX0>, with one or two classmates. Evaluate the public health nurse in terms of structure–process and outcomes as well as a peer evaluation of the PHN. With your classmates, discuss the PHN's strengths and weaknesses, and identify what actions you would emulate, change, or leave as is. Identify five instances in the video that made you feel uncomfortable, discuss with your classmates why these occurrences affected you, and discuss ways to process these feelings.

# CHAPTER 15

## *Community as Client*

*“The health of the public is another shared value. Not only does each individual have an interest in staying healthy, but all of us together share an interest in having a healthy population.”*

—Dan E. Beauchamp & Bonnie Steinbock, *New Ethics for the Public's Health*

## **KEY TERMS**

Assets assessment Community as client Community development  
Community diagnosis Community-oriented, population-focused care  
Community subsystem assessment Conceptual model Descriptive  
epidemiologic study Key informants Outcome criteria Partnerships Priority  
setting Problem-oriented assessment Social determinants of health  
Windshield survey

## **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Discuss three essential characteristics of nursing service when a community is the client.
2. Describe the contributions of two models of nursing practice to community/public health nursing practice.
3. Describe the characteristics of a healthy community.
4. Describe the meaning of community as client.
5. Articulate three specific considerations of each of the three dimensions of the community as client.
6. Discuss methods of community health assessment.
7. Delineate five sources of community data.
8. Describe the role of the community health nurse as a catalyst for community development.

# INTRODUCTION

When you open the door of a senior center where you will be promoting cardiovascular fitness, advocating for exercise equipment, and suggesting changes in the on-site meal program, how might theories of public health nursing contribute to your success? When you approach your city council about the need to increase staffing for public health services, what models of public health nursing practice might support your argument? What are *theories*, *models*, and *principles*, and what is their relevance to day-to-day public health nursing practice? These are the key issues explored in the first three sections of this chapter.

The remainder of the chapter explores the definition of a healthy community, dimensions of the community as client, and application of the nursing process to the community as client. Included in this discussion are the types of community needs assessment, methods of collecting and sources of community data, data analysis and diagnosis, and making, implementing, and evaluating plans for community health promotion.

# WHEN THE CLIENT IS A COMMUNITY: CHARACTERISTICS OF COMMUNITY/PUBLIC HEALTH NURSING PRACTICE

Nursing exists to address people's health care needs, and nurses fulfill this purpose through their work in various specialty areas. Specialties are characterized by the unit of care for which the specialty is responsible and by the goal of the specialty. Each specialty requires a particular area of knowledge and a set of skills for excellence in practice.

Public health nursing is a specialty in which the unit of care is a specific community or aggregate, and the nurse has responsibility to promote group health. The goal of this specialty is health improvement of the community. Some of the skills required for excellence in public health nursing practice include epidemiology, research, teaching, community organizing, and managing programs and outcomes related to interpersonal relational care.

Public health nursing is characterized by **community-oriented, population-focused care** and is based on interpersonal relationships. In the following sections, each of these characteristics is examined in more depth.

A community is a collection of people interacting with one another because of geography, common interests, characteristics, or goals. These interactions include social institutions, such as schools, government agencies, and social services. The concept of community as client refers to a group or population of people as the focus of nursing service ([Anderson & McFarlane, 2019](#)).

As described in [Chapters 1 and 2](#), understanding the concept of the community as client is a prerequisite for effective service at every level of community nursing practice. Population-focused practice distinguishes community health nursing from other nursing specialties ([American Nurses Association \[ANA\], 2018](#); [American Public Health Association, Public Health Nursing Section, 2013](#)).

*Community orientation* is a process that is actively shaped by the unique experiences, knowledge, concerns, values, beliefs, and culture of a given community. For example, when an outbreak of hepatitis occurs, the public health nurse (PHN) does more than simply treat infection in individuals. The nurse also

- Uses disease investigation skills to locate possible sources of infection (see [Chapter 7](#))
- Determines how the community's knowledge, values, beliefs, and prior experiences with infectious disease may influence its interpretation of the disease, response to the outbreak, and treatment preferences
- Uses knowledge and suggestions gathered from the community to develop, in collaboration with other health professionals, a community-specific program to prevent future outbreaks

A community-oriented nurse who provides education about sexually transmitted diseases to a group of students at a Catholic university includes consideration of community values regarding sexual behavior. Similarly, a community-oriented nurse who provides nutritional counseling to a community of Hispanic older adults considers the meaning of food in their culture, the types of food most commonly consumed, and the cooking methods most commonly used.

A *population* refers to all people occupying an area, such as a city, county, or state. Parts of populations may be subpopulations or aggregates. Smokers and refugees are two subpopulations. The nurse's place of employment commonly limits the population that the nurse serves. For example, a nurse who works for a county health department is limited professionally to caring for the population residing in that county.

A *population focus* requires that a nurse use population-based knowledge and skills such as epidemiology, community assessment, and community organizing as bases for interventions. For example, a population-focused nurse employed by an autoworkers' union may study all cases of repetitive use injury occurring in the auto industry in the United States in the past 5 years, develop a program for reducing repetitive use injury, and lobby industry executives for adoption of the program.

Community-oriented, population-focused care employs population-based knowledge and skills and is shaped by the characteristics and needs of a given aggregate, community, or population. C/PHNs provide community-oriented, population-focused care when they count and interview homeless people sleeping in a park and, based on these data, help develop a program to provide food, clothing, shelter, health care, and job training for this population.

# THEORIES AND MODELS FOR COMMUNITY/PUBLIC HEALTH NURSING PRACTICE

Nursing is a theory-and evidence-based profession. “Theory-guided, evidence-informed practice is the hallmark of any professional discipline” (Smith, 2019, p. 3). As a nursing specialty, community/public health nursing is not only guided by theories and evidence that pertain to the nursing profession, but also theories and evidence that have been specifically developed and tested for the specialty. Borrowed and shared theories are also major parts of the practice of community and public health nursing. Examples of shared theories are health behavior, learning theory, and diffusion of innovations.

In the classical definition, a theory is “a set of interrelated constructs, definitions, and propositions that present a systematic view of phenomena by specifying relations among variables, with the purpose of explaining and predicting the phenomena” (Kerlinger, 1973, p. 9). A theory is based either explicitly or philosophically on a conceptual model (also referred to as a conceptual framework, a conceptual system, or a paradigm). A **conceptual model**, as originally defined, is a set of concepts and the propositions that integrate them into a meaningful configuration (Lippitt, 1973). These concepts are presented in a framework format used to explain the relationships among variables. A conceptual model cannot be used directly in research or clinical practice. Linking a conceptual model with one or more theories to form the conceptual-theoretical systems of knowledge is needed for action (Fawcett, 2017).

Having been exposed to nursing theories throughout your nursing program, you will recall that nursing theories are usually classified as grand theories, middle-range theories, and situation-specific theories (Smith & Liehr, 2018).

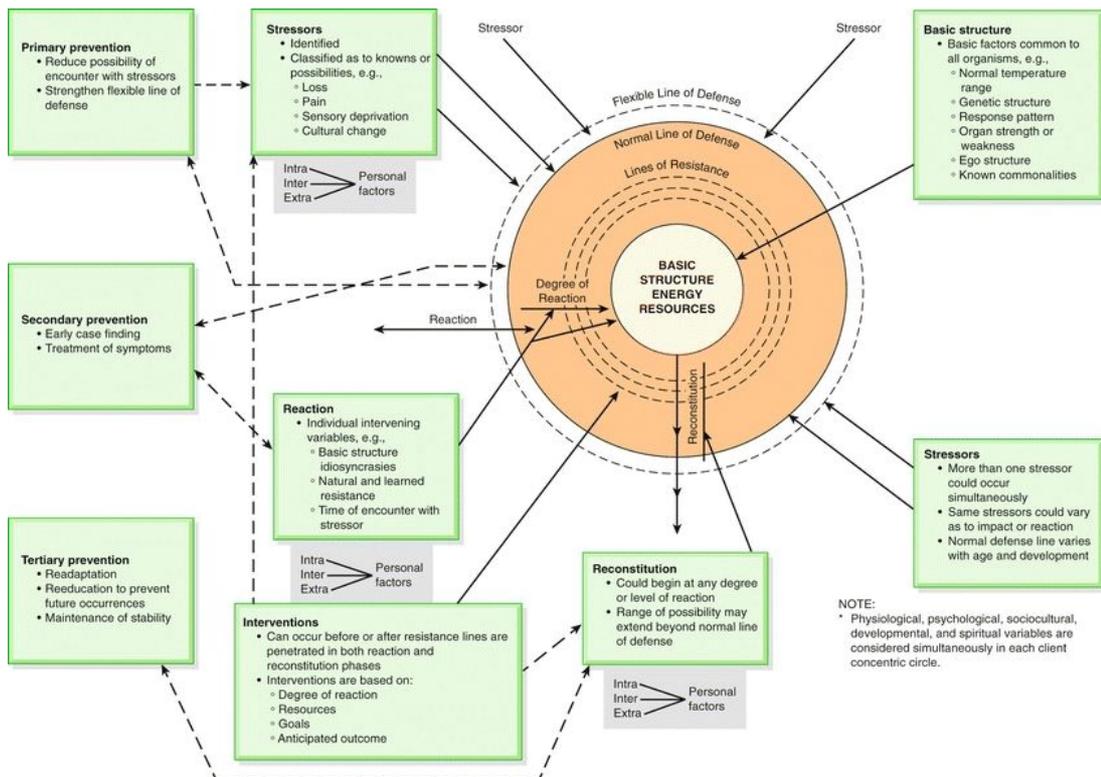

*Grand theories* are frameworks composed of concepts and relational statements that explain abstract phenomena (Smith, 2019). These theories have a high level of abstraction and are not directly applicable to nursing practice. An example of a grand theory is Rogers' Model of the Science of Unitary Human Beings. This model emphasized that the individual and environment should be viewed as one unit; that is, focusing on the individual without examining her or his environment or examining parts of a community, such as its health care or housing, does not provide an adequate

picture of its totality in relation to the person (Johnson & Webber, 2015). Rogers also incorporated developmental theory into her model by describing the development of “unitary” persons or systems according to three principles: (1) life proceeds in one direction along a rhythmic spiral, (2) energy fields follow a certain wave pattern and organization, and (3) human and environmental energy fields interact simultaneously and mutually, leading to completeness and unity (Rogers, 1990).

*Middle-range theories* have more limited scope and are less abstract than grand theories. These theories are intended to be used for practice as well as research. An example of a middle-range theory is self-care of chronic illness (Riegel, Jaarsman, & Stromberg, 2012). The core elements of this theory are self-care maintenance, self-care monitoring, and self-care management. Self-care management is a process of recognizing changes in signs and symptoms, making decisions about self-care actions, and evaluating outcomes of that action. Several factors influence whether a patient is successful in performing self-care, such as confidence, motivation, and support from others. Community/public health nurses provide care to many individuals who use self-care to manage their chronic illnesses. This theory would be helpful to care for these individuals.

*Situation-specific theories* focus on specific nursing phenomena that reflect clinical practice and are limited to specific populations or to particular fields of practice. “They are theories that are more clinically specific, that reflect a particular context, and that may include blueprints for action” (Im & Meleis, 1999, p. 13). An example of a situation-specific theory is depression in Black single mothers (Atkins, 2016). The investigator hypothesized and tested a model of the relationships of perceived stress, perceived racism, and self-esteem to depression. Although further study is needed, this model of situation-specific theory of depression can be used to improve care to single Black mothers (Atkins, 2016).

Betty Neuman's Systems Model provides a comprehensive holistic and system-based approach to nursing that contains an element of flexibility (Fig. 15-1). The theory focuses on the patient's response to actual or potential environmental stressors and the use of primary, secondary, and tertiary nursing prevention intervention for retention, attainment, and maintenance of patient system wellness. Table 15-1 shows an example of applying Neuman's model to the prevention of cardiovascular disease (CVD) in an ethnic minority population (Neuman, 1980).

**FIGURE 15-1** Neuman's health care systems model. (Adapted with permission from Neuman, B., & Fawcett, J. (2011). *The Neuman systems model* (5th ed., Fig. 1-3, p. 13). Upper Saddle River, NJ: Pearson. Original diagram copyright © 1970 by Betty Neuman.)

**TABLE 15-1 Applying Neuman's Model to Prevention of Cardiovascular Disease (CVD) in an Ethnic Minority**

## Population

Part of Model	Description	Application to CVD Prevention
Flexible line of defense	Buffer that expands and contracts to protect normal line of defense from stressors.	Primary prevention efforts include culturally competent education on risk factors for CVD (hypertension, diabetes, obesity, high cholesterol, smoking) and promoting health through regular exercise, healthy eating, and not smoking.
Normal line of defense	Typical responses to stressors; changes over time. Behaviors strengthen or weaken this line in response to stressors.	Promotion of regular medical care and limitation of sodium, sugar, and fat intake. Screening and monitoring cholesterol, blood sugar, B/P.
Lines of resistance	These lines are final protection for the central core.	Providing culturally competent smoking cessation, healthy eating, and exercise programs. Encouraging referrals to cardiologists/other specialists for continued follow-up of early signs/symptoms. Education on importance of continuing medications, self-checks of B/P, food/sodium intake, and weight.
Central core	This component is the basic client system structure common to all people.	CVD may be influenced by genetic factors as well as strength and weaknesses of the system parts.
Stressors	These can originate in the external or internal environment.	Stressors include: <ul style="list-style-type: none"> <li>■ Intrapersonal (within the self—e.g., how one deals with stress)</li> <li>■ Interpersonal (a result of how one copes with others/ family/work)</li> <li>■ Extra-personal (from outside the self—e.g., discrimination, financial crisis, no health insurance, limited health care providers)</li> </ul>

## **Salmon's Construct for Public Health Nursing**

Although not a theory, Salmon proposed a model to specifically guide community health nursing practice. [Salmon \(1982, 1993\)](#) described public health as an organized societal effort to protect, promote, and restore the health of people and public health nursing as focused on achieving and maintaining public health.

The model describes three practice priorities:

- Prevention of disease and poor health
- Protection against disease and external agents
- Promotion of health

The three general categories of nursing intervention are:

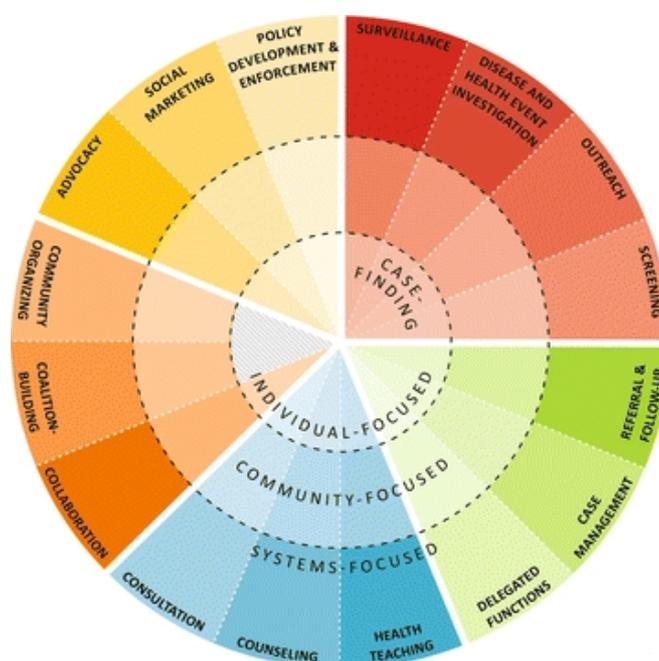

- Education that is directed toward voluntary change in the attitudes and behavior of the subjects
- Engineering that is directed at managing risk-related variables
- Enforcement that is directed at mandatory regulation to achieve better health

The scope of practice spans individual, family, community, and global care. Interventions target determinants in four categories: human/biologic, environmental, medical/technologic/organizational, and social.

Using Salmon's approach, a C/PHN attempting, for example, to reduce the transmission of tuberculosis, would use education, engineering, and enforcement in working with the population of affected individuals and families. Strategies could include collaboration with the client community on a variety of interventions, from mandating isolation precautions to providing education about medications and connecting the client and his or her family to social support, in an effort to prevent further disease in the community and to promote global health.

## Minnesota Wheel: The Public Health Interventions Model

The Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section, developed a model that depicts public health interventions and applications for public health practice. In the form of a wheel (Fig. 15-2), the model contains 17 different interventions for population-based interventions within three levels of public health practice: community-focused practice, systems-focused practice, and individual-focused practice (Minnesota Department of Health, 2019).

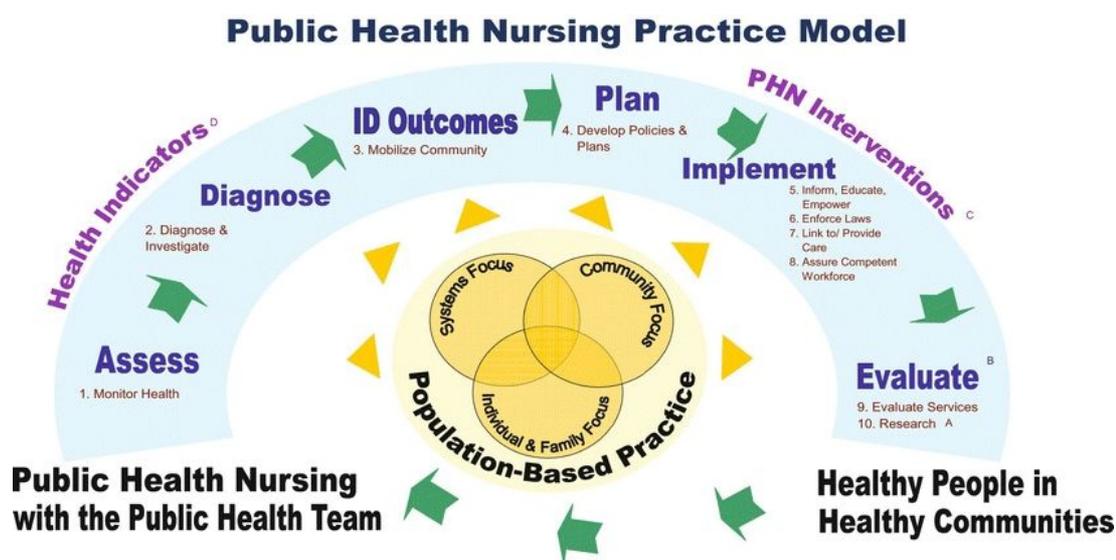

**FIGURE 15-2** The Minnesota wheel. (Reprinted with permission from Minnesota Department of Health, Division of Community Health Services, Public Health Nursing Section. Retrieved from <https://www.health.state.mn.us/communities/practice/research/phncouncil/docs/PHInterventions.pdf>)

The Wheel can be applied in a variety of activities, including public health practice, nursing education, and management. Keller and colleagues emphasized that the “use of the Wheel has empowered nurses to explain in a better way how their practice contributes to the improvement of population health” (Keller, Strohschein, Lia-Hoagberg, & Schoffer, 2004, p. 454). The wheel is useful for C/PHNs because it visually depicts the comprehensive list of interventions nurses must consider in the scope of practice. Schaffer,

[Anderson, and Rising \(2016\)](#) described how school nurses used the model interventions in their day-to-day work.

## Public Health Nursing Practice Model

The Los Angeles County Public Health Nursing (LAC PHN) Practice Model was developed in response to an identified need for a model that could blend public health nursing practice and the principles of public health, which could be applicable to both the generalist nurse and nurses working in specific programs (Smith & Bazini-Barakat, 2003). The LAC PHN Practice Model (Public Health Nursing, Los Angeles County Department of Health Services [PHN, LAC-DHS], 2013) integrates foundational nursing and public health guiding documents, including the Public Health Nursing Standards of Practice, the 10 essential public health services, the *Healthy People* health indicators, and the Public Health Nursing Practice Model (Fig. 15-3). The LAC PHN Practice Model provides a “conceptual framework that assists in clarifying the role of the C/PHN and presents a guide for public health practice applicable to all public health disciplines” (Smith & Bazini-Barakat, 2003, p. 42).

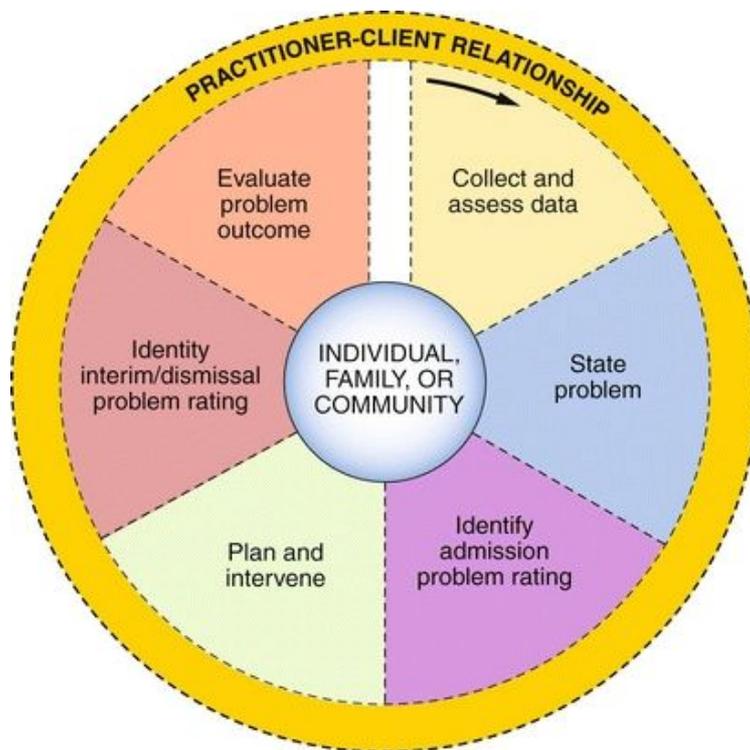

**FIGURE 15-3** Public health nursing practice model. (Reprinted from the Los Angeles County Department of Public Health, Public Health Nursing. Retrieved from <http://publichealth.lacounty.gov/phn/docs/PracticeModelfinal2.pdf>)

The principles of population-based practice are included in the LAC PHN Practice Model (PHN, LAC-DHS, 2013; Smith & Bazini-Barakat, 2003). C/PHNs integrate assessment, policy development, and assurance into their work. The three levels of population-based practice—individuals and families, community, and systems—are addressed, with the nursing process applied throughout the model. The 17 interventions, as first presented in the

Minnesota Public Health Nursing Model described above, are also incorporated into the LAC PHN Practice Model. This model promotes the concepts of an interdisciplinary public health team working together with an emphasis on primary prevention. The model also recognizes the importance of active participation of the individual, family, and community ([PHN, LAC-DHS, 2013](#); [Smith & Bazini-Barakat, 2003](#)).

## Omaha System

The Omaha System (Fig. 15-4) is a multidisciplinary standardized interface that incorporates documentation of nursing assessment and interventions (Thompson, Monsen, Wanamaker, Augustyniak, & Thompson, 2012). It is a comprehensive system, with the following components (Martin, 2005):

**FIGURE 15-4** Omaha system model of the problem-solving process. (Reprinted with permission from Martin, K. S. (2005). *The Omaha System: A key to practice, documentation, and information management* (2nd ed.). Omaha, NE: Health Connections Press.)

- *The problem classification scheme* is a holistic, comprehensive method for identifying clients' health-related concerns. Included are domains, problems, modifiers, and signs/symptoms. Problems can be identified at the individual, family, or community level.
- *The intervention scheme* provides a framework for documenting plans and interventions in the client record in the areas of health teaching, guidance, and counseling; treatments and procedures; case management; and surveillance.
- *The problem rating scale* for outcomes consists of a Likert-type scale that is a systematic and recurring method to document the progress of clients in the record and in case conferences during their time of service in the agency. It is used in conjunction with any problem in the problem

classification scheme. Central to problem rating is quantifying outcomes in three dimensions: knowledge (what the client knows), behavior (what the client does), and status (how the client is).

The model is applicable to individuals, families, and communities and provides a mechanism to evaluate both individual and group change over time. With ongoing pressure for public health program funding, outcome data are vital and can be captured through the application of the Omaha System.

# PRINCIPLES OF COMMUNITY/PUBLIC HEALTH NURSING

Public health nursing is “...evidence-based and focuses on promotion of the health of entire populations and prevention of disease, injury, and premature death” (ANA, 2013, p. 3). The key elements of this practice include (ANA, 2018)

- Population-level focus on issues including health inequities and the needs of special vulnerable populations
- A comprehensive and systematic assessment with particular attention to the determinants of health
- A focus on primary prevention
- Implementation of interventions of primary, secondary, and tertiary levels of prevention

The ANA recognizes that C/PHNs function as part of an interdisciplinary team from various organizations and agencies and collaborate with members of the communities they serve and recommends a baccalaureate education for entry-level C/PHNs. The Public Health Intervention Wheel and the 10 Essential Public Health Services serve as guides to the C/PHN's activities (ANA, 2018).

Principles are universals to help achieve the most beneficial outcomes. The goals of public health nursing, to promote and protect the health of communities, are facilitated by adhering to eight principles identified by the ANA (2018) for public health nursing practice. These principles are summarized in Box 15-1 and discussed in depth below (ANA, 2018).

## **BOX 15-1 Principles of Public Health Nursing**

1. **Focus on the Community.** The client or unit of care is the population.
2. **Give Priority to Community Needs.** The primary obligation is to achieve the greatest good for the greatest number of people or the population as a whole.

3. **Work in Partnership With the People.** The processes used by public health nurses (C/PHNs) include working with the client as an equal partner.
4. **Focus on Primary Prevention.** Primary prevention is the priority in selecting appropriate activities.
5. **Promote a Healthful Environment.** Public health nursing focuses on strategies that create healthy environmental, social, and economic conditions in which populations may thrive.
6. **Target All Who Might Benefit.** A C/PHN is obligated to actively identify and reach out to all who might benefit from a specific activity or service.
7. **Promote Optimum Allocation of Resources.** Optimal use of available resources to ensure the best overall improvement in the health of the population is a key element of the practice.
8. **Collaborate With Others in the Community.** Collaboration with a variety of other professions, populations, organizations, and other stakeholder groups is the most effective way to promote and protect the health of the people.

Adapted from [American Nurses Association \(2018\)](#), pp. 8–9).

## **Principle 1: Focus on the Community**

The first principle reminds us that the ultimate responsibility of public health nursing is to direct services to the population as a whole. Even though C/PHNs may intervene to address individual, family, or group needs, the entire community is the client ([Ervin & Kulbok, 2018](#)).

## **Principle 2: Give Priority to Community Needs**

The second principle deals with the ethical obligation of the C/PHN to give priority to the needs and preferences of the whole community over those of one individual. This means that the nurse must consider interventions that will lead to the greatest good for the most people ([Rushton & Broome, 2015](#)).

### **Principle 3: Work in Partnership With the People**

The third principle requires the C/PHN to work in partnership with the community. The nurse and the community members (or groups) each bring their own values, beliefs, and expertise to the partnership ([Anderson & McFarlane, 2019](#)). Policy development and assurance are more likely to be accepted and applied if there is mutual consideration of and respect for these elements. Developed policies need to be communicated in language that reflects an understanding of the community

## **Principle 4: Focus on Primary Prevention**

The fourth principle of public health nursing underscores the importance of primary prevention in promoting the health of people. Public health nursing has an obligation to prevent health problems and injuries and to promote a higher level of wellness ([Anderson & McFarlane, 2019](#)).

## **Principle 5: Promote a Healthful Environment**

The fifth principle highlights the importance of ensuring that people live in conditions conducive to health. C/PHNs, along with other public health professionals, understand the effects of social determinants of health and work to improve those ([O'Brien, 2019](#)).

## **Principle 6: Target All Who Might Benefit**

The sixth principle involves outreach strategies to meet the obligation to serve all people who might benefit from an intervention. This tenet requires that the nurse examine policies or programs to determine whether they are accessible and acceptable to the entire population in need and advocate for change if necessary ([Ervin & Kulbok, 2018](#)).

## **Principle 7: Promote Optimum Allocation of Resources**

The seventh principle addresses resource allocation decisions. In most communities, the available resources are not sufficient to meet all needs of all people. The nurse must ensure that the community is using limited resources in ways that lead to the greatest improvement in health (Swider, Berkowitz, Valentine-Maher, Zenk, & Bekemeier, 2017). To promote optimum allocation of resources, the nurse must

- Know the latest research on the effectiveness of various programs in addressing needs
- Collect information about the short-and long-term costs of programs
- Evaluate existing programs and policies for ways to improve or discontinue them
- Communicate this information to community decision makers, so that they can make resource allocation decisions that are most likely to improve the community's health

C/PHNs should continue to work on all levels to promote greater funding for public health programs and more effective allocation of resources.

## **Principle 8: Collaborate With Others in the Community**

The eighth principle underscores the importance of collaboration with other nurses, health care providers, social workers, educators, spiritual leaders, business leaders, and government officials within the community. This interdisciplinary collaboration is essential to execute effective programs and improve health outcomes. Programs that are planned and implemented in isolation can lead to fragmentation, gaps, and overlaps in health services (Ervin & Kulbok, 2018).

# WHAT IS A HEALTHY COMMUNITY?

Just as health for an individual is relative and will change, all communities exist in a relative state of health. A community's health can be viewed within the context of health being more than just the absence of disease and including things that promote the maintenance of a high quality of life and productivity. A key vision for healthy communities is presented in *Healthy People 2030* the national agenda for health and well-being published by the U.S. Department of Health and Human Services ([USDHHS, 2020](#)). See [Chapter 1](#). The five overarching goals for the health of the nation are to:

- Attain healthy, thriving lives and well-being free of preventable disease, disability, injury, and premature death.
- Eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all.
- Create social, physical, and economic environments that promote attaining the full potential for health and well-being for all.
- Promote healthy development, healthy behaviors, and well-being across all life stages.
- Engage leadership, key constituents, and the public across multiple sectors to take action and design policies that improve the health and well-being of all ([USDHHS, 2020](#)).

*Healthy People 2030* objectives and targets provide guidelines for communities to follow to promote the health of their members. By encouraging collaboration across communities, empowering individuals to make better choices, and measuring progress toward set benchmarks, *Healthy People 2030* can be used as a road map for achieving longer and healthier lives for all Americans.

The National Prevention Strategy (NPS), largely based on *Healthy People* priorities, was developed in 2011 to further national health improvement efforts. The NPS aims to guide national efforts in the most effective and achievable means for improving health and well-being. The strategy prioritizes prevention by integrating recommendations and actions across multiple settings to improve health and save lives. To realize this vision and achieve this goal, the strategy identifies four strategic directions and seven targeted priorities ([Association of State and Territorial Health Officials, 2019](#)).

The *strategic directions* provide a strong foundation for all of our nation's prevention efforts and include core recommendations necessary to build a prevention-oriented society. They include

- Healthy and safe community environments: Create, sustain, and recognize communities that promote health and wellness through prevention.
- Clinical and community preventive services: Ensure that prevention-focused health care and community prevention efforts are available, integrated, and mutually reinforcing.
- Empowered people: Support people in making healthy choices.
- Elimination of health disparities: Eliminate disparities, improving the quality of life for all Americans.

Within this framework, the *priorities* provide evidence-based recommendations that are most likely to reduce the burden of the leading causes of preventable death and major illness and include

- Tobacco-free living
- Preventing drug abuse and excessive alcohol use
- Healthy eating
- Active living
- Injury-and violence-free living
- Reproductive and sexual health
- Mental and emotional well-being

The NPS serves as a road map for community health nurses collaborating with stakeholders and community partners, to address priority areas such as healthy eating, active living, and tobacco control through the prioritization of prevention and integration of recommendations and actions across multiple settings. By working on shared priorities, community health nurses can serve as a valuable partner in identifying community health needs and connecting communities with available resources. Nurses can also serve as community educators, empowering people with information to make healthy choices while working to create environments where healthy choices are more accessible and affordable, which is the ultimate intent of the strategy (Lushniak, Alley, Ulin, & Graffunder, 2015).

# DIMENSIONS OF THE COMMUNITY AS CLIENT

The health of a community can be characterized through a number of perspectives. Donabedian's classic theory of structure, process, and outcomes provides unique insight into the health status of the community (Donabedian, 2005).

- *Status/people* is the most common measure of the health of a community. It typically comprises morbidity and mortality data identifying the physical, emotional, and social determinants of health.
- *Structure* of a community refers to its services and resources. Community associations, groups, and organizations provide a means for accessing needed services. Adequacy and appropriateness of health services can be determined by examining patterns of use, number and types of health and social services, and quality measures. These measures provide key information and correlate to health status.
- *Process* reflects the community's ability to function effectively. It includes processes within the community and between the community and the state or national levels to maintain health and improve outcomes.

These characteristics are discussed in more detail later in this chapter under the discussion on “Planning to Meet the Health Needs of the Community.” See [Chapter 1](#) for more information on healthy communities.

Addressing community health by examining the process, in addition to the structure and status dimensions, provides a broader view into the complexities of community health and community actions for change. It is a key not only to examine health outcomes but also to consider how the interactions between processes and structure impact health outcomes ([Public Health Accreditation Board, 2019](#)). These are detailed in [Tables 15-2](#) and [15-3](#).

## TABLE 15-2 Community Profile Inventory: Location Perspective

Location Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All—Various Internet Sites)
Boundary of community	These serve as basis for measuring incidence of wellness and illness and for determining spread of disease.	Where is the community located? Is it a part of a larger community? Smaller communities included?	Google Maps State maps County maps City maps City directory Public library
Location of health services	Use of health services depends on availability and accessibility.	Where are the major health institutions located in the community? Outside the community?	www.Healthfinder.gov Chamber of commerce State health department County or local health departments Maps
Geographic features	Injury, death, and destruction may be caused by floods, earthquakes, volcanoes, or hurricanes. Recreational opportunities at lakes, seashore, and mountains promote health and fitness.	What major landforms are in or near the community? Which features pose possible threats? Which offer opportunities for healthful activities?	Atlas Chamber of commerce Maps State health department Public library www.NGMDB.USGS.gov
Climate	Extremes of heat and cold affect health and illness. Extremes of temperature and precipitation may tax community's coping ability.	What are the average temperature and precipitation? What climatic features affect health and fitness? Is the community prepared to cope with emergencies?	www.CLIMATE.gov Chamber of commerce State health department Maps Local government Weather bureau Public library
Flora and fauna	Poisonous plants and disease-carrying animals can affect community health. Plants and animals offer resources as well as dangers.	What plants and animals pose possible threats to health?	State health department Poison control center Police department Emergency rooms Encyclopedia Public library
Human-made environment	All human influences on environment (housing, dams, farming, type of industry, chemical waste) can influence levels of community wellness.	What are the major industries? Are there air, land, and water pollution concerns? What is the quality of housing?	Chamber of commerce Local government City directory State health department University research reports Public library

**TABLE 15-3 Community Profile Inventory: Population Perspective**

Population Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All—Various Internet Sites)
Size	The number of people influences number and size of health care institutions.	What is the population? Is it an urban, suburban, or rural community?	State health department Census data Chamber of commerce
Density	High and low density often affects the availability of health services.	What is the density of the population per square mile?	Census data State health department
Composition	Composition of the population often determines types of health needs.	What are the population's demographic?	Census data State health department U.S. Department of Labor Statistics
Rate of growth or decline	Rapidly growing communities may place excessive demands on health services. Marked decline in population may signal a poorly functioning community.	How has population size changed over the past two decades? What are the health implications of this change?	Census data State health department
Cultural differences	Health needs vary among subcultural and ethnic populations. Utilization of health services varies with culture. Health practices and extent of knowledge are affected by culture.	What is the ethnic breakdown of population? What racial groups are represented? What subcultural populations exist? Are different ethnic and cultural groups included in health planning?	Census data State health department Social and cultural research reports City government Health planning boards
Mobility	Mobility of the population affects continuity of care. Mobility affects availability of service to highly mobile populations.	How frequently do members move into and out of the community? Are there any specific populations that are highly mobile? Is the community organized to meet the health needs of mobile groups?	State health department Census data Health agencies serving migrant workers Program serving transients and the homeless
Income level	Economic disparities may lead to health disparities.	What percentage of the population is below federal poverty levels? How many children qualify for free or reduced cost school lunch?	Census data State data Local data (schools)
Education level	Education disparities may lead to health disparities.	What is the literacy rate?	State data Local data (schools)
Unemployment rate	Health insurance is often tied to employment. Lack of regular income can be a family stressor. Both can lead to health disparities.	What is the rate of unemployment? How variable is this rate?	U.S. Department of Labor State data Local data
Population by age	A high proportion of children and elderly can overburden health care and social systems.	What is the dependency ratio? Has this rate changed dramatically? What is the trend?	Census data State data Local data
Health status	Community members' status relative to the 10 Leading Health Indicators can impact overall community health.	What is the rate of obesity/overweight? What are the rates of tobacco use and substance abuse? What is the immunization rate? What are rates of injury and violence? What are the STD and HIV/AIDS rates?	State data Local data Centers for Disease Control and Prevention (CDC) data Vital statistics—numbers of births, deaths, marriages, and infant mortality rate (Compare local to state data; state to national data)
Environmental health status	Poor environmental health (e.g., presence of coliform bacteria in well water, toxic chemicals, or poor air quality) can lead to increased incidence of communicable or chronic diseases.	What are rates of communicable or chronic diseases (e.g., <i>Escherichia coli</i> infections, asthma)?	CDC data State data Local data

## Location

The health of a community is affected by location, because placement of health services, geographic features, climate, plants, animals, and the human-made environment are intrinsic to geographic location. The location of a community places it in an environment that offers resources and also poses threats.

The healthy community is one that makes wise use of its resources and is prepared to meet threats and dangers. In assessing the health of any community, it is necessary to collect information not only about variables specific to location but also about relationships between the community and its location. Do groups cooperate to identify threats? Do health agencies cooperate to prepare for an emergency such as a flood, tornado, or earthquake? Does the community make certain that its members are given available information about resources and dangers?

Table 15-2 describes the location perspective of the Community Profile Inventory, including the six location variables: community boundaries, location of health services, geographic features, climate, flora and fauna, and the human-made environment.

### *Community Boundaries*

To talk about the community in any sense, one must first describe its boundaries. Measurement of health within a community must be preceded by definition of geographic and informal boundaries around the target population. Nurses need to be clear, for example, that a target community of older adults includes a description of age and location (e.g., all persons 65 years and older in a given city or county). Some communities are distinctly separate, such as an isolated rural town, whereas others are closely situated to one another, such as the suburbs of a large metropolis. Therefore, it is important for the nurse to know the nature of each location and clearly define its boundaries.

### *Location of Health Services*

If the members of a town must travel 200 miles to the nearest clinic or dental office, the health of the community will be affected. When assessing a community, the community health nurse needs to identify the major health centers and know where they are located. For example, an alcoholism treatment center for indigent alcoholics was located 30 miles outside of one city. This location presented transportation problems and profoundly affected the length of time they remained at the center and the willingness of clients to voluntarily seek treatment there. If a well-baby clinic is located on the

edge of a high-crime district, parents may be deterred from using it. It is often helpful to plot the major health institutions, both inside and outside the community, on a map that shows their proximity and relationship to the community as a whole.

## *Geographic Features*

Communities have been constructed in every conceivable physical environment, and environment certainly can affect the health of a community (see [Chapter 9](#)). A healthy community is one that takes into consideration the geography of its location, identifies possible problems and likely resources, and responds in an adaptive fashion. For example, Anchorage, Alaska, and San Francisco, California, are both located on a geologic fault line and are subject to major earthquakes. In such places, the health of the community is determined, in part, by its preparedness for an earthquake and its ability to cope and respond quickly when such a crisis occurs.

## *Climate*

Winter weather patterns are expected to become more variable as average global temperatures continually increase. Research findings indicate that there is a relationship between temperature variability and health outcomes, including cardiovascular, respiratory, cerebrovascular events, and all-cause morbidity and mortality. Populations most vulnerable to global changes are older adults, residents of rural areas, children living in poor countries, and those with preexisting medical conditions ([World Health Organization, 2019a, 2019b, 2019c](#)).

## *Flora and Fauna*

Plant and animal populations in a community are often determined by location. The way a community responds to these populations, whether wild or domesticated, can affect the health of the community.

Public health officials note chronic environmental factors as a possible cause for increased asthma cases: pollution from high-traffic areas, secondhand smoke in homes, and poor living conditions characterized by dust mites, mold, industrial air pollution, mouse and cockroach droppings, and animal dander.

C/PHNs need to know about the major sources of danger from plants and animals affecting the community under study. Are there community agencies that provide educational information about these dangers? Does the populace understand their significance? Are emergency services, such as a poison control center, available to community members?

## *The Built Environment*

Every community is located in the midst of an environment created and transformed by human ingenuity. People build houses and factories, dump wastes into streams or vacant lots, fill the air with gases, and build dams to control streams. All of these human alterations of the environment have important implications for community health. A C/PHN might improve the health of a community by working with community members, legislators, and stakeholders to improve the design of the built environment to promote health and well-being.

## Population Characteristics

When one considers the community as the client, examining the health status of the total population in a given community is a critical component. [Table 15-3](#) presents the population perspective section of the Community Profile Inventory.

### *Size*

Knowing a community's size provides community health nurses with important information for planning. For example, when conducting emergency preparedness planning, knowledge of the population size will ensure that an adequate number of resources can be made available in the event of an emergency. See [Chapter 27](#) for issues related to rural and urban population health.

### *Density*

In some communities, thousands of people are crowded into high-rise apartment buildings. In others, such as farm communities, people live great distances from one another. Population density, or the number of people residing within a square mile area, is used to describe how many people live within a community. Living in high-density, crowded communities affects individual and community health by increasing community members' exposure to pollution and an urbanized diet ([The Healthy City, 2018](#)). A low-density community, however, may also pose problems. When people are spread out, provision of health care services can become difficult.

A healthy community takes into consideration the density of its population. It organizes to meet the differing needs created by its density levels (e.g., it recognizes differences in density between the inner city and the suburbs and allocates services accordingly). See [Chapter 27](#) for more on health risks specific to rural and urban areas.

### *Composition/Demographics*

Communities differ in the types of people who live within their boundaries. Age, sex, educational level, occupation, and many other demographic variables affect health concerns ([CDC, 2019a](#)). Understanding a community's composition is an important early step in determining its level of health. For example, when planning a cost-free vaccination program, knowledge of community demographics allows nurses to identify those who are eligible and those who would benefit most from the program.

## *Rate of Growth or Decline*

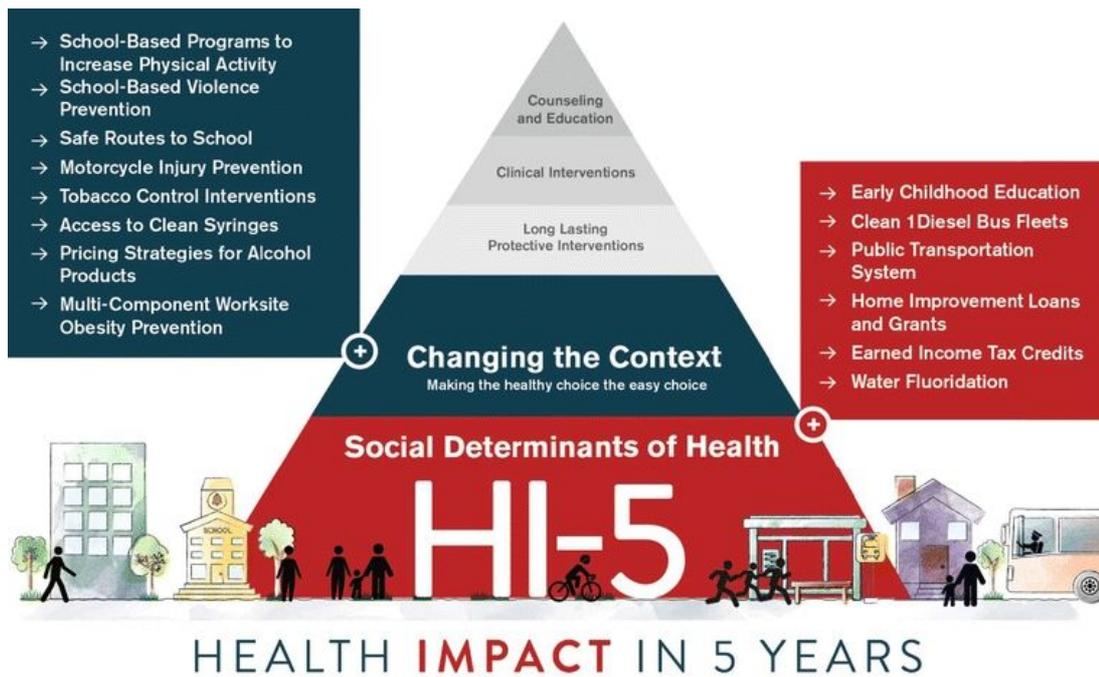

Community populations change over time. Some grow rapidly. As people leave to find new employment or better living conditions, consumption of goods and services drops. Community morale may suffer, and community leadership may decline. Even a stable community can have problems (e.g., members may resist needed change because they notice little fluctuation in their population; commercial and residential properties may be abandoned or left vacant). This trend is widely observed across the country, as the United States has progressed from being a manufacturing society to a postindustrial and technologically focused one.

## *Cultural Characteristics*

A healthy community is aware of the diversity and the needs of the cultural subgroups (McElfish et al., 2017). See [Chapter 5](#) for more about transcultural nursing in the community.

## *Social Class and Educational Level*

**Social determinants of health** impact a wide range of health, functioning, and quality of life outcomes ([Fig. 15-5](#); [National Academies of Sciences, Engineering, and Medicine, 2019](#); [USDHH, 2020](#)). They reflect social factors and the physical conditions in the environment in which people are born, live, learn, play, work, and age. They are shaped by the distribution of money, power, and resources at global, national, and local levels and contribute to health inequities among different groups of people based on social and economic class, gender, and ethnicity. For these reasons, social determinants of health are an underlying cause of today's major societal health dilemmas ([National Academies of Science, Engineering, and Medicine, 2019](#)). See [Chapter 23](#).

**FIGURE 15-5** Health impact pyramid. (Reprinted from CDC. (2018). *Health Impact in 5 years*. Retrieved from <https://www.cdc.gov/policy/hst/hi5/>)

It is generally known that different groups have different health problems, as well as a variety of resources for coping with illness and diverse ways of using health services. A healthy community recognizes these differences and creates health care services to meet these varied needs.

### *Mobility*

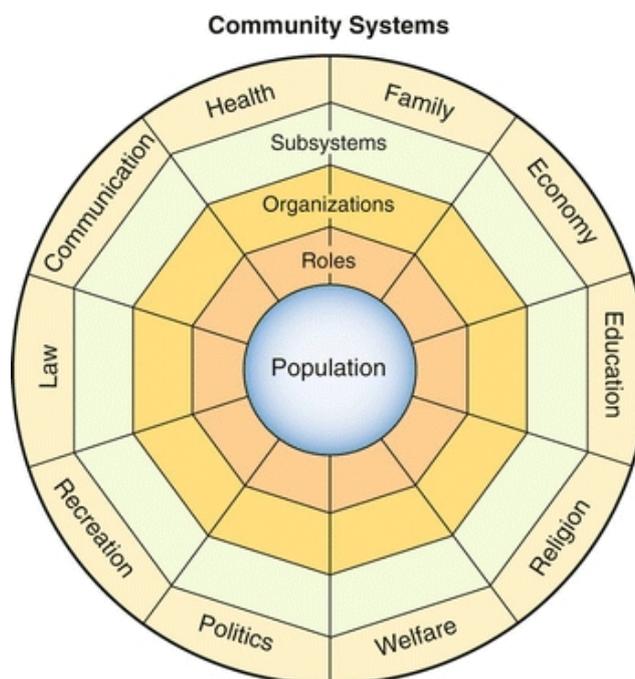

Americans are a mobile population. Outcomes from the 2017 American Community Survey indicate that approximately 40 million people moved annually within their region, 3.8 million moved between regions, and nearly another 2 million moved to the United States from abroad between 2013 and 2017. Oftentimes these fluctuations are linked to social and economic factors (U.S. Census Bureau, 2019). If the population turnover is extensive, continuity of services may suffer. Leadership for improving the health of the community may change so frequently that concerted action becomes difficult. High turnover may necessitate special attention to health education about local conditions.

Population groups may arrive and depart in seasonal swings; fluctuations in the number of migrant farm workers, tourists, or college students can affect a community. Immigrants and refugees may represent a significant population subgroup in many areas of a country, and public health officials must recognize their unique health needs and barriers (Philbin, Flake, Hatzenbuehler, & Hirsch, 2018). A healthy community neither ignores nor

overreacts to this kind of mobility. Rather, its members work collaboratively to recognize and address their unique needs and barriers to health.

## Social System

In addition to location and population, every community has a third feature—a social system. The various parts of a community's social system that interact and influence the health of a community are called social system variables. These variables include health, family, economy, education, religion, welfare, politics, recreation, law, and communication (Fig. 15-6). Whether assessing a community's health, developing new services for the mentally ill within the community, or promoting the health of older adults, the community health nurse needs to understand the community as a social system. A community health nurse working in a tiny village in Alaska needs to understand and work with the social system of that village no less than a nurse practicing in New York City. When a group of organizations are linked and have similar functions, such as all those providing social services, they form a community system or subsystem. The various community systems have a profound influence on one another. Because this interaction among parts determines the health of the whole, it is the total social system that concerns community health nurses. Table 15-4 guides the nurse in assessing a community's social system variables.

**FIGURE 15-6** The community as a social system. Each of the 10 major systems of a community includes a number of subsystems that are made up of organizations. Members of the community occupy roles in these organizations.

**TABLE 15-4 Community Profile Inventory: Social System Perspective**

Social System Variables	Community Health Implications	Community Assessment Questions	Information Sources (For All—Various Internet Sites)
Health system Family system Economic system Educational system Religious system Welfare system Political system Recreational system Legal system Communication system	Each system must fulfill its functions for a healthy community. Collaboration among the systems to identify goals and problems affects health of community. Undue influence of one system on another may lower the health of the community. Agreement on the means to achieve community goals affects community health. Communication among organizations in each system affects community health.	What are the functions of each major system? What are the major subsystems of each system? What are the major organizations in each subsystem? How well do the various organizations function? Are the subsystems in each major system in conflict? Is there adequate communication among the major systems? Is there agreement on community goals? Are there mechanisms for resolving conflict? Do any parts of the total system dominate the others? What community needs are not being met? # THE NURSING PROCESS APPLIED TO THE COMMUNITY AS CLIENT

Consisting of a systematic, purposeful set of interpersonal actions, the nursing process provides a structure for change that remains a viable tool employed by the community health nurse. This chapter examines the use of the nursing process as applied at the aggregate or community level. Five components—assessment, diagnosis, planning, implementation, and evaluation—give direction to the dynamics for solving problems, managing nursing actions, and improving the health of communities and community health nursing practice. Three characteristics support the use of the nursing process in community health nursing.

- First, the nursing process is a problem-solving process that addresses community health problems at every aggregate level with the goals of preventing illness and promoting public health.
- Second, it is a management process that requires situational analysis, decision-making, planning, organization, direction, and control of services, as well as outcome evaluation. As a management tool, the nursing process addresses all aggregate levels.
- Third, it is a process for implementing changes that improve the function of various health-related systems and the ways that people behave within those systems.

The nursing process provides a framework or structure on which C/PHN actions are based (ANA, 2013). Application of the process varies with each situation, but the nature of the process remains the same. Certain characteristics of that process are important for community health nurses to emphasize in their practices. The Quad Council of Public Health Nursing Organizations (which is now the Council of Public Health Nursing Organizations), building on the work of the Council on Linkages Between Academia and Public Health Practice, developed a list of core competencies for C/PHNs. These competencies have helped clarify the role of the community health nurse within the context of community as client (see the appendix and [http://www.quadcouncilphn.org/wp-content/uploads/2018/05/QCC-C-PHN-COMPETENCIES-Approved\\_2018.05.04\\_Final-002.pdf](http://www.quadcouncilphn.org/wp-content/uploads/2018/05/QCC-C-PHN-COMPETENCIES-Approved_2018.05.04_Final-002.pdf); Quad Council, 2018).

## **Deliberative**

The nursing process, like the research process in evidence-based practice, is deliberative—purposefully, rationally, and carefully thought out. It requires the use of sound judgment that is based on adequate information. C/PHNs often practice in situations that demand the ability to think independently and make difficult decisions. Furthermore, thoughtful, deliberative problem solving is a necessary skill for working with the community health team to address the needs and problems of aggregates in the community. The nursing process is a decision-making tool to facilitate these determinations ([ANA, 2018](#)).

## **Adaptable**

The dynamic nature of the nursing process enables the community health nurse to adapt it appropriately to each situation and apply it to meeting aggregate health needs. Furthermore, its flexibility is a reminder to the nurse that each client group and each community situation is unique. The nursing process must be applied specifically to the individual situation and group of people. Based on assessment and sound planning, the nurse adapts services to meet the identified needs of each community client group.

## **Cyclical**

The nursing process is cyclical and in constant progression. Steps are repeated over and over in the nurse–aggregate client relationship. The nurse engages in continual interaction, data collection, analysis, intervention, and evaluation. As interactions between nurse and client group continue, various steps in the process overlap with one another and are used simultaneously. The cyclic nature of the nursing process enables the nurse to engage in a constant information feedback loop: the information gathered and lessons learned at each step of the process promote greater understanding of the group being served, the most effective way to provide quality services, and the best methods of raising this group's level of health.

## **Client Focused**

The nursing process is used for and with clients. Community health nurses use the nursing process for the express purpose of addressing the health of populations. They are helping aggregate clients, directly or indirectly, to achieve and maintain health. Clients as total systems—whether groups, populations, or communities—are the targets of the C/PHN's nursing process (ANA, 2018).

## **Interactive**

The nurse and clients are engaged in a process of ongoing interpersonal communication. Giving and receiving accurate information is necessary to promote understanding between nurse and clients and to foster effective use of the nursing process. Furthermore, because of the movement toward informed use of health care, demands for clients' rights and the concept of self-care have gained emphasis. Client groups and community health nurses have increasingly joined forces to assume responsibility for promoting community health. The nurse–aggregate client relationship can and should be a partnership, a shared experience by professionals (nurses and others) and client groups ([Tucker, Arthur, Roncoroni, Wall, & Sanchez, 2015](#)).

## **Need Oriented**

A long association with problem solving has tended to limit the focus of the nursing process to the correction of existing problems. Although problem solving is certainly an appropriate use of the nursing process, the community health nurse can also use the nursing process to anticipate client needs and prevent problems. The nurse should think of nursing diagnoses as ranging from health problem identification to primary prevention and health promotion opportunities. This focus is needed if the goals of community health—to protect, promote, and restore the people's health—are to be realized.

## **Interacting With the Community**

All steps of the nursing process depend on interaction, reciprocal exchange, and influence among people. Although nurse–client interaction is often an implied or assumed element in the process, it is an essential first consideration for community health nursing. This type of engagement was observed during the Flint water crisis, where C/PHNs established relationships with community members and were thereby able to identify and directly aid in addressing their needs. These relationships also facilitated communication between community members and service providers (see [Chapter 10](#) for more details). Listening to a group of older people, teaching a class of expectant mothers, lobbying in the legislature for the poor, working with parents to set up a dental screening program for children—all of these involve relationships, and relationships require interaction. Mutual give and take between nurse, clients, and community stakeholders—whether a family, a group of mothers on a Native American reservation, or representatives from resource agencies within the community—is an expected and much needed skill that should be integrated throughout the nursing process.

### *Need for Communication*

C/PHNs can serve as effective liaisons—facilitating communication between stakeholders and clients to ensure that health needs are both identified and adequately addressed.

### *Interaction and Effective Communication*

Through open and honest sharing, the nurse (and others on the health team) can begin to develop trust and establish lines of effective communication. For instance, the nurse explains the nurse's role and purpose for being there. The nurse encourages the group members to talk about themselves. The nurse and group members together discuss their relationship and clarify the desired nature of that alliance. Does the group want help to identify and work on its health needs? Would its members like this nurse to continue regular contacts? What will their respective roles be? Effective communication, as a part of interaction, is essential to develop understanding and facilitate a free exchange of information between nurse and client.

### *Interaction Is Reciprocal*

Sharing of information, ideas, feelings, concerns, and self goes both ways. The community health nurse (and other collaborating health professionals) represents one system and the client group represents the other. Health care professionals tend to prioritize based on their own perspective and many

times neglect to take the clients' wishes into account. Whether the client is a parent group, a homeless population, or an entire community, this exchange involves a two-way sharing between the nurse and client group. The key elements of interaction are mutuality and cooperation.

Consider the following example: After several weeks of meeting with a community member focus group to discuss disease management and physical activity, a C/PHN noticed that community violence was a recurring theme during group discussions. Community residents described conditions in the neighborhood as unsafe and many indicated that they were afraid to adopt the nurse's recommendations to increase physical activity because of ongoing violence near their homes. The nurse initially felt unprepared to address this issue but, after consulting with other support agencies within the community, realized that resources were available. After meeting and coordinating with community members and support agencies, the nurse was able to develop a feasible and safe physical activity plan for residents. Engagement with community members and communication were the first step in reapplying the nursing process and allowed goals for the group to be accomplished.

### *Interaction Paves the Way for a Helping Relationship*

As nurse and client interact, each learns about the other. A test period occurs before trust can be fully established (Summach, 2011). For a female school nurse working with middle school students about health education and human sexuality, establishing interaction was more difficult at the time of the initial contact with the boys than with the girls. They had been reluctant to talk and felt embarrassed to discuss personal subjects with an adult they did not know. Nonetheless, their interests in bodybuilding and personal appearance were strong enough to bring them to these optional sessions. Interaction began with a friendly exchange on nonthreatening topics and gradually deepened, as the boys seemed ready to discuss personal subjects. Eventually, it was relatively simple to talk about a new “problem” (and start the nursing process over again), because a helping relationship had already been developed. The nurse had a track record. The boys trusted, respected, and liked the nurse, so they were happy to interact around a newly stated need.

### *Aggregate Application*

As noted in earlier chapters, community health practice focuses largely on the health of population groups; therefore, interaction goes beyond the one-on-one with individual patients. The challenge that the community health nurse faces is a one-to-aggregate approach. A group of parents concerned about teenage alcohol abuse, people with physical disabilities needing access ramps, and a neighborhood's older adult population frightened by muggings

and thefts are all aggregates or clients with different concerns and opinions. As defined in [Chapter 1](#), an aggregate refers to a mass or grouping of distinct individuals who are considered as a whole and who are loosely associated with one another. Each person in an aggregate is influenced by the thoughts and behavior of other group members. Nursing interaction with an aggregate client demands an understanding of group behavior, group dynamics, and group-level decision-making. It requires interpersonal communication skills applied at the group level. Interaction is more complex and challenging with an aggregate than with an individual but also can be rewarding. Once community health nurses acquire an understanding of aggregate behavior, they can capitalize on the potential of group influence to make a far-reaching impact on the health of the total community. [Chapter 10](#) more closely examines communication and interaction with groups.

## Forming Partnerships and Building Coalitions

Community-level nursing practice also requires teamwork. The job of planning for the health of an entire community or a community subsystem requires that the nurse collaborate with other professionals. Usually, the nurse is part of an organized team, separate from the agency that employs the nurse. The team is brought together with the goal of improving the health of the community. Each group member brings expertise and a particular view of the problem. These interprofessional work groups are often formed as either partnerships or coalitions (Wyer, Umscheid, Wright, Silva, & Lang, 2015).

The Maryland Collaborative is an example of a collaborative practice approach to reduce college drinking and related problems (Arria & Jernigan, 2018). A priority for the Maryland Department of Health and Hygiene was to reduce excessive drinking among college students. A collaboration was formed with the state health department, the Chancellor of the UC System, and other university presidents in the state to address excessive drinking on college campuses through the lens of individual, interpersonal networks, and organizational and environmental factors. Using assessment techniques, hot spot areas on campuses were identified, and campus teams worked with local community members to develop strategies to reduce excessive drinking and related problems. An evidence-based and community partnership approach can address serious health issues at the individual and community, level thereby providing a "...positive academic and social experience for students, quality of life for the campus community, and viability of the surrounding neighborhoods" (Arria & Jernigan, 2018, p. 311).

**Partnerships** are agreements between people (and agencies) that support a joint purpose. A partnership can be large (e.g., a multinational corporation and several high schools; a city government and the county jail system), or it can be a more modest endeavor (e.g., a group of older adult citizens and a preschool program; a Girl Scout troop and a community recycling program).

To enhance the outcomes of a program for the homeless while improving the health needs of homeless individuals and families, the Shelter Nurse Program and public health nursing service, along with community members, worked in partnership to develop a plan to demonstrate population outcomes formalizing goals and objectives for the agency (Minnich & Shirley, 2017). By collaborating on this project, the partnership identified program needs, developed goals and objectives, and created a comprehensive evaluation plan to meet the needs of the local homeless population. Working together to develop areas for improvement to meet the needs of homeless clients, both the agency and the shelter nurses learned the value of a program development model and the importance of front-line workers' participation in the process (Minnich & Shirley, 2017).

Community-wide partnerships require more planning and coordination than do small partnerships. For example, because of increased student enrollment, a college may need two additional temporary and part-time faculty members who can teach the C/PHN course. The county public health department is interested in more new graduate nurses coming to work in the agency. The nursing program and the health department form a partnership and design a plan to solve both problems. The health department selects two staff nurses who have master's degrees and are qualified to teach undergraduate clinical courses in C/PHN one day a week for two semesters. The benefits for everyone are numerous. The nursing program solves a temporary staffing problem; the nurses from the health department share their expertise with students, enhancing their practice and the students' learning experience; and the health department successfully introduces a pool of students, who may be potential staff members, to the agency and the services that it provides for the community.

A coalition is an alliance of individuals or groups that work together to influence the outcomes of a specific problem. Coalitions are an effective means to achieve a collaborative and coordinated approach to solving community problems. Steps to coalition building include ([CDC, 2015b](#))

- Defining goals and objectives
- Conducting a community assessment
- Identifying key players or leaders
- Identifying potential coalition members

Staying in touch with the coalition members, running effective meetings, and keeping every participant involved are means of keeping the coalition active.

Sound public health practice depends on pooling resources—including people—in ways that will best serve the public. In planning for a community's health, the community (represented by appropriate individuals and agencies) must be involved. Community health nurses cannot lose sight of the need for client involvement at all levels and in all stages of community health practice ([Box 15-2](#)).

## BOX 15-2 PERSPECTIVES

**A Public Health Nurse's Viewpoint on Addressing Adolescent Pregnancy** I am a public health nurse and my health department serves a community with a large proportion of adolescents and young adults aged 18 to 24. After reviewing data from a recent community health status assessment, members of our community council observed a significant increase in the number of unplanned pregnancies among members of this age group. We proceeded to convene a group of community stakeholders with the intention of partnering with them to identify and implement solutions to address these issues. Several meetings were held, and key members of the community were invited to participate, including a local church pastor, youth group leaders, and administrators representing nonprofit organizations targeting this same issue. Further analysis of this issue, the group agreed to develop a plan to address unplanned pregnancy and to also target resources toward secondary prevention in order to support those who had experienced unplanned pregnancies and were now raising their children as single parents.

An assessment of community resources was conducted to identify available programs and resources. We searched the literature for best practices on this topic and collaborated with program planners to develop an implementation plan for our target population. The group engaged local leaders to request funding for areas where gaps in services were identified. After 2 months of planning, community resources were identified and coordination was conducted to begin marketing and outreach efforts. Referral mechanisms in local clinics were used to link potential clients to our program, and we received several word-of-mouth recommendations for

participants. The program consists of birth control education, counseling, participation in group informational sessions, and the assignment of a primary care manager in our community-based clinic.

A 6-and 9-month outcome evaluation is planned to monitor the effect of our program. Anecdotal feedback has been resoundingly positive. The commitment of our partners is evident as our efforts have been embraced and supported by a wide range of leaders and community members. This commitment appears to have yielded a great response from program participants. Participants have remarked about the quality of services received, and many have commented on the quality of care they received in our program.

*Tara, public health nurse*

# TYPES OF COMMUNITY NEEDS ASSESSMENT

Assessment is the key initial step of the nursing process; it involves collecting and evaluating information about a community's health status to discover existing or potential needs and assets as a basis for planning future action ([Anderson & McFarlane, 2019](#)). Assessments are also a critical requirement for public health department accreditation ([Public Health Accreditation Board, 2019](#)).

Several models or frameworks can be used for assessment. Three such models are

- Mobilizing for Action through Planning and Partnerships
- Protocol for Assessing Community Excellence in Environmental Health
- Planned Approach to Community Health

These models have been developed through partnership with the Centers for Disease Control and Prevention (CDC) to improve community assessment in relation to healthy people goals ([CDC, 2015a](#)) and to assist communities in assessing health promotion and chronic disease prevention programs. The *Healthy People* Web site also provides planning tools and toolkits to assist local communities (see internet resources on [thePoint](#)). These are all valuable resources that provide specific guidelines focusing on local-level strategies to improve the health of communities.

Assessment involves two major activities:

- Collection of pertinent data
- Analysis and interpretation of data

These actions overlap and are repeated constantly throughout the assessment phase of the nursing process. While assessing a community's ability to enhance its health, the nurse may simultaneously collect data on community lifestyle behaviors and interpret previously collected data on morbidity and mortality.

Community health assessment is the process of determining the real or perceived needs of a defined community. In some situations, an extensive community study may be the first priority; in others, all that is needed is a study of one system or even one organization. At other times, community health nurses may need to perform a cursory examination or **windshield**

**survey** to familiarize them with an entire community without going into any depth ([Anderson & McFarlane, 2019](#)).

## **Familiarization or Windshield Survey**

A familiarization assessment is a common starting place in evaluation of a community. Familiarization assessment involves studying data already available on a community and then gathering a certain amount of firsthand data in order to gain a working knowledge of the community. Such an approach may use a windshield survey—an activity often used by nursing students in public health courses and by new staff members in community health agencies. Nurses drive (or walk) around the community of interest; find health, social, and governmental services; obtain literature; introduce themselves and explain that they are working in the area; and generally become familiar with the community and its residents. This type of assessment is needed whenever the community health nurse works with families, groups, organizations, or populations.

The windshield survey provides knowledge of the context in which these aggregates live and may enable the nurse to better connect clients with community resources (Box 15-3). See an example in Box 15-4.

**BOX 15-3 Community Familiarization (Windshield) Survey** A windshield survey is often done to help you become familiar with a new community or public health service area. Walking/driving around neighborhoods and interacting with community members can provide a context for further community assessment. You might begin at the local Chamber of Commerce or government building to determine history, current statistics, and demographics and to access maps and further resources for data you might use

## for a more formal community health assessment.

### Physical

- Look at the age and conditions of the buildings, the density (apartments, houses on large lots) and materials used (bricks, plywood), and the zoning and maintenance of yards/empty lots. What clues does that give you about the community as a whole?
- How similar are the houses (are some neighborhoods very rich, others very poor)? Are there abandoned vehicles, piles of excess trash, large numbers of stray animals/for sale signs, or vacant houses?
- Are there open spaces (parks, agricultural areas, public/private areas like golf courses) and are they being used; by whom?
- Are there boundaries separating the community (e.g., natural boundaries like rivers, economic boundaries, commercial/residential boundaries)?
- What about air/water quality, signs of pollution?

### Economic

- Does the area look like it is a thriving community?
- Are there areas where homeless gather? Soup kitchens?
- Is there adequate shopping (e.g., grocery stores, shopping centers)?
- Does it appear that food stamps are accepted/welcomed?
- Are there businesses, industries, manufacturing, and adequate places for employment? What is the unemployment rate?

### Services

- Are there schools (how many, in what condition)? School nurses? What are the main concerns or problems with the educational system here (e.g., dropout rates)?
- Are there libraries? Do they provide additional services (e.g., internet)? Are they well used?
- Are there recreational facilities (e.g., gyms, playgrounds, soccer fields, baseball diamonds)? Are these being used and by whom?
- How many churches do you see? What denominations?
- Is there adequate health care? Does the community have a hospital? Are there adequate health care services (e.g., physicians, clinics, nurses, mental health/substance abuse facilities, PH department services, nursing homes, traditional health care

providers)? Is it a medically underserved area or a health professions shortage area?

- What types of social services are available (e.g., welfare/social workers, shelters, mental health counseling)? Do you see one main location for social services (e.g., government center) or are they dispersed around the community?
- What types of public/private transportation are available? Are highways and roads crowded with traffic? Accident rate? Are there bike paths/trails and adequate sidewalks? How is transportation access for the disabled?
- Does the community “feel” safe to you? Is there adequate fire and police protection? What is the crime rate? What are the most common types of crimes?
- Are there signs of political activity (e.g., posters, notices of meetings, predominant party affiliations)? Do people feel that they can be involved in decisions made by their local government?

## **Social**

- Are there common “hangouts” (e.g., teen gathering spots, chess playing for older adults)? What about local newspapers, radio, and TV (e.g., satellite dishes)?
- Who do you see on the streets? Are there indications of homogeneity or diversity of ethnicities, languages spoken, SES (socioeconomic status), and occupations? How are people dressed?
- How do people feel about living in this community? What problems or concerns do they express? What strengths do they note? How “healthy” is their community?
- What are your impressions of this community?

Source: [Anderson and McFarlane \(2019\)](#).

**BOX 15-4 STORIES FROM THE FIELD: WORKING WITH THE COMMUNITY ON A SAFETY ASSESSMENT CONSIDER THE FOLLOWING EXAMPLE: AFTER SEVERAL WEEKS OF MEETING WITH A COMMUNITY-MEMBER**

**FOCUS GROUP TO DISCUSS DISEASE MANAGEMENT AND PHYSICAL ACTIVITY, A PUBLIC HEALTH NURSE (C/PHN) NOTICED THAT COMMUNITY VIOLENCE WAS A RECURRING THEME DURING GROUP DISCUSSIONS. COMMUNITY RESIDENTS DESCRIBED CONDITIONS IN THE NEIGHBORHOOD AS UNSAFE AND MANY INDICATED THAT THEY WERE AFRAID TO ADOPT THE NURSE'S RECOMMENDATIONS TO INCREASE PHYSICAL ACTIVITY DUE BECAUSE OF ONGOING VIOLENCE NEAR THEIR HOMES. THE NURSE INITIALLY FELT UNPREPARED TO ADDRESS THIS ISSUE BUT AFTER CONSULTING WITH OTHER SUPPORT AGENCIES WITHIN THE COMMUNITY, SHE REALIZED THAT RESOURCES WERE AVAILABLE. AFTER MEETING AND COORDINATING WITH COMMUNITY MEMBERS AND SUPPORT AGENCIES, SHE**

**WAS ABLE TO DEVELOP A FEASIBLE AND SAFE PHYSICAL ACTIVITY PLAN FOR RESIDENTS. ENGAGEMENT WITH COMMUNITY MEMBERS AND COMMUNICATION WERE THE FIRST STEP IN REAPPLYING THE NURSING PROCESS AND ALLOWED GOALS FOR THE GROUP TO BE ACCOMPLISHED.**

1. *What should the C/PHN know about location, population, and social system to be better prepared to work with this group?*
2. *How can the C/PHN use the nursing process to direct the plan of care with this community?*

## **Problem-Oriented Assessment**

A second type of community assessment, problem-oriented assessment, begins with a single problem and assesses the community in terms of that problem. Instead of working to gather information about the larger community, the nurse would identify resources, programs, and support networks of potential benefit to the family. Steps taken to complete this assessment would include collecting data on local prevalence and incidence, interviewing officials to obtain information on processes and policies, and identifying local programs and services.

The problem-oriented assessment can be used when familiarization is not sufficient, and a comprehensive assessment is not feasible. This type of assessment is responsive to a particular need and should also seek to describe contextual issues associated with the need. The data collected can support community efforts to address specific problems. Data should address the magnitude of the problem to be studied (e.g., prevalence, incidence), the precursors of the problem, and information about population characteristics (e.g., community resources, strengths, and weaknesses), along with the attitudes and behaviors of the population being studied ( [Kirst-Ashman, 2014](#)).

## **Community Subsystem Assessment**

In **community subsystem assessment**, the C/PHN focuses on a single dimension of community life. For example, the nurse might decide to survey churches and religious organizations to discover their roles in the community. What kinds of needs do the leaders in these organizations believe exist? What services do these organizations offer? To what extent are services coordinated within the religious system and between it and other systems in the community?

In one situation, churches and other cultural leaders were instrumental in providing information to address the local public health department's concerns. A small county health department worked with the nearby university C/PHN clinical instructor and the instructor's students to determine why two specific racial/ethnic groups did not use free women's health clinics. Students from the university conducted focus groups with local clergy and representatives from the racial groups to better understand the group's health seeking behaviors. Health department officials reviewed transcripts from the focus groups and discovered that most members of the groups were unaware of the services provided through the county health department. The students then conducted additional interviews with families within the groups and found that, as part of their cultural practice, husbands generally accompany their wives when getting prenatal care or family planning services. They also learned that members of the group felt more comfortable with health care personnel of their own race and that there was a provider from their ethnic group practicing in a neighboring county. As a result of these subsystem engagements, health department staff were able to tailor their service offerings to better meet the needs to these groups and a partnership for health was established with local clergy and group members.

Community subsystem assessment can be a useful way for a team to conduct a more thorough community assessment. If five members of a nursing agency divide up the 10 systems in the community and each person does an assessment of two systems, they could then share their findings to create a more comprehensive picture of the community and its needs.

## Comprehensive Assessment

Comprehensive assessment seeks to discover all relevant community health information. It begins with a review of existing studies and all the data presently available on the community. A survey compiles all the demographic information on the population, such as its size, density, and composition.

Key informants are interviewed in every major system—education, health, religious, economic, and others. **Key informants** are experts in one particular area of the community, or they may know the community as a whole. Examples of key informants would be a school nurse, a religious leader, key cultural leaders, the local police chief or fire captain, a mail carrier, or a local city council person. Then, more detailed surveys and intensive interviews are performed to yield information on organizations and the various roles in each organization.

A comprehensive assessment describes the systems of a community and also how power is distributed throughout the system, how decisions are made, and how change occurs ([Anderson & McFarlane, 2019](#)).

Because comprehensive assessment is an expensive, time-consuming process, it is not often undertaken. Performing a more focused study, based on prior knowledge of needs, is often a better and less costly strategy. Nevertheless, knowing how to conduct a comprehensive assessment is an important skill when designing smaller more focused assessments ([Box 15-5](#)).

### BOX 15-5 PERSPECTIVES

**A Public Health Nursing Student Viewpoint on Addressing Adolescent Pregnancy After completing my Med-Surg courses, I was excited to begin my Community Health rotation. I looked forward to stepping outside of the clinical environment to engage community members but I**

**absolutely I dreaded the thought of having to complete the perfunctory comprehensive community health assessment. To my delight, the assessment process had recently been revamped and, instead of repeating the task of collecting the same data that the previous classes had collected, my class was able select from a list of community health projects for which data were needed. These projects were directly related to grants currently being written by staff and state-directed program evaluations that the department was working on. The fact that these were real-time projects made the assignment feel less like a task and more like a meaningful opportunity to contribute to the health of community members served by the department. My class voted to collect data for a grant-funded project to address teen pregnancy, and we set about creating our own survey tools drawing from standardized assessment products. We were excited about our work and tackled the project bunch of detectives chasing down leads! We divided into subgroups, gathered data, problem-solved and worked together to achieve our goals. We also worked with other agencies and NGOs, and spoke with local health care providers and members of the community. Toward the end of our project, we collaborated with the program director for a teen pregnancy program to distribute questionnaires to local teens so that we could gather information on sexual activity and attitudes. At that time, the conservative county**

**that we worked in had the highest rate of teen pregnancies in the state and many parents opposed *Sex Ed*. However, we were able to gather information and statistics on teen pregnancies in this county and compared it with state and national data. After investigating best practices for teen pregnancy prevention programs, we formed into smaller work groups, some met with school officials, high school students, teachers, and parents to educate them about this project. In the end, everyone in my class felt that by working on this project, they made a meaningful contribution to the community and the health department and the university heartily agreed!**

Mikinsey, nursing student

## Community Assets Assessment

Assets mapping focuses on the strengths and capacities of a community rather than its problems (Jakes, Hardison-Moody, Bowen, & Blevins, 2015) and evaluates variables such as the needs that exist, the goals to be achieved, and the resources available for carrying out the study.

Although it is difficult to determine the type of assessment needed in advance, understanding the various types of community assessment in advance helps to facilitate your decision. Based on a classic model developed by McKnight and Kretzmann in the 1980s (Kretzman & McKnight, 1993), the **assets assessment** provides a framework for conducting a complete functional community assessment and serves as a guide to the community for the nurse, as well as the foundation for community development.

The previously mentioned methods are needs oriented and deficit based—in other words, they are *pathology* models, in which the assessment is performed in response to needs, barriers, weaknesses, problems, or perceived scarcity in the community. This may result in a fragmented approach to solutions for the community's problems rather than an approach focused on the community's possibilities, strengths, and assets. The assets assessment also provides the community the ability to “identify a variety and richness of skills, talents, knowledge, and experience of people” and “provides a base upon which to build new approaches and enterprises” (p. 4).

Assets assessment begins with what is present in the community (Jakes et al., 2015). The capacities and skills of community members are identified, with a focus on creating or rebuilding relationships among local residents, associations, and institutions to multiply power and effectiveness. This approach requires that the assessor look for the positive or see the glass as half full. The nurse can then become a partner in community intervention efforts, rather than merely a provider of services. Assets assessment includes three levels (Kramer, Seedat, Lazarus, & Suffla, 2011):

1. Specific skills, talents, interests, and experiences of individual community members such as individual businesses, cultural groups, and professionals living in the community.
2. Local citizen associations, organizations, and institutions controlled largely by the community such as libraries, social service agencies, voluntary agencies, schools, and police.
3. Local institutions originating outside the community controlled largely outside the community such as welfare and public capital expenditures (p. 14).

The key, however, is linking these assets together to enhance the community from within. The community health nurse's role is to assist with

those linkages.

# METHODS FOR COLLECTING COMMUNITY DATA

The health status of the community may be assessed using a variety of methods. Regardless of the assessment method used, data must be collected. The Community Health Assessment and Group Evaluation (CHANGE) Tool (<https://www.cdc.gov/nccdphp/dch/programs/healthycommunitiesprogram/tools/change/downloads.htm>) is an example of a current process to prioritize community needs for community-based improvements (CDC, 2019d). The tool assists C/PHNs and community members through the community change process (commitment, assessment, planning, implementation, and evaluation). Once a CHANGE team is assembled, data must be gathered to fully assess the community's need. Data collection in community health requires the exercise of sound professional judgment, effective communication techniques, and special investigative skills. Four important methods are discussed here: surveys, descriptive epidemiologic studies, community forums or town meetings, and focus groups.

## Surveys

A survey is an assessment method in which a series of questions is used to collect data for analysis of a specific group or area. Surveys are commonly used to provide a broad range of data that will be helpful when used with other sources or if other sources are not available.

To plan and conduct community health surveys, the goal should be to determine the variables (selected environmental, socioeconomic, and behavioral conditions or needs) that affect a community's ability to control disease and promote wellness. The nurse may choose to conduct a survey to determine such things as health care use patterns and needs, immunization levels, demographic characteristics, or health beliefs and practices.

The survey method involves self-report, or response to predetermined questions, and can include questionnaires, telephone, or in person interviews (Polit & Beck, 2017).

Survey findings can be combined with other health data in order to better understand the health status of the community and the determinants of health. These data include reports of health risks and outcomes by zip code (Agarwal, Menon, & Jaber, 2015; Wang, Ponce, Wang, Opsomer, & Yu, 2015) and CDC Environmental Health Tracking Network reports of local environmental health exposures (Charleston, Wilson, Edwards, David, & Dewitt, 2015). Consideration of these data along with survey results allows for a more comprehensive understanding of the community's health status and the conditions impacting health.

## **Descriptive Epidemiologic Studies**

A second assessment method is a descriptive epidemiologic study, which examines the amount and distribution of a disease or health condition in a population by person (Who is affected?), by place (Where does the condition occur?), and by time (When do the cases occur?). In addition to their value in assessing the health status of a population, **descriptive epidemiologic studies** are useful for suggesting which individuals are at greatest risk and where and when the condition might occur. They have also long been known to be useful for health planning purposes and for suggesting hypotheses concerning disease etiology ([Merrill, 2017](#)). Their design and use are detailed in [Chapter 7](#).

## **Geographic Information System Analysis**

In [Chapter 10](#), the concept of GIS was introduced as a health information technology. GIS technology is an integration of research methods and analytic techniques from both medical geography and spatial epidemiology. It has been well documented as a tool that can collect, organize, and display public health data, and it is widely used in assessment and research of health disparities, resource availability, and health-related behaviors ([WHO, 2019a](#)).

Harvard's T.H. Chan School of Public Health offers a Web site designated to the use of GIS in public health, including particular research studies. For instance, one line of research examines effects of air pollution on MI rates within the community of Worcester and spatial mapping of incidence and levels of pollution. Researchers are also working on developing a predictive model for pollution's effect on death rates in Eastern Massachusetts. A prospective study of normative aging began with data collected from healthy cohort of 2,500 individuals in the 1970s; and GIS data on exposure are used to estimate cumulative exposure to pollution and its association with COPD, MI, and death ([Harvard University, 2019](#)). The WHO has been using GIS for leprosy elimination ([WHO, 2019a](#)).

## Community Forums and Social Media

The community forum or town hall meeting is a qualitative assessment method designed to obtain community opinions. It takes place in the neighborhood of the people involved, perhaps in a school gymnasium or an auditorium. The participants are selected to participate by invitation from the group organizing the forum.

Members come from within the community and represent all segments of the community that are involved with the issue. For instance, if a community is contemplating building a swimming pool, the people invited to the community forum might include potential users of the pool (residents of the community who do not have pools and special groups such as the Girl Scouts, elders, and disabled citizens), community planners, health and safety personnel, and other key people with vested interests. They are asked to give their views on the pool: Where should it be located? Who will use it? How will the cost of building and maintaining it be assumed? What are the drawbacks to having the pool? Any other pertinent issues the participants may raise are included. This method is relatively inexpensive, and results are quickly obtained.

A drawback of this method is that only the most vocal community members, or those with the greatest vested interests in the issue, may be heard. This format does not provide a representative voice to others in the community who also may be affected by the proposed decision.

Town halls are used to elicit public opinion on a variety of issues, including health care concerns, political views, and feelings about issues in the public eye, such as school safety.

Frequently, local news may stream important city government or school board meetings. Other methods of opinion gathering include e-mailing to support a particular view, Web-based survey sites, and text messaging a Yes or No vote on an issue. Social media sites, like Facebook and Twitter, are also popular forums for opinion sharing. Digital media is often used to elicit grassroots opinions from local community members. See more ideas on the use of social media in [Chapter 10](#).

## Focus Groups

Focus groups are similar to the community forum or town hall meeting in that it is designed to obtain grassroots opinion with a small group of participants, usually 5 to 15 people.

The members chosen for the group are homogeneous with respect to specific demographic variables. For example, a focus group may consist of female community health nurses, young women in their first pregnancy, or retired businessmen. Leadership and facilitation skills are used in conjunction with the small group process to promote a supportive atmosphere and to accomplish set goals. The interviewer guides the discussion according to a predetermined set of questions or topics. A focus group can be organized to be representative of an aggregate, to capture community interest groups, or to sample for diversity among different population groups. Whatever the purpose, however, some people may be uncomfortable expressing their views in a group situation.

The choice of assessment method varies depending on the reasons for data collection, the goals and objectives of the study, and the available resources. It also varies according to the theoretical framework or philosophical approach through which the nurse views the community. In other words, the community health nurse's theoretical basis for approaching community assessment influences the purposes for conducting the assessment and the selection of methodology. For example, Neuman's health care systems model forms the basis for the “community-as-partner” assessment model developed by (Anderson & McFarlane, 2019). Additional resources on methodologies for assessing community health (e.g., list of internet resources) are available on [thePoint](#) .

# SOURCES OF COMMUNITY DATA

The community health nurse can look in many places for data to enhance and complete a community assessment. Data sources can be primary or secondary, and they can be from international, national, state, or local sources. Web sites for many primary and secondary data sources are included in internet resources on [thePoint](#) .

## **Primary and Secondary Sources**

C/PHNs make use of many sources in data collection. Community members, including formal leaders, informal leaders, and community members, can frequently offer the most accurate insights and comprehensive information.

Information gathered by talking to people provides primary data, because the data are obtained directly from the community. Specific examples are health team members, client records, community health (vital) statistics, census bureau data, reference books, research reports, HEDIS measures, and community health nurses.

Secondary sources of data include people who know the community well and the records such people create in the performance of their jobs. Because secondary data may not totally describe the community and do not necessarily reflect community self-perceptions, they may need augmentation or further validation through focus groups, surveys, and other primary data collection methods.

## **International Sources**

International data are collected by several agencies, including the World Health Organization (WHO) and its six regional offices and health organizations, such as the Pan-American Health Organization. The WHO publishes health statistics by country and information about specific diseases and health measures in their annual Global Health Observatory. Information from these official sources can give the nurse in the local community information about immigrant and refugee populations he serves. More information on international health agencies can be found in [Chapter 16](#).

## National Sources

C/PHNs can access a wealth of official and nonofficial sources of national data (see [Chapter 6](#) for more information). Official sources develop documents based on data compiled by the government. The following are the major official agencies: **USDHHS**. This is the main agency from which data can be retrieved, and the National Center for Health Statistics (NCHS) at the **Centers for Disease Control and Prevention (CDC)** was specifically established under its auspices for the collection and dissemination of health-related data. This agency is the nation's principal health statistics agency, compiling data from many sources. These data provide information for many functions, including health status for various populations and subgroups, identification of disparities, monitoring trends, identifying health problems, and supporting research.

USDHHS also developed *Healthy People 2030* ([USDHHS, 2020](#)), designed to focus America's attention on the major national health problems, including realistic goals for national, state, and local agencies to work toward over one decade. Other data sources are also available through the [CDC \(2019b\)](#).

**U.S. Census Bureau.** This agency undertakes a major survey of American families every 10 years, gathering data on health, socioeconomic, and environmental conditions. This information is available on the Web or on a CD-ROM, allowing numerous variables to be viewed in combination, for easier development of a community profile ([U.S. Census Bureau, 2019](#)).

**National Institutes of Health (NIH).** This system focuses on improving the health of the nation. An emphasis is placed on discovery of new cures or treatments and preventing disease. Employees of these agencies prevent, diagnose, and treat diseases and conduct research and disseminate research findings ([NIH, 2019](#)).

Nongovernmental organizations (NGOs) have data sources generated from research they conduct that focuses on the population, disease, or condition they were developed to serve. Each agency collects data at the national level; however, the more accessible arm for services functions at state, county, and local levels. Examples of these agencies are the American Cancer Society (ACS), American Heart Association (AHA), the American Association of Retired Persons (AARP), Mothers Against Drunk Drivers (MADD), and Students Against Drunk Drivers (SADD). The [Public Health Foundation \(2020\)](#) offers information on many areas of interest to C/PHNs: teams toolbox, critical thinking tools, population health driver diagrams, and other quality improvement tools for public health. The Kaiser Family Foundation and the RAND Corporation have a variety of fact sheets and compilations of data from various sources. The Gallup Poll provides national

survey information on various topics, including health. Information from such national sources allows community health assessment teams to compare local data with national and state statistics and trends—a very valuable function. The [Robert Wood Johnson Foundation's \(2019\) County Health Rankings and Roadmaps](#) is based on a model of population health that emphasizes the many factors that, if improved, can help make communities healthier places to live, learn, work, and play. Proprietary data sources include the American Hospital Association, the American Medical Association, or various health insurance companies. See [Chapter 6](#) for a list of data collection systems.

## State and Local Sources

For nurses, the most significant state source of assessment data comes from the state health department. This official agency is responsible for collecting state vital statistics and morbidity data.

The Behavioral Health Surveillance System (BRFSS) is the world's largest telephone health survey that monitors health risk at the state level (CDC, 2019c). Supported by the CDC, the information is used at various levels to identify risk and prevent disease. As a resource to local health departments, the state health department provides invaluable support services, and it is the main source of health-related data on the state level.

Nonofficial agencies have state chapters or headquarters and compile their information at the state level. Local nonofficial agency chapters have documents of compiled state and national data on the population, disease, or condition they address.

State and county budgets or public health agency Web sites may also provide helpful information. All states collect vital statistics (e.g., births, deaths), and many collect information on hospitalization and morbidities related to infectious diseases, cancer, or cardiovascular disease. State departments of education may have school-based data on immunizations and overall school health. Information on traffic accidents, mental health, and environmental hazards is often available at the state level. States may also organize their statistics by county level, making it easier to compare your county's data with others.

Many sources of information may be obtained at the local level. Some key sources are the local visitor's bureau, city chamber of commerce, city planner's office, health department, hospitals, social service agencies, county extension office, school districts, universities or colleges, libraries, clergy, business and service organizations, and community leaders and key informants. Some of these sources compile their own statistics, but all have views of the community particular to their discipline, interest, or knowledge base. Some agencies at the local level develop city or county directories. These are updated periodically and are valuable resources for community health assessment teams and community health nurses. More detailed information on national, state, and local health agencies, and information available from them, can be found in [Chapter 6](#).

# **DATA ANALYSIS AND DIAGNOSIS**

This stage of assessment requires analysis of the information gathered, so that inferences or conclusions may be made about its meaning. Such inferences must be validated to determine their accuracy, after which a nursing diagnosis can be formed.

# The Analysis Process

First, the data must be validated: Are they accurate, complete, representative of the population, and current? Several validation procedures may be used ([Northwest Center for Public Health Practice, n.d.](#)):

- Data can be rechecked by the community assessment team.
- Data can be rechecked by others.
- Subjective and objective data can be compared.
- Community members can consider the findings and verify them.

Validated data are then separated into categories such as physical, social, and environmental data. In many instances, data spreadsheets are used to provide a structure for data organization. Next, each category is examined to determine its significance. At this point, there may be a need to search for additional information to clarify the meaning of the data. Only then can inferences be made and a tentative conclusion about the meaning of the data be reached ([Anderson & McFarlane, 2019](#)).

Big data have increasingly become a go-to source for clinical and community health professionals seeking to learn more about the health status of communities. Defined as large volumes of data that is amassed, managed, and analyzed from multiple sources, big data provide the level of detail necessary predict and understand public health risks and to develop interventions for specific groups within a larger population. These data are used in disease surveillance, predicting health risk, targeting interventions, and understanding disease ([Zhu et al., 2019](#)). It can be found in clinical information systems (i.e., electronic health records), public payer data claims (i.e., Medicare), and research databases.

Some computer programs are designed to analyze community assessment data. For large, complex, or ongoing community assessment plans, this may be the best method. For smaller, one-time assessments, the paper-and-pencil method may be sufficient and less unwieldy. Some communities may hire an outside professional assessment service. These teams often use the latest technology when analyzing data. Not all communities can afford such a service, and if key leaders become familiar with assessment, analysis, and diagnostic processes, an investment in a computer program may be worthwhile. Regardless of the analysis method used, data interpretation remains a critical phase of the process.

In data interpretation, the ever-present danger exists of making inaccurate assumptions and diagnoses. The importance of validation cannot be overemphasized. Before making a diagnosis, all assumptions must be validated: Are they sound? Community members should participate actively

in validation efforts by clarifying perceptions, explaining the circumstances surrounding the situation, and acting as sounding boards for testing assumptions. Other resources, such as the health team members and community leaders, are used to explore and confirm inferences. Data collection, data interpretation, and nursing diagnosis are sequential activities, with validation serving as the bridges between them. When performed thoroughly, these steps lead to accurate diagnoses.

## Community Diagnosis Formation

The next step of the nursing process, after analysis, is the development of the community diagnosis. **Community diagnosis** stems from analysis of assessment data.

The diagnosis “describes a situation” and “implies a reason” or etiology focusing on a specific community ([Anderson & McFarlane, 2019](#)).

Various taxonomies and classification systems are used in nursing to describe specific nursing problems, and each one has its limitations when dealing with community-level diagnoses. The North American Nursing Diagnosis Association (NANDA) is much more oriented to nursing diagnoses of individuals and families than to community-level problems. Nursing Outcomes Classification (NOC) is also generally individual oriented. The Omaha System, originally designed by the Omaha Visiting Nurse Association and described earlier in this chapter, is again primarily used in nursing diagnoses of individuals, families, and small groups, and some community health applications have been developed ([Omaha System, 2017](#)).

An example of a research study that used the Omaha System was one in which researchers evaluated the following behaviors of Syrian refugees living in urban areas of Turkey ([Ardic, Esion, Koc, Bayraktar, & Sunal, 2018](#)):

- In the environmental domain: income, sanitation, and residence
- In the psychosocial domain: communication with community resources, social contact, interpersonal relationships, mental health, neglect, and caretaking/parenting
- In the physiological domain (communicable/infectious conditions)
- Health-related behaviors (nutrition, personal care, substance use, health care supervision, and medication regimen)

A sociodemographic questionnaire provided individual and housing characteristics, and the Omaha System-Problem Classification List was used to identify issues and plan for intervention based on the specified nurse-identified domains and behaviors of concern. Due to language issues and limited time with an interpreter, there was no detailed evaluation of outcomes. However, The Omaha System components can be used by the local health departments to support the diagnosis and planning of further initiatives for the refugee population ([Ardic et al., 2018](#)).

This chapter discusses nursing diagnosis as characterized by [Neufeld and Harrison \(1996\)](#), based on the classic work of [Mundinger and Jauron \(1975\)](#).

These authors proposed the use of nursing diagnoses in the community by substituting the term *client, family, group, or aggregate* for the word *patient*.

Neufeld and Harrison (1996) described a nursing diagnosis as the statement of a [client's] response which nursing intervention can help to change in the direction of health and which also identifies essential factors related to the unhealthful response.

Nursing diagnosis was used by Neufeld and Harrison as the foundation for development of wellness diagnosis (Neufeld & Harrison, 1996): "...the statement of a client's [or community's] healthful response which nursing intervention can support or strengthen. It should also identify the essential factors related to the healthful response."

In 1996, Stolte developed a manual dedicated solely to nursing wellness diagnosis which were later incorporated with community diagnosis by Carpenito (2017) in her well-known handbook of nursing diagnosis application.

By substituting the term community for client, family, group, or aggregate, the nursing or wellness diagnosis can be applied to the community as a whole. These diagnoses identify the conclusion the nurse draws from interpretation of collected data and describe a community's healthy or unhealthy responses that can be influenced or changed by nursing interventions. These findings allow the nurse to collaborate with community and health team members to affect positive changes in outcomes.

In community health, nurses do not limit their focus to problems; they consider the community as a total system and look for evidence of all kinds of responses that may influence the community's level of wellness. Responses encompass the whole health–illness continuum, from specific deficits, such as a lack of senior centers or day care programs, to opportunities for maximizing a community's health, such as promoting farmer's markets for better access to fresh fruits and vegetables or improving the safety of the roadways. The statement of community response—the diagnosis—can focus on a wide range of topics.

## Community Diagnoses

Data have been gathered from a variety of sources and have been validated by several means. The data have been recorded, tabulated, analyzed, and synthesized, so that patterns and trends can be seen. The use of charts, graphs, and tables assists in visualizing the synthesized data. The community assessment team should present their findings to peers and colleagues and use their expertise to assist in the formulation of the community diagnoses.

Inferences are drawn from the data, and these statements refer to *actual* or *potential* problems. Additional statements involve *etiology*, by stating that this condition is *related* to certain conditions or problems. There may be a number of these statements, involving several subsystems, for every one diagnosis. Signs and symptoms of the diagnosis relate to the *magnitude* or *duration* of the problem, usually documented “as manifested by” (Anderson & McFarlane, 2019).

Continuing with the nursing process format, nursing diagnoses for the community are developed. Community diagnoses refer to nursing diagnoses about a community's ineffective coping ability and potential for enhanced coping. The statements about the community should include the strengths of the community and possible sources for community solutions, as well as the community's weaknesses or problem areas.

Community-level diagnoses can be developed (Carpenito, 2017). These diagnoses are used as tools as the community begins to plan, intervene, and evaluate outcomes. Diagnostic categories for individuals (e.g., knowledge deficit of senior services, high risk for injury or falls) can often be applied at the community level.

Community-level nursing diagnoses should portray a community focus, include the community response, and identify any related factors that have potential for change through community health nursing. These may also include wellness diagnoses, which indicate maintenance or potential change responses (due to growth and development), when no deficit is present.

Community nursing diagnoses must also include statements that are narrow enough to guide interventions, have logical linkages between community responses and related factors, and include factors within the domain of community health nursing intervention.

Examples of wellness and deficit community nursing diagnoses and several diagnoses for a specific community follow:

1. *Wellness nursing diagnosis for an assisted living community of elders.*  
The senior residents of an assisted living center (*community focus*) have the potential for achieving optimal functioning related to (*host factors*) their expressed interest in exercise, diet, and meaningful activities and

to (*environmental factors*) their access to exercise opportunities, nutritional information, and social outlets.

2. *Deficit community nursing diagnosis for a rural farmworker community.* The inhabitants of (*name of the town*) in (*name of the state*) are at risk for illness and injury related to (*host factors*) exposure to pesticides, lack of motivation to add or use safety devices on farm machinery, lack of safety knowledge, choice to take unnecessary risks (*environmental factors*), lack of family income to purchase newer equipment, and long hours of work that lead to stress and exhaustion.
3. *Community diagnoses for Anytown, Kansas.* Anytown, Kansas, is experiencing an increase in crime, a problem compounded by the small size of the police force and an influx of many new community members. The community has worked together constructively in the past, communicates well, and has strong recreational outlets for community members. The community:
  - Has expressed vulnerability and feels overwhelmed related to threats to community safety
  - Has failed to meet its own expectations related to inadequate law enforcement services
  - Has expressed difficulty in meeting the demands of change related to an influx of new community members
  - Has a successful history of coping with a previous crisis of teenage pregnancy
  - Has positive communication among community members
  - Has a well-developed program for recreation and relaxation

Such diagnoses can guide communities toward maximizing or improving their health as they plan, implement, and evaluate changes to be measured by established outcome criteria. Broad goals can form the basis for planning interventions. From these goals, more specific activities, interventions, and targeted programs can be designed. Measurable objectives can be written and evaluated ([Anderson & McFarlane, 2019](#)). **Outcome criteria** are measurable standards that community members use to measure success as they work toward improving the health of their community. Outcome-based or evidence-based nursing practice applies to aggregates in the community as well as to patients in acute care settings.

Nursing diagnoses change over time because they reflect changes in the health status of the community; therefore, diagnoses need to be periodically reevaluated and redefined. The changing diagnosis can be a useful means of moving a community toward improved health because it gives community members a clear standard against which to measure progress.

# PLANNING TO MEET THE HEALTH NEEDS OF THE COMMUNITY

Planning is the logical decision-making process used to design an orderly, detailed series of actions for accomplishing specific goals and objectives. Planning for community health is based on assessment of the community and the nursing diagnoses formulated, but assessment and diagnosis alone do not prescribe the specific actions necessary to meet clients' needs (Anderson & McFarlane, 2019; Minnesota Department of Health, n.d.a). See Chapter 12 for more on program planning.

Knowing that a group of mothers at the well-child clinic need emotional support does not tell the nurse what further action is indicated. A diagnosis of culture shock (adjustment deficit to a contrasting culture) for a family newly arrived from Cuba does not reveal what action to take. The nurse must systematically develop an appropriate plan (Box 15-6). See Chapter 12 for more on planning, implementing, and evaluating community health.

## BOX 15-6 Levels of Prevention Pyramid

**The Problem of Child Abuse SITUATION:**  
**Desire to reduce the incidence of child abuse in a given community by 50% within 2 years.**

**GOAL:** Using the three levels of prevention, avoid or promptly diagnose and treat negative health conditions, and restore the fullest possible potential.

Tertiary Prevention		
Rehabilitation	Prevention	
	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Establish rehabilitation programs for abused children, including safe home placement, physical and emotional treatment, and self-esteem building</li> <li>Rebuild the family unit if appropriate or possible</li> </ul>	<ul style="list-style-type: none"> <li>Provide family life education programs for families</li> <li>Develop resources to support health promotion programs</li> </ul>	<ul style="list-style-type: none"> <li>If unable or inappropriate to rehabilitate the abuser or family, keep abuser away from victim through incarceration or court order</li> </ul>

**Secondary Prevention**

*Early Diagnosis*

*Prompt Treatment*

- Develop early detection programs through schools, clinics, and physicians' offices
- Promote enforcement of child protection laws
- Establish programs to provide prompt treatment for abused children and abusing parents

**Primary Prevention**

*Health Promotion and Education*

*Health Protection*

- Assess factors contributing to child abuse
- Institute family life education programs through schools and community groups
- Develop community resources to support health protection programs
- Identify families in the community who are at greatest risk (e.g., parents with history of child abuse, families under great stress)
- Develop community resources to support health promotion programs

## Tools to Assist With Planning

- A wide variety of tools are available to enhance community health improvement planning; these include activity descriptions, templates, and models ([Minnesota Department of Health, n.d.a](#); [NACCHO, 2015](#)).
- Such tools help prioritize health issues, develop goals and objectives, specify interventions, and anticipate client outcomes.
- Tools that assist with planning also enable the nurse to test ideas and adjust solutions before actual implementation. Finally, the use of standardized tools enhances the planning process and promotes effectiveness of services, as well as professional standards of practice.

In addition to using tools, a systematic approach guides the community health nurse in the development of a feasible plan that adequately and appropriately addresses the needs of the community ([Anderson & McFarlane, 2019](#)). As they do in the rest of the nursing process, community health nurses collaborate with clients and other appropriate professionals throughout each of these planning activities.

## **The Health Planning Process**

The health planning process is a four-stage system used to design new health-related programs or services in the community and includes

- Priority setting
- Establishing goals and objectives
- Implementing health promotion plans
- Evaluating implemented programs

The process is often used by health educators when designing educational programs or by administrators in community health agencies when initiating new services. The nursing process is similar to the health planning process. Each model helps to promote service effectiveness in addition to maintaining standards of practice. Community health nurses familiar with both the health planning process and the nursing process should be able to work collaboratively with community health professionals using either model.

## Setting Priorities

**Priority setting** involves assigning rank or importance to the identified needs to determine the order in which goals should be addressed.

There are numerous ways to set priorities in the planning process. Many have identified useful criteria that can guide ranking problems for order of action ([National Association of County & City Health Officials, n.d.](#); [Office of the Assistant Secretary for Planning and Evaluation, n.d.](#); [Public Health Institute, 2012](#)). They are presented here as a combination of criteria:

1. Significance of the problem or the number of people affected in the community
2. Level of community awareness of the problem
3. Community motivation to act on the problem (or, Is this important to the community?)
4. Nurse and partnership's ability to reduce risk and/or influence the solution
5. Cost of risk reduction in terms of financial, social, and ethical capital
6. Ability to identify a specific target population for an intervention
7. Availability of expertise to solve the problem within the partnership, coalition, or community
8. Severity of the outcome if left unresolved or the consequences of inaction
9. Speed with which the problem can be resolved

A common test for priority setting is called PEARL, an acronym for “propriety, economics, acceptability, resources, and legality” ([Public Health Institute, 2012](#), p. 50). A priority matrix may also be developed, but decisions must not be unilateral and should include input from all stakeholders, including community members. For example, a community assessment not only revealed that a group of elderly residents living within a specific zip code were fearful of crime but also identified the lack of public transportation as issues to be addressed. Using the above criteria, the community health nurse working in this community identified that 85% of residents of the community had fears about crime but did not see transportation as an issue. The residents saw crime as an important concern and were also motivated to act on the crime issue but were not willing to explore the transportation issue at the current time. The nurse, along with the community coalition partners, would be better able to influence the crime problem by helping to form town watch groups and getting the local police district to provide increased patrols during evening hours when robberies were more likely to occur. However, the partners had little influence to extend the hours of operation on buses or influence the creation of new bus routes. Members of the coalition included the local police chief and chamber of commerce director. If the crime problem was left unchecked, more people could be adversely affected, including businesses, because people would not be willing to leave their homes to shop or might even be forced to move away. Finally, these initiatives could be put in place rather quickly and

inexpensively after the formation and training of volunteer town watch groups. There certainly are no adverse social, economic, or ethical consequences attached to addressing this problem. Therefore, it would seem that the crime issue would take priority over the transportation issue. It is important to remember that each community diagnosis is examined separately and then compared. Priorities for action are discussed, ranked, and then prioritized for action ([Hauck & Smith, 2015](#)).

## Establishing Goals and Objectives

Goals and objectives are crucial to planning and should be feasible, specific, and measurable (Anderson & McFarlane, 2019). The diagnosis that identifies needs must be translated into goals to give focus and meaning to the nursing plan.

- Goals are broad statements of desired outcomes.
- Objectives are specific statements of desired outcomes, phrased in behavioral terms that can be measured.

Target dates for expected completion of each objective are also stated. Objectives are the stepping-stones to help one reach the end results of the larger goal. For the elderly group concerned about crime in the neighborhood, the need, the goal, and the objectives were defined as follows:

- *Need:* The group of elderly people has altered coping ability related to their fear of crime.
- *Goal:* Within 6 months, this group of elderly people will feel comfortable to walk the streets of their neighborhood without experiencing any incidents of criminal assault.
- *Objectives:*
  1. By the end of the 1st month, a safety committee (composed of senior citizens, nurses, police, and other appropriate community members) will be established to study the crime patterns in the neighborhood.
  2. The safety committee will develop strategies for crime reduction and elder protection, which will be presented to the city council for approval by the end of the 3rd month.
  3. Safety strategies, such as increased police surveillance, town watch patrols, and escort services, will be implemented by the end of the 5th month.
  4. By the end of the 6th month, nursing assessment will determine that senior citizens feel free to walk about the neighborhood.
  5. By the 6th month, there will be fewer reported incidents of criminal assault.

Development of objectives depends on a careful analysis of all the ways in which one could accomplish the larger goal. C/PHNs should first select the course of action that is best suited to meet the goal and then build objectives. For the group of elderly people, other alternatives, such as staying indoors or always walking in pairs, were considered and rejected. The ultimate choice was to find a way to make their environment safe and enjoyable.

Some rules of thumb are helpful when writing objectives.

- First, each objective should state a single idea. When more than one idea is expressed—as in an objective to both obtain equipment and learn procedures—it is more difficult to measure the completion of the objective.
- Second, each objective should describe one specific behavior that can be measured. For instance, the fourth objective from the list states that the seniors will report feeling free to walk outdoors within 6 months. It describes a behavior that can be measured at some point in time. One can more readily evaluate objectives that include specifics—such as what will be done, who will do it, and when it will be accomplished. Then it is clear to everyone involved exactly what has to be done and within what time frame.
- Writing measurable objectives makes a tremendous difference in the success of planning. See [Chapter 11](#) for more information on writing behavioral objectives.

The acronym SMART is another useful guideline when writing objectives ([Minnesota Department of Health, n.d.b](#)). SMART objectives are

- **Specific:** Concrete, detailed, and well defined so that you know where you are going and what to expect when you arrive.
- **Measurable:** Numbers and quantities provide means of measurement and comparison.
- **Achievable:** Feasible and easy to put into action.
- **Realistic:** Considers constraints such as resources, personnel, cost, and time frame.
- **Time bound:** A time frame helps to set boundaries around the objective.
- Planning means thinking ahead. The nurse looks ahead toward the desired end and then decides what intermediate actions are necessary to meet that goal.
- Sometimes, an objective itself describes the intermediate actions. At other times, an objective may be further broken down into several activities. For example, the second objective states that the safety committee will be charged with developing strategies, presenting them to the city council, and gaining their approval. Good planning requires this kind of detail.
- Making decisions is an important part of planning. Decisions must be made during the process of establishing priorities. Decisions are necessary for selecting goals and for choosing the best course of action from many possible courses. Further decision-making is involved in selecting objectives and taking action to accomplish the objectives.

- To facilitate planning and decision-making, the community health nurse involves other people. Clients must be included at every step because they are the ones for whom the planning is being done. Without their insight and cooperation, the plan may not succeed. Additionally, the involvement of other nurses may be important.
- Team meetings, nurse–supervisor conferences, and nurse–expert consultant sessions are all useful resources for planning. In addition, it is essential that you confer with members of other health and professional disciplines (e.g., teachers, social workers, mental health professionals, hospital representatives, city planners). Interdisciplinary team conferences are valuable for gaining a broader perspective and enlisting wider support for the evolving plan.

# IMPLEMENTING HEALTH PROMOTION PLANS FOR THE COMMUNITY

Implementation is putting the plan into action. The nurse, other professionals, or clients carry out the activities of the plan.

Implementation is often referred to as the action phase of the nursing process. In community health nursing, implementation includes not just nursing action or nursing intervention, but collaboration with clients, stakeholders, and other professionals. An example of this process can be seen in the community action plan of the CHANGE tool ([CDC, 2019d](#)). After community data are assessed and analyzed, the final step is to create an action plan using SMART objectives. The action plan should include big-picture outcomes as well as incremental progress ([CDC, 2019d](#)).

When bringing about change in a community organization, implementation involves the greatest commitment of time and planning. This often includes an implementation timetable, as well as funding or organizing physical/informational/staff/management resources, collaboration with outside agencies, training staff and working with community volunteers as needed for program implementation, and actually putting into action those interventions created during the planning phase ([Anderson & McFarlane, 2019](#); [Public Health Institute, 2012](#)).

Certainly, the nurse's professional expertise and judgment provide a necessary resource to the client group. The nurse is also a catalyst and facilitator in planning and activating the action plan. However, a primary goal in community health is to help people learn to help themselves in achieving their optimal level of health. To realize this goal, the nurse must constantly involve clients in the deliberative process and encourage their sense of responsibility and autonomy. Other health team members may also participate in carrying out the plan. All are partners in implementation.

## Preparation

The actual course of implementation, outlined in the plan, should be fairly easy to follow if goals, expected outcomes, and planned actions have been designed carefully. Professionals and clients should have a clear idea of *who*, *what*, *why*, *when*, *where*, and *how*. Who will be involved in carrying out the plan? What are each person's responsibilities? Do all understand why and how to do their parts? Do they know when and where activities will occur? As implementation begins, nurses should review these questions for themselves, as well as for clients. This is the time to clarify any doubtful areas, thereby facilitating a smooth implementation phase. An operations manual may be needed, as well as organizational charts, clear budgets, and social marketing plans (Anderson & McFarlane, 2019).

Even the best planning may require adjustments. For example, some nurses who planned a health fair for seniors discovered that the target group would not have transportation to the site because the volunteering bus company had withdrawn its offer. To smoothly implement the plan, the nurses arranged for volunteers from local churches to pick up the seniors, bring them to the health fair, and deliver them afterward to their homes. Implementation requires flexibility and adaptation to unanticipated events.

## Activities or Actions

The process of implementation requires a series of nursing actions or activities:

- The nurse applies appropriate theories, such as systems theory or change theory, to the actions being performed.
- The nurse helps to facilitate an environment that is conducive to carrying out the plan (e.g., a quiet room in which to hold a group teaching session or solicitation of support from local officials for an environmental cleanup project).
- The nurse and other health team members prepare clients to receive services by assessing their knowledge, understanding, and attitudes and by carefully interpreting the plan to clients. This interaction nurtures open communication and trust between nurse and clients. Professionals and clients (or representatives if the aggregate is large) form a contractual agreement about the content of the plan and how it is to be carried out.
- The plan is carried out, or modified and then carried out, by professionals and clients. Modification requires constant observation and interchange during implementation, because these actions determine the success of the plan and the nature of needed changes.
- The nurse and the team monitor and document the progress of the implementation phase by process evaluation, which measures the ongoing achievement of planned actions ([Anderson & McFarlane, 2019](#)).

# EVALUATION OF IMPLEMENTED COMMUNITY HEALTH IMPROVEMENT PLANS

Evaluation is usually seen as the final step, but because the nursing process is cyclic in nature, the nurse is constantly evaluating throughout the entire process. For instance, in the assessment phase, the nurse must evaluate whether the collected data are sufficient and appropriate to beginning planning.

- Evaluation methods must be addressed during the planning phase as goals and objectives as well as interventions are identified ([Anderson & McFarlane, 2019](#)).
- Evaluation refers to measuring and judging the effectiveness of goal or outcome attainment. Too often, emphasis is placed primarily on assessing client needs and on planning and implementing service. The nursing process is not complete until evaluation takes place.
- Ideally, the nursing process should be observed as cyclical instead of linear, and when this occurs, it is obvious that evaluation guides the next assessment.
- The [Community Toolbox \(2019\)](#) provides suggestions for participatory evaluation that includes examination of the process (e.g., how the assessment was conducted), implementation (e.g., how the program was designed and executed), and outcomes (e.g., if desired results were accomplished). Appropriate questions include the following: Was all potential information assessed? How effective was the service provided? Were client needs truly met? How has health status changed? Professional practitioners owe it to their clients, themselves, and other health service providers to fully and effectively evaluate a program ([Box 15-7](#)).

**BOX 15-7 STORIES FROM THE  
FIELD: COMMUNITY ASSESSMENT  
OF A RURAL COUNTY IN A WEST  
COAST STATE OUR GROUP  
COMPLETED A COMMUNITY**

**ASSESSMENT OF A RURAL COUNTY IN A WEST COAST STATE. WE FOUND DATA FROM MANY SOURCES (E.G., CENSUS, HEALTH DEPARTMENT REPORTS), INCLUDING KEY INFORMANTS AND A COMMUNITY SURVEY COMPLETED BY COMMUNITY MEMBERS. MANY RESOURCES WERE AVAILABLE ON THE CDC WEB SITE FOR MOBILIZING FOR ACTION THROUGH PLANNING AND PARTNERSHIPS (MAPP) ([HTTPS://WWW.NACCHO.ORG/PROGRAMS/PUBLICHEALTH-INFRASTRUCTURE/PERFORMANC E-IMPROVEMENT/COMMUNITY-HEALTH-ASSESSMENT/MAPP/PHASE-3-THE-FOUR-ASSESSMENTS](https://www.naccho.org/programs/publichealth-infrastructure/performance-improvement/community-health-assessment/mapp/phase-3-the-four-assessments)).**

### **Windshield Survey**

The windshield survey had the following findings.

#### **Physical**

In touring the area, it is noted that there are many older homes in need of repair. Some homes are vacant and boarded up on the SW part of town. Sidewalks are broken up, making them unsafe to walk on. Few playgrounds are noted on this side of town. The NE area has new home

subdivisions and a new park. the NW area of town has apartment buildings, while the SE side has a large tomato processing plant. Most of the county is open land or is used for agriculture. Two state prisons are at opposite ends of the county. There is a community swimming pool in the largest town. The downtown areas of the larger towns have different types of businesses, but some areas are vacant. In the more rural areas, there are acres of land in production (e.g., dairies, cotton, cattle, pistachios, almonds, tomatoes, walnuts, corn), and some abandoned old farmhouses or dilapidated buildings can be found.

## **Economic**

There are two large supermarkets in the largest town, and most of the smaller towns have at least one local market. Convenience/liquor stores are found in every community and some rural crossroads areas. There are a bulk warehouse store and two pharmacies in the largest city and a small local pharmacy in a smaller community at the far southern edge of the county. Food stamps are accepted in many places. The largest town has a farmer's market and a flea market weekly. There is a shopping mall, and smaller towns have secondhand and antique stores. Most jobs are agriculture related. People gather in the parking lot of the local home improvement store looking for day work. There is a small military base on the outskirts of the county with medical services and a store. There is an American Indian reservation with housing, a casino, and a small health clinic.

## **Services**

For transportation, there is a county bus, but times/days are limited; there is an Amtrak station that includes intercity bus service. Medical transport services and cabs are available. A freeway runs through the middle of the county. Most people drive their own cars, but bus ridership has increased over the past few years. A community hospital is located in the largest city, and there are two small hospitals in the most distant small towns (now closed or used as clinic). The county is a Health Professional Shortage Area (HPSA) for primary care, dental care, and mental health. There is a county public health department in the largest town, with satellite clinics or rotating C/PHN access in every smaller town. There are two dialysis clinics in the largest town and one in the adjoining town, and several rural health clinics. The nearest Planned Parenthood clinics are in two adjoining counties. There are churches in every community (some in poor repair). There is a county library, with some service to smaller towns. Fire, police, and sheriff department offices are found in several areas throughout the county, along with eight post offices. There are high schools in three larger

towns, and K-8 schools are found in local communities throughout the county. There is also a community college satellite center.

## Social

There is a local newspaper. Most people have access to TV/radio, and there are Spanish language stations available. There are political bumper stickers on some cars and also billboards in populated areas. People can be seen smoking and occasionally vaping outside of stores or when walking downtown. Homeless individuals gather in several areas of the county. High school students gather after school at local fast food restaurants and arcades. People shopping at grocery stores are overheard speaking English, Spanish, and Portuguese.

## Data Collection

The data collected are shown in the following table.

	County	State
Population	150,467	30.5 million
<b>Mortality Rates</b>		
Average adjusted death rate	696.2 per 100,000	610.3 per 100,000
Diabetes death rate	30.3	20.4
Lung cancer death rate	38.4	27.5
Motor vehicle accidents death rate	15.5	9.5
Firearm death rate	10.5	7.9
<b>Morbidity Rates</b>		
Smoking (adults)	14.5%	11.3%
Hypertension on discharge	30.3%	28.4%
Adolescent mothers	30.4 per 1,000 live births	15.7 per 1,000 live births
Infant mortality rate	6.8	4.4
Prenatal care, 1st trimester	71.1	83.5
% Births late/no prenatal care	8%	2.9%
% Births $\leq$ 24 mo prior birth	16.8%	13.1%
<b>Socioeconomic Data</b>		
Ethnicity (majority)	53.5% Hispanic/Latino	39.3% Hispanic/Latino
Median household income	\$49,742	\$67,169
Children < poverty level	35.3%	22.8%
No high school diploma	30.1%	17.5%
Bachelor's degree or higher	10.2%	30.6%
Have health insurance	87.3%	91%
Unemployment	12%	5.3%
Of working population		
Worked 50–52 wk/y	40%	57%
Did not work/past year	32%	25%
Worked part of year/seasonal	28%	18%
Violent crime rate	4.6 per 1,000	3.96 per 1,000
Property crime rate	23.0	24.4

1. List the strengths and weaknesses of this community.
2. What diagnoses would you apply, and why?
3. What interventions might be done to address these issues? Identify one that your student group might be able to complete during this clinical experience.

- a. Who would be involved (what collaboration would be needed)?
- b. What level of prevention (primary, secondary, tertiary) does the intervention represent?
- c. What outcomes could you measure to show improvement?
- d. How can your plan best be evaluated?

Evaluation is woven throughout the Community Change Process and the CHANGE tool. The evaluation process should assist in determining if the team is creating the measurable impact envisioned (CDC, 2019d). An example of evaluation to improve program plans includes the Health in Action Project (Nieves et al., 2019). In conjunction with the East Neighborhood Health Action Center, this project implemented a participatory grant-making process to fund projects that improved the community's health. The project engaged stakeholders in decision-making by including local residents in the decision-making process for allocation of grant funds. Evaluation findings showed that inclusion of residents as part of the process for decision-making was a strength of the project. Participants learned about the local organizations and services, and they felt included in a process that affected them and their neighborhood. Reciprocally, the funded organizations expanded their work and piloted new programs, forming new partnerships and building community networks (Nieves et al., 2019).

As stated earlier, evaluation is an act of appraisal in which one judges value in relation to a standard and a set of criteria. Evaluation requires a stated purpose, specific standards, and criteria by which to judge and judgment skills.

## Types of Evaluations

To determine the success of their planning and intervention, community health nurses use two main types of evaluation: formative and summative evaluation.

The focus of *formative* evaluation is on process during the actual interventions. In formative evaluation, performance standards are developed and used to determine what is and is not working throughout the process. These could include the physical and organizational structure of the agency, as well as resources that provide a foundation for any interventions. Formative evaluation essentially looks at the step-by-step process of program implementation. Could I do anything better or differently to increase my desired outcome? An example would occur when looking at the poor attendance at two sessions of an evening health promotion class for senior citizens. The nurse identifies the reason for poor attendance as being seniors' reluctance to attend an evening class because they either don't drive at night, have low vision at night, or fear coming out in the dark. The class is rescheduled for midmorning, and the attendance dramatically increases.

*Summative* evaluation focuses on the outcome of the interventions: Did you meet your goals? Summative evaluation examines outcomes of the interventions. The *effect*, or degree to which an outcome objective has been met, informs the agency or program leader of the program's impact on clients' health. As an example, one manufacturing company had an 80% adherence rate for employees who were supposed to wear proper protective devices (goggles, safety shoes, and hard hats) in the plant. Noncompliance on the part of some workers was a concern to union representatives, the health and safety team, and the company management. They were concerned that 20% of their employees were at risk for injury that would cause pain, suffering, loss of work time, disruption to the manufacturing process, and reduced profitability. The occupational health nurse along with the safety officer began a month-long safety campaign that included safety mini-classes, posters, and incentives for departments with 100% safety equipment adherence. Three months after the program, 95% of the employees were adhering to the safety regulations. This 15% increase was attributed to the effect of the safety program.

The *impact* of a program determines how close it comes to attaining its goals. In the earlier example, the objective of the safety campaign was to increase safety equipment use, and use was significantly increased as a result of the program. However, if the goal of the program had been to decrease accidents and save the company money, the result could be determined only with additional information. Were there fewer injuries caused by accidents? Were there fewer days lost to injuries? Did the company save money as the

direct result of employee safety adherence? What was the cost–benefit ratio? Depending on the answers to these questions, the overall goal of the program may or may not have been met, even though the objective of the program was met. The full impact of the program cannot be determined without additional data. See [Chapter 12](#) for more on program evaluation.

## Community Development Theory

An outcome of effective community-level nursing practice is community development. **Community development** is the process of collaborating with community members to assess their collective needs and desires for positive change and to address these needs through problem solving, collaboration with community stakeholders, and resource development (Leigh & Blakely, 2013). A community development perspective assumes that community members participate in all aspects of change—assessment, planning, development, delivery of services, and evaluation. With this approach, the focus is on healthful community changes generated from within the community, as a partnership between health care providers and inhabitants, rather than a commodity dispensed by health care providers.

Houghtaling, Banks, Ahmed, and Rink (2018) addressed breastfeeding in American Indian culture by looking at the role of American Indian grandmothers to inform breastfeeding practices in a rural community in the United States. Interviews with American Indian grandmothers identified the following: the importance of breastfeeding for healthy maternal–infant bonding, the passing of knowledge for family support for breastfeeding including attachment and bonding, and an overburdened health care system as a barrier to maternal–child health. Outcomes of the study were that breastfeeding practices need to be grounded in tribal resources and that American Indian grandmothers and health care professionals need to use a collaborative community approach (Houghtaling et al., 2018). The community as partner model exemplifies this approach (Anderson & McFarlane, 2019). Chapter 11 details community change theory.

- The outcomes are more positive when community members have a sense of ownership in the health programs and services that address their needs. This enhances empowerment among members of the community and enables them to more effectively control and participate in transforming their environment and their personal circumstances.
- This implies that health care agency infrastructures are appropriate additions to services that are planned and delivered in an acceptable manner to the community. This empowerment leads to greater resilience and ultimately, wellness (RAND Corporation, 2015).

When applying community development theory, the agent of change (often the C/PHN) is considered a partner rather than an authority figure responsible for the community's health. To achieve acceptance as a partner, the nurse must listen and learn from the community members, because they are the experts with respect to their health care needs, culture, and values. They have mastered adaptation to the community, and they have firsthand

knowledge of prevention methods and interventions that are appropriate to their lifestyles. Members of the community are engaged as coresearchers, and time is spent building trust and developing collaborative relationships with community members, stakeholders, and neighborhood health care providers. The expertise of community members is valued and can be useful in designing recruitment strategies, as well as in data analysis. This experience can enrich the community as a whole, as well as the actual participants.

The outcomes of the services provided by any organization can be benchmarked against those of other groups. *Benchmarking* involves comparing an organization's outcomes against those of a similar organization or an organization that is known for its excellence in a particular area of client care (Haustein et al., 2011). Information from this comparison can be used to identify an organization's areas of weakness and to focus attention on specific outcomes. The establishment of *best practice* activities entails constant comparisons between high-and low-performance programs and interventions (Ettorchi-Tardy, Levif, & Michel, 2012).

From a global perspective, the Conference on Primary Health Care held at Alma-Ata in 1978 concluded that people have little control over their own health care services and that the emphasis should be on health problems identified by the members of the community in their attempts to attain a state of wellness (WHO, 2019b). Leadership in the use of community development methods to improve global health includes

- Promote active, representative participation to influence decisions affecting community members' daily lives.
- Engage community members in economic, social, political, environmental, psychological, and other issues that impact them.
- Interest them in learning more about alternative courses of action.
- Incorporate diverse cultures, ethnic and racial groups, and varied interests in the process of community development.
- Refrain from supporting efforts that are likely to adversely affect disadvantaged members of the community.
- Actively work to build leadership capacity of community leaders and groups, and individuals.
- Work toward long-term sustainability and community well-being.

# SUMMARY

- Public health nursing is a community-oriented, population-focused nursing specialty that is based on interpersonal relationships.
- The unit of care is the community or population rather than the individual, and the goal is to promote healthy communities.
- Theories and models of community/public health nursing practice aid the nurse in understanding the rationale behind community-oriented care.
- Salmon's construct for public health nursing prescribes education, engineering, and enforcement with individuals, families, communities, and nations.
- Models used in public health nursing practice, the Minnesota Intervention “Wheel,” the LAC PHN Practice Model, and the Omaha System Model of the Problem-Solving Process provide guidance for C/PHNs to assess, plan, intervene, and evaluate the care they provide to communities.
- The eight principles of public health nursing provide a framework within which the nurse works to promote and protect the health of populations.
- Characteristics of healthy communities include those elements that enable people to maintain a high quality of life and productivity by increasing health and decreasing disease and disparities in health and health care delivery. The effectiveness of community health nursing practice depends on how well the nursing process is used as a tool to enhance aggregate or population health. The nursing process involves appropriate application of a systematic series of actions with the goal of helping clients achieve their optimal level of health. The components of this process are assessment, diagnosis, planning, implementation, and evaluation.
- The concept of **community as client** refers to a group or population of people as the focus of nursing service. The community's health is reflected in its status (e.g., morbidity and mortality rates, crime rates, educational and economic levels), structure (availability, use, and quality of services and resources), and processes (how well it functions in regard to its strengths and limitations). The dimensions of a community's health may be seen in regard to its location (e.g., climate, vegetation, boundaries), population (e.g., diversity or homogeneity, old, young, pregnant, addicted, or academic members), and social systems (e.g., schools, businesses, communications, health care, and religious organizations, among others).

- Assessment for community health nurses means collecting and evaluating information about a community's health status to discover existing or potential needs and assets as a basis for planning future action. Assessment involves two major activities. The first is collection of pertinent data, and the second is analysis and interpretation of that data.
- Community health nurses may use various assessment methods to determine a community's needs. They include *familiarization assessments*, such as windshield surveys, which involves studying data already available on a community; **problem-oriented assessment**, which focuses on a single problem and looks at the community in terms of that problem; *community subsystem assessment*, by which the community health nurse focuses on a single dimension of community life; a complicated and often time-consuming *comprehensive assessment*, to discover *all* relevant community health information; or an *assets assessment* that focuses on the strengths of a community as opposed to its deficits. Combinations may also prove useful (e.g., problem oriented and assets assessments).
- Community data may be provided by many means—surveys, descriptive epidemiologic studies, community forums, and town meetings. Focus groups as well as primary and secondary sources (e.g., people who are familiar with the community and its character and history) are also common sources of data, along with Web sites, and government departments and agencies that compile statistics (e.g., U.S. Census Bureau, state or county health departments). Sources can include national, international, state, county, and local agencies, as well as business and social organizations.
- Using the nursing process in the community would not be complete without looking at the role of the C/PHN as a catalyst for community health improvement. Community development theory is the foundation that supports citizen empowerment and use of key players in the community to plan for the health and safety of that community.

# ACTIVE LEARNING EXERCISES

1. Using “Enable Equitable Access” (1 of the 10 essential public health services; see [Box 2-2](#) ), search your local public health agency's Web site to determine what population-focused programs are offered in your locality. How do you know if the programs are population-focused?
2. Talk with a public health nursing director or a program manager to explore nursing's role in the assessment, development, implementation, and evaluation of population-focused programs offered by the local health department.
3. Discuss with a public health nursing director or supervisor how public health nurses might expand their population-focused interventions.
4. Describe a situation in community/public health nursing practice in which the use of an educational intervention would be most appropriate. Do the same with engineering (Salmon) and enforcement interventions. Discuss your rationale for matching each situation with that intervention.
5. What populations define your community? What are the needs and deficits for specific groups? Use the nursing process to assess potential or actual problems. Using data and your assessment, determine a community diagnosis. As the community/public health nurse, what are next steps in addressing your community's issues?

# CHAPTER 16

## *Global Health Nursing*

*“When it comes to global health, there is no ‘them’... only ‘us’.”*

—Global Health Council (2010)

### **KEY TERMS**

Community health worker (CHW) Demographics Disability-adjusted life year (DALY) Era of Chronic, Long-Term Health Conditions Era of Infectious Diseases Era of Social Health Conditions Global health Global burden of disease (GBD) Primary health care (PHC) Sustainable Developmental Goals (SDGs) Years lived with disability (YLD) Years of life lost (YLL) World Health Organization (WHO)

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Describe a framework for delivering community-based nursing care within the context of global health.
2. Explain how epidemiologic and demographic transition theories assist in understanding the impact of disease patterns on the health of a community, country, or region.
3. Define the global burden of disease according to common social determinants of health.
4. Describe the major health care trends currently affecting the world's populations.
5. Explain how a focus on primary health care provides the basis for health promotion and disease prevention.
6. Describe issues of global health conduct and regulation, including ethical concerns.

# INTRODUCTION

The world has come to us; we encounter the world every day where we live. In the Los Angeles Unified School District, second largest K-12 district in the nation, students speak 92 languages other than English at home ([Los Angeles Regional Adult Education Consortium, 2018](#)). Even Montana, a sparsely populated state, has identified 22 world languages spoken in their homes ([City-Data, 2020](#)). Local health has become global health.

What do you think of when you hear the phrase “global health?” Would you first think about the survival rates of women and children? Or basic nutrition as a foundation for health worldwide? More likely, you might think about the news of respiratory pandemics spreading from one country to another. What would you do if an international traveler from a pandemic area is admitted to your unit for care? Knowledge about global health could guide you to find targeted resources when you write a nursing care plan for your traveler patient. What are the special health needs of refugees fleeing conflict or extreme weather, or of immigrants simply looking for better opportunities? These questions all point to the importance of understanding the concept of global health, or the “world as client,” which is the focus of this chapter. How can the whole world be our client as the recipient of nursing care? Even if you think you will never practice nursing overseas, it is important to realize that global events affect nursing actions locally and the health of others globally.

This chapter describes the intersection of global health and community/public health nursing. It introduces basic global health concepts and how global events can impact the health and health care of a community, country, region, or the world.

- We begin with a quick review of the context for global health and some key events over the years that show the evolution of global health. **Global health** includes health within the borders of each nation, within population groups with unique cultures and languages, and across international borders and cultures.
- We briefly examine selected global health trends and examine the influence of global political initiatives. Usually when we think of global health trends, we think of data describing epidemiology and contagious diseases. Other trends are equally important, such as management of noncommunicable diseases and increased access to primary health care (PHC). One important initiative is *Health in All Policies* (HiAP), which aims to address the health impact of every program or initiative.

- We also consider how these trends influence global health goals. We know health promotion and disease prevention are important goals, but do some strategies work better than others? Smaller nations with emerging economies have figured out how to deliver quality health care despite limited resources and challenging infrastructure. How do these countries achieve success? Sometimes they partner with a nongovernmental agency (NGO), which is a nonprofit or voluntary citizens' group formed to address a social issue. Which agencies achieve the best results? Could we adapt their successes for our local communities? Good ideas anywhere can improve good health everywhere and make the world a better place for all.

This chapter ends with a brief discussion of global health ethics. You are already familiar with the primary ethical concept in nursing of nonmaleficence, “first do no harm” (see [Chapter 4](#)). This is also a key principle in global health ethics. Someday you might have the opportunity to participate in an overseas internship or perhaps volunteer as a nurse following a disaster in another country. Being aware of the special ethical concerns unique to global health will help you be successful wherever you practice nursing. Ultimately, we want the nursing care we provide to be ethical and positive with lasting benefits, whether we care for patients down the street or across the world.

# A FRAMEWORK FOR GLOBAL HEALTH NURSING ASSESSMENT

The slogan, *think globally and act locally*, captures the essence of caring for our interconnected world. When community/public health nurses (C/PHNs) partner with the community client to assess health status, one useful guide is the universal imperatives of care. For instance, determining how many nurses a community needs depends in part on knowing the characteristics of the community, the people, and the predominant state of health. These universal imperatives are reflected in the elements of the following community assessment framework:

- Patterns of care
- Demographic transitions
- Epidemiologic transitions

After completing a community assessment, C/PHNs determine which services to provide by referring to the core functions and 10 essential public health services to guide their care (CDC, 2017c). See [Chapter 2](#) and examples throughout this book.

## Patterns of Care

As with any assignment in nursing, our first task is to assess the client. When the client is an entire population, the assessment can be quite substantial. In this case, we can use a framework to guide our review. Certain social conditions of living are known to influence and even determine health among all populations. When the social determinants of health are reviewed together, we quickly learn about the client population and their knowledge, behavior, and values. We also assess the health infrastructure within their country or region. Data describing these patterns have proven to be good predictors of the overall health of a population. Patterns allow us to design culturally appropriate care solutions affecting health, wellness, and illness of populations, both within and between countries and communities. These patterns of **demographics** are recognizable and measured across populations. What other aspects can you think of to add to the categories shown in [Box 16-1](#)?

### BOX 16-1 Patterns of Care

- Patterns of place or the lived environment
  - Rural
  - Urban
  - Climate influence
- Patterns of perceptions of health care
  - Influence of culture
  - Influence views and acceptance of healing treatments
  - Influence acceptance of nurses and other health care providers
  - Affected by attitudes toward women
- Patterns of privilege or inequality
  - Living conditions, including access to nutritional food and clean water
  - Daily functioning including physical safety
  - Quantity and quality of education for children, especially girls and women
  - Level of health literacy
  - Preference of learning style
  - Access to employment
  - Access to affordable health care resources
  - Informed health care decisions, including who lives or dies
- Patterns of population health differences (demographics)
  - Birth rates (fertility)
  - Infant and child survival rates

- Life expectancy rates
- Rates of infectious and communicable diseases
- Rates of noncommunicable diseases and chronic illnesses (morbidity)
- Death rates (mortality)
- Patterns of providers
  - Traditional healers
  - Trained community health workers
  - Community health nurses
  - Midwives and physician extenders
  - Physicians
  - Differing education levels and requirements for licensure
- Patterns of procedures and interventions
  - Sustainable and culturally appropriate
  - Primary care
  - Health promotion
  - Primary prevention
- Patterns of partnerships
  - Peripheral health unit and health station
  - District hospitals
  - Public health and governmental health care agencies
  - Nonprofit and nongovernmental organizations (NGOs)
  - Universities
- Patterns of politics and policies
  - Universal health care
  - Access to treatment and pharmaceuticals
  - Payment to providers
  - Local health care policies
  - Municipal governments
  - National governments
  - International collaboration
  - Cooperation versus conflict or violence
- Patterns of personal insight of health care workers
  - Personal health and physical well-being
  - Personal values and cultural beliefs, including religious beliefs and attitudes
  - Personal knowledge of community health nursing theory and practice

## Demographic Transitions

The next type of assessment is to determine the demographics of a population group by evaluating whether they are increasing or decreasing in number based on the balance between births and deaths and whether there are any migrations, such as rural-to-urban (Slogett, 2015). Demographic transition theory explains that population demographics in high-income countries changed slowly over several centuries. As low-and middle-income countries began to evolve in the 20th century, populations changed more rapidly over a few decades. Below is a summary of both demographic transition trends (Colburn & Seymour, 2018). Where do you see opportunities for nursing care?

- “Long life, small family”: Starting in the 18th century, high-income Western European and English-speaking countries followed four stages in population change at a fairly slow rate. The final result for such populations today is a demographic with low fertility rates, an aging population, and decline in total numbers. Reasons for decline in mortality are thought to be from advances in public health, nutrition, medical care, and management of infectious disease.
- “Short life, large family”: During the 20th century, low-income countries experienced a rapid growth in the total population, primarily from a rapid decline in deaths while birth rates remained high resulting in a very young population. Socioeconomic development in low-income countries also resulted in the movement of populations from rural to urban settings in search of employment while also gaining improved access to health. The availability of family planning has also had a stabilizing influence on population size (Colburn & Seymour, 2018).

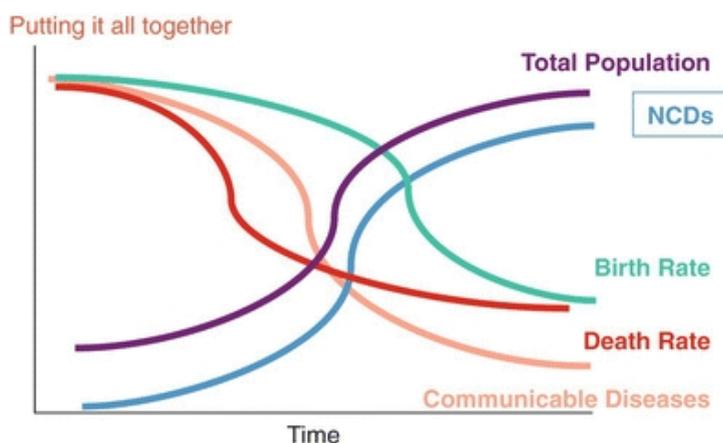

## Epidemiologic Transitions

The third concept in our framework of population assessment is to evaluate epidemiologic transitions. These are grouped according to the predominant health outcomes, or levels of public health, experienced by a society. There are three eras of epidemiologic transitions of public health, named according to historical trends of health and health conditions as described in a classic articles by [Breslow \(2006\)](#) and [Omran \(2005\)](#). In high-income nations, these eras progressed sequentially. However, in our world today, some countries may experience two or all three eras in different regions of their nation at the same time.

- **The Era of Infectious Diseases:** Throughout most of history, populations died from infectious diseases such as the plague, tuberculosis, puerperal fever, measles, and others. The death rate was high, and life expectancy was not very long. During this era, the birth rate was also high. Families had many children because they knew that most children would die before adulthood and yet as adults aged, they depended on their children for care.
- **The Era of Chronic, Long-Term Health Conditions:** With the advent of antibiotics, people survived common infections and started to live longer. Because children survived into adulthood, the birth rate dropped. As people survived infections and aged, they developed chronic, long-term illnesses such as heart disease, cancer, and arthritis.
  - **The Era of Social Health Conditions:** More recently, a new array of health conditions are affecting world populations. These new problems are anchored in social issues, as reflected in the slogan, *where you live determines your health* ([Colburn & Seymour, 2018](#)).
  - The wealth or poverty of your neighborhood reflects whether the streets are safe, housing is adequate, healthy food options are available, and schools and municipal services are adequate.
  - Personal lifestyle behaviors contribute to social health conditions, such as addictions and obesity, while social behaviors contribute to others, such as gang membership, prostitution, sexual abuse, and deviant behavior. The popular press has exposed many of these conditions.
  - Documentaries and reports have helped raise awareness about the effects of methamphetamine on entire communities, the abuse of opioid prescription painkillers, the obesity epidemic growing throughout the world, and the exploitation of children through human trafficking ([Brundage & Levine, 2019](#); [Bureau of Justice Assistance, 2019](#); [Colburn & Seymour, 2018](#)).

## Bringing Together the Framework Components

Review each component in the community assessment framework. What examples from your own experience explain longevity in your community? Consider the combination of patterns of care, the demographic transition theory, and the epidemiology transition theory together. What is the impact of communicable diseases and noncommunicable diseases? See Figure 16-1.

**FIGURE 16-1** Demographic and epidemiologic transition theories combined. (Reprinted with permission from Seymour, B., & Colburn, C. (2018). Module 1: Global trends. In: B. Seymour, J. Cho & J. Barrow (Eds.), *Toward competency-based best practices for global health in dental education: A global health starter kit* (p. 18). A project of the Consortium of Universities for Global Health Global Oral Health Interest Group. Retrieved from <https://hsdm.harvard.edu/globalhealth-starter-kit>; Data from: Omran, A. R. (2005). The epidemiologic transition: A theory of the epidemiology of population change. *Milbank Quarterly*, 83(4), 731–757.)

Explore differences between the development of countries through the concept of “we” in the Western world and “them” in the third world. In his Ted Talk, Hans Rosling debunks myths about the “developing world” in *The best stats you’ve ever seen* (19:46): [https://www.ted.com/talks/hans\\_rosling\\_the\\_best\\_stats\\_you\\_ve\\_ever\\_seen?utm\\_campaign=tedsread&utm\\_medium=referral&utm\\_source=tedcomshare](https://www.ted.com/talks/hans_rosling_the_best_stats_you_ve_ever_seen?utm_campaign=tedsread&utm_medium=referral&utm_source=tedcomshare)

# **GLOBAL HEALTH CONCEPTS**

Key global health concepts, discussed below, include global burden of disease (GBD), the Health for All and HiAP initiatives, primary health care (PHC) achievements, sustainable development goals (SDGs), telehealth, and women's health.

## Global Burden of Disease

Data collection and data analysis are an important part of the C/PHN toolkit. In addition to morbidity and mortality rates, one data tool used in global health helps to measure what it costs society when not everyone is healthy and helps answer the following questions.

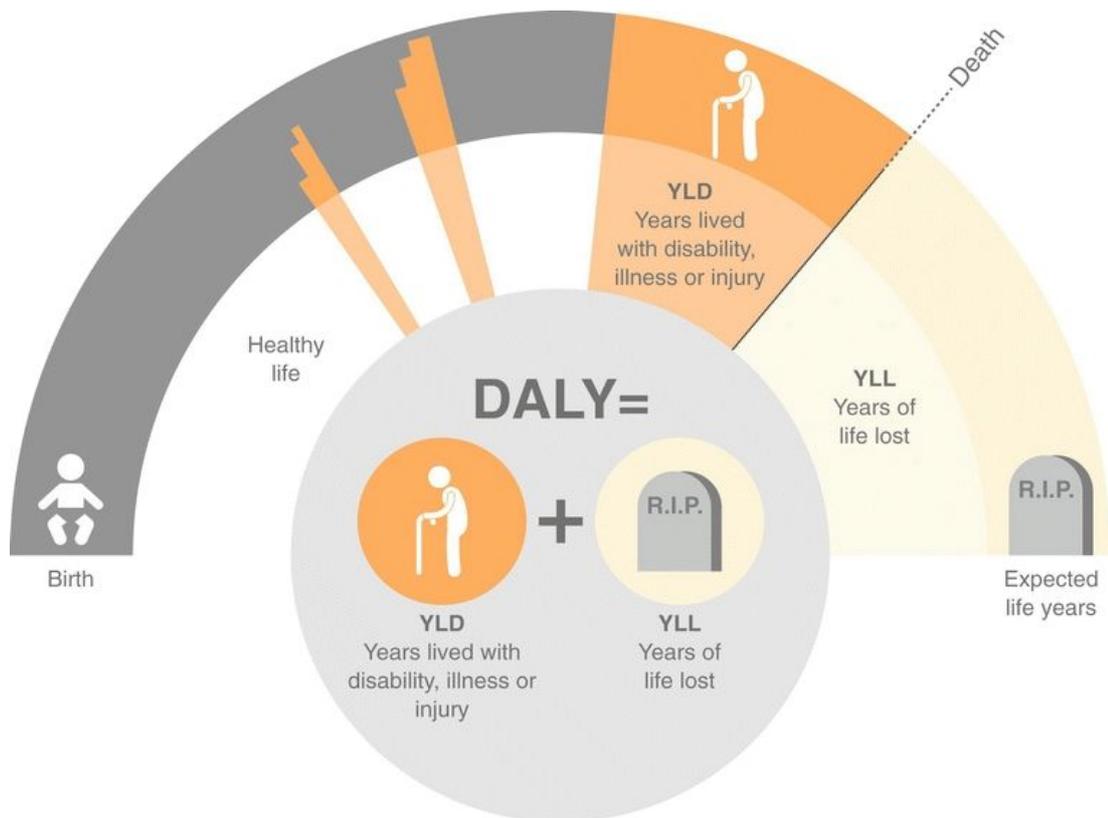

- If a member of your family dies, what is the impact to your family?
- What does it cost if you miss a month of work or school because of an illness?
- What does it cost a country when adults have high rates of diabetes or depression, or when the greatest cause of disability in children age 5 to 14 years is from iron deficiency?

When populations or societies experience disadvantages socially, economically, or environmentally, these differences are called health disparities. The calculation of health disparities is the goal of a series of studies known as the **global burden of disease (GBD)**.

The first GBD study was commissioned by the World Bank in 1990. It was unique for its time because it brought together economists and health experts to evaluate health as an economic investment. That same year, the World Health Organization (WHO) assumed responsibility for the GBD study which emphasized the impact of disability (morbidity) and death (mortality) rates ([Institute for Health Metrics and Evaluation \(IHME\), 2019a, 2019b](#); [WHO, 2020f](#)). Since 2010, the IHME has repeated the study at regular intervals. Because the GBD studies attempt to assess all health conditions using the same methodology, comparison of one condition to another is now possible. We can also compare disease rates and trends over time and by location.

The 2017 GBD report published by the independent IMHE provided data for 195 countries and territories around the globe. Updated mortality and morbidity estimates covered 359 diseases and injuries and 80 new risk-outcome data pairs were added (IMHE, 2019a). GBD data were also used to generate projections of health into the future ([WHO, 2020b, 2020f](#)). Review the report and other GBD resources at the IHME Web site (<http://www.healthdata.org/gbd/gbd-2017-resources>).

How is the GBD calculated? GBD is the measure for a population of **disability-adjusted life years (DALY)**, which is an equation that adds the total **years of life lost (YLL)** due to diseases and premature mortality to the **years lived with disability (YLD)** ([Population Services International \[PSI\], 2014](#); [WHO, 2014](#)). The impact of public health interventions is calculated the same way, but using presumed years saved. See [Figure 16-2](#).

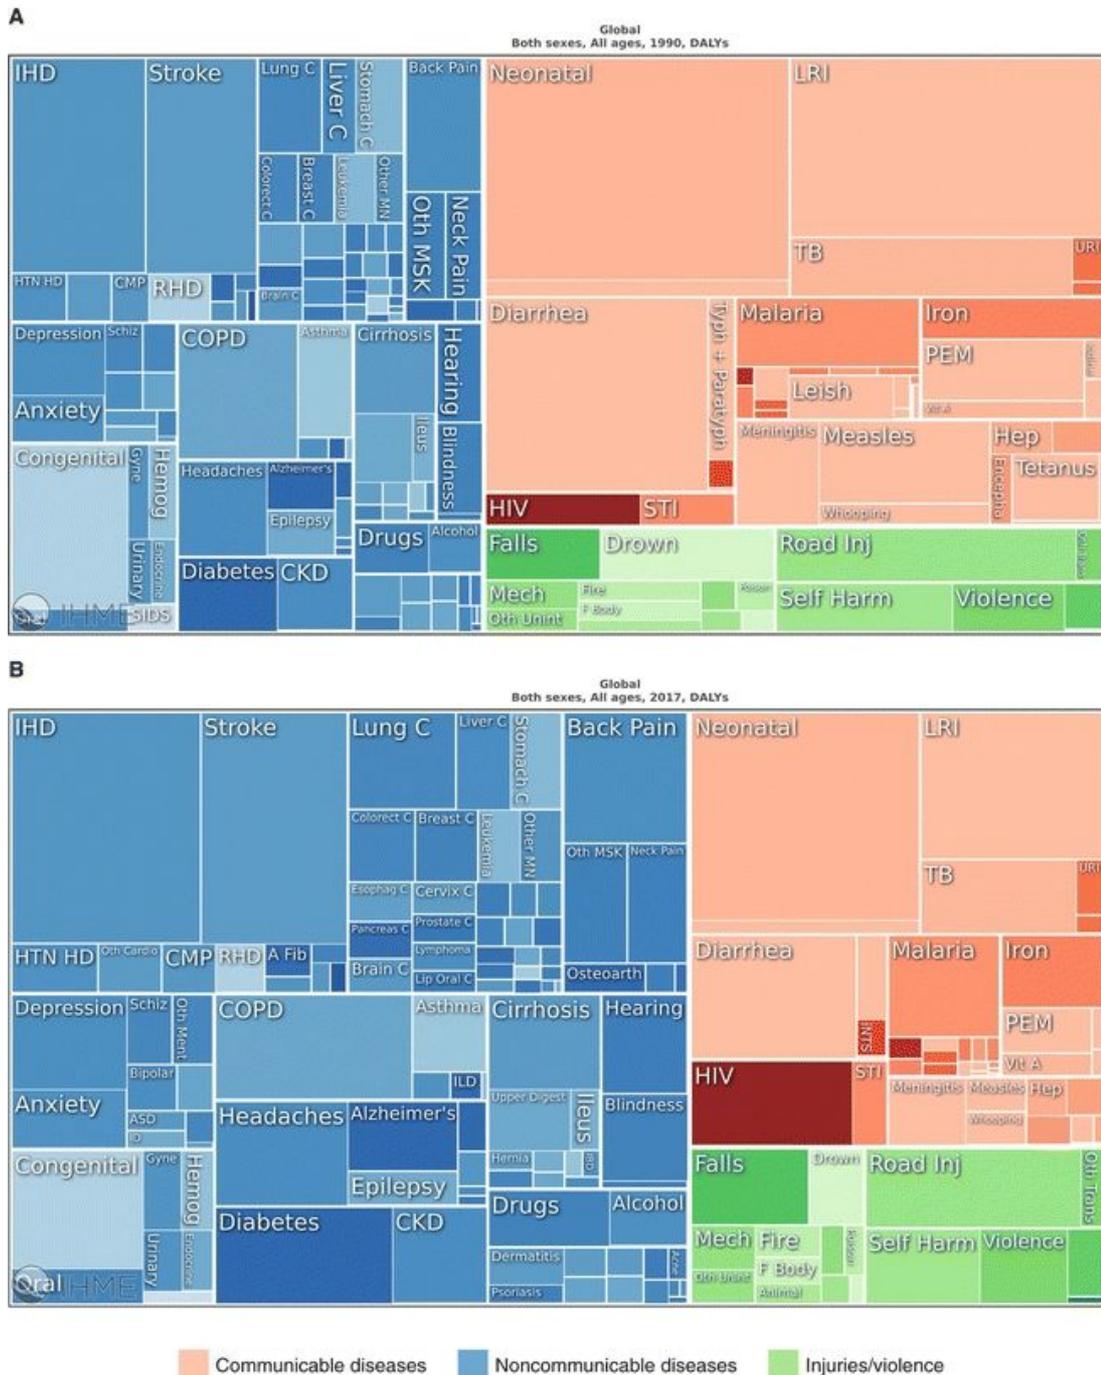

**FIGURE 16-2** Calculating the global burden of disease by DALYs. (Reprinted from Newton, J. (September 15, 2015). *The burden of disease and what it means in England*. Public Health Matters Blog. Retrieved from <https://publichealthmatters.blog.gov.uk/2015/09/15/the-burden-of-disease-and-what-it-means-in-england/>)

For example, let's say one community has a high rate of death from measles for children under 5 years of age, but after a measles vaccine campaign the next year, there are no deaths from measles. When the DALYs are calculated from the year with measles, they are able to demonstrate the burden of measles on that community related to the lost lifetime productivity of the children who died. Comparing DALYs to the year without measles demonstrates the impact of the vaccine. Children who might have died did not die and are now counted among those in the community who are healthy. Children who received the vaccine can become productive adults. The GBD on the community is lessened with the vaccine.

The information obtained from calculating the GBD informs decisions related to investments in health, research, human resource development, and physical infrastructure. Assessment of global and regional information on diseases and injuries can be reviewed directly online using the *GBD Compare* interactive tool at <http://www.healthdata.org/data-visualization/gbd-compare>.

Compare the global disease trends by DALYs for 1990 and 2017 in [Figure 16-3](#). Notice that 1990 had a greater area for burden of communicable disease. By 2017, there was a shift, showing a greater burden of noncommunicable disease. How might changing demographics account for that?

**FIGURE 16-3** Global disease trends in DALYs by cause, 1990 (A) and 2017 (B). (Reprinted with permission from Institute for Health Metrics and Evaluation. (2020). *GBD Compare DALYs (global, by*

*cause, all ages, both sexes*). Retrieved from  
<https://vizhub.healthdata.org/gbd-compare/>)

## Health for All: A Primary Health Care Initiative

In its earlier years after World War II, the focus of the WHO was on building hospitals and costly health establishments throughout the world. The thinking was that hospitals brought health to a region. However, many countries could not afford to build health care centers, nor could they afford to train large numbers of health professionals. Because of those emerging trends and, believing that a major change in thinking and practice was needed, many health leaders from throughout the world met in AlmaAta, Kazakhstan, in 1978 at the International Conference on Primary Health Care. They created a sweeping set of recommendations emphasizing the importance of PHC that became the *Declaration of AlmaAta* (see [Chapter 1](#)) or *Health for All*. Section VI in the Declaration ([International Conference on Primary Health Care, 1978](#)) states that **primary health care (PHC)** “is essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford to maintain... spirit (underscoring) self-reliance and self-determination” (p. 1–2).

It was a lofty goal to implement PHC for all by the year 2000. Each country was encouraged to develop goals for their specific population needs ([WHO, 2019c](#)). The United States responded by launching *Healthy People* in 1979 with the specific goal to reduce preventable death and injury. Updated every decade since the first report, *Healthy People 2030* represents the nation's current health goals and objectives for the next decade. *Healthy People 2030* covers many objectives for health attainment while still including objectives for the prevention of death and injury. Global health objectives can be found at <https://health.gov/healthypeople/objectives-and-data/browse-objectives/globalhealth> Compared to the initial goals from 40 years ago, one can see the evolution in our understanding of how to best achieve health for all ([Haskins, 2017](#); [USDHHS, 2020](#)).

*Health for All* emphasized PHC that is affordable, culturally acceptable, appropriate, accessible, and delivered through partnerships between national health services and local communities. Communities assumed responsibility for identifying their own priority health concerns, with planning and implementing PHC services that match their unique needs. Common PHC services include health promotion, disease prevention, treatment, and rehabilitative care provided by health care workers who live in the same community ([Fig. 16-4](#)) ([WHO, 2020a](#)).

**FIGURE 16-4** Community health worker measuring a child's head circumference at a community health clinic in Surabaya, Indonesia.

## **Health in All Policies**

In 2006, *Health for All* was expanded to *HiAP* as an essential component of PHC. The idea of HiAP is that good health in any society requires policies across all sectors to actively support health. This expanded approach requires policymakers to incorporate consideration of the health impact in policies for transportation, housing, employment, nutrition, water and sanitation, and education. By acknowledging the impact that any policy has on health, optimal health is maintained for the community's benefit ([WHO, 2020e](#)). See [Chapter 13](#) on policymaking and advocacy.

## Achievements of PHC

One example in the achievement of PHC is in Portugal with the extensions of comprehensive services to their full population. In a classic example, [Waddington \(2008\)](#) reported how Portugal organized Family Health Units (FHU) across the country. FHUs are designated groups of physicians, nurses, and staff who work to provide care to local patients and families and make decisions together with them about health needs. Since the 1970s, Portugal's infant mortality rate has dropped by 50% every 8 years to only 3 per 1,000 by 2006. Life expectancy jumped 9.2 years in one generation. Patients register for government-sponsored health services through their family physician, which guarantees each patient has a PHC medical home. MD/RN salaries are based on FHU productivity and performance. However, continued improvement in life expectancy (81.3 years in 2014) has been tempered by ongoing health inequalities. Since 2011, efforts at cost containment have included a greater focus on governance and regulation, health promotion, more reliance on generic drugs, and increased taxes and cost-sharing. The total health expenditures in 2014 totaled 9.5% of GDP, or about half the amount paid in the United States ([Simoes, Augusto, Frontiera, & Hernandez-Quevedo, 2017](#)).

Many other nations are working toward *Health for All* by making health care a right for all citizens and expanding services to meet the needs of rural populations and high-risk groups. Future action regarding PHC calls for strengthened collaboration among governmental agencies and NGOs in public and private sectors. Only when PHC is accessible to all people will the world have a realistic chance of achieving all the goals set out in the Declaration of AlmaAta ([WHO, 2020](#)).

# Sustainable Development Goals

In 2000, during the Millennium Summit, the United Nations (UN) approved eight international health goals for the year 2015. These goals were named the Millennium Development Goals (MDGs), targeting health improvement, eradication of poverty and hunger, and achievement of universal education and gender equality. All UN member states and 22 international organizations committed to developing global partnerships. By combining resources, skills, and knowledge, these partnerships were assumed to facilitate goal achievement. Although some MDGs were accomplished before the 2015 deadline, progress between countries was uneven. Some countries found some of the goals were not appropriate for their populations.

Drawing on the experience from the MDGs, a revision and expansion was approved. The **Sustainable Development Goals (SDGs)** were launched as the future global development framework to be achieved by 2030 (Fig 16-5).

**FIGURE 16-5** Sustainable development goals. Reprinted with permission from United Nations Sustainable Development Goals. Retrieved from <https://www.un.org/sustainabledevelopment/>. The content of this publication has not been approved by the United Nations and does not reflect the views of the United Nations or its officials or Member States.

- The SDGs are a collection of 17 global goals and “are a call for action by all countries—poor, rich, and middle-income—to promote prosperity while protecting the planet” (UN, 2020, para. 1).
- Interestingly, only goal 3, Good Health and Well-Being, is specifically devoted to health and wellness. However, because the goals are all interconnected in the spirit of HiAP, each one of the goals reflects an important health element.

Through the pledge to leave no one behind, the SDGs are looking for “life-changing zeros”: zero “poverty, hunger, AIDS, and discrimination against women and girls” (UN Development Program, 2020, para. 3).

## Telehealth

Achieving these goals has been facilitated by the expansion of broadband and the Internet throughout the world. Ministries of health are training community care workers in communication, observation, and technical skills for telehealth systems that link remote areas to academic health centers (Fig. 16-6). For example, in Brazil's Minas Gerais state, PHC centers in 608 municipalities, some in remote areas, are now connected through the country's Telehealth Network (TN). In the first 5 years of the TN, 6,000 health professionals were trained in its use. The system was shown to be cost-effective and simple to use. With access to specialist teleconsultations, users of the TN were able to prevent 81% of case referrals from leaving the local community (Alkmim et al., 2012). A 2016 evaluation study found that the network had expanded to include 88% of Minas Gerais state with 40 teleconsults occurring each day. User satisfaction with the services provided through the TN was reported at 95%, demonstrating that this telehealth service is successful and sustainable (Marcolino et al., 2016).

**FIGURE 16-6** Mother and child sleeping in a hammock near the Amazon River in Peru.

A feasibility study in India networked five rural health clinics with a large teaching hospital. Electrocardiographs (EKGs) were transmitted from portable EKG tablet devices using WiFi hotspots at the clinics. The 12-lead EKGs were transmitted as secure PDF files for cardiologists to read (Shetty, Samant, Nayak, Maiya, & Reddy, 2017). Individuals and their local primary care providers now receive support and information from distant providers

without traveling or being away from home. See [Chapter 10](#) for more on technology and telehealth.

## Women's Health

The WHO estimates that almost 295,000 women died in 2017 from complications of pregnancy and childbirth. Ninety-four percent of these deaths are in economically poor countries. Nigeria and India had an estimated 35% of all maternal deaths in 2017. Pregnant women living in rural areas and adolescent mothers face higher mortality rates. The death of a mother profoundly impacts the well-being of the entire family. Between 2000 and 2017, due to efforts to improve prenatal and delivery care, global rates of maternal mortality dropped by 38% (Box 16-2; WHO, 2019a, 2019b). Women's health continues to be a major emphasis in Health for All. See Chapters 19 and 21.

### BOX 16-2 PERSPECTIVES

**Volunteering as a Nurse-Midwife in Africa**  
**Delivering babies in the United States is vastly different from experiences I encountered while delivering babies for 1 year in remote areas near the Ethiopian border. I remember one case in particular. It was during the monsoon season, and I was called to help a young woman having her first baby. Because a hospital delivery was impossible due to a powerful rainstorm that made roads impassable, my aide and I walked for miles on very soggy dirt roads to reach her village.**

When we arrived, people in the village said that the baby had died, and upon entering the house I rushed toward the limp baby girl. The mother had delivered the baby on the mat used to cover the dirt floor. I could still feel a very muffled heartbeat on the umbilical cord that was still attached to the young mother. I reached for my mask and bag and started resuscitation. I checked the heartbeat and continued bagging the baby.

Women in the small village had crowded into the house, which could be described as a hut; some had been crying and wailing. Now, they were quietly sitting or standing near the door, speaking to each other in hushed tones while watching me work. My aide checked the mom, who appeared to be stable and had only a little bleeding. I kept bagging the baby and asked the women to get me some warm water to help keep the baby's temperature stable. I alternated warm water with cold water to try to stimulate the baby to breathe on her own; she produced only an occasional breath. I removed excess air from the baby's stomach after inserting a nasogastric tube, and she pinked up. Within a short while, she began to breathe independently.

The mother was relieved, and I checked her to be sure that there had been no tearing. My aide and I remained there through the night to be sure that no further respiratory problems returned. Word of the baby's recovery spread quickly through the village. I felt that we had truly made a difference!

Robin, nurse–midwife

All populations we serve deserve respect for their personal choices, including our health care colleagues. See [Box 16-3](#).

## BOX 16-3 PERSPECTIVES

**A Nurse Volunteer's Viewpoint on Personal Challenges While Serving Overseas** From an early age, I was exposed to nursing. My mother was a nurse, and I saw firsthand how she cared for us as a family and how she cared for her friends when they were in need. I also listened intently when she talked about the patients she helped over the years. Furthermore, I witnessed how she integrated her own faith with her nursing practice in the simplest of forms: genuine service to others.

## **After I became a nurse, I also felt a deep calling to use my nursing skills in volunteer ways to serve others.**

My first volunteer experience was in the rural mountains of Guatemala where I worked with indigenous women to improve birth practices. I thought I was going there to teach them how to safely deliver babies. But after spending 2 months caring for women during pregnancy and childbirth, they actually taught me more about the miracle of birth than I ever learned in my hospital-based experiences. We shared our knowledge with each other and I came away from the experience with a deeper understanding of what it means to become a mother.

Later in life, I met a nurse with the same deep passion for service to others. She was preparing to move to West Africa to serve women with childbirth injuries. She and I had both been raised within the same Christian faith and we both felt our nursing practice was very integrated into our values and beliefs. Then, we fell in love with each other. This was a challenging time for us, as we navigated the minority of being in a same-sex relationship within the Christian community. We struggled as some of our friends and family made it clear they did not approve of our relationship. But we also found new friends and family in the journey as well who were willing to see the greater value of who we were together.

In addition to navigating our home-front challenges, we also had to negotiate our relationship abroad. My wife was working for a faith-based organization in a predominately Muslim country, both of which do not condone same-sex relationships. In order for me to visit with her, to spend time together, and to also offer myself for service when I was there, we had to be silent about the depth of our relationship. We acted only as friends, with no public displays of affection. This was a compromise we both felt committed to in order to make a difference in the lives of the nurses and the women we cared for. Although some might find this compromise too costly, we continue to be grateful for the opportunities we had to serve and would do it again in a heartbeat.

Posted anonymously in order to protect future service opportunities.

# GLOBAL HEALTH TRENDS

The overarching perspective of global health nursing is one planet of interdependent nations. What happens in one country affects others in important ways. For example, air travel can transport health problems from any remote village halfway around the world to any major city within 36 hours. Detecting disease quickly has become more urgent for everyone's health since the outbreak of SARS in 2003 and more recently the COVID19 pandemic, caused by the novel coronavirus SARS-CoV2. By February 16, 2020 China had 51,174 cases and 1,666 deaths, but there were only 683 cases and 3 deaths outside of China ([WHO, 2020b](#)). By October 2, 2020, the United States had 7,260,425 total cases and 207,302 deaths, with 302,093 new cases in the last 7 days ([CDC, 2020a](#)). Other global issues with an impact on population health include ongoing efforts to eradicate old diseases such as TB or malaria while maintaining ongoing efforts to improve basic health care services. See [Box 16-4](#).

## **BOX 16-4 STORIES FROM THE FIELD**

**Addressing Malaria in the Community** The Kenya Strategy for Community Health 2014 to 2019 included an objective to “enhance community access to health care in order to improve productivity and thus reduce poverty, hunger, and child and maternal deaths, as well as improve education performance across all stages of life” ([Kenya Ministry of Health, 2014](#), para. 1). The goal was to empower Kenyan communities to take charge of improving their own health. One community strategy was to develop the capacity of the community health extension workers (CHEWs) and community-owned resource persons (CORPs) to recognize

## **and respond to emerging health trends in the community.**

Atieno is a community nurse working as a CHEW in Siaya County. Over a period of 3 months, she noted a rise in the number of malaria cases involving children in one particular community. Though the county is a malaria endemic area, Atieno was concerned about the new trend and began to have conversations with the mothers.

The steady increase in the number of children under 5 years of age with fever-related symptoms coincided with the start of the rainy season. Some of the mothers thought the fever was from children playing in the stagnant ponds and catching cold.

On her return to her health unit, she proposed a visit by the extension team. The visit was arranged with the community elders. During the visit, the team learned that the community had recently started making clay bricks as an income-generating venture. Almost every home was participating and had built furnace-like structures. These were surrounded by freshly dug clay pits that quickly became small ponds of stagnant rainwater which attracted mosquitoes. The team sought permission to check sleeping areas and noticed that most did not have mosquito bed nets.

A “*baraza*” (public meeting) with the brick works managers, the community elders, and CHEWs was arranged to discuss the situation. The team shared the connection between their findings and the new cases of malaria. The community acknowledged that the brick-making venture had contributed to the increase in stagnant water that became breeding pools for malaria-transmitting mosquitoes. Together, they developed a plan to reduce and treat the cases of malaria without compromising the community's new business venture:

- Drain stagnant water around the homesteads.
- Use treated bed nets, especially with pregnant women and young children.
- Monitor malarial symptoms. When fever develops, seek immediate medical attention.

Collaborative roles and shared responsibilities were also approved:

- All households were encouraged to purchase and use locally available bed nets treated with approved insecticides. The community leader negotiated for free insecticide-treated bed nets for the most vulnerable households.

- Workers committed to relocating their brick works away from homes.
- The local brick works leader coordinated with health dispensary officials for fumigation of existing mosquito breeding grounds.
- The CHEW enhanced existing community-based health services for malaria with additional health education, outreach services, and community–facility referrals.
- Community nurses provided information directly to residents of the community on the causes, symptoms, and the importance of early treatment of malaria. They also demonstrated the proper treatment and use of bed nets.

Once the plan was put into action, malaria cases decreased in the community overall while encouraging their new business venture. The community leaders and local population had the tools and knowledge to manage their own environment and take preventative steps against future cases of malaria. This account demonstrates highly effective PHC and community-owned action, all spurred by one community nurse's observations and follow-up.

1. *What steps of the nursing process are demonstrated in this global health nursing story where the community is client?*
2. *Which of the 10 essential public health services are pertinent to this situation?*
3. *What was the role of the community meeting (the “baraza”) in reducing the number of malaria cases?*
4. *What would happen if the solution for malaria prevention and treatment were not managed by the community, but by health experts coming from outside the local area?*

Missie Oindo, BA, MCHD, and Serah Malaba-Kambale, BSc, MPH, PRINCE2 Practitioner, Kenya

Source: [Kenya Ministry of Health \(2014\)](#).

While we think of the CDC as a U.S. government agency, it also has a global focus that includes global health security and outbreak investigation (Fig. 16-7).

## UN and WHO

- At the end of World War II after earlier attempts to form international agreements, the United Nations (UN) Charter was signed and ratified in 1945 by 50 countries who were “committed to maintaining international peace and security, developing friendly relations among nations and promoting social progress, better living standards and human rights” ([UN Systems Chief Executives Board for Coordination \[UNSCEB\], 2016](#), para. 1). The UN today supports and manages several international funds, programs, and specialized agencies that focus on health. Some of these existed before World War I, some were part of the League of Nations, and some were established more recently to meet emerging needs such as the Joint UN Programme on HIV/AIDS ([UNSCEB, 2016](#)).
- Located in Geneva, Switzerland, the **World Health Organization (WHO)** is a specialized agency under the UN with the objective for “the attainment by all peoples of the highest possible level of health” ([WHO, 2006](#), p. 2). As of 2020, there are 194 member states in the WHO divided into 6 geographical regions for the purposes of reporting, analysis, and administration ([WHO, 2020m](#)).

Other organizations are also active in promoting health internationally but are not necessarily sponsored by governments. Nongovernment organizations (NGOs) are often philanthropic and some are for profit. See [Table 16-1](#) for a list of selected global health organizations and their areas of focus.

**TABLE 16-1 Global Health Organizations**

Organization	Type	Funding Source	Purpose/Audience
World Health Organization (WHO)	Intergovernmental agency related to UN	Dues of member countries Donations (governments, private)	Directing, coordinating authority on international health Improves global health
United Nations International Children's Emergency Fund (UNICEF)	UN agency	Voluntary contributions of governments (70%) and private sources (30%): NGOs, foundations, corporations, and individuals	Promotes maternal and child health and welfare across the globe
United Nations Educational, Scientific, & Cultural Organization (UNESCO)	UN agency	Voluntary contributions of governments, NGOs, foundations, corporations, and individuals	Assists people in forming peaceful and inclusive societies Preserves the heritage of countries (World Heritage Centre)
The World Bank (WB)	Intergovernmental agency related to the UN	Primarily financed by selling AAA-rated bonds in the world's financial markets, from reserves paid in by 188-member country shareholders	Not a bank in the ordinary sense but a unique partnership of five institutions to reduce poverty and support development with financial and technical assistance to developing countries
Pan American Health Organization (PAHO)	Intergovernmental agency	Member country (52) assessments Funds from WHO, UN, private donations	Coordinating agency for public health in Western hemisphere Provides technical and epidemiologic assistance
U.S. Agency for International Development (USAID)	Independent, bilateral agency of the U.S. executive branch, under the Secretary of State	Congressional justifications, annual appropriations bill, budget for the State Department	Strategic global health priorities for developing countries: (1) preventing child and maternal deaths; (2) controlling the HIV/AIDS epidemic; and (3) combating infectious diseases Advances U.S. foreign policy
Centers for Disease Control and Prevention (CDC; including the Center for Global Health)	U.S. federal agency within the U.S. Department of Health and Human Services	Congressional justifications, annual appropriations bill	Works 24/7 to protect America from health, safety, and security threats, both foreign and domestic
Partners in Health	501(c)(3) nonprofit corporation	Corporate and government donations, academic and public sector partners	To provide a preferential option for the poor in health care, strives to achieve two overarching goals: to bring the benefits of modern medical science to those most in need of them and to serve as an antidote to despair
Medecins Sans Frontieres (Doctors Without Borders)	NGO	International agencies and governments, along with private donors	International, neutral organization sending emergency medical assistance in times of war, epidemics, disasters, or denial of care
Bill and Melinda Gates Foundation	Private foundation	Endowment fund from the Bill and Melinda Gates Foundation Trust	Provides grants to U.S. tax-exempt organizations that are independently identified for partnership on global health, development, growth and opportunity, policy and advocacy, and U.S. educational improvement
International Council of Nurses (ICN)	Professional federation	Membership dues, limited to one nursing organization per nation (The American Nurses Association is the organization representing U.S. nurses.)	Represents the global interests and concerns of the nursing profession. Maintains the role of nursing in health care through its global voice Includes nursing organizations from 130 countries, representing 20 million nurses

NGO, nongovernmental organization; UN, United Nations.

# Managing Global Diseases During Epidemics and Pandemics

An example of the interdependency of all nations is the cooperation needed when epidemics or pandemics occur. The WHO has led the way with developing an approach to respond to, coordinate, and assist all nations during such outbreaks.

- The Global Outbreak Alert and Response Network (GOARN) was established by WHO in 2000.
- GOARN initially responded to national outbreaks such as cholera and yellow fever.
- Today GOARN is made up of more than 600 partners, including public health institutions, government agencies, NGOs, and labs specializing in epidemiology.

Through GOARN, the WHO's true impact was first realized with the coordination of the global response to the SARS epidemic in 2002 to 2003. From this response, the WHO established international networks and created standards for mutual assistance in anticipation of future threats (WHO, 2020d). The WHO Health Emergency Dashboard is an interactive web-based platform, refreshed every 15 minutes, that shares real-time information about global public health events and emergencies. Review current public health emergencies on the WHO public emergency dashboard at <https://extranet.who.int/publicemergency>.

## *International Health Regulations*

In 2005, the International Health Regulations (IHR) of the WHO (2008) was accepted as a legally binding, international treaty between all member states. The IHR require that all countries will independently perform the following (Fig. 16-8):

# International Health Regulations (IHR) Protecting people every day

## What are the IHR?

The International Health Regulations (IHR) represent an agreement between 196 countries, including all WHO Member States, to work together for global health security. Under the IHR, all countries must report events of international public health importance.

We share a responsibility to protect our world from outbreaks of infectious diseases and other health threats. The goal of the IHR is to stop events in their tracks before they become international emergencies.

Source: Report to the Director-General of the Review Committee on Second Extensions for Establishing National Public Health Capacities and on IHR Implementation, November 2014

**FIGURE 16-8** International health regulations. (Reprinted from CDC. (2015). *International Health Regulations (IHR). Protecting people every day*. Retrieved from <https://www.cdc.gov/globalhealth/healthprotection/ghs/ihr/ihr-infographic.html>)

- Detect: Make sure surveillance systems and laboratories can detect potential threats
- Assess: Work together with other countries to make decisions in public health emergencies
- Report: Report specific diseases, plus any potential international public health emergencies
- Respond: Respond to public health events (CDC, 2015)

Each nation has committed to meeting these four obligations within their own borders and to the development of an internal public health strategy and implementation plan for addressing domestic public health emergencies (WHO, 2020b).

Before public health events happen,

- The IHR direct the WHO (2020a) to provide tools, guidance, and training in support of any country.

During public health events,

- The WHO offers decision support to affected areas for rapid assessment, critical information, and communications, and
- GOARN coordinates sending teams with technical expertise upon request as needed.

According to the IHR reporting protocols, when there is a new reportable event, the affected nation first assesses the public health risk within 48 hours. If the event meets IHR reporting criteria, the country notifies the WHO within 24 hours. The WHO will then assess the event using the Emergency Response Framework (ERF). The ERF provides guidance for the level of response that is indicated. There are four response levels, from Ungraded (requiring no response or monitoring only) to Grade 3 requiring a major response across regions); see Table 16-2. The response needed is based on risk, as follows:

**TABLE 16-2 WHO Emergency Response Framework (ERF) Levels for Graded Emergencies**

Level	Definition/WHO Response	Additional Information
Ungraded	A public health event or emergency <ul style="list-style-type: none"> <li>Monitoring only</li> <li>No operational response</li> </ul>	<ul style="list-style-type: none"> <li>Does not require a WHO operational response</li> </ul>
Grade 1	<ul style="list-style-type: none"> <li>Single-country emergency</li> <li>Requires <b>limited</b> response</li> </ul>	<ul style="list-style-type: none"> <li>Exceeds the usual country-level cooperation that the WHO Country Office (WCO) has with the Member State.</li> <li>Most WHO response can be managed with in-country assets.</li> <li>Organizational and/or external support required by the WCO is limited.</li> <li>Provision of support to the WCO is coordinated by an Emergency Coordinator in the Regional Office.</li> </ul>
Grade 2	<ul style="list-style-type: none"> <li>Single-country or multiple-country emergency</li> <li>Requires <b>moderate</b> response</li> </ul>	<ul style="list-style-type: none"> <li>The level of response required by WHO always exceeds the capacity of the WCO.</li> <li>Organizational and/or external support required by the WCO is moderate.</li> <li>Provision of support to the WCO is coordinated by an Emergency Coordinator in the Regional Office.</li> <li>An Emergency Officer is appointed at WHO headquarters to assist with the coordination of Organization-wide support.</li> </ul>
Grade 3	<ul style="list-style-type: none"> <li>Single-country or multiple-country emergency</li> <li>Requires <b>major or maximal</b> response</li> </ul>	<ul style="list-style-type: none"> <li>Organizational and/or external support required by the WCO is major.</li> <li>Requires the mobilization of Organization-wide assets.</li> <li>Provision of support to the WCO is coordinated by an Emergency Coordinator in the Regional Office(s).</li> <li>An Emergency Officer is appointed at WHO headquarters to assist with the coordination of Organization-wide inputs.</li> <li>On occasion, the WHE Executive Director and the Regional Director may agree to have the Emergency Coordinator based in headquarters.</li> <li>For events or emergencies involving multiple regions, an Incident Management Support Team at headquarters will coordinate the response across the regions.</li> </ul>

Source: WHO (2018a).

- Very low or low risk event: The WHO team may simply monitor the event. Mitigation, preparedness, and readiness may be part of the low-risk response.
- High or very high-risk event: The Incident Management System may be activated with an appropriately scaled response.

### *Public Health Emergencies of International Concern*

Once Public Health Emergencies of International Concern (PHEIC) are declared, the WHO coordinates an active response with the reporting country and with other countries as indicated (WHO, 2020b). The response may include controlling borders as well as containing the source of the public health threat (WHO, 2020a). These were the steps followed in 2016 by Brazil with the Zika virus outbreak and in 2019 with the novel, SARS-CoV2 outbreak in Wuhan, China (CDC, 2020b, 2020d; CDC Division of Global Health Protection, 2019). Most epidemics or emergencies do not fulfill criteria to be considered a PHEIC. For example, WHO Emergency Committees (ECs) were not convened for the cholera outbreak in Haiti after the earthquake, for the use of chemical weapons in Syria, or following the Fukushima nuclear disaster in Japan (WHO, 2020b).

- Four critical diseases will always be considered extraordinary and require mandatory notification: smallpox, poliomyelitis due to wild-type poliovirus, human influenza due to a new subtype, and severe acute respiratory syndrome (SARS).
- Other conditions are potentially notifiable events according to IHR criteria, whether infectious disease, biological, radiological, or chemical events ([CDC Division of Global Health Protection, 2019](#)). See [Figure 16-8](#).
- Review the IHR reporting requirements at <https://wwwn.cdc.gov/nndss/ihr.html>

### *Global Influenza Surveillance Network*

Another important cooperative agency is the Global Influenza Surveillance and Response System (GISRS), a network of international laboratories established in 1952 by the WHO. GISRS has emerged as a critical player coordinating worldwide efforts for surveillance and control of influenza. Functions of GISRS include the following:

- Maintaining physical presence in 144 National Influenza Centres (NICs), 6 WHO Collaborating Centres, 4 Essential Regulatory Laboratories, and 13 WHO H5 reference laboratories ([WHO, n.d.](#), p. 1)
- Recommending the composition of twice yearly seasonal influenza vaccine, and aid in its development
- Posting on an open access platform for the specific gene sequence of an influenza virus (reference viruses)
- Providing open access to confirmed lab protocols for testing and disease confirmation
- Developing test kits for shipping to requesting countries free of charge ([Association of Public Health Labs, 2011](#))

### *Global Health Security Agenda*

In 2014, the United States helped launch the Global Health Security Agenda (GHSA), an independent group of 67 countries, international organizations, nongovernmental organizations, and private sector companies who also have as their vision a world that is safe and secure from infectious diseases. The [GHSA \(n.d.\)](#) 2024 target is for 100 countries to complete assessment, planning, and mobilization to minimize gaps in health care services. Each country has agreed to demonstrate improvement in at least 5 of 11 technical areas according to measures within the WHO IHR Monitoring and Evaluation Framework. Because of GHSA partnerships, when SARS-CoV2 became a PHEIC, there was more information readily available to all nations than in any previous outbreak ([CDC, 2020f](#)). See [Figures 16-9](#) and [16-10](#).

## Key Achievements in Five Years of GHSA

Over the course of the first 5 years of GHSA implementation, all 17 CDC-supported countries have improved their capacity to prevent, detect, and respond to infectious disease threats.

				
<b>Highlights</b>	<b>Laboratory Systems</b> <b>11 countries</b> demonstrated successful detection and reporting of antimicrobial resistant pathogens in the last 12 months	<b>Surveillance Systems</b> <b>10 countries</b> can conduct laboratory tests to detect national priority pathogens that cause disease, outbreaks, or death	<b>Workforce Development</b> <b>All 17 countries</b> established or expanded their program to train disease detectives	<b>Emergency Management and Response</b> <b>All 17 countries</b> have a Public Health Emergency Operations Center (PHEOC), and each country has sent personnel to be trained at CDC's Public Health Emergency Management (PHEM) Fellowship course
<b>Why it Matters</b>	Confirming a diagnosis with laboratory results allows health workers to respond rapidly with the most effective treatment and prevention methods, reducing spread of disease and deaths	Effective disease surveillance along with rapid laboratory diagnosis enables countries to quickly detect and stop outbreaks and continuously respond to potential risks	To maintain global health security capabilities, countries need a disease detective workforce that can quickly investigate potential outbreaks and take swift action	PHEOCs bring together experts and stake holders to efficiently and effectively coordinate response to an emergency or public health threat

**FIGURE 16-9** Key achievements in 5 years of GHSA. (Reprinted from Centers for Disease Control and Prevention (CDC). (2020). *Key achievements in five years of GHSA*. Retrieved from <https://www.cdc.gov/globalhealth/resources/factsheets/5-years-of-ghsa.html>)

## Smarter, Faster Outbreak Response in Liberia

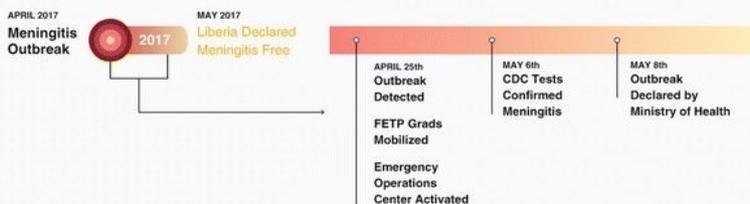

### Outbreak Response BEFORE GHSA Implementation:

**+2 Years** from Detection to Outbreak End

### Outbreak Response AFTER GHSA Implementation:

**23 Days** from Detection to Outbreak End

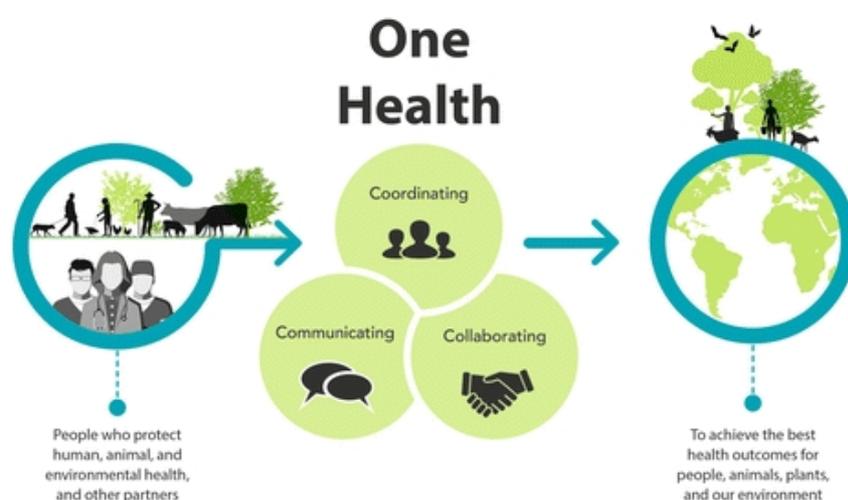

**FIGURE 16-10** Outbreak response in Liberia before and after GHSA. (Reprinted from Centers for Disease Control and Prevention (CDC). (2020). Retrieved from <https://www.cdc.gov/globalhealth/security/ghsa5year/outbreak-response.html>)

## One Health

One Health is a coordinated approach, recognizing that PHEICs are increasingly related to the interconnectedness between humans, the health of animals, and our shared physical environment. The One Health initiative cuts across all sectors of society from local, regional, national, and global levels. It is especially crucial for low-resource emerging economies, but novel infectious diseases (e.g., Ebola, COVID19) can impact many countries around the world (Gebreyes et al., 2014).

- The Food and Agricultural Organization of the U.N. (FAO, 2020) uses a One Health interconnected approach with an established early warning monitoring system to alert for changes in zoonotic diseases, food safety, and agricultural production.
- In the United States, the CDC uses One Health to gain an understanding about how diseases spread among people, animals, and the environment.
- The foundation of One Health is three-fold: the multidisciplinary cooperation for communication, coordination of effort, and collaboration on activities at the animal–human–environment interface (CDC, 2018). See Figure 16-11.

**FIGURE 16-11** One health. (Reprinted from Centers for Disease Control and Prevention (CDC). (2018). Retrieved from <https://www.cdc.gov/onehealth/images/multimedia/onehealth-definition-graphic-with-bats.jpg>)

Review the One Health in Action Web site: <https://www.cdc.gov/onehealth/in-action/index.html>

- Select one of the listed case studies. Identify the partnerships across disciplines, involved animals, and the environmental impact.

- What resolution for health was achieved? What was the role of cross-discipline cooperation?

## *The Centers for Disease Control and Prevention*

In the United States, the Centers for Disease Control and Prevention (CDC, 2020b, 2020c) is the agency responsible for leading the federal response to an internal public health emergency. Each state is also required to have a strategic plan outlining the response of each local health agency (LHA). When a local public health event or emergency occurs somewhere within the United States, the LHA reports upstream to the state who then reports to the CDC. If the event has a potential international impact, the CDC evaluates the event according to the WHO IHR, as described above, and reports the concern to the WHO, as indicated for monitoring or mobilization of international support (CDC, 2017a, 2020e). See the infographic Anatomy of an Outbreak at <http://thepoint.lww.com/Rector10e>.

The CDC also has an outward facing global mission supporting global health security and disease outbreak investigation throughout the world. CDC scientists work collaboratively through 10 state-of-the-art global disease detection (GDD) Centers located in different regions of the world (CDC, 2017b). The expertise of the GDD centers evolved over the first four global epidemics of the 21st century (see Fig. 16-7).

The CDC plays a lead role in global health security when outbreaks occur anywhere. CDC disease experts join with stakeholders to address more than 400 diseases and health threats. Strengthening critical public health services globally protects Americans and saves lives worldwide. The CDC also maintains an emergency surge staff of responders ready to be deployed as needed. See Figure 16-12.

**FIGURE 16-12** CDC's emergency response surge staff. (Reprinted from Centers for Disease Control and Prevention (CDC). (2017). Retrieved from <https://www.cdc.gov/globalhealth/infographics/globalhealth-security/global-rapid-response-team.html>)

Partners in the CDC response effort include the following:

- Foreign governments and ministries of health
- Other U.S. government agencies
- The WHO and other international organizations
- Academic institutions
- Foundations
- Nongovernmental organizations (NGOs)
- Faith-based organizations
- Businesses and other private organizations

The C/PHN may participate with One Health principles anywhere and everywhere. The C/PHN's response during an infectious disease epidemic or pandemic may include one or more areas of focus as described by the WHO (2018a, 2018c):

Focus 1. Provide community education in support of an individual's response, such as wearing masks in public, handwashing, and physical distancing.

Focus 2. Explain evolving risk with communication to support life-saving actions using local data indicators.

Focus 3. Facilitate access to timely treatment for persons who display symptoms and ensure protection of the health care workforce.

Review the variety of disciplines represented in the CDC's Emergency Response Surge Staff (depicted in Fig. 16-12).

- Which disciplines are a surprise?
- Which surge staff role would you be interested in joining? Why?

View stories on creative global health partnerships with the CDC. <https://www.cdc.gov/globalhealth/stories/>

### *SARS-CoV2 (COVID19)*

In late December 2019, China gave an initial report to the WHO about an outbreak cluster of an unusual respiratory disease in the city of Wuhan. A week after the Chinese report, the WHO (2020h) announced to the world the preliminary identification of a previously unknown novel coronavirus named

SARS-CoV2. At that time, nothing was known about where the virus came from or how it spread.

- Within 2 weeks of the report to the WHO in mid-January 2020, Chinese health officials posted the full genetic sequence of the virus online in the public genetic sequencing database, GenBank, at the National Institutes of Health (NIH). This made it possible for labs worldwide to develop lab tests and to make firm diagnoses on travelers from China who showed symptoms ([National Center for Biotechnology Information \[NCBI\], 2020](#)).
- By late January 2020, the CDC activated its Emergency Operations Center to assist in the global response to the epidemic. A few days later, the CDC had developed a real-time test to diagnose the disease using clinical specimens from affected patients. Several different lab assays from top labs worldwide were also posted online, providing lab protocols freely and globally ([CDC, 2020c](#)).
- The UK provided a large grant to the Coalition for Epidemic Preparedness Innovations (CEPI), a global pharmaceutical company whose goal was to release a vaccine within 6 to 8 months of the first announcement of the epidemic ([CEPI, 2020](#)). On the 11th of August, 2020, the Russian Federation reported approval of a vaccine (Sputnik V), bypassing the usual protocol of completing phase three trials before release. By the end of August, 2020 4 other vaccines were in phase three trials, 7 others were in phase two, and 15 others were in phase one. Additional vaccine candidates were in either early research or preclinical phases ([Craven, 2020](#)).

This initial response between the member states of the WHO in the first month after identification of the new disease demonstrated a coordinated worldwide action following the guidelines of the IHR. As the virus spread worldwide, different countries implemented their national plans in whole or in part, while some countries delayed their plans or ended efforts prematurely.

New Zealand was successful in eliminating COVID19 within 6 months of the initial outbreak by embracing standard epidemiology measures ([Ministry of Health–Manatū Hauora, 2020a](#)). These actions included the following:

- Sequestering at home during the initial outbreak
- Maintaining robust border controls
- Implementing widespread testing of the population
- Providing rapid isolation of infected individuals
- Managing comprehensive contact tracing of patients with confirmed cases using public health informatics

- Launching a personal phone app for creating the digital diary of places visited (NZ Covid Tracer app)
- Enforcing quarantine of those who had contact with confirmed cases
- Encouraging public adoption of personal hygiene behaviors when in public

Central to the approach in New Zealand was the responsibility of each person to record their whereabouts every day to accelerate contact tracing. To accomplish their cyber-tracing, businesses and public locations posted QR codes which persons could scan with their smartphones. These QR scans created digital diaries of an individual's daily itineraries. Then when a case of COVID19 was confirmed, the NZ Covid Tracer app notifies the app user that they have been exposed. The user decides if and to whom to disclose their movements in society. With strong data privacy provisions completely under control of the user, contacts with infected cases could be easily identified. The phone app supplemented official contact tracing by expediting communication. With that level of speedy notification, community spread could be more successfully managed as New Zealand society reopened.

New Zealand citizens were quick to participate, following the slogan of the app: “Protect yourself, your whānau [extended family], and your community” (Ministry of Health, 2020b, para. 1).

As stated by the New Zealand Ministry of Health (2020a, para. 1), their elimination strategy was a “sustained approach to keep it out, find it out, and stamp it out.” The goals embraced standard public health epidemiology responses to prevent transmission of new cases from overseas travelers, develop effective treatments, and embrace an eventual vaccine.

- Watch a video explaining the use of the NZ Tracer App at <https://youtu.be/j3GdnugLles>.
- Explore this novel use of public health informatics at the NZ Tracer App Web site: <https://tracing.covid19.govt.nz/>.

As of early May 2020, no new, locally spread cases were reported in New Zealand, but a cluster of cases (about 30) erupted in early August 2020. The alert level was quickly raised to 3 in the affected Auckland area, and only essential movement was permitted, while the remainder of the country was raised to a level 2 that prohibited mass gatherings and promoted more social distancing. The search for the source of the outbreak was ongoing during early September (Lewis, 2020).

By August 31, 2020, the United States had 6,023,368 confirmed cases of COVID19, and 183,431 confirmed deaths—the highest total numbers in the world. However, the U.S. case fatality ratio falls in the middle of the 20 most affected countries. Worldwide, a total of 25,344,339 confirmed cases were

reported, and confirmed deaths were reported at 848,084 (Johns Hopkins Coronavirus Resource Center, 2020). For a world map indicating outbreaks, see: <https://extranet.who.int/publicemergency>.

## *Ebola*

Ebola disease virus (EDV) is an infectious disease with repeated outbreaks, mostly in Africa. Although EDV was first identified in 1976 in an outbreak near the Ebola river in the Democratic Republic of Congo (DRC), epidemiologic data suggests the virus has been around much longer. Population growth, deforestation, and cultural food habits (eating exotic animals or “bushmeat”) are thought to have contributed to the frequency of EVD outbreaks in our world today (CDC, 2019).

The 2014 to 2016 EVD outbreak in West Africa became a global PHEIC crossing international borders within months. Numerous emergency responders from a variety of disciplines including nursing rushed to help as teams tried to contain the spread of the deadly virus. They reported challenges that were met with ingenuity as they struggled without adequate supplies. One challenge was working with the communities to adapt cultural burial practice traditions that contributed to the spread of the disease. Two vaccines were ultimately developed and continue to be administered to vulnerable populations (CDC, 2019). For stories of responders to EVD and how they overcame challenges, visit these Web sites:

- Ebola outbreak responder stories: <https://www.cdc.gov/about/24-7/cdcreponders/>
- Ebola reports on overcoming challenges: <http://www.cdc.gov/about/ebola/overcoming-challenges.html>

## *Tuberculosis*

Tuberculosis (TB) is an infectious disease caused by the tubercle bacillus (see Chapter 8). TB has been known for hundreds of years and was commonly referred to as *consumption*. Over time, the causative organism has become resistant to the medications used to treat it. TB continues as a worldwide chronic endemic disease. The WHO continues the Stop TB campaign that realized a milestone in 2018 when 7 million people were diagnosed and treated. There is an SDG to eradicate TB by 2030; however, large gaps in detection and treatment have led to an estimated 3 million people still not receiving the care they need (WHO, 2020k).

- One quarter of the world's population is thought to be infected, but only 5% to 15% of those become symptomatic within their lifetime.
- TB disproportionately affects poor people around the world.

Multidrug resistant TB (MDR-TB) is an increasing problem around the world.

- Globally, estimates of new cases of MDR-TB are 4.1%, with 240,000 deaths from MDR-TB in 2016.
- MDR-TB threatens to reverse progress made with the Stop TB campaign ([WHO, 2020c](#)).

## *Malaria*

Malaria is a serious and sometimes fatal disease caused by the parasite *Plasmodium falciparum* or *Plasmodium vivax*. Malaria is a vector-borne disease spread by bites of the female Anopheles mosquito. Vaccines against parasites are difficult to create. Even though it is a serious disease, illness and death from malaria can usually be prevented with appropriate interventions such as sleeping under bed nets ([Fig. 16-13](#)) and complying with medical treatment. Malaria disproportionately affects people living in poverty, especially impacting people of working age with damaging effects on emerging economies.

**FIGURE 16-13** A child sleeping under a mosquito net in a refugee camp in South Sudan.

- In 1998, half the world was at risk for malaria. The Roll Back Malaria (RBM) Program, an ambitious international campaign, was launched with the goal to reduce the global burden of malaria ([CDC, 2020g](#)).
- Led by the WHO, UNICEF, UN Development Programme (UNDP), and the World Bank, 500 partners joined together in the RBM worldwide action plan.
- By 2003, RBM showed disappointing results.

- By 2010, a revised goal was accepted to reduce the incidence of malaria by 50% worldwide.
- In 2019, half the world remained at risk ([End Malaria, n.d.](#)).

Then, three interventions were developed in rapid order that gave the world hope that malaria could be entirely eliminated. A new campaign, End Malaria (EM), replaced RBM. The three ongoing interventions with EM are as follows:

1. Artemisinin-based oral drug therapy: An estimated 3 billion courses of therapy were completed between 2010 and 2018.
2. Insecticide-treated mosquito nets (ITNs): Between 2016 and 2018, 578 million ITNs were delivered globally.
3. Rapid diagnostic lab tests (RDTs): In 2018, 412 million RDTs were distributed globally ([End Malaria, n.d.](#)).

The End Malaria program was renewed to focus on endemic regions with the goal to control malaria by 2030.

- By 2018, 27 countries reported fewer than 100 indigenous cases.
- By 2019, the WHO awarded certification of elimination with zero indigenous cases to Paraguay, Uzbekistan, Algeria, Argentina, China, El Salvador, Iran, Malaysia, and Timor-Leste.
- Current focus is on sub-Saharan Africa to eliminate 228 million global cases and eliminate 405,000 deaths ([End Malaria, n.d.](#)).

The challenge remains in countries with emerging economies where there are large populations without sewer systems and clean water sources. Because people prefer to build their homes close to sources of water, mosquitoes that carry malaria are attracted to the standing water in those communities ([Fig. 16-14](#)).

**FIGURE 16-14** A woman gets water from a well to take back to her village.

The primary role of the C/PHN to end malaria is as a community educator. The topics of client education would cover simple measures:

- Proper placement and use of netting around a bed during the night
- Elimination of pools of standing water around the home
- Covering the body with light cotton clothes (Department of Health, Republic of South Africa, 2020). Balami, Said, Zulkefli, Bachok, and Audu (2019) provided a malaria education program to pregnant women and found significant improvements in motivation, knowledge, and skills. Women were taught how to use insecticide-treated bed nets and received intermittent preventive medication during their clinic visits. See Box 16-4.
- Watch this video to see how the RBM campaign evolved. Partnership to End Malaria—20th Anniversary (2:23): <https://youtu.be/iuq6-H1HuAM>.
- Visit the Malaria Vaccine Initiative Web site to see the challenges for making a vaccine: <https://www.malariavaccine.org/malaria-and-vaccines/vaccine-development/life-cycle-malaria-parasite>.

### *Global HIV/AIDS Response*

HIV has claimed the lives of more than 32 million people since HIV was identified in 1985. Between 2000 and 2018, as a result of global initiatives implementing evidenced-based practices, new HIV infections fell by 37% saving 13.6 million lives (WHO, 2020).

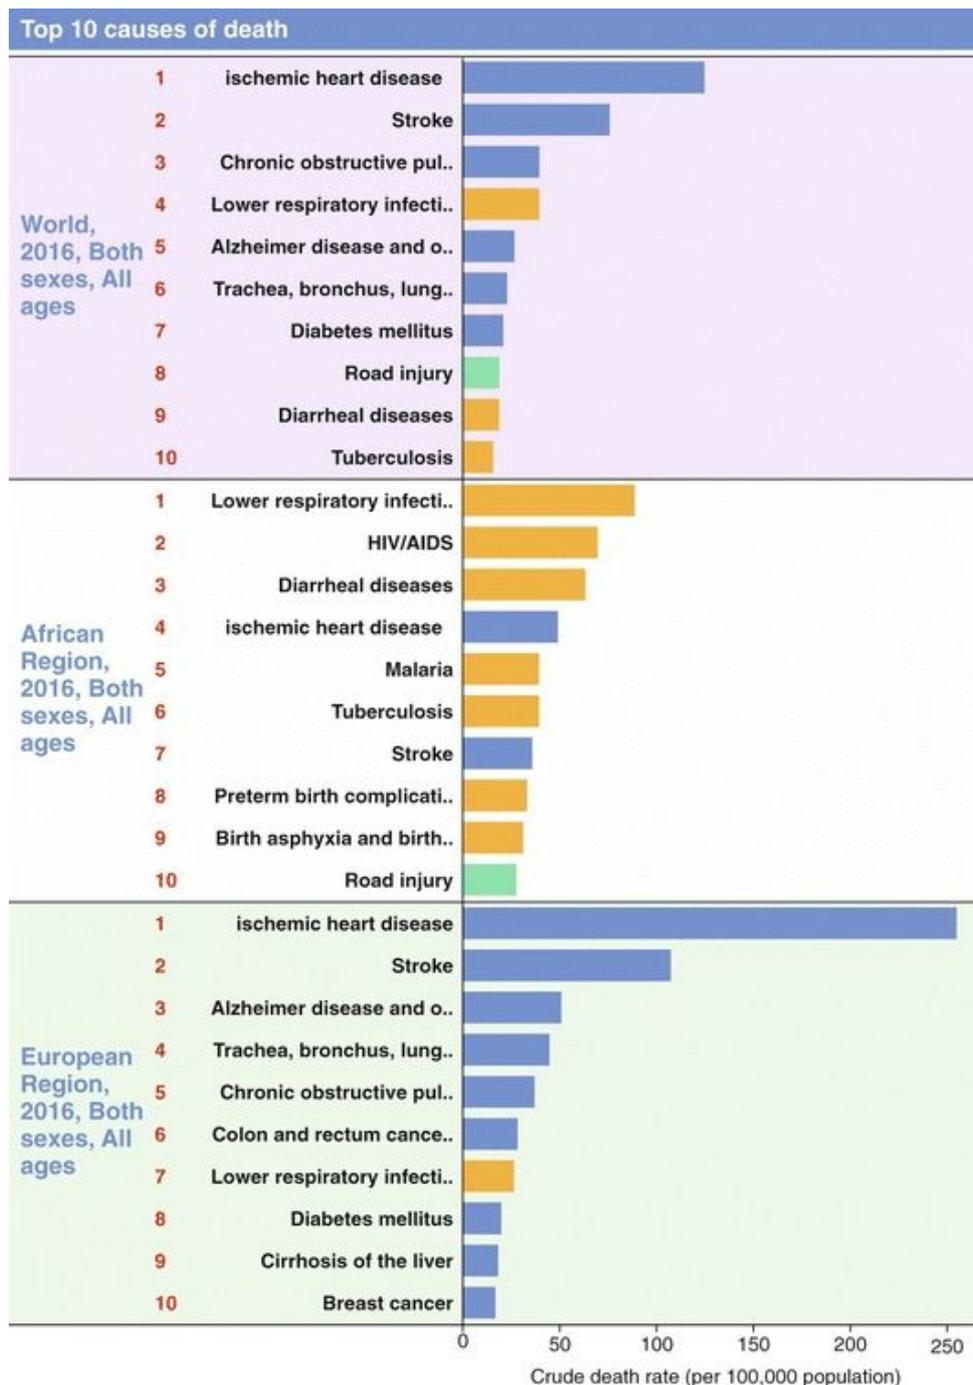

By the end of 2019, this was the global status of HIV/AIDS:

- New cases: approximately 800,000 new HIV cases confirmed with Sub-Saharan Africa accounting for nearly 66% of new infections globally
- Living with HIV: an estimated 38 million people worldwide lived with HIV

Annual deaths: 690,000 million people died annually from HIV-related causes. (Avert, 2018; WHO, 2020g). Although there remains no cure for HIV infection, effective treatment controls the virus so people live productive lives. Treatment also helps prevent transmission. Current trends in HIV care focus on prevention, early testing, and treatment. With surveillance testing, people can know their status and take measures to either remain HIV negative or start treatment, thus preventing transmission to others. See Chapter 8.

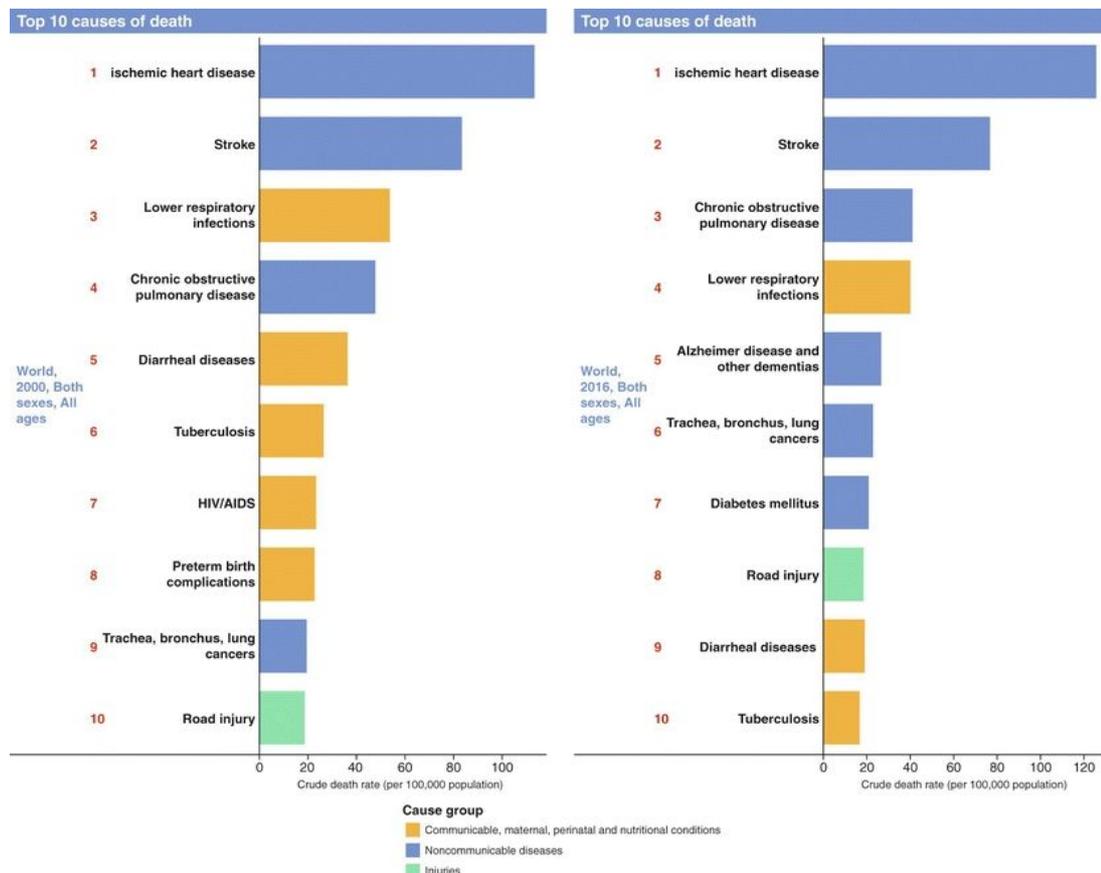

- HIV is diagnosed through rapid diagnostic tests that provide same day results.
- Once HIV-positive status is known, treatment with antiretroviral therapy (ART) is initiated.
- Globally, in 2018, 62% of adults and 54% of children living with HIV were receiving ART.
- Concurrent assessment and treatment for possible TB infections and prevention of mother-to-child transmission have shown positive outcomes for improving maternal health and reducing HIV transmission to newborns ([WHO, 2020a](#)).

The success of HIV/AIDS management is noted by its change in status among the top 10 causes of death between 2000 and 2016, comparing the World to African and European Regions ([Fig.16-15](#)).

**FIGURE 16-15** Ranking of 10 leading causes of death worldwide: European and African regions compared, all ages, both sexes, 2016. (Reprinted with permission from Global Health Observatory (GHO). (2018). *Top 10 causes of death* [Online interactive dashboard]. Available at [https://www.who.int/gho/mortality\\_burden\\_disease/causes\\_death/top\\_10/en/](https://www.who.int/gho/mortality_burden_disease/causes_death/top_10/en/))

- Examine how other top 10 causes of death worldwide have changed between 2000 and 2016 (Fig. 16-16).
- Explore the WHO interactive webpage, Sexual and Reproductive Health and Rights and HIV (SRHHIV) linkages toolkit, to learn more about recent, relevant, and important resources: <http://toolkit.srhhivlinkages.org/>.

**FIGURE 16-16** Global death rate per 100,000: Selected causes, 2000 and 2016 compared. (Reprinted with permission from Global Health Observatory (GHO). (2018). *Top 10 causes of death* [Online interactive dashboard]. Available at [https://www.who.int/gho/mortality\\_burden\\_disease/causes\\_death/top\\_10/en/](https://www.who.int/gho/mortality_burden_disease/causes_death/top_10/en/))

## *Acute Respiratory Tract Infections*

The most common illness in the world and a leading cause of mortality is acute respiratory tract infection (ARI; Box 16-5). Pneumonia is the leading cause of death in children under 5 years of age, claiming nearly 1 million children annually. It is treatable, especially when caught early. Simple interventions such as vaccines, good nutrition, safe hygiene practices, and improved indoor air quality can help avoid ARI altogether (WHO, 2018b).

## BOX 16-5 Levels of Prevention Pyramid

### Acute Respiratory Infection in Children

**SITUATION:** Acute respiratory tract infections (ARIs) that affect the lower respiratory tract and lungs, such as pneumonia and influenza, are among the leading causes of death in children worldwide.

**GOAL:** Prevent acute respiratory tract infections in children in developing countries. Using the three levels of prevention, partner with communities and families to avoid risk factors, to promptly diagnose and treat negative health conditions, and to restore health to the fullest possible potential.

Tertiary Prevention		
Rehabilitation	Treatment and Focused Prevention	
	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Provide adequate nutrition.</li> <li>Provide adequate rest.</li> <li>Restore child to optimal level of functioning through the recovery period.</li> </ul>	<ul style="list-style-type: none"> <li>Diagnose and treat ARIs early.</li> <li>Monitor for hypoxemia with pulse oximetry.</li> <li>Provide oxygen therapy with oxygen concentrators as indicated.</li> <li>Provide culturally appropriate symptomatic care.</li> <li>Reinforce compliance with treatment plan.</li> <li>Teach caregiver the signs and symptoms of complications.</li> </ul>	<ul style="list-style-type: none"> <li>Educate for prevention of recurrence and spread of disease.</li> <li>Promote practices that prevent spread of disease among family members.</li> </ul>

  

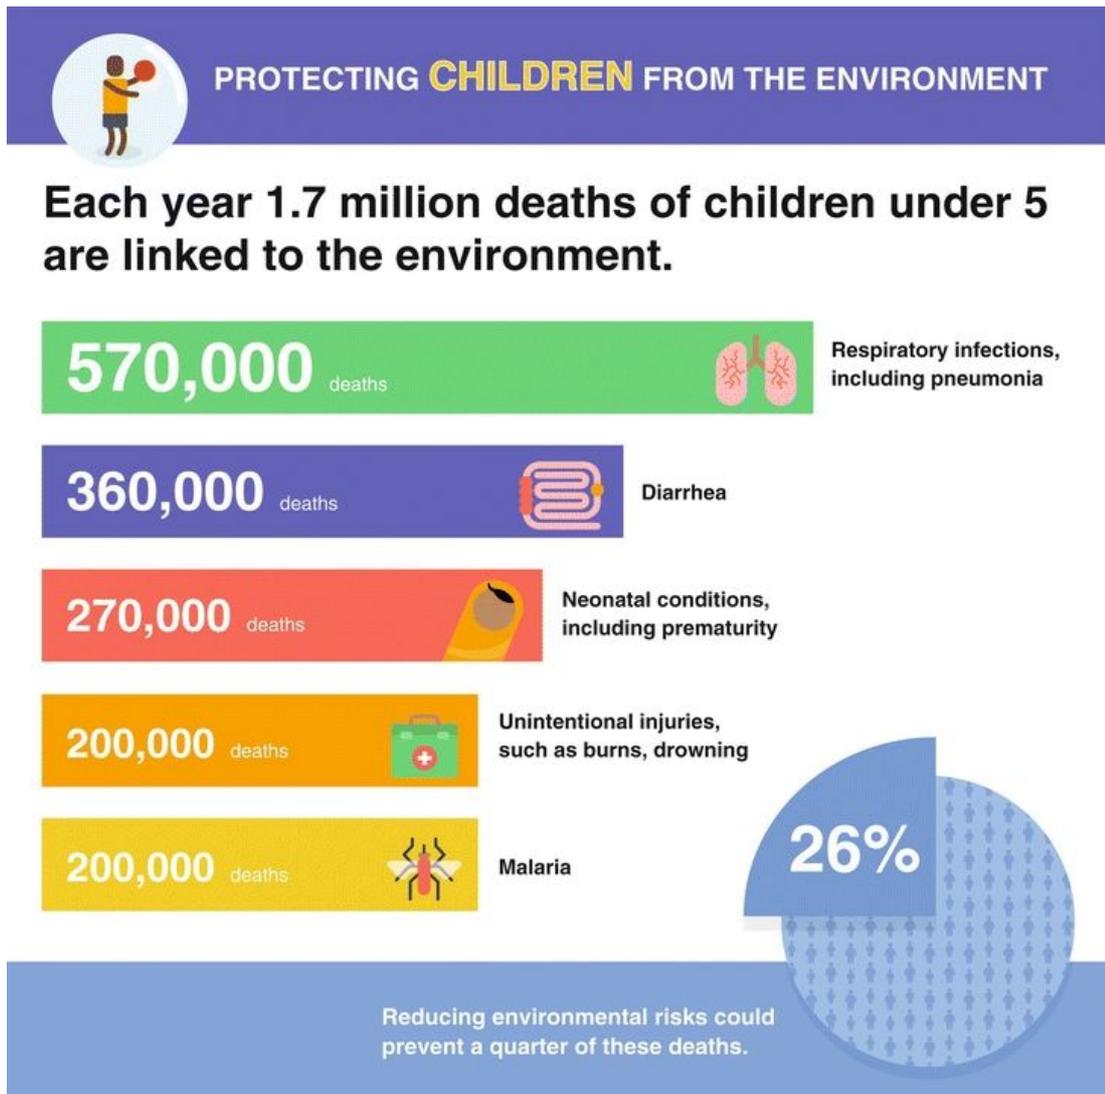

Secondary Prevention	
Early Diagnosis	Surveillance and Focused Prevention
<ul style="list-style-type: none"> <li>Teach caregivers when to seek medical attention for an ARI.</li> <li>Refer early for prompt diagnosis of ARI to prevent further progression and ensure cost-effective management.</li> </ul>	<ul style="list-style-type: none"> <li>Administer appropriate immunizations.</li> <li>Screen and monitor children for early signs and symptoms of ARI.</li> </ul>

Primary Prevention	
Health Promotion and Education	Health Protection for Respiratory Conditions
<ul style="list-style-type: none"> <li>Promote general health education among community members.</li> <li>Teach good hygiene and childcare practices.</li> <li>Promote child spacing and good prenatal care.</li> <li>Support exclusive infant breast-feeding with adequate nutrition after weaning.</li> <li>Eliminate poverty and household crowding.</li> </ul>	<ul style="list-style-type: none"> <li>Promote early prenatal care to avoid low birth weight</li> <li>Promote healthy nutrition habits, including breastfeeding for infants.</li> <li>Treat all respiratory infections (HIV, TB, ARI).</li> <li>Reduce or avoid exposure to common respiratory risk factors such as indoor cook stoves without chimneys.</li> <li>Avoid direct or indirect exposure to smoke, including cigarette, cigar, or pipe smoking, and wood smoke.</li> </ul>

- Primary risk factors include low birth weight, poverty, crowding, lower educational levels, poor nutrition including early weaning, inadequate childcare practices, a lack of health education about ARI, and delays in seeking treatment.
- Additional risk factors include smoking and air pollution, both indoor and outdoor.
- Indoor air pollution is much higher among villages in areas experiencing poverty.
- Indoor air pollution is mostly from indoor cook stoves that use organic fuel and kerosene.
- Worldwide, over 2.4 billion people, mostly living in poverty, burn wood, coal, peat, and dung-cake inside their homes.
- Indoor cooking stoves kill 3.8 million people annually and are a contributing factor in 45% of all pneumonia deaths in children <5 years old.
- The risk of pneumonia in children is doubled with exposure to indoor air pollution ([Ashwani & Kalosona, 2016](#); [WHO, 2018b](#)). See [Fig. 16-17](#).

**FIGURE 16-17** Protecting children from the environment. (Reprinted with permission from World Health Organization (WHO). (2020i). *Protecting children from the environment [PHE Infographic]*. Retrieved from <https://www.who.int/phe/infographics/protecting-children-from-the-environment/en/>)

Measures for better control of ARI include immunizations, birth spacing, better nutrition including breast feeding, improved living conditions (including the use of smokeless cooking stoves), and immunizations.

One threat to reducing the incidence of pneumonia, however, is the increase in drug-resistant organisms. **Community health workers** (local people trained by health professionals) are being trained to diagnose and promptly treat early signs of pneumonia, when drugs will be the most effective, along with other environmentally related interventions. The C/PHN

can also provide community education encouraging mothers to seek care and treatment early. See [Figure 16-17](#).

These selected conditions show the impact when people are exposed to emerging health conditions with environmental impact. Global health issues become everyone's concerns when conditions spread within or beyond borders. When we commit resources to any country in need, we all benefit.

## Interdependence of Nations During Migration

When hardships come, people would rather try to adapt and stay where they are, but if there is limited assistance from their government to remain, then people will leave. Populations may relocate within their own countries or move across borders or oceans to find safety after natural disasters. Climate change in today's world, which causes more frequent and severe wildfires (Fig. 16-18) and rising oceans (from melting glacial ice), can result in population migration. Population movement may also be in response to

**FIGURE 16-18** An Australian brushfire.

- Economic opportunities for workers and their families
- a nation's need to invite immigrants to offset low birthrates
- Large migrations of people fleeing violence or armed conflict (Fig. 16-19), or
- Food insecurity (UN Department of Economic and Social Affairs, 2017)

**FIGURE 16-19** Syrian people in a refugee camp in Suruç, Turkey, in 2015 who escaped from Kobane because of Islamic state attack.

In each case, the challenge is to ensure that human rights are met first, followed by the maintenance of environmental law and refugee or migration law. In 2016, the UN adopted the Global Compact for Migration as a framework for international cooperation for orderly migration. Unfortunately, the actual migration process has become quite political. As of 2020, there were no global agreements or policies to support either present migration humanitarian crises or the impact on environmental rights breaches (Corendea, 2018; Gamlen & Gamlen, 2019).

- View the UN University video, *How-to Guide for Environmental Refugees*, describing the migration events of Carteret Islanders in Papua New Guinea at <https://ourworld.unu.edu/en/how-to-guide-for-environmental-refugees>
- Explore the Web site for the UN International Organization for Migration at: <https://www.iom.int/wmr/>

## Armed Conflict, Uprisings, Wars, and Humanitarian Emergencies

An armed conflict is defined as major if the number of deaths has reached 1,000. Increasingly, conflicts are internal rather than between nations. Combatants seeking economic and political power often target the lives and livelihoods of civilians associated with opposing factions (Clark & Simeon, 2016; Themnér & Wallensteen, 2013).

- Armed conflicts and uprisings initially cause governments and agencies to place a high priority on injuries, but the ability to sustain routine health care is reduced as time goes on.
- The health infrastructure itself becomes vulnerable during conflicts and uprisings as a consequence of political instability. Often, opposing factions raid hospitals and clinics.

During national conflicts, health services become disorganized with decreased resources from disrupted supply chains. Such actions have been repeated over the years as conflicts have emerged. See [Box 16-6](#).

### BOX 16-6 PERSPECTIVES

**A World Health Organization Regional Advisor's Viewpoint on the Effect of War on International Cooperation During the war in Yugoslavia, Bosnians and Serbs worked with the European Regional Office of the World Health Organization (WHO/EURO) in Copenhagen, Denmark, to develop interventions for women and children's health. WHO/EURO developed the training program to be held in Denmark but was not certain that the roads between Sarajevo and the**

**coast would be open and safe for travel. Snipers had continued operating in the mountains surrounding Sarajevo and along the roads to the country's borders. Once the workshop started in Copenhagen, the nurses, physicians, and midwives, both Bosnians and Serbs, collaborated professionally during breakout sessions. However, the facilitator had to ensure separate dining spaces, because casual communication was difficult and awkward while the conflict was ongoing.**

Marie, WHO regional advisor

C/PHNs need to become aware of who is involved in an immediate local conflict and who is influencing the situation from abroad. Outside help is needed in these instances, and often, international help is available. Funding and sustaining health projects may depend ultimately on a variety of factors, not the least of which is providing care when the safety and survival of patients and nurses may also be threatened.

The CDC describes complex humanitarian emergencies as situations that affect civilian populations and distinguishes them from factors related to war or civil strife, shortage of necessities such as food, and the displacement of local populations. During wars and other man-made disasters, infrastructures fail, and epidemics are almost inevitable. As conflict wears on, the health care needs of the combatants often take priority over health care needs of civilians. As communities and families are relocated, thousands of children may be injured, orphaned, or become at risk for disease. Additionally, conflict disrupts food cultivation, harvest, and distribution, leaving populations at risk for malnutrition, which can lead to disease (Clark & Simeon, 2016; WHO, 2017). These circumstances can result in complex humanitarian emergencies, with increased mortality rates beyond what is expected under normal circumstances (Abbas et al., 2018). See Box 16-7.

## **BOX 16-7 What Do *You* Think?**

**Effects of Conflict on International Cooperation**  
In today's world, international cooperation could collapse due to changing national relationships, internal disruptions from natural disasters or violence, or political disagreements over policies such as withdrawal from the Paris Agreement on climate. What would be some of the social, political, and economic consequences in terms of health if international cooperation were diminished?

# **GLOBAL HEALTH ETHICS**

Certain ethical considerations guide global health even as basic ethical principles guide the delivery of health care. Ethics of justice, equality, diversity, and inclusivity become even more important in an interconnected, multicultural world.

## **Clinical Service Learning for the C/PHN**

Opportunities for participating in a global health activity may be offered for experiential learning. C/PHNs should familiarize themselves with global health ethical considerations whether engaging with global communities to conduct research or deliver clinical care in the community. Positive outcomes for the C/PHN from community and global health service learning include the following:

- Increased awareness caring for patients who are economically and socially disadvantaged
- Improved cultural awareness
- Increased interest in public health and primary care career-related opportunities.

Communities who host C/PHN students also enjoy documented benefits. These include the following:

- An influx of resources
- Extra hands
- Extra supplies and equipment

The presence of well-trained health volunteers can lead to skills transfer within the community, either intentionally through education or more indirectly through observation. Volunteers and host communities may develop a sense of solidarity. Sometimes the host community may gain social capital with nearby communities because foreign health care providers have spent time with them ([Lasker et al., 2018](#)).

# Ethical Considerations for the Global Health Volunteer

C/PHNs and host communities. Enjoy mutual benefit when all parties are mindful of three main ethical considerations:

1. The weight of authority
2. The volunteer effect
3. The burden of hosting (Lasker et al., 2018, p. 22)

The weight of authority is a concept observed by Minkler in 2004 when, despite her positive intentions, she ended up creating distrust in a host community. This happened because she “was of a dominant culture (urban, white), received significant financial support..., and came from an outside institution” (Lasker et al., 2018, p. 22). Whether real or perceived, weight of authority can happen due to power differentials that often exist between volunteer students and the host community. As mentioned in the example, power differentials could be financial, racial, educational, or even institutional. Power dynamics are often deeply embedded in the political, social, and economic histories of the community, yet students might present themselves to the community without full awareness of these factors (Lough, Tiessen, & Lasker, 2018).

The volunteer effect happens when the C/PHN volunteer “travels to a community because the existing health care system there is weak or under resourced” (e.g., low-resources, disaster) (Lasker et al., 2018, p. 23). Volunteer nurses bring “donated equipment and supplies or provide education and training” to supplement the care that the existing system is unable to provide (Lasker et al., 2018, p. 23). Even though the volunteers are well-intentioned, their efforts might not be in tune with the area's health care system, or they may undermine local methods. Volunteer efforts may duplicate local services and thus waste important resources. It has been reported that some community members wait for volunteers to return rather than seek care from local health care sources, because the services of volunteers are free of charge. This devalues the local health care providers even further, creating dependency on the volunteers and their services. The result is that the volunteer promotes “direct competition with local providers trying to make a living in their own communities” (Lasker et al., 2018, p. 23; Lough et al., 2018).

The burden of hosting is from the perspective of the host in the community who houses the C/PHN volunteer. Even though the C/PHN is providing services and activities at no cost, the host must provide housing, meals, transportation, and perhaps pay for a translator. In addition, hosts commit to accommodate learning experiences, often suspending their own

work to do so. Typically, these learning opportunities are created for the student and are not spontaneous. Providing necessary support to “keep students safe, healthy, and productive during their time” with the community can place an extensive burden on the hosts (Lasker et al., 2018, p. 24). Volunteers should always be respectful to hosts and be helpful guests (Lough et al., 2018).

C/PHN volunteers should not presume that good intentions providing free health care activities or work exempt them from ethical concerns. Rather, regular self-reflection on how to embrace the ethical principle of “first do no harm” should come first before attempting to do good. Furthermore, it is important to consider that in any endeavor, we are all learners who first listen and observe, rather than begin with “doing” (Lasker et al., 2018, p. 24).

### *Individual Motivations*

The C/PHN volunteer should honestly assess personal motivations when considering global health service. Motivations generally fall into one of two types: “volunteer-centric” focused on the volunteer's personal goals and interests and “community-centric” focused on the community's beneficial outcomes (Aluri et al., 2018; Lasker et al., 2018, p. 25; Philpott, 2010). See Table 16-3.

Action	Motivational Focus	Seeking	Impact
<b>Use Caution</b>	<ul style="list-style-type: none"> <li>▪ Volunteer centric</li> <li>▪ Self-focused</li> </ul>	Adventure and excitement more than offering help. Wants to share “superior” knowledge and skills with the population.	Looking for self-affirmation with an opportunity to prove themselves. Perhaps take a vacation doing medical or “poverty tourism” (p. 26).
<b>Acceptable</b>	<ul style="list-style-type: none"> <li>▪ Volunteer centric</li> <li>▪ Community-focused</li> </ul>	A good global health learning experience. Can benefit both the volunteer and the host when the greater awareness is in favor of the community's goals. Seeks a sense of mutual reward and purpose, like-mindedness, and an opportunity to broaden clinical experience.	Linked with altruism that helps improve global understanding of health and disease. Bonus that the volunteer will better understand future patients, especially those who are immigrants (p. 27).
<b>Optimal</b>	<ul style="list-style-type: none"> <li>▪ Community-centric</li> <li>▪ Community-focused</li> </ul>	Emphasis on global health learning experience focused on foundational global health principles	Community development, capacity building, partnership, and health system strengthening (p. 28).

Source: Lasker et al. (2018).

### *Consequences of Being a Global Health Volunteer*

Global volunteering can be very expensive and may not offer long-term health or financial benefits to the communities served; it may actually be burdensome. Identifying opportunities that are both “ethical and sustainable” will preserve the dignity of the communities while supporting local empowerment and developing leadership opportunities (Lasker et al., 2018,

p. 41). This approach will also provide a more meaningful experience for volunteers.

C/PHNs who develop and nurture community-centric positive motivations are in a position to make a positive impact on themselves and their host communities. The C/PHN volunteer is likely to acquire the state of mind of a global citizen (Lasker et al., 2018, p. 25; Philpott, 2010). The result for the C/PHN volunteer is as follows:

- Improved understanding of global health and disease
- Developing new partnerships and teamwork in challenging settings
- Implementing shared solutions
- Experiencing the scope of social determinants of health
- Acquiring specific skills, especially those of improved patience, listening, and observation.

Ultimately, optimal global health learning opportunities will provide C/PHNs with increased insights while developing experience with disease-specific interventions and activities. Overall, C/PHN contributions to community-led efforts can become part of the community's long-term sustainable goals. In the end, the outcomes will be better for communities. Global C/PHNs experience a more robust career where their unique skills and knowledge can be applied in a globalizing world (Lasker et al., 2018). Like transcultural nursing, described in Chapter 5, expanding one's horizons either in unfamiliar neighborhoods here or abroad (see Box 16-8) can promote a broader understanding and provide richer experiences for the C/PHN. Many of our clients are not far-removed from their countries of origin, and a global perspective provides C/PHNs with a more welcoming presence. The skills gained from global health experiences can help us better understand and work with all of our clients, wherever they may live.

## BOX 16-8 PERSPECTIVES

**A Student Nurse's Viewpoint on Studying Abroad in Ecuador I never thought I would study abroad, but when the opportunity arose to take one of my nursing classes in Cuenca, Ecuador, I decided to**

**embrace it, expecting a great learning experience. Little did I imagine that it was going to be anything short of life changing. Simply stated, it was humbling to be a guest in a host family's home, accepted like family. It was awesome to become immersed in a culture so different from our own. During our 1-month stay, our itinerary was packed with school as well as experiences in hospitals, clinics, school, and even an orphanage.**

I recall a particular hospital where I assisted a compassionate nurse in giving bed baths with limited resources. I ripped three pairs of small-sized latex gloves before managing to keep a pair on my large hands. I learned that being a good nurse was not dependent on the availability of supplies but rather in maximizing the potential to deliver compassionate care in any circumstance.

I am happy I made the decision to study abroad. In addition to the learning experience, I gained insight, respect, humility, and gratitude for life and for others. It is as if I have become aware of what living fully is, something unattainable without the smells, sights, sounds, and interactions I encountered abroad.

Ella, student nurse

# SUMMARY

- Community/public health nursing services are critical to the ultimate health of a community, providing important primary, secondary, and tertiary levels of health promotion and prevention throughout the world.
- Community assessment includes a comprehensive review of the patterns of care, demographic transitions, and epidemiologic transitions.
- Major principles of global health care include the global burden of disease (GBD), Health in All Policies (HiAP), Sustainable Development Goals (SDGs), and One Health.
- The GBD is calculated in a population or country by adding Years of Life Lost (YLL) to Years Lived With Disability (YLD) to determine the Disability-Adjusted Life Year (DALY). The higher the DALY, the greater the GBD.
- The United Nations and the World Health Organization are the integrating agencies for health around the world. Additional international agencies also support global health efforts.
- The International Health Regulations (IHR) guide the interdependence of nations at times of global epidemics or pandemics.
- Global ethical considerations include understanding of the weight of authority, the volunteer effect, and the burden of hosting.
- Global service-based learning requires careful self-reflection of one's own personal motivation behind volunteer efforts.

# ACTIVE LEARNING EXERCISES

1. Describe three infectious diseases that are common around the world. What current efforts are being implemented to combat them? Over the last 25 years, what progress been made in reducing incidence, as well as morbidity and mortality for these diseases? List 4 (or more) of the 10 essential public health services that have been utilized to combat these infectious diseases.
2. Which of the worldwide leading risk factors for health are also present in the United States? Why? How can a local C/PHN address these risk factors? What partnerships could be developed locally that reflect international approaches? What interventional programs are available from your state or county health agencies that could be used to reduce these risk factors?
3. Conduct your own needs assessment in a familiar community. Use the community assessment framework described in this chapter to identify strengths of the community and gaps of care. After your assessment, select one C/PHN intervention as a priority for that community. Which of the 10 essential public health services support your proposed intervention? Provide a rationale for your choices.
4. Using the GBD, compare interactive tool at <http://www.healthdata.org/data-visualization/gbd-compare>, examine the most current results for a country with an emerging economy compared to the United States. Use all ages and both sexes in your comparison (e.g., all cause DALYs per 100,000 map; DALYs by causes treemap). How are the patterns different or similar? What factors could influence your findings? Compare the same two countries in 1990 and evaluate how the patterns of causes have changed for both.
5. Identify a country or community in which you would like to practice community/public health nursing. Before you begin a review of this country or community, write down your own knowledge, attitudes, and beliefs about the country or community, the people, and the culture. Examine your own motivations for wanting this experience. Identify how you might feel if you received services rather than provided services.

Triage

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Describe a variety of disasters, including their causation, number of casualties, scope, and intensity.
2. Discuss three factors contributing to a community's potential for experiencing a disaster.
3. Identify the four phases of disaster management.
4. Describe the role of the community/public health nurse (C/PHN) in preventing, preparing for, responding to, and supporting recovery from disasters.
5. Use the levels of prevention to describe the role of the C/PHN in relation to acts of chemical, biologic, or nuclear terrorism.

# INTRODUCTION

Have you, or someone you know, been affected by a recent disaster? In this millennium, we have witnessed multiple devastating natural disasters, such as Category 5 hurricanes, tsunamis, and earthquakes, and manmade destructive acts of terrorism (e.g., bombings) causing multiple fatalities. Natural and manmade disasters are ever-present possibilities regardless of where one lives or works, and health care professionals have an obligation to be skilled in disaster preparedness and response. This chapter will increase your understanding of the community/public health nurses (C/PHN's) role in preparing for, responding to, and recovering from natural disasters and terrorism.

# DISASTERS

A **disaster** is any natural or manmade event that causes a level of destruction or emotional trauma exceeding the abilities of those affected to recover from without community assistance. Airplane crashes, mass shootings, and chemical explosions are all situations that are devastating to a community and, by definition, constitute disasters.

The geographic distribution and types of disasters vary around the world due to environmental, sociopolitical, and topographic factors. For example, California, Alaska, and Tennessee are associated with earthquakes and the Gulf Coast with hurricanes and oil spills. Similarly, it is not surprising to hear of drought in Ethiopia, floods in India during the monsoon season, or bombings in Afghanistan or Syria. When certain types of disasters are anticipated, communities are usually prepared for them. For instance, California has strict building codes to prevent destruction of structures in the event of earthquakes, but most California homes lack the basements and insulation that characterize homes east of the Rocky Mountains, which may be subject to severe storms or tornados. Similarly, residents of the northern United States, Germany, Austria, and Russia are better prepared for blizzards than are the southern regions of the United States and Europe.

Sadly, throughout history, disasters have affected every section of the globe. [Table 17-1](#) lists only a few of them. However, technological advances, such as satellite data, have improved disaster management worldwide ([International Charter, 2019](#)).

**TABLE 17-1 Major Disasters: 2015 to 2020**

Date and Location	Description
August to October 2015, Washington State, United States	Wildfires and mudslides in the state of Washington killed three firefighters and damaged or destroyed hundreds of homes.
October 2015, United States	Severe storms cause serious flooding in North and South Carolina, leading to 25 deaths and billions of dollars in property damage. Just prior to this, severe flooding in Kansas, Oklahoma, and Texas was responsible for 43 deaths and much destruction.
November 2015, Paris, France	A coordinated, multisite terrorist attack kills 130 people and injures over 350 people. Earlier, in January, terrorists attacked offices of a magazine and a Jewish market, killing 17.
January 2016, United States	Blizzard affected the northeast, mid-Atlantic, and southeast sections of the United States, killing 38 people.
March 2016, Belgium	Coordinated terrorist attacks at the airport and metro system killed 35 and injured over 250 people.
August 2017, Sierra Leone	Heavy rainfall and flooding sparked a huge mudslide, killing at least 600 and directly affecting more than 6,000
August 2017, Houston, TX	Hurricanes Harvey, Category 4 largest storm to hit the United States since the disastrous Hurricane Katrina in 2005
September 2017, Miami, FL	Hurricane Irma was the first Category 5 hurricane on record to strike the Leeward Islands. She made landfall on the Florida Keys as a Category 4 storm with a diameter covering Alabama, Georgia and South Carolina.
September 2017, Dominica, U.S. Virgin Islands, and Puerto Rico	Hurricane Maria hit the small Caribbean island of Dominica as a Category 5 storm, and then the U.S. Virgin Islands. The powerful storm made landfall in Puerto Rico as a Category 4 storm, the strongest hurricane to directly hit Puerto Rico since 1932. Millions of Puerto Ricans were without power for months after the hurricane made landfall.
September 2017, Mexico	7.1 magnitude earthquake in Mexico City, killing at least 225 people
October 2017, Las Vegas, NV	Mass shooting killing 58 and more than 500 injured (How the Las Vegas Strip shooting unfolded By Washington Post Staff <a href="https://www.washingtonpost.com/graphics/2017/national/las-vegas-shooting/?noredirect=on&amp;utm_term=.2da5ecfb2ed1">https://www.washingtonpost.com/graphics/2017/national/las-vegas-shooting/?noredirect=on&amp;utm_term=.2da5ecfb2ed1</a> )
December 2017 to January 2018, Southern California	Thomas Fire: State's largest-ever wildfire, scorching more than 280,000 acres, or 440 square miles—nearly the size of New York City One month later the area experienced devastating mudslides closing major roadways, destroying hundreds of homes, and killing 17 people.
November 2018, Northern California	Camp Fire is one of the largest and deadliest fires in California history: 85 people died (Brekke, 2019), 19,000 buildings (mostly homes) were destroyed, and 153,336 acres were burnt (Miller, 2018).
November 2018, Southern California	Thousand Oaks, CA: Borderline Bar shooting: 12 people died and 128 injured (local college students) (Wilson, 2019). Two days later many of the families affected were told to evacuate due to the Woolsey Fire.
September 2019, Bahamas	Hurricane Dorian, a Category 5 hurricane, struck the Bahamas in which at least 53 people died, 1,300 are still missing, and 7,500 people are affected. The costs are expected to exceed \$7 billion (Ailworth, 2019).
2019, California	6,190 incidents of fire, 198,392 estimated acres burned, with 732 structures damaged or destroyed, and 3 fatalities ( <a href="https://www.fire.ca.gov/incidents/2019">https://www.fire.ca.gov/incidents/2019</a> )
2019/2020, Australia	More than 240 days of wildfires left Australia with 25.5 million acres burned, thousands of homes destroyed, 33 people dead, and over a billion animals feared to have perished, including over 30,000 koalas. In the capital of Australia, the air quality index reached more than 23 times higher than air quality that is considered hazardous. ( <a href="https://www.theverge.com/2020/1/3/21048891/australia-wildfires-koalas-climate-change-bushfires-deaths-animals-damage">https://www.theverge.com/2020/1/3/21048891/australia-wildfires-koalas-climate-change-bushfires-deaths-animals-damage</a> )
2020, global	The COVID-19 pandemic affected 210 countries and territories. As of July 14, 2020, there were 4,975,294 people currently infected worldwide. A total of 8,366,172 were closed cases, including 7% that were deceased. ( <a href="https://www.worldometers.info/coronavirus/">https://www.worldometers.info/coronavirus/</a> )

## Characteristics of Disasters

Disasters are often characterized by their cause.

- A **natural disaster** is caused by natural events, such as earthquakes and tsunamis.
- A **manmade disaster** is caused by human activity, such as mass shootings, the bombing of significant landmarks in major cities, or the riots in major cities after a sociopolitical event. Other manmade disasters include nuclear reactor meltdowns, industrial accidents, oil spills, construction accidents, and air, train, bus, and subway crashes. In fact, manmade disasters can and frequently do follow natural disasters, as occurred with the nuclear reactors in Japan following the earthquake and tsunami in 2011.
- A **casualty** is someone who has been injured or killed by or as a direct result of an accident or natural disaster.
- If casualties number more than two people but fewer than 100, the disaster is characterized as a **multiple-casualty incident**.
- Although multiple-casualty incidents may strain the health care systems of small or midsized communities, a **mass-casualty incident**—often involving many casualties—can completely overwhelm the health care resources of even large cities (DeNolf & Kahwaji, 2019).

Preparedness for mass-casualty incidents is essential for all communities. For instance, community leaders should closely track and report through various media the path and time of landfall of a hurricane to inform residents in the storm's path and support early evacuation of families and businesses. Communities can help minimize devastation from flooding by building reservoirs or refusing to grant building permits in flood-prone areas and by reinforcing areas around waterways with sandbags during rainy weather. In fire-prone areas, communities can heighten awareness of fire danger and enforce regulations supporting precautionary preventive measures. Unfortunately, some disasters occur without warning. For example:

- The terrorist attacks in New York City caught thousands of civilians by surprise. They were trapped in buildings with limited escape routes and very little time to retreat to safety.
- During the 2015 Paris terrorist attacks, survival depended on being in the right place at the right time.
- Coworkers were trapped in a building during the 2015 San Bernardino, CA terrorist attack when a married couple fired on them with automatic weapons. A total of 14 were killed and 27 were injured.
- Wildfires in California during 2017 and 2018, though not completely unanticipated, were uncharacteristically large, and control was hindered

by drought conditions, along with heat and high winds.

- The mass shootings in Newtown, Connecticut; Aurora, Colorado; Las Vegas, Nevada; and Thousand Oaks, California occurred without warning and were the result of mentally unstable individuals acting alone.

Some disasters, such as the natural gas leak in a southern California community during 2015–2016, are at first unknown to the public. After residents began noticing headaches, nosebleeds, respiratory problems, and other symptoms, the Southern California Gas Company acknowledged that a deep well gas leak had occurred in a difficult-to-reach canyon miles away. The company assured the public that the leak did not pose an imminent health risk, although it had been occurring for months and would take several more months to stop. It was estimated that over 30,000 kg/hour of methane was released into the atmosphere, and the area became a no-fly zone per the Federal Aviation Administration (Reilly, 2016). The gas leak was finally stopped and “permanently sealed” in late February 2016 (Pamer, Wynter, & McDade, 2016, p. 4).

The **scope** of a disaster is the range of its effect, either geographically or in terms of the number of people impacted. The **intensity** of a disaster is the level of destruction and devastation it causes. For instance, an earthquake centered in a large metropolitan area and one centered in a desert may have the same numeric rating on the Richter scale yet have very different intensities in terms of the destruction they cause. As of seven months after its initial detection, the COVID19 pandemic, stemming from a novel coronavirus that started in Wuhan, China in December 2019, had infected more than 12.5 million worldwide and caused over half a million deaths (CDC, 2020a).

The terrorist attacks on September 11, 2001 are the worst disaster in U.S. history, as a total of 2,996 people, including 19 terrorists, died in three attacks on U.S. soil. Terrorists took control of four airplanes and used them as missiles. Two planes hit the World Trade Center in New York City, killing 2,753 (Engel & Ioanes, 2020). The third plane hit the Pentagon, killing 125 in the Pentagon and the 64 aboard the plane. Passengers in the fourth plane, United Flight 93, were aware of the attacks and, once their plane was hijacked, attempted to take back the plane. The plane crashed in a field in Shanksville, Pennsylvania, killing 40 (Engel & Ioanes, 2019). Every year on September 11th, the country remembers those who perished in the attacks. Only 60% of the bodies have been identified thus far. The remains of firefighter Michael Haub were identified this year (Karimi, 2019). At least 200 firefighters have died to date from Ground Zero–related illnesses (Stanglin, 2019).

## Persons Impacted by Disasters

Because disasters are so variable, there is no typical person impacted in a disaster, nor can anyone predict whether he or she will ever be impacted by a disaster. Those who are **directly impacted by disaster** experience the event firsthand, whether fire, flooding, mass shooting, vehicular accident, or bombing. They also constitute the dead and the survivors of the event; these survivors are likely to have health effects from their experience, even if they are without physical injuries directly caused by the event. Some may be without shelter or food, and many experience serious psychological stress long after the event is over, such as victims of the Thomas Fire. This fire, California's largest wildfire to date, was started by sparks from powerlines during a powerful wind, destroyed 1,063 structures, and burned 281,893 acres (Box 17-1; Diskin, 2019).

### BOX 17-1 PERSPECTIVES

**Viewpoint of a Victim of the Thomas Fire Dry easterly winds and a spark of fire on the night of December 4, 2017 changed many lives, including my own. That spark of fire grew to be known as the Thomas Fire that destroyed over 500 structures, including our home of 20 years. The power had been out and the glow of flames appeared incredibly close—a setting for panic that told me to just get out. We left fast with only clothes for the next couple of days. My husband and I learned the next afternoon that our home had burned with nothing left but ashes and odd pieces of survival, like a whole wall of decorative master bathroom tile!**

Over the next month, I felt a wave of emotions that included not only the obvious of sadness but a conflict between feeling both immense gratitude and highly overwhelmed from the countless people who reached out to us. It often seemed like I was just floating to get through the day yet appreciating the little things, like the smell of shower soap and taste of coffee at our daughter's home where we were staying. Interestingly, one word kept popping into my head over that immediate time period: resilience. I found strength in knowing I could be resilient through the kindness of others who truly cared.

Ever since the fire, I feel anxious during dry windy weather, the sound of fire department sirens and seeing the outbreak of fire. California has continued to be affected by devastating fires. The aftermath of fire destruction leads me to wonder where those people are at emotionally and physically in rebuilding their lives, knowing from personal experience how some plow through and others go through extreme grief. Each day I wake up taking a deep breath, reminding myself of having resilience, and knowing I have the ability to rebuild anew.

Colleen Nevins, DNP, RN

Depending on the cause and characteristics of the disaster, some direct survivors may become displaced persons or refugees. **Displaced persons** are forced to leave their homes to escape the effects of a disaster. Usually, displacement is a temporary condition and involves movement within the person's own country. The term **refugee** is reserved for people who are forced to leave their homeland because of war or persecution (United Nations, n.d). Returning displaced persons or refugees can place economic and social strains on the county of origin. Along with needs for employment and shelter, these influx situations raise concerns, especially regarding early or forced marriages, child labor, and human trafficking (United Nations, n.d.). Whether the displacement of refugee status is permanent or not, the lasting impact to both the country of origin and the host country is significant.

Those who are **indirectly impacted by disaster** are the relatives and friends of persons directly impacted by the disaster. These supporters often undergo extreme anguish while trying to locate loved ones or accommodate their emergency needs. If bodies cannot be found or are unidentifiable, the supporting persons experience even greater anguish and may not be able to accept that a loved one did not survive. Family members of those killed on 9/11 in New York City worked with architects to develop a memorial that meets the expectations of most of those indirectly impacted by the attack and honors their loved ones. This effort, along with the Flight 93 National Memorial in Shanksville, PA, and the Pentagon Memorial, helps with the

long healing process of the supporters and serves as a reminder of the impact that day had on each of our lives.

## Factors Contributing to Disasters

It is useful to apply the host, agent, and environment model (epidemiological triad) to understand the factors contributing to disasters, because manipulation of these factors can be instrumental in planning strategies to prevent or prepare for disasters. See [Chapters 7](#) and [8](#).

### *Host Factors*

The *host* is the human being who experiences the disaster. Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and socioeconomic factors. For instance, older residents of a mobile home community may be unable to evacuate independently in response to a tornado warning if they can no longer drive. Residents of a low-income apartment complex in a large city may be aware that their building is not compliant with city fire codes but avoid alerting authorities for fear of the complex being closed and being homeless due to their inability to afford new, safe housing.

### *Agent Factors*

The *agent* is the natural or technologic element that causes the disaster. For example, the high winds of a hurricane and the lava of an erupting volcano are agents, as are radiation, industrial chemicals, biologic agents, and bombs.

### *Environmental Factors*

*Environmental factors* are those that could potentially contribute to or mitigate a disaster. Common environmental factors include a community's level of preparedness; the presence of industries that produce harmful chemicals or radiation; the presence of flood-prone rivers, lakes, or streams; above-average amount of rainfall or snowfall; above-or below-average high or low temperatures; proximity to fault lines, coastal waters, or volcanoes; and the presence or absence of political unrest.

# Agencies and Organizations for Disaster Management

In 1803 the United States first recognized the need to prepare for emergencies through law and dedicated organizations. The first law was written as a direct response to a major disaster, the Portsmouth, New Hampshire fire of 1803, which swept through the seaport town. The majority of subsequent legislation was in response to specific crises and created many different agencies to respond to those disasters. The one constant was that the response of the federal government to disasters remained more reactive than proactive and was ad hoc in nature, only becoming coordinated with the establishment of the Federal Emergency Management Agency (FEMA) in 1979 and the passage of the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 (Haddow, Bullock, & Coppola, 2016). In response to World War II and the specter of all-out nuclear war with the Soviet Union, the United States created Civil Defense, a series of programs and agencies designed to protect the population from “counter-value” nuclear strikes and increase the survivability of a nuclear war. The U.S. Department of Health, Education, and Welfare (USDHEW), predecessor to the U.S. Department of Health and Human Services, created the *Handbook for Civil Defense Emergency Planning in Welfare Institutions*, which was a guide to protect individuals and help staff prepare for fallout from a nuclear event (USDHEW, 1961). Significant in this handbook was the attention given to family responsibilities and the likelihood that staff, including nurses, would choose family responsibilities over professional responsibilities. To help alleviate the problems associated with absenteeism as a result of the nurses' conflicting responsibilities, the handbook recommended:

- Reminding staff of their responsibility as public servants,
- Providing shelter for families within the institution,
- Planning for getting families to the shelter,
- Planning for families to assist the staff during a crisis (USDHEW, 1961).

Under the 1950 version for the United States Civil Defense Plan, health services were to remain under the control of existing health agencies to avoid unnecessary duplication of services and would be subject to the rules and regulations of civil defense. The U.S. Public Health Service (USPHS) was responsible for providing staffing for civil defense offices and would work for the state health officer who would have the lead. The roles have been in continual transition since that time, but the basic principles remain the same.

Public health has become recognized as a critical component of emergency planning, preparedness, and response. National public health

response requires coordination with state and local authorities, to include nongovernmental agencies ([Centers for Disease Control and Prevention \[CDC\], 2019a](#)). The CDC website has an assortment of educational materials to explore disasters such as videos, online modules, and statistics.

Among disaster-relief organizations, perhaps none is as famous as the Red Cross, which is referred to as the American Red Cross in the United States and the Red Crescent Societies in Islamic countries. The American Red Cross was founded in 1881 by Clara Barton and was chartered by the U.S. Congress in 1905. It is authorized to provide disaster assistance free of charge across the country through its more than half a million volunteers and staff. The duties assumed by the Red Cross in the event of a disaster are to provide shelter, food, basic health and mental health services, and distribution of emergency supplies ([American Red Cross, n.d.](#)).

President George W. Bush sought to consolidate the roles and responsibilities of agencies and organizations involved in disaster response and to align them with emergency support functions (ESFs; [Table 17-2](#)).

**TABLE 17-2 Emergency Support Functions Responsibilities**

ESF	Scope	Coordinating Agency
1. Transportation	Coordinates the support of management of transportation systems and infrastructure, the regulation of transportation, management of the Nation's airspace, and ensuring the safety and security of the national transportation system	Department of Transportation
2. Communications	Coordinates government and industry efforts for the reestablishment and provision of critical communications infrastructure and services, facilitates the stabilization of systems and applications from malicious activity, and coordinates communications support to response efforts	DHS/Cybersecurity and Communications
3. Public works and engineering	Coordinates the capabilities and resources to facilitate the delivery of services, technical assistance, engineering expertise, construction management, and other support to prepare for, respond to, and recover from a disaster or an incident	Department of Defense—U.S. Army Corps of Engineers
4. Firefighting	Coordinates the support for the detection and suppression of fires. Functions include but are not limited to supporting wildland, rural, and urban firefighting operations	U.S. Department of Agriculture/U.S. Forest Service and DHS/ FEMA/ U.S. Fire Administration
5. Information and planning	Supports and facilitates multiagency planning and coordination for operations involving incidents requiring federal coordination	DHS/FEMA
6. Mass care, emergency assistance, temporary housing, and human services	Coordinates the delivery of mass care and emergency assistance	DHS/FEMA
7. Logistics	Coordinates comprehensive incident resource planning, management, and sustainment capability to meet the needs of disaster survivors and responders	General Services Administration and DHS/FEMA
8. Public health and medical services	Coordinates the mechanisms for assistance in response to an actual or potential public health and medical disaster or incident	Department of Health and Human Services
9. Search and rescue	Coordinates the rapid deployment of search and rescue resources to provide specialized lifesaving assistance	DHS/FEMA
10. Oil and hazardous materials response	Coordinates support in response to an actual or potential discharge and/or release of oil or hazardous materials	Environmental Protection Agency
11. Agriculture and natural services	Coordinates a variety of functions designed to protect the Nation's food supply, respond to plant and animal pest and disease outbreaks, and protect natural and cultural resources	Department of Agriculture
12. Energy	Facilitates the reestablishment of damaged energy systems and components, and provides technical expertise during an incident involving radiological/nuclear materials	Department of Energy
13. Public safety and security	Coordinates the integration of public safety and security capabilities and resources to support the full range of incident management activities	Department of Justice/Bureau of Alcohol, Tobacco, Firearms, and Explosives
14. Cross-sector business and infrastructure	Coordinates cross-sector operations with infrastructure owners and operators, businesses, and their government partners, with particular focus on actions taken by businesses and infrastructure owners and operators in one sector to assist other sectors to better prevent or mitigate cascading failures between them. Focuses particularly on those sectors not currently aligned to other ESFs (draft for 2019 4th ed.)	DHS/Cybersecurity and Infrastructure Security Agency
15. External affairs	Coordinates the release of accurate, coordinated, timely, and accessible public information to affected audiences, including the government, media, NGOs, and the private sector. Works closely with state and local officials to ensure outreach to the whole community	DHS

DHS, Department of Homeland Security; ESF, Emergency Support Functions; FEMA, Federal Emergency Management Agency; NGO, nongovernmental organization.

Reprinted from The Department of Homeland Security. (2019 draft). *National response framework* (4th ed., pp. 39–42).

Retrieved from <https://www.fema.gov/media-library-data/1559136348938-063ec40e34931923814dd50df638b448/NationalResponseFrameworkFourthEdition.pdf>

- The Department of Homeland Security (DHS) was organized in 2002 and incorporates many of the nation's security, protection, and

emergency response activities into a single federal department (DHS, 2015).

- In 2003, FEMA, along with parts of 23 agencies, became part of the DHS.
- FEMA, established in 1979, is the federal agency responsible for assessing and responding to disaster events in the United States and provides training and guidance in all phases of disaster management.
- The DHS includes other widely known agencies, including the Transportation Security Administration, U.S. Customs and Border Protection, U.S. Immigration and Customs Enforcement, U.S. Citizenship and Immigration Services, U.S. Coast Guard, and U.S. Secret Service (DHS, 2018).

FEMA provides oversight of the National Incident Management System (NIMS), developed to allow responders from different jurisdictions and disciplines to work more cohesively and proactively in response to natural disasters, emergencies, and terrorist acts.

NIMS is the National **Incident Command System (ICS)**, meaning that it takes a unified approach to incident management, incorporates standard command and management structures, and emphasizes preparedness, mutual aid, and resource management (Fig. 17-1; FEMA, 2017a). Nurses and other health care professionals must understand this system and are encouraged to take courses dealing with the ICS. These courses are available for free online from FEMA Emergency Management Institute at <http://www.training.fema.gov/EMI/>. The most important courses for a nurse are (1) IS-100 Introduction to the Incident Command System, (2) IS-200.C Basic Incident Command System for Initial Response, (3) IS-700 Introduction to the NIMS, and (4) IS-800.b Introduction to the National Response Framework. Students are encouraged to explore the FEMA distance learning platform at <https://training.fema.gov/is/>.

**FIGURE 17-1** Incident command system. FEMA. *Incident Resource Center*. (Adapted from <http://training.fema.gov/EMIWeb/IS/ICSResource/index.htm>.)

The Department of Health and Human Services (DHHS) is the lead federal agency for public health and medical services during a public health or medical disaster. Supplemental services are provided to state, local, and territorial governments and may include Disaster Medical Assistance Teams (DMAT), USPHS officers, epidemiological personnel from the CDC, and veterinary support to name a few. Various international nongovernmental organizations (such as Doctors Without Borders, the International Medical Corps, and Operation Blessing), religious groups, and other volunteer agencies provide needed emergency care (Fig. 17-2; see Chapter 16).

**FIGURE 17-2** Mobile hospitals are often deployed during disasters.

Governments often send their military personnel and equipment in response to international disasters. However, political agendas may prevent aid typically accepted by countries experiencing catastrophe to reach the impacted communities. Fortunately, the USPHS Commissioned Corps was allowed to provide aid for the 2008 tsunami and earthquake survivors in Indonesia and Haiti. The USPHS has also worked collaboratively with the U.S. Navy to provide nursing and other medical care on combined humanitarian missions to South America and the South Pacific, and was sent to Africa to assist with the Ebola crisis (USPHS, 2019). See [Chapter 28](#) for additional information about the role of the USPHS Commissioned Corps Nurses in emergency preparedness.

## Phases of Disaster Management

In developing strategies to address the problem of disasters, it is helpful for the C/PHN to consider each of the four phases of disaster management: preventive/mitigation, preparedness, response, and recovery and become familiar with the language typically used in disaster preparedness (Emergency Management terms and definitions, [FEMA, 2018](#)).

### *Prevention or Mitigation Phase*

Activities during this phase are focused on preventing future emergencies or minimizing their effects. The shaping of public policies and plans that either modify the causes of disasters or mitigate their effects on people, property, and infrastructure are critical activities during this phase. Mitigation activities take place *before* and *after* disaster emergencies.

To reduce our vulnerability to disasters, the United States has strengthened its disaster management activities over the past decade and continues to do so today (FEMA, n.d).

- The screening process at airports and shipping ports includes advanced imaging technology scanning and random hand-carried luggage or canine searches preboarding.
- Nonpassengers cannot go beyond the security entrance area, and photographic identification is required at two or more points before boarding.

Although globally we have experienced a pandemic and much will be learned from it, the Global Health Security has steps in place designed to help decrease the risk of pandemics. These steps include surveillance systems that detect possible threats, laboratories to identify the agent, a workforce for follow-up and containment, and emergency management systems to coordinate the activities ([CDC, 2020b](#)). To prevent possible contamination by Covid19, individuals are advised to wash hands for 20 seconds, to wear a face mask when going out in public, and to maintain a 6 ft distance between each other ([CDC, 2020c](#)).

### *Preparedness Phase*

Disaster *preparedness* involves improving community and individual reaction and responses, so that the effects of a disaster are minimized. Disaster preparedness includes plans for communication, evacuation, rescue, victim care, and recovery. Preparedness may be hazard-specific or a general all-hazard approach. For example, the Centers on Medicare and Medicaid

Services (CMS) recommends that an “all-hazards approach” be taken by health care agencies when taking into consideration their location and disasters common to that area (CMS, 2017).

- For instance, although plans may differ in states at higher risk of earthquakes from those in tornado alley, the preparedness plans apply to numerous disasters.
- Communities must ensure that warning systems are tested routinely to ensure appropriate notifications to the residents of a tornado or hurricane, or any other potential threat.
- The [Office of the Assistant Secretary for Preparedness and Response \(2020\)](#) oversees the Strategic National Stockpile (SNS), which contains doses of vaccines, medical countermeasures, and needed medical supplies stored around the country in various strategic locations.
- The CDC reports that the SNS contains enough medications and medical supplies to manage a large public health emergency and protect the American public (CDC, 2016).
- Examples of preparedness include duck, cover, and hold during an earthquake and run, hide, or fight for an active shooter incident (FEMA, 2020a).

Nurses have a role in preparedness as well. Leaving one's home to assist in a disaster is difficult, especially if one, or one's family, is not prepared. Therefore, nurses need to be prepared with an individual and family plan and supplies that could possibly be needed. Enrolling in disaster classes or/and registering with a disaster agency such as the Red Cross, reinforces professional preparedness. On a community level, nurses can enhance preparedness by participating in community drills often held by public health agencies. Preparedness activities take place *before* an emergency occurs. We cannot provide adequate disaster relief until we are prepared on all three levels.

## *Response Phase*

The *response phase* begins immediately after the onset of the disastrous event and *during* the emergency. Response is putting your preparedness plans into action immediately, with the goals of saving lives and preventing further injury or damage to property. Activities during the response phase include rescue, triage, on-site stabilization, transportation of injured, and treatment at local hospitals and clinics. Disaster triage differs from triage done in the emergency departments. START, the most commonly used technique in the United States, consists of triaging individuals in 30 to 60 seconds during a mass casualty. The four categories consist of the walking wounded/minor (green tag), delayed (yellow), immediate (red), and deceased (black). These

categories are based on ambulation, respirations, perfusion, and mental status (Bazyar, Farrokhi, & Khankeh, 2019).

Response also requires recovery, identification, and refrigeration of deceased remains, until notification of family members is possible (USDHHS, 2020b). Persons trained in mortuary services are an essential part of any emergency planning and response effort. The mortuary teams includes pastoral personnel to ensure that remains are always treated with respect and in accordance with religious traditions. Supportive care, including food, water, and shelter for survivors and relief workers, is a critical element of the total disaster response. Veterinary response teams are essential to address the acute and long-term needs of the animals impacted by the disaster. Many shelters will not accept pets, causing confusion and delays in sheltering displaced persons (Fig. 17-3).

**FIGURE 17-3** Victims of Superstorm Sandy receiving assistance at a temporary shelter.

Individuals with chronic health conditions and/or mental illness may need specific interventions in recovery from a disaster. Those with serious mental illness such as bipolar disorder and schizophrenia are less likely to be prepared for disasters than the general population. Although these disorders are not caused by disasters, the effects of the disaster can cause higher hospitalizations and higher levels of avoidance behavior (SAMHSA, 2019). C/PHNs need to be aware of support agencies for this population because their needs may increase due to lack of support systems and poor coping skills. In recent years, it has become clear that all of us need to have a plan in place so that we recover as quickly as possible if a disaster arises.

- Individuals on medications need at least a 3-day supply of medications. Special diet foods may be hard to locate during a disaster; therefore,

advise patients to eat healthy as much as possible if their special diet foods are unavailable during a disaster.

- Be prepared for possible power outages (CDC, 2019a).
- The Emergency Prescription Assistance Program helps to replace medications and equipment that is lost due to a disaster (Public Health Emergency, 2020).
- Knowledge of the community assists the C/PHN in ensuring all populations have services needed, with special attention paid to those who are most vulnerable.

## *Recovery Phase*

During the *recovery phase*, the community joins together to repair, rebuild, or relocate damaged homes and businesses, and restore health, social, and economic vitality to the community. There will be many opportunities during this phase to enhance prevention and increase preparedness, thus reducing future vulnerabilities. Both survivors and relief workers may experience psychological trauma and should be offered mental health services to support their recovery (Box 17-2). The traumatic emotional scars may last a lifetime. The Substance Abuse Mental Health Services Administration (SAMHSA) offers guides and a disaster kit for managing stress in crisis for both professionals and victims (SAMHSA, 2011). Recovery activities take place *after* an emergency, and may extend over a period of months or even years.

### BOX 17-2 PERSPECTIVES

**Viewpoint of a Survivor of the Route 91 Mass Shooting** As the first volleys of automatic gunfire rained down upon myself and the other 20,000 people watching Jason Aldean perform at the Route 91 Harvest Music Festival in Las Vegas, NV, my three friends and I looked around, trying to determine the source of the horrific sound that we had thought were firecrackers. Until that point, it

**had been one of the best weekends of my life and it seemed as if nothing could bring me down from the mountain of joy I felt. However, as Jason Aldean ran off stage and someone running past us yelled, “There's blood! That girl has been shot!” the mountain of joy came crumbling down and the devastation of what would eventually become an estimated 1,200 rounds of lethal ammunition, killing 58 beautiful souls, began to sink in.**

Quickly, we moved towards the exit and stopped behind a barrier, trying to determine where the shooting was coming from and which way to go. As I looked back towards the emptying venue, I saw a young girl, shot through her eye, lying there. My work experience as an EMT kicked in, and a small group of strangers and I quickly carried her to the outer walls of the venue, passing her off to other strangers who said they had medical experience. From there, the adrenaline rushing through my veins led me and many others to aid and carry other gunshot victims out of what had become a war zone.

As the shooting eventually stopped and the only victims left inside the venue were those who were covered in a makeshift shroud to shield our eyes from the horror that lay underneath, the emotional roller coaster set in. I teetered between anger, extreme sadness, numbness, and confusion. I could not comprehend the magnitude of what had happened in front of my eyes. For weeks, it was all I could think about, replaying the steps I took, the sounds of gunfire, the cries, the feeling of a stranger's blood across my skin. Unless I was around my friends I had been at the concert with, I felt alone and uneasy in a crowded room. The posttraumatic stress was real, and it would take months of therapeutic counseling before I even felt remotely close to “normal.”

Over 2 years later, I still occasionally see a counselor to discuss the emotions and visions that are only a loud “pop” away. Though I do not bear any physical scars from the night of October 1, 2017, the emotional scars run deep and can be easily broken open. While I am able to function throughout my daily life and work life as an EMT in the emergency department seemingly fine, there is still not a day that goes by that I am not somehow reminded of that night.

Gabriel Mosse

During the recovery phase, special attention should be given to the needs of children who are approximately 25% of the population in the United States and even higher in other countries. The CDC has resources in English and Spanish to assist children that have experienced disasters. One example is the coloring book *Coping After a Disaster* ([CDC, 2019b](#)).

## Role of the Community/Public Health Nurse

The C/PHN has a pivotal role in preventing, preparing for, responding to, and supporting recovery from a disaster ([Association of Public Health Nurses \[APHN\] Public Health Preparedness Committee, 2014](#)). After a thorough community assessment for risk factors, the C/PHN may initiate the formation of a multidisciplinary task force to address disaster prevention and preparedness in the community.

### *Preventing Disasters*

Disaster prevention may be considered on three levels: primary, secondary, and tertiary ([Box 17-3](#)).

## **BOX 17-3 Levels of Prevention Pyramid**

**Responding to a Tornado SITUATION: A natural disaster—tornado GOAL: Prepare, promptly diagnose, and treat and/or restore individuals, families, and communities to the fullest by using the three levels of prevention.**

Tertiary Prevention		
Rehabilitation	Prevention	
	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Remain safe during the immediate recovery period.</li> <li>Accept help from others—friends, family, and community services.</li> <li>Rebuild family lives through counseling and other services to reestablish stable life physically, emotionally, spiritually, and financially.</li> </ul>	<ul style="list-style-type: none"> <li>Educate community members about the need to enhance planning against damage from future natural disasters, based on experiences with the current disaster.</li> </ul>	<ul style="list-style-type: none"> <li>Keep recommended immunizations current.</li> <li>Community physical structures need rebuilding, with infrastructure planning and supports that improve ability to withstand natural disasters.</li> </ul>
Secondary Prevention		
Early Diagnosis	Prompt Treatment	
<ul style="list-style-type: none"> <li>Remain in your position of safety until a community all-clear warning signal is sounded or until rescued.</li> <li>Leave a damaged building cautiously, if able and not seriously injured, and do not return until it is declared safe.</li> </ul>	<ul style="list-style-type: none"> <li>Rescue individuals promptly and get appropriate care for those injured as soon as possible.</li> <li>The infrastructure of the community becomes/remains intact, keeping community members safe from hazards such as live wires, broken gas lines, and fallen debris.</li> </ul>	

Primary Prevention	
Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>▪ Increase community awareness.</li> <li>▪ Increase community preparation through education.</li> <li>▪ Each person is as prepared as possible both physically and emotionally.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Community members know what to do and where to go, whether at home, work, school, or elsewhere in the community.</li> <li>▪ Get to safety before the impact—southwest corner of a home's basement or an interior room away from windows and under heavy furniture.</li> </ul>

## *Primary Prevention*

Primary prevention of a disaster means keeping the disaster from ever happening by taking actions that completely eliminate its occurrence—or, if that is not possible, to minimize damage through primary prevention. Primary prevention includes providing and participating in training sessions on prevention of disaster risk factors, knowing high-risk groups through community assessments, and working with community partners (CDC, 2019a). Primary prevention of disasters can be practiced in all settings in the workplace and home—with defined processes to reduce safety hazards and in the community, to monitor risk factors, reduce pollution, and encourage nonviolent conflict resolution (CDC, 2019b). Primary disaster prevention efforts should include awareness of a community's physical, psychosocial, cultural, economic, and spiritual stance. The C/PHN educates people at home, at work, at school, or in a faith community, and has a unique opportunity to be aware of the community perspective about safety and security focused on preventing a disaster. There are many prevention actions the C/PHN can initiate (APHN Public Health Preparedness Committee, 2014). These prevention actions can include the following:

- Completing a community assessment, including the residents with special needs and those in high-risk categories
- Collaborating with community leaders to provide general community prevention and preparation education activities. For instance, working with community partners C/PHNs promote policies that better prepare vulnerable populations. These relationships are built on trust and a common goal of serving the population. C/PHNs work closely with these community partners acting in a leadership role to ensure populations are assessed and have the services needed if a disaster occurs (APHN, 2014). The second aspect of primary disaster prevention is anticipatory guidance. Disaster drills and other anticipatory exercises help the community and relief workers experience some of the feelings of chaos and stress associated with a disaster before one occurs (APHN, 2014). It is much easier to do this when energy and intellectual processes are at a high level of functioning.

- The C/PHN has a role in community collaborative disaster drills through committee membership, organization of drills at the place of employment, or activism at the grassroots level to assist in holding community-wide disaster drills on a regular basis.

## *Secondary Prevention*

Secondary disaster prevention focuses on the earliest possible detection and treatment. After a disaster, the local health department's C/PHNs work with the American Red Cross to coordinate and provide emergency assistance. Secondary prevention corresponds to immediate and effective response. Agencies who provided early evacuation, identified shelters for special-needs patients outside the high-risk area, implemented volunteer cascading communication systems, and conducted pre-event mock evacuation plans and included volunteers in their disaster plan were most successful with their response efforts. Recommendations to improve responses include identification of patients who may be reluctant to evacuate, the provision of adequate security at special-needs shelters, and, most importantly, practice drills (APHN, 2014; DHS, n.d.). Many local communities have developed preparedness programs to inform, prepare, and ensure residents are ready for any type of manmade or natural disaster, such as the City of New Orleans's NOLA READY (for more details, visit <https://ready.nola.gov/home/>).

## *Tertiary Prevention*

Tertiary disaster prevention involves reducing the amount and degree of disability or damage resulting from a disaster. This level involves rehabilitative work and can help a community recover and reduce the risk of further disasters.

Since 9/11, the American Psychiatric Nurses Association has provided access to many resources for nurses dealing with traumatic events (American Psychiatric Nurses Association, 2016). Visit <https://www.apna.org/m/pages.cfm?pageID=5196> for a detailed list of resources for dealing with traumatic events, and SAMHSA apps at <https://store.samhsa.gov/product/samhsa-disaster> for easy access when in the field. In addition to these references, the Office of the Assistant Secretary for Preparedness and Response (2019) offers a three-module series on compassion fatigue and secondary trauma for health care providers that can be found at <https://files.asprtracie.hhs.gov/documents/asprtracie-dbh-self-care-for-health-care-workers-modules-description-final-8-19-19.pdf>

## *Preparing for Disasters*

**Disaster planning** is essential for a community, business, and hospitals. Details of preparation and management by all involved, including

community leaders, health and safety professionals, and lay people must be considered. Despite many disaster drills and numerous iterations of disaster plans before Hurricane Katrina, some hospitals in New Orleans were better prepared for terrorism events than for the hurricanes and flooding that were not uncommon to that geographic area. C/PHNs can be very instrumental in disaster preparedness (APHN, 2014). and must ensure they have their own family disaster preparation plan in place. For information on nurses' personal preparation for disaster and online courses on disaster preparedness, see [Box 17-4](#).

**BOX 17-4 Nurses' Personal Preparation for Disasters and Available Training**  
Nurses are ready, willing, and well positioned to respond to disasters; however, nurses receive minimal disaster-focused instruction as part of their formal education. Due to the reality that a disaster can occur at any time, it becomes all the more urgent for nurses to be well prepared through valid and low-cost education in disaster management ([Brand, 2016](#)).

American Nurses Association (ANA) has educational opportunities for nurses on disaster preparedness. When we are a prepared profession, we can cope and help our communities recover from disasters better, faster, and stronger. See <https://www.nursingworld.org/practice-policy/work-environment/health-safety/disasterpreparedness/> for the following documents from the ANA:

- Position Statement Background Information: Registered Nurses' Rights and Responsibilities Related to Work Release During a Disaster
- Position Statement Background Information: Work Release During a Disaster—Guidelines for Employers

Other educational opportunities include:

- HHS Guidance for Mass Decontamination: Patient Decontamination in a Mass Chemical Exposure Incident: National Planning Guidance for Communities (available at <http://www.phe.gov/Preparedness/responders/Documents/patient-decon-natl-plng-guide.pdf>)
- A Nurse's Duty to Respond in a Disaster: Unresolved issues of legal, ethical, and professional considerations of disaster medical response remain a challenge, and could hamper the ability of nurses to respond. A concerted effort to solving these problems is needed, with nurses and stakeholders at the national, state, and local levels (available at [https://www.nursingworld.org/~4ad845/globalassets/docs/ana/who-will-be-there\\_disaster-preparedness\\_2017.pdf](https://www.nursingworld.org/~4ad845/globalassets/docs/ana/who-will-be-there_disaster-preparedness_2017.pdf)).
- IOM Report on Establishing Crisis Standards of Care to use in Disaster Situations (PDF) (available at <https://www.nursingworld.org/~4ad845/globalassets/docs/ana/stds-of-care-letter-report-2.pdf>)

The American Nurses Association also offers the National Healthcare Disaster Certification (NHDP-BC); information on this program can be found at <https://www.nursingworld.org/our-certifications/national-healthcare-disaster/>. Nurses are able to take the certification exam once certain requirements are met.

Personal preparedness means that the nurse has read and understands workplace and community disaster plans and has developed a disaster plan for his or her own family ([San Diego County Office of Emergency Services, n.d.](#)). The prepared nurse should also have participated in disaster drills, have documented up-to-date vaccinations, be a certified basic life support (BLS) provider, and be able to provide basic first aid. Nurses preparing to work in disaster areas as “spontaneous volunteers” should have copies of their nursing license and driver's license, durable clothing, and basic equipment, such as stethoscopes, flashlights, and cellular phones to facilitate appropriate task assignments during the disaster response.

To increase understanding of and the ability to work within an emergency situation, every nurse should become familiar with the National Incident Management System (NIMS). The NIMS is “a systematic, proactive approach to guide all levels of government, NGOs, and the private sector to work together to prevent, protect against, mitigate, respond to, and recover from the effects of incidents.” ([FEMA, 2017a](#), p. 77). In essence, NIMS provides a framework for management of incidents in support of the national preparedness

system. Free online courses are offered through FEMA at [www.fema.gov](http://www.fema.gov). In addition to the FEMA courses, other options include the following

- CDC Emergency Preparedness and Response Training and Education: <https://emergency.cdc.gov>
- Federal Emergency Management Agency (FEMA): <http://training.fema.gov/emi.aspx>
- Public Health Foundation—Train.org: <https://www.train.org>
- National Institutes of Health—Radiation Emergency Medical Management: <http://www.remm.nlm.gov/training.htm>
- University of Minnesota, School of Public Health: <http://www.sph.umn.edu/academics/ce/tools/>

### *Assessment for Risk Factors and Disaster History*

The C/PHN is uniquely qualified to perform a community assessment for risk factors that may contribute to disasters (Quad Council Coalition, 2018). In addition, the nurse should review the *disaster history* and preparedness plans of the community. Have earthquakes, tornadoes, hurricanes, floods, blizzards, riots, or other disasters occurred in the past? If so, what (if any) were the warning signs? Were they heeded? Were people warned in time? Did evacuation efforts remove all people in danger? What were the community's on-site responses, and how effective were they? What programs were put in place to rehabilitate the community? Community health assessment tool may assist with identifying critical needs of the community (FEMA, 2020b).

### *Establishing Authority, Communication, and Transportation*

In addition to assessing for preparedness, the effective disaster plan follows the NIMS model and establishes a clear chain of authority, develops lines of communication, and delineates routes of transport. Establishing a clear and flexible chain of authority is critical for successful implementation of a disaster plan (CDC, 2018).

- Usually, the chain is hierarchical, with, for example, the community's governmental head (e.g., mayor) initiating the plan, alerting the media to broadcast warnings, authorizing the police to begin evacuations, and so on.
- Within each level of the organization, the hierarchy continues. For example, at the local hospital, the hospital administrator may be responsible for alerting nurse managers to call in additional personnel.

- Flexibility is essential, because key authority figures may themselves be survivors of the disaster. If the home of the chief of police is destroyed in an earthquake, his or her second-in-command must have equal knowledge of the community's disaster plan and be able to step in without delay.

Effective communication is often a point of breakdown for communities attempting to cope with major disasters. After the terrorist attacks in Oklahoma City and New York City, phone lines were damaged and cellular sites were overwhelmed, making communication difficult. Communication was possible only through handheld radios or by way of couriers on foot. At times of heightened chaos and stress, as well as after physical damage to communication facilities and equipment, misinformation and misinterpretation can flourish, leading to delayed treatment and increased loss of life.

Again, clarity and flexibility are the watchwords for establishing lines of communication.

- How will warnings be communicated?
- What backups are available if the normal communication systems are destroyed in the disaster?
- How will communication between relief workers at the disaster site, hospital personnel, police, and governmental authorities be maintained?
- What role will local media play, both in keeping information flowing to the outside world and in broadcasting needs for assistance and supplies?
- Significant forms of communication have developed since the 9/11 terrorist attacks. Social media has become a critical method of communicating important health and safety information to the public since the 2001 terrorist attacks. Social media and disaster communication leaderships have collaborated and formed a partnership to disseminate information as quickly as possible (FEMA, 2020c).
- How will friends and family members be informed of the whereabouts or health status of loved ones?
- The CDC offers Crisis and Emergency Risk Communication (CERC) to ensure the correct messages by the correct authorities are communicated during emergencies. The training materials can be found on the CDC Web site at <https://emergency.cdc.gov/cerc/index.asp>.

The CDC Sample Single Overriding Communications Objective (SOCO) is an effective template to disseminate information concisely and quickly to the media during a disaster (see Box 17-5).

## BOX 17-5 THE CDC SAMPLE SINGLE OVERRIDING COMMUNICATIONS OBJECTIVE (SOCO) TEMPLATE

- In one BRIEF paragraph, state the key point or objective you want to accomplish by doing the interview. This statement should reflect what you, the author or speaker, would like to see as the lead paragraph in a newspaper story or broadcast report about your topic.
- What are the three or four facts or statistics you would like the public to remember as a result of reading or hearing about this story?
- Who is the main audience or population segment you would like this message to reach?
- What is the ONE message you want the audience to take away from this interview/report?

Reprinted from CDC. (n.d.). Sample single overriding communications objective (SOCO). Retrieved from [https://www.cdc.gov/tb/publications/guidestoolkits/forge/docs/13\\_samplesingleoverridingcommunicationsobjective\\_soco\\_worksheet.doc](https://www.cdc.gov/tb/publications/guidestoolkits/forge/docs/13_samplesingleoverridingcommunicationsobjective_soco_worksheet.doc)

Closed or inefficient routes of transportation can also increase injury and loss of life. For example, if a single, narrow mountainous road is the only means of transporting firefighters to or evacuating residents from the scene of a forest fire, then disaster planners should propose widening the road or clearing a second road. Disaster planners must also consider what routes emergency vehicles will take when transporting disaster survivors to local and outlying hospitals or health care workers to the disaster site. What if the chosen routes are inaccessible because of floodwaters, advancing fires, mountain slides, avalanches, or building rubble? Are alternative routes designated? Also, how will people move about after the disaster? For example, after the Japanese earthquake and tsunami in 2011, [Nakanishi, Matsuo, and Black \(2013\)](#) examined planning methodologies and future hypothetical disaster scenarios to help answer these types of questions.

### *Mobilizing, Warning, and Evacuating*

In many natural disasters, local weather service personnel, public works officials, police officers, or firefighters have the earliest information indicating an increasing potential for a disaster. These officials typically have a plan in place for providing community authorities with specific data indicating increased risk ([FEMA, 2018](#)). They may also advise the mayor's office or other community leaders of their recommendations for warning or

evacuating the public. Additionally, they may recommend actions the community can take to mitigate damage, such as spraying rooftops in the path of fires, sandbagging the banks of rising rivers, or imposing a curfew in times of civil unrest.

- Disaster plans must specify the means of communicating warnings to the public, as well as the precise information that should be included in warnings (DHS, 2016).
- Planners should never assume that all citizens can be reached by radio or television or that broadcast systems will be unaffected by the disaster. Broadcast media may indeed be a primary means of communicating warnings, but alternative strategies, such as social media or police and volunteers canvassing neighborhoods, should be considered.
- Social media options such as Facebook, Twitter, and blogs are reliable methods used by news stations and public health agencies that must not be ignored. Over 20 million tweets were sent by utilities after Hurricane Sandy, and Google's Web application, *Person Finder*, was especially helpful during the Boston Marathon bombings (SAMHSA, 2020a).
- In multilingual communities, messages should be broadcast in multiple languages.
- Not only homes but also businesses must be informed.
- Information that should be communicated includes the nature of the disaster; the exact geographic region affected, including street names if appropriate; and the actions citizens should take to protect themselves and their property.
- A study on the use of GPS devices in a simulated mass casualty found the devices useful in tracking patient locations throughout the drill (Gross et al., 2019). Technology improves tracking of injuries and fatalities.

An evacuation plan is an essential component of the total disaster plan (CDC, 2019a). The plan should include notification of the police, local military personnel, or voluntary citizens' groups of the need to evacuate people, as well as methods of notifying and transporting the evacuees. A plan should also be made for responding to citizens who refuse to evacuate. For example, will police authorities forcibly remove an elderly citizen from his home to a shelter? Will evacuation plans include household pets? If farms or ranches are in the path of fires or floods, will animals be evacuated? How? Who will do this and where will they be taken/sheltered?

## *Responding to Disasters*

At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue, triage, and treat disaster survivors.

One of the first obligations of relief workers is to remove survivors from danger (Fig. 17-4).

**FIGURE 17-4** Rescue of a Hurricane Katrina victim.

## *Rescue*

The job of rescue typically belongs to firefighters and urban search and rescue teams that have personnel with special training in search and rescue. Depending on the disaster agent, protective gear, heavy equipment, and special vehicles may be needed, and dogs trained to locate dead bodies may be brought in (Fig. 17-5). Sometimes, the immediate disaster site is not the best place for the disaster nurse, who can be far more effective in triage and treatment of survivors during this time. However, the C/PHN's population-based approaches, as well as knowledge of community resources and particularly vulnerable aggregates (Quad Council Coalition, 2018) are needed during this response phase.

**FIGURE 17-5** A firefighter-handler with a canine rescue dog.

Rescue workers face the logistically and psychologically difficult task of determining when to cease rescue efforts. Some factors to consider include increasing danger to rescue workers, diminishing numbers of survivors, and diminishing possibilities for survival. For example, after a plane crash on a snowy mountain, rescue efforts may cease if it is deemed that anyone who might have survived the crash would subsequently have died of exposure.

### *Triage*

Knowing the principles and practices of triage allows the responding C/PHN to provide the most effective nursing skills (Wagner & Dahnke, 2015). **Triage** is the process of sorting multiple casualties in the event of a war or major disaster. It is required when the number of casualties exceeds immediate treatment resources. The goal of triage is to effect the greatest amount of good for the greatest number of people. For an image showing the four basic categories of the international triage system on a triage tag commonly used in disaster responses, visit [thePoint](#) .

- The most common method of triage used by first responders at a mass-casualty incident in the United States is the simple triage and rapid treatment (START) for adults and JumpSTART for pediatric patients. (For other triage methods, see [thePoint](#) .)
- START and JumpSTART are forms of triage used to sort victims into four categories (immediate, delayed, minor, or morgue/deceased) and are consistent with international triage system.

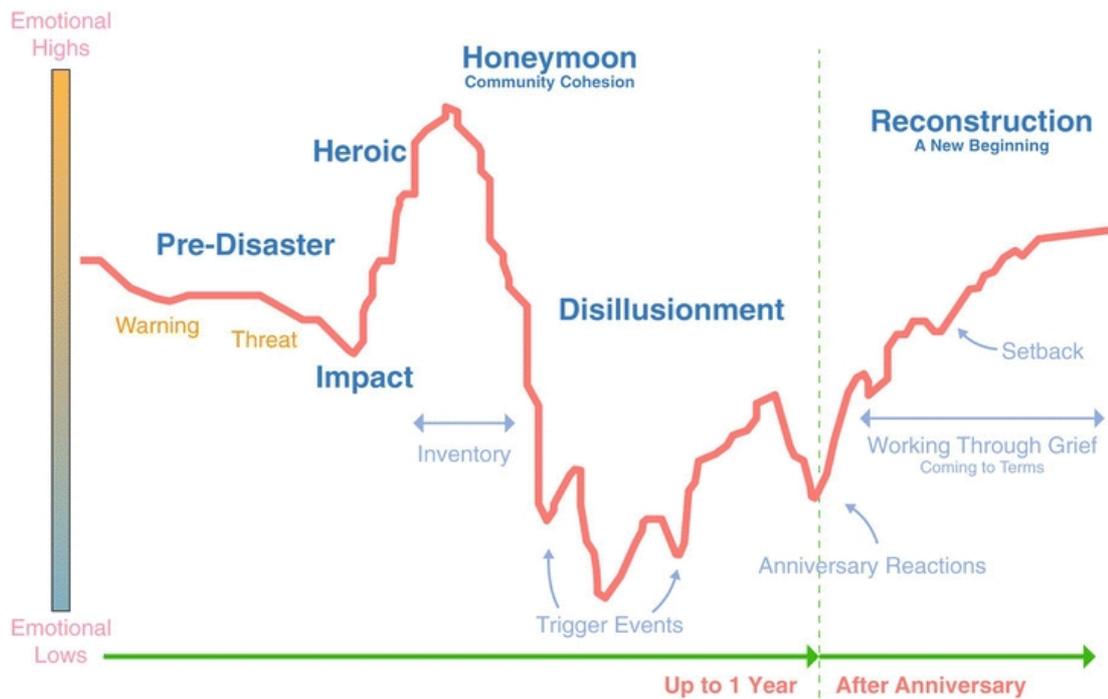

Prioritization of treatment may be very different in a mass-casualty event as opposed to an average day in a hospital emergency department. Under normal circumstances, a person presenting to a hospital emergency

department with a myocardial infarction and showing no pulse or respirations would receive immediate treatment and have a chance of recovery. At a disaster site, a person without a pulse or respirations would most likely be placed in the nonsalvageable category.

- The term *mass casualty* refers to a number of persons impacted that is greater than that which can be managed safely with the available community resources, such as rescue vehicles and emergency facilities to serve disaster survivors while also meeting the needs of the rest of the community (Zarocostas, 2017).
- In mass-casualty occurrences, the broader community will need to become involved, including requests for rescue vehicles, firefighters, and police officers from neighboring towns, and/or the use of neighboring hospitals. Depending on the magnitude of the mass casualty, state and federal resources may also be needed.

This adds another layer of disaster management coordination that must be considered. The hurricane season of 2017 was one of the worst in US history (FEMA, 2017b) and, along with the California wildfires of 2017, stretched FEMA resources. FEMA provided support to millions of individuals. “By May 2018, nearly 4.8 million households...registered for assistance-more than the previous 10 years combined” (FEMA, 2018, p. 6). Based on the disasters of 2017, FEMA is revising the National Response Framework to improve relationships with the private sector and to improve their readiness outside the continental United States to name a few of the new revisions (FEMA, 2018).

C/PHNs should acquaint themselves with the phases of disaster a community experiences. According to the Substance Abuse and Mental Health Services Administration (SAMHSA) there are six **phases of disasters** (Fig. 17-6; SAMHSA, 2018).

**FIGURE 17-6** Six phases of disasters. (Reprinted from Substance Abuse and Mental Health Services Administration. (2020). Phases of disasters. Retrieved from <https://www.samhsa.gov/dtac/recovering-disasters/phases-disaster>. Adapted from Zunin & Myers as cited in DeWolfe, D. J. (2000). *Training manual for mental health and human service workers in major disasters* (2nd ed., HHS Publication No. ADM 90-538). Rockville, MD: U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration, Center for Mental Health Services.)

- Phase 1: Predisaster phase—fear and uncertainty
- Phase 2: Impact phase—range of intense emotional reactions
- Phase 3: Heroic phase—high level of activity with a low level of productivity
- Phase 4: Honeymoon phase—dramatic shift in emotion
- Phase 5: Disillusionment phase—realize the limits of disaster assistance
- Phase 6: Reconstruction phase—overall feeling of recovery

### *Immediate Treatment and Support*

Disaster nurses provide treatment on-site at emergency treatment stations, at mobile field hospitals, in shelters, and at local hospitals and clinics (Box 17-6). In addition to direct nursing care, on-site interventions might include arranging for transport once survivors are stabilized, and managing the procurement, distribution, and replenishment of all supplies. The nurse may

also manage provision or distribution of food and beverages, including infant formulas and rehydration fluids, and arrange for adequate, accessible, and safe sanitation facilities at the treatment location. Finally, the nurse often may also arrange for psychological and spiritual care of survivors of disasters (APHN Public Health Preparedness Committee, 2014).

**BOX 17-6 Mobile Field Hospital On August 25, 2007, California featured the first state-owned mobile field hospital in a statewide disaster-training exercise. The tent hospital is one of three 200-bed hospitals purchased by California and prepositioned around the state in the event of a major emergency. The hospital can be deployed and on-site within 72 hours and comes equipped for 7 days of full patient care. Used together, the hospitals can be reconfigured into a 400-or 600-bed hospital, if needed. This is the same type of mobile field hospital used by the military, and it was modeled after the hospitals used by the Air Force and Navy. The various units within the hospital mirror services provided in any modern facility including emergency room, surgical suite, laboratory, x-ray, surgical intensive care, and even a pediatric unit.**

More recently, mobile field hospitals were erected worldwide to treat patients with Covid19, such as in New York's Central Park (below exterior view) and in Lombardia, Italy (below interior view).

Source: [Rodriguez \(2016\)](#).

Some survivors who seem physically uninjured may, in fact, be suffering from major injuries but be unable to relate their symptoms to a relief worker because of shock or anxiety. For instance, a father pulling debris away from his collapsed house after a tornado may be so worried about a missing child that he does not realize that he has a broken arm.

Other survivors may be so emotionally traumatized by the disaster that they act out, disrupting efforts to assist them and other survivors and possibly engaging in dangerous activities. These survivors must be assessed for head trauma and internal injuries, because their behavior may have a physiological cause ([SAMHSA, 2020b](#)).

## *Care of Bodies and Notification of Families*

Identification and safe transport of the dead to a morgue or holding facility is crucial, especially if a contagion is feared, though this is rare in mass-casualty situations. Toe tags make documentation visible and accessible. Records of deaths must be accurately documented and maintained, and family members should be notified of their loved ones' deaths as quickly and compassionately as possible. If feasible, a representative from each of the area's faith communities should be available to assist families awaiting news of missing loved ones. A family's recovery from loss is often delayed when notification of their relative is not possible because the recovered bodies are badly damaged or not found ([USDHHS, 2020b](#)).

## *Supporting Recovery From Disasters*

Disasters do not suddenly end when the rubble is cleared and the survivors' wounds are healed. Rather, recovery is a long, complex process often including long-term medical treatment, physical rehabilitation, financial restitution, case management, and psychological and spiritual support ([FEMA, 2019](#)).

### *Long-Term Treatment*

Long-term treatment may be required for many survivors of disasters, straining the local rehabilitative care facilities and resources.

- Children who are survivors may have to deal with lifelong disabilities or scars from their ordeal, and families may be without adequate financial support for their child's medical care.
- Elderly citizens who had been in excellent health but who sustained serious injuries in the disaster might suddenly find that they can no longer live independently and must move to a long-term care facility.
- After floods, landslides, fires, or earthquakes, extensive property damage may cause some residents or businesses to relocate rather than rebuild on land they now deem to be disaster prone.
- A disaster that creates numerous persons impacted in a small community may alter the entire social fabric of that community permanently ([SAMHSA, 2020b](#)).

### *Long-Term Support*

Immediately after a disaster, some survivors may be unable to concentrate on anything beyond fulfilling their immediate needs and those of their family. Disaster survivors may need funding to repair or rebuild their homes or to reopen businesses, such as stores, restaurants, childcare facilities, and other

services needed by the community. Insurance settlements, FEMA funding, and private donations may assist in financing community rehabilitation. The FEMA Individual Assistance Program and Policy Guide can be found at: <https://www.fema.gov/media-library-data/1551713430046-1abf12182d2d5e622d16accb37c4d163/IAPPG.pdf>

Psychological support is often required after a disaster, both for survivors and for relief workers. Some individuals may experience posttraumatic stress disorder (PTSD). Many survivors, especially elderly persons displaced from their homes, may quietly lose their will to live and drift into apathy and malaise. Depression and anxiety are positively correlated in the elderly following earthquakes (Liang, 2017). While, some individuals may question their faith after a disaster, a systemic review found religion and spirituality may assist with coping and coming to terms with the disaster (Aten et al., 2019). These survivors in spiritual distress often require not only empathetic listening but also long-term skilled spiritual counseling. In assessing a community's citizens for counseling needs after a disaster, the PHN should not forget to include children. Often, children do not have words to express their feelings or fears and may act out in ways adults find difficult to understand, unless age-appropriate psychological intervention is provided. Medical responders to disasters are at risk of depression and PTSD with nurses being a greater risk than physicians. Risk factors included inadequate social support, inadequate coping skills, and insufficient training (Naushad et al., 2019).

Long-term support must be considered when assessing a community and planning for disasters. Each community may be unique in their needs, and each disaster requires a unique array of services and planning. Many communities may be efficient in providing services in quick response to a disaster; however, they often do not factor in the long-term needs and provide the structure and support (Reifels et al., 2015) needed by the community residents.

### *Need for Self-Care*

Self-care, including stress education for all relief workers after a disaster, is a common practice and actively encouraged in many communities. Proponents report that stress education helps to reduce anxiety and put the situation into proper perspective. **Critical incident stress debriefing (CISD)** provides relief workers with professional debriefing that consists of phases followed by individual sessions and support services as needed (Harrison & Wu, 2017). CISD is generally provided between 24 and 72 hours after the disaster event. Proponents of CISD claim that it typically produces positive effects by:

- Accelerating the healing process

- Equipping participants with positive coping mechanisms
- Clearing up misconceptions and misunderstandings
- Restoring or reinforcing group cohesiveness
- Promoting a healthy, supportive work atmosphere
- Identifying individuals who require more extensive psychological assistance

A CISD addresses all components of the human response to trauma, including physiologic effects, emotions, and cognition ([Occupational Safety and Health Administration, n.d.](#)). The research on CISD has been mixed, but [Mitchell \(n.d.\)](#) reports that if the personnel providing the intervention are well trained and follow acceptable CISD practice standards, the outcomes are more positive. Self-care comes in many forms and is part of a prescription for emotional healing after a traumatic event. Self-care is for everyone touched by trauma including the rescue workers ([CDC, 2018](#)).

Trauma-informed care acknowledges the impact of various types of trauma on the individual's lifetime potential for health problems and “engaging in health-risk behaviors” ([Menscher & Maul, 2016](#), para. 2). Both relief workers and recent trauma victims can benefit from this approach, which seeks to limit secondary traumatic stress by promoting empowerment and collaboration, as well as providing safety and choice. Earlier life experiences, such as abuse and neglect or systemic bias, may exacerbate experiences with traumatic events.

## Psychological Consequences of Disasters

More research is needed in the monitoring of long term psychological effects and the evaluation of interventions following disasters (Généreux et al., 2019). It is estimated that 20% of Americans will experience a natural disaster (Wilson-Genderson, Heid, & Pruchno, 2018). Awareness of your perceptions and how your actions are viewed are essential in dealing with trauma victims. Fitzgerald & Hurst (2017) identify the prevalence of implicit bias even in health care providers. Their review of literature indicates that health care professionals exhibit the same amount of implicit bias as the general public and that diagnosis and treatment may be affected. In addition, trauma victims during a crisis may have previous trauma experiences related to power inequities, preventing a willingness to seek care or comply with medical instructions (Tello, 2018). Trauma-informed care requires the C/PHN to ask permission and be supportive (Tello, 2018). As health professionals, C/PHNs must be aware of their biases and prejudices (see <https://implicit.harvard.edu/implicit/takeatest.html> for a self-test for implicit bias).

Survivors of natural disasters experience a significant increase rate of psychological distress, PTSD, and depression (Beaglehole et al., 2018) The C/PHN and community mental health nurses, through education, screening, assessment, and referral, have an important role in the primary, secondary, and tertiary prevention of psychological disturbances due to a disaster.

### *Primary Prevention*

Although a disaster, by its very nature, is often unforeseen, people's ability to cope with the disaster can be determined in part by their previous experiences and resources available.

Behavioral health is essential for overall health and wellness especially in the face of a disaster. Due to the uncertainty of when a disaster might occur, it is imperative to fortify personal and external resources before one happens. Interventions should include strengthening of cognitive, psychosocial, psychological, physical, and emotional domains of the individual and the community (Makwana, 2019). During these times, lessons learned from primary health education and interventions may help with the survival and recovery phases. Consideration must be given to the life stages of the survivors.

The American Psychological Association (2016) describes **resilience** as a process of behaviors, thoughts, and actions. The building of competency or resilience is an important primary prevention strategy, since a competent person or community can make informed decisions based on availability of

resources and problem-solving skills. Community disaster training must include information on resiliency and resources to support individual and community resilience (APHN, 2014; CDC, 2019c; Makwana, 2019).

C/PHNs can contribute to primary prevention in the face of disaster by advocating for improving the social structure and economic conditions of the community, including housing, work, schools, child care, and recreational areas. It is also important for the C/PHN to advocate for the resources necessary for the community to meet both the physical and psychological challenges of a disaster.

## *Secondary Prevention*

Survivors of disasters often feel anxious and overwhelmed and may be in *mental health crisis*, where the usual coping mechanisms are no longer effective in the face of the overwhelming disaster (Boyd, 2018). **Crisis intervention** is a secondary prevention intervention that the trained C/PHN can employ to minimize the stress and psychological consequences of the disaster (American Psychiatric Association [APA], 2016). Crisis intervention is a short-term intervention with the goal of alleviating negative effects of a disrupting, unexpected event such as disasters (APA, 2018). The phases of crisis interventions are closely related to the nursing process: assessment, planning of interventions, implementing the interventions, and evaluation and future planning (Townsend & Morgan, 2018).

## *Tertiary Prevention*

People who have experienced or witnessed a disaster and have been unable to adequately cope with its consequences can develop *acute stress disorder* or the long-term effects of PTSD. According to the fifth edition of *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5), text revision (American Psychiatric Association, 2019), both acute stress disorder and PTSD can occur after any traumatic event to which a person responds with intense fear, helplessness, or horror.

**Posttraumatic stress disorder (PTSD)**, an anxiety disorder, occurs in some people after a traumatic event such as a disaster, crime, combat, or an accident (APA, 2019). It is important for the C/PHN to be aware of the symptoms of stress-related disorders and make referrals to the available mental health professionals.

# **TERRORISM AND WARS**

At the start of the 21st century, the world is a global community. This is particularly evident with the increased international communication and travel practices. The incidence and sophistication of terrorist threats and acts around the world highlights our vulnerability, and dramatically emphasizes the need for increased preparedness within our communities for any type of biological, chemical, or nuclear terror attacks. One only needs to turn on the news to learn of terror attacks throughout the world.

## History of Terrorism

The U.S. Federal Bureau of Investigation (FBI, n.d.b.) categorizes **terrorism** in one of two ways—as international terrorism or domestic terrorism. International terrorism is committed by persons or groups allied with foreign terrorist groups, whereas domestic terrorism is executed by individuals linked to U.S.-based extremist groups (FBI, n.d.b.). Generally, terrorism involves dangerous acts, violating laws, that are injurious to human life; it also involves a type of coercion or intimidation that affects government (U.S. Department of Justice, 2020). Terrorism and terrorist acts are not new. The term *terrorism* can be traced to 1798, and the use of terrorist tactics precedes this date. See [Box 17-7](#) for a brief history of terrorist acts.

### BOX 17-7 A Brief History of Terrorist Acts

- A highly organized religious sect called the *Sicarii* attacked crowds of people with knives during holiday celebrations in Palestine at about the time of Christ.
- During the French and Indian War of 1763, British forces gave smallpox-contaminated blankets to Native Americans.
- During World War I, the German bioweapons program developed anthrax, glanders, cholera, and wheat fungus as weapons targeting cavalry animals.
- In World War II, the Japanese tested biologic weapons on Chinese prisoners, and the Nazis conducted medical experiments with Jews forced into concentration camps (Spendlove & Simonsen, 2018).

## Bioterrorism and Nuclear and Chemical Warfare

Three major countries operated offensive bioweapons programs in recent years: the United Kingdom until 1957, the United States until 1969, and the former Soviet Union until 1990. Iraq started its bioweapons program in 1985 and continued to develop weapons until 2003. Bioweapons include mustard gas, sarin, and VX gas, as well as anthrax (Spendlove & Simonsen, 2018). Terrorists typically use biologic or chemical agents, explosives, or incendiary devices to deliver the agents to their targets.

A terrorist attack using nuclear weapons or destruction of a nuclear plant would cause multiple and prolonged deaths with extensive damage and negative effects for decades.

**Chemical warfare** involves the use of chemicals such as explosives, nerve agents, blister agents, choking agents, and incapacitating or riot-control agents to cause confusion, debilitation, death, and destruction (Organisation for the Prohibition of Chemical Weapons [OPCW], 2020).

- Terrorists in the Middle East, willing to murder others and knowing they will be committing suicide, strap bombs to their bodies and detonate the explosives in or near targets.
- Others plant explosives at large outdoor events like the 2013 Boston Marathon (CNN, 2020) or crash vehicles loaded with explosives into crowds of people or into a building.
- The aircraft used on September 11, 2001, were incendiary devices because they were carrying thousands of tons of jet fuel.

The success of the mission depended on the surprise of the attack, severe damage to recognizable buildings, and the deaths of many people.

**Biologic warfare** involves using biologic agents to cause multiple illnesses and deaths. Biologic agents are graded as category A, B, or C by the CDC (see Table 17-3 for some examples). There are over 180 pathogens that have been used or studied as possible biologic warfare (Smith, Hayoun, & Gossman, 2019). Typical biologic agents are anthrax, botulinum, bubonic plague, Ebola, and smallpox. These agents could be used to contaminate food, water, or air. Deliberate food and water contamination remains the easiest way to distribute biologic agents for the purpose of terrorism (American Academy of Pediatrics, 2020).

Category	Definition	Agents/Diseases
A	<ul style="list-style-type: none"> <li>▪ Pose highest risk to national security/public health:</li> <li>▪ Can be easily disseminated or transmitted from person to person</li> <li>▪ Result in high mortality rates and have the potential for major public health impact</li> <li>▪ Might cause public panic and social disruption</li> <li>▪ Require special action for public health preparedness</li> </ul>	<ul style="list-style-type: none"> <li>▪ Anthrax (<i>Bacillus anthracis</i>)</li> <li>▪ Botulism (<i>Clostridium botulinum</i> toxin)</li> <li>▪ Plague (<i>Yersinia pestis</i>)</li> <li>▪ Smallpox (<i>variola major</i>) and other pox viruses</li> <li>▪ Tularemia (<i>Francisella tularensis</i>)</li> <li>▪ Viral hemorrhagic fevers</li> </ul>
B	<ul style="list-style-type: none"> <li>▪ Second highest risk to national security:</li> <li>▪ Are moderately easy to disseminate</li> <li>▪ Result in moderate morbidity rates and low mortality rates</li> <li>▪ Require specific enhancements of CDC's diagnostic capacity and enhanced disease surveillance</li> </ul>	<ul style="list-style-type: none"> <li>▪ Q fever (<i>Coxiella burnetii</i>)</li> <li>▪ Brucellosis (<i>Brucella</i> species)</li> <li>▪ Melioidosis (<i>Burkholderia pseudomallei</i>)</li> <li>▪ Psittacosis (<i>Chlamydia psittaci</i>)</li> <li>▪ Ricin toxin (<i>Ricinus communis</i>)</li> <li>▪ Epsilon toxin of <i>Clostridium perfringens</i></li> <li>▪ <i>Staphylococcus enterotoxin B</i> (SEB)</li> <li>▪ Typhus fever (<i>Rickettsia prowazekii</i>)</li> <li>▪ Food- and waterborne pathogens</li> </ul>

The United States is very concerned about the possibility of biologic warfare or bioterrorism. The anthrax infections and deaths that occurred after September 11, 2001, added to these concerns. It was years before the government investigation led to a scientist at Fort Detrick as the cause of this terroristic act. Although charges were never filed because of the individual's suicide, the FBI believes that he was solely responsible for this act of domestic terrorism (FBI, n.d.a.). Regardless of the source of terrorism, the outcomes are the same: fear, death, and destruction.

## Trauma From the Warfront

Nurses, or men and women acting in that capacity, have provided comfort and care to soldiers long before Florence Nightingale arrived in the Crimea during the mid-19th century (see [Chapter 3](#)). Nurses continued to help during the Civil War and both World Wars, and their services continue today ([Brooks & Hallett, 2015](#); [Judd & Sitzman, 2014](#)). Military nurses serving in the wars provide care to those with serious injuries and multiple casualties many times for extended periods of time. They may experience disturbing long-term psychological effects when returning home including feeling disconnected from civilian hospitals and feeling isolated upon their return ([Finnegan, Lauder, & McKenna, 2016](#)). It is important that appropriate psychological and physical interventions are provided for these servicemen and women ([Krueger et al., 2015](#)).

The trauma of warfare can be devastating and may continue to affect individuals for many years after completion of active service ([Box 17-8](#); [Magruder et al., 2016](#)). Traumatic brain injury (TBI) is considered to be the “signature injury of the Iraq and Afghanistan wars” ([Department of Defense, 2017](#), p. 3).

### **BOX 17-8 STORIES FROM THE FIELD**

**Missed Opportunities for an Older Veteran**  
**Tom Walton is a 70-year-old retired salesperson from an equipment manufacturer and a Vietnam veteran who served in the U.S. Navy. He has been a widower for the past year, and his adult children live out of state. Tom's health has declined dramatically since his wife's death, and he is struggling to control his hypertension and diabetes. Tom is noncompliant with medications and diet restrictions, and he seems to have more frequent outbursts of anger than usual.**

Sadly, Tom's case is not one that is rare or unusual. I work at a Veteran's Administration (VA) clinic, and I often see cases like Tom's in our clinic. Many veterans do not deal with the traumas they experienced during warfare, and when support systems are weakened or they are no longer busy with work and family, these long-repressed feelings begin to reemerge. For Tom, his case could easily result in a deteriorating health care spiral that will ultimately lead to multiple hospitalizations or his demise. But, as a veteran, Tom may be a candidate for posttraumatic stress disorder (PTSD) treatment, mental health care treatment programs, or other proven treatment modalities offered by the VA. Unfortunately, many of our nation's veterans fail to take advantage of this resource, or even acknowledge that they may have this type of problem. In this case, having a working knowledge of the resources available to veterans in your community provides an opportunity for you, as a public health nurse, to assist Tom in accessing services that meet his health care needs and may prolong his life.

1. *What might you consider in providing care to veterans?*
2. *What resources are available in your area for veterans?*

—Bryan, VA Clinic Manager

- Between 2000 and 2018, a staggering 383,947 Armed Service members were diagnosed with TBI peaking between 2011 and 2012 ([Defense and Veterans Brain Injury Center, 2019](#)).
- The most common causes of TBI include blast, object hitting head, and falls.
- TBI is associated with higher depression, PTSD, and suicidal ideation ([Lindquist, Love, & Elbogen, 2017](#)).
- Caregivers of veterans with traumatic brain injury are four times more likely to experience depression than the general population ([Malec, Van Houtven, Tanielian, Atizado, & Dorn, 2017](#)).
- Military personnel that have experienced a TBI are at a 4 times greater risk than personnel without a history of TBI ([Loignon, Ouellet, & Belleville, 2020](#)).
- One study found combat experiences and severity of PTSD were factors if the PTSD was chronic or not ([Armenta et al., 2018](#)).

C/PHNs should be aware of the needs of veterans, especially during disasters, terrorist attacks, and other traumatic events that may bring these past experiences to the forefront again. It is also important to ask patients if they have military experience during the initial assessment. This information may impact the planned interventions. C/PHNs should be aware of services

available to veterans and treatments that are effective ([Jain, McLean, Adler, & Rosen, 2016](#)).

## Factors Contributing to Terrorism

Political factors are the most common contributors to terrorism. Anti-American sentiment runs high in many foreign countries, especially those that perceive the United States as a threat to their military, economic, social, or religious self-determination. Terrorist acts are committed against American military installations abroad, in airports, in airplanes, at American embassies, and even on American soil targeting civilian populations. The war in Iraq in 2003 was based on information about suspected bioterrorism weapons and reports that Iraq was harboring anti-Western terrorists; these two pieces of information resulted in the toppling of the Saddam Hussein political regime. However, hundreds of military lives were lost and many thousands of civilians were killed, and no weapons of mass destruction were found ([History, 2020](#)).

Within the United States, domestic terrorism involves extremist views of a social, environmental, racial, political, or religious nature ([FBI, n.d.b.](#)). In 2019, a young man fatally shot 22 people at a Wal-Mart in El Paso, Texas. The FBI considers it an act of terrorism ([Dilanian, 2019](#)). As of November 2019 there have been 372 mass shootings, almost as many days in a year ([Gun Violence Archive, 2020](#)).

## Role of the Community/Public Health Nurse

C/PHNs need to be prepared for the possibility of terrorist activity. They have a role in primary, secondary, and tertiary prevention.

### *Primary Prevention*

C/PHNs are in ideal situations within communities to participate in surveillance. They must look and listen within their communities for antigroup sentiments, for example, antireligion, antigay, or antiethnic feelings, and appropriately report any untoward activities accordingly.

Nurses should be alert to signs of possible terrorist activity and develop the basic knowledge and skills to plan and respond to disasters including acts of terrorism (Veenema, 2018). The National Prevention Framework, produced by Homeland Security, provides guidelines to prevent or stop an act of terrorism. Pre- and postdisaster preparation to include critical, specific nursing competencies and evidence-based practices are strongly recommended by many hospitals and health care organizations for all health care personnel. The American Nurses Association (ANA, 2016) has developed policies, resources, and educational opportunities for nurses on disaster preparedness acknowledging the importance of nurse preparation before a critical event (Fig. 17-7). The American Nurses Credentialing Center (ANCC) offers a certification in National Healthcare Disaster at <https://www.nursingworld.org/our-certifications/national-healthcare-disaster/>.

**FIGURE 17-7** Disaster drills help prepare communities and health care workers.

### *Secondary and Tertiary Prevention*

Although prevention of terrorist incidents is primarily the responsibility of the Department of Defense, the DHS, and public health and law enforcement agencies, C/PHNs must be ready to handle the secondary and tertiary effects of such attacks. Knowledge of the lethal and incapacitating chemical, biological, and radiological weapons potentially used by terrorists is important. Many of the communicable disease organisms that could be used by terrorists were discussed in [Chapter 8](#).

Realizing that terrorist attacks may result in large numbers of casualties, the C/PHN must be prepared to act quickly, safely, and competently, and to access information and effectively use resources rapidly. Formulating, updating, and following a disaster plan is one of the most effective community-based strategies to minimize injury and mortality from terrorism. However, a recent systematic review discovered that nurses were unprepared to manage a disaster and did not feel confident ([Labraque et al., 2018](#)).

Most C/PHNs will not be on the front line of uncovering or immediately responding to terrorist activities; however, their skills will be needed with groups, families, or individuals who experience a terrorist-related event. C/PHNs provide direct care to survivors, help survivors with coping, or provide guidance to those who want to do something to help. After experiencing a traumatic event such as a terrorist attack, people do not know how to cope; they are warned to expect more attacks and to be vigilant. The terror we are fighting is often our own. This is a new experience for most people, and assistance from the C/PHN can help them cope effectively.

C/PHNs can make major differences in grassroots efforts to bring about change, on a day-to-day basis. For example, providing information on foods to avoid and nonmedical treatment options such as support groups, hypnosis, and biofeedback are a few examples of how nurses can assist with coping mechanisms. Community resilience is the goal of the interventions.

## Current and Future Opportunities

There are many ways in which nurses, especially nursing students, can prepare both personally and professionally for emergency events in their own communities. Various governmental and educational programs are available as free online training covering a broad range of topics. Many schools of nursing have now begun to formalize their emergency preparedness plans in coordination with local hospitals, public health departments, or faith institutions. Nursing students should discuss their role, in the event of a local emergency with their faculty.

Knowing the nurse's role in an emergency will provide peace of mind regarding response capabilities and expectations. FEMA offers four particular courses within the incident command system (ICS 100, ICS 200, IS 700, & IS 800B), which are recommended for all health care personnel. Finally, make sure you have a family plan to reconnect with and care for children, spouses, and parents.

Increasingly, communities are conducting emergency preparedness exercises (e.g., mass-casualty exercises and tabletop exercises) in response to the need to prepare local resources to coordinate emergency response efforts for maximum effectiveness (CDC, 2016). Nursing students may be asked to participate in one of these exercises as a “victim.” Take the opportunity anticipating the knowledge you gain from this experience will enhance your understanding of the process, and you may be able to help identify gaps in services or areas in need of improvement. You may be asked to have **moulage** applied to simulate injuries, and you will likely be given a brief description of your trauma (Box 17-9). Your assigned health problem may be emotional and not physical, allowing you to utilize your understanding of behavioral health issues and crisis intervention. Just as immunizations help fight against infections, participating in an emergency preparedness drill can build your tolerance and competency for responding appropriately in a real event.

### BOX 17-9 What is Moulage?

Pronounced *mü-läzh*, the term *moulage* comes from the French word *mouler*, which means “to mold.” In emergency preparedness training, moulage refers to the art of applying mock injuries for use in mass-casualty exercises. These injuries can be very simple or more complex, depending on available resources and the skills of the person applying the moulage. The use of moulage typically provides a more realistic experience for personnel participating in mass-casualty exercises.

Of the many online resources for information regarding equipment needed and how-to advice, one such Web site is Community Emergency Response Team (CERT) LAFD CERT, Moulage (<https://www.cert-la.com/cert-training-education/moulage/>).

Many organizations, both private and governmental, are seeking volunteers. If you wish to become more active in emergency preparedness volunteer efforts, the American Red Cross and your local Medical Reserve Corps are two options. You can continue your relationship with these organizations after you receive your nursing license, and your role with them will likely evolve.

As a registered nurse, you may add your name to the registry along with your specialty training and contact information. Registration does not obligate you to any service; you agree only to be contacted if the need arises.

The [APHN Public Health Preparedness Committee \(2014\)](#) position paper, *The Role of the Public Health Nurse in Disaster, Preparedness, Response, and Recovery*, presented specific core competencies for public health nurses related to emergency preparedness, which can serve as a guide for students and practicing public health nurses. Please see [thePoint](#) for more information.

An adapted version of the 2014 position paper's table of disaster phases and corresponding nursing process actions is found in [Box 17-10](#). Many options are available to you as both a student and a practicing nurse. What is important is that you are prepared. Assuring that you understand the role you may assume in the event of a local disaster or emergency situation is critical to your own welfare as well as to your community. You decide your level of participation, and be aware that resources are available for you to become as prepared as possible.

# BOX 17-10 C/PHN USE OF THE NURSING PROCESS

## Disaster Preparedness, Response, and Recovery

<i>Disaster Cycle</i>	<i>Definition</i>	<i>Assessment</i>	<i>Planning</i>	<i>Implementation</i>	<i>Evaluation</i>
Preparedness	<p>Includes Prevention, protection, mitigation</p> <p>What is needed to prevent a disaster or reduce the impact of one (lives lost, property damage)?</p>	<p>Do you have specific populations in your service area that are vulnerable and at risk because of problems with access and functional needs during disaster (e.g., physically/mentally disabled, those with Alzheimer's, frail elderly)?</p> <p>Determine any hazards or threats that pose risks.</p>	<p>Plan for additional assistance and accommodations for those at risk and vulnerable populations during disasters or other emergencies.</p> <p>Work with other stakeholders to meet their needs and the needs of your service area population (e.g., sheltering in place, evacuation, mass-casualty surge capabilities).</p>	<p>Conduct drills, trainings, and exercises regarding care of individuals, families, and communities during disasters.</p> <p>Focus on at-risk and vulnerable populations you have identified previously (e.g., physically/mentally disabled, those with Alzheimer's, frail elderly).</p>	<p>Evaluate the drills, trainings, and exercises in regard to care of at-risk and vulnerable populations.</p> <p>Identify gaps and any residual needs. Conduct evaluation of operational plans (e.g., preparedness, response, recovery for at-risk and vulnerable populations).</p>
Response	<p>Includes Lifesaving</p> <p>Protection of property</p> <p>Meeting basic human needs postdisaster</p> <p>What services and personnel are needed to save lives and protect property in a disaster?</p> <p>What services and personnel are needed immediately after the disaster to meet basic needs?</p>	<p>Using population-based triage, assess the impact of any communicable disease outbreak.</p> <p>Who is susceptible? Who has been exposed? Who is infected?</p>	<p>Work with stakeholders to develop or choose triage plans and methods of patient flow based on present symptoms and known history (e.g., COPD).</p>	<p>Work to organize PHNs and other trained personnel to provide care per triage plans.</p> <p>Perform ongoing rapid needs assessments during this phase, and ensure planning for community care support.</p>	<p>During the disaster, take part in continuing response planning and service planning.</p> <p>Ensure that necessary PHN care is provided.</p>
Recovery	<p>Includes assistance in recovery after a disaster</p> <p>What core skills and capacities are needed to ensure effective recovery?</p>	<p>Continue intermittent rapid needs assessment to ascertain health status and capacity for critical resources after the disaster (e.g., floods).</p>	<p>Together with stakeholders, make plans for any identified long-term health concerns, and pinpoint key resources needed for recovery.</p>	<p>Contribute to restoration of critical community services and sustaining the social and health infrastructures.</p> <p>Work to help the community achieve stabilization after the disaster.</p>	<p>Help with evaluation of disaster's long-term impact on the community.</p> <p>Through the work of PHNs, promote essential public health services.</p>

## Objectives for *Healthy People 2030*

Healthy People 2030 includes four developmental objectives related to preparedness in disasters. These include (1) parents/guardians are aware of their children's school emergency and evacuation plans, (2) actions to take should a contagious disease occur, (3) adults who are aware of the transportation needs should a disaster occur and they need to evacuate, and (4) household emergency plan that includes vulnerable individuals (USDHHS, 2020a).

*Healthy People 2010* focused upon increasing quality and years of healthy life and to eliminating health disparities. Formulated in the years before January 2000, many disasters, both natural and manmade, were unknown in recent times. The United States had not yet faced the national failures in the response to the hurricanes Katrina and Rita. We would also learn 18 months after the publication of *Healthy People 2010* that our nation was not immune from acts of terrorism. The objectives of *Healthy People 2020* directly addressed issues of emergency preparedness and response under the new topic of *Preparedness*. Additional topics also included preparedness activities, such as the objectives for public health infrastructure. The goal of the new topics and objectives were to improve our “ability to prevent, prepare for, respond to, and recover from a major health incident” (USDHHS, 2016, p. 1). Those specific objectives provide the support needed to enhance public health surveillance activities, laboratories, training, development of professional competencies, and performance standards for public health organizations. Healthy People 2030 builds on this with personal plans, awareness of the needs of vulnerable groups, and inclusion of contagions as part of a disaster response (USDHHS, 2020a). See Box 17-11.

### BOX 17-11 HEALTHY PEOPLE 2030

#### Objectives Related to Disaster Preparedness

##### Core Objectives

- |         |   |
|---------|---|
| PREP-01 | Increase the rate of bystander CPR for nontraumatic cardiac arrests   |
| PREP-02 | Increase the rate of bystander automated external defibrillator (AED) use for nontraumatic cardiac arrests in public places |

##### Developmental Objectives

- |          |  |
|----------|--|
| PREP-D01 | Increase the proportion of parents and guardians who know the emergency or evacuation plan for their children's school |
| PREP-D02 | Increase the proportion of adults who prepare for a disease outbreak after getting preparedness information            |
| PREP-D03 | Increase the proportion of adults who know how to evacuate in case of a hurricane, flood, or wildfire                  |
| PREP-D04 | Increase the proportion of adults who have emergency plan for disasters  |

# SUMMARY

- A disaster is any event that causes a level of destruction that exceeds the abilities of the affected community to respond without assistance. Disasters may be caused by natural or manmade/technologic events and may be classified as multiple-casualty incidents or mass-casualty incidents.
- Persons impacted by disasters include those directly impacted (those injured or killed) and indirectly impacted (the loved ones of directly impacted). Displaced persons are those who are forced to flee their homes because of the disaster, and refugees are those who are forced to leave their homelands.
- Host factors that contribute to the likelihood of experiencing a disaster include age, general health, mobility, psychological factors, and socioeconomic factors. The disaster agent is the fire, flood, bomb, or other cause. Environmental factors are those that could potentially contribute to or mitigate a disaster.
- In developing strategies to address the problem of disasters, it is helpful for the C/PHN to consider each of the four phases of disaster management: mitigation, preparedness, response, and recovery.
- Communities experience six phases in a disaster: predisaster, impact, heroic, honeymoon, disillusionment, and reconstruction.
- An effective disaster plan establishes a clear chain of authority, develops lines of communication, and delineates routes and modes of transport. Plans for mobilizing, warning, and evacuating people are critical. At the disaster site, police, firefighters, nurses, and other relief workers develop a coordinated response to rescue survivors from further injury, triage survivors by seriousness of injury, and treat survivors on-site and in local hospitals. Care and transport of the dead bodies and support for the loved ones of the injured, dead, or missing need to be included in the disaster plan as well.
- Survivors of disasters suffer physical injuries and psychological trauma that can affect them for life. The importance of prevention, early crisis intervention, and ongoing treatment for those in need is evident. The C/PHN plays a key role in assessing individuals for symptoms of psychological trauma and intervening to prevent long-term consequences. Self-care, including stress education for all relief workers after a disaster, helps to lower anxiety and put the situation into perspective.
- Terrorism is the unlawful use of force or violence against persons or property to intimidate or coerce a government or civilian population in

the furtherance of political or social objectives. Terrorism may be nuclear, biologic, or chemical and may involve the use of nerve agents and explosive devices. The C/PHN should be alert to signs of possible terrorist activity and prepared to address the secondary or tertiary effects of such attacks.

- Many opportunities are available for both student nurses and experienced C/PHNs to become involved in emergency preparedness and response efforts. Agencies such as the American Red Cross and the Medical Reserve Corps are options available to students and at a higher level of involvement, once licensed. With the development of *Healthy People 2030*, ongoing efforts to help communities prepare for disasters and emergencies will require more nurses willing and able to respond to a call for action.

# ACTIVE LEARNING EXERCISES

1. Think about your own community and its residents. What environmental factors might be significant? What interventions could be included in a disaster plan to reduce these risk factors?
2. Think about your state and any sites that might be a target of terrorism. What is your state doing to address these issues? Examine Web sites (e.g., U.S. Homeland Security, Centers for Disease Control and Prevention, World Health Organization) for strategic planning or documents that could be helpful in assessing terror threats and preventing attacks. If an attack does occur, how would health professionals be most effective?
3. Using “Build a Diverse and Skilled Workforce” (1 of the 10 essential public health services; see Box 2-2), check with your local hospital about their disaster plan. Do they collaborate with your local health department and other agencies in designing and executing this plan? How often are “disaster drills” or simulations occurring? Who is involved in these? How many types of emergency situations do they cover?
4. As a C/PHN practicing in an area with a high concentration of veterans, what knowledge and skills do you think are necessary to provide culturally competent, evidence-based care to this segment of the population?
5. Interview a C/PHN who was involved in a disaster. Some topics to discuss might be—what kind of disaster preparedness did they have? Was their family affected by the disaster and what was it like to leave their family to help others?

# CHAPTER 18

## *Violence and Abuse*

*“The right things to do are those that keep our violence in abeyance; the wrong things are those that bring it to the fore.”*

—Robert J. Sawyer (1960), *Calculating God*

### **KEY TERMS**

Abusive head trauma (AHT) Child abuse Child maltreatment Cycle of violence Elder abuse Emotional abuse Implicit bias Infanticide Intimate partner violence (IPV) Mandated reporters Neglect Neonaticide Physical abuse Protective factors Risk factors Sexual abuse Spectrum of prevention

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Explain the dynamics of a crisis.
2. Discuss community risk factors and protective factors related to violence.
3. Describe the history of violence against women and children in the United States.
4. Identify the different types of violence against children and specific abusive situations.
5. Define intimate partner violence and explain the stages of the circle of violence.
6. Define elder abuse and discuss related vulnerability factors and prevention measures.
7. Identify other types of violence affecting individuals and communities.
8. Explain how each of the levels of prevention applies to addressing violence in individuals, families, and the community.
9. Use the nursing process to outline nursing actions in response to acts of violence.

# INTRODUCTION

Violence is a global public health issue. It is not limited by sociodemographic or geographic factors—anyone may experience violence or abuse at any point in one's lifetime. For example, a toddler who is intentionally burned with a hot curling iron, a teenager who is being emotionally and physically bullied at school, an adult strangled by an intimate partner, an older adult restrained and left sitting for hours in urine and feces, a person stabbed during a physical assault, or a nurse violently attacked when triaging a patient. George Floyd, an African American man, died while being arrested by a white police officer. The deputy restrained Mr. Floyd by kneeling on his neck, causing neck compression and cardiopulmonary arrest; his death was ruled a homicide. The police officer has been charged with murder. This event set off largely peaceful demonstrations around the country highlighting Black Lives Matter, but in some cities, small groups looted, set fires, and committed other acts of violence (Eligon, Furber, & Roberston, 2020; Kazan, 2020). Acts of violence may occur once or multiple times and involve a single perpetrator or a group of perpetrators who may or may not be known to the person experiencing violence. Violence and abuse may occur in any setting—at home, in public, at work, or at school.

The World Health Organization (WHO, 2020a, para. 2) defines violence as “the intentional use of physical force or power, threatened or actual, against oneself, another person, or a group or community, that either results in or has a high likelihood of resulting in injury, death, psychological harm, maldevelopment, or deprivation.” Violence is a complex phenomenon affecting individuals, groups, communities, and all of society. There is no single factor or group of factors to explain why a specific person is at risk of using violence or why one community experiences a higher incidence of violent acts than another community. Likewise, there is no single factor that specifically identifies an individual's or a community's vulnerability for experiencing violence.

In 1985, Surgeon General C. Everett Koop placed the concept of violence as a public health issue into the consciousness of the health care community and onto the national agenda. In 1992, the Centers for Disease Control and Prevention (CDC) formalized its role in addressing violence through the National Center for Injury Control and Prevention (<https://www.cdc.gov/injury/index.html>). Today, the CDC (2018c, para. 1) continues to address the public health issue of violence across the life cycle, stating: “Violence is a serious public health problem. From infants to the

elderly, it affects people in all stages of life. Many more survive violence and suffer physical, mental, and or emotional health problems throughout the rest of their lives.” These statements are supported by research findings, including the Adverse Childhood Experiences Study; the National Intimate Partner and Sexual Violence Survey; and other violence-related research. The effects of violence are seen across the biopsychosocial and spiritual continuums of health (CDC, 2020a). Community/public health nurses are uniquely positioned to respond to populations affected by violence through trauma-informed practices and violence prevention activities.

Acts of violence can result in a crisis, which is a stressful and disruptive event (or series of events) that comes with or without warning and disturbs the equilibrium of the individual, family, or community. A crisis can occur when usual problem-solving methods fail. Everyone experiences periods of crisis. If you reflect on your own history, you can probably identify one or more periods of crisis that you, your family, or your community experienced.

People respond to crises differently, including crises resulting from acts of violence. Some people approach a crisis as a challenge, an event to be reckoned with, whereas others may feel overwhelmed and defeated or give up. Some survivors of violence seek help and many experience minimal disruptions, perhaps perceiving themselves as even stronger than before the crisis occurred. Some people may have difficulty coping with the crisis, experience severe psychological distress, or express their feelings of rage, frustration, or powerlessness to others.

Regardless of their responses, people who are in crisis after experiencing violence need support, and C/PHNs have a unique opportunity and responsibility to provide support in a variety of situations and settings. For example, a nurse assisting a 15-year-old transgender patient at a free community-based sexually transmitted infection clinic refers to the patient using the patient's preferred name and pronoun and asks the patient when she last ate and whether she has a safe place to sleep that night. By being respectful and genuinely showing interest in the teen's well-being, the nurse gains the teen's trust and learns she is homeless and a victim of sex trafficking. Or, a pregnant woman reschedules her appointment at a community clinic twice and then arrives at the appointment with multiple faded bruises on her face and arms. The clinic nurse uses sensitivity and caring while screening for intimate partner violence (IPV) and identifying opportunities for appropriate referrals to community-based agencies.

Primary and secondary prevention measures used by C/PHNs that help prevent crises include teaching families communication skills and coping strategies and connecting them with community resources. In addition to assessment and education, C/PHNs provide tertiary responses with direct assistance during times of crisis or in the immediate aftermath of experiencing violence. This chapter discusses the knowledge and skills

C/PHNs use in their practice of crisis prevention and intervention aimed at promoting improved health for individuals and communities who may be affected by acts of violence.

Throughout this chapter, difficult topics are discussed. Some topics may bring up unwanted memories, feelings of anger related to abuse, assault, implicit bias, compassion fatigue, or/and secondary trauma. Nurses are at risk for compassion fatigue when placed in stressful situations and the continuous offering of themselves (Peters, 2018). Compassion fatigue and secondary traumatic stress were closely related (Mottaghi, Poursheikhali, & Shamel, 2020). Health care providers that work with the abusers need to be aware of the higher level of **vicarious** trauma, the higher the risk for posttraumatic stress disorder (PTSD) (Newman, Eason, & Kinghorn, 2019). **Implicit bias**, or the “unconsciously held set of associations (or stereotypes) about a social group,” can affect the quality of care C/PHNs provide their patients (Berghoef, 2019, para. 1). The Joint Commission's material on implicit bias can be found at [https://www.jointcommission.org/-/media/deprecated-unorganized/imported-assets/tjc/system-folders/jointcommission-online/quick\\_safety\\_issue\\_23\\_apr\\_2016pdf.pdf?db=web&hash=A5852411BCA02D1A918284EBAA775988](https://www.jointcommission.org/-/media/deprecated-unorganized/imported-assets/tjc/system-folders/jointcommission-online/quick_safety_issue_23_apr_2016pdf.pdf?db=web&hash=A5852411BCA02D1A918284EBAA775988).

# DYNAMICS AND CHARACTERISTICS OF A CRISIS

Each person is a dynamic system living within a given environment under the circumstances unique to that person alone. A person's conscious and subconscious behavior is gauged to maintain a balance within oneself and in one's relations with others. When an internal or external force disrupts one's balance and alters functioning, a loss of equilibrium occurs. The individual then attempts to restore equilibrium by using whatever resources are available to the individual, attempting to cope with the situation.

Coping refers to those actions and ways of thinking that assist people in dealing with and surviving difficult situations. If a person cannot readily cope with a stressful event, the person experiences a crisis (Boyd, 2018). Crises are usually resolved, either positively or negatively, within 4 to 8 weeks (Kanel, 2019). However, there may be long-term biopsychosocial health consequences related to experiences of violence and other adverse events. People's strong need to regain homeostasis and the intense nature of crises contribute to making the crisis itself a temporary condition.

Crises may be precipitated by a specific identifiable event that becomes too much for the problem-solving skills of those involved, may result from sudden unexpected or traumatic events, or may be related a person's perception of an event. Box 18-1 summarizes three common types of crisis.

## BOX 18-1 Major Differences Between Types of Crisis

### Developmental Crisis

- Part of normal growth and development that can upset normalcy
- Precipitated by a life transition point
- Gradual onset
- Response to development demands and society's expectations

### Situational Crisis

- Unexpected period of upset in normalcy
- Event jeopardizes an individual's physical and psychological well-being

- Event may be internal (e.g., cancer) or external (being laid off)

## Traumatic Crisis

- Unexpected, overwhelming and unusual event (e.g., disasters or acts of violence)
- Occurs to an individual or a group
- Events cause death, destruction, injury, or sacrifice

Source: [Wheeler and Boyd \(2018\)](#).

When a community crisis occurs on a large scale or is so unexpected that it also involves people who are hundreds of miles away, it can affect distant friends and relatives. Examples include an arson fire at an apartment building killing 12 people and injuring dozens of others; the terrorist attack in San Bernardino in 2015; the mass shooting at the Route 91 Harvest Music Festival in Las Vegas on October 1, 2017; and the terrorist attacks in New York City on September 11th, which indirectly affected people hundreds of miles away.

- A traumatic crisis is a stressful, unexpected, disruptive event arising from external circumstances that occur suddenly to a person, group, aggregate, or community. Typically, the external event requires behavioral changes and coping mechanisms beyond the abilities of the people involved ([Wheeler & Boyd, 2018](#)).
- The crisis occurs to people because of where they are in time and space. These events, which involve loss or the threat of loss, represent life hazards to those affected.
- C/PHNs may assist in a variety of traumatic crises, including those arising from acts of violence. In each situation, people feel overwhelmed and need help to cope. Skilled intervention can make the difference between a healthy and an unhealthy response to the crisis.

# OVERVIEW OF VIOLENCE ACROSS THE LIFE CYCLE

Violence affects people across the life cycle, from birth through death. It may involve chronic or long-term acts of abuse, neglect, or maltreatment or situational acts of violence that may be unexpected and sudden. C/PHNs encounter many different types of violence, including child abuse and neglect, youth violence, gang violence, bullying, IPV, dating violence, sexual violence, and elder abuse and maltreatment. Multiple types of violence can occur within a single household, community, or neighborhood, affecting people at different stages in life.

As mentioned in the introduction, there is no single factor that can explain a specific act of violence. However, decades of research reveal that different types of violence are interconnected. For example:

- People who experience one form of violence are likely to experience other forms of violence.
- People who use violence in one context are likely to use violence in another context.
- Different types of violence share common short-and long-term biopsychosocial health effects that may contribute to chronic health conditions such as cancer, cardiovascular disease, lung disease, and diabetes.
- Different types of violence have shared risk factors and protective factors ([CDC, 2016](#)).

Violence is a complex phenomenon. Understanding the neurobiological effects, potential subsequent health effects, and overlapping causes of violence can help community health nurses to enhance protective factors and reduce risk factors and can help inform violence intervention and prevention activities.

## **Neurobiology of Trauma**

Over the past few decades, neuroscience research has clarified the neurobiological response to trauma. This body of research has provided professionals responding to acts of violence a better understanding of human behavior and how people respond to trauma, contributed to trauma-informed practices, and enhanced the capacity of multidisciplinary responders to serve victims of violence. This knowledge is critical because many victims have been disregarded, not believed, dismissed, or revictimized through victim-blaming practices because well-intended professionals misunderstood what was normal human behavior after experiencing traumatic experiences.

An expanded definition of trauma includes all the events and experiences that are subjectively traumatic to an individual, which are different from person to person. Just as the brain is complex, so are a person's potential reactions and behaviors in response to an experience. This complexity is further compounded by many potential extraneous factors, such as substance use, past trauma, underlying pathologies, and established neural patterns. Although there are common responses, there are no absolute responses for all people; this is a fundamental concept behind trauma-informed care. Trauma-informed practices are improving how nurses interview victims, anticipate the support they need for coping with the physiological and psychological impact of traumatic experiences, and link them with community agencies ([Wilson, Lonsway, & Archambault, 2016](#)).

## Protective Factors and Risk Factors

Many factors contribute to increasing or decreasing the occurrence of violence. **Risk factors** are factors known to increase the likelihood of experiencing violence. **Protective factors** are factors known to reduce the likelihood of experiencing violence or increase one's resilience when violence is experienced. Individual lived experiences and a person's own characteristics may also be risk factors or protective factors. For example, growing up in a high crime area and witnessing violence is a risk factor, whereas having communication and problem-solving skills that allow one to address conflict without using violence is a protective factor. The [CDC \(2020c\)](#) recognized the following protective factors and risk factors related to youth violence.

Protective factors:

- *Community protective factors* include coordinated resources and services among community agencies; access to mental health and substance abuse services; and community support and connectedness.
- *Relationship protective factors* include family support and connectedness; caring relationships between youth and adults; association with prosocial peers; and a commitment to or connection with one's school.
- *Individual protective factors* include skills that support solving problems nonviolently.

Risk factors:

- *Societal risk factors* include cultural norms supporting aggression toward others; depiction of violence in the media; societal income inequity; poor health, educational, economic, and social policies or laws; and harmful norms related to the concepts of masculinity and femininity.
- *Community risk factors* include neighborhood poverty; a high number of locations selling or providing alcohol; community violence; diminished economic opportunities and high unemployment rates; and poor neighborhood support and cohesion among residents.
- *Relationship risk factors* include social isolation and lack of social support; a poor parent–child relationship; family conflict; economic stress; associating with delinquent peers; and gang involvement.
- *Individual risk factors* include low educational achievement; lack of nonviolent problem-solving skills; poor behavioral control or impulsivity; history of violent victimization; witnessing violence; psychological and mental health problems; and substance use.

Community windshield surveys and other community-based learning opportunities often reveal community-level risk factors and protective factors. For example, the level of safety described by residents can greatly vary from one neighborhood to the next. There are neighborhoods in all cities where residents describe feeling unsafe and witnessing crimes. Such neighborhoods or communities are often referred to as high poverty or high crime areas. In these communities, residents experience an overwhelming number of community risk factors compared with protective factors. The [CDC \(2016\)](#) publication *Connecting the Dots* reveals the following:

- In neighborhoods where residents do not support or trust each other, residents are more likely to experience child maltreatment, IPV, and youth violence.
- People who are socially isolated and do not have supportive relationships with family, friends, or neighbors are at greater risk for using violence, including acts of child maltreatment, IPV, and elder abuse.
- A lack of economic and employment opportunities is associated with an increased risk for using violence, including acts of child maltreatment, IPV, self-directed violence, sexual violence, and youth violence.
- Communities in which societal norms support aggressive or coercive behaviors have an increased risk for violent acts such as physical assault of children, IPV, sexual violence, youth violence, and elder maltreatment.
- Witnessing community violence increases one's vulnerability for being bullied and the risk of using sexual violence against others.

To counteract community risk factors, residents need support to enhance their protective factors. For example, communities having coordinated resources and services among the different community agencies experience greater protective factors. Access to mental health and substance abuse services increases protective factors. Receiving community support and having connections within the community and with the family, prosocial peers, and school can also increase community protective factors and decrease individual vulnerability. What are some of the protective factors in your community?

# HISTORY OF VIOLENCE AGAINST WOMEN AND CHILDREN

Violence against women and children is not new. For centuries, children were considered the property of their parents and most countries had animal welfare laws long before child welfare laws were adopted. The first documented case of child abuse occurred in 1874, involving Mary Ellen Wilson. However, due to the lack of child abuse laws of the period, her case was filed under the Animal Welfare Agency. This 9-year-old was so badly beaten and neglected by her foster mother that the public was shocked during the trial in the New York Supreme Court. This case changed public opinion on society's role in the protection of children and resulted in the forming of the Society for Prevention of Cruelty to Children in New York, the first organization of its kind ([Smithfield, 2016](#)). In the early 1900s, leaders concerned with child welfare issues promoted the development of international agencies focused on factors affecting the health of children. In 1924, the League of Nations adopted the Declaration of the Rights of the Child, which later informed the United Nation's Declaration of the Rights of the Child (1959) and the Convention on the Rights of the Child (1989). This committee meets three times yearly to address global concerns related to children's rights, including violence against children ([Office of the United Nations High Commissioner for Human Rights, 2020](#)).

Historically, women were also treated as property and often experienced gender-based violence resulting in biopsychosocial injuries. Recent global prevalence figures indicate that 35% of women worldwide have experienced IPV or nonpartner sexual violence in their lifetime ([WHO, 2017](#)). In 2010, the United Nation's Entity for Gender Equality and the Empowerment of Women was established and prioritized the prevention of and response to violence against women. The first global and regional estimates of violence against women were published in 2013, resulting in clinical and policy guidelines that have been widely disseminated, and 35 countries have participated in programs to build community capacity ([WHO, 2016](#)).

## **Public Laws and Protection in the United States**

In the 1960s, the Children's Bureau began to focus on child abuse and supported the development of a mandatory child abuse reporting law that could be used as a model for state laws. The law required health professionals and childcare workers to report suspected child abuse to appropriate officials. In 1974, the Child Abuse Prevention and Treatment Act (CAPTA) was passed, becoming Public Law 93-247 (PL 93-247). This law served to reinforce the earlier mandatory reporting law model and was aimed at solving the growing problem of child abuse in the country. PL 93-247 has been amended several times since 1974. The CAPTA Reform Act of 1978 preceded the Family Violence Prevention and Services Act of 1984. Later, all three acts were consolidated into the Child Abuse Prevention, Adoption, and Family Services Act of 1988 (PL 100-294), and most recently, the Act (PL 108-36) was amended and reauthorized as the Keeping Children and Families Safe Act of 2003 ([Child Welfare Information Gateway, 2019a](#)). The Administration on Aging supports similar programs including the [National Center on Elder Abuse \(n.d.b\)](#) that works to educate and assist families, seniors, health care, and legal providers regarding elder abuse.

## Myths and Truths About Violence and Abuse

Many myths about violence and abuse need to be dispelled. Strongly held myths by members of society, including C/PHNs and other health care providers, may interfere with their ability to help people in crisis get the help they need. [Table 18-1](#) displays some common myths and truths about violence and abuse.

**TABLE 18-1 Common Myths and Truths About Abuse in Families**

Myth	Truth
Domestic abuse is only physical	Abuse can take all forms: physical, sexual, stalking, and psychological aggression
Men are the only abusers	Domestic violence has no gender boundaries on the batterer or battered
Domestic violence occurs most frequently among the low-income and uneducated families	Violence occurs across all incomes, educational levels, and across all racial, ethnic, and cultural groups
The situation must be bearable if the victim doesn't leave	Implies victim must be okay with the abuse. Victims stay because of fear of the abuser, fear of deportation, lack of money, or concern for children
Abusers cannot control their anger	Anger does not cause abuse. Abuse is a means to gain control

Source: [Arizona Law](#) (n.d.); [Paisner](#) (2018).

# VIOLENCE AGAINST CHILDREN

- **Child abuse** is defined by the federal CAPTA (42 USCA, 5106g) as “any recent act or failure to act on the part of a parent or caretaker which results in death, serious physical or emotional harm, sexual abuse or exploitation; or an act or failure to act which presents an imminent risk of serious harm” ([Child Welfare Information Gateway, 2019b](#), para. 1).
- **Child maltreatment** is defined as abuse and neglect toward a child under age 18 including “physical and/or emotional ill-treatment, sexual abuse, neglect, negligence and commercial or other exploitation, which results in actual or potential harm to the child's health, survival, development or dignity in the context of a relationship of responsibility, trust or power” ([WHO, 2020c](#), para. 1).

Identifying and gathering worldwide data about child abuse is difficult because many cases are not investigated, death reports may not be classified as a result of abuse or homicide, and definitions of maltreatment may vary. Despite, this, the following global statistics reveal a concerning reality:

- A total of 25% of adults reported being physically abused during childhood, over 36% reported emotional abuse, and 16.3% reported neglect.
- Health effects of maltreatment include long-term physical and mental health impairments.
- Child maltreatment results in adverse social and occupational community outcomes ([WHO, 2020c](#)).

The National Child Abuse and Neglect Data System reported that 3.5 million referrals were investigated or had alternative responses by Child Protective Service departments in 2017 and 1,720 child fatalities due to abuse and neglect. Infants had the highest victimization rate at 25.3 per 1,000. Neglect (74.9%) continued as the category of highest occurrence followed by physical abuse (18.3%). Either one or both parents were responsible for almost 92% of all child maltreatment ([Children's Bureau, 2019](#)). Polyvictimization, experiencing two different types of maltreatment in a single report or different types of maltreatment across several reports, was reported in 14% of the cases of child maltreatment ([Children's Bureau, 2019](#)).

Nationally, measures have been taken to improve data gathering and information about violence toward children, as well as outcomes for these

children. One of the largest investigations ever conducted to assess associations between childhood maltreatment and adult health and well-being is the Adverse Childhood Experiences (ACE) Study. The seminal 1998 study conducted by [Felitti \*et al.\* \(1998\)](#) has led to new research on the long-term consequences of maltreatment in children. Further information can be found on <https://www.cdc.gov/violenceprevention/childabuseandneglect/acestudy/about.html>.

## Neglect

**Neglect** occurs when the physical, emotional, medical, or educational resources necessary for healthy growth and development are withheld or unavailable. Neglect is obvious to an observer if a very young child is playing unattended outside, is not dressed appropriately for the weather, or has an unkempt appearance ([Box 18-2](#)). However, neglect is not always so obvious ([Psychology Today, 2019](#)):

### **BOX 18-2 Signs and Symptoms of Neglect and Emotional Abuse**

**Signs and Symptoms of Neglect Neglect may be suspected if one or more of the following conditions exist:**

- Lacks adequate medical (including immunizations), vision, or dental care.
  - Often sleepy or hungry.
  - Consistently dirty, demonstrates poor personal hygiene, or is inadequately dressed for weather conditions.
  - There is evidence of poor or inadequate supervision for the child's age.
  - The conditions in the home are unsafe or unsanitary.
  - Malnourished, failure to thrive, poor weight gain.
  - Substance abuse.
- 
- Parents may refuse to buy eyeglasses for a child who needs them or to access dental care for severely decayed teeth (medical neglect).
  - An 8-year-old may get to school only 3 days a week, possibly without breakfast and no lunch money or packed lunch (educational neglect).
  - A family with three children may live in a sparsely furnished apartment with very little food available and only intermittent heat and multiple people coming and going in the residence, while the children may appear at school unwashed and without coats in winter weather (general neglect).
  - Emotional neglect may be seen when demands placed on a child are excessive or inappropriate for his or her development, or the caretaker berates or verbally humiliates a child frequently and without reason.

**Signs and Symptoms of Emotional Abuse**  
**Emotional abuse may be suspected if the child**

## **displays the following behavioral indicators:**

- Shows extremes in behavior such as extremely demanding, passive, or compliant
- Inappropriately takes on parent role or infantile in behavior
- Physical or emotional development is delayed
- Depression or suicidal thoughts
- Unable to develop emotional bonds with others

Source: [Child Welfare \(2019\)](#); [Stanford Medicine \(2019\)](#).

C/PHNs need to assess if the neglect is due to lack of knowledge of child development, lack of finances, or lack of health care. Providing services such as WIC, education developed for health literacy level, and assisting parents to enroll children in a Child Health Insurance Program may provide the needed support for many families with children. Because of the invisibility of neglect, its prevalence is hard to estimate. Often, cases of neglect are brought to the attention of the proper authority only during the investigation of other forms of abuse or family issues.

## Physical Abuse

**Physical abuse** is intentional harm to a child by another person that results in pain, physical injury, or death (Fig. 18-1). The abuse may include striking, biting, poking, burning, shaking, or throwing the child (Box 18-3). Some parents cannot control the degree of physical punishment they give their child (Child Welfare Information Gateway, 2019b). In one case, a mother repeatedly physically assaulted her young daughter while getting her into the car. The mother's behavior was recorded by the store's parking lot surveillance camera. Intervention and follow-up occurred, including incarceration and counseling for the mother and foster home placement for the child. If physical punishment is administered in anger, while the parent is under the influence of mind-altering substances or out of a sense of frustration, the punishment may cross over to become battering of the child. A parent or caregiver may claim the injuries are the fault of the child, such as a 2-week-old rolling off the bed and hitting their head. C/PHNs need to be knowledgeable about the stages of developmental growth to understand if a child is capable of performing such a skill.

**FIGURE 18-1** Young girl with signs of physical abuse.

### **BOX 18-3 Signs and Symptoms of Physical Abuse**

#### **Does the Child or Caregiver...Important Questions to Ask Yourself**

- Frequent emergency department visits

- Caregiver blames child for injuries
- Delay in seeking health/medical care or changes provider frequently
- Explanation changes, doesn't match the child's developmental ability, or contradicts injuries

## **Signs of Physical Abuse The most common systems affected are the integumentary, skeletal, and central nervous system.**

Health care providers including C/PHNs must consider language and cultural differences when interviewing a child and parent. Interviewing with a translator is important with these cases.

- Has unexplained injuries, explanation does not match the injury, or injuries are inconsistent with medical diagnosis. such as
- Injuries may include bruises, bite marks, abrasions, lacerations, head injuries, internal injuries, and fractures
- Bruising from defensive injuries to forearms
- Burns from cigarettes, ropes, or immersion into hot water or hot grid
- Traumatic alopecia with possible hematoma area and is tender to touch
- Trauma to ear
- Appears depressed, withdrawn, anxious, or aggressive
- Appears scared of parent and does not want to go home

## **Behavioral Indicators of Physical Abuse These behaviors are often exhibited by physically abused children:**

- Attempts to hide injuries; child wears excessive layers of clothing, especially in hot weather.
- Frequently absent from school or misses physical education classes.
- Fearful, clingy, anxious, withdrawn, hypervigilant, or aggressive.
- The child is apprehensive when other children cry.
- Wary of physical contact with adults.
- Exhibits drastic behavioral changes in and out of parental/caretaker presence.
- The child suffers from seizures or vomiting.

- Exhibits depression, self-mutilation, suicide attempts, substance abuse, or sleeping and eating disorders.
- Fearful of going home.

Other indicators of physical abuse may include the following:

- A statement by the child that the injury was caused by abuse (chronically abused children may deny abuse).
- Knowledge that the child's injury is unusual for the child's specific age group (e.g., any fracture in an infant).
- Knowledge of the child's history of previous or recurrent injuries.
- Parent or caregiver shows little concern for the child or seeking or fails to seek medical care for the child's injury.

Source: [Child Welfare \(2019\)](#); [Stanford Medicine \(2019\)](#).

## Sexual Abuse

- **Sexual abuse** of children includes acts of sexual assault or sexual exploitation of a minor and may consist of a single incident or many acts over a long period. Sexual abuse is considered “The employment, use, persuasion, inducement, enticement, or coercion of any child to engage in, or assist any other person to engage in, any sexually explicit conduct or simulation of such conduct for the purpose of producing a visual depiction of such conduct” ([Legal Information Institute, n.d.](#), para. 1).
- Rape, molestation, prostitution, and human trafficking of minors are included in the definition.

In a behavioral analysis of perpetrators, grooming is often used to gain access to child. Depending on the age of the child either the child or the parents are groomed. If these tactics do not work, the perpetrator may become more aggressive ([Bryce, Robinson, & Petherick, 2019](#)).

- Incest is sexual abuse among family members who are related by blood (e.g., parents, grandparents, older sibling). Intrafamilial sexual abuse refers to sexual activity involving family members who are not related by blood (e.g., stepparents, partner of a parent).

Child sexual abuse accounts for 6.7% of all maltreatments against children ([Children's Bureau, 2019](#)). The child may blame himself or herself for tempting or provoking the abuser. Indicators of sexual abuse are expressed in various ways, and attention should be given to a history of sexual abuse, sexual behavior indicators, behavioral indicators in younger children and behavioral indicators of sexual abuse in older children and adolescents, and physical symptoms of sexual abuse ([Box 18-4](#)). As **mandated reporters**, C/PHNs should be aware that sexual abuse of a child may surface through a broad range of physical, behavioral, and social symptoms. Some of these indicators, taken separately, may not be symptomatic of sexual abuse and should be examined in the context of other behaviors or situational factors ([Box 18-5](#)).

### **BOX 18-4 Indicators of Sexual Abuse**

#### **Physical Signs**

- Sexually transmitted infections.

- Trauma to the perineal area including bleeding, bruising, or pain. Blood may be seen on sheets or undergarments.
- Discharge from genitals or anus.
- Pain during bowel movements or urination.

## Behavioral Signs

- Enuresis and/or fecal soiling in bed when behavior has been outgrown
- Inappropriate sexual behavior for age
- Not wanting to be left alone with certain people or fearful to leave parent or caregiver
- Refuses to remove clothing
- Has money, gifts, or toys unexpectedly
- Self-injury/suicide attempts
- Sexually promiscuity in teens
- Substance use

## Emotional Signs

- Nightmares or fear of being left alone at night
- Extreme worry or fear
- Sexually explicit language or explicit knowledge about sexual topics beyond age of child
- Mood changes

Nursing students are encouraged to research the topic to learn more.

Source: [RAINN \(2019\)](#); [Stop It Now! \(2019\)](#).

## BOX 18-5 PERSPECTIVES

**A School Nurse's Viewpoint on Child Sexual Abuse—Emily's Secret** I am a school nurse at the only K-3 school in a small, rural town. Every child in those grades attends this school (1,000 children). I have a busy school nurse office, but I

**try to be observant to subtle cues. Sadly, sometimes it's so busy that I worry I miss things. Emily, a third grader, came to my office with stomachaches and vague complaints off and on for several months. Thinking back, this usually happened within the last hour of school. After school, she walked to her aunt's house and stayed there for a few hours until her mother picked her up after work. Emily was a petite child, well behaved, very quiet, and usually only responded with a few words when I asked about her ailments.**

One day Emily came in with another stomachache and wanted to lie down. When I asked what was going on, she shrugged her shoulders and didn't really respond. When the final bell rang, I told her if she didn't feel well enough to walk home, I could call her aunt. The aunt was the emergency contact, so the procedure was to start there. She just seemed to really be avoiding going to her aunt's house and wanted me to call her mom at work.

I had a feeling something was wrong. I remembered from a recent workshop on child sexual abuse that sometimes the hardest thing was to break through the guilt and shame for the child to open up. I told Emily she “could tell me anything, and I wouldn't think she was bad.” She began talking. Well, it was more like “verbal vomiting”—the words just came spilling out. She told me her uncle had been “touching her” and she “didn't want to go back there.” She began crying, and I told her we would call her mom and someone from CPS to help her. I also sent someone to get her teacher, a person she felt comfortable and safe with, who stayed with Emily through the lengthy process.

Later, as I thought about the constant stream of children coming into my office every day, I wondered how many of those kids with subtle, vague complaints might have something going on that is as serious as Emily's secret. Now I try to be even more vigilant and open to their concerns—whatever they may be.

Zoey, school nurse

Care for children who have been sexually abused varies, as the duration of the molestation, the age, and symptoms of the child will influence their care measures. Long-term consequences of CSA have been well documented. A recent study found adolescent males who had been sexually abused were at a greater risk of substance use; while, girls were more likely to be suicidal and depressed (Gray & Rarick, 2018). Parents may also need counseling and support following the investigation and proceedings involving their child's victimization.

## Commercial Sexual Exploitation

- Commercial sexual exploitation of children (CSEC) is “a range of crimes and activities involving the sexual abuse or exploitation of a child for the financial benefit of any person or in exchange for anything of value (including monetary and nonmonetary benefits) given or received by any persons” ([Office of Juvenile Justice and Delinquency Prevention \[OJJDP\], n.d.](#) para.1).
- Nonmonetary items may include food, shelter, clothing, drugs, transportation, or protection from another person. Forms of CSEC include child sex trafficking (prostitution of children), child sex tourism, production of child pornography, and transmission of live video of a child engaged in sexual acts in exchange for something of value. Internet-based marriage brokering, early age marriages, and performing in sex-related venues are also forms of CSEC ([OJJDP, n.d.](#)).

## Emotional or Psychological Abuse

- **Emotional abuse** of children involves psychological mistreatment or neglect, which impairs a child's self-worth and sense of security and being loved. Types of psychological abuse includes rejection, scorn, terrorism, isolation, exploitation, lack of emotional response, exposure to domestic violence, and verbal threats or void of loving comments ([Gluck, 2019](#)).
- Emotional abuse alone is rarely reported because it is another hidden form of abuse. However, mandated reporters are required by law to report *suspected* cases of severe emotional neglect or abuse or deprivation in addition to *suspected* neglect and physical or sexual abuse ([Child Welfare Information Gateway, 2019b](#)).

## Specific Abusive Situations

The previous information addressed the major types of child abuse in families, yet other patterns of abuse against children need to be discussed. Abusive head trauma, Munchausen syndrome by proxy, and parental filicide are uncommon, but by the time the symptoms are recognized, it is often too late. Diagnoses may be made at autopsy or after resulting comorbidities have developed. Technology-facilitated crimes against children are an increasingly common fear of parents. Technology-related crimes against children are occurring more often as children and adolescents have increased time, and access to computers such as when both parents (or a single parent) are at work and children are alone or with sitters. Another area of growing concern for parents and communities is school violence (Bryce et al., 2019).

### *Abusive Head Trauma*

- **Abusive head trauma (AHT)**, sometimes called shaken baby syndrome, is the intentional action of violently shaking a child, usually 2 years of age or younger; children 1 year of age and younger are at the greatest risk. AHT is the leading cause of death related to physical child abuse (CDC, 2020b).
- Injuries related to shaking, blunt impact, or a combination of both may result in neurological injury to the child (Vinchon, 2017). These types of injury very seldom occur through play, as in minor falls or as a result of being tossed into the air.
- Symptoms of AHT may include bilateral retinal hemorrhage, subdural or subarachnoid hematomas, the absence of other external signs of abuse, breathing difficulties, seizures, dilated pupils, lethargy, and unconsciousness (American Association of Neurological Surgeons [AANS], 2020).

The National Center on Shaken Baby Syndrome at <https://www.dontshake.org> offers resources for parents and health care providers. Explanations for injuries are often vague such as stating the baby was “fine” and then suddenly went into respiratory arrest or began having seizures—both common symptoms of AHT—or they may attribute the injuries to falling out the crib or off of the sofa. In the United States, approximately 1,300 children annually are injured or die due to AHT (National Center on Shaken Baby Syndrome [NCSBS], 2020). Children who survive AHT may require lifelong care, with approximately 80% having learning, physical, visual, and speech disabilities; hearing impairment; cerebral palsy; cognitive impairment; and seizures (NCSBS, 2020). Considering perpetrators of AHT are most often a parent or caregiver,

C/PHNs can play a critical role in caregiver education and preventative mental health referrals.

### *Munchausen Syndrome by Proxy*

*Munchausen syndrome by proxy* is a mental illness in which the parent or caregiver attempts to bring attention to self by injuring or inducing illness in their child. About 85% to 98% of perpetrators are the child's biological mother, who often forms close bonds with health care providers. Many of these abusers have a mental health illness or a history of abuse as a child (Boyd, 2018). The following scenarios can be typical of these cases:

- Serious medical problems or conditions that have no medical basis.
- The child experiences “seizures” or “respiratory arrest” only when the parent or caretaker is present.
- While the child is hospitalized, the parent or caretaker shuts off intravenous tubes or life-support equipment, causing the child distress, and then turns everything back on and summons help.
- The parent or caretaker induces illness by introducing a mild irritant or poison into the child's body.
- The child may have many school absences and a complicated medical history according to the child's mother or father who may seem overinvolved or demanding.

### *Child Murder by Mother or Father*

- *Filicide* is a rare yet concerning type of child death, defined as child murder by a parent. **Infanticide** is defined as the murder of a child during the first year of life, whereas **neonaticide** is the murder of an infant within the first 24 hours of life. Maternal filicide is known to occur in all areas of the world. The United States has the highest rate of child murders than any developed country with the parent being the main perpetrator (Resnick, 2016).
- Risks factors include the maternal age of 19 or younger, lack of prenatal care, less than a high school diploma poverty, social isolation, depression, or suicidality (Debowska, Boduszek, & Dhingra, 2015; Resnick, 2016).
- In 2017, homicide was among the top 15 leading causes of death for children from birth to 18 years. In the United States, the child homicide rate is 7.2 deaths per 100,000 infants under the age of 5. Infants are most likely to be killed by their mother during the first week of life, but thereafter are more likely to be killed by a male perpetrator (Kochanek, Murphy, Xu, & Arias, 2019).

Measures for prevention and support to mothers include parenting classes, emotional support, providing emergency numbers for support, as well as treating maternal substance abuse and postpartum depression. Safe haven laws are in place to prevent infant abandonment, leading to potential injury or death, by denoting safe places to relinquish a newborn infant, such as a fire or police station ([Child Welfare Information Gateway, 2017](#)). See [Box 18-6](#) for two examples of neonaticide.

## **BOX 18-6 STORIES FROM THE FIELD**

### **Neonaticide**

#### **Case 1**

After realizing she was pregnant, a 17-year-old honor student chose not to tell her parents, friends, or boyfriend. She kept her pregnancy a secret by wearing loose clothing and complaining about “gaining weight” over the holidays. While home alone after school, she went into labor sitting on the toilet. She lay down on the bathroom floor and labored for several hours, experiencing significant blood loss. After delivering the newborn, she used scissors to cut the umbilical cord. She was afraid because she had not stopped bleeding. Blood was everywhere. She got the keys to the car and drove herself to a local hospital. On the way, she became dizzy and felt like she passed out. Coming to, she continued to drive to the hospital. Upon admission, she was treated to control the hemorrhaging. Later, an emergency department nurse asked about the newborn and the girl said, “I left it, It’s on the bathroom floor.” Police located the dead newborn as described and no formal charges were filed.

#### **Case 2**

A 16-year-old girl became pregnant after having sex with her boyfriend. She thought she was having stomach or GI problems and her mother took her to the pediatrician’s office. The doctor prescribed medication for her symptoms, but she still felt ill. Concerned about being pregnant, she took an over-the-counter pregnancy test. The result was negative. A friend encouraged her to go to a walk-in clinic for a pregnancy test, the test result was inconclusive, and she began spotting. She continued to take her birth control pills, thinking she was not pregnant. A few months later during a family barbeque, she felt like she is getting the “stomach flu” and told her mother she was going to bed. Before going to bed, she

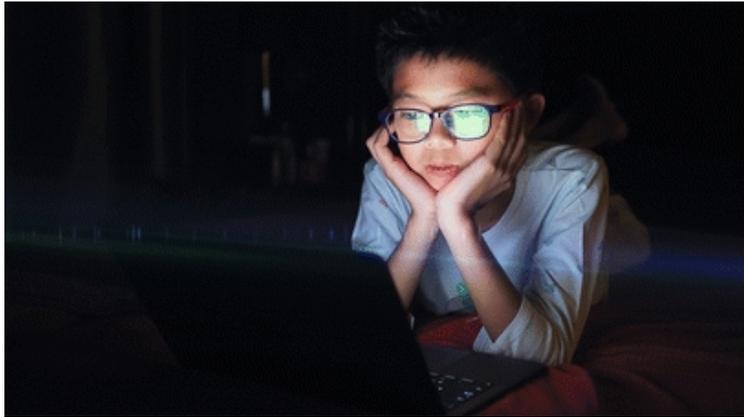

tried to have a bowel movement, but nothing happened. She thought she might be in labor and lay down on the floor of the bathroom. To her shock and horror, she gave birth, quickly stabbed the newborn, and hid it in a trash bin where the body was later discovered. A court psychiatrist examined the girl, and she described “watching the birth and the stabbing from a vantage point above her body.” Her defense was limited to testimony about whether she noticed the newborn's fingers moving and trying to counter the pathologist's findings that the lungs had inflated. Her attorney was not allowed to bring up issues surrounding her pregnancy and *neonaticidal syndrome*. The jury found her guilty of murder, and she was sentenced to prison for a life term.

1. *What are your thoughts about the two cases?*
2. *Have you seen examples like these in your local or regional newspapers or online news sources?*
3. *What preventive programs and policies might be helpful in addressing this issue? Are there EBP population-focused interventions available to address this problem?*

Source: [Malmquist \(2013\)](#).

## *Internet Crimes Against Children*

Internet and technology-facilitated crimes are insidious because they come right into the home (Fig. 18-2). Children may unintentionally or intentionally access a chat room or Web site developed or used by perpetrators. The perpetrator establishes contact, usually pretending to be a teenager or young man who has similar interests and is affectionate and understanding about the youth's “problems.” After gaining the child's trust, the perpetrator may engage in sexually explicit dialogue with the minor. Many minors find the attention from this stranger inviting or exciting and make plans to meet the person. When this happens, the minor falls victim to this individual, putting the child/adolescent at great risk for harm. Technology-enabled child abuse has led to the U.S. Attorney General authorizing a national awareness and justice program focusing solely on technology-facilitated sexual exploitation and abuse against children, named *Project Safe Childhood* (USDOJ, 2020) and the creation of Internet Crimes Against Children (ICAC) task forces. ICAC task forces assist federal, state, and local law enforcement agencies by enhancing their ability to investigate technology-facilitated crimes against children.

**FIGURE 18-2** Children and youth can be victims of Internet crimes.

C/PHNs can assist families to prevent technology-facilitated crimes by the following:

- Encouraging parents to openly discuss with their children the dangers of online friendships that seek face-to-face meetings; downloading photos or uploading/posting photos to people they do not know; giving identifiable information about themselves (name, phone number, school they attend, home address); responding to e-mails, instant messages, or tweets that are suggestive or harassing; and, being aware of phishing and other forms of attempted identity theft.
- Establishing parent–child contracts for devices that can connect to web-based applications (e.g., computer, tablet, smartphone, gaming systems).
- Blocking or only permitting specific phone numbers for smartphone and web-based application calls and regularly checking for deleted phone calls and texts.
- Monitoring the amount of time that a child uses Internet accessible devices and reviewing user history for applications used and Web sites visited.
- Placing computer and gaming consoles in a high-traffic area in the home, affording easy observation of usage by the child.
- Using available parental controls or blocking software on all devices with Internet connectivity.
- Installing a firewall, antivirus, and malware/spyware programs that increase privacy and restrict usage.
- Discouraging downloading of apps, games, and other media that might contain hidden applications or programs that enable remote access by unauthorized users.
- Having access to their child's e-mail and other web-based accounts; randomly checking e-mails and text messages. Being aware of safeguards in place at their child's school, public areas the child

frequents, and homes of their friends ([Federal Bureau of Investigation \[FBI\], n.d.a](#)).

There is a constant stream of news around cyberbullying and cyberstalking incidents. Cyberstalking is “the use of electronic communication to harass or threaten someone with physical harm” ([Merriam-Webster, 2020](#), para. 1). Nationwide nearly 15% of all students have been cyberbullied including with slightly <20% of high school girls and 10% of boys being victims ([CDC, 2018d](#)). Effects of cyberbullying can be more far-reaching than those of traditional schoolyard bullying. Nurses can ensure families are prepared to identify and appropriately respond to cyberbullying, sexting, and threats from online predators.

- The destructive effects of cyberbullying were highlighted in the news when a 12-year girl committed suicide after receiving texts saying she was fat, had no friends, and that she should kill herself ([Gillis, 2019](#)).
- In 2019, a 21-year-old young man jumped from a parking structure at the university he was to graduate from in 20 hours. His girlfriend is being charged with manslaughter for sending him tens of thousands text messages telling him to kill himself ([Boston25News, 2019](#)).
- These stories put a face on a recent study that found that being a victim of cyberbullying increases the risk of suicidality ([Chang, Xing, Ho, & Yip, 2019](#)).

Parents can contact the Cyber Tip Line at (800) 843-5678 or access their Web site ([www.cybertipline.com](http://www.cybertipline.com)) if they suspect an online predator has contacted their child ([National Center for Missing and Exploited Children, 2020](#)).

## *Child Abduction*

Although child abduction by a stranger happens infrequently, it remains one of the greatest fears for parents. Intense media coverage gives the impression that such crimes occur frequently, and this causes great stress among parents and community members. Child abduction by family members or intimate partners is more common. Nationally, the Amber Alert program and the Child Abduction Response Teams (CART) were established to provide an informed, prompt, and professional response to child abduction. Amber Alerts are sent through the radio, television, road signs, and the Wireless Emergency Alerts (WEA) system to millions of cell phone users. The goal of the Amber Alert is to provide instant collaboration and partnership in the community to assist in the search and safe recovery of the child and, as of May 2020, a total of 988 children have been rescued ([USDOJ, n.d.a](#)).

Prevention of child abduction is difficult, and at times, parents who think they have taught their children well may have a false sense of security.

C/PHNs can help parents improve their child's safety by promoting close supervision of young children and practicing behaviors to promote anonymity, such as:

- Placing the child in the seat of a shopping cart and holding their hand when in malls or stores
- Keeping a young child in sight always when playing outside
- Sharing parental supervision with another parent when children play
- Do not put the child's name or initials on clothing or backpacks
- Teaching the child a “password,” which only the parents and child know, to use when a different person is picking them up from an activity
- Teaching children to recognize when they feel unsafe and to go get help
- Involving children in making safety plans and having them practice getting help
- Helping children understand when it is okay to give personal information (e.g., at school, medical office, lost in a store) and when it is not (e.g., a stranger they don't know)
- Practicing “think first” and “keep walking” activities with their children ([Kidpower, 2020](#))

Older children and teens who go outside the home unattended by parents should be encouraged to use the following behaviors that promote safety: staying with groups of other children or teens, having a cell phone, leaving an itinerary with the parents, and not changing their plans without contacting parents.

### *Crimes Against Children by Babysitters*

Abuse by caretakers is a fear of parents who work and leave their children with others. The C/PHN can help parents assess childcare settings by providing them descriptors for finding good childcare providers. Parents who use neighbors as babysitters should get references and drop by the home or childcare setting at various times during the day. They should assess their infants and follow up on any bruises, rashes, burns, conditions, or behaviors they observe that are not normal for their child. Parents need to listen to their children and ask about their day and activities. Parents must not ignore signs, such as a child's fear of going to the babysitter or reports of spankings, being shouted at, or other inappropriate treatment.

Childcare centers and many home childcare programs are licensed by the state. When parent complaints have been filed with licensing agencies, those programs are monitored more closely and the state is mandated to make changes or close the facility if necessary. Parents need to know that their

child is safe and cared for when they leave them to pursue their employment or educational activities. A daycare owner was recently arrested for hiding 26 toddlers behind a fake wall in the basement of her home; there were only 2 care providers, and the business was only licensed for 6 children. When notified by law enforcement to pick up their children, parents were shocked to find their children in filthy conditions in the basement. One mother told reporters when she dropped off her child the home was clean; she had no idea the owner cared for children in the basement. The owner had previously lost her license to operate daycare centers in California for similar violations (Jensen, 2019).

## *School Violence*

Violence in the school setting is an area of growing concern for parents and communities. Violence in schools may range from bullying, slapping, or punching to weapon use (CDC, 2019h). Random shootings and hostage situations in schools over the past decades have fueled fears about the safety of students and promoted research on how to prevent this type of community violence affecting children.

- Since the 1999 shootings at Columbine High School in Colorado where 13 students died, a total of 11 mass shootings in which 4 or more persons were killed has resulted in 127 student deaths through 2014 (Keneally, 2019).
- Seventeen more died during a mass shooting at the high school in Parkland, Florida in 2018 (Andone, 2020).
- The largest mass shooting event occurred in 2017 at an outdoor concert in Las Vegas where 58 people were killed and almost 1,000 injured (Romo, 2019).

Shootings have occurred at large universities, small community colleges, high schools, and elementary schools. They have taken place throughout the country and no segment of the population is immune. The mass shootings have occurred in public and private schools, including the killing of 5 young girls at an Amish one room schoolhouse in Pennsylvania (Walters, 2016).

- Bullying is defined as “any unwanted aggressive behavior(s) by another youth or group of youths, who are not siblings or current dating partners, involving an observed or perceived power imbalance and is repeated multiple times or is highly likely to be repeated” (CDC, 2019b, p. 1).
- Bullying can be verbal, social, or physical or happen through electronic communication (cyberbullying).
- Children at high risk of being bullied may have delayed puberty, be gender nonconforming, have a unique physical appearance, or be

socially rejected and isolated (Simms, Bushman, & Pederson, 2020).

- Gay, lesbian, bisexual, and transgender youth were more likely than were heterosexual youth to report high levels of bullying (CDC, 2017a).
- Bullying is interconnected with other types of youth violence including gang violence (Simms, Bushman, & Pederson, 2020).

The Youth Risk Behavior Survey collects information about health and prevention issues among adolescents. Included in the survey are questions about violence risks such as fighting, use of illegal drugs, carrying a weapon, and being threatened or injured with a weapon on school property. In 2017, of a national representative sample of youth in grades 9 to 12 found the following:

- 8.5% of 9th through 12th graders reported being in a physical fight on school property in the 12 months before the survey.
- 19% reported being bullied on school property and 14.9% reported being bullied electronically.
- 6.7% missed 1 or more days of school because they felt unsafe at school or on their way to and from school.
- 3.8% reported carrying a weapon on school property in the 30 days before the survey.
- 6.0% reported being threatened or injured with a weapon on school property (Kann et al., 2018).

School violence has immediate and long-term effects on students demonstrated by an increase in depression, anxiety, psychological problems, and fear (CDC, 2016). See Chapter 20 for more on school-age children and adolescents.

The U.S. Department of Education, the Department of Health and Human Services, and the Department of Justice have collaborated to provide funding, programs, and training that improve school safety through the *Safe Schools Healthy Students Framework*. Five elements identified for attention in building safe school climates are as follows:

- Create a safe and *violence* free school environment.
- Prevent behavioral health problems.
- Promote emotional, mental, and behavioral health.
- Provide early childhood psychosocial and emotional development programs.
- Connect communities, schools, and families (National Center for Healthy Safe Children, 2019).

Similar to community risk factors, those factors surrounding youth violence can be categorized as individual risks, relationship risks, and

community or societal risks. Individual risks for perpetrating youth violence may include a history of violent victimization; a history of early aggressive behaviors, attention deficit, hyperactivity, or learning disorders; an association with delinquent peers; gang involvement; high emotional distress; social rejection; family violence and conflict; or poor behavioral control (CDC, 2020c). Low parental involvement, parental substance abuse or criminality, poor supervision, low emotional attachment to the parent, and harsh, lax, or inconsistent forms of discipline increase a child/adolescent's risk for violence. Community and societal risk factors for youth violence are associated with diminished economic opportunities, a high concentration of poverty, transiency, and family disruption, with low levels of community participation (CDC, 2020c).

Youth development programs address these risk factors in schools and communities, as well as promoting activities to help students in meeting individual needs. Mentoring programs are beneficial for at-risk teens when the mentors are appropriately trained and supported. Social skills, conflict resolution, and programs supporting student sports, arts, and extracurricular interests decrease an individual's risk of being involved in violence. School and societal strategies include surveillance, maintenance of facilities, and consistent classroom management techniques, along with adequate student supervision (USDHHS, n.d.). Parent involvement and education are expanding through programs such as *Healthy Start* and parent-participation preschools, *Loving Solutions* for elementary age students, and the *Parent Project* for parents of difficult adolescents (The Parent Project, 2019).

# INTIMATE PARTNER VIOLENCE

**Intimate partner violence (IPV)** is the abuse or aggression that occurs within close relationships that are either current or previous. There are four types of IPV: physical violence, sexual violence, stalking, and psychological aggression (CDC, 2019d).

- 1 in 4 women and 1 in 10 men have experienced physical and/or sexual violence and/or stalking.
- 1 in 5 women and 1 in 7 men have been victims of severe physical violence.
- 1 in 5 women and 1 in 12 men have experienced sexual violence.
- 16% of all homicides have been committed by an intimate partner.
- 10% of women and 2% of men have been stalked.
- 43 million women and 38 million men have experienced psychological aggression (CDC, 2019f).

According to the WHO (2017), global prevalence figures for women indicate the following:

- IPV is a leading cause of morbidity and mortality in women worldwide, as well as a public health and human rights issue 35% of women have experienced either IPV or nonpartner sexual violence in their lifetime.
- 30% of women report being physically abused by an intimate partner at some point in their lives.
- 38% of all women who were murdered were murdered by their intimate partner.

While research related to IPV against members of the LGBTQ community is limited (Rollè, Giardina, Caldarera, Gerino, & Brustia, 2018), the most recent in-depth study conducted by the CDC (2010) found the following:

- A total of 26% of gay men and 37% of bisexual men experienced rape, physical violence, and/or stalking by an intimate partner at some point in their lifetime.
- Individuals who self-identify as lesbian, gay, and bisexual have an equal or higher prevalence of experiencing IPV, SV, and stalking as compared to self-identified heterosexuals.
- A total of 44% of lesbian women and 61% of bisexual women experienced rape, physical violence, and/or stalking by an intimate partner in their lifetime.

- Approximately 1 in 8 lesbian women (13%) and nearly half of bisexual women (46%) have been raped in their lifetime.
- A total of 40% of gay men and nearly half of bisexual men (47%) have experienced SV other than rape in their lifetime. The [Human Rights Campaign \(2020, para. 1\)](#) found that approximately 47% of transgender people are sexually assaulted “at some point in their lifetime.”

Researchers often describe domestic violence, a form of IPV, as punching, grabbing, shoving, slapping, choking, kicking, biting, hitting with a fist or some other object, being beaten, or being threatened with a knife or gun by a spouse or cohabiting partner. The [USDOJ \(n.d.b, para. 2\)](#) defines domestic violence as “a pattern of abusive behavior in any relationship that is used by one partner to gain or maintain power and control over another intimate partner”; it may be emotional, economic, physical, psychological, or sexual in nature ([Box 18-7](#)).

## BOX 18-7 PERSPECTIVES

**Viewpoint of a Victim of Intimate Partner Violence My family was always shouting at each other. The hitting wasn't nearly as bad as all the yelling. Now here I am in the same boat all over again—the yelling, the hitting, but now I've got this new baby to take care of. I'm just so tired.**

When the nurse showed up today to check on me and the baby, I swore to myself that I wouldn't tell her about last night. Then she looked at me and asked if I felt safe and that triggered me...I said “NO!” before I realized my mouth was even open. I told her how he punched me here in my side when I was changing the baby's diaper. That nurse was so nice. She helped me look at my options. Because I was holding the baby when he hit me, she said she was required to make a report of child abuse.

That was just awful news and I started crying; but like she said, I could have dropped my baby, or he could have missed me and hit her. I knew he'd be furious when he found out and I really started to panic. Then she told me about this place, a place downtown where I can stay with my baby. Then

she helped me make arrangements. I'm so tired and scared, but I know now that I have to keep my baby safe. I still don't know what made me tell that nurse—I guess it was because she asked.

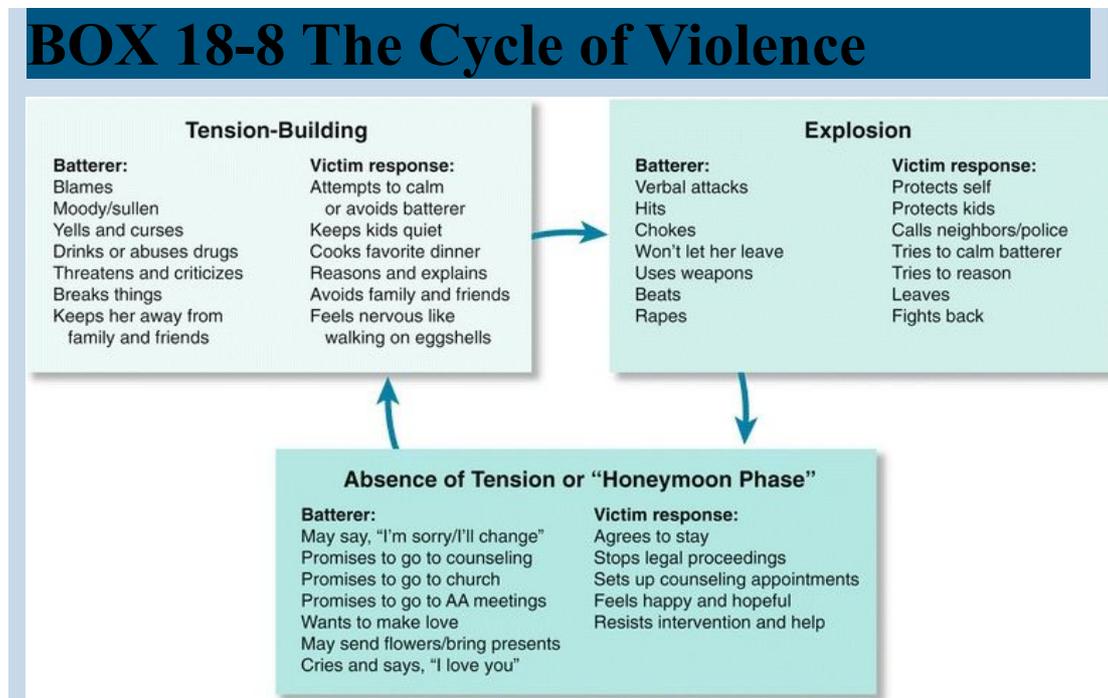

Angie

Because of the nature of IPV, the problems are difficult to study and believed to be underreported. Much remains unknown about factors that increase or decrease the likelihood that one person will use violence against another person within an intimate relationship or in the course of seeking that relationship. However, models have been developed to aid in the understanding of the repetitive cycles often seen in intimate partner and domestic violence.

## Cycle of Violence

The **cycle of violence** is a repetitive, cyclic pattern of abuse seen in domestic violence situations (Box 18-8). Developed by Walker in 1979, the cycle is still in use today. The cycle includes the tension-building phase, the explosion (acute battering incident), and the honeymoon phase (SexInfo Online, 2017; White Ribbon, 2019). For more information, refer to <https://sexinfo.soc.ucsb.edu/article/cycle-domestic-violence>. The

psychological dynamics of these three phases help explain why the person experiencing abuse feels guilty and ashamed of their partner's violence toward them, and why they find it so difficult to leave, even when their lives are in danger.

### Tension-Building Phase

- Considered the longest of the phases—up to several weeks.
- Victim may feel they are “walking on eggshells.”
- Abuser is edgy, negative mood, verbally abusive, and controlling.
- Minor augments occur.
- Victim attempts to appease partner in hopes calming situation and to avoid the acute explosion phase.

### Acute Explosion Phase

- Shortest phase usually lasting 1 to 2 days.

- Most violent phase as tension is released.
- Violence may take many forms such as sexual, physical, verbal, psychological, and emotional abuse.
- Phase is triggered by an external event or the abuser's state of mind.
- Abuser may blame victim for the abuse.
- Victim may fight back, leave the person, or try and placate the abuser.

## Honeymoon Phase

- Abuser may feel embarrassed and become withdrawn or attempt to justify actions.
- Abuser expresses remorse and pledges it will not happen again.
- Abuser promises to make behavioral changes such as work less, stop drinking, and be more attentive to victim.
- Abuser is excessively romantic to victim such as giving expensive gifts, flowers, candy.
- Victim forgives abuser.
- Intimacy may increase.
- Tension-building phase begins again.

## Denial

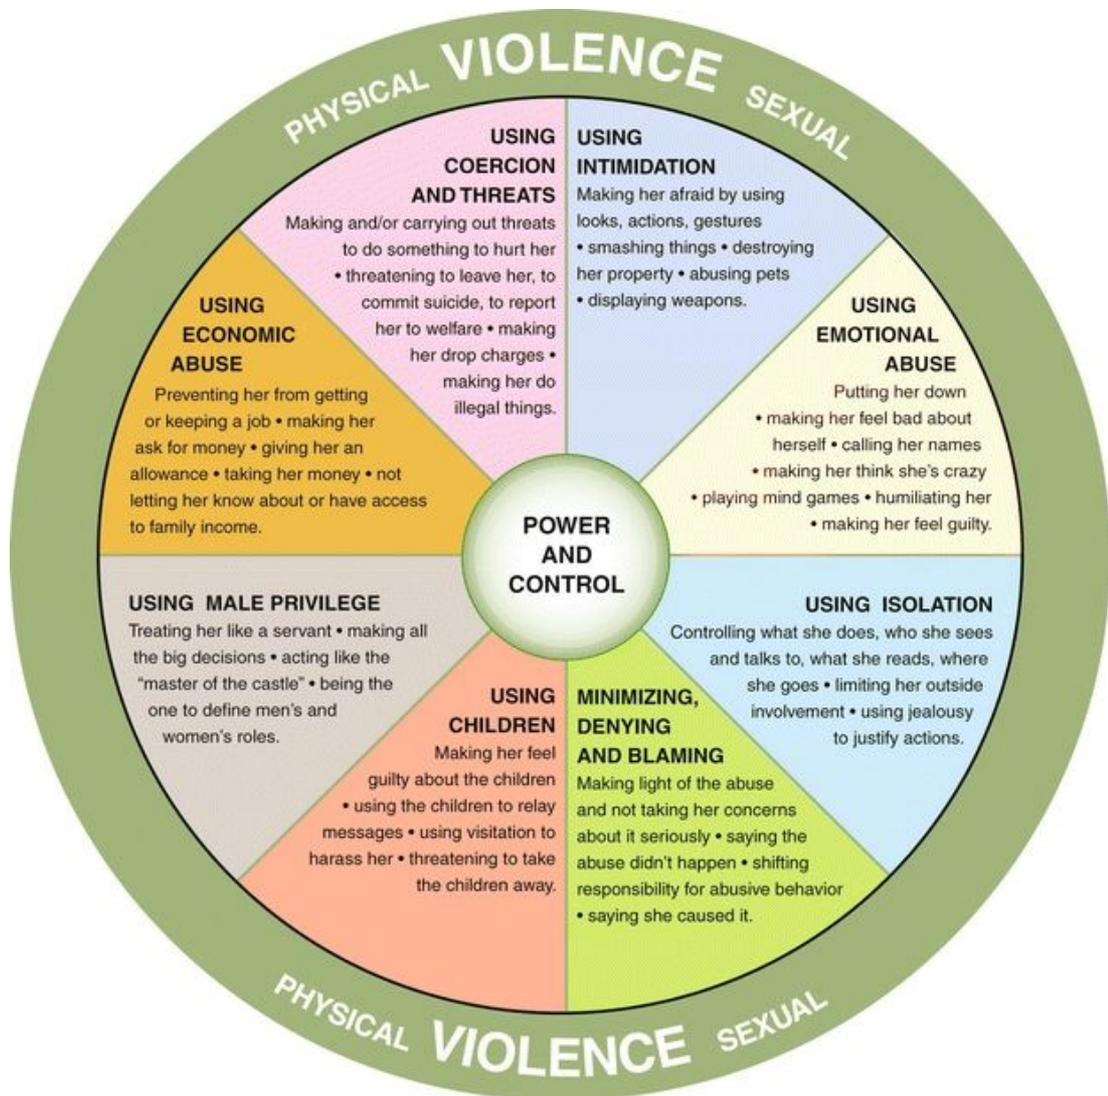

- Common in each phase.
- Used to minimize seriousness of behavior.
- Creates a false sense of reality in victim.
- Family and friends use denial to lessen their responsibility.
- Abuser uses denial to diminish the abuse is their fault, that it wasn't abusive behavior, or the behavior was deserved.

Source: [White Ribbon Australia \(2019\)](#); [SexInfo Online \(2017\)](#). Figure reprinted with permission from Hatfield, N. T., & Kincheloe, C. (2018). *Introductory maternity and pediatric nursing* (4th ed., Fig. 16-3). Philadelphia, PA: Wolters Kluwer.

Often, as the cycle of violence continues, the frequency of the cycle increases, with the tension-building phase and the acute battering incident occurring more often and diminishment or elimination of the loving reconciliation phase. Without intervention, this shorter, more violent cycle becomes increasingly risk-filled for outcomes that may lead to injury or maiming of a partner, incarceration, or death. Although early research focused on women who experience violence by men, the same descriptive cycle holds true regardless of the victim's or the aggressor's gender ([Hinsliff-Smith & McGarry, 2017](#)).

The Domestic Abuse Intervention Project in Duluth, Minnesota, developed a wheel of violence, identifying power and control at the center and citing eight categories of perpetrator behaviors ([Fig. 18-3](#)). This model is

a useful tool for visualizing the multidimensional nature of abuse in which threats, coercion, isolation, blaming, intimidation, and use of children, male privilege, and economics convene to control the victim.

**FIGURE 18-3** Wheel of violence.

Reducing violence and its effects happens strategically at all three levels of prevention.

- Primary prevention efforts attempt to identify risk factors, reduce risks, and increase social support to prevent violence from occurring.
- Secondary prevention effort involves developing an immediate response to violence that addresses the short-term consequences through emergency response and medical care.
- Tertiary prevention interventions work to address the long-term effect of trauma through counseling and rehabilitation (CDC, 2019a).

Health care providers have a responsibility and opportunity to assess and initiate a safety plan when these patients report experiencing violence. A compendium of assessment tools for IPV can be found on the CDC Web site.

## Teen Dating Violence

Teen dating violence includes physical violence, sexual violence, psychological aggression, and stalking between teenagers who are or have been in a casual or serious dating relationship. It can be electronic or in person and might occur between a current or former partner (CDC, 2019f).

- The 2017 National Youth Risk Behavior Study revealed that 8% of high school students reported physical dating violence and 7% reported sexual dating violence in the past 12 months; furthermore, people who experience dating violence in adolescence are at higher risk for dating violence in college (CDC, 2018d).
- Documented risk factors include poverty, limited education, substance abuse, poor family functioning, child maltreatment, and childhood exposure to IPV (Stewart, Vigod, & Riazantseva, 2016).
- Research on male aggressors found that those who exhibited physical and psychological dating aggression often had a history of suicide attempts, reports of past physical aggression, and low relationship satisfaction/instability and jealousy (Collibee & Furman, 2016).

Teens, regardless of gender, who experience dating violence in adolescence, are more at risk for binge drinking, suicide attempts, doing poorly in school, physical fighting, and sexual activity (CDC, 2018a). Programs through schools and communities, such as *Dating Matters*, are part of a national effort to address harmful beliefs about dating violence and promote healthy and respectful dating relationships (CDC, 2018a). Dating violence in adolescent relationships is a serious problem and because of its prevalence, community health nurses should include screening for dating violence in all encounters with teens.

## **Stalking**

*Stalking* may occur by either partner in a relationship, demonstrated as a “pattern of repeated and unwanted attention, harassment, contact, or any other course of conduct directed at a specific person that would cause a reasonable person to feel fear” ([USDOJ, n.d.d](#), para. 2). Approximately, 17% of women report a lifetime prevalence of being a victim of stalking behavior, and 5.9% of men ([CDC, 2018b](#)). Cyberstalking, a technology-based attack, can also take many forms that can involve harassment, embarrassment, and humiliation of the victim. Twenty-five percent of those stalked were cyberstalked as well ([Bureau of Justice Statistics \[BJS\], n.d.](#))

## Violence During Pregnancy

IPV during pregnancy increases the vulnerability of the woman and the fetus. For example, when abusive partners target a woman's abdomen, not only are they hurting the women but also potentially jeopardizing the pregnancy (WHO, 2017).

- Worldwide the exact number of women abused during pregnancy may never be known. While a U.S. study of more than 36,500 pregnant women found <2% experienced IPV, the consequences of IPV during pregnancy are grave (CDC, 2017b).
- Victims of physical abuse and sexual abuse during childhood increases the risk of IPV during pregnancy. Violence during pregnancy increases risk of depression, anxiety, and negative self-image (Hrelic, 2019). Additionally, abuse during pregnancy results in higher rates of intrauterine growth retardation and preterm labor that can lead to low birth weight and neonatal risks (WHO, 2017). See Chapter 19 for more on maternal–child health issues.
- Pregnant teens are at a greater risk of IPV. One study found that among teenage couples 64% had no IPV, while the remaining couples experienced either the males, mutual, or females as the perpetrators of the violence (Lewis et al., 2017).

The prenatal care visit is one of the few times when providers have an important opportunity to identify women who are abused and therefore at risk for homicide. It is imperative that nurses conduct an assessment for danger and lethality so that the women can be aware of their level of risk and take safety precautions as needed. A series of questions requiring a “yes” or “no” response and inquiries about occurrences of abuse, escalation of abuse, frequency, severity, weapons, drugs or alcohol use by the perpetrator, and safety of other children should be incorporated into prenatal home visit assessments. All health care providers, including C/PHNs, should have regular training on IPV. According to The American College of Obstetricians and Gynecologist (ACOG) (2019), when choosing a tool to assess for IPV, avoid ones that include words such as “abuse,” “rape,” or “violence” as they may cause the person to feel stigmatized. The ACOG offers sample of a tool on their Web site. Numerous tools can also be located in *Intimate Partner Violence and Sexual Violence Victimization Assessment Instruments for Use in Healthcare Settings* (<https://www.cdc.gov/violenceprevention/pdf/ipv/ipvandsvscreening.pdf>).

Annual screenings for IPV and providing interventions and referrals are part of the Women's Preventive Services Guidelines (HRSA, 2019). These are especially important for women who have not followed through with prenatal

care, thereby allowing health care professionals to monitor the progress of their pregnancies. C/PHNs are uniquely situated to screen for IPV during pregnancy, particularly through *Healthy Start* and *Nurse Family Partnership Programs*.

## Batterer Characteristics

Although a person of any gender may become a batterer, many studies and statistics are specific to male aggressors. The following attributes represent personal characteristics often seen in male aggressors of IPV:

- Poor sense of self-worth
- Low earnings or unemployed
- Not doing well in academics or dropping out of school
- Conduct disorders as a child
- Heavy substance use
- Mood disorders such as depression
- Exhibiting angry and hostile behavior
- Personality disorders (PD) such as borderline and antisocial PDs
- Physically abusive to others
- A loner with few or no friends
- Emotional immaturity
- “Belief in strict gender roles (e.g., male dominance and aggression in relationships)
- A desire for power and control in relationships”
- Being a prior “victim of physical or psychological abuse—this is consistently one of the strongest predictors of perpetration” (CDC, 2019i, para. 4)

Relationship, community, and societal factors may also affect a perpetrator's risk for aggressive IPV behaviors.

- Relationship factors include marital fights and tension, divorce and separations, money problems, issues with jealousy/being possessive, and problematic and difficult family relationships, as well as the male's need for dominance and control in the relationship.
- Community factors involve a lack of resources in the community, failure or unwillingness of others to intervene or contact authorities when they are aware of the abuse, and factors associated with poverty, such as overcrowding and unemployment.
- Societal factors include strict role stereotyping about male and female roles in marriage (CDC, 2019i).

## Victim Characteristics

Increasing the victim's abilities to manage and improve their behaviors and understanding of relationship patterns and abuse allows victims to change their risk of being further victimized. Individual risk factors for IPV victims include the following:

- A prior history of IPV
- Being female
- Young age, especially if pregnant
- From low-income household
- Witnessing or experiencing violence as a child
- Lower education level
- Unemployment
- Being a single parent with children or separated/divorced/previously widowed
- For men, having a different ethnicity from their partner
- For women, having a greater education level than their partner
- For women, being American Indian/Alaska Native or African American
- For women, being disabled
- Childhood sexual and/or physical violence
- For women, having a verbally abusive, jealous, or possessive partner
- Veterans and active-duty military
- Some research indicates higher levels of IPV (especially emotional victimization) in same-sex couples ([Ludermir, Barreto de Araújo, Valongueiro, Muniz, & Silva, 2017](#); [Yakubovich et al., 2018](#))

Marked differences between partner's incomes, levels of education, or job status place a victim more at risk for IPV. Community characteristics are similar to those of the perpetrator, revealing that those communities with fewer available resources, in areas of poverty, and having a lack of sanctions against violent behaviors increase one's risk; there is some indication that rates of IPV are higher in rural versus urban areas. Traditional gender roles, such as a belief that men work and women are submissive and should stay home, are societal risk factors associated with higher IPV risk ([Zapata-Calvente, Megías, Moya, & Schoebi, 2019](#)).

## Effects of Violence on Children

A national study found that over 40% of children were physically assaulted within the last year (Finkelhor, Turner, & Shattuck, 2013). The consequences of exposure to violence and abuse hinder children's health and development and can have a lifelong impact, negatively affecting health and increasing the risks of further victimization and becoming a perpetrator of violence (Box 18-9; WHO, 2020c).

### **BOX 18-9 Evidence-Based Practice**

**Generational Transmission of Intimate Partner Violence About one quarter of women will experience intimate partner violence (IPV) or domestic violence during their lifetime (CDC, 2019d), and research has linked child exposure to IPV and later adult domestic violence behavior (CDC, 2019i). Some posit that children adopt behaviors that have been role modeled by parents; however, most children who have witnessed IPV do not abuse their partners in adulthood.**

Others found that abused children, compared to IPV-exposed children, have a similar or even higher risk of becoming perpetrators of IPV as adults. Research has also indicated that there may be an even greater effect for those children who are both abused and who witness interparental violence.

Eriksson and Mazerolle (2015) wanted to know if examining gender role-specific behavior would give a clearer indication of generational transmission. Their research revealed a possible gender-specific connection to male IPV perpetration (e.g., male children who observe their fathers beating their mothers are more likely to do the same as adults).

- Given this evidence and after examining other research on this topic, what interventions might you consider when working with families dealing with domestic violence?

Literature reviews consistently suggest that a positive correlation exists between children's witnessing IPV and some aspects of impaired child development. Young children are particularly vulnerable to the effects of violence, as they lack the ability to understand the trauma and are likely to exhibit somatic complaints (e.g., headaches, eating or sleep problems) and/or behavior regression, such as clinging, whining, or becoming nonverbal ([National Child Traumatic Stress Network, n.d.](#)). Meanwhile, school-age children and adolescents are more likely to either act out with delinquent behaviors or withdraw. Children in families with domestic violence are at risk for depression, negative mental health effects, and consequences that last far into their adult lives. These maladjustments may be behavioral (aggression and conduct problems), emotional (withdrawal, anxiousness, fearfulness), social, cognitive (learning disabilities), and/or physical.

- Researchers have linked physical alterations in the child's brain (e.g., cerebral cortex, limbic system, corpus callosum, hypothalamus) with PTSD following child exposure to domestic violence ([Tsavoussis, Stawicki, Stoicea, & Papadimos, 2014](#)).
- For some children, high cortisol and other hormonal responses may lead to chronic levels of arousal, aggression, anxiety, depression, eating disorders, and other problems (e.g., self-harm, general irritability). In others, during adulthood, attempts to adjust to new stressors may lead to down-regulation of receptors and the ability to only respond minimally to stress hormones ([Tsavoussis et al., 2014](#)).

Providers who work with children need to listen in a sincere, nonjudgmental manner and provide ongoing support when assisting the child and family with resources, such as counseling, education, or community violence prevention programs.

# ELDER ABUSE AND MALTREATMENT OF OLDER ADULTS

**Elder abuse** is the “intentional act, or failure to act, by a caregiver or another person in a relationship involving an expectation of trust that causes or creates a risk of harm to an older adult” (CDC, 2019c, para. 1). Examples include physical, sexual or abusive sexual contact, emotional or psychological abuse, neglect, financial or material exploitation, confinement, passive neglect, and willful deprivation (CDC, 2019c; National Council on Aging, n.d). As with other types of abuses against vulnerable populations, the true incidence and prevalence of elder abuse is not known.

- A total of 90% of adults over the age of 65 live in the community on their own or with family (USDOJ, 2018b).
- It is estimated that 1 in 10 older adults experience some type of abuse (USDOJ, 2018a). Worldwide estimates are as high as 1 in 6 adults over age 60 experience abuse (WHO, 2020b).
- Approximately two thirds of elder abuse victims are women, often about half of individuals have dementia (USDOJ, 2018a).
- Risk factors include low social support, dementia, poor physical health, and functional impairment (NCEA, n.d.b).
- Perpetrators are often adult children or spouses, male, history of substance disorders, or mental health issues (NCEA, n.d.b).
- The most reported abuse includes neglect, followed by financial exploitation and emotional abuse (USDOJ, 2018a).
- Two thirds of staff employed in skilled or assisted nursing facilities admitted to abusing residents within the past year (WHO, 2020b).

Forms of physical abuse include rough handling during caregiving, pinching, hitting, and slapping. Emotional abuse, which can take many forms, included being shouted at or threatened and having needed care withheld. Older adults may also be sexually assaulted or sexually abused. Some elders are neglected by those they depend on to meet their caregiving needs. Elders with dementia and those requiring assistance for all activities of daily living are more vulnerable to experiencing maltreatment due to caregiver stress or burnout, factors known to increase risk for maltreating older adults. A neglected older adult may appear unwashed and unkempt, be malnourished or dehydrated, or have pressure sores. Financial exploitation

includes theft of Social Security or retirement money, savings or investments, and the use of these funds by the abuser. Criminals often approach elders with get-rich-quick schemes, sham investment opportunities, overpriced home repairs, or pose as collectors for illegitimate charities, thereby preying on the trusting nature of older adults ([USDOJ, 2018a](#); [NCEA, n.d.b](#)). See [Chapter 22](#) for more on older adults.

## Vulnerability Factors

Individual characteristics associated with vulnerability of abuse include poor health, increased age, and disability. Lesbian, gay, bisexual, and transgender older adults and those who are residents of an assisted living facility are also more vulnerable to experiencing maltreatment (NCEA, n.d.a). The older LGBT community experiences discrimination due to age and sexual orientation leading to social isolation. This population may experience abuse and discrimination from medical providers and law enforcement (Bloemen et al., 2019). Dementia and newly diagnosed cognitive impairment correlate with occurrences of abuse. If violence or threats of violence by the elder toward the caregiver accompany dementia, this contributes to the elder's risk for abuse. Harmful effects of abuse for this vulnerable population include longer convalescence period, permanent damage, premature death, depression, and anxiety (WHO, 2020b).

The *invisibility* of elders in general, and abused elders specifically, increases an older adult's vulnerability of being abused. Reasons for invisibility among the elderly are multifaceted. Older adults may have less contact with the community, they are no longer in the workforce or in public on a regular basis, which keeps their problems hidden longer. Older adults are reticent to admit to being abused or neglected. Because the abuser is often a family member, the elder attempts to protect the abuser to avoid being entirely alone. On the other hand, the elder may fear reprisal from the abuser for coming forward with a self-report of abuse or telling someone about the home situation. Cultural and societal values also contribute to keeping “family matters” private, while shame and embarrassment make it difficult for many elders to tell others of the abuse (New York City Elder Abuse Center, 2013).

- Older adults may be considered a vulnerable population for several reasons. Individuals may experience a diminished capacity in self-determination, impaired cognitive ability, decreased physical strength, lack of or inadequate education including low health literacy, and lack of resources (Barbosa et al., 2017).
- Many elders who are frail are dependent on others for some aspect of their day-to-day survival. The degree to which an older adult needs assistance is often kept hidden from others because the elder fears being removed from his present living situation and being placed in a more restrictive environment.
- Additionally, vulnerability in elders is increased when any of the following characteristics are present: (1) being female, (2) 85 years and older, (3) widowers, (4) a decrease in health, (5) low income, and (6) lack of education and low health literacy (Barbosa et al., 2017).

## **Prevention of Elder Abuse**

Elders who are dependent on others for their care often do not report abuse for fear of being abandoned. They feel powerless and at a loss about how to attain help. They often fear reprisal from the perpetrator if they tell others about the abuse. Awareness of elder abuse and education about the types of abuse via public and professional media campaigns has improved community recognition of the problem. C/PHNs need knowledge in screening procedures and risk factors for abuse and perpetrators. Respite care can provide valuable relief to family members. Training for caregivers as well as health care and social service providers that focus on recognizing stress and initiating intervention measures has developed a new understanding of effective interventions. Statutory requirements for reporting abuse and providing crisis hotlines for reporting elder abuse are also integral aspects of a community's response to the problem of elder abuse ([WHO, 2020b](#)). World Elder Abuse Awareness Day has been designated as an annual observance on June 15th to promote public awareness and prevention education regarding elder abuse ([United Nations, n.d.](#)).

# **OTHER FORMS OF VIOLENCE**

Additional forms of violence include self-directed violence (including suicide), homicide, sexual assault, and human trafficking.

## Self-Directed Violence

*Self-directed violence* (SDV), an intentional act to cause injury to one's self, is a public health issue worldwide. SDV is considered a range of behaviors involving fatal and nonfatal self-harm. Examples of self-harm include cutting, head banging or hitting, self-scratching, self-biting, burning self, attempted suicide, and suicide. Suicidal ideation, although not a behavior, is often included due to an association with SDV (CDC, 2019e).

*Suicide* is taking action that causes one's own death. According to the CDC, suicide rates are rising in every state in the United States. In 2017 alone, more than 47,000 people committed suicide in the United States. It touches all age groups; it is

- Second leading cause of death among 10-to 34-year-olds
- Fourth leading cause of death among 35-to 54-year-olds
- Eighth leading cause of death among 55-to 64-year-olds (CDC, 2019e)

In 2017, 10.6 million individuals in the United States considered suicide, of those 3.2 million had a plan and 1.4 million attempted suicide (CDC, 2019e).

It is important to be aware of warning signs of potential suicide when working with people in crisis. The strongest risk for suicide is a previous suicide attempt (WHO, 2019a). Warning signs fall into three categories: what the person talks about, types of behaviors, and mood. The more warning signs, the greater the risk (American Foundation for Suicide Prevention [AFSP], 2020). An individual may talk about not having a reason to live, feeling trapped, or suicide. Threats or comments that indicate a plan or giving personal items away are potential indicators of a person contemplating suicide. Isolation, sleeping too much, acting recklessly, and increased use of alcohol or drugs are high-risk behaviors for suicide. Moods that may reflect increased risk are depression, irritability, rage, humiliation, and anxiety.

Community awareness campaigns and education programs are needed to help a person recognize the risks and the importance of initiating prevention for someone who is suicidal (Box 18-10). Crisis hotlines with 24-hour access are a vital resource for a distraught individual, friend, or loved one to contact and find help during a crisis and to learn about local resources to contact.

### **BOX 18-10 STORIES FROM THE FIELD**

**Helping Youth Build the Strength to Prevent Suicide** Mark LoMurray is the founder and Executive Director of *Sources of Strength*, a youth suicide prevention program that address bullying, violence, and substance abuse. The program uses peer leaders with adult advisors in the school setting. The peer leaders help their classmates address emotions they're grappling with and cultivate strengths to use to change. The goal is to remove suicide intervention from the crisis mode and focus on development of appropriate coping skills. The main focus is positivity; instead of dwelling on negative emotions, strengths are emphasized. There are 8 strengths students can use to help develop coping skills. Arranged in a wheel the 8 sources of strength include mentors, positive friends, family support, mental health, medical access, spirituality, generosity, and healthy activities. Students are taught to reframe stressful situations to what will help the situation using the 8 strengths as a guide. A variety of modalities are used, for instance, playing games, talking, use of social media, and art. More information can be found at <https://sourcesofstrength.org/>.

1. *As you read this chapter, how might this program decrease violence in our communities?*
2. *Examine the 8 strengths and identify 3 to 4 that may have helped you in a stressful situation.*
3. *The Sources of Strength address several Healthy People 2030 objectives. After examining the topic areas of Health Behavior;*

*Populations, and Social Determinants of Health, reflect on how Sources of Strength addresses these objectives.*

Source: [ODPHP \(2020a\)](#).

# Homicide

*Homicide* is any non-war-related action taken to cause the death of another person. In 2017, globally, intentional homicide took the lives of 464,000 people ([United Nations Office on Drugs and Crime, 2019](#)). In 2017, there were 19,510 homicides reported in the United States alone. It was the 16th leading cause of death among all age groups and the 3rd leading cause of death of young people between the ages of 15 and 24 years ([Kochanek, Murphy, Xu, & Arias, 2019](#)).

Evidence suggests that violence can be prevented by measures aimed at individuals, families, relationships, community, and society. The Guide to Community Preventive Services (Community Guide) provides evidence-based recommendations and interventions for 22 health topics including or violence prevention for each level of prevention ([USDHHS, n.d.](#)). Although biologic and personal factors may influence one's predisposition to violence, an interaction between one's family, community, cultural, and other factors combine to create violence ([WHO, 2019b](#)). The WHO cites four key steps in developing a public health approach to violence. These steps include the following:

- Define the problem
- Discover the causes and risk factors
- Develop and test interventions
- Implement and scale effective interventions ([WHO, 2019b](#))

Prevention methods include education programs for preschool, school-aged children, and adolescents to decrease bullying and improve social skills; parent education courses and parent resources such as advice lines, support groups, or a crisis nursery; and community measures that improve firearm safety and reduce firearm injuries.

## Sexual Assault

*Sexual assault* is defined as “any nonconsensual sexual act proscribed by Federal, tribal, or State law, including when the victim lacks capacity to consent” (USDOJ, n.d.c, para. 2). According to the [U.S. Department of Justice \(USDOJ\) \(2016\)](#), this definition includes threats of sexual violence, attempted rape, and rape. The percent of sexual assaults are staggering:

- 30% of sexual assault victims were raped.
- 23% experienced attempted rape.
- 24% were sexually assaulted.
- 18% of victims received threats of sexual assault.
- 6% experienced “unwanted sexual contact without force.”
- 19% of women and 1.5% of men... “have been victims of rape or attempted rape.”
- For close to 78% of females who were raped, the assault was recorded before they turned 25.
- Over 67% of males who were sexually assaulted, victimization occurred before age 25 ([USDOJ, 2016](#), p. 17).

The majority of perpetrators were either current or former intimate partners or acquaintances.

Community measures useful in preventing sexual assault involve education and prevention provided through state sexual assault coalitions, sexual assault programs for adolescents and college students, dating violence education, hotlines staffed to provide help for victims of sexual assault and interpersonal violence, and having trained professionals, such as Sexual Assault Response Team (SART) members, on hand ([CDC, 2019g](#)). Rape crisis centers and state sexual assault coalitions work together with law enforcement, health care providers, and community-based organizations (CBOs) to provide community education and care and support to victims. SART (Sexual Assault Response Team) consists of multidisciplinary members that are trained to understand the psychological and physical assessment needs of the victim, as well as the legal requirements for an investigation and court proceeding ([National Sexual Violence Resource Center \[NSVRC\], 2018](#)). The CDC's Rape Prevention and Education program provides current tools, training, and support works ([CDC, 2019g](#)). Unfortunately, only 33% of sexual assaults are reported to law enforcement ([USDOJ, 2016](#)).

A common role in the SART is a sexual assault nurse examiner (SANE). A SANE's role is more explicit than that of the C/PHN in assisting people who are affected by sexual violence, including victims, suspects, and the accused. For people who have experienced sexual assault, SANEs provide

forensic medical exams and appropriate follow-up referrals based on the patient's individual needs. SANEs may specialize in pediatrics, adolescents, adults, or a combination of all three. A SANE represents one subspecialty of forensic nursing practice; forensic nurses work in a variety of community settings and specialize in many different types of patient populations affected by violence including elder abuse, IPV, homicide, human trafficking, and more ([Adams & Hulton, 2016](#); [DailyNurse®, 2019](#)).

## Human Trafficking

Human trafficking of adults and children on a national and international scale is recognized by the United States in the Trafficking Victims Protection Act (TVPA) of 2000.

- This federal law defined human trafficking as the “recruitment, harboring, transportation, provision, or obtaining of a person” for compelled labor or commercial sex or for labor or services through the “use of force, fraud, or coercion” ([National Human Trafficking Hotline, n.d.](#), para. 5). The law specifically identified any child <18 years who engaged in commercial sex as a victim of trafficking when coerced or forced.
- Since 2000, a total of 11 laws, revisions, and reauthorizations of the TVPA have been implemented; the most recent in 2018 ([USDOS, 2019](#)). Victims of human trafficking are not associated with any one specific demographical factor. Victims can be anyone of any age, ethnicity, economic status, or gender and are trafficked into various forms of human abuse such as commercial sex, medically assisted reproduction, many types of physical labor, and more.

In February 2020, during a weeklong investigation, federal, state, and county officials in California made over 500 arrests in a human trafficking sting operation. Twenty-seven suspects and 270 customers were arrested for sex trafficking. A total of 11 children and 76 adults were rescued ([City News Service, 2020](#)). Despite the significant number of known cases, the actual prevalence of human trafficking is not known. This, combined with the well-established negative health consequences, have made this into a public health problem, and one that is difficult to mitigate. Research shows that the majority of victims have encounters with health care providers. However, victims of human trafficking most often do not self-identify as victims during the health care encounter and health care providers do not readily recognize them as potential victims of human trafficking ([Chisolm-Straker et al., 2016](#)). This places nurses at the forefront of screening for human trafficking victims and also facilitating effective response protocols. A major response measure implemented by the USDHHS was the establishment of the [National Human Trafficking Hotline \(n.d.\)](#) at <https://humantraffickinghotline.org/>. The center is responsible for the 24-hour crisis line available in over 200 languages, plus additional texting (233733), live chat, and online resources to assist in the recognition and response to victims.

## Gang Violence

According to the [FBI \(n.d.b\)](#), there are 33,000 violent gangs in the United States, consisting of street, motorcycle, and prison gangs. Violent activities involve prostitution, human trafficking, drug sales, robberies, and gun trafficking. Los Angeles City and County combined are considered the gang capital of the world with a total of 450 violent gangs comprising 45,000 individuals ([Los Angeles Police Department \[LAPD\], 2019](#)). Since 2016, there have been 491 homicides, 5,510 robberies, 98 rapes, and 7,050 felony assaults ([LAPD, 2019](#)). Teens join gangs for several reasons:

- Identity or recognition
- Fellowship
- Intimidation
- Protection
- Criminal activity ([Office of Justice Programs \[OJP\], n.d.](#))

Teens involved in gangs are at higher risk of not graduating from high school, teen parenthood, and unemployment ([OJP, n.d.](#)).

## Gun Violence

- A Pew Research Center Survey discovered 30% of Americans own a firearm, 11% live with someone that owns a firearm, nearly 60% have friends that own guns, and 72% of those that responded to the survey have fired a gun (Gramlich & Schaeffer, 2019).
- Most gun owners cite the Second Amendment to the Constitution as their right to own a firearm. Reasons for owning a firearm include protection (67%), followed by hunting, sport shooting, collector, and requirement of job (Gramlich & Schaeffer, 2019).
- In 2016, death from firearms was estimated to be 251,000 worldwide (Naghavi, 2018). The countries that account for 50% of these deaths include Brazil, the United States, Mexico, Colombia, Venezuela, and Guatemala. Homicide was the leading cause of firearm deaths at 64%, with suicides at 27%, and unintentional deaths by guns at 9% (Naghavi, 2018).
- In 2017, the United States had 39,800 deaths due to firearms; the highest number since 1993 (Gramlich & Schaeffer, 2019).

Of the 7,639 bills introduced in Congress from January to August 2019, 110 related to guns (Desjardins, 2019). The two bills with the most support were the Bipartisan Background Checks Act and the Concealed Carry Reciprocity Act. Grassroots movements include Moms Demand Action (<https://momsdemandaction.org/>), a movement to protect against gun violence by public safety measures; Everytown For Gun Safety (<https://everytown.org/>), a group that advocates for changes in gun laws; and March For Our Lives (<https://marchforourlives.com/>), whose Web site opens to voter registration and was started by the students of Marjory Stoneman Douglas high school in Parkland, Florida, after a mass shooting there that killed 17 and injured 17 in 2018 (Marjory Stoneman Douglas High School Public Safety Commission, 2019).

## Workplace Violence

Workplace violence is defined as “any act or threat of physical violence, harassment, intimidation, or other threatening disruptive behavior that occurs at the work site” (OSHA, n.d., para. 2). The violence can take the form of threats, verbal abuse, physical assaults, or homicide. According to the U.S. Department of Labor, those at greatest risk include health care providers, customer service workers, employees working in small groups or alone, public service employees, and law enforcement officers (OSHA, n.d.).

Workplace injuries due to violence account for 12% of injuries among registered nurses. While this figure may appear low, it is three times greater than injuries due to violence when compared to any other occupation. Nurses employed in nursing and residential care are at greater risk, followed by hospitals and ambulatory care clinics (U.S. Bureau of Labor Statistics, 2018). In hospitals, those nurses working in emergency departments and in-patient psychiatric units have the highest risk of injuries due to violence. Health care workers underreport workplace violence by patients because of unclear definitions of workplace violence, feeling that the patient was not responsible for actions due to mental status, or believing violence is part of the job (JCAHO, 2018). The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) standards and recommendations related to workplace violence are located at <https://www.jointcommission.org/resources/patient-safety-topics/sentinel-event/sentinel-event-alert-newsletters/sentinel-event-alert-59-physical-and-verbal-violence-against-health-care-workers/>.

The phrase “nurses eat their young” has long been a lament of novice nurses (Colduvell, 2017). Bullying or incivility among nurses is a common occurrence. It is estimated 44% of nurses have been bullied within the health care setting (JCAHO, 2016). In a CINAHL search of “bullying” and “nurses” between 2017 and 2019, a total of 375 results were found. Several countries were represented including the United States, Russia, Iran, Korea, and Australia demonstrating this is an epidemic in health care. While, incivility is considered part of the job by some, it has a negative impact on health care. Horizontal and vertical bullying increases burnout, turnover rate, patient care errors (e.g., medication errors and higher infection rates), and costs (JCAHO, 2016). However, the bullying can have fatal consequences. In 2018, a registered nurse in Wales committed suicide related to workplace bullying (Stephenson, 2018).

## **C/PHN Self-Care**

The American Nurses Association ([ANA](#)) announced 2017 as the Year of the Healthy Nurse. Each month focused on a different topic of health such as sleep, happiness, mental health wellness, physical activity, and healthy eating (ANA, n.d.). Practicing these health promotion themes throughout our careers place us a better position to handle individual, family, community, and global violence. These topics should be a part of every C/PHN daily routine. Unfortunately, due to work requirements and family commitments nurses may not practice self-care techniques even though we teach these practices to our communities ([Ross, Bevans, Brooks, Gibbons, & Wallen, 2017](#)). Nurse leaders need to highlight and encourage self-care practices in the workplace ([Ross \*et al.\* 2017](#)); for instance mediation lunches, walking groups, or infographics on self-care.

# HEALTHY PEOPLE 2030 AND VIOLENCE PREVENTION

The problem of violence is pervasive, affecting the people who experience violence directly and family members and society indirectly. Progress on selected violence and abuse objectives for *Healthy People 2030* include the following ([Office of Disease Prevention and Health Promotion \[ODPHP\], 2020b](#)):

- Reduce homicides: In 2018, the baseline for homicides was 5.9/100,000. The target for 2030 is to decrease this to 5.5/100,000.
- Reduce emergency department visits for nonfatal self-harm injuries: Reduce these emergency department visits from 182.7/100,000 in 2017 to 144.7/1,000 for person 10 years and older.
- Reduce gun carrying among adolescents: In 2017, 4.8% of students in grades 9 through 12 carried a firearm at least 1 day within the past year. The target for 2030 is 3.7%.

See [Box 18-11](#) for selected Healthy People 2030 violence-related objectives.

## BOX 18-11 HEALTHY PEOPLE 2030 Selected Violence-Related Objectives

### Core Objectives

IVP-09	Reduce homicides
IVP-10	Reduce nonfatal physical assault injuries
IVP-11, 12	Reduce physical fighting and gun carrying among adolescents
IVP-13	Reduce firearm-related deaths
IVP-14	Reduce nonfatal firearm-related injuries
IVP-15	Reduce child abuse and neglect deaths
IVP-16	Reduce nonfatal child abuse and neglect
IVP-17	Reduce adolescent sexual violence by anyone
IVP-18	Reduce sexual or physical adolescent dating violence
OSH-05	Reduce work-related assaults

### Developmental Objectives

IVP-D04	Reduce intimate partner violence
AH-D03	Reduce the proportion of public schools with a serious violent incident

Reprinted from Office of Disease Prevention and Health Promotion (ODPHP). (2020a). *Healthy People 2030: Browse objectives*. Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>.

# **LEVELS OF PREVENTION: CRISIS INTERVENTION AND FAMILY AND INTIMATE PARTNER (IP) VIOLENCE**

C/PHNs are in a unique position to prevent, identify, and intervene during crisis situations involving family violence. Because C/PHNs encounter people in their own settings, a more accurate assessment with direct observation, discussion, and intervention can occur. The nurse's assessment skills, familiarity with the community, and access to resources enhance his ability to help families in crisis. By using the three levels of prevention, the nurse can assist families in a variety of ways to counter problems arising from family and IP violence ([Box 18-12](#)).

## **BOX 18-12 Levels of Prevention Pyramid**

### **Promoting Crisis Resolution SITUATION:**

**Traumatic crisis due to act of violence regarding a mass shooting**  
**GOAL: To use the three levels of prevention, to avoid promptly diagnose and treat the community's negative health conditions, and to restore the fullest possible potential.**

<b>Tertiary Prevention (Postcrisis)</b>		
<i>Rehabilitation</i>	<i>Primary Prevention</i>	
	<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>▪ Promote adaptation to a changed level of community wellness</li> <li>▪ Identification and use of additional resources</li> </ul>	<ul style="list-style-type: none"> <li>▪ Yearly review of safety measures</li> <li>▪ Reinforce newly learned coping strategies</li> <li>▪ Continue to promote educational programs that promote safety</li> </ul>	<ul style="list-style-type: none"> <li>▪ Reevaluate affected community members' mental health</li> <li>▪ Educate on the prevention of violence</li> </ul>
<b>Secondary Prevention (Crisis)</b>		
<i>Early Diagnosis</i>	<i>Prompt Treatment</i>	
<ul style="list-style-type: none"> <li>▪ Get a prompt diagnosis on situation</li> </ul>	<ul style="list-style-type: none"> <li>▪ Assist with reaction to the event</li> <li>▪ Allow for feelings of anger and grief</li> <li>▪ Set goals with clients and community</li> <li>▪ Refer to resources</li> <li>▪ Ensure safety—follow orders of police</li> <li>▪ Partner with community and agencies to provide needed services</li> </ul>	
<b>Primary Prevention (Precrisis)</b>		
<i>Health Promotion</i>	<i>Health Protection</i>	
<ul style="list-style-type: none"> <li>▪ Promote education on gun violence</li> <li>▪ Lobby for gun restrictions and bans on certain models</li> <li>▪ Teach and reinforce new coping strategies</li> <li>▪ Reinforce protective factors in the community</li> </ul>	<ul style="list-style-type: none"> <li>▪ Educate public on steps to increase safety</li> <li>▪ Provide anticipatory guidance by conducting active shooter drills at job and school sites</li> <li>▪ Reinforce newly learned behaviors and lifestyle changes</li> </ul>	

## Primary Prevention

The cycle of violence can be interrupted. Primary prevention is the most effective level of intervention in terms of promoting clients' health and containing costs. Primary prevention reflects a fundamental human concern for well-being and includes planned activities undertaken by the nurse to prevent an unwanted event from occurring, to protect current health and healthy functioning, and to promote improved states of health for all members of a community. For the C/PHN, any activity that fosters healthful practices will counteract unhealthful influences, thereby empowering an individual or family to avoid or better respond to a crisis. Health promotion considerations include the biopsychosocial and spiritual needs of the individual and family.

Opportunities for interventions include promoting positive relationships and parenting practices, improving communication skills, and developing positive self-esteem. Healthy self-esteem also improves education and occupational success. If poverty is a contributing factor to the violence being experienced, adequate educational preparation and having a successful employee role may help to eliminate this stressor. Parenting influences children's coping strategies, decision-making, and sense of self-confidence. Parenting classes are an important resource, particularly for parents who are at high risk, such as teens, people with no exposure to children in their upbringing, and people raised in violent and abusive families. Parenting classes offer an opportunity for parents to discuss challenges, while learning new strategies for managing their children's behaviors and appropriate physical, emotional, and developmental expectations for their children's ages (Dutton, James, & Kelley, 2015).

Home visiting has been formalized into community/ public health nursing model programs around the country, based on two decades of work by David Olds (NurseFamily Partnership, 2020) and others. This evidenced-based program has shown that nurse follow-up and interventions during the pregnancy and for the first 2 years of the child's life was effective in preventing child abuse, decreasing the mother's reliance on government assistance, having mothers with longer spacing between their children and fewer subsequent pregnancies, and improving health habits, such as less smoking by mothers (USDHHS, 2019). To date, the NFP has served over 309,000 families in the United States (NurseFamily Partnership, 2019). See Chapter 4. For more information on this unique partnership, refer to <https://www.nursefamilypartnership.org>. The effectiveness of home visit programs to pregnant women and families with a child from birth to 5 years are evaluated yearly by the Office of Planning, Research, and Evaluation (Sama-Miller, Akers, Mraz-Esposito, Coughlin, & Zukiewicz, 2019). This

report provides an in-depth evaluation of home visit programs across the United States and is a valuable tool when starting a home visit program.

The interrelatedness between families and communities cannot be overlooked or underestimated. Neighborhoods need to be enfranchised, developed, and attentive to the needs for health and safety for all community members. Empowered families and communities can take back their neighborhoods from criminals, and their empowerment acts as a source of growth for other families.

## Secondary Prevention

Early diagnosis and prompt treatment of the effects of family crisis or violence is the focus of secondary level prevention strategies. Secondary prevention seeks to reduce the intensity and duration of a crisis and to promote adaptive behavior. By creating a positive relationship with family members in their homes, the C/PHN can often uncover and intervene in a crisis or stop abusive situations.

Those affected by a violence-related crisis is rendered temporarily helpless and unable to cope on their own and are especially receptive to outside influence. C/PHNs can implement crisis resolution models to assist clients at the secondary level. The following process outlines a proven crisis intervention process ([James & Gilliland, 2017](#)):

1. Establish rapport.
2. Assess the individual and the problem for lethality.
3. Identify major problems and intervene.
4. Deal with feelings.
5. Explore alternatives and coping mechanisms.
6. Develop an action plan.
7. Follow up, including anticipatory planning for coping with future crises.

People in crisis will seek and generally receive some kind of help, but the nature of that help may act in favor of or against a healthy outcome from which the participants can grow and evolve. A client's desire for assistance gives the helping professional a prime opportunity to intervene; this opportunity also presents a challenge to make the intervention as effective as possible. Behaviors found to be helpful in these interventions include the following:

- Respect the client's confidentiality.
- Listen to the client and validate the client's experiences.
- Acknowledge any violation and oppression.
- Allow clients to make their own decisions.
- Assist the client and the client's family to plan for future safety.
- Promote access to community services ([James & Gilliland, 2017](#)).

The Quality and Safety Education for Nurses Project [QSEN] provides a guide for preparing future nurses to improve the quality and safety of the health care system in which they work ([QSEN Institute, 2020](#)). Knowledge, skills, and attitudes are delineated for the domain of safety. Although framed specifically for acute care settings, the domain of safety identifies factors that create a culture of safety such as communication and reporting systems (i.e., mandatory reporting). Effective use of strategies to assess and reduce harm is

important when working with families in crisis. Valuing safety, vigilance, monitoring, and reporting are skills necessary for community/public health nursing practice.

- One goal of crisis intervention should be to help clients reestablish a sense of safety and security while allowing them to share their feelings and have those feelings validated. This process helps reestablish equilibrium at as healthy a level as possible and can result in client change and growth.
- Minimally, the goal is to resolve the immediate crisis and restore clients to their precrisis level of functioning. Overall, intervention seeks to improve their functioning to a healthier, more mature level that will enable them to cope with and prevent future crises.
- As discussed earlier, crises tend to be self-limited; intervention time generally lasts from 4 to 8 weeks, with resolution within 2 or 3 months (James & Gilliland, 2017).
- The urgency of the situation represents a window of opportunity that invites prompt, focused attention by the client and nurse in working together to achieve intervention goals.

At times, the nurse may be responding to a referral regarding suspected abuse; at other times, an abusive or neglectful situation may be uncovered on a home visit made for another reason. In any case, the C/PHN has an important role in reporting suspected abuse and encouraging the child, partner/spouse, or elder to go to the appropriate facility to seek care and to file required documentation about the abuse (Box 18-13).

## **BOX 18-13 STORIES FROM THE FIELD**

**Community/Public Health Nursing and a Potential Family in Crisis You are a PHN employed by the Smithville Health Department. You are following up on a referral from a community clinic's family planning clinic involving a 19-year-old woman, Sarah, who exhibited inappropriate behaviors with her 6-month-old daughter during a clinic visit. Per the referral, staff observed the mother shouting**

**at the child, accusing her of “being spoiled rotten,” the mother appeared quite anxious, and seemed to have difficulty waiting the 15 minutes for her examination. Although the behaviors described were insufficient to warrant a report to social services, the staff felt that this young mother would benefit from intervention on the part of the nurse.**

In preparation for the home visit, you review the medical records of Sarah and her child to determine whether the family has had previous involvement with social service agencies such as Child Protective Services (CPS). You find that the maternal grandparents made a referral to child welfare staff on behalf of Sarah when she was 15. The grandparents were concerned about a sexual relationship between Sarah and her stepfather. The findings of the investigation were inconclusive, and the charges were never pursued.

You discuss the case with family planning and immunization clinic staff, because the family receives services at both clinics. The staff are familiar with Sarah and her husband Jacob. Their only interaction with Jacob was during a family planning clinic visit 2 months ago. They report Sarah appeared anxious and rushed, stating, “I really need to hurry, Jacob is waiting in the car, and he gets impatient.” Shortly after that, the staff tell you, Jacob came running into the clinic shouting, “What the hell is taking you people so long?” He reportedly glared at Sarah, and the two quickly exited the clinic.

You phone the client and introduce yourself as a nurse with the local health department, explaining that nurses often visit new mothers to assist them in finding resources. You add that as a PHN, you will be available to talk with her about her child's growth and development. The client expresses interest in the visit and states, “I want you to show me some things about feeding her and stuff. I need help figuring out what to do at night, she still isn't sleeping much and it's driving me crazy.” You advise the client that you will be happy to discuss those issues with her and that you will bring information to review together. Noting that the father of the baby is living in the home, you assure her that she may involve other family members, including the father of the baby, in the home visit. You jointly decide that the visit will occur the following day at 10:30 AM and that the father of the baby will be present if his work schedule allows.

On the day of the visit, as you walk up the stairs toward the apartment, you notice someone looking at you through the curtains. As you near the apartment door, the curtains close. Your repeated knocking on the door is met with no response. You call the client's name but there is no answer.

1. *Does this scenario provoke anxiety for you? How would you deal with your reaction?*
2. *How is this different from being in a hospital setting where a supervisor is readily available?*
3. *Given this scenario, what actions will you take?*
4. *If you had been working in the family planning clinic on the day that Jacob came in, what, if anything, would you have done differently?*
5. *As young parents, Jacob and Sarah are part of an aggregate that has unique risk factors for parenting. List as many of these risk factors as you can think of and brainstorm about possible community/public health nursing interventions for each.*
6. *What methods would you suggest the clinic staff utilize to detect signs and symptoms of physical, sexual, or emotional abuse among this aggregate?*

## *Reporting Abuse*

All states have reporting laws for suspected abuse, although states differ on aspects of the timeline for reporting, who to notify, and the sequence of events. The following steps represent one state's guidelines for reporting suspected child abuse ([California Department of Education, 2020](#)):

1. All mandated reporters must report known or suspected abuse or neglect.
2. Immediately, or as soon as practically possible, the designated agency such as the local child protective agency (police department after normal working hours) must be contacted by telephoned and given a verbal report. During this verbal report, mandated reporters must give their name—which is kept confidential and may be revealed only in court or if the reporter waives confidentiality (others can give information anonymously)—the name and age of the child, the present location of the child, the nature and characteristics of the injury, and any other facts that led the reporter to suspect abuse or that would be helpful to the investigator.
3. The mandated reporter must notify the appropriate agency immediately or as soon as possible, followed by a written report within 36 hours. It is imperative that nurses know their state laws for reporting. If a mandated reporter fails to report known or suspected instances of child abuse, they

may be subject to criminal liability, punishable by up to 6 months in jail or/and a fine of \$1,000.

Similar steps are required for nurses when reporting elder abuse and other vulnerable adults. Such cases of suspected maltreatment are reported to a local area agency on aging, Adult Protective Services, or to the police, and a screening/documentation form is used to gather and record pertinent information. Guidelines for filing the report and agency notification are specific within each state. In cases of partner/spousal abuse, adults who are mentally competent cannot be removed involuntarily from the abusive situation. The C/PHN can communicate concern for the client's safety, emphasize the importance being in a safe environment, and provide information regarding community resources, such as a shelter (Fig. 18-4). If the adult has a life-threatening injury or illness, medical follow-up must be encouraged; however, the victim may still be reluctant to seek help.

**FIGURE 18-4** Public health nursing client in a homeless shelter.

## *Tools*

Assessment of suspected abuse cannot be overemphasized. The C/PHN may be the only person entering the home of a family in crisis where abuse is occurring. Asking the right questions, being a careful observer, and following the correct reporting process and recording procedures may mean the difference between life and death for a person or family experiencing violence. (See <http://thepoint.lww.com/Rector10e> for the following sample tools: a Suspected Child Abuse Report, a two-page Medical Report of Suspected Child Abuse, and a Domestic Violence Screening/Documentation Form.) C/PHNs must be observant for hazards and personal safety. Follow agency policy if ever feel in harm's way. Some agencies assign nurses to go

in pairs or with law enforcement to ensure safety. If the batterer is in the home, meet the victim in a public place and not in the home.

## Tertiary Prevention

Tertiary prevention focuses on the rehabilitation of the person or family from the violence and crisis they have experienced. They may be alone, such as a trafficked teenager estranged from his family. Or, they may never again have the same relationships because partners may separate—by choice, motivated by fear or hatred; by court order, if the perpetrator is incarcerated; or due to a death. Regardless of an individual, or a couple or a family, long-term intervention may be needed to establish a climate more conducive to normalcy. Many of the services discussed as part of the secondary level of prevention are continued into the tertiary prevention phase to promote healing and to restore and promote family growth.

If incarceration is a part of tertiary prevention, the effects of having one person living in this environment must be factored into the services and support provided by the C/PHN to the other people involved (see [Chapter 28](#) for information on working in correctional facilities). If children are involved, even if the partner/spouse has separated from the perpetrator, the perpetrator usually has legal rights to see the children. This may mean that other family members, usually from the abuser's side of the family, can bring the children to the prison to visit their parent. Making arrangements for these visits can create stress for adult survivors, children, and the visitors. The C/PHN needs to be aware of the complicated dynamics and emotional stress such difficult situations can produce for all family members. The victim–perpetrator relationship is as complex as the forces that created the violence and abuse (NCADV, n.d.b).

# VIOLENCE FROM OUTSIDE THE HOME

There has always been some degree of violence that affects people in their homes, such as burglaries, murder, or abduction (Fig. 18-5). *Home invasion*, the purposeful and sudden entry into a home by force while people are home and awake, is a form of terror that relies on surprise. Confrontation is often sought, and offenders are often younger (under age 30) and male, working in small groups. They often look for victims who may be more vulnerable and are believed to have money or desired goods that they can pawn or sell (Heinonen & Eck, 2012). Motivation may be material or thrill; household belongings are frequently stolen while members of the home are incapacitated by being bound, blindfolded, and/or gagged. In some cases, people are murdered. Often, the perpetrators are under the influence of drugs or alcohol, and at times, the violence may be gang related.

**FIGURE 18-5** Crime is a type of community violence that can affect families.

Other forms of violence include the potential for terrorist activities through planned community violence (e.g., 9/11 attacks, Sandy Hook school shooting, Route 91 Harvest Music Festival) and biologic, chemical, or radioactive actions (see Chapter 17). Communities have developed resources such as the National Organization for Victim Assistance (NOVA) and crisis response teams (CRT), to assist individuals and groups experiencing a disaster or violent event (e.g., child murder or school shootings).

The *Global Study on Homicide 2019* provides an in-depth investigation into crime. Lethal violence can create a climate of fear and uncertainty. Intentional homicide victimizes individuals, families, and the community of the victim ([United Nations Office on Drugs and Crime, 2019](#)). Fear of violence can create psychological and physiologic stress reactions. These fears should not be ignored.

Historically, society has depended on the criminal justice system to respond to community violence with emphasis on deterrence and incarceration, which has limited prevention capacity. Today, violence is considered a public health issue requiring more than a criminal justice action. To put primary prevention into practice, an integrated multifaceted approach is required.

- The **spectrum of prevention** offers a systematic framework for developing effective and sustainable primary prevention programs.
- Developed by Larry Cohen, the spectrum of prevention identifies multiple levels for community intervention: strengthening individual knowledge and skills; promoting community education; educating providers; fostering coalitions and networks; changing organizational practices; and influencing policy and legislation.
- When used together, these levels are complementary and create synergy that results in greater effectiveness ([Prevention Institute, n.d.](#)).

Nurses may work at each level of the spectrum, by educating individuals and high-risk target populations, working on coalitions to foster increased awareness and use of screening tools by health care providers, and working with multisector partnerships to foster change in workplace, organizational, and community policy. Nurses may work with extended family members of the victims or families who have reported such an incident in their neighborhood and are now fearful of a reoccurrence. See [Chapters 11 and 12](#).

# THE NURSING PROCESS

## *Assessment and Nursing Diagnosis*

Initially, the nurse must assess the nature of the crisis and the client's or community's response to it in a focused community assessment. How severe is the problem, and what are the risks? Who is at risk? Assessment must be rapid but thorough and focused on specific areas.

- First, the nurse concentrates on the immediate problem during the assessment. Why have clients asked for help right now? What are the injuries? How do they define the problem? What precipitated the crisis? When did it occur?
- Next, the nurse focuses on the clients' perceptions of the event. What does the crisis mean to them, and how do they think it will affect their future? Are they viewing the situation realistically? When a crisis occurs to a family or group, some members see the situation differently from others.
- Determine who is available to offer support to the individual or family. Consider family, friends, clergy, other professionals, community members, and agencies. Who are the clients close to, and whom do they trust?
- Finally, the nurse assesses the clients' or community's coping abilities and resources. Have they had similar kinds of experiences in the past? What techniques have they tried in this situation, and if they did not work, why not? Clients should be encouraged to think of other stress-relieving techniques, perhaps ones they have used in the past, and to try them.

After the assessment, a nursing diagnosis is developed. Nursing diagnosis priorities should focus on Maslow's (1971) Hierarchy of Needs at the Physiological and Safety levels related to the act of violence. Ineffective coping related to the client's or community's traumatic event provides a means to increase coping skills. When the violence problem is more community centered, the Omaha System of documentation and information management may be useful as a nomenclature as it comprehensively includes the family and community as clients or modifiers. The system consists of three relational, reliable, and valid components used together: The Problem Classification Scheme, Intervention Scheme, and the Problem Rating Scale for Outcomes ([Omaha System, 2019](#)). The Problem Classification Scheme

includes neighborhood/workplace safety in the environmental domain. See [Chapters 12 and 15](#).

## Planning Interventions

Several factors influence clients' reaction to crises. Nurses should try to determine what factors are affecting clients before making intervention plans. The major balancing factors—clients' perceptions of the event, social supports, human resources, and clients' coping skills—have been assessed in the first step (James & Gilliland, 2017). While continuing to explore these, the nurse now also considers the clients' age, past experiences with similar types of situations, sociocultural and religious influences, general health status, and the actual assets and liabilities of the situation. This assessment helps clarify the situation and gives the nurse an opportunity to further encourage the clients' participation in the resolution process. If clients are defensive, resistant, and rigid, they are not processing clearly and can complete only simple tasks. It will take time before these clients can begin to solve problems related to the effects of the crisis on themselves and the loss they are experiencing, but the nurse will want to encourage them to reach this level.

A plan is based on multiple factors:

- The crisis
- The effect the crisis is having on clients' lives
- Where they are in coming to resolution of the crisis
- The ways in which significant others are affected and respond
- Their level of preparation for such a crisis
- The clients' strengths and available resources

## Implementation of Interventions

During implementation, the partnership between the nurse and clients is important. Discussions about what is happening, reviewing the family's plan and rationale for this approach, and making appropriate changes are necessary. Know the resources in the community so as to make referrals as needed. Referrals may include social workers, mental health practitioners, clergy, law enforcement, or support groups. The C/PHN needs to:

- *Demonstrate acceptance of clients.* Clients need to feel the support of a positive, caring person who does not judge their feelings or behavior.
- *Use therapeutic communication.* Verbal and nonverbal therapeutic communication allows clients to feel safe in expressing their feelings of fear, anger, guilt, or other negative emotions.
- *Assist client in making and reaching achievable goals by using strengths.*
- *Communicate changes with client prior to making them.*
- *Do not offer false reassurance.* Clients need to face reality, not avoid it. A statement such as “Don't worry, it will all work out” is demeaning and meaningless.
- *Discourage clients from blaming others.* Clients often blame others as a way to avoid reality and the responsibility for problem solving.
- *Help clients learn new coping skills by providing alternatives.* Explore and test old and new techniques to reduce stress and anxiety. Ask questions.
- *Encourage clients to accept help from their social support system and spiritual resources as needed.* Denial in the early phases of crisis cuts off help. Encouraging clients to acknowledge the problem is a first step toward acceptance of help.
- *Promote development of new positive relationships.* Clients who have lost significant others through unintentional or intentional death, divorce, incarceration, or an act of perpetrated violence should be encouraged to find new connections, purpose, and people to fill the void and provide needed supports and satisfactions (Ackley, Ladwig, & Makic, 2017).

## **Evaluation**

In the final step, clients and the nurse evaluate, stabilize, and plan for the future. Evaluating the outcome of the intervention might address the following:

- Are the clients using effective coping skills and exhibiting appropriate behavior?
- Are adequate resources and support persons available?
- Is the diagnosed problem solved?
- Have the desired outcomes been met?
- Are modifications needed in the assessment, outcomes, or interventions?

Analysis of these outcomes will provide a greater understanding for coping with future crises.

Clients' plans for the future should include setting realistic goals and means to implement them. Review with clients how their handling of the present crisis can help them cope with, minimize, or preferably prevent future crises.

# SUMMARY

- Violence affects individuals, families, groups, communities, and all of society. Experiencing violence may result in a crisis, a temporary state of severe disequilibrium for persons who face a threatening situation.
- A crisis is a state that individuals can neither avoid nor solve with their usual coping abilities and occurs when some force disrupts normal functioning, thereby causing a loss of balance or normalcy in life. Crises create tension; subsequently, efforts are made to solve the problem and reduce the tension. If such efforts meet with failure, people feel upset, redefine the situation, and try other solutions, and if failure continues, the person eventually reaches the breaking point.
- Violence is a global public health issue. It is not limited by sociodemographic or geographic factors—anyone may experience violence or abuse at any point in their lifetime.
- Acts of violence can result in a crisis—a *crisis* is a stressful and disruptive event (or series of events) that comes with or without warning and disturbs the equilibrium of the individual, family, or community.
- Understanding the neurobiological effects, potential subsequent health effects, and the overlapping causes of violence can help community nurses to enhance protective factors, reduce risk factors, and inform violence intervention and prevention activities.
- Child abuse occurs among children of all ages, from infancy through the teen years, and may be physical, emotional, and/or sexual. Neglect and sexual exploitation are additional forms of child abuse.
- Community violence creates fear and uncertainty and impacts individuals and families that may live, work, play, and pray in close proximity.
- Maltreatment of older adults, often called elder abuse, may involve physical, sexual, emotional or psychological abuse; neglect; abandonment; financial or material exploitation; or self-neglect or any combination of these mistreatments.
- Community health nurses use three levels of prevention when working with families.
  - Primary prevention focuses on providing people with the skills and resources to prevent violent situations.
  - Secondary prevention involves immediate intervention at the time of the violent episode. Secondary level prevention may include medical attention, emotional support, police, and social services involvement.

- Tertiary prevention offers rebuilding services and helps establish equilibrium with a structure that may be different, but healthier. The spectrum of prevention offers a multidimensional approach to building community capacity to address issues of violence.
- People in crisis need and often seek help.
  - Crisis intervention builds on these two phenomena to achieve its primary goal—reestablishment of equilibrium. Crisis intervention begins with assessment of the situation, followed by planning a therapeutic intervention. The nurse then implements and carries out the intervention, building on the strengths and self-care ability of clients. Crisis intervention concludes with resolution and anticipatory planning to avert possible future crises.
- Regardless of the method of intervention used by the C/PHN, the steps of the nursing process provide an intervention framework. Assessing the assets and liabilities, a person's willingness to change, and the nature of the violence help the nurse form a nursing diagnosis. With this diagnosis, the nurse can begin to plan appropriate interventions and implement plans. Evaluation of the intervention techniques provides the nurse with new data to assist with ongoing assessment of the progress and additional anticipatory guidance needs.

# ACTIVE LEARNING EXERCISES

Some activities may be uncomfortable to participate in, please give yourself the freedom to decline on any that cause undue stress.

1. Acts of violence affect the individual, the family, and the community. C/PHNs may practice or live in the area affected by the violence. As registered nurses, it is imperative that we engage in self-care so as to care for our clients. What are some successful self-care methods you have practiced? Is there research that confirms your self-care practice? How might you use that research to help your clients?
2. Gun violence in schools and social events have become part of society. Research legislative bills dealing with gun violence in your community or state. Write a letter in favor of or against the bill based in current statistics and facts.
3. Research “Assess and Monitor Population Health” and “Investigate, Diagnose, and Address Health Hazards and Root Causes” (2 of the 10 essential public health services; see Box 2-2) in relationship to racism and inequity in your community. As a C/PHN, what other essential public health services might you use to make changes?
4. A classmate comes to class with a black eye and upper arm bruising. Describe what you would, or would not, do and why. Role play with a classmate if possible. Although, gender was not mentioned did you assume the classmate was female? Do your actions differ if your classmate is a male? Research what your local community offers on the three levels of prevention of IPV. Where do you see the gaps and how might you correct them?
5. After reviewing your state's child abuse reporting form what do you think would be the most difficult about the process?
  - Research what your state and county laws are regarding filing.
  - What is the policy at your clinical agency?
  - Does your agency follow state law?
  - Self-care is important when working with children abuse cases. Does your agency use debriefing methods?

# **UNIT 5**

## **Aggregate Populations**

# CHAPTER 19

## *Maternal–Child Health*

*“Be gentle with the young.”*

—Juvenal (55–127 AD)

### **KEY TERMS**

Abusive head trauma Alcohol-related birth defects Alcohol-related neurodevelopmental disorder Child abuse Environmental tobacco smoke (ETS) Fetal alcohol effects Fetal alcohol spectrum disorders (FASDs) Fetal alcohol syndrome (FAS) Gestational diabetes mellitus (GDM) Head Start High-risk families Infant Low birth weight (LBW) Preschooler Shaken baby syndrome Sudden infant death syndrome (SIDS) Toddler Very low birth weight (VLBW)

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Identify major health problems and concerns for childbearing women, infants, toddlers, and preschoolers globally and in the United States.
2. Discuss major risk factors and special complications for childbearing families.
3. Describe the important considerations in developing effective health promotion programs to fit the needs of diverse maternal–child populations.
4. Describe various roles of a public and community/public health nurse (C/PHN) in serving the maternal–child population.
5. Recognize resources available regarding recommended immunization schedules for infants and children.
6. Discuss methods and interventions the C/PHN might use in working with infants, toddlers, and preschoolers to help promote their health.
7. Give examples of methods and interventions the C/PHN might use in working with infants, toddlers, and preschoolers to help promote their health.

# INTRODUCTION

*Maternal and child* populations have always been priorities for public health and community and public health nurses (C/PHNs). These populations consist of childbearing women (including pregnant adolescents), infants, children, and adolescents. In this chapter, the focus is specifically on childbearing women (including adolescents) and children from birth through age 4 years. Often, more than half of the practice of C/PHNs in official public health agencies involves primary prevention work with mothers, such as family planning, preconception care, provision of prenatal care, and monitoring infant health. Why should maternal–infant populations require this amount of attention from C/PHNs? Despite advanced technology and availability of excellent perinatal services in the United States, we often have less than optimal birth outcomes—for instance, 318,847 low birth weight and 381,321 preterm infants were born in 2014 ([Centers for Disease Control and Prevention \[CDC\], 2016d](#)). Also, certain segments of the maternal and infant populations, such as adolescent mothers, those who are economically disadvantaged, and women and children of color, remain at high risk for disparities in regard to maternal deaths and complications and child risk and illness. Although some women receive excellent prenatal care and benefit from diagnostic and technological resources, many others lack access to prenatal care.

This chapter addresses major areas of concern regarding population health for maternal–infant clients. It also explores the global needs of and related services available to the youngest and thus most vulnerable of society's members. Health services that are commonly available in the United States for pregnant and postpartum women, infants, toddlers, and preschoolers are examined, and the role of the C/PHN in providing those services is explored.

# **HEALTH STATUS AND NEEDS OF PREGNANT WOMEN AND INFANTS**

C/PHNs constitute a key group of health professionals involved in both program planning and the actual delivery of services to mothers and babies in the community. In the public health sector, these nurses are the largest group of professionals practicing public health. A solid understanding of vital statistics and other data regarding mothers and infants is important to determine the appropriateness and the effectiveness of programs and services. A review of some global and national vital statistics provides insight into the major problems facing maternal and child populations.

## Global Overview

Maternal and newborn health has been thrust into the global community spotlight since the publication of the Sustainable Development Goals in 2015 ([Global Burden of Disease 2015 Maternal Mortality Collaborators, 2016](#)). The goal was to improve women's and children's health on a global scale through 17 sustainable development goals. The main key to decreasing maternal mortality is to increase prenatal care benefits and coverage.

### *Maternal Mortality Rate*

One of the major indicators of population health is maternal health, which is often measured by the maternal mortality rate (MMR). The MMR is a measure of obstetric risk and is determined by dividing the number of maternal deaths by the number of live births per 100,000. Most maternal deaths are the result of direct causes (complications of pregnancy, labor, and delivery), hypertensive disorders, intervention omissions or incorrect treatment, the chain of events resulting from any one of these, and unsafe abortions. In developing countries, the MMR is 239 per 100,000 live births, compared with developed countries, where the MMR is around 12 per 100,000 live births—a very wide disparity ([World Health Organization \[WHO\], 2018a](#)). The U.S.'s MMR has risen from 7.2 per 100,000 live births in 1987 to 16.9 per 100,000 live births in 2016, although it has fluctuated between a low of 14.1 and a high of 17.8 per 100,000 live births since 2002 ([CDC, 2018j](#)). Although worldwide the MMR has decreased since 1990 by 44%, the worldwide goal is to eliminate preventable maternal death by 2030 ([WHO, 2018a](#)). This goal is achievable because most countries have implemented successful policies to eliminate maternal–child inequities ([Box 19-1](#)).

### **BOX 19-1 Evidence-Based Practice**

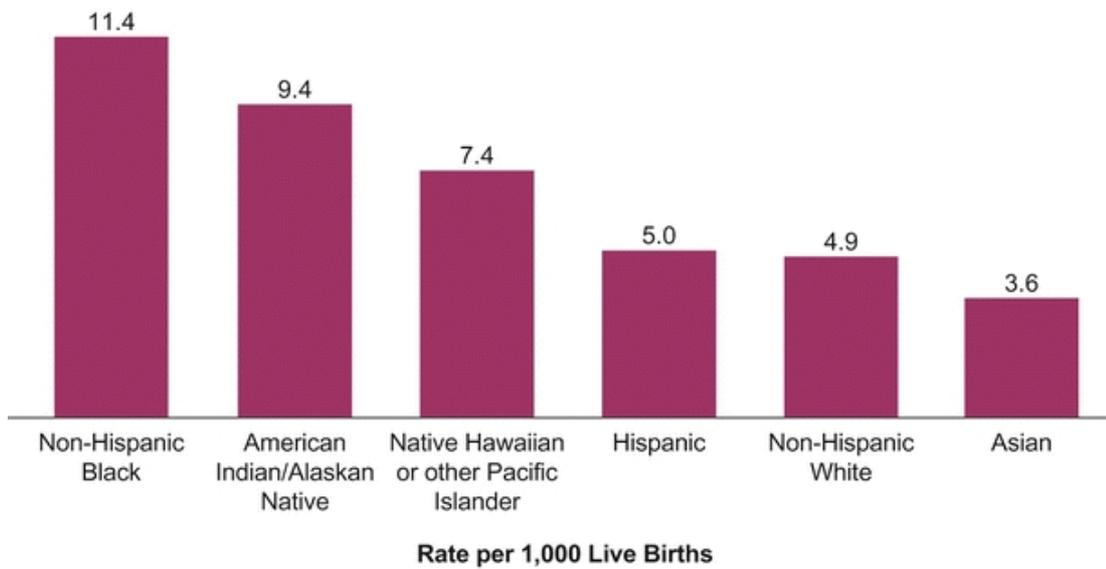

**Reducing Child Mortality in Bangladesh** Child mortality rates have declined significantly in Bangladesh over the last 25 years. Bangladesh has experienced a 76% reduction in the under-five mortality rate from 144 per 1,000 in 1990 to 34 per 1,000 in 2016. Additionally, the neonatal mortality rate was decreased by 68% from 64 per 1,000 in 1990 to 20 per 1,000 in 2016 ([World](#)

**Bank Group, 2018). Routine childhood immunizations, oral rehydration therapy, and supplementation of vitamin A are interventions that have significantly influenced this reduction in child mortality rates. Full vaccination of children 12 to 23 months increased from 60% in 2000 to 84% in 2014. Children receiving oral rehydration therapy for diarrhea increased from 74% in 2000 to 84% in 2014 (Ministry of Health & Family Welfare, 2015). Vitamin A supplementation increased from 49% in 1994 to 62% in 2014. Furthermore, the government of Bangladesh implemented a nutrition plan in its National Health Strategy. Children who were underweight decreased from 43% in 2004 to 33% in 2014. Although these improvements are dramatic, additional developments in sustainable trends and equity are essential (Baruah et al., 2013).**

Source: Baruah *et al.* (2013); Ministry of Health and Family Welfare, Bangladesh, Partnership for Maternal, Newborn, & Child, WHO, World Bank and Alliance for Health Policy and Systems Research (2015); World Bank Group (2018).

### *Infant Mortality Rate*

Another critical population health indicator is the infant mortality rate (IMR). Globally, 4.2 million children under 5 years of age died in 2016, which is a significant decrease from the 8.8 million who died in 1990 (WHO, 2018b). Of these 4.2 million deaths, 44% took place during the neonatal period and were primarily caused by preterm birth, birth asphyxia, and infection. More than half of the deaths for children under 5 years of age are preventable and the interventions are affordable (WHO, 2018b). In the United States, the IMR was 5.9 per 1,000 live births in 2016 (CDC, 2018j). Although this is a decrease from years past, 23,000 infants still died in 2016 in the United States. See [Figure 19-1](#) for U.S. IMR ethnic comparison data.

**FIGURE 19-1** Infant mortality rates by race and ethnicity, 2016. (Reprinted from Centers for Disease Control and Prevention. (n.d.). *User guide to the 2016 Period Linked Birth/Infant Death Public Use File* (p. 80). Retrieved from <https://www.cdc.gov/reproductivehealth/maternalinfanthealth/infantmortality.htm>)

## National Overview

In the United States, the birth rate has decreased each year since 2007; in 2018, nearly 3.8 million women gave birth, a decline in the birth rate of 2% from the previous year (Martin, Hamilton, Osterman, & Driscoll, 2019). The general fertility rate declined to a total of 59.1 births per 1,000 women aged 15 to 44 years. Birth rates declined for non-Hispanic White, Hispanic, and African American women. Just over 40% of births were to unmarried women (Martin et al., 2019). When unmarried women rely on a single income, financial resources are more limited, and many of these women raise their children at poverty or near-poverty income levels, which impacts their health and their children's health over the life course of both (Fig. 19-2).

**FIGURE 19-2** Support for mothers and children helps ensure healthier families.

Child Health USA (U.S. Department of Health and Human Services [USDHHS], Health Resources and Services Administration [HRSA], Maternal and Child Health Bureau [MCHB], 2014) reports that adequate prenatal care is associated with adequate health insurance. In 2012, 88% of privately insured women and 83% of Medicaid-insured women received adequate prenatal care (defined as four or more provider visits during pregnancy). Seventy-two percent of those who were uninsured were least likely to receive adequate prenatal care. This correlates with health inequity characteristics such as race and ethnicity, poverty, and low maternal education levels (less than high school education).

Historically, the health of U.S. women and children has largely fallen under the umbrella of Title V of the Social Security Act, enacted in 1935. (For more on the Social Security Act, see Chapter 6.) Funding for state

Maternal and Child Health and Crippled Children programs was part of this original legislation, as was some provision for child welfare services. Title V is “the longest-standing public health legislation in American history” and came to fruition after other legislation established a National Birth Registry; provided *Infant Care*, the first educational pamphlet; established the Children's Bureau; and provided protection against child labor practices (i.e., the first Child Labor Law of 1916; MCHB, n.d.b, para. 4). For an illustration of MCHB functions and programs, see [Box 19-2](#).

## **BOX 19-2 Types of Services Offered Through Federal Maternal–Child Health Funding**

### **Direct Health Care Services (Gap Filling)**

**Examples: Basic Health Services and Health Services for Children with Special Health Care Needs (CSHCN)**

**Enabling Services Examples: Transportation, Translation, Outreach, Respite Care, Health Education, Family Support Services, Purchase of Health Insurance, Case Management, Coordination with Medicaid, WIC, and Education**

**Population-Based Services Examples: Newborn Screening, Lead Screening, Immunization, Sudden Infant Death Syndrome Counseling, Oral Health, and Injury Prevention**

**Infrastructure Building Services Examples: Needs Assessment, Evaluation, Planning, Policy Development, Coordination, Quality Assurance, Standards Development, Monitoring, Training,**

# Applied Research, Systems of Care, and Information Systems

Source: U.S. Department of Health and Human Services (2008).

In 1909, formal prenatal care was first provided in Boston by the Instructive District Nursing Association and spread across the country to outpatient clinics (MCHB, n.d.a). Since the inception of Title V, many programs have been developed with the goal of improving the health of women of childbearing age, as well as infants and children. Research areas have included prenatal and pregnancy health, child development and parenting, and improving health care systems and delivery of care, as well as obesity, nutrition, medical homes, school services and outcomes, and behavioral health (MCHB, n.d.b). Healthy Start grants were first awarded in 1991 to 15 agencies, with the goal of reducing rates of infant mortality, low birth weight, premature births, and maternal deaths (MCHB, n.d.c). Evaluation of Healthy Start programs reveals that almost all programs provide home visitation to prenatal clients, and most continued these visits to infants and toddlers. Health education, smoking cessation counseling, services for perinatal depression, and involvement of male partners are hallmarks of most programs.

In 2017, \$374.4 million in grants were awarded to expand the Maternal, Infant, and Early Childhood Home Visiting Program (Home Visiting Program). This program provides C/PHN visits, assistance from social workers, teaching from early childhood educators, and services from other professionals to expectant families, much like the program designed by David Olds (HRSA, 2018). Early improvements in six benchmark areas were noted (MCHB, n.d.d, p. 3):

- Maternal and newborn health
- Child injuries, child maltreatment, and emergency department visits
- School readiness and achievement
- Crime or domestic violence
- Family economic self-sufficiency
- Service coordination/referrals for other community resources/support

## *Birth Weight and Preterm Birth*

Birth weight is one of the most important predictors of infant mortality. **Low birth weight (LBW)** refers to babies who weigh <2,500 g (or <5.5 lb) at birth; **very low birth weight (VLBW)** refers to babies who weigh <1,500 g (or <3 lb 4 oz) at birth. An estimated 15 million infants are born prior to 37 weeks of gestation, making them preterm, and this number is still on the rise (Fig. 19-3; WHO, 2018b). Complications from infants born preterm led to 1

million deaths in 2015 and are the number-one cause of death under the age of 5 years.

**FIGURE 19-3** Infant in the neonatal intensive care unit.

Infant complications of preterm birth include hearing and vision problems; acute respiratory, gastrointestinal, and immunologic problems; and central nervous system (CNS), motor, cognitive, behavioral, and socioemotional disorders. A variety of growth concerns as well as acute and chronic health and developmental problems often occur, and the families of these infants are burdened with additional economic and emotional costs. In a study of children from birth to age 2 years who were preterm as infants, those with feeding difficulties or at risk for feeding difficulties had significant neurodevelopmental problems, such as impaired cognition and impaired language, motor, and socioemotional skills, that led to increased parental stress, poorer maternal mental health, or increased family stressors compared with those preterm infants who did not have feeding difficulties. Maternal mortality, LBW, and VLBW are three areas requiring attention by health care providers and the public health system. Nurses can contribute to reducing these rates and societal costs through outreach, surveillance, health teaching, counseling, and referral ([Save the Children, n.d.](#)).

In addition to infant deaths and LBW, the effects of pregnancy and childbirth on women are other important indicators of health and reflect discrepancies in access to reproductive health care. The United States is not ranked among the top 10 countries in maternal–child health in the *2015 Mother's Index*. It is ranked 33rd out of the more developed countries. The U.S. ranking is largely due to poorer scores on the indices of maternal and child health. The Eastern European countries of Slovakia, the Czech Republic, Belarus, and Croatia and the developing countries of Peru and Ethiopia rank higher than the United States ([Save the Children, n.d.](#)).

In the United States, the MMR is higher than in other developed countries, mostly because of the disparities found among women of color. The MMR for Blacks (42.4 per 100,000 live births) is between three and four times greater than that for Whites (13.0), and the gap has continued to widen since 1986, when the MMR surveillance was initiated ([CDC, 2020e](#)). Pregnancy-related death risk increases with age and with lack of prenatal care for women of every race, but the risk of pregnancy-related death for U.S. Black women is three to four times greater than for White women. Even though the rate of maternal deaths is low, most maternal deaths are preventable.

One of the maternal–child objectives for *Healthy People 2030* is to improve the proportion of infants who are breastfed. Breastfeeding is beneficial to both mother and infant, and recently, 79.2% of mothers reported ever breastfeeding. Only 49.4% of U.S. infants were breastfed for the recommended 6-month period, and 18.8% were breastfed exclusively for this 6-month period. It is estimated that if 90% of U.S. families would comply with the recommended American Academy of Pediatrics guidelines regarding exclusive breastfeeding, \$3.7 billion in direct and indirect pediatric health costs and \$10.1 billion in costs related to premature death resulting from pediatric disease would be saved ([AmericanPregnancy.org, 2018](#)). See [Box 19-3](#) for *Healthy People 2030* maternal, infant, and child health objectives.

### **BOX 19-3 *HEALTHY PEOPLE 2030***

**Objectives for Maternal, Infant, and Child Health**  
**Improve the health and safety of infants; prevent pregnancy complications and maternal deaths; improve women's health before, during, and after pregnancy; and improve the health and well-being of children.**

### Core Objectives

MICH-01	Reduce the rate of fetal deaths at 20 or more weeks of gestation
MICH-02	Reduce the rate of all infant deaths
MICH-03	Reduce the rate of deaths in children and adolescents aged 1–19 years
MICH-04	Reduce maternal deaths
MICH-05	Reduce severe maternal complications identified during delivery hospitalizations
MICH-06	Reduce cesarean births among low-risk women with no prior births
MICH-07	Reduce preterm births
MICH-08	Increase the proportion of pregnant women who receive early and adequate prenatal care
MICH-09	Increase abstinence from alcohol amongst pregnant women
MICH-10	Increase abstinence from cigarette smoking among pregnant women
MICH-11	Increase abstinence from illicit drugs among pregnant women
MICH-12	Increase the proportion of women of childbearing age who get enough folic acid
MICH-13	Increase the proportion of women who had a healthy weight before pregnancy
MICH-14	Increase the proportion of infants who are put to sleep on their backs
MICH-15	Increase the proportion of infants who are breastfed exclusively through age 6 months
MICH-16	Increase the proportion of infants who are breastfed at 1 year
MICH-17	Increase the proportion of children who receive a developmental screening
MICH-18	Increase the proportion of children with autism spectrum disorder who receive special services by age 4 years
MICH-19	Increase the proportion of children and adolescents who receive care in a medical home

### Developmental Objectives

MICH-D01	Increase the proportion of women who get screened for postpartum depression
MICH-D02	Reduce the proportion of women who use illicit opioids during pregnancy
MICH-D03	Increase the proportion of infants who are put to sleep in a safe sleep environment

## *Adolescent Mothers*

In 1991, after a steady 5-year upward trend, the United States reached a 20-year high in the number of children born to teen mothers (aged 15 to 19 years) of 61.8 per 1,000. That trend then reversed, with 2007 marking a decline in teen birth rates to 41.5 per 1,000. In 2018, the trend continued, with 17.4 births per 1,000 females aged 15 to 19 years ([Martin et al., 2019](#)). Furthermore, 38 states saw a decrease in birth rates among this age group ([Martin et al., 2019](#)). The decrease in teen birth rate can be attributed to several behavioral changes, such as decreased sexual activity, increased use of contraception at first sex and at most recent sex, and the increased use of contraception methods. Although the United States has seen a decrease in teen births, the country continues to have much higher teen birth rates compared with other developed countries, including Canada with a birth rate of 6.6 per 1,000 ([Elflien, 2019](#)). See [Chapter 20](#) for more on adolescent pregnancy.

The *Healthy People 2030* ([USDHHS, 2020](#)) document encompasses specific goals and objectives for the maternal–child population, based on the previous achievements in the same or similar areas. After years of working

toward improving maternal–child health, the United States has made limited progress. One objective, however, has been met; 70% of infants are now sleeping on their backs, up from a 35% baseline. The rate for sudden infant death syndrome had dropped by over 50% since 1994. This can be attributed to the national public health education campaign known as “Back to Sleep” (Eunice Kennedy Shriver National Institute of Child Development and Health, 2016).

## **Risk Factors for Pregnant Women and Infants**

Most pregnant women in the United States are healthy; they have normal pregnancies and produce healthy babies. Many factors contribute to the health problems of those mothers and babies who figure in the statistics on infant mortality and LBW. The factors associated with LBW and infant mortality can be grouped into three categories (CDC, 2017b):

1. Lifestyle: Smoking, secondhand smoke exposure, inadequate nutrition, alcohol consumption, substance abuse, late prenatal care, environmental toxins, stress, violence, and lack of social support
2. Sociodemographic: Maternal age below 15 or above 35 years, low educational level, poverty, domestic violence, and unmarried status
3. Medical and gestational history: Primiparity, multiple gestation, short interpregnancy intervals, premature rupture of the membranes, uterine abnormality, febrile illness during pregnancy, spontaneous abortion, genetic factors, gestation-induced hypertension, less-than-ideal weight gain during pregnancy, and diabetes

It is in the area of lifestyle choices that nurses can have the most significant impact on pregnancy outcomes such as LBW, preterm birth, and infant mortality. Programs that provide access to and funding for C/PHNs are available through federal, state, and local funding (Box 19-4).

### **BOX 19-4 Evidence-Based Practice**

**Home Visiting** There are many ways C/PHNs can help moms and babies. One of the programs in which a nurse can do this, in a very fundamental way, is through the NurseFamily Partnership (NFP) program. The program was created by Dr. David Olds and came out of his experience working in a daycare. He quickly realized that to make an impact, he needed to reach families earlier in life. Thus, the NFP was born. Dr. Olds has done research to test and improve the program in Elmira, NY; Memphis, TN; and Denver, CO. The results have been consistent; NFP improves

**the lives of both moms and babies through the tenacious work of a registered nurse (RN). The program is guided by a robust theoretical framework that includes; self-efficacy, human ecology, and attachment theories. Nurses follow a curriculum based on these theories from the time the client finds out she is pregnant until the baby turns 2 years old. NFP nurses go through a rigorous and well-planned training curriculum. This training includes courses in Denver, Colorado at the National Service Office, in a way that ensures fidelity to the NFP model.**

Previous research has been completed in 2002, 2004, and 2014 examining both paraprofessionals and nurses visiting clients. The studies showed that RNs had a more significant impact on varying outcomes of the program. The relationship that is formed between the RN and the client is one based on trust and support. The client begins to see the nurse as part of the family, and someone that she can go to with any concern. The NFP nurse home visitor becomes a life coach, lifting the client up in one of the toughest parts of a women's life pregnancy and the first 2 years of motherhood. NFP nurses offer praise and screen the baby to make sure milestones are being met. Parenting skills are taught, references are made, if needed, and encouragement is given. Clients can contact their NFP nurse with questions about their bodies, their babies, future plans, relationships, and so much more. The program provides the kind of consistency and advocacy that many of the clients have never experienced. The NFP nurse is a true ally and fierce advocate for both mom and baby in the critical early years of motherhood.

Source: [NurseFamily Partnership \(2018a, 2018b\)](#); [Olds et al. \(2002, 2004, 2013\)](#).

### *Substance Use and Abuse*

Another area of concern is substance use and abuse among the childbearing population. The range of adverse consequences associated with the use of tobacco, alcohol, and illicit drugs during pregnancy is wide and includes preterm birth, LBW, and fetal alcohol spectrum disorders (described later in

this chapter). This puts these women and their unborn children in double jeopardy; not only are they at risk from the consequences of alcohol or drug use, but also they do not receive the preventive prenatal care that can eliminate or reduce other obstetric complications. This is most often related to the pregnant woman's concerns about legal ramifications of substance use while pregnant if they do seek care.

Substance abuse during pregnancy is a problem with staggering social and medical implications, such as preterm births, LBW, miscarriage, placental abruption, developmental delays, and child behavior and learning problems later in life ([American Pregnancy Association, 2016](#)). The precise rate of substance abuse among pregnant women is difficult to determine. In a large study ( $n = 27,874$ ) of substance abuse and pregnancy, 26.3% of the women reported previous use and 2.6% current use. Adverse outcomes of these pregnancies included LBW, preterm birth, babies born small for gestational age, and admissions to neonatal intensive care units (NICUs).

The United States has seen an increased incidence of neonatal abstinence syndrome (NAS) as a result of heroin or other opioid use in pregnancy, with a NAS diagnosis every 25 minutes ([Anbalagan & Mendez, 2020](#)). The [U.S. Agency for Healthcare Research and Quality \(2019\)](#) reports 7 per 1,000 newborns are hospitalized for NAS. Between 1999 and 2014, there was a 333% increase in NAS ([Anbalagan & Mendez, 2020](#)). The states with the highest numbers of newborns hospitalized include West Virginia (48.1), Maine (33.1), Delaware (26.4), and Kentucky (22.9), with South Dakota at the lowest with 1.5 ([U.S. Agency for Healthcare Research and Quality, 2019](#)). Yet, not all states mandate the reporting of NAS, and/or states may differ in the NAS definition, which causes problems in determining rates ([Anbalagan & Mendez, 2020](#)). NAS occurs as a result of the sudden discontinuation of fetal exposure to substances such as heroin or other opioids during pregnancy. Withdrawal symptoms experienced by these infants include irritability, excessive or high-pitched crying, tremors, and gastrointestinal problems such as diarrhea. In the event that nonpharmacologic care does not alleviate these symptoms, morphine is the most commonly used pharmacologic treatment for withdrawal symptoms related to NAS. The long-term effects of NAS are not fully understood known due to socioeconomic and environmental factors of the mother, but these children may have poor school performance, vision problems, cognitive disabilities, neurodevelopmental delays, and higher mortality rates ([Anbalagan & Mendez, 2020](#)). It is clear more research needs to be done on this vulnerable population.

A lifestyle choice that includes the use of drugs during pregnancy and results in maternal addiction has placed millions of children at risk. These children are seen in NICUs, foster care, special education programs in the public schools, and later in the juvenile court system. Family structure

patterns are altered because grandparents may find themselves primary caregivers for their grandchildren. A woman who uses alcohol or drugs may lose her inhibitions and engage in high-risk sexual behaviors, which can introduce other public health problems, such as acquisition of sexually transmitted infections (STIs), including HIV, and possible spread of the infection to the fetus or others (CDC, 2019g). The primary, secondary, and tertiary prevention interventions of the C/PHN cannot be underestimated when drug use takes such a high toll on every aspect of society.

## *Alcohol Use*

Another societal problem is the use of and addiction to alcohol. It is difficult to establish accurate statistics on the number of women who drink during pregnancy, but results from the 2011 to 2013 Behavioral Risk Factor Surveillance System indicate that roughly 1 in 10 pregnant women drank alcohol within the past 30 days, compared with 53.6% of nonpregnant women. Prevalence of binge drinking was 18.2% for nonpregnant women and 3.1% for pregnant women, with a 4.6-times greater rate for unmarried pregnant women (CDC, 2015b).

The conditions that can occur in a child due to maternal drinking of alcohol during pregnancy are collectively known as **fetal alcohol spectrum disorders (FASDs)**. The most severe type of FASD is **fetal alcohol syndrome (FAS)**, which can result in facial abnormalities, delayed growth and development, neurologic defects, learning and sensory problems, and even death. What was once termed **fetal alcohol effects**, characterized as causing some but not all of the symptoms of FAS, is now separated into the more descriptive categories of **alcohol-related birth defects**, indicating problems with hearing, bones, heart, and kidneys, and **alcohol-related neurodevelopmental disorder**, represented by mental or functional problems, including cognitive and/or behavioral abnormalities (CDC, 2020b). Physical signs of FASDs are often much more subtle than in cases of FAS. However, those with FASD may have one or more of the following behaviors or characteristics (CDC, 2020c):

- Small size for gestational age or small stature in relation to peers
- Facial abnormalities (e.g., smooth philtrum)
- Poor coordination
- Hyperactivity, attention problems, and learning disabilities
- Difficulties in school, especially with math
- Developmental disabilities (e.g., speech and language delays)
- Intellectual disability or low intelligence quotient (IQ)
- Vision and hearing problems; problems with heart, kidneys, and bones
- Poor reasoning and judgment skills
- Sleep and sucking disturbances in infancy

It is important to provide evidence-based primary prevention before pregnancy and to reach women before drinking becomes such a part of their lives that they are unable or unwilling to abstain during pregnancy. For example, the Pregnancy Risk Assessment Monitoring System (PRAMS) is a surveillance system developed by the CDC and state health departments to collect population-based information on maternal preconception, prenatal, pregnancy, and postpartum behaviors and experiences. Data collected from 2016 revealed that <10% of women used tobacco 3 months prior to conception, and 7.1% continued to smoke while in the first trimester. This percent dropped in each trimester, with a decrease to 5.7% in the third trimester (Kondracki, 2019). Children are also at risk based on maternal alcohol use during child-rearing, especially for adolescent mothers aged 15 to 19 years.

Working with women of childbearing age to improve their general health behaviors and promote better preparation for pregnancy is essential. For those pregnant women and mothers already using substances, maternal drug and alcohol treatment programs that focus on supportive parent–child attachment, enhancement of parenting and child-rearing capabilities, and encouragement of the use of support systems that can improve child health and cognitive development are needed. In-home family skills training and parenting education programs that are evidence based and promote C/PHN and client rapport can be effective methods of working with substance-abusing mothers and their at-risk children; however, more studies are recommended. In a systematic review of home visitation with alcohol-and drug-using mothers, there was no significant reduction of substance abuse among mothers entering drug and alcohol rehabilitation programs compared with those receiving home visitation. However, individual studies showed significance of home visitation in reducing these mothers' involvement with Child Protective Services, indicating a positive effect on parenting and childcare practices even if it did not effectively diminish the addictive behavior (Dauber et al., 2017).

### *Tobacco Use*

Tobacco use has increased dramatically among women, especially since the women's movement of the 1970s, inevitably affecting maternal and newborn health. The nicotine in tobacco is a major addictive substance, and smoking is an addiction that many people find difficult to stop. Although the risk factors of smoking are well documented, many pregnant women continue to smoke. Smoking during pregnancy is one of the most studied risk factors in obstetric assessment. Women, who may have started smoking as adolescents, often continue to smoke in response to life stressors. From a population and C/PHN perspective, one study found that the higher the density of tobacco stores in a neighborhood, the higher the prevalence of smoking among

pregnant women ([Galiatsatos et al., 2020](#)). The use of e-cigarettes, or vaping, is considered to be a health danger for pregnant women and developing fetuses. This nicotine delivery system poses threats to the baby. Also, the exhaled aerosol that is advertised to be “water vapor” actually contains nicotine and other chemicals such as metals, nitrosamines, and volatile organic compounds ([CDC, 2016b](#)).

Passive smoking or **environmental tobacco smoke (ETS)**—exposure to tobacco smoke from other people smoking in one's environment—also puts a person at risk for smoking-related disease. The Surgeon General has outlined major conclusions related to ETS based on years of research findings. One conclusion is that there is no risk-free level of secondhand smoke. Related to children and ETS, there is an increased risk of SIDS, more acute respiratory infection, ear disease, worse asthma, and risk for poor lung growth ([Dede & Cinar, 2016](#)). If a pregnant woman lives with a smoker, she and her fetus can be negatively affected by the other person's addiction. An initial health history of a pregnant woman should always include the assessment of tobacco use, smoking status, and exposure to smoke in the personal environment.

C/PHNs and other health care professionals must be involved in the control of tobacco products on many levels, especially in health policy development, community outreach, education, and advocacy. It is very common to see smoking incentives and advertisements in poorer neighborhoods and communities of color. It is also important to have skills in smoking risk assessment, cessation options, and symptom management interventions for smoking withdrawal. Nurses should serve as positive nonsmoking role models and to be active in research implementation using clinical guidelines and evidence-based practices. In the case of tobacco control, health policy development has made important strides at the grassroots level (see [Chapter 13](#)).

The C/PHN must not only advise clients to quit smoking but also offer supportive and empathetic approaches to stress reduction during smoking cessation, including methods or interventions that can help other symptom management that is associated with smoking cessation. For example, the C/PHN may counsel clients individually, refer for behavioral therapy, provide self-help manuals, or recommend nicotine replacement therapy or medication. Other approaches, such as support groups, can be helpful. Any permanent reduction in the number of cigarettes smoked, amount of secondhand smoke inhaled, or amount of smokeless tobacco products used is helpful in improving the health of the mother and her fetus. Particular attention should be paid to adolescent mothers (15 to 19 years), as their rates of smoking are much higher than for adolescents of similar age who are not mothers ([Substance Abuse & Mental Health Services Administration, 2014](#)).

## *Intimate Partner Violence*

Intimate partner violence (IPV) is any sexual, physical, economic, and/or psychological abuse taken by someone against an intimate partner or ex-partner ([New York City Department of Health and Mental Hygiene, 2020](#)). Pregnancy is a vulnerable period for women and can increase their risk for IPV. It is estimated that 1 in 6 pregnant women from all walks of life experience IPV per year ([March of Dimes, n.d.](#)). Reasons for increased IPV during pregnancy can be an unintended pregnancy, increased stress related to supporting a child, and jealousy. These women may also avoid prenatal care services for a variety of reasons such as injuries, control by their partners, and a lack of resources such as transportation or money for mass transit. Pregnant women who experience psychological IPV have a 1-fold increase in the risk of suicidal ideation ([Tabb et al., 2018](#)). IPV can also have effects on the newborn and infant. In a longitudinal study of women who had experienced IPV, posttraumatic effects were found to have negative effects on the infants' and toddlers' language and neurologic development ([Udo, Sharps, Bronner, & Hossain, 2016](#); see [Chapter 18](#)).

## *Sexually Transmitted Infections and Sexually Transmitted Diseases*

Although STI and STD have been used interchangeably for some time, there are differences between the two terms. STIs refer to a person being infected but asymptomatic, and sexually transmitted disease (STD) is used when symptoms are present ([Rudderown, 2019](#)). The CDC estimates the prevalence of all STI cases in the general population to be 110 million, with an annual incidence of 20 million, and health care costs of \$16 billion. The [CDC \(2016e\)](#) has recommended STD screening of all pregnant women at the initial prenatal visit for *Chlamydia*, hepatitis B (and hepatitis C for high-risk mothers), HIV, and syphilis. Further, they recommend screening high-risk pregnant women for gonorrhea.

STIs can pass from mother to baby. Syphilis can cross the placenta and infect the fetus, as can HIV—which can also be passed to the infant through breastfeeding ([CDC, 2016e](#)). Congenital syphilis (CS) is on the rise at alarming rates. Between 2012 and 2017, the rate of CS increased 750% in California ([California Department of Public Health, 2019](#)). This increase is seen across the United States, where there has been a 153% increase from 2013 to 2017 to 918 cases ([Schmidt, Carson, & Jansen, 2019](#)). Other STIs (e.g., gonorrhea, hepatitis B, *Chlamydia*, genital herpes) can infect the baby as it passes through the birth canal during delivery. LBW, stillbirth, conjunctivitis, blindness, deafness, neurologic damage, chronic liver disease, and cirrhosis, along with neonatal sepsis and pneumonia, are possible infant complications of maternal STIs. Mothers may have premature rupture of

membranes and resultant infection or may have a premature onset of labor. Some STIs can lead to cervical and other cancers, pelvic inflammatory disease, infertility, chronic hepatitis, and many other health problems ([CDC, 2019f](#)).

A pregnant woman who discovers she has an STI often feels ashamed, betrayed, embarrassed, and angry. Those who are asymptomatic may not realize they are infected or deny the existence of the disease and fail to carry out the treatment plan after diagnosis. Although educating the pregnant client about the effects of STIs is critical, providing information alone is not enough. The C/PHN has a pivotal role in enhancing the empowerment of women so they can act on the information they receive. The C/PHN engages with pregnant clients and helps them understand that they have control over their bodies. Usually, STIs are first discovered in pregnancy during routine prenatal screening, which places the clinic nurse and the nurse who may make home visits in the position to take an affirmative approach to treatment and follow-up.

## *HIV and AIDS*

There are 36.9 million individuals living with human immunodeficiency virus (HIV). Almost 70% of all cases are found in sub-Saharan Africa ([WHO, 2016](#)). Most children with acquired immunodeficiency syndrome (AIDS) are children of HIV-positive mothers ([WHO, 2020](#)). Mother-to-child transmission (MTCT) of HIV can be almost fully prevented with antiretroviral treatment for mother and infant ([WHO, 2020](#)). To reduce MTCT, women must seek prenatal care early enough in their pregnancies for the antiretroviral drug to be effective. Antiretroviral therapy was provided to an estimated 20.9 million persons in 2017 ([HIV.gov, 2018](#)).

Early detection of HIV/AIDs and antiviral therapy has shown decline in the number of infants born with HIV since the height of the epidemic. A large-scale study conducted from 2005 to 2012 examining the association between mother and child HIV transmission in 15 jurisdictions of the United States found that 2% were diagnosed with HIV. It was concluded that there was an increased risk of having an HIV-infected infant among those mothers who received late testing/prenatal care or no prenatal antiretroviral therapy ([Camacho-Gonzalez et al., 2015](#)). An HIV-positive woman who is pregnant or who has delivered a baby requires special nursing management of the pregnancy and of the family after the birth of the newborn. There are many teaching opportunities for the C/PHN during a high-risk pregnancy, such as helping the client identify, change, or curtail high-risk behaviors and promoting adherence to prenatal and HIV care. Success in changing behaviors often requires an interdisciplinary approach of health care, social,

emotional, and financial resources ([Bungay, Massaro, & Gilbert, 2014](#); [CDC, 2015a](#)).

In the United States and other developed nations, HIV-infected women are advised not to breastfeed their infants because there is a chance that the infants will become infected with HIV from breast milk ([CDC, 2020d](#)). The C/PHN focuses teaching on providing a safe, available, and low-cost form of infant formula. In developing countries, the lack of clean water still makes formula feeding dangerous, and breastfeeding is usually recommended. The infection rate for HIV from breastfeeding and the mortality rate from formula made with impure water are about the same, resulting in a dilemma for women and health care providers in developing countries.

### *Poor Nutrition, Weight Gain, and Oral Health*

Research has demonstrated a positive correlation between weight gain during pregnancy and normal birth weight in the babies. In 2009, the Institute of Medicine (IOM) released new guidelines for weight gain during pregnancy based on body mass indices (BMIs). Weight gain between 25 and 35 lb during pregnancy is recommended for women with BMIs ranging from 18.5 to 24.9, and the recommendation is 28 to 40 lb for underweight women with a BMI under 18.5, whereas overweight women with a BMI between 25 and 29 should gain 15 to 25 lb, and obese women with a BMI over 30.0 should hold their weight gain to between 11 and 20 lb ([IOM, 2009](#)). The American College of Obstetricians and Gynecologists (ACOG) reaffirmed in 2016 that the 2009 IOM gestational weight gain guidelines are important for clinicians to use. It is recommended that clinicians determine a woman's BMI at the initial prenatal visit and discuss weight gain, diet, and exercise goals initially and throughout the pregnancy ([Fig. 19-4](#); [ACOG, 2013](#) and reaffirmed in [2016](#)).

**FIGURE 19-4** Weight gain during pregnancy should be monitored regularly.

Obesity currently affects about 39.8% of all adults (CDC, 2018a). Studies have shown that about 48% of pregnant women in the United States gain more than the recommended amount of weight (CDC, 2016f). Gestational diabetes poses the greatest risk to obese pregnant women and increases the risk for preterm birth (CDC, 2017c). C/PHNs who work with morbidly obese pregnant women can help them most by emphasizing good nutrition and by encouraging them to maintain their pre-pregnant weight without drastically reducing caloric intake. This can be accomplished primarily by a marked decrease in consumption of “empty calories” from junk food and replacing with increased intake of fruits, vegetables, and low-fat sources of calcium. Pregnancy is never a time for dieting. Nutritional counseling can have an additional benefit in that it may ultimately decrease the risk of obesity or eating disorders in the client's children. For women who

are prone to gaining too much weight, nutrition-rich, low-calorie foods are recommended.

Exercise during pregnancy is essential and can moderate maternal weight gain and improve overall fitness that is desirable for the labor and delivery process. After assessment, the C/PHN can determine whether the unwanted weight gain is related to the consumption of additional calories, to limited activity, or to fluid retention. Each cause must be managed differently. Underweight women have twice as many LBW babies as women whose weight is within normal range. Nutritional teaching is part of the C/PHN's role when working with a pregnant woman who has difficulty gaining the recommended weight during pregnancy. Finding ways to add calories to foods and increasing the woman's desire to eat are effective methods to improve maternal weight gain. Insufficient caloric intake in pregnant adolescents (who themselves are still growing) is an additional concern for their future health and health of the infant over the life course.

Periodontal infection may affect around 40% of women of childbearing age and is especially common among disadvantaged and ethnic or racial minorities who may not have adequate access to dental health care. Maternal periodontal disease has been linked to preterm birth, LBW, preeclampsia, and early fetal loss; however, recent studies have not shown the reduction of preterm birth or LBW among those infants whose mothers received periodontal therapy in pregnancy. Although the research is conflicting, it is evident that dental health procedures have generally been found to be effective and safe for pregnant women, especially during the second trimester (because of possible nausea during the first trimester and being uncomfortable in the third trimester) (Mark, 2018). Not only is dental health important during pregnancy, but poor dental hygiene and disease have been linked to health conditions, such as cardiovascular disease and diabetes. High maternal levels of the bacteria that cause cavities have been associated with a greater chance of subsequent dental caries in the infant (CDC, 2019d).

C/PHNs should teach women of childbearing age the importance of regular dental health checkups and proper dental hygiene, along with making referrals for dental treatment when needed. Because there is frequently a shortage of dental providers to see vulnerable or low-income women, the nurse sometimes has to advocate for pregnant women who have major oral health treatment problems, such as gingivitis or dental caries or infections. Dental health should be a part of general primary preventive education for all childbearing-age women and a major teaching and screening element of prenatal care.

## *Socioeconomic Status and Social Inequality*

As noted earlier, poverty plays a role in pregnancy and birth outcomes. Social and economic disparities are factors in preterm birth in both developed and developing nations and reflect some of the social determinants of health (SDOH). These relationships may be more indirect, as poorer women often lack health insurance, have less access to quality prenatal care services, have poorer nutrition, and are exposed to more situational and psychological stressors. In the United Kingdom, a retrospective study with a very large sample ( $n = 59,487$ ) was done that focused on the poorly understood factors that delay seeking antenatal care and engagement in that care. Findings indicated that higher parity, pregnancy during the teenage years, non-White ethnic background, unemployment, unmarried, poor social support, and smoking were significantly associated with late access to antenatal services and poor fetal outcomes (Kapaya et al., 2015). Prenatal stress is difficult to research because of the multiple variables that can affect prenatal stress. All areas of perceived stressors should be assessed (e.g., unintended pregnancy; nutrition; chronic stress and daily hassles; levels of social support; mental health issues, such as depression or anxiety, work stressors, racism, or discrimination; and any significant life events, such as death or other significant losses).

A systematic review of literature looked at SDOH and pregnancy of young people. Within the review, 17 of the studies found a link between at least one SDOH and pregnancy among young people with the area of poverty and family structure most represented (Maness & Buhi, 2016). Other critical areas identified within the SDOH include neighborhood-built environment (crime and violence and environmental conditions), social and community context (family structure and incarceration/institutionalization), economic stability (poverty and housing stability), and education (high school graduation rates) (Maness & Buhi, 2016). The American College of Obstetricians and Gynecologists identify the role of SDOH and the impact it has on outcomes of health (ACOG, 2019). Social, economic, political, and cultural structures contribute to reproductive health issues. Practices that address inequalities are necessary for improving health outcomes while addressing national morbidity and mortality inequalities. Consider the following example. A C/PHN discovers during the interview that a pregnant patient with gestational diabetes has not been checking her blood sugar routinely. Rather than labeling the patient noncompliant, the nurse asks the patient what challenges she has encountered that prevent her from completing this task and discovers that the woman lacks a stable living environment in which to keep her supplies. The C/PHN makes arrangements with social services to address the housing concerns (ACOG, 2019).

The C/PHN can play a role in reproductive health care and equity. Nurses can inquire regarding structural determinants such as access to food and safe water. Does the client have utility needs, and is the home and

community environment safe? Nurses can ensure access to social services and other services to support needs (ACOG, 2019).

Prenatal care is crucial to ensure good outcomes of pregnancy. Studies continue to reiterate the need for regular care visits, showing an association between regular and early care and fewer preterm deliveries and higher infant birth weights. Significant disparities in prenatal care are present among Black, Hispanic, and American Indian/Native American women (HRSA, n.d.). Access to obstetrical and gynecologic health care is difficult in many areas of the country. It is at crisis levels in some rural areas. Lack of adequate access to prenatal care leaves many pregnant women in danger (Box 19-5). Other factors, outlined in more detail in Chapter 25, may also affect the health of both mothers and babies.

## BOX 19-5 PERSPECTIVES

**A Nursing Student's Viewpoint on the Dangers of Childbirth I began working as a nurse's aide at our local hospital when I started nursing school. I learned firsthand the dangers of childbirth and the consequences that can result. One night, a female reported to the emergency room in labor and was admitted to the labor and delivery department. The young mother-to-be was very excited. Her contractions continued, though she did not progress with the labor process, so she was to be started on oxytocin (Pitocin) to increase the effectiveness of her labor. The nurse midwife checked on her patient frequently, but problems began after the first 8 hours of labor. As the dosage was increased, the fetus reacted with bradycardia, and the nurse midwife did not notify**

**the physician. The Pitocin dosage was decreased and then the heart rate stabilized; this process continued for three cycles. The nurse midwife signed off her 12-hour shift and handed care of the patient over to the nurse midwife coming on shift. Again, whenever the Pitocin dosage was increased to the point of becoming effective, the fetus would respond with bradycardia. The physician in charge was still not notified. After 24 hours of a failed labor process and at this point severe bradycardia, and the fetus was in irreversible distress. The physician was finally notified of an emergency and reported to the bedside within 5 minutes. An emergency cesarean section was performed. The Apgar scores at delivery were 0, 0, 0, and 3 after 15 minutes of resuscitative effort. The infant was severely neurologically damaged. I found out later that the infant was diagnosed with severe cerebral palsy and will never walk, talk, or feed normally. She cannot swallow and will require suctioning, gastrostomy tube feeding, and total care throughout her lifetime. She is also cortically blind. A multimillion-dollar award was given, and the nurses and nurse midwives employed by the hospital were fired due to negligence. It is sad to think that this tragedy could have been avoided with prudent nurse–patient advocacy, reporting, and appropriate documentation—the things our nursing instructors are always drumming into our heads. I know that as a new graduate, I am now in**

**a position of responsibility to make decisions to notify the physician or not. I have decided that the choice should always be to notify the physician. Even though it may seem inconvenient, it really should be done. I will never forget this case and its long-reaching consequences for the child and family, as well as for the nursing staff and nurse midwives.**

Lyndsay, student nurse

### *Adolescent Pregnancy*

Pregnancy during the adolescent years (13 to 19 years old) is considered a health risk because of the ongoing physical growth and the demands of psychosocial development during these years. The United States leads most developed nations in the rates of teenage pregnancy, abortion, and childbearing. Young maternal age at time of pregnancy and birth creates several medical risks for the mother and baby. Teen pregnancy is discussed further in [Chapter 20](#).

### *Maternal Developmental Disability*

For couples that are developmentally disabled, having a child puts increased stress on a system that is already burdened. Parenting requires attending to not just the child's physical care but socialization and developmental stimulation, well-child and illness health care, emotional nurturing, and age-appropriate supervision. Depending on the social support, and coping skills of the developmentally delayed parent, the stress and need for emotional control and positive decision-making can be monumental. Evidence from a seminal cohort study in Britain found that, for 4-to 6-year-olds, there was “no association of parental IQ with conduct or emotional problems” in the children; however, for children age 7 into adolescence, “strong evidence was observed” between lower parental IQ and child “conduct, emotional, and attention problems” (Whitley, Gale, Deary, Kivimaki, & Batty, 2011, p. 1032). Confounding variables included the environment of the home, parental affect, and child IQ. Even though there may not be strong evidence for these problems, children are still at risk for under-stimulation and environmental insecurity. Parent training/childcare skills programs, peer-to-peer support groups, community agencies, and careful home monitoring can

reduce the risk of child abuse and neglect and promote more effective parenting ([Promising Practices Network, n.d.](#)).

How does the C/PHN work with developmentally disabled parents effectively? Most importantly, nursing support must enhance the natural resilience of the family.

The establishment of a trusting relationship between the nurse and the family is of foremost importance. Teaching by demonstration with many visual aids and prompts, along with games and creative approaches to engage and sustain attention, can challenge the nurse's creativity. Modeling of appropriate parenting behavior needs to occur on each visit. Supervision and monitoring of family functioning must continue until the child reaches adulthood. As part of the transition to other systems of care, C/PHNs often advocates for families with maternal developmental disability regarding the plan of care, interpreting it for other professionals and multiple disciplines. Many agencies employing nurses cannot provide the intensive follow-up that such a family requires. It is then necessary to make referrals to organizations that can provide support, such as the American Association of Retarded Citizens or Exceptional Parents Unlimited. The nurse may stay involved as a consultant to the paraprofessionals or make periodic home visits at times of developmental or situational crisis.

## Complications of Childbearing

Some maternal deaths are not preventable (e.g., amniotic fluid embolism). Morbidity is also a factor, and although some major risk factors among pregnant women and infants have been discussed, several common medical complications of childbearing bear mentioning. The effects of hypertensive disease in pregnancy, gestational diabetes, postpartum depression, and grief in families who have lost a child are important areas in which the C/PHN can intervene effectively.

### *Hypertensive Disease in Pregnancy*

Hypertension in pregnancy may be chronic or related specifically to pregnancy. Chronic is diagnosed prior to 20 weeks of gestation, and gestational (pregnancy related) is diagnosed after 20 weeks but goes away by 6 weeks postpartum. Chronic hypertension affects 1% to 5% of pregnancies and gestational about 5% to 10% (Friel, 2017).

Preeclampsia results in new-onset high blood pressure and protein in the urine, along with nondependent edema, and can result in eclampsia (characterized by convulsions and/or coma), pulmonary edema, liver rupture, renal failure, disseminated intravascular coagulopathy, and cortical blindness, as well as maternal death. The effects from pregnancy-induced hypertension on infants are often serious because placental health is associated with fetal growth (Dulay, 2017). Preeclampsia occurs in about 3% to 7% of pregnancies, with 25% of cases developing in the postpartum period (Dulay, 2017). Various methods are employed to attempt to prevent and control hypertension during pregnancy, namely, careful and constant monitoring of blood pressure, use of blood pressure medications if needed, frequent prenatal visits with monitoring of lab tests, a diet rich in fresh fruits and vegetables, lower sodium food choices, adequate fluid intake, weight gain limitations, rest, and regular exercise. Intermittent fetal monitoring may be required. These remain the most common preventive suggestions that C/PHNs, in collaboration with the clients' primary health care providers, can give to their pregnant clients. A calm environment, periods of rest, and the pregnant woman either elevating her feet or reclining in a left side lying position are also recommended. Additional assessment data may guide the nurse to focus teaching on stress reduction techniques and modification or elimination of smoking. As care providers C/PHNs can provide frequent monitoring of blood pressure and other symptoms and encourage the client to be vigilant in keeping prenatal appointments. However, medication or even hospitalization may be necessary. The C/PHN can offer support and understanding while continuing to be a resource for the client as the pregnancy progresses and the infant is born.

## *Gestational Diabetes*

**Gestational diabetes mellitus (GDM)** occurs in pregnant women who have never had a problem with high blood glucose but do during pregnancy. The average onset for GDM is around the 24th week of pregnancy ([American Diabetes Association, n.d.](#)). GDM is estimated to occur in about 2% to 10% of pregnancies in the United States ([CDC, 2017b](#)). For the mother with GDM, there is a higher risk of hypertension, preeclampsia, urinary tract infections, cesarean section, and future risk of type 2 diabetes. As far as pathophysiology, GDM is similar to type 2 diabetes, and 50% of women with GDM eventually develop type 2 diabetes during their lifetimes. Because growth and maturation of the fetus are closely associated with the delivery of maternal nutrients, particularly glucose, maintenance of appropriate glucose levels is essential to the health of the fetus. Daily self-monitoring of blood glucose levels is recommended. Women should be encouraged to monitor blood glucose levels regularly 6 weeks postpartum and periodically throughout their life ([CDC, 2017c](#)).

The infant is at increased risk for fetal death because GDM has been associated with macrosomia, or large-for-gestational-age babies, birth injuries such as broken shoulders, breathing problems, and abnormally low blood sugars at birth ([CDC, 2017c](#)). The C/PHN can help in the control of GDM by encouraging early prenatal care, adequate nutrition, rest and exercise, and adherence to the particular dietary, activity, and blood glucose monitoring regimen suggested by the woman's health care provider. Those C/PHNs working with pregnant women should provide education on early warning signs for GDM and the importance of regular prenatal care, reminder about getting the glucose tolerance test around the 24th week of pregnancy, and follow-up.

## *Postpartum Depression*

Although most people recognize the common fleeting mood swings immediately after childbirth known as “baby blues,” high-profile cases like Andrea Yates, who suffered from postpartum psychosis and drowned her five small children, are rare (1 or 2 per 1,000 births) but nonetheless tragic ([Criminal Justice, n.d.](#)). Actresses Chrissy Tiegen and Reese Witherspoon, among others, have discussed their postpartum depression and treatment with antidepressant medications, making this condition more visible and less stigmatizing ([Davis, 2016](#)).

According to need studies, one in seven women will experience postpartum depression ([Lieber, 2018](#)). Also, depression and posttraumatic stress disorder have been found in both mothers and fathers subsequent to a healthy birth following a prior perinatal loss ([Gundersen Health, n.d.](#)). Risks for postpartum depression include a family history of psychiatric illness,

poor social support, stressful life events, anxiety during pregnancy, the personality traits of neuroticism, and more recently perfectionism ([National Institute of Mental Health \[NIMH\], n.d.](#)). Depression can affect anyone, even women without a history of prior depression. Perinatal depressive symptoms may not indicate major clinical depression. Nevertheless, symptoms may cause considerable psychological distress, such as irritability and restlessness; feeling hopeless, sad, and overwhelmed; having little energy or motivation and crying unexpectedly; sleeping and eating too little or too much; problems with cognition (memory, decision-making, focus); loss of pleasure or interest in usually pleasant activities; and withdrawal from family and friends ([Fig. 19-5](#)).

**FIGURE 19-5** C/PHNs need to watch for signs of postpartum depression among their clients and offer assistance.

There are several nonpharmacologic interventions the nurse can initiate in addition to the ones mentioned above. First, caffeine can lead to sleep disturbance, and alcohol is a depressant that has been implicated in depression. A simple yet helpful suggestion is the elimination of both. Getting adequate sleep is important because sleep deprivation exacerbates psychiatric symptoms. Napping when the baby naps, resting when possible throughout the day, and going to bed early (albeit with the knowledge that sleep may be interrupted two or more times to feed the infant) will provide more hours of rest and sleep. Exercise is helpful and raises levels of endorphins. Anxiety symptoms often coexist with depression. Relaxation techniques that reduce anxiety can be helpful, including listening to relaxing music, doing yoga, or performing a simple exercise routine. Having a daily routine and setting realistic goals are also helpful ([NIMH, n.d.](#)). Participation in a support group allows women to identify with others who may be

experiencing similar difficulties. Through discussion, women provide each other with both emotional and practical support.

C/PHNs can intervene by initiating primary preventive mental health and coping measures that promote mental health throughout pregnancy and the postpartum period. Helping pregnant women to appreciate themselves and their strengths, embrace their new body changes, and positively anticipate their new role is primary preventive intervention for good mental health and promotion of attachment to their infant. If women are assessed to be at risk, mental health resources can be identified, and then, positive mental health outcomes may be fostered by supporting their self-esteem, optimizing the quality of their primary intimate relationships, anticipatory guidance on issues that may arise during pregnancy and the postpartum period, and reducing day-to-day stressors. At times, the nurse's efforts alone are not sufficient, and a referral to community mental health services for early detection and treatment is essential for the women and their children.

### *Fetal or Infant Death*

An infrequent role for nurses in maternal–child health is that of grief counselor, but this may be a role for the advanced practice nurse in certain settings or communities. A couple may experience a miscarriage or ectopic pregnancy, stillbirth, or the death of an infant from **sudden infant death syndrome (SIDS)**. The exact cause of SIDS is not certain, but it may be associated with brainstem control of heart and lung functions ([Illinois Department of Public Health, n.d.](#)). It is more common in boys and most often occurs in infants between 1 and 4 months of age ([Safe to Sleep, n.d.](#)). Increased rates of SIDS are associated with side/stomach sleeping position, exposure to cigarette smoke, premature birth, cosleeping, having a sibling that died of SIDS, and soft bedding in the crib. SIDS is the leading cause of death for infants from 1 to 12 months of age; about 2,000 infants die annually from SIDS. Since 1990, the SIDS rate has dropped, but the rates for Black and American Indian/Alaska Native infants are disproportionately higher ([Illinois Department of Public Health, n.d.](#)).

In each situation of loss, the C/PHN has an important supportive role. People respond to grief in a variety of ways: some express deep sadness, shock, or disbelief; some weep and are unable to talk; and others talk incessantly about regrets or guilt. Even if a miscarriage occurs early in a pregnancy, the bonding between the mother and fetus has begun, and expressions of grief may be as intense as with the loss of an infant or child. Women often have feelings of abandonment, bereavement, and guilt, thinking that they did something wrong. When parents are unable to identify the exact cause of their fetal loss, they have a more difficult time letting go of grief and anxiety. Increased anxiety levels are also found, sometimes more

frequently than depression. Psychological counseling has been associated with greater decreases over time in levels of worry, grief, and self-blame (Gundersen Health, n.d.). For couples that have delivered a stillborn baby, the shock is compounded by the experience of carrying the pregnancy to full term, along with the anticipation of an imminent delivery and the expectation of an addition to the family. This is especially true if all signs before the birthing event itself were positive.

Mothers who experience stillbirths recognize the need for spiritual and psychosocial support from professional caregivers. Families must acknowledge the death of the child and integrate the loss into their family lives. Home visitation and simply being there for the family and listening well are invaluable nursing interventions. Referral to mental health counseling or support groups specific to parents of stillborn children where they can share their feelings may be very helpful (March of Dimes, 2019). Providing continuity and support to the family for months after the death of an infant gives the C/PHN an opportunity to assess the family for signs of unresolved grief. Grieving families may find comfort, support, and helpful information from support groups and resources such as Compassionate Friends or First Candle. When a family experiences loss of an infant after the baby has been brought home from the hospital, grief and guilt are compounded by the loss of an anticipated future and the disrupted continuity in family life. An infant may die of SIDS, a congenital anomaly, an infection, or an accident. There are constant reminders of the infant's presence in the home from memories, photos, videos, and accumulated possessions. This death disrupts family homeostasis and the psychological and physiologic equilibrium of the family. In many cases, the police are involved, and an autopsy is required, contributing to the anguish of the grieving family. This promotes both guilt and loss of self-esteem and can even threaten the marriage.

# INFANTS, TODDLERS, AND PRESCHOOLERS

Healthy children are a vital resource to ensure the future well-being of nations. They are the parents, workers, citizens, leaders, and decision makers of tomorrow, and their health and safety depend on today's decisions and actions. Their futures lie in the hands of those people responsible for their well-being, including the C/PHN, whose dominant responsibility is to the community and populations, such as dependent children.

The well-being of children has been a subject of great public health concern globally and in the United States. Its importance has been emphasized through development of numerous laws and services, yet the needs of many children continue to go unmet. Young children (up to age 4 years) are totally dependent on their caregivers. This contributes to their vulnerability during these years. Many young children often go to bed hungry; some infants and toddlers do not receive even the most basic immunizations before they reach school age. Accidents and injuries are a leading cause of death; preventable communicable diseases increase mortality among the very young.

Adverse childhood events (ACE) are potentially traumatic events that occur in childhood (aged 0 to 17 years) such as experiencing violence or abuse, witnessing violence in the home or community, and having a family member attempt or die by suicide (CDC, 2019e). Any aspect of a child's environment that can undermine their sense of safety, stability, and bonding are linked to chronic health issues, mental illness, and substance abuse as an adult. According to the CDC (2019e), 61% of adults surveyed in 25 states reported experiencing at least one type of ACE; one in six reported experiencing four or more types of ACEs. Women and minority groups are at greater risk for experiencing four or more types of ACEs. The CDC-Kaiser Permanente Adverse Childhood Experiences (ACE) study is the largest investigation of childhood neglect and abuse showing the effects of violence exposure and later-life health and well-being (Felitti et al., 1989). This seminal study identified seven categories of adverse childhood experiences that were correlated with multiple health risk factors later in life. ACE can have lasting and negative effects on children, increasing the risk of injury, maternal and child health problems, teen pregnancy, sex trafficking, STIs, and a wide range of chronic diseases. It is estimated that the effects of ACEs can cost families, communities, and society billions of dollars each year (CDC, 2019e).

Home environment and safety are current areas of concern for many children and families. Children in families make up approximately 33% of the homeless populations ([National Alliance to End Homelessness, 2020](#)). Point in time data show 56,342 family households identified as homeless, with approximately 16,000 families living on the street, in a car, or in other places not designated for human habitation. Typically, homeless families are headed by single women as head of household with limited education ([National Alliance to End Homelessness, 2020](#)). Children who are homeless have higher levels of emotional and behavioral problems and may have lower academic performance due to transience. Access to services and transition into permanent housing provides stability ([National Alliance to End Homelessness, 2020](#)). See [Chapter 26](#) for Working with the homeless.

Whereas the United States provides leadership in many arenas, its failure to protect and promote the health of its youngest citizens represents a significant population health breakdown. However, in many other nations—mostly less-developed countries—child health and well-being are in even greater jeopardy.

## **Global History of Children's Health Care**

Only recently in the history of the world have children been considered valuable assets, even in countries where there are now well-developed programs of infant health promotion and protection, infant and child day care services, and strict educational expectations for all children. In some countries today, however, female infants and children or those born with congenital anomalies are not valued. Countries, such as India and China, provide inequitable care for male and female children. Gender-selective abortions or infanticide also occur. Some birth, growth, and developmental rituals are harsh and would be considered illegal if judged by Western standards. Cultural practices that are fostered by political forces prevent many countries from improving the health of infants and young children ([Save the Children, n.d.](#)). For these reasons, there are great differences globally in child health care systems. The health of children in one country can affect that of children in other countries, including the United States. Major natural disasters place whole populations at risk, especially the very young and the very old.

## **National Perspective on Infants, Toddlers, and Preschoolers**

The **infant** (birth to 1 year), **toddler** (aged 1 to 2 years), and **preschooler** populations (aged 3 to 4 years) are generally healthy years. Most U.S. children have a usual source of health care (96.9%), and their parents report them to be in excellent or very good health (CDC, 2017b; Larson, Cull, Racine, & Olson, 2016). Growth and development of infants and young children should be monitored regularly. Pediatricians and C/PHNs often provide anticipatory guidance for parents so that they better understand what to expect as their child grows and can plan for safety issues that may arise. See [thePoint](#) for a link to online growth charts.

The mortality rate for children ages 5 to 14 years is 13.0 per 100,000. Major causes are unintentional injuries (motor vehicle crashes, falls, drowning, fires, and burns), cancer, and suicide (CDC, 2016c). Some variation in mortality rates continues among racial/ethnic groups.

## Accidents and Injuries

Toddlers and preschoolers are at risk for many types of accidents and unintentional injuries, such as those caused by unsafe toys, falls, burns or scalding, drowning, motor vehicle crashes, and poisonings. These unintentional injuries are the leading cause of mortality and morbidity for children from age birth to 19 years (CDC, 2016c). Male children have higher rates of death from injuries than females; it is almost twice the rate. Causes of injury deaths vary across age groups. For those children under age one, about 66% are caused by suffocation. Between ages 1 and 4, drowning is the leading cause. In 15-to 19-year-olds, being a passenger in a motor vehicle crash was the most frequent cause of injury death. American Indian/Alaska Native children had the highest death rates from injury, and Asian/Pacific Islander children had the lowest. The loss of children's lives resulting from all injuries combined represents a staggering number of productive life years lost to society. Childhood unintentional injuries lead to almost 12,175 deaths annually (CDC, 2017b).

The *National Action Plan for Child Injury Prevention* addresses child safety and provides an agenda for injury prevention (CDC, 2012). It brings together 60 partners in implementing injury prevention activities and providing a blueprint for collecting/interpreting data and surveillance and plans to promote research and enhance communication/education/training on injury prevention. Improving the outcomes of childhood injuries by working with health care and health systems and supporting strong policies to prevent injuries are further goals. Risks for childhood injuries that increase child vulnerability include “poverty, crowding, young maternal age, single parent households, and low maternal educational status” (CDC, 2012, p. 9). Using a public health model, the three levels of prevention are utilized to prevent injuries from occurring (e.g., safety latches on cabinets containing cleaning supplies or medications), minimize injuries (e.g., child safety seats), and improve emergency response and care after injury occurs (e.g., paramedic, trauma care). For instance, to prevent infant suffocation and SIDS, infants should go to sleep on their backs, in a crib or child-friendly bed without soft bedding or pillows, and parents should be cautioned about risk factors for SIDS and the potential dangers of sleeping with their babies. Information about the SIDS prevention campaign *Back to Sleep* should be provided to all parents of infants, and education should begin with hospital nurses and continue with C/PHNs in the community.

Burn injuries can affect children of all ages. Bath water that is too hot can also cause serious scalding injuries. Cigarette lighters and matches are fascinating to young children. Toddlers or preschoolers may be able to start a flame, injuring or killing themselves or others. The sound of a smoke alarm

may frighten young children, and it is important for C/PHNs to instruct parents not only to teach their young children about fire prevention but also to be aware of the sound of the alarm and know what actions to take when they hear it, such as the *Stop Drop and Roll* program taught in Head Start and other preschool programs ([National Fire Protection Association, n.d.](#)). The C/PHN should also take every opportunity on home visits and in other health education settings to ask or observe if parents have a functional smoke detector in their home. Most community fire departments will install and test smoke detectors for free. Preventing the sources of injury or death from burns may be accomplished by eliminating opportunity and source. Through child supervision, safe storage of matches and lighters, and keeping children away from stoves and electrical outlets, burns and fires can be prevented.

Drowning is another category of unintentional injury in children. Brief lapses in supervision can have disastrous consequences. Young children are at risk for drowning wherever water occurs in depths exceeding a few inches—such as in toilet bowls, bathtubs, mop buckets or cans filled with rainwater, puddles, ponds, spas, and swimming pools. Lakes, rivers, streams, and irrigation ditches or canals are other water hazards. Infants, toddlers, and preschool-aged children are especially vulnerable because they are not aware of water dangers and they explore without fear. Poor children, especially children of color, are at higher risk for drowning because of lack of access to swimming lessons. The C/PHN can work with community groups and recreation centers to promote swimming for children. Parents need to provide a drown-free environment. Guidelines include the following ([American Academy of Pediatrics, 2016](#); [CDC, 2020a](#); [Government of Alberta, 2018](#)):

- Bathe young children in shallow water.
- Never leave young children unattended during a bath.
- Keep toilet lids down and bathroom doors closed—preferably secured with childproof safety handles.
- Never leave full mop buckets unattended.
- Eliminate water collection sites around the home by turning over or removing empty buckets, containers, flowerpots, and other items that can collect rainwater.
- Fence swimming pool areas and install childproof locks or alarm devices that sound when the water is disturbed.
- Promote water safety measures, including teaching young children to swim.
- Be aware of the dangers of open pool drains and suction outlets that can lead to drain entrapment and hair entanglement and ensure that drain covers and safety vacuum-release systems are installed.
- Vigilant supervision of young children at play to prevent involvements with neighborhood water sources

Supervising children in or around bathtubs, spas, pools, or other water receptacles is critical and requires close (arm's length) distances. Parents of young children should be encouraged to get cardiopulmonary resuscitation training. The real dangers of accidental drowning are related in [Box 19-6](#).

## **BOX 19-6 STORIES FROM THE FIELD**

**Mop Bucket Drowning** I am a Head Start nurse, and one of my assigned centers is located within a farm-labor camp. There are many large, hardworking families in the camp. Older siblings often watch over young children and help with household chores. Most families keep their cinder block homes tidy and clean, and floors are constantly being mopped (no one has carpeting—it is a bare-minimum type of accommodation). One day, several children were absent from school, and when I made home visits to determine the cause of the absences, I discovered that one of the Garcia family's children, a toddler named Miguel, had unexpectedly died. Because many of the absent children were cousins, parents had kept them home while attending to the family. I knew the Garcia family well, and when I stopped by to check on them, they told me that Miguel had fallen into a large mop bucket the older sister had been using to clean the kitchen floor. She had gone outside for just a minute to separate the 5-year-old twins who were fighting, and when she returned, she found Miguel headfirst

**in the bucket. She tried to revive him but could not. The parents were working, trying to earn extra money for an elderly grandmother who needed surgery, and only learned of the tragedy when they returned home at the end of a long day. It was a very sad situation, and it reminded me of how even an everyday item can become deadly. Safety and prevention of unintentional injuries, especially with curious toddlers and preschoolers, is extremely important to teach all families.**

- 1. Address levels of prevention as this concept relates to childhood accidents. What could you do now to assist this family?*
- 2. What strategies can C/PHNs use in their community to prevent drowning situations like this from happening again?*

Myra, Head Start nurse

Injuries and deaths from motor vehicle crashes continue to be a major safety problem in the United States. Of the 23,714 vehicle fatalities in 2016 only about 53% to 62% of drivers and passengers were wearing safety restraints (CDC, 2017d). A recent study found that more than 685,000 children ages 0 to 12 were not correctly placed in child safety seats or boosters as least at some point (CDC, 2017a). Many families have them and use them regularly but do not install them properly, placing the child at as much risk as if there were no restraint. The most current recommendations for safety seat use are categorized by age. For children birth up to age 2 years, a rear-facing seat should be used (placed in car's back seat); the child should continue in rear-facing seat until reaching the height or weight limit of the seat placed in the back seat; age 2 to at least 5 years, child should use forward-facing car seat until reaching upper weight and height limit for the seat; age 5 years and up, keep child in back seat with a seat belt–buckled booster seat until they reach height limit of 57 in. and can use a car seat belt alone; seat belts are considered to be properly fitting when the lap belt portion lays across the upper thighs (not stomach area) and the seat belt lays across the chest and not the neck (CDC, 2016a). There is much opportunity in this area for the C/PHN to educate the public and ensure that parents have the information and skills to secure their children properly when traveling by

car. Safety seat clinics, where installations are checked and corrected, can help to promote the proper use of age-appropriate child restraints (Box 19-7).

## **BOX 19-7 Evidence-Based Practice**

### **Getting Families to Use Child Booster Seats**

Many health departments, law enforcement, and social service agencies educate parents about the laws and benefits related to the use of child safety seats. Still, not every family consistently uses them. Education and awareness are essential to increase the use of child safety seats.

The Strike Out Child Passenger Injury (Strike Out) intervention program provided booster seat education for children ages 4 to 7 years at instructional baseball programs in four states. Twenty communities participated in the nonrandomized, controlled trial. The study tested the effectiveness of the education program before and after baseball season in increasing proper restraint use among participating children.

Findings revealed that the intervention program did increase the use of child restraint use in three of the four participating states (Alabama +15.5%, Arkansas +16.1%, and Illinois +11.0%). The study reinforces the importance that unique interventions can positively influence child safety use. It is essential for C/PHNs to use evidence and a variety of approaches to combat public health problems. For more information on selecting the proper car seat for children according to age and size, visit: <https://www.cdc.gov/features/passengersafety/index.html>.

Source: Aitken *et al.* (2013).

Poisoning is a constant safety concern for young children, and toddlers are most often at risk. Sources of poisoning include household plants, prescription medications, over-the-counter drugs, unintentional medication overdoses, household cleaning products, other chemicals stored within a child's reach, and lead. Parents should be provided with the number for the

Poison Help Hotline (1-800-222-1222) and encourage them to post it next to each telephone and call immediately in the event of a suspected poisoning or overdose ([American Association of Poison Control Centers \[AAPCC\], n.d.b](#)). They can also educate and demonstrate for parents how to childproof the home by eliminating major sources of poisoning. This includes keeping plants out of a child's reach or eliminating them from the home until the child is older, locking up household chemicals (e.g., toilet bowl cleaner, bleach, mouthwash, oven and drain cleaners, pesticides, gasoline, paint thinner, hair products) and storing them out of a child's sight and reach, using childproof medication containers, and storing all medicines in a locked box with a key that is kept out of reach ([AAPCC, n.d.a](#)). Alcoholic beverages should also be kept out of reach, as should tobacco products. Outside hazards, such as wild mushrooms and poisonous plants, flowers, and berries, must also be considered ([AAPCC, n.d.b](#)). It is also important to eliminate sources of lead in and around the home.

## Lead Poisoning

Lead poisoning historically resulted in encephalopathy and death. Today, morbidity from lead poisoning is subtle and most often affects the child's CNS with long-term changes in behavior and IQ. The CDC estimates that half a million children between the ages of 1 and 5 years have elevated blood lead levels, or 5  $\mu\text{g}$  of lead per deciliter of blood (CDC, 2018i). Lead in paint, dust, and soil can be inadvertently consumed, and lead also crosses the placental barrier. It can be transferred in breast milk and is also found in some infant formulas (American Academy of Pediatrics, 2018b). Lead is one cause of childhood poisoning. There is no safe level of lead, and the elimination of elevated blood lead levels in children is a U.S. Health Goal. The primary sources of lead exposure in preschool-aged children continue to be lead-based paint and lead-contaminated soil and house dust. The critical age of exposure (or peak level) is thought to be between ages 18 and 36 months. Levels generally begin to decline after age 3 years. Children who live in poverty and play in substandard housing areas remain at risk for direct exposure to significant sources of lead. Lead safety and housing code enforcement, along with periodic monitoring to detect new lead hazards, can help prevent future lead exposures. C/PHNs working together with environmental health sanitarians, should promote opportunities for blood lead screening, especially if it is suspected that children in certain homes, apartments, or neighborhoods are at risk for lead poisoning. Children have also been exposed to lead in some toys, candies, cosmetics, traditional medicines, and eating or drinking utensils imported from other countries. Many of these have been tested and revealed to have high levels of lead. Education and public awareness campaigns can help prevent this type of lead poisoning. The C/PHN can alert clients to the dangers of lead and its sources and work as an advocate for policies to reduce this danger for infants and children. See [Chapter 9](#) for more on lead poisoning and water contaminated with lead.

## Child Maltreatment

An estimated 678,000 children were victims of **child abuse** or maltreatment in 2018 ([National Children's Alliance, 2019](#)). Child maltreatment includes physical, emotional, and sexual abuse and neglect (e.g., withholding feeding or medical care) that occurs in anyone under 18 years old. Neglect is more an act or acts of omission in which a child's basic needs are not met. Children under age 4 years are at the greatest risk for severe abuse and neglect ([CDC, 2018k](#)). **Shaken baby syndrome** is often an overlooked form of abuse. **Abusive head trauma**, which includes shaken baby syndrome, is the leading cause of all child maltreatment deaths ([National Center of Shaken Baby Syndrome, 2020](#)). Shaken baby syndrome can be suspected in infants or toddlers who exhibit traumatic brain injuries caused by violent shaking or impact, is characterized by a triad of symptoms: retinal hemorrhage, subdural hemorrhage, and/or subdural hemorrhage with few signs of external trauma ([American Academy of Pediatrics, 2018a](#)). The soft brain tissues are injured as they move violently against the rough cranial bones as the infant is shaken or thrown against a hard object. The C/PHN has an important role in the prevention of shaken baby syndrome by providing parents with education regarding the triggers and intervention strategies. Educating parents that baby crying patterns are more severe in the first few months and progressively improve along with baby soothing techniques are essential before and after delivery ([CDC, 2018k](#)).

Failure to thrive (FTT) is characterized by slowing growth rate in height and weight, as well as head circumference among infants and toddlers. If an infant's growth rate is consistently below 3rd to 5th percentiles, drops more than two percentiles, or is lower than the 80th percentile of median weight for height, a diagnosis of FTT may be made. Problems with growth may be due to food insecurities and many behavioral or physiologic etiologies for infants but can also be related to child neglect or abnormal maternal–infant bonding. Child neglect differs from child abuse in that the action of the parent or guardian is more one of omission with neglect rather than commission as in the case of an injury related to abuse. Risk factors that point to child neglect as the basis for FTT include those most often cited for abuse and neglect, along with specific concerns about parents intentionally withholding food, being resistant to recommended interventions, and having rigid beliefs about nutrition and health regimens that may jeopardize the infant. The exact incidence of FTT is difficult to determine, and no accurate estimates are available. The C/PHN can take a careful nutritional history and determine the mother's knowledge of basic infant needs, as well as checking for developmental milestones. A psychosocial history is also helpful (e.g., income/poverty level, cultural beliefs, social support networks, domestic abuse, substance abuse, mental health disorders), with careful attention to

maternal bonding and feeding practices. Growth problems in the first 2 months of life may result in cognitive, language/speech, and fine motor deficits in childhood, and early intervention programs that involve home visitation have been effective in attenuating the long-term effects of FTT (Homan, 2016).

C/PHNs play a role in the prevention and management of child abuse and maltreatment. Preventive strategies such as parent education should begin prenatally and continue throughout the life span. Parent training programs can help teach parents to cope and child sexual abuse prevention programs may also be helpful. Home visiting programs that provide anticipatory guideline education will also help to prevent abuse and neglect. Early recognition and reporting of suspected abuse or/and neglect is a responsibility of C/PHNs.

See [Box 19-8](#) and [Chapter 18](#) for more on child abuse and neglect.

**BOX 19-8 Reports of an Emergency Foster Home** The following are examples of the various situations from which abused and neglected children come, as reported by a couple who had an emergency foster home for the county department of social services. The examples represent children placed with them over a 2-year period in which they cared for 256 children.

- 2-Week-old Jose was taken to their home because the parents (under the influence of drugs) were found swinging Jose upside down in circles in an infant carrier as they walked along a downtown street at 3 AM. After being returned to his parents, he returned to foster care 1 month later after being found abandoned in an infant carrier at the county fair.
- Andre, Otis, and Selma, ages 8, 5, and 4, went to the foster home when the social services agency discovered they had been living with their father in an abandoned car for 2 years. They stayed for 3

weeks while the social worker found suitable housing for this family and counseling for the father.

- Victoria, 5 years old, a loving and passive child, arrived wearing a diaper and appeared developmentally delayed. She had a history of being physically and sexually abused. Her family was very dysfunctional, and it took the social worker several weeks to sort out relatives and their intentions before placing Victoria in a long-term foster home.
- Ronald and Randall, 6-year-old twin boys who were forced to “sexually please their mother” for several years, came to the emergency foster home before being placed with relatives while their mother underwent psychiatric treatment. The boys began counseling during their stay in the emergency foster home.
- Antoinette, age 7, had severe asthma and was very withdrawn. She came to the emergency foster home because her mother (and the mother's boyfriend) refused to care for her. The child came with every photograph of herself and personal mementos because the mother wanted no reminders of the child. The social worker located a grandmother who would be the child's guardian.
- 13-Year-old Robert came home from school one day and found his mother and all their furniture gone. After a few weeks of Robert living in the basement of the apartment building, someone alerted the social services agency, and he was placed in the emergency foster home for 2 months. His mother finally called social services after 6 weeks, saying Robert was too difficult for her to handle, but she may want to see him again someday. Robert was eventually placed in a group home for boys.
- Quyn, a 17-year-old Laotian girl, came into foster care after being referred by the school nurse because of wounds observed on her wrists and ankles. Quyn reported being strapped to a chair for 12 or more hours at a time by her father because she was not following the old ways and was shaming the family by being seen in public with a boy, and without a chaperone. Several meetings were held between the parents, a Southeast Asian community leader, and the social worker to resolve this situation so that Quyn could go home safely.

## Communicable Diseases

Infants, toddlers, and preschool-aged children experience a high frequency of acute illnesses, more so than any other age group. Acute conditions commonly seen from birth to age 5 include sore throat, ear pain, urinary tract infection, skin infection, and respiratory infections (including ear infections, colds, influenza). Communicable diseases are prevalent in these age groups, as very young children are building an immune system and are just beginning to come in contact with a greater number of people outside their families (Fig. 19-6; American Academy of Pediatrics, 2017).

**FIGURE 19-6** Infants, toddlers, and preschoolers are constantly putting things in their mouths and sharing items with others, contributing, in part, to the increased incidence of accidents and infections among them.

Acute respiratory illnesses are common in children under the age of 5 years. C/PHNs need to emphasize that over-the-counter cough and cold medications should not be used for children under age 2. The U.S. Food and Drug Administration (FDA) questioned their safety and effectiveness at a hearing in October 2007, and manufacturers removed medication targeted to infants and toddlers; they also changed labels all cold and cough medications to read that they should not be used in children under age 4 (FDA, 2018). Parents need to be informed of the dangers and suggest safer interventions.

Bronchiolitis is the most common type of lower respiratory infection among infants and starts with a runny nose, fever, and cough. It is a common cause of hospitalization in this age group; about 2% of children with respiratory syncytial virus (RSV), the most common cause of bronchiolitis, are hospitalized every year. The majority of hospitalizations for bronchiolitis

are for infants 6 months and younger. RSV is the cause in 70% of cases and can rise to 100% during winter epidemics. Although wheezing, tachypnea, and chest retractions can be frightening to parents, most healthy infants survive (95%). However, C/PHNs working with at-risk infants need to work with parents and pediatricians to ensure that palivizumab (monoclonal antibody) or RSV immunoglobulin is given to preterm infants or those born closer to term but exposed to environmental pollution or to other children. An effective RSV vaccine has not yet been found, but palivizumab (Synagis) can be used to help prevent the most severe cases of RSV in high-risk infants (e.g., premature, congenital heart problems) and is given monthly by injection during RSV season ([CDC, 2018I](#)).

## *Vaccine-Preventable Diseases*

Vaccines are one of the greatest achievements of public health. Since 1980, there has been a 99% or greater decrease in deaths because of the vaccine-preventable diseases of mumps, pertussis, tetanus, and diphtheria and 80% or greater decline in deaths associated with vaccines instituted since 1980: hepatitis A and B, *Haemophilus influenzae* type B (HiB), and varicella. Worldwide, vaccine coverage has increased because of effects of manufacturers and philanthropists (e.g., Bill & Melinda Gates Foundation). The WHO has specific disease eradication and vaccine promotion programs around the world (see [Chapter 16](#)). Smallpox has been eradicated worldwide, and the viruses for polio, rubella, and measles are no longer endemic in the United States. Newborns immature immune systems and lack of exposure to antigens, along with somewhat porous physical barriers to microbes, put them at high risk of infection. By the age of 4 to 6 months, however, a brisker antibody response to vaccines becomes possible. Successful infant and childhood immunization programs have been responsible for high vaccine coverage and the subsequent decline in morbidity and mortality from these preventable diseases.

State-level immunization registries help track vaccine coverage at all age levels. Because day care centers and schools require proof of immunization, vaccination rates have improved over the last two decades. The financing of immunizations for infants and children has significantly improved as a result of two major initiatives. The Vaccines for Children Program and the Child Health Insurance Program (CHIP) cover children on Medicaid, uninsured children, and American Indian/Alaska Native children. In addition, underinsured children who receive immunizations at federally qualified health centers and rural health clinics are covered. Additional state programs and funds help provide free or low-cost vaccines for children who are not covered by the other programs. There are several ways for C/PHNs to help all families obtain free or low-cost immunizations and contribute to

maintaining adequate levels of community immunity to communicable disease (see [Chapters 8, 10, and 12](#)).

Even if financial barriers are removed, there are other barriers. Transportation is a significant problem for some parents, especially in rural areas and for families in urban areas who have several children and need to take public transportation. All 50 states provide for medical exceptions to mandatory vaccination, and 47 allow religious exemptions; 18 permit philosophical or personal exemptions ([National Conference of State Legislatures, 2017](#)). Despite public health announcements in the media, some mothers remain unaware of the disabling consequences of diseases such as polio and do not realize the importance of fully vaccinating their children. Also, as more vaccines become available and the deadly diseases they prevent become a distant memory in the public's mind, more concerns about the safety of vaccines emerge. There has not been any link established between thimerosal, a vaccine preservative, and autism (CDC, 2018e). The use of thimerosal has been reduced or completely curtailed; single-dose packaging does not require the ethyl mercury preservative (CDC, 2018e) (see [Chapter 8](#) for information about vaccine hesitancy). Numerous Web sites have emerged that advise against childhood immunization and provide graphic horror stories about the handful of severe reactions to vaccination. Media coverage and online Web sites about vaccine adverse events also contribute to decreased compliance on the part of parents in getting their children immunized. C/PHNs and other health professionals are encouraged to provide parents of very young children with meaningful stories of preventable deaths because of vaccines and to educate parents about scientifically based Web sites and resources rather than relying solely on dispassionate facts and figures.

## Chronic Diseases

Infants and young children can be afflicted with chronic diseases that affect their quality of life.

*Dental caries* is the most common chronic disease among the 6 to 19 year age group (CDC, 2019c). Young children's diets, often unreasonably high in sugar, increase the incidence of dental caries in this population group. The practice of allowing infants to feed from the bottle beyond 15 to 16 months, or to fall asleep with a bottle, can lead to *baby bottle tooth decay* or *nursing caries*. Baby bottle tooth decay occurs when others persist in giving toddlers and preschool-aged children milk, juice, sodas, or sugared drinks continually throughout the day (American Academy of Pediatrics, 2018d). Frequent snacking and sippy cups filled with juice or sugary drinks can lead to cavities. It is recommended that sugary foods be eaten at mealtimes and not as snacks and that regular snack times be established. Also, between ages 6 and 12 months, sippy cups are often used to wean infants from the breast or bottle, but between-meal drinks should consist of water or milk. Nighttime breastfeeding beyond what is needed for nutrition can also lead to increased risk of dental caries (American Dental Association, 2016). Parents of infants older than 6 months who have several erupted teeth should be instructed to rub the infant's gums with a damp, clean cloth and to begin tooth brushing, using a soft pediatric toothbrush with a very small amount of fluoride toothpaste—about the size of a grain of rice. The first dental examination should be made within 6 months of the first tooth eruption. Addressing parental misconceptions about dental health and understanding cultural beliefs and practices related to dental health and hygiene are important (American Academy of Pediatrics, 2018d).

Dental caries is a preventable condition that can be addressed with proper nutrition and hygiene. The younger the age when dental caries first appear, the greater the risk for future tooth decay that increases the risks of chronic health conditions due the inflammatory response. Untreated dental caries can also lead to serious infections. Pain can interfere with learning at school. Many health departments are using fluoride varnishes as a means of preventing dental caries in young children. Dental hygienists and C/PHNs may be trained to apply the sealants and varnishes while making home visits, or children and families may visit clinics for treatment (American Academy of Pediatrics, 2018d).

*Asthma* symptoms may begin in infants and toddlers. Approximately 6 million children ages 0 to 17 years have asthma (CDC, 2018c). Inner-city, low-income, and minority children are disproportionately affected, and asthma hospitalizations are common. C/PHNs can assist families in finding appropriate health care providers and encourage proper administration of

asthma medications and treatments. They can also teach families to reduce the presence of asthma triggers in their homes (see [Chapters 9](#) and [20](#) for more information on environmental triggers, asthma, and other chronic diseases of childhood and adolescence).

*Autism* is a developmental spectrum disorder that is often first noticed in toddlers. Parents become aware that the child's communication and interaction with others are different and that the child may also display obsessive and narrow interests. Autism spectrum disorder (ASD) is a complex developmental disorder, and spectrum of ASD indicates that symptoms for each child varies and may range from mild to severe ([CDC, 2018b](#)). A child's communication skills and interaction with others are most often affected, along with obsessive behavior and narrowed interests. Behaviors associated with autism include:

- Language problems (no language, delay in language, repetitive use of language)
- Motor mannerisms (often repetitive rocking, hand flapping, object twirling)
- Fixation on objects (restricted interests)
- No spontaneous play or make-believe play ([Fig. 19-7](#)); no interest in peers (problems making friends)
- Little or no eye contact (may also resist hugging)

**FIGURE 19-7** Dress-up and playtime are important for toddler and preschooler development.

Boys are four times more likely than girls to develop autism. An estimated 16.4/1,000 children were identified to have ASD in 2014 ([CDC, 2018c](#)). The causes of autism are unclear—some genetic links have been found, but environment may also be a factor. There is a higher risk of

subsequent children having autism in a family with one autistic child or a parent with ASD (CDC, 2018b). It is often associated with other disorders (e.g., congenital rubella syndrome, Down syndrome, fragile X syndrome, tuberous sclerosis), but the exact causes are not fully understood (CDC, 2018b). Families may need to be referred to early educational intervention programs and social service agencies for assistance. Parents need to be vigilant with daycares and preschools about their child's environmental sensitivities. It is important for C/PHNs to educate parents that parenting practices are *not* a cause of autism and that multiple, large-scale research studies on childhood immunizations have shown that there is no relationship between immunizations and autism (CDC, 2018d).

*Sickle cell disease*, an inherited blood disorder, affects thousands of children in the United States, most often those of African or Hispanic Caribbean ancestry. The characteristic chronic and severe anemia are common in young children with this condition, and it can affect memory, learning, and behavior. Children can also exhibit jaundice, gallstones, and joint pain. When both parents have the genetic mutation, the newborn will be afflicted with the disease. Those with the sickle cell trait have no symptoms of the disease but can pass it on to their offspring. In many states, routine newborn screening for sickle cell anemia is offered. Because sickle cell anemia can lead to splenic sequestration (or pooling of blood in the spleen), many children either have nonfunctioning spleens or have had them surgically removed. Risk of infection is always a concern when this occurs before age 5 (CDC, 2019a). C/PHNs working with populations at risk for this disease can educate and refer families for diagnosis and treatment.

*Food allergies* is a growing problem in children. Infants with close family members who have atopic diseases are at risk for development of allergies. Prolonged breastfeeding for 1 year is recommended for these infants or the use of hypoallergenic infant formula. The CDC (2018m) does not recommend a delay in the introduction of the most allergic foods (milk, eggs, and peanuts) for infants past the usual 4 to 6 month of age as this will not prevent a child from developing an allergy. Fortunately, once allergies are diagnosed, they can be managed through dietary changes and by avoidance of allergy-producing foods. Parents need to be educated, so that they can consistently read food labels and alert family members to the young child's allergy so that inappropriate foods are avoided.

*Muscular dystrophy* (MD) and *cystic fibrosis* (CF) are two diseases that not only affect quality of life but also severely shorten the child's life. MD is a constellation of genetic disorders characterized by progressive atrophy and weakening of skeletal muscles. The onset of some forms of MD begins in infancy or early childhood, and MD is more common in boys (1 in than 3,500 male births). Girls are usually carriers, but a few may be “manifesting carriers” that have milder symptoms of muscle weakness (National

[Organization of Rare Disorders, 2016](#)). *Duchenne MD* usually begins before age 6 and progresses rapidly until most boys are wheelchair bound and require a ventilator ([NINDS, 2017](#)). Recently in 2016 and 2017, the FDA released a disease-modifying drug, eteplirsen for DMD followed by deflazacort for the treatment of DMD ([Muscular Dystrophy Association, 2018](#)). Genetic testing can determine who is a carrier of the gene and can aid in confirming the clinical diagnosis.

*CF* is a genetic disease that usually begins in infancy—about 1,000 new *CF* cases are diagnosed annually and 75% are diagnosed before a child reaches age two ([Cystic Fibrosis News Today, 2018](#)). *CF* is characterized by a persistent cough or wheeze, shortness of breath, poor weight gain despite a good appetite, and a salty taste to the skin. Sticky, thick mucus builds up in the lungs and digestive tract. Respiratory infections become increasingly more frequent as the child ages. It is the major cause of severe chronic lung disease in children. Chest physiotherapy to help mobilize secretions is performed daily, usually by the parents. Sometimes, a vibrating inflatable vest is used that loosens mucus. Aerosolized antibiotic treatments and mucus-thinning medications help to improve lung function and reduce respiratory infections. Mucus also affects the pancreas and prevents release of digestive enzymes needed to digest food and absorb nutrients. Pancreatic enzyme supplements help with nutrient absorption ([University of Pittsburgh Medical Center, 2018](#)). C/PHNs reinforce these techniques and teach the family to avoid exposure to respiratory infections and to initiate prescribed antibiotic prophylaxis promptly. As much as feasible, the young child should be involved in his own care, offered valid choices, and encouraged to participate in decision-making. The family needs genetic counseling and emotional support as members work through feelings of anticipatory grief.

## Nutrition

Proper nutrition is foundational to well-being later in life. The American Association of Pediatrics recommends exclusive breastfeeding for the first 6 months of life then gradually adding solid foods along with breastfeeding until 1 year of age (2018d). Bonding between mother and infant and overall maternal health are predictors of infant weight gain. Both nutrition and bonding can be accomplished by breastfeeding (Fig. 19-8). Along with convenience and no to low cost, there are other benefits of breastfeeding which include the following (American Academy of Pediatrics, 2016):

**FIGURE 19-8** Breastfeeding has many benefits for both infant and mother.

- *Nutrition:* Breast milk provides sugar, fat, and protein; the proteins are easily digested, and fats are well absorbed; it is the most complete form of nutrition for human infants.
- *Anti-infective and anti-allergic properties:* Breast milk contains immunoglobulins, enzymes, and leukocytes that protect against pathogens, and it decreases the incidence of allergy by eliminating exposure to potential antigens. Babies exclusively breastfed for 6 or more months have fewer respiratory illnesses, ear infections, and cases of diarrhea. The chance of hospitalization for infants that are breastfed for more than 4 months is reduced.
- *Infant growth:* Breastfed babies usually gain weight at a more moderate rate and are leaner than bottle-fed babies; rapid weight gain in infancy has been associated with later chronic diseases.
- *Long-term health effects:* Breastfeeding exclusively for at least 6 months is associated with reduced risk of overweight in later life, and less change of developing atopic dermatitis, asthma, and leukemia and

lymphoma. There has also been a 36% reduction in the risk of SIDS among breastfed babies and a decreased incidence of type 1 diabetes.

- *Benefits for mothers:* Breastfeeding burns extra calories, helps to reduce postpartum bleeding, and delays ovulation and menstruation; it also lowers the risk of later ovarian and breast cancers. Studies show that the longer the period of lactation, the lower chance she has of developing hyperlipidemia, hypertension, cardiovascular disease, and diabetes.

The C/PHN can encourage pregnant women to consider the benefits of breastfeeding their infants and provide education and interventions to assist them with the most common barriers: concern about insufficient supply of breast milk, problems with the baby latching onto the breast, painful nipples, and scheduling problems. Women often choose to breastfeed their babies when they fully understand the health effects for their infants and themselves and when they receive positive influence from family and friends. The C/PHN can join with labor and delivery nurses and lactation consultants in promoting breastfeeding among mothers in the community. Nurses can lobby local hospitals to educate new mothers about the benefits of breastfeeding and stop the routine distribution of free samples of infant formula.

Child and adolescent obesity prevalence in 2015 to 2016 was 18.5% (Hales, Carroll, Fryar, & Ogden, 2017). In 2015 to 2016, there was a higher prevalence of obesity among Hispanic children and adolescents (25.8%) and non-Hispanic Blacks (22%) than among non-Hispanic Whites (14.1%) and non-Hispanic Asians (11%) (Hales et al., 2017). The Orr *et al.* (2019) study identified food insecurities associated with childhood obesity as mediated through feeding practices and beliefs. Families from insecure households were more likely to provide food to stop a baby from crying or to console a child. Another study identified that weight compared to length decreased from 14.5% in 2010 to 12.3% in 2014 among infants aged 3 to 23 months enrolled in Women, Infants, and Children (WIC) programs (Freedman et al., 2017).

Overfeeding can lead to nutrition problems and poor infant growth. The pattern of growth may also be important, such as growth problems in infancy along with overweight in later childhood. The most common sources of energy and nutrients for infants and toddlers are breast milk, formula, and milk. Fortified foods (e.g., grain-based foods with added vitamin A, folate, and iron) become increasingly more significant in toddler diets. In general, most nutrition recommendations include providing for a wide variety of foods for children. C/PHNs can encourage parents to continue to introduce new healthy foods to their toddlers and not give up or give in too soon.

# **HEALTH SERVICES FOR INFANTS, TODDLERS, AND PRESCHOOLERS**

A variety of programs that directly or indirectly serve the health needs of very young children may be found in most communities. Nurses play a major and vital role in delivering these services especially for the working poor and vulnerable populations. In public and community health, programs fall into three categories, which approximate the three priorities of C/PHN practice: prevention, protection, and promotion.

## Preventive Health Programs

Neighborhood community centers found in urban and rural settings provide families with parenting education, health and safety education, immunizations, various screening programs, and family planning services. In some areas, nurse-run clinics are established at local schools or community centers to assist in outreach services to the community. In collaboration with an interdisciplinary team, C/PHNs are often the primary care providers in these programs. The major goals are to keep communities healthy by focusing on primary and secondary prevention services. Three examples of preventive health programs for infants and young children are immunization programs, parent training programs, and quality day care health services.

### *Immunization Programs*

Health departments, community clinics, and private health care providers continue to offer immunizations against the major childhood infectious diseases—measles, mumps, rubella, varicella, polio, diphtheria, tetanus, pertussis, hepatitis A and B, and Hib—some of which can cause permanent disability and even death. Pneumococcal, meningococcal, and influenza vaccines are also recommended, as is the vaccine for rotavirus (CDC, 2018h). Many of these diseases no longer plague infants and children, and newer vaccines offer an even greater promise of health. The current immunization schedule is available at <https://www.cdc.gov/vaccines/schedules/easy-to-read/child-easyread.html> (CDC, 2018k).

Although the threat of these diseases has been substantially reduced, vigilance is still essential. Low immunization levels in many areas of the United States, particularly among the poor and medically underserved, and increased disease rates signal the need for constant surveillance, outreach programs, and innovative educational efforts. The C/PHN can help young families find low-cost vaccinations by using the Vaccines.gov Web site (<https://www.vaccines.gov/getting/where>). Whenever infants and young children come in contact with public health and other community clinics, it is always important to check immunizations and provide the necessary vaccines. C/PHNs are deeply involved in preventive activities that promote immunizations. One important intervention is to provide each parent with immunization record that they can keep so that they have a record of their children's immunizations. Immunization information systems are in place but vary from state to state; therefore, it is essential that parents maintain a record (CDC, 2018g).

## *Parent Training Programs*

Parent education and training programs have been useful in providing parents with the tools needed to deal with the stresses and challenges of parenting effectively. These programs provide education regarding appropriate growth and developmental milestones, anticipatory guidance, positive discipline techniques, parenting skills, appropriate play, and parent–child interaction promotion ([Child Welfare Information Gateway, n.d.c](#)). There are a variety of programs available for parents at local, state, and national levels with resources available at <https://www.childwelfare.gov/topics/preventing/prevention-programs/parented/>

## *Quality Day Care and Preschool Programs*

It is estimated that 24% of children under the age of 5 spend time in center-based child care ([Center for American Progress, 2018](#)). Quality child care centers improve school readiness, reduce family stress, and result in overall improvements in health and well-being for children and their families ([The Children's Cabinet, 2018a](#)).

Although safe, affordable child care is important, the long-term benefits of early childhood education are numerous. These benefits include higher rates of high school completion, college attendance, and full-time employment and lower rates of felony arrests, convictions, and incarcerations ([The Children's Cabinet, 2018b](#)). **Head Start**, a federally funded program that offers early childhood education to low-income children between ages 3 and 5, has consistently demonstrated significant improvements in preschoolers' social, emotional, and cognitive development, and those attending Head Start do better on several developmental and educational measures. Head Start children are also more likely to receive dental and health screenings, to have up-to-date immunization coverage, to have better school attendance, and to be less likely to be held back in school. The benefits of Head Start extend to families because more Head Start parents read more frequently to their children than do parents of children not enrolled in the program ([National Head Start Association, 2018](#)). However, the quality of day care and preschool programs varies considerably; licensing laws can regulate only minimum safety and health standards. In addition, numerous childcare operations are too small to require licensing, leaving quality and compliance unevaluated. As educators, C/PHNs play a role in providing education and referrals. Also, nurses can influence and advocate for quality of day care and preschool programs through active childcare consultation efforts that focus on health educational efforts for staff, monitoring of health and safety standards, and working to improve the state's or community's role in passing stronger licensing laws.

## Health Protection Programs

Health protection programs for infants and young children are designed to protect them from illness and injury. Ultimately, these programs may even protect their lives.

### *Safety and Injury Protection*

Accident and injury control programs serve a critical role in protecting the lives of children. Efforts to prevent motor vehicle crashes, a major cause of death, may include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into the causes of various types of crashes. Injury prevention and reduction have been addressed through strategies such as state laws requiring the use of safety restraints (e.g., seat belts, child safety seats), availability of front and side driver and passenger airbags, substitution of other modes of travel (air, rail, or bus), lower speed limits, stricter enforcement of drunk-driving laws, safer automobile design, and helmets for motorcyclists, bicycle riders, and skaters.

For infants, toddlers, and preschool-aged children to be safe when traveling in vehicles, they must be restrained in an approved infant carrier, child restraint seat, or booster seat. General guidelines recommend that all children under the age of 2 years ride in rear facing car seats. Forward facing seats with a harness are to be used when children have outgrown the rear-facing height and weight limit requirements. It is recommended that children use these as long as possible as allowed by the car safety seat manufacturer. Car seats must be positioned and secured as described by the manufacturer; used at all times, even for the shortest distances; and installed in the appropriate position (facing rear or front) based on the weight or age of the infant or young child. Belt positioning booster seats are recommended when weight or height requirements have exceeded forward facing car seat limits. All children younger than 13 should ride in the back seat ([American Academy of Pediatrics, 2018c](#)). C/PHNs collaborate with other community agencies, hospitals, law enforcement, and other community agencies to provide training, education, and child safety seat checks.

Lead poisoning prevention programs can be found in most state and local health departments. The Lead Contamination Control Act of 1988 provided for CDC funding and programs to eliminate childhood lead poisoning (CDC, 2018e). The CDC provides technical assistance, training, and surveillance at a national level. Another role of the C/PHN is to help with targeted screening and case management and provide education to clients and communities about lead poisoning at the local level. They also work with environmental

health personnel and epidemiologists to reach out to neighborhoods and communities at risk for testing. See more on this in [Chapter 9](#).

## *Protection From Child Abuse and Neglect*

Services to protect children from abuse and neglect begin with a collaborative approach that includes social services, law enforcement, education, community health providers, and child advocacy. Protection begins with prevention efforts. Child abuse and maltreatment can be prevented by strengthening family economic and social support systems. Furthermore, C/PHNs must advocate for policies that support improved family economic and social systems ([CDC, 2018g](#)). “Policies that strengthen household financial security can reduce child abuse and neglect by improving parents' ability to satisfy children's basic needs (e.g., food, shelter, medical care), provide developmentally appropriate child care, and improve parental mental health, support positive parenting, ensure quality education and healthcare for children” ([Fortson, Klevens, Merrick, Gilbert, & Alexander, 2016, p. 15](#)). Additionally, social support systems and quality childcare and early education programs for children in communities are essential for prevention of child abuse and maltreatment. Working alongside community leaders, C/PHNs strive to ensure that communities have adequate resources to support healthy development of children ([CDC, 2018g](#)). Protecting children from abuse and maltreatment also includes the importance of early recognition of the signs of abuse and reporting this to authorities (see [Chapter 18](#)). Nurses along with day care providers, teachers, social workers, doctors, clergy, coaches, and all others working with children that suspect child abuse or maltreatment are required by law to report it. In addition, animal humane workers and commercial photograph developers are mandated reporters. Child abuse or maltreatment should be reported to local child protective services or law enforcement agency when it is suspected. Most states have hotline or toll-free numbers available for reporting ([Child Welfare Information Gateway, n.d.b](#)).

To promote safe and nurturing relationships and environments where children live and play free from abuse and violence, ACE must be addressed in our communities. C/PHNs must recognize those at risk for ACE and history of ACE in adults referring clients and families to resources; ACE is preventable. To combat ACE in the community, Washington state has directed efforts to addressing ACE in the community through legislation that aims to reduce prevalence through primary prevention of child maltreatment and community engagement to improve the public's health. Secondary measures include policy enacted through TANF to strengthen ACE families through Head Start parenting programs. Tertiary efforts include additional support for juvenile high-ACE offenders through functional family programs ([CDC, 2019b](#)).

## *Primary Prevention*

Primary prevention measures include the use of social norming that promote positive parenting, family support groups, and public awareness campaigns about child maltreatment and how to report it, along with establishing community education to enhance the general well-being of children and their families. Educational-type services are designed to enrich the lives of families, to improve the skills of family functioning, and to prevent the stress and problems that might lead to dysfunction and abuse or neglect (CDC, 2018g).

Primary prevention also focuses on parent preparation during the prenatal period; practices that encourage parent–child bonding during labor, delivery, the postpartum period, and early infancy; and provision of information regarding support services for families with newborns. This is often the ultimate outcome sought by home visitation programs carried out or managed by C/PHNs. It is also helpful to provide parents of children of all ages with information regarding child-rearing strategies, anticipatory guidance for developmental milestones and tasks, and community resources.

## *Secondary Prevention*

Services are designed to identify and assist families who may have risk factors for impaired parenting to prevent abuse or neglect. **High-risk families** are those families that exhibit the symptoms (risk factors) of potentially abusive or neglectful behavior or that are under the types of stress associated with abuse or neglect. These can include families living in poverty, substance abuse or mental health problems, parents who were abused when they were children, and parents or children with developmental disabilities. Early intervention with high-risk families can improve emotional and functional coping and help prevent further problems. High school parent education programs for pregnant adolescents, home visitation programs targeted to at-risk families, and respite care for families of children with disabilities are all examples of secondary prevention actions. Family resource centers in schools or community centers located in low-income neighborhoods can offer resource and referral services to families who may be dealing with multiple sources of stress. Evidence-based home visitation programs, such as the Nurse–Family Partnership, Early Head Start, and Healthy Families America, provide parental support and education and promote healthier family functioning and have resulted in decreased rates of child abuse and neglect (Child Welfare Information Gateway, n.d.a).

## *Tertiary Prevention*

Intervention and treatment services are designed to assist a family in which abuse or neglect has already occurred, so that further abuse or neglect may be

prevented, and the consequences of abuse or neglect may be minimized. There are several evidence-based programs that have been found effective in reducing the reoccurrence of child abuse. *Safe Environment for Every Kid (SEEK)* is an example of an enhanced primary care program; *Parent–Child Interaction Therapy*, *SafeCare*, and *The Incredible Years* are examples of behavioral training programs; and Trauma-Focused Cognitive Behavioral Therapy (TF-CBT) helps to reduce the consequences of posttraumatic stress disorder and depression after abuse has occurred (Fortson et al., 2016). Often, families are referred to mental health counselors to improve family communication and functioning. Some families may require crisis respite when they feel they cannot manage the stresses of child care. Parent mentoring programs can provide support and coaching to these parents (Child & Family Services, 2018).

The C/PHN and school nurse have major roles in all levels of prevention of child maltreatment. In addition, the nurse is in a unique position to detect early signs of neglect and abuse. The nurse must establish rapport with families and assist with appropriate interventions and referrals at the secondary and tertiary levels of prevention. The advanced practice nurse may also work with families of abused and neglected children as part of an interdisciplinary approach with teachers, the department of social services, the judicial system, foster families, and other health care providers if needed. The effectiveness of local programs depends, in large measure, on the willingness of health professionals to increase their awareness and work as a team to detect, report, develop, and evaluate interventions for the perpetrators and victims of abuse and neglect. Ongoing education of health care providers is recommended to increase awareness of changing child abuse patterns, new reporting laws, and resources available to families.

## Health Promotion Programs

Early childhood development and intervention programs are designed to have positive effects on the outcomes of children's cognitive and social development. Some health promotion programs have considered children's physical health, and fewer have focused on parent–child interaction and child social development. All are considered important health promotion programs from birth through preschool years.

### *Infant Brain Development Research and Parent–Child Interactions*

Research into the normal brain development of infants and toddlers has revealed that brain maturation in the first few years of life is very rapid: the brain grows to 80% of adult size by age 3, and the myelination pattern of an 18-to 24-month-old child is similar to that of an adult (Gilmore, Santelli, & Gao, 2018). The prefrontal cortex of 4-year-olds is already functional and becomes more organized throughout later adolescence. Early environment exerts a lasting influence on brain development, even in the womb. Appropriate early nutrition and stimulation promotes healthy development.

Early in life, rapid myelination is taking place, children need higher fat levels in their diet (50% of total calories should come from fat). Breast milk or formula will provide this fat during the first year of life, then breast milk or whole milk can be used after the first birthday. After age 2, children should reduce fat content to no more than 30% of calories coming from fat and 1% or 2% milk should be used (Zero to Three, 2018). Meaningful parent–child interactions should be established early; they include holding, rocking, comforting, touching, talking, and singing. When parents talk to infants and read to young children, children later demonstrate more advanced language and literacy skills. Providing a caring and supportive environment, with opportunities to learn and explore, is supportive of healthy brain development and promotes secure infant attachment (CDC, 2018g). Important parental behaviors that promote social development include gazing into an infant's eyes, paying attention to and interacting with toddlers, and listening to and answering preschoolers' questions. Providing infants and young children with secure, learning-rich environments where they can use their senses to discover new things helps them to maximize their potential. Emotional comfort and a secure environment ensure that young children will better deal with their feelings. It is important for the C/PHN to provide information to parents on the most current research results about brain development as well as tangible suggestions such as low-cost brain-stimulating toys and community resources to encourage quality parent–child

interactions that promote appropriate physical growth and cognitive and social development.

## *Developmental Screening*

With the emphasis on infant and early childhood development, C/PHNs often routinely carry out developmental screenings (Fig. 19-9). The American Academy of Pediatrics recommends developmental screening surveillance for children at each health visit along with an evidence-based developmental screening tool used at 9, 18, and 30 months, or anytime there is a concern. Autism-specific screenings are recommended at 18 and 24 months and social-emotional screenings should be conducted at regular intervals (2018e). There are a variety of screening tools available with resources available at <https://screeningtime.org/star-center/#/screening-tools>.

**FIGURE 19-9** Allowing children to play with health care equipment can help alleviate fear and anxiety.

Developmental screening tools are also helpful in educating parents about normal child development and can provide a means of anticipatory guidance on developmental milestones and future safety issues. *Bright Futures*, an important resource for nurses and parents, provides tools to help families determine appropriate developmental milestones and expected behaviors, along with suggestions about when to seek help from professionals. A variety of screening tools available to nurses and other health professionals, ranging from parent report instruments to those that involve direct assessment of behaviors and skills, can examine overall physical and cognitive development or screen for such things as temperament, behavior, autism, and speech and language problems. It is important for the C/PHN to use tools that have reported validity and

reliability. Early identification of problems can lead to interventions such as enrollment in early intervention programs and help children with school readiness. These early intervention programs are available in most communities or through the public school system ([Bright Futures, 2018](#)).

### *Programs for Children With Disabilities*

Many children have special needs. They may have a congenital or acquired developmental disability, birth defect, or a chronic emotional, mental, or physical disease. About 1 in every 33 U.S. infants are born with a birth defect each year ([CDC, 2018f](#)). Some children suffer injuries after birth ([Box 19-9](#)). Autism and other mental or behavioral disorders develop after infancy and may require special services. Educational, health, and social or recreational services should be available for all children.

## **BOX 19-9 STORIES FROM THE FIELD**

**A Case of Kernicterus** A young mother was hospitalized for the birth of her second daughter, a beautiful little girl born without incident. The infant had difficulty latching on for breastfeeding and was not an active feeder. The mother told her obstetrical nurse that the infant seemed very different from her first child. The infant was irritable, but the nurse reassured the mother that the baby was fine and “not all babies are alike.” Still, the new mother was concerned.

By the second day, the mother noticed that the baby was not very alert and did not want to feed. She also noticed that the baby's color was “yellowish,” and the mother notified the nurse. Again, the nurse reassured the mother that this was “normal” for infants of Asian descent. The baby still was not feeding well, and there was yellowish-orange color stool in the baby's diaper. The mother notified the nurse and asked the nurse to call the doctor. The nurse refused and told the mother that she was “overreacting.” The nurse again reassured the mother that the baby was “fine” and no action was taken. The young

mother was not satisfied with the nursing care and requested additional assistance. A referral was made to the breastfeeding specialist at the hospital to help the new mother feed her infant. There were no phone calls documented to the physician nor was there documentation of the “yellowish-orange” stool. (The young mother kept the diaper for further proof of her concerns, though.) There was no documentation of irritability, inability to breastfeed, lethargy, or jaundiced appearance of the skin. The physician discharging the infant did not receive any information regarding irritability, yellowish stool, and yellowish tone of lower extremities and abdomen. No blood work was done. No referrals were made to home health or public health for follow-up.

Within 48 hours of discharge, the young mother brought her lethargic baby to the hospital's emergency room. On day 4 of life, the infant's bilirubin was 46. The infant was severely neurologically damaged, and the brain damage that resulted was irreversible. She was diagnosed with severe cerebral palsy, secondary to kernicterus (excessive bilirubin). The child has normal intelligence but will never be able to walk or talk. She will be fed through a gastrostomy tube for the rest of her life. The family was devastated.

The physician and hospital (nurses) were sued. The nurses on duty could not defend their actions with their charting or lack thereof. The attorneys for the hospital, representing the physician and nurses, could not defend the actions of their clients. A multimillion-dollar settlement was granted, and the nurses were fired. Unfortunately, this is not an isolated case. The irreversible brain damage that occurs as a result of untreated hyperbilirubinemia should not occur in the 21st century. This was a no-win situation that could have been avoided with proper nursing intervention. Hyperbilirubinemia should always be in the forefront of newborn assessment during the first few days of life.

The nurses involved in this case were not acting as the patient's advocate. The physician should have been notified immediately when signs and symptoms were first noted. Incorrect assumptions were made because of the nationality of the patient, an indication of lack of cultural competence. Home health nursing or public and community health nursing care should have been arranged for infant follow-up after discharge.

Linda O., certified life care planner, nurse consultant

1. *As a new C/PHN, what services do you think this family needs? Do you believe these services will change over time? If so, what type of anticipatory guidance should you provide the family and child?*
2. *This family may not have any trust of health care providers. How can you earn this family's trust?*

### *3. How can you become culturally competent when working with a culture you are not familiar with?*

Federal law mandates early identification and intervention services for those with a variety of developmental disabilities. Developmental delays are characterized by slower development in one or more areas. The Individuals with Disabilities Education Act (IDEA) provides early intervention services, usually at home, for those from birth to age 2 who have developmental delays in physical, cognitive, communication, social/emotional, and adaptive development. Intervention services are also available to children with a mental or physical problem that is likely to result in a developmental delay. Newborns can receive infant stimulation services at home or in some schools specially designed to meet the needs of the very young. These programs are offered on a part-time basis for 1 to 2 hours, two to three times a week. Special education preschools are available for young children from ages 3 to 5. By preschool age, children may advance to half-day programs. Additional services can be provided to assist the families in getting children to the programs. Door-to-door bus service in specially equipped small buses or vans safely transports young children who arrive at school in wheelchairs or with other assistive devices (Parlakian, 2018).

Availability of health services for children with disabilities varies with the size of the community. In small rural communities, children and their parents may have to travel long distances to receive specialized services, and in inner-city neighborhoods, lack of money for transportation can make even nearby services equally inaccessible. Accessibility is also influenced by lack of knowledge, attitudes, and prejudices. The nurse must recognize the power of these immobilizing factors and be able to deal with them effectively to make positive changes. See [Chapter 23](#) for more on barriers to health care.

Most communities offer additional social and recreational programs for children that are disabled. For example, American Lung Association affiliate offices sponsor camping programs for children with asthma or other lung diseases. Often, these are camps for school-aged children that may last up to 1 week and be located in mountain or beach areas, but they may also be day camps, with parents in attendance for preschoolers. Many of these camps have C/PHNs either working or volunteering. Nationwide programs, such as the Special Olympics, offer recreational competition for the children in a variety of sports, such as bowling, track and field, skiing, and swimming. The C/PHN best serves families as a resource for such programs. Some parents are not aware of the rights or services available for their children with disabilities. Nurses can advocate for parents and help establish services in communities where needed services are lacking.

## *Nutritional Programs*

Adequate nutrition must begin before birth. One of the most productive health promotion programs is the Special Supplemental Food Program for Women, Infants, and Children (WIC). In addition to supporting women and young children with nutritious foods and achieving the initial goals of decreasing the rates of preterm and LBW babies, increasing the length of pregnancy, and reducing the incidence of infant and child iron deficiency anemia, WIC also improves pregnant women's nutritional status. WIC is not an entitlement program, but rather, Congress sets funding and eligibility requirements yearly (U.S. Department of Agriculture, 2018).

WIC provides information to parents about eating healthfully and promoting healthy rates of growth. Parents become more aware of the need to reduce consumption of saturated fat, salt, sugar, and over-processed foods. The C/PHN, through nutrition education, reinforcement of positive practices, and referral, plays a significant role in promoting the health of infants and young children (Box 19-10). For more information about WIC, see Chapter 20.

## **BOX 19-10 Levels of Prevention Pyramid**

**Prenatal and Newborn Care SITUATION: Desire for a healthy, full-term infant GOAL: Using the three levels of prevention, avoid negative health conditions, and promptly diagnose, treat, and/or restore the fullest possible potential.**

<b>Tertiary Prevention</b>		
<i>Rehabilitation</i>	<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>▪ The parents and significant others begin to bond with the newborn.</li> <li>▪ Parents get to know the newborn and establish a successful breast- or bottle-feeding routine.</li> <li>▪ The infant returns home in an age-appropriate infant car seat, which is used properly when traveling.</li> <li>▪ The infant's birth is celebrated according to cultural and religious preferences.</li> <li>▪ Parents resume sexual intercourse using a family planning method of their choice.</li> <li>▪ The parents enjoy the new life they have created.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Educate about benefits of early postpartum care.</li> <li>▪ Set goals with client to make and keep appointments for postpartum and newborn visits to health care providers.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Educate to avoid exposure to people with infectious diseases.</li> <li>▪ Educate and follow up to assure that infant immunization schedule begins on time and continues through childhood.</li> </ul>
<b>Secondary Prevention</b>		
<i>Early Diagnosis</i>	<i>Prompt Treatment</i>	
<ul style="list-style-type: none"> <li>▪ The mother starts prenatal care early in the first trimester and continues care at regular intervals throughout the pregnancy.</li> </ul>	<ul style="list-style-type: none"> <li>▪ The mother does not use alcohol, tobacco, or other mood-altering substances during the pregnancy.</li> <li>▪ The mother takes a daily prenatal vitamin with folic acid.</li> <li>▪ Parents avoid exposure to people with infectious disease.</li> <li>▪ The mother has adequate nutrition, rest, sleep, and exercise.</li> <li>▪ The mother begins supportive services if eligible (WIC, Temporary Assistance for Needy Families).</li> <li>▪ Family and significant others continue to be supportive.</li> <li>▪ The parents attend labor preparation, infant care, and parenting classes.</li> <li>▪ Name(s) is selected for the infant.</li> <li>▪ Delivery method and location are selected.</li> <li>▪ The home is prepared for the infant, e.g., adequate infant furnishings and supplies are acquired within the parents' budget.</li> <li>▪ Preparations and plans are made regarding breast- or bottle-feeding.</li> <li>▪ A pediatrician or pediatric nurse practitioner is selected.</li> <li>▪ An infant car seat is acquired and properly installed.</li> <li>▪ Plans are made to get to the chosen health care facility when in labor.</li> </ul>	
<b>Primary Prevention</b>		
<i>Health Promotion and Education</i>	<i>Health Protection</i>	
<ul style="list-style-type: none"> <li>▪ The pregnancy is planned.</li> <li>▪ Pregnancies are spaced 2 years (or more) apart.</li> <li>▪ Mother has a positive attitude going into the pregnancy.</li> <li>▪ A health care provider is chosen.</li> <li>▪ There are financial resources to meet the expanding family's needs.</li> <li>▪ Family and significant others are supportive.</li> <li>▪ Mother's weight is as close to ideal as possible before conception.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Parents do not use alcohol, tobacco, or other mood-altering substances when planning to conceive.</li> <li>▪ The mother begins a vitamin regimen containing folic acid before the pregnancy.</li> </ul>	

# ROLE OF THE C/PHN

C/PHNs face the challenge of continually assessing each population's current health problems as well as determining available and needed services. Interventions are implemented for the maternal, infant, toddler, and preschool populations that focus on health promotion, health protection, and early intervention. Interventions may include work in family planning or high-risk clinics, telephone information services and hotlines, outreach interventions, child care consultation, or home visitation programs. The nurse uses educational and health coaching interventions when teaching family planning, nutrition, safety precautions, and appropriate health seeking or childcare skills. Such interventions involve providing information and encouraging client groups (parents and young children) to participate in their own health care. Other interventions include strategies in which the nurse uses a greater degree of persuasion or positive manipulation, such as conducting voluntary immunization programs, working in a lead screening program, encouraging smoking cessation during pregnancy, preventing communicable diseases, and encouraging appropriate use of child safety devices such as car seats. Finally, the nurse may use interventions that motivate people into adherence with laws that require certain immunizations or mandate reporting of suspected child abuse and environmental health standards violations, such as sanitation issues. Home visiting programs are effective in addressing needs of high-risk and hard to reach families (USDHHS, 2018). See [Chapter 6](#) for new programs available through health care reform.

The C/PHN acts as an advocate and a resource for childbearing women and couples and families of young children. The nurse may be called upon to provide information to young mothers about infant temperament, sleep schedules, colic, parenting, discipline, toilet training, television or video choices, and nutrition and feeding. The nurse should be aware of federal, state, and local laws that preserve and protect the rights of children and families. Knowledge about educational, medical, social, and recreational services needed by young families is helpful. The nurse works to secure these services in the community. Ensuring that families have the resources to provide a safe and healthy environment for their children can take many forms. The nurse may lobby to change existing laws, initiate the effort needed to establish programs and services in the community, and teach families about infant safety or the importance of immunizations. The C/PHN also has skills of community and neighborhood assessment. These skills are vital to health departments and community-based organizations and primary

care centers for development of programs needed for women and children (Aston et al., 2016).

# SUMMARY

- Maternal–child health clients are an important population group to C/PHNs because their physical and emotional health is vital to the future of society.
- The United States does not fare well in comparison to other developed nations on maternal–child health indicators.
- Problems of substance abuse, STIs, and teen pregnancy can lead to less than optimal outcomes for newborns.
- Complications of pregnancy and childbirth, such as hypertension, gestational diabetes, postpartum depression, and fetal or infant death, offer opportunities for C/PHNs to provide education, outreach, monitoring, and support.
- IMRs in the United States are higher than those in many other countries around the world. Toddler and young child mortality and morbidity are often related to unintentional injuries
- Preventive services include immunization programs, along with quality day care and preschool.
- Health protection services include accident and injury prevention and control, as well as services to protect children from child abuse.
- Health promotion services include infant development through effective parent–child interaction, developmental screening, and services to children with special needs.

# ACTIVE LEARNING EXERCISES

1. Using “Assess and Monitor Population Health” (1 of the 10 essential public health services; see [Box 2-2](#) ), how do your county's statistics compare with those of others in your state on (1) infant mortality rates (collectively and by specific ethnic groups), (2) incidence of low birth weight and very low birth weight in infants, and (3) incidence of birth defects? What is the major cause of death among infants, toddlers, and preschool-aged children in the United states, in your state or local area?
2. Locate some national Web sites that give you current information about progress toward meeting some of the *Healthy People 2030* goals with mothers, infants, toddlers, and preschool-aged children. Are we making progress? What can a C/PHN do locally to promote meeting these goals? What needs to be done on the regional, state, or national level?
3. What is the major cause of death among infants, toddlers, and preschool-aged children in the United states, in your state or local area? What community-wide interventions could be initiated to prevent these deaths? Select one intervention for each age group and describe how you and a group of community health professionals might develop this preventive measure.
4. Look at the pertussis, maternal mortality rate, and maternal–child health vital statistics in your county or community. What do these statistics tell you about your community's health? What other related statistics are important to gather to determine if your community is a positive and healthy place for childbearing women and young children?
5. Go to the Centers for Disease Control and Prevention Web site ([www.cdc.gov](http://www.cdc.gov)) and look up the current childhood immunization schedule for children ages 0 to 4 years. How would you determine how to modify the schedule for a 30-month-old who is missing his last set of immunizations?

# CHAPTER 20

## *School-Age Children and Adolescents*

*“Youth is the spirit of adventure and awakening. It is a time of physical emerging when the body attains the vigor and good health that may ignore the caution of temperance. Youth is a period of timelessness when the horizons of age seem too distant to be noticed.”*

—Ezra Taft Benson

### **KEY TERMS**

Adverse childhood experiences (ACE) Anorexia nervosa

Asthma action plan

Attention deficit hyperactivity disorder (ADHD) Autism spectrum disorder (ASD) Binge eating

Bulimia nervosa

Learning disorders

Obese

Overweight

Pediculosis

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Explain how poverty is a significant social determinant of health in children and adolescents.
2. Identify major health problems and concerns for U.S. school-age children and adolescents.
3. Discuss the relationship of academic achievement to health status.
4. Describe and analyze mortality and injury trends among school-age children and adolescents.
5. Evaluate *Healthy People 2030* objectives affecting children and adolescents and the barriers that may be involved in attaining these objectives.
6. Evaluate health promotion programs and services for school-age children and adolescent populations at the primary, secondary, and tertiary levels.

# INTRODUCTION

According to Erick Erickson's developmental framework, the school-age and adolescent years are a time of task mastery and development of competence and self-identity. During these years, children grow physically, as well as emotionally and socially. They move from being under the total control of parents and families during the infant and toddler years to being more and more influenced by those outside the home—classmates, teachers, peers, and other groups ([Hockenberry, Wilson, & Rodgers, 2019](#)).

Poverty, a significant social determinant of health, poses a challenge to the health of many school-age children and adolescents. Other challenges for this population include chronic diseases, behavioral and learning problems, emotional and mental health issues, disabilities, injuries, communicable diseases, developmental issues, school concerns, and the risk behaviors characteristic of teenage years. This chapter explores the health needs of school-age children and adolescents and describes various services that address those needs, along with the community health nurse's role in assisting families with children.

# SCHOOL: CHILD'S WORK

Children and adolescents spend most of their waking hours in school. The quality of their educational experiences (e.g., teacher–child interactions) can influence learning, and their academic success can predict future education, employment, and income. Therefore, their future success as tomorrow's parents, workers, leaders, and decision-makers depends in good measure on the achievement of their educational goals today.

Child health has been linked to school success—healthy children are found to be more motivated and prepared to learn ([Centers for Disease Control and Prevention \[CDC\], 2017a](#))—and coordinated school health programs are linked to academic achievement ([CDC, 2019a](#)). This is well known to school nurses and community and public health nurses (C/PHNs) that work in schools.

In 2018, approximately 56.6 million school-age children and adolescents (5 to 18 years old) attended elementary and secondary schools in the United States. Of these students, approximately 50.7 million are educated in public schools and 5.9 million in private schools ([National Center for Education Statistics \[NCES\], 2018a](#)).

In 2016, the U.S. population aged 0 to 17 years was 51.1% White/non-Hispanic, 13.8% Black/non-Hispanic, 4.9% Asian/non-Hispanic, 24.7% Hispanic, and 4.2% all other groups (Federal Interagency Forum on Child and Family Statistics [FCFS], 2019c).

# POVERTY: A MAJOR SOCIAL DETERMINANT OF HEALTH IN SCHOOL-AGE CHILDREN AND ADOLESCENTS

Although the United States is making strides against poverty, around 21% of children still live in poverty. In 2016, 44% of children under the age of 3 years lived in low-income families and 21% lived in poor households. Moreover, this burden of poverty is not equally shared among racial and ethnic groups. In comparison with White children, children of color are almost three times as likely to live in a poor household. One of every ten White children live below the poverty line and approximately one of every three Black, Hispanic, and Native American children live below the poverty line ([National Center for Children in Poverty \[NCCP\], 2018](#)).

Poverty has profound and lasting effects on children, as research has consistently shown over many years. In the most recent NCCP report, Dr. Heather Koball stated, “We’re seeing promising movements in the year-to-year measurements of child poverty and economic stability....But while the number of children experiencing poverty is on the decline, the rate of poverty for kids still remains stubbornly high, compared to the size of the population. Children are also more likely to suffer the material hardships associated with living in poverty; the anxiety, depression, and constant stress of being financially vulnerable leaves a lasting mark on children as they grow to adulthood, affecting earnings potential and health outcomes as adults” ([NCCP, 2018](#)).

Children living in poverty have poorer health overall and are more likely to experience:

- Chronic health condition (e.g., asthma, anemia)
- Injuries and accidents
- Behavioral problems, including academic failure, alcoholism, antisocial behavior, depression, substance abuse, and adolescent pregnancy
- Poor brain growth, neurodevelopment, and learning
- Developmental delay
- Exposure to environmental toxins, parental substance abuse and neglect, maternal depression, trauma and abuse, divorce, violent crime, low-quality child care, inadequate nutrition, and decreased cognitive stimulation and exposure to vocabulary in early childhood and infancy,

all of which can contribute to social, emotional, and behavioral problems ([Center for the Study of Social Policy, 2017](#); [Van Ryzin, Fishbein, & Biglan, 2018](#))

- Lead poisoning
- Iron deficiency anemia
- Increased susceptibility to illness
- Family and community violence, leading to a view of the world as a hostile and dangerous place and mental health issues ([Child Trends Databank, 2018a, 2018b](#))

Social determinants of health (SDOH)—which are the social, economic, and physical conditions in which children live—can affect their health and wellbeing; “Growing up in poverty is a powerful SDOH because it can affect children's access to many [of these] health-promoting conditions” ([Francis et al., 2018](#), para 1). Children growing up in impoverished and unhealthy conditions can stress a child's response system, increasing the risk for poor physical, behavioral, social–emotional, and cognitive health ([Francis et al., 2018](#)). The relationship between lower socioeconomic status (SES) and poor health persists throughout childhood and adolescence into adulthood. Children who spend half of their life in poverty are 40% more likely to be living in poverty by the age of 35 years. As adults, these children are less likely to have completed high school and more likely to have lower occupational status and lower wages.

A classic longitudinal study, along with a series of preliminary studies, on the many stresses of childhood poverty (e.g., crowded homes/classrooms, inadequate child care, low socioeconomic status, family/peer problems) found that levels of the stress hormone cortisol influenced results on school readiness testing and affected cognitive functioning (e.g., impulse/emotional control, planning, attention), which, in turn, affects school success ([Blair, 2012](#)). For more affluent children, other stressors (e.g., divorce, learning disabilities, harsh parenting) can affect stress levels and outcomes. Continuing periods of high stress can lead to either high levels of cortisol or levels that are immediately high but then drop very low and that blunt children's responses to new challenges. Both those with blunted responses and those with very high cortisol responses were found to have lower executive function and more problems with writing, math, and reading, as well as poor self-control in class. The reverse was found for those with more characteristic patterns of cortisol response (elevated with a stressful event and then normalized afterward).

The children in this study were tested in Head Start and again in kindergarten. Parenting style was also examined, and parents of lower socioeconomic status were more prone to harsher forms of discipline that demanded obedience. Their children had lower executive functioning and

either high or blunted cortisol levels. Parents using a more sensitive approach, who interacted with children during play and allowed more exploration, had children with better executive function and normal cortisol response. Researchers saw this as evidence that parenting style was an important part of child stress response. They noted that psychological stress in childhood “can substantially shape the course of their cognitive, social, and emotional development ... and impair specific learning abilities in children, potentially setting them back in many domains of life” (p. 67).

The negative impact of childhood poverty on learning and later income along with health continues to be well documented. [Van Ryzin et al. \(2018\)](#) indicate, “Researchers found that attaining economic security later in life did not completely attenuate this link between early poverty and health problems, suggesting that poverty and adverse social experiences early in life made the strongest contribution to negative long-term health effects” (p. 130).

Because the lifelong effects of poverty can be deeply rooted in children and adolescents, countering its effects requires a multilayered public health approach. Prevention programs that increase childhood nurturing have been shown to decrease behavioral, emotional, cognitive, and neurophysiological problem development and may be either family or school based.

Family-based prevention programs focus on teaching family management skills and improving family relationships. Change outcomes associated with these programs involve cultivating skills for monitoring and managing child behavior, negotiating conflicts, and improving overall family environment quality. Studies indicate that parenting programs can alter cortisol rhythms, improve stress regulation, and improve standard of living over time. One of these programs, the Nurse Family Partnership program has directly led to decreased use of welfare and other governmental assistance, improved employment for mothers, and improved birth spacing (see [Chapter 4](#)).

School-based programs focus on child development and the need to remediate the effects of low-income and deficient home environments. Change outcomes involve social–emotional and character development, such as improving decision-making skills, improving management of difficult situations, and establishing positive relationships. An example of a school-based program is Cooperative Learning, which focuses on instructional strategies and can be used in elementary, secondary, and postsecondary education settings. It involves group learning methods such as peer tutoring, reciprocal teaching, and collaborative reading. Teachers design their own small-group activities that focus on “positive interdependence.” Members of the group are each responsible to achieve their goals and the success of the group. Such activities improve friendships, increase personal acceptance, and foster academic achievement ([Van Ryzin et al., 2018](#)).

Reaching families in need and disseminating programs to larger populations require policy initiatives and funding at the local, state, and national levels. Prevention programs can be implemented through improved access to health care systems. Using new technology strategies such as telehealth enables health service access and reduces provider-level barriers to health care. All of the strategies and programs discussed require ongoing evidence-based practice and community partnerships to educate public and policy makers, with the goal of disrupting the intergenerational effect of poverty (Van Ryzin et al., 2018). For more on poverty, see [Chapter 23](#).

Several government programs and legislative reforms have provided assistance to the poor and attempted to help them move out of poverty. Welfare reforms enacted in 1996 (i.e., the Personal Responsibility and Work Opportunity Reconciliation Act) have been successful in moving many families from welfare to work. With a combination of welfare time limits, increasing work requirements/sanctions, and reducing financial disincentives for work, welfare reform and work success programs were projected to lead to greater employment. After 22 years, however, many are questioning whether the resulting safety net of Temporary Assistance for Needy Families (TANF) is adequate. The number of families receiving cash assistance through TANF decreased since its implementation from 68 of every 100 families in poverty receiving cash assistance in 1996 to 23 of every 100 families in poverty receiving cash assistance in 2016 ([Center on Budget and Policy Priorities \[CBPP\], 2018](#)). The majority of TANF adult recipients are single mothers with young children, and Hispanic children represented the greatest number of recipient children in 2015 ([CBPP, 2018](#); [Child Trends Databank, 2018a](#)).

The Supplemental Nutrition Assistance Program (SNAP), formerly the Food Stamp Program, is one of the largest programs offered by federal Food and Nutrition Services. In 2016, the number of children receiving SNAP benefits was approximately 19 million. Positive health benefits for children are linked with SNAP. These positive outcomes include improved birth outcomes and improved adult health and self-sufficiency. However, the effectiveness of this program is also being questioned, as many families exhaust the resource by the end of the month and fall short of groceries ([Child Trends Databank, 2018b](#)).

Safety-net programs such as TANF and SNAP have demonstrated a reduced risk of nutrition-related problems (e.g., anemia, nutritional deficiency, failure to thrive), improved overall health, and decreased health care costs. They have also been associated with a reduction in the risk of child abuse and neglect. Research regarding SNAP and TANF programs suggests that increased evaluation is needed regarding the effectiveness at reducing poverty, the overall effect for children's health, and the use of health care services ([Carlson & Keith-Jennings, 2018](#)). Public insurance now covers

the majority of poor and low-income children. In 2016, the rates of uninsured children reached an historic low, with only 5.3% of U.S. children lacking health insurance. Although Medicaid and Children's Health Insurance Program offer insurance coverage for low-income children, insurance premiums are associated with increased numbers of uninsured children (Dubay & Kenney, 2018; Kaiser Family Foundation, 2019). See Chapters 6 and 23 for more on insurance and vulnerable populations.

# HEALTH PROBLEMS OF SCHOOL-AGE CHILDREN

The wellbeing of children is a concern both nationally and internationally. Many organizations have focused their resources on improving the health and wellbeing of children, including the World Health Organization (WHO), United Nations International Children's Education Fund, and U.S. governmental agencies, nonprofit groups, and charitable foundations. Unfortunately, the needs of millions of children in the United States and worldwide remain unmet.

The *Healthy People 2030* framework for children is shown in [Box 20-1](#).

## **BOX 20-1 HEALTHY PEOPLE 2030**

### **Objectives to Improve the Health and WellBeing of Children**

## Core Objectives

EMC-01	Increase the proportion of children and adolescents who communicate positively with their parents
EMC-02	Increase the proportion of children whose parents read to them at least 4 days per week
EMC-03	Increase the proportion of children who get sufficient sleep
EMC-04	Increase the proportion of children with developmental delays who get intervention services by age 4 years

## Research Objectives

EMC-R01	Increase the proportion of children with developmental delays who get intervention services by age 4 years
---------	--

## Developmental Objectives

EMC-D01	Increase the proportion of children who are developmentally ready for school
EMC-D02	Reduce the proportion of children and adolescents who are suspended or expelled

Reprinted from U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives.

Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

Even in the wealthiest nations, many children face complex and often chronic health problems that cause them to miss school days or marginally participate in the classroom. Childhood is a critical period during which certain health behaviors or conditions can develop that can lead to more serious adult illnesses. The chronic health problems of children younger than age 18 years are characterized by the duration and persistence of symptoms and their impact on social functioning. Examples of chronic conditions in school-age children include:

- Asthma
- Autism spectrum disorder (ASD)
- Diabetes
- Neuromuscular disorders
- Poor oral health
- Seizure disorders
- ADHD
- Nutritional problems—[anemia or obesity/overweight](#)
- Food allergies
- Mental illness ([CDC, 2017b](#))

## Chronic Diseases

Stomachaches, headaches, colds, and flu are frequent complaints of school-age children. Common problems such as hay fever, sinusitis, dermatitis, tonsillitis, and hearing difficulties are also seen. Chronic health problems can affect a child's ability to learn and/or his or her physical and social development. Other more serious conditions, such as asthma, diabetes, hypertension, seizure disorders, food allergies, and poor oral health, have effects on academic achievement and educational attainment, affect the entire family, and can lead to developmental and social issues for children, as well as missed school days and eventual school failure. Understanding the influence of chronic diseases in children and families is key for public health and school nurses as they assist children and families in managing health (CDC, 2019a; Leroy, Wallin, & Lee, 2017; Miller, Coffield, Leroy, & Wallin, 2016).

With the prevalence of childhood chronic conditions increasing over the past two decades, approximately 25% of school-age children in the United States now have chronic health conditions and 5% have multiple chronic conditions. An increasing prevalence of asthma, food allergies, epilepsy, diabetes, and hypertension are common in the school setting (Table 20-1; Miller et al., 2016). Three common chronic disorders in children directly influenced by socioeconomic status and environment are (Food, Allergy, Research, and Education, n.d.):

	Asthma	Food Allergies	Epilepsy	Diabetes	Hypertension
Percentage of school-age children with condition	7.3%–9.5%	4%–8%	0.7%	0.3%	0.17%

Source: Miller et al. (2016).

- Asthma
- ADHD
- ASD

These chronic disorders have been evaluated according to social determinant influences such as poverty. Recent studies indicate that impoverished children have higher-than-average reported prevalence of asthma, ADHD, and comorbid health conditions. Prevalence of and comorbidities associated with ASD were comparable across income levels (Pulcini, Zima, Kelleher, & Houtrow, 2017).

In a study examining the prevalence and health care–related costs for children ages birth to 18 years with asthma, epilepsy, hypertension, food allergies, and diabetes; gender and ethnic variances were noted.

- Females had a higher prevalence of all chronic conditions except diabetes.
- African American children had nearly 50% higher rates of asthma than did White children, and the odds of having diabetes were 85% higher for White children than for Asian children and 60% lower for Hispanic children than for non-Hispanic children.
- Prevalence of epilepsy was higher in Hispanic children than in non-Hispanic children, and adolescents and children ages birth to 5 years had 29% greater odds of having epilepsy than adolescents aged 12 to 18 years.
- Food allergy prevalence was comparable across races, with American Indian children and adolescents having the greatest percentage at 0.50% (Miller et al., 2016).

With the numbers of children with chronic conditions increasing, more children with significant health problems are present in schools (Leroy et al., 2017). Some children require specialized physical health care procedures, such as catheterization, suctioning, or ventilator care while in the school setting, even though school nurses are not always present in each school building every day (Toothaker & Cook, 2018).

The Individuals with Disabilities Education Act (IDEA) and Section 504 of the Rehabilitation Act of 1973 mandate that services must be provided for children identified as *disabled*. Many conditions may be characterized as disabling under these two laws, including autism, deafness or hearing impairment, blindness or vision impairment, emotional disturbances, mental retardation, specific learning disabilities, speech or language impairments, or other health impairments (e.g., ADHD, asthma). Once identified as disabled, children may qualify for special educational services. Children with chronic health conditions that can affect learning (e.g., diabetes, seizure disorders) may receive medications or other related services while in school to maintain health and promote ability to learn (U.S. Department of Education, 2018).

Many children with chronic health conditions take multiple medications at home and at school. This is a critical time for teens to develop schedules and optimal health behaviors. Medication adherence challenges can be particularly daunting for adolescents as they prepare to manage health as an adult. Common medication adherence barriers may include medication adverse effects, scheduling challenges, desire to appear “normal,” and lack of family, social, or medical support. One recommendation to engage adolescents and improve medication adherence is the use of mobile technology-based interventions (Badawy, Thompson, & Kuhns, 2017). Home visits and consultations by C/PHNs and school nurses could also be helpful to parents and children or youth with chronic health conditions. See Chapter 28 for more on school nursing.

## *Asthma*

Asthma is one of the most common chronic diseases of childhood. It is estimated that 8.4% of children younger than age 18 have been diagnosed with asthma. Childhood asthma rates steadily increased over the past two decades. Although reasons for increased asthma rates are somewhat unclear, experts speculate that better recognition and diagnosis of the disease, overcrowded conditions, and exposure to air pollution (indoor or outdoor), allergens, and irritants in the environment are probable culprits and may trigger asthma attacks.

Recent research indicates that prenatal and early postnatal exposure to environmental triggers and even prenatal stress and gender may increase asthma susceptibility. Children and adolescents with asthma may have attacks triggered by infections, exposure to cigarette smoke, stress, strenuous exercise, or weather changes (e.g., cold, wind, rain). Asthma disproportionately affects minority groups and families living below the poverty level (Bose et al., 2017; Miller & Lawrence, 2018; National Heart, Lung, and Blood Institute, 2018).

Children with asthma incur greater health care costs associated with increased emergency department visits and hospitalizations. Treatment for chronic asthma usually includes cromolyn sodium, leukotriene modifiers, inhaled and oral corticosteroids or long-acting beta agonists, and anti-immunoglobulin E therapy, but acute symptoms may involve inhaled beta<sub>2</sub> agonists and sometimes anticholinergics (National Heart, Lung, and Blood Institute, 2018). Asthma education programs are central to effective disease control and management. In 2018, the National Center for Environmental Health of the CDC published “EXHALE: A Technical Package to Control Asthma.” The EXHALE program focuses on the following evidence-based strategies:

- **E**—Education on asthma self-management (AS-ME)
- **X**—X-tinguish smoking and secondhand smoke
- **H**—Home visits for trigger reduction and asthma self-management education
- **A**—Achievement of guidelines-based medical management
- **L**—Linkages and coordination of care across settings
- **E**—Environmental policies or best practices to reduce asthma triggers from indoor, outdoor, and occupational sources

School nurses and C/PHNs often work with students, families, and physicians to develop an **asthma action plan** to control, prevent, or minimize the untoward effects of acute asthma episodes. It is hoped that professionals in public health, health care, education, social services, and nongovernmental organizations will use the EXHALE program tools to

improve asthma control/management and monitor and evaluate program success (Hsu, Sircar, Herman, & Garbe, 2018).

C/PHNs are in a unique position to implement many of the EXHALE strategies, especially education for children and their families. Education should include foundational asthma self-management (AS-ME) concepts including medication use, asthma self-management techniques, symptom recognition and appropriate treatment, and asthma trigger reduction.

Monitoring asthma medications and teaching proper methods of inhaler use are vital school nursing or C/PHN functions. Evidence indicates that AS-ME results in better asthma control, improved medication adherence, decreased health care costs, and fewer missed school days (Healthy Schools Campaign, 2018; Hsu et al., 2018).

## *Autism Spectrum Disorder*

**Autism spectrum disorder (ASD)** is a complex developmental disorder frequently noticed within the first few years of life and typically lasts throughout a person's lifetime. The spectrum of ASD indicates that symptoms for each child varies and may range from mild to severe and from gifted to severely challenged (CDC, 2020a). A child's communication skills and interaction with others are most frequently affected, along with obsessive behavior and narrowed interests. Behaviors associated with autism include the following:

- Social issues such as
  - Does not respond to name by 12 months of age
  - Avoids eye contact
  - Prefers to play alone
  - Has flat or inappropriate facial expressions
  - Does not understand personal space boundaries
- Communication issues such as
  - Language problems—delay in language, repetitive use of words
  - Talks in flat, robot-like or sing-song voice
  - Does not pretend in play
- Unusual interests and behaviors
  - Is very organized
  - Has to follow certain routines
  - Fixation on objects and/or interests
  - Repetitive motions such as rocking or spinning (CDC, 2020a)

Autism has become an urgent public health concern with prevalence estimated at 1 of every 59 children by the age of 8 years. The disorder varies among racial/ethnic groups and communities with greater prevalence among

males than females, and whites than minority group, although gender and ethnic prevalence differences are decreasing (Baio et al., 2018).

The yearly expense for autistic children is approximately \$11.5 billion to \$60.9 billion (2011 US dollars). This estimate includes a variety of costs including health care, special education, and lost parental productivity. Health care costs for children and adolescents with ASD are 4.1 to 6.2 times greater than for those without ASD, and when intensive behavioral therapy is required, the cost differential is even greater (CDC, 2020b).

The cause of autism is not clear—some genetic links have been found, but environment may also be a factor. There is a higher risk of subsequent children having autism in a family with one autistic child or a parent with ASD and for children born to older parents (CDC, 2020b).

ASD is frequently associated with genetic and chromosomal disorders, but the exact causes are not fully understood (CDC, 2020b). Through the CDC sponsored multi-year Study to Explore Early Development (SEED), additional autism risk factors are being identified. These include a family history of immune conditions and birth spacing (Croen et al., 2019; Schieve et al., 2018).

C/PHNs may come in contact with families dealing with autism through work in well-child or immunization clinics. It is important to assist families in accessing services for their children (early intervention is advantageous). It is also important to educate that parenting practices are *not* a cause of autism and that multiple, large-scale research studies on childhood immunizations do not indicate a relationship between immunization and autism (CDC, 2019b).

## *Diabetes*

Although diabetes ranks lower as a prevalent childhood chronic illness, it is associated with significant complications and self-management challenges.

- Type 1 diabetes mellitus (T1DM) is usually diagnosed in early childhood and is the leading cause of diabetes in children and adolescents with non-Hispanic Whites having the greatest number of new cases.
- Type 2 diabetes mellitus (T2DM) is generally diagnosed later in life and associated with metabolic syndrome and being overweight. It is more prevalent in U.S. minority groups than non-Hispanic Whites (CDC, 2018a; Miller et al., 2016).
- Both type 1 (T1DM) and type 2 diabetes (T2DM) are found in school-age children, with T2DM rising almost exponentially in this age group, leading some scientists to call this a major public health crisis. This epidemic is thought to stem from increasing rates of childhood obesity,

sedentary lifestyle, and the predisposition of certain ethnic groups (e.g., African American, Native American/Alaska Native, Hispanic/Latino, Pacific Islander) to the disease. A family history of T2DM and having one or more conditions related to insulin resistance also plays a role (CDC, 2017d).

A recent review by Mayer-Davis *et al.* indicates that the health burden of T1DM and T2DM among children and adolescents has increased substantially, especially among minority racial and ethnic groups. These findings are parallel to an increased prevalence of obesity and reflect an increased need for public health interventions to reduce the disease burden disparity. It is possible that variations in the prevalence of obesity will contribute to variations in insulin resistance and an increasing incidence of T2DM. Over time, there will be a substantial increase in U.S. youth with diabetes, especially in minority groups (Mayer-Davis *et al.*, 2017).

Yoshida and Simoes (2018) discuss the increasing evidence about the relationship between sugar-sweetened beverages (SSB), obesity, and T2DM in children and adolescents. Their report indicates that the intake of SSB by children and adolescents corresponds with the rising obesity prevalence. Public health solutions that are all-inclusive and wide-ranging are needed to combat the obesity and T2DM epidemic. Programs that limit the availability and access to SSBs, improve the quality of all foods available in schools, and increase physical activity are being evaluated. Initiatives involving SSB taxation and healthy beverages subsidization are being considered. It is hoped that such a program will increase revenue available for health promotion and develop awareness of SSB consumption health risks. Multiple challenges for these programs exist, including inconsistency among school wellness and nutrition policies, SSB substitution by other high-calorie drinks, increased student calorie intake at home, and opposition from the beverage industry (Yoshida & Simoes, 2018).

Research continues on the pathophysiology of diabetes and prevention strategies (e.g., lifestyle changes, causes of autoimmunity), as well as refining methods of diagnosis and treatment (e.g., insulin pumps, continuous glucose monitoring, closed loop systems).

- School-based interventions focusing on lifestyle modifications, weight loss, healthy eating, and exercise have effectively decreased T2DM risk factors short term. Additional research to determine long-term effects is recommended (Geria & Beitz, 2018).
- Studies regarding oral medication adherence in children and adolescents with T2DM demonstrate that self-management and medication adherence is similar to youth with other chronic diseases. Social and family support, pairing medication dosing with daily routines, and

developing personal problem-solving skills improved self-management (Venditti et al., 2018).

Younger children with T1DM, especially those who use insulin pumps, may need careful monitoring, something that is not always possible for the school nurse assigned to several school sites. It is important for C/PHNs and others working with children and youth who have diabetes to consider their psychosocial needs, as well as their physical needs (Box 20-2). A multidisciplinary team approach coordinating family, school staff, and physician collaboration is optimal. See Chapter 28 for more on the school nurse's role with school-age children with diabetes.

## **BOX 20-2 Evidence-Based Practice**

**Emotional Impact on Children and Youth of Having Diabetes Children and adolescents with diabetes (both T1DM and T2DM) cope with unique disease self-management and health challenges. They are required to pay stricter attention to their health and management of their chronic condition. In addition, there are emotional challenges such as anxiety.**

In a descriptive pilot study, nurses Elertson, Liesch, and Babler (2016) explored expressing emotion through drawings by youth with T1DM. Participating youth were given a blank piece of white paper and asked, “If diabetes had a face, what would it look like?” A variety of emotions and self-expression were portrayed through pictures depicting sadness, tears, helplessness, frustration, and even monster-like images. Some of the drawings portrayed happiness, guilt, anger, judgment, and resentment. Some included written messages describing their experience with diabetes, for example, “Diabetes is my blood sucking monster”; “mad, angry, scared, it hurts”; and “diabetes has an effect on everyone, even people you don't think about” (Elertson et al., 2016, p. 36).

In another study, youth with T1DM are at increased risk of mental health symptoms. Nurses Rechenberg, Whittemore, and Grey (2017) wanted to better understand the emotional impact of children with diabetes. They conducted an integrative review of the literature about anxiety in youth with T1DM. Their research indicates that approximately 20% of youth with T1DM are positive for significant anxiety and depressive symptoms. The review evaluated health

outcomes and anxiety-related symptoms including hypoglycemia fears, family conflict, glycemic control, depressive symptoms, blood glucose monitoring, general anxiety, quality of life, and interventions.

[Rechenberg et al. \(2017\)](#) found that it is important to distinguish the anxiety type when designing interventions. For example, state anxiety (“transient experience of the physiological arousal associated with feelings of dread and tension”) has been more highly associated with depressive symptoms, and trait anxiety (“likelihood to respond anxiously to a stimulus”) is associated with fear of hypoglycemia ([Rechenberg et al., 2017](#), pp. 66, 69). Hypoglycemia fears are more prominent in girls and linked to poorer HbA1c levels and worse self-management. Social anxiety was associated with a poorer quality of life and decreased adherence. Promising interventions included behavioral–cognitive therapy and feasible implementations that strengthen connectedness among youth with T1DM. Adults (e.g., parents, caretakers, nurses) need to be aware of children's physical needs and offer assistance. They also must consider their emotional and psychosocial needs.

Source: [Elertson et al. \(2016\)](#); [Rechenberg et al. \(2017\)](#).

Children and adolescents with diabetes may be reluctant to comply with their medical regimen, but strict adherence has proved to reduce later microvascular complications. Intensive insulin regimens are recommended for T1DM and for some cases of T2DM. Automated insulin delivery systems should be considered and glucose levels monitored multiple times each day.

Research is ongoing regarding the long-term effects of diabetes and best management strategies. It is important for school nurses and C/PHNs to understand each child's unique needs and circumstances and keep in mind a child's developmental stages. In addition to meeting the obvious emergency health–related concerns for diabetic children, it is imperative to teach children and families that proper diet, oral antidiabetic medications or insulin administration, physical activity, and blood glucose testing are vital strategies to keep blood glucose levels as close to normal as possible. This includes alerting teachers and school personnel to the signs and symptoms (as well as treatment) of hypoglycemia. Alerting teachers to these concerns may help them better understand the academic complications of this disease and ensure their support ([Chiang et al., 2018](#)).

The prevention of T2DM through education and improvement in exercise, nutrition, and lifestyle can be one of the most important areas of focus for health professionals who work with the school-age population—including C/PHNs who may come into contact with them during immunization or child health clinics ([Box 20-3](#)). Health education and health

promotion to decrease childhood obesity and sedentary lifestyles may help stem the tide of T2DM in children and adolescents (Geria & Beitz, 2018).

## BOX 20-3 Levels Of Prevention Pyramid

**Prevention of Type 2 Diabetes Mellitus in School-Age Children**  
**SITUATION:** The public health nurse and children with type 2 diabetes (T2DM)

**GOAL:** By using the three levels of prevention, avoid or promptly diagnose and treat negative health conditions and/or restore the fullest possible potential.

Tertiary Prevention		
Rehabilitation	Primary Prevention	
	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Monitor the child's health</li> <li>Work closely with the child, family, physician, and teacher to ensure proper follow-up</li> <li>Be alert to monitor for any possible complications (e.g., medication side effects)</li> </ul>	<ul style="list-style-type: none"> <li>Continue to promote a healthy lifestyle that includes appropriate food choices, daily physical activity within the limitations of T2DM, and medication adherence</li> </ul>	<ul style="list-style-type: none"> <li>Educate teachers on safety precautions for children diagnosed with T2DM in their classroom</li> <li>Monitor children taking medications for T2DM (e.g., over- or underdosage and adverse reactions)</li> </ul>
Secondary Prevention		
Early Diagnosis	Prompt Treatment	
<ul style="list-style-type: none"> <li>Teach older children to calculate their body mass index (BMI)</li> <li>Monitor BMI scores</li> <li>Yearly screenings for height and weight (calipers are useful)</li> <li>Complete health histories on at-risk children</li> </ul>	<ul style="list-style-type: none"> <li>Initiate referrals for health care provider follow-up in collaboration with parents of students at risk for T2DM</li> <li>Initiate referrals to health care providers in collaboration with parents of students with signs and symptoms of T2DM</li> </ul>	
Primary Prevention		
Health Promotion and Education	Health Protection	
<ul style="list-style-type: none"> <li>Educate to promote good nutrition and a physically active lifestyle</li> <li>Provide classroom contact in the early primary grades to encourage children to make good food choices</li> <li>Limit passive activities and increase sports and physical activity</li> <li>Teach older children how to make better food choices at fast-food restaurants</li> </ul>	<ul style="list-style-type: none"> <li>Advocate for policies that limit access to sugary beverages and snacks at school and programs that raise awareness and family involvement in better nutrition and promote physical activity for families</li> <li>Organize T2DM prevention programs, focusing on healthy nutrition and physical activity</li> </ul>	

## Seizure Disorders

Seizure disorders are fairly common in the school-age population. Epilepsy is a disorder of the brain in which neurons sometimes transmit abnormal signals. Epilepsy is considered to be one of the most common disabling neurologic conditions, and it is most common in the very young and in elderly populations.

Approximately 3.4 million people in the United States live with seizures, and of those, 470,000 are children ([Epilepsy Foundation, n.d.](#)). Lifetime prevalence of seizure disorders/epilepsy is estimated at 48 per 100,000, and new cases are most common in younger children and families of low-socioeconomic status.

Those with seizure disorders have an increased risk for developmental (ASD, delays), mental health (e.g., anxiety, depression, ADHD, conduct disorders), and physical comorbidities (e.g., headaches) ([Epilepsy Foundation, n.d.](#)).

Although there are some instances of intractable or drug-resistant epilepsy, many children diagnosed with seizure disorders/epilepsy can have their seizures controlled with antiepileptic medications. Treatment is based upon many factors including the type of seizures, history, and physical status. Vagus nerve stimulators, deep brain stimulation, and ketogenic diets are used in some cases after other treatments have failed ([Mayo Clinic, 2018b](#)).

Rectal diazepam is commonly prescribed for younger children and those with developmental disabilities, yet nurses are not always available to make an appropriate nursing assessment of the child before the drug is given to stop a seizure. Often, school staff is trained to give the emergency medication—highlighting the conflict between education laws and nurse practice acts ([CDC, 2017b](#); see more on this in [Chapter 28](#)).

Parents may be reluctant to disclose a seizure diagnosis due to associated stigma. Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying. They may exhibit signs of school avoidance, or they may have problems learning. Seizure activity, along with the side effects of antiepileptic medications, may lead to problems with memory and learning, as well as changes in behavior. Moreover, seizures can affect short-term memory or language functions. Health care providers are in a position to educate and support families as they cope with the unique challenges of epilepsy ([Benson, Lambert, Gallagher, Shahwan, & Austin, 2017](#); [Kerr & Fayed, 2017](#)). It is important to monitor medication adherence and teach school staff about first-aid measures for seizure victims. When teachers are anxious about having a child with epilepsy in the classroom, educational programs for them and other school staff members can be provided. Community health nurses or school nurses can help allay fears and promote appropriate and timely care.

## *Childhood Cancers*

In 2017, cancer was the second leading cause of death from disease among U.S. children between infancy and age 14 years. Leukemias and brain, central nervous system, and neuroblastoma cancers are the most common types of childhood cancers. Childhood cancers, especially leukemias, now have better outcomes than ever before. Five-year survival rates for childhood cancers have increased by 0.6% each year since 1975 ([Simon, 2018](#)).

More children are surviving childhood cancers, and concern has shifted to later complications of treatment rather than about cancer recurrence. Survivors are at greater risk of cognitive and vision impairments, pituitary problems, delayed growth, and heart disease. Also, children who have been treated with chemotherapy and/or radiation may develop a second primary cancer, and the risk of leukemia may be increased ([American Cancer Society, 2017a](#)).

The cause of most childhood cancers remains unknown; however, high levels of ionizing radiation, Down syndrome, and other genetic syndromes (e.g., Beckwith-Wiedemann syndrome) have been linked to a higher risk for some childhood cancers. Pesticide exposure may be a factor, but research findings have not been decisive. Parental smoking may be linked to an increased cancer risk, but evidence for this is also inconclusive ([National Cancer Institute \[NCI\], 2017](#)).

Because many children return to school after initial hospitalization and treatment for cancer, school nurses or C/PHNs can help make this transition easier by educating classmates about cancer (e.g., it is not contagious), helping the children make necessary adjustments, and vigilantly protecting any immunocompromised students from communicable diseases ([American Cancer Society, 2017b](#)).

## Behavioral and Learning Problems

Other childhood health problems, less easy to detect and measure but often just as debilitating, are those of emotional, behavioral, and intellectual development. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished. Emotional or behavior problems and learning disabilities are prevalent in childhood. It is estimated that one of every five children in the United States has learning and attention issues and yet only a few are actually identified ([National Center for Learning Disabilities \[NCLD\], 2017](#)).

### *Learning Disorders*

Children with attention and learning issues come from all income levels and all nationalities ([NCLD, 2017](#)). **Learning disorders (LDs)**, also known as learning disabilities, are often recognized as the child progresses in school, and special education services may be needed. The cause of LDs is not known; however, differences in brain structure have been noted. Maternal alcohol or substance abuse during pregnancy, poor nutrition, childhood exposure to toxins, and traumatic brain injury may also contribute to LDs ([Eunice Kennedy Shriver National Institute of Child Health and Human Development, 2018a](#)).

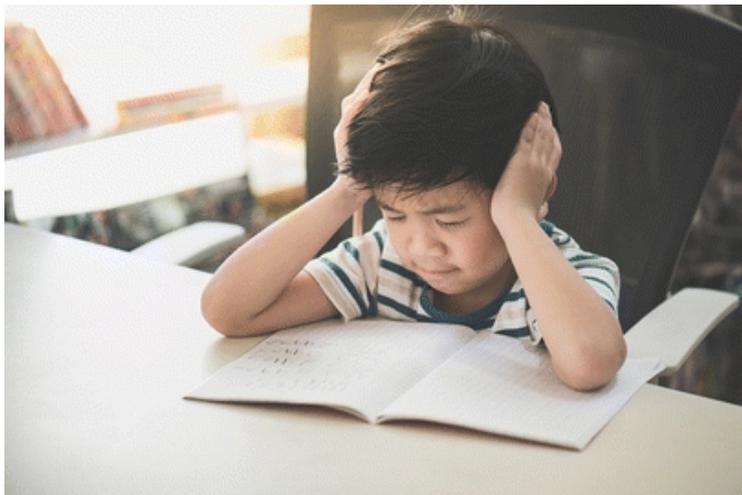

Some LDs are apparent in early school years, whereas others do not present problems until early adolescence. Battles over homework, poor grades, acting out in school, or frequent child complaints about school, teachers, or schoolwork are often harbingers of LDs. Children with LDs are more likely to repeat a school grade, miss multiple school days, be suspended from school, and drop out ([NCLD, 2017](#)). Early identification and intervention are key to the success of a child with LDs. Students must first be carefully identified through specialized testing; then, special education or resource teachers can build on the child or adolescent's strengths while working to compensate for weaknesses.

The recently legislated Research Excellence and Advancements for Dyslexia Act and the Every Student Succeeds Act provide initiatives and strategies for early identification and response for struggling students ([NCLD, 2017](#)).

Common signs of LDs are ([Eunice Kennedy Shriver National Institute of Child Health and Human Development, 2018b](#); [NCLD, 2017](#)):

- Reading problems ([Fig. 20-1](#))

- Writing problems (fine motor control and handwriting; problems with spelling, grammar, punctuation, capitalization; difficulty controlling flow of thoughts)
- Math problems (problems learning and understanding concepts, missing steps or sequencing of problems, and placement of numbers in columns)
- Language problems (cannot quickly process what is heard, problems with multiple instructions, difficulty organizing thoughts and speaking in classroom situations)
- Motor problems (problems with fine motor planning activities, such as tying, cutting, coloring; gross motor planning, such as jumping and running; trouble with visual–motor activities, such as hitting or catching a ball)
- Sequencing (getting letters or numbers out of order); organization (messy binders)
- Memory (difficulty retaining what was learned); abstraction (confused or not understanding what was said)

**FIGURE 20-1** Reading is important to education and may be problematic for children with learning disabilities.

If LDs are not dealt with in childhood and adolescence, they can lead to later, more serious, problems related to employment, relationships, and quality of life in adulthood (NCLD, 2017). The C/PHN and school nurse can assist individuals and families in recognizing LDs and locating necessary resources. Some students with significant LDs may qualify for special education services, and school nurses can be helpful in facilitating this process along with teachers and learning specialists.

### *Attention Deficit Hyperactivity Disorder*

**Attention deficit hyperactivity disorder (ADHD)**, a common childhood disorder, is a cluster of problems related to hyperactivity, impulsivity, and inattention ([National Institute of Mental Health \[NIMH\], n.d.a](#)). The number of children with ADHD has increased over time; however, due to variations in testing and survey criteria, it is difficult to ascertain if percentages reflect the numbers of children with ADHD or the numbers of children diagnosed.

It is estimated that in 2016, 9.4% children ages 2 to 17 years had ever been diagnosed with ADHD, representing 1.6 million U.S. children. Of children with ADHD, approximately 62% were taking medications, 60% were being treated with behavioral therapy, and nearly 64% had a co-occurring condition such as anxiety, autism, depression, or behavioral issues ([CDC, 2018b](#)).

Diagnosis of ADHD involves a several-step process and should include reports from parents/guardians, teachers, and mental health providers if applicable. The primary care clinician generally makes the final diagnosis after considering all symptoms and reports, and ruling out other possible symptom causes. Boys are often recognized as having ADHD in early elementary grades, because they most often exhibit hyperactivity symptoms. Girls, on the other hand, are at increased risk for not receiving appropriate services because they exhibit lack of attention more frequently than hyperactivity ([CDC, 2019c](#)).

The exact cause of ADHD remains unknown. Research indicates, however, that a number of factors may be linked, including:

- Genetics and heredity
- Fetal exposure to cigarette smoking, alcohol use, drug use, or environmental toxins during pregnancy
- Childhood exposure to environmental toxins, such as high levels of lead
- Premature birth and/or low birth weight
- Brain injuries and/or central nervous system development problems ([Mayo Clinic, 2018a](#); [NIMH, 2018](#))

At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school may be involved in conflicts with peers and have problems organizing tasks. They may be more prone to accidents and may have more school-related problems, such as grade retention and suspension or expulsion. As adolescents, they may show less hyperactivity but continue to have restlessness, difficulty focusing, and impulsivity. These symptoms often continue into adulthood. Compared with non-ADHD teens, they may have more conflict with their parents, poorer social skills, and ongoing problems at school. They are also more likely to use tobacco and alcohol and have delinquent behaviors. As young adults, they are less likely to be enrolled in college and more likely to

experience lower job performance ratings than their peers. In adulthood, they tend to have more marital and occupational problems ([Mayo Clinic, 2018a](#); [NIMH, 2018](#)).

In a recent longitudinal cohort study, the frequency of digital media-use among adolescents was associated with subsequent ADHD symptoms. Researchers recommend that this area of research be expanded for further insights to ADHD causes ([Ra et al., 2018](#)).

Collaboration among the child's family, school, and physician is needed to diagnose ADHD and to plan appropriate interventions and educational accommodations. Although parents have a wealth of knowledge about the child, teacher confirmation of ADHD-related behaviors is very important. School nurses and C/PHNs can assist parents in recognizing the symptoms of ADHD and in obtaining appropriate treatment and follow-up.

A multimodal treatment approach is recognized as most effective. The main goals of medical treatment are to strengthen positive behaviors and decrease unwanted behaviors. Treatment strategies include medication, usually methylphenidate (Ritalin, Metadate, or Concerta), dextroamphetamine (Dexedrine), or combined dextroamphetamine and amphetamine (Adderall); school accommodations for learning problems; and social skills training for the child with ADHD.

Nonstimulant medications, such as clonidine, atomoxetine (Strattera), and guanfacine hydrochloride (Intuniv), are also used in children and adolescents ([Mayo Clinic, 2018a](#); [NIMH, 2018](#)).

Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this treatment method. Recent research indicates that highly effective treatment includes group parent behavior therapy and/or individual parent behavior therapy with child participation ([CDC, 2019c](#)).

Parental resistance to treatment may result from side effects (e.g., problems with sleep, appetite, greater anxiety) or stem from fears about later abuse of substances. Alternative treatments that have been tried but not proven effective through research include yoga or meditation; special diets with decreased sugar and allergens such as wheat or milk, vitamin or herbal supplements, or increased omega-3 oils; and increased exercise ([Mayo Clinic, 2018a](#)). School nurses and C/PHNs can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens.

## *Behavioral and Emotional Problems*

Good mental health is important to our overall health and wellbeing. Monitoring and understanding children's mental health is an important public health issue. Approximately 13% to 20% of U.S. children experience a mental health disorder each year. The lifetime prevalence of any mental disorder among 13-to 18-year-olds is 49.5%, and of those diagnosed, 22.2% have severe impairment. It is estimated that one out of every seven U.S. children between the ages of 2 and 8 years has had a diagnosed mental, behavioral, or developmental disorder ([CDC, 2019d](#); [NIMH, 2017](#)).

Living in an environment where children are not safe or that undermines their stability or ability to bond—such as households with mental health issues, substance misuse, or separation due to prisons—can have lasting and negative effects on their health and wellbeing ([CDC, 2020c](#)). **Adverse childhood experiences (ACE)** are traumatic events that occur in childhood (ages 0 to 17), such as violence, abuse, or having a family member attempt or die by suicide. ACE is linked to mental illness, substance misuse, and chronic health problems; it can also negatively impact employment opportunities and education ([CDC, 2020c](#)). Associated conditions related to ACE (such as food insecurities or living in under-resourced or racially segregated neighborhoods) compound an already stressful environment, leading to toxic stress. As children grow up, they may have difficulty forming healthy or stable relationships, with these effects being passed on to their children; this chain reaction can result in such individuals or their children being more likely to perpetrate or be the victims of acts of violence ([CDC, 2020c](#)). ACE is preventable through education, strong economic support for families, legislation that protects against violence, and community support for safe and nurturing environments for children.

Of the millions of children living with mental health issues, ADHD (see previous section) is the most prevalent among children and youth ages 3 to 17 years. Children between the ages of 3 and 17 years of age experience additional types of mental health disorders including behavioral or conduct disorders (3.5%), anxiety (3.0%), depression (2.1%), ASD (1.1%), Tourette's syndrome (0.2% ages 6 to 17 years), and posttraumatic stress disorder (PTSD). Disruptive behavior disorders include oppositional defiant disorder (ODD) and conduct disorder (CD). Coexistence of ODD or CD with ADHD occurs in 1/3 to 1/2 of all children with ADHD. Males are more frequently diagnosed with both disorders as well as children of divorced parents and lower socioeconomic status. These children are more likely to be aggressive and hostile and have an increased risk of serious school or social delinquency. Early recognition, treatment, family support, school management, and child and family therapy increase the child's success ([National Resource Center on ADHD, 2018](#)). It is important to find referral sources for these children and their families, and this may be difficult in more rural or outlying areas.

Children are barometers of their environment. About 40% to 50% of couples in the United States divorce, and the second marriage rate of divorce are even higher. In 2016, 65% of children age 0 to 17 years lived with two married parents, 23% of children lived only with their mothers, 4% lived only with their fathers, 4% lived with unmarried parents, and 4% did not live with either parent. Children of divorce are more likely to exhibit behavior problems, with children who are products of highly contentious divorces most at risk ([FCFS, 2019b](#)).

Being aware of a child's family situation and living arrangements is helpful for understanding social, economic, and developmental wellbeing. C/PHNs can be alert to early symptoms and refer parents to marital counseling or suggest family therapists. Some schools also offer support groups for children of divorce.

School refusal, where a child develops a pattern of refusing to go to school or remain in school for the entire school day, is common in school-age children and differs from truancy. Unlike truancy, school refusal is commonly associated with symptoms of emotional distress—usually anxiety or depression—but may also be associated with oppositional defiant disorder, ADHD, or other disruptive behavior disorders. Often, the children complain of headaches, stomachaches, or other physical ailments, but some are motivated to miss school to gain parental attention. School refusal is most commonly found in children between ages 5 and 7 or ages 11 and 14. Transitional periods, such as school entry or moving to middle school or high school, are often the most difficult.

Children usually present to the school nurse or C/PHN with headaches and/or abdominal pains. They may throw tantrums, cry, or exhibit panic and fear to their parents in an attempt to stay home from school. Sometimes, children are afraid of something in the school environment (e.g., bullies, teachers, test taking), or they may have separation anxiety ([American Academy of Child & Adolescent Psychiatry \[AACAP\], 2018](#)). Family enmeshment or detachment, or high levels of family conflict, may contribute to school refusal problems, as well as parental anxiety disorders like agoraphobia and panic disorder ([Maynard et al., 2015](#)).

The best interventions include early return to school, with parental involvement in school, systematic desensitization (graded exposure to the classroom), relaxation training, emphasize positive aspects of going to school, and counseling being the most effective ([ADAA, n.d.](#)). If symptoms persist, evaluation by a mental health provider is recommended. C/PHNs and school nurses can serve as a liaison with the child, family, school, and health care/mental health care providers to promote a positive outcome.

## Disabilities

In 2014 to 2015, the number of children ages 3 to 21 years served under IDEA was approximately 6.7 million—accounting for 13% of the total school-age population. Specific learning disabilities and speech or language difficulties were the two most common disabilities reported, followed by other health impairments (asthma, chronic illnesses), autism, intellectual disability, developmental delay, and emotional disorders. American Indian/Alaska Native children (17%) had the highest prevalence, followed by Black (16%), White (14%), Hispanic and Pacific Islander (both at 12%), and Asian (7%) (NCES, 2018b).

Many children with perceived disabilities or problems are referred for assessment and considered for placement in special education programs each year. School nurses often serve as a liaison between parents, physicians, and educators and are part of the team developing an individualized education plan (IEP) for children who qualify for special education services. Most children receive special services in a regular classroom because *full inclusion* or *mainstreaming* legislation mandates that fewer children be segregated into special classes or separate schools.

See [Chapter 24](#) for more on clients with disabilities and [Chapter 28](#) for more on school nursing.

## Injuries

The loss of children's lives that results from all injuries combined suggests a staggering loss to society in the number of years of productive life lost. An injury is damage to the body, either unintentional or intentional, but use of the word accident is considered incorrect, as injuries may be prevented through environmental, individual behavioral, legislative, and institutional policy changes.

In the United States, unintentional injuries are the leading cause of death and disability for children between the ages of 1 and 19 years. Approximately 31.3% of deaths between age 1 and 9 years and 39.6% of deaths between age 10 and 24 years result from unintended injuries ([Heron, 2017](#)). Falls are the leading cause of injury between the ages of 1 and 14 years, followed by being struck by or against an object or person ([FCFS, 2019c](#)). Injuries not resulting in death often cause permanent disabilities or emotional and physical consequences for children and their families. (See [thePoint](#) for an infographic and a link to more information on falls in children and youth.) Although injury death rates have dropped over the past two decades, injuries are responsible for approximately 75% of deaths during adolescence.

- Being struck by or against an object is the leading cause of injury between the ages of 15 and 19 years, followed by falls, motor vehicle crashes (MVC), overexertion, and being cut or pierced ([FCFS, 2019d](#)).
- During 2015, the leading causes of adolescent deaths were motor vehicle accident or firearms related ([FCFS, 2019a](#)).
- Suicide was the second leading cause of death of 15-to 19-year-olds during 2016 and homicide ranked third. Firearms were involved in 44.5% of teen suicides and 88.7% of teen homicides ([CDC, 2020d](#)).

Disparities exist among racial and ethnic groups. In 2014, homicide was the second leading cause of death among ages 1 to 24 years. In 2014, it was the leading cause of early death for non-Hispanic Black males, the second leading cause of Hispanic male death, and the third leading cause of death among non-Hispanic White males ([CDC, 2017c](#)). (See [thePoint](#) for an infographic and a link to more information on the homicide rate in this age group.) Two public health concerns contributing to child and adolescent MVC are alcohol use and cell phone use while driving. A large-scale study examining the relationship between alcohol policies and fatal motor vehicle crashes (MVCs) found that alcohol was a factor in more than 25% of cases of motor vehicle fatalities involving children, adolescents, and young adults <21 years of age. Research indicated that restrictive alcohol policies are

associated with reduced alcohol-related MVC among youth (Hadland et al., 2017).

Another concern for adolescents (and the general population) is use of cell phones while driving (Fig. 20-2). Adolescent cell phone use while driving has been legislatively banned in several states and yet reports indicate continued cell phone use while driving. Research investigating self-reported cell phone use indicates decreased handheld cell phone use but continued adolescent texting while driving—perhaps because of decreased visibility to officers and difficulty in enforcing bans. Increased education and intervention are recommended public health interventions for the adolescent population (Rudisill, Smith, Chu, & Zhu, 2018).

**FIGURE 20-2** Cell phone use while driving—whether talking, texting, or using an app—is dangerous.

Cell phone use while driving is dangerous, especially for inexperienced adolescent drivers (Fig. 20-2).

In 2015 to 2016, approximately 69% of public schools reported one or more violent incidences. Fifty-seven percent of primary schools, 88% of

secondary schools, and 90% of high schools reported violent incidents as defined by criminal incidents, violent victimization, and physical violence (NCES, 2017).

C/PHNs can promote injury prevention and control through education, promotion of safety engineering and environmental protection strategies, and legislative advocacy.

- C/PHNs can advance the prevention of unintentional injuries and deaths by working with families to initiate consistent use of seat belts and child safety seats in vehicles and the use of helmets and other protective gear for children riding bikes and skateboarding (Box 20-4).
- Where water is a natural hazard, wearing life jackets while boating and swimming can help decrease accidental drowning.
- Promotion of smoke and carbon monoxide detectors, poison prevention, and sudden infant death syndrome (SIDS) education can help to further decrease injury death rates.
- Teaching parents about presetting hot water heaters to lower than 130°F, recognizing the hazards of infant walkers, storing matches and lighters safely, and using pool fencing can help to prevent common unintentional injuries (Safe Kids Worldwide, 2018).
- Advocacy for stricter seat belt and child safety seat enforcement, as well as programs to provide child safety seats and bicycle helmets, has been shown to positively affect mortality and injury rates. Enforcement of seatbelt laws, graduated driver licensing programs, and adolescent education about MVC causes are also effective (CDC, 2020e).

**BOX 20-4 STORIES FROM THE FIELD WHY PARENTS AND CAREGIVERS ARE INCONSISTENT IN THEIR USE OF CAR RESTRAINTS FOR CHILDREN A LEADING CAUSE OF CHILDHOOD INJURY AND DEATH CONTINUES TO BE MOTOR VEHICLE CRASHES (MVC). THE USE OF RESTRAINTS (SEATBELTS, INFANT CAR SEATS,**

**CHILD BOOSTER SEATS) HAS BEEN SHOWN TO BE AN EFFECTIVE POPULATION-LEVEL INTERVENTION THAT REDUCES FATALITIES AND SERIOUS INJURIES (CDC, 2019K). I WAS PART OF A TEAM OF NURSES, EPIDEMIOLOGISTS, AND PHYSICIANS FROM AN EASTERN CENTER FOR INJURY RESEARCH AND PREVENTION WHO STUDIED FACTORS ABOUT PARENT AND CAREGIVER USE OF BOOSTER SEATS. OUR GOAL WAS TO UNDERSTAND WHY PARENTS AND CAREGIVERS INCONSISTENTLY USE CAR RESTRAINT SYSTEMS. OUR GROUP DESIGNED A CROSS-SECTIONAL ONLINE SURVEY WITH A CONVENIENCE SAMPLE OF PARENTS IN THE UNITED STATES. SURVEY PARTICIPANTS WERE >18 YEARS OF AGE, SPOKE AND READ ENGLISH, WERE THE PARENT OR CAREGIVER OF A CHILD BETWEEN 4 AND 10 YEARS**

**OF AGE, AND HAD DRIVEN THEIR CHILD AT LEAST SIX TIMES IN THE PAST 3 MONTHS. PARTICIPANTS ANSWERED QUESTIONS ABOUT THE SITUATIONAL USE OF CAR SEATS AND BOOSTER SEATS WITH THEIR CHILD AGE 4 TO 10 YEARS AND CARPOOLING CHILDREN. OUR RESEARCH FOUND THAT PARENTS AND CAREGIVERS USING BOOSTER SEATS DID NOT FULLY RESTRAIN A CHILD DUE TO PRACTICAL REASONS MORE OFTEN THAN PARENTS/CAREGIVERS USING CAR SEATS DID. PRACTICAL SITUATIONS FOR NOT USING A CRS INCLUDED DRIVING SHORT DISTANCES, TOO MANY PEOPLE IN THE CAR, AND NOT HAVING A CRS IN THE CAR. DECREASED USE OF CRS PUTS CHILDREN AT A HIGH RISK OF INJURY. IT IS IMPERATIVE THAT HEALTH CARE PROVIDERS CONTINUE TO EDUCATE**

## **PARENTS/CAREGIVERS AND IMPLEMENT PROGRAMS TO PROMOTE CRS USE.**

—Catherine, RN

1. *As a C/PHN, what resources would you provide to a family with young children using a car seat?*
2. *What does the data in your community indicate regarding childhood morbidity and mortality for MVA? What strategies would work best for prevention in your community?*

Source: [CDC \(2019k\)](#); [McDonald et al. \(2018\)](#).

Community health nurses can work with their local health departments and community action groups to provide seats and helmets to families who cannot afford them, organize clinics to educate about proper installation and use, and encourage local law enforcement to enforce seat belt and safety seat laws.

## Communicable Diseases

The mortality rates of school-age children 5 to 14 years old are comparatively low and have decreased substantially over the last century, a reduction that can be attributed to the effective prevention and control of the acute infectious diseases of childhood, a significant achievement in the last century. Although mortality rates are low in this country, worldwide mortality because of communicable diseases continues with lower respiratory infections the most deadly. Globally, among children ages 5 to 14 years, the risk of dying from communicable disease has significantly decreased, whereas the prevalence of mortality related to injuries has increased to 25% (WHO, 2018b).

It is estimated that immunizations save 33,000 lives, prevent 14 million causes of disease, and save approximately \$40 billion. The U.S. public health efforts (Healthy People 2030) focus on reducing vaccine-related illnesses and disease. School-age children must show proof of required vaccinations before they are allowed to enroll in school, although most states still allow exemptions for personal or religious beliefs (for information on which states allow religious and philosophical exemptions, visit: <http://www.ncsl.org/research/health/school-immunization-exemption-state-laws.aspx>). Vaccine hesitancy by parents has been linked to outbreaks such as measles; however, individual cases in 2017 to 2018 were similar to recent years (CDC, 2019e, 2020f).

- Results from a 2016 national immunization survey revealed that around 90% of children between ages 19 and 35 months received vaccinations for polio, MMR, varicella, and hepatitis B.
- Non-Hispanic Black children were less likely to receive the full immunization series than non-Hispanic White children. Children in poverty, those covered by Medicaid, and children without insurance were also less likely to receive the full immunization series (see CDC for childhood immunization schedule, available at <https://www.cdc.gov/vaccines/schedules/easy-to-read/child.html>).

The National Immunization Survey–Teen (NIS-Teen) indicates that adolescent vaccination coverage in the United States has gradually increased. However, disparities continue with teens living in nonmetropolitan statistical areas undervaccinated (see CDC adolescent immunization schedule available at <https://www.cdc.gov/vaccines/schedules/easy-to-read/preteen-teen.html>).

Over the past several decades, the incidence of vaccine-preventable deaths has decreased; however, infectious diseases continue as a major cause of childhood illnesses, disability, and death. Vaccines are one of the most

cost-effective health promotion services ([ODPHP, 2018](#)). Strong campaigns have been taken by health departments to get children immunized.

- Strategies shown to improve vaccination rates include the Vaccine for Children (VFC) Program, cost reduction, home visits, and linking vaccination opportunities with WIC visits.
- Public health professionals should continue to focus on eliminating socioeconomic barriers, strengthening school-entry requirements, and addressing vaccine misinformation.
- A Cochrane review by [Jacobson Vann, Jacobson, Coyne-Beasley, Asafu-Adjei, and Szilagyi \(2018\)](#) indicates that vaccination increases are seen in all age groups when reminders by telephone or text message, letter, or postcard are used. Combinations of reminders were also effective; however, reminding people over the phone are the most effective.
- Cancer prevention for preteens and adolescents through HPV vaccinations is effective. While HPV immunization rates have increased 5% from 2016 to 2017 with 66% of adolescents receiving the first dose to start the vaccine series, and 49% of adolescents completing all vaccinations in the series, there is still room for improvement. Parental resistance and a focus on vaccinating only girls can inhibit successful immunizations efforts in communities ([CDC, 2018c](#)).

Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is another communicable illness seen in the school-age children population. C/PHNs and school nurses must be alert when skin infections or other conditions do not resolve quickly in children and adolescents. Sports teams, for instance, may spread this infection as team members come into close contact or use common-use facilities such as swimming pools. Referral to an infectious disease specialist may need to be considered ([CDC, 2019f](#)).

**Pediculosis** (head lice), another highly communicable disease, is a frustrating and common problem for many preschool and school-age children, and the incidence has been increasing with approximately 6 to 12 million 3-to 11-year-olds infected annually.

- Preschoolers and elementary-age children and their caretakers and family members are at highest risk for head lice.
- Close crowded conditions can also be a risk factor. Although lice are wingless, because children frequently play close to each other, they easily move from child to child.

Head lice may be white, gray, or brown in color—about the size of a sesame seed. They attach to the scalp and lay eggs (nits) in the hair. Nits typically hatch within 8 to 9 days. They reach adulthood during the next 9 to 12 days

and live about 30 days. Without treatment, the cycle repeats every 3 weeks. Complete eradication generally requires that all viable nits be removed along with lice; family and close contacts should be checked for head lice and, if found, treated at the same time. Treatment typically involves over-the-counter insecticide shampoos (or pediculicides), such as pyrethrin-based *RID and Nix* or prescribed medications such as *Ulesfia, Natroba, or Sklice* ([U.S. Food & Drug Administration \[FDA\], 2017](#)).

School nurses and C/PHNs also need to educate families about reducing re-infestations by careful application of pediculicides, retreating in 2 weeks if necessary, and cleaning of any fomites (e.g., combs, hats, towels, sheets, clothing, and upholstered furniture) and removal of any viable nits. Drying sheets, blankets, and towels on high heat and washing all hats and clothing are effective measures. It is not necessary to use fumigant sprays, as they can be toxic ([U.S. Food & Drug Administration \[FDA\], 2017](#)).

## Other Health Problems

Other health problems found in this age group include nutritional problems (primarily overeating and inappropriate food choices) and poor dental health. Obesity often begins in childhood and is a risk factor for CVD, diabetes, cancer, stroke, and osteoarthritis later in life. The percentage of children and adolescents has more than tripled in the last 40 years. Risk factors contributing to childhood obesity include genetics, metabolism, short sleep duration, eating and physical activity behaviors, and community environment (CDC, 2018d).

Food allergies can also play a role in poor nutritional status, especially with school-age children and adolescents. Researchers estimate that about 6 million children have food allergies, with teens and young adults being at greatest risk of anaphylactic reactions ([Food, Allergy, Research, and Education \[FARE\], n.d.](#)). Food allergies can be especially problematic in the school setting as strict avoidance of the food is the only way to prevent a reaction (see [Chapter 28](#)). It is recommended that parents and adolescents carefully read labels at the time of each use and that education systems have a plan to prevent allergic reactions and an response plan if an emergency should arise (CDC, 2018d; [FARE, n.d.](#)).

Dental caries is another common problem among school-age children. Approximately 18.6% of U.S. schoolchildren (5 to 19 years) have untreated cavities. In 2015, 84.7% of children age 2 to 17 visited a dentist during the year ([CDC, 2017e](#)).

### *Childhood Obesity*

- About one in five U.S. children are obese, making childhood obesity a national concern. The CDC uses the term **overweight** for children and youth at or above the 85th percentile and less than the 95th percentile for youth the same age and gender. Children with a BMI greater than the 95th percentile are defined as **obese** (see [Box 20-5](#) for an explanation and examples).
- Obese children are more likely to become obese adults and are at increased risk of chronic health diseases such as asthma, sleep apnea, bone and joint problems, metabolic syndrome, type 2 diabetes, cancer, and heart disease. They are also more likely to be teased, bullied, and suffer from social isolation, depression, and poor self-esteem ([CDC, 2018d](#)).

**BOX 20-5 EXPLANATION AND EXAMPLES OF OVERWEIGHT CLASSIFICATION FOR CHILDREN AND TEENS** BMI IS USED AS A SCREENING TOOL TO IDENTIFY WEIGHT PROBLEMS IN CHILDREN AND TEENS. THE CRITERIA ARE DIFFERENT FROM THOSE USED FOR ADULTS, AS BODY FAT DIFFERS BETWEEN BOYS AND GIRLS AND THE AMOUNT OF BODY FAT CHANGES WITH AGE. BMI-FOR-AGE GROWTH CHARTS FOR BOYS AND GIRLS ARE AVAILABLE AT [HTTPS://WWW.CDC.GOV/GROWTHCHARTS/CLINICAL\\_CHARTS.HTM](https://www.cdc.gov/growthcharts/clinical_charts.htm).

<b>Weight Status Category</b>	<b>Percentile Range</b>
Underweight	Less than the 5th percentile
Healthy weight	5th percentile to less than the 85th percentile
At risk of overweight	85th to less than the 95th percentile
Overweight	Equal to or greater than the 95th percentile

Source: Centers for Disease Control and Prevention (2018m).

Preventive measures and early management of cardiovascular risk factors are now considered more effective forms of treatment than just clinical treatment of the disease complications after the fact.

- Multiple factors influence childhood obesity including genetics, decreased physical activity, increased television time, familial weight, poor nutrition knowledge, food insecurity, parental smoking, not having family mealtime, perceived neighborhood safety, and low economic status.
- Early childhood may be the best time to modify preventable factors influencing obesity. Studies recommend that health care providers begin discussing behaviors such as family mealtime and parental smoking with families of young children to reduce the risk of childhood obesity (Williams et al., 2018, p. 515).

Schools have been identified as a setting to promote healthy behaviors and provide nutrition for children. The Healthy, Hunger-Free Kids Act of 2010, authorized funding for foundational child nutrition programs at schools. A legislative goal was to provide balanced nutrition for children and reduce childhood obesity. Ninety percent of schools now report that they meet updated national meal provision standards, school lunch revenues have increased, and children are being educated to choose healthier food options (USDA Food & Nutrition Service, 2017). Centeio et al. (2018) examined the influence of the “Building Healthy Communities: Elementary School Program” on 5th grade children. This comprehensive program focused on physical activity, health education, and creating a healthy school culture. Study outcomes demonstrated decreased body mass index (BMI) and waist-to-height ratio (WHtR). School culture change and sustainability are predicted as school personnel were mentored to maintain the program (Centeio et al., 2018). Practice applying the nursing process to the problem of childhood obesity is shown in Box 20-6.

## **BOX 20-6 C/PHN Use Of The Nursing Process**

**Addressing Childhood Obesity James Lopez is entering 3rd grade. His teacher comes to you, the school nurse, because she is concerned about his poor performance in school. He frequently comes to school late and often puts his head on his desk and appears to be falling**

**asleep. You notice that James has gained a significant amount of weight over the summer. His face is much fuller now than in his 2nd grade picture.**

**Assessment (Initial Visits) You do the following:**

- Call James' mother and make an appointment for a home visit.
- Complete a health history, noting family history of diabetes, current eating, activity, and sleeping patterns for James and the family, and determine whether he has a regular physician and insurance or Medicaid.
- Assess his vital signs, height and weight, hearing, and vision.
- Talk with James' teacher about his playground activity level and any signs of excessive thirst, hunger, or general fatigue.

**Nursing Diagnoses After a home visit, a meeting with James' teacher, and two observations and interviews with James, you decide a nursing diagnosis would look at:**

- James' body requirements are more than what is required. James has a sedentary lifestyle, and he may be eating as a way to cope.
- Changes in the family's home life. Mother is single and attending truck-driving school necessitating several days' absence at a time. James cared for by a married teenage sister and her husband.

**Findings, Plan, and Implementation For the past 3 months, since his mother started her training, James has been eating large quantities of snack food and fast-food meals. He stopped participating in soccer and baseball because of lack of transportation. James' bicycle was recently stolen, and he now spends a lot of time playing video and computer games. James says that he misses his mother when she is away and that he “stays up late watching television” and**

## **has “trouble getting up for school” when he is at his sister's house.**

You plan to work with the family to refer James to his physician to rule out diabetes. A family meeting is scheduled to provide health education on childhood obesity and inactivity. You discuss some possible interventions that the family can put into place:

- Decrease reliance on fast-food meals.
- Have a regular evening mealtime and encourage less snacking.
- Provide fresh fruit and vegetable snacks and decrease purchases of high-calorie, high-fat snack foods.
- Decrease sedentary activity (e.g., video and computer games, television viewing) and increase physical activity (e.g., team sports, walking, bicycling, active outdoor games).
- Establish a reasonable bedtime and consistently enforce it.
- Offer referral for family counseling so James can discuss his feelings in a safe environment.
- With the family's input, seek ways to improve contact between James and his mother and opportunities for his sister to improve understanding of good parenting practices.
- Meet with the teacher, family, and James to discuss ways to help with school performance.
- Continue to monitor James' progress with monthly height and weight checks, personal interviews, home visits, and teacher conferences.

## **Evaluation**

The physician reported that James does not have diabetes; however, if he continues to gain weight and remains inactive, he is at a higher risk for type 2 diabetes. Evaluation of nursing diagnoses 1 and 2 includes the following goals:

- The family will report less reliance on fast-food and more meals cooked at home.
- The family will report more purchases of fresh fruits and vegetables and fewer purchases of high-calorie, high-fat snacks.
- James will report more physical exercise (by the use of a calendar) and fewer hours spent in sedentary activity (corroborated by family).
- James will exhibit less tardiness and fewer signs of sleep deprivation at school, and his school performance will improve.

- James and his family will complete sessions with a family counselor.
- James' weight will remain stable or will decrease as his height increases over time.

The causes of childhood obesity are multifactorial, and as a result, health care providers should take a multiple health behavior approach. Parental support and influence are key. Parents can help their younger children develop healthy eating habits by following recommendations of the [American Heart Association \(2018\)](#) and the CDC (2020g), for example:

- “Eat the Rainbow.” Provide a variety of fruits and vegetables. Let children pick fruits/vegetables and have them help cook or prepare it.
- Choose lean meats, poultry, beans for protein.
- Watch out for added sugars. Avoid/limit sugar-sweetened drinks.
- Help kids be physically active at least 60 minutes each day ([Fig. 20-3](#)).
- Serve whole-grain/high-fiber cereals and breads.
- Serve low-fat and fat-free dairy products (two to three cups of milk daily).
- Read food nutrition labels—pick healthy nutritional foods.
- Be a role model—help your child develop healthy habits early ([American Heart Association, 2018](#); [CDC, 2020g](#)).

**FIGURE 20-3** Physical activity is important for health and in childhood obesity prevention.

The benefits of following a healthy diet, increasing physical activity, and maintaining a healthy diet are well-documented. Research has also shown that there is a link between obesity, cognition, and school achievement among children. A recent systematic review by [Martin et al., \(2018\)](#) explored

the connection between cognition, school achievement, and school-based interventions to reduce weight and improve nutrition with child and adolescent obesity/weight. Their research indicated the following:

- School and community-based physical activity benefited cognitive function of obese or overweight children.
- School-based dietary interventions may benefit general school achievement.
- Nutritional diets at school can lead to improved general school achievement.
- Future studies should assess academic and cognitive outcomes along with physical outcomes.

### *Inadequate Nutrition*

Poor nutritional status of schoolchildren is a global issue but also a problem in this country. Undernutrition can also have serious consequences, including effects on the cognitive development and academic performance of children and chronic health. Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition. Infection and illness that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics. Food insecurity has been associated with child development problems, psychological and social issues, and poor general health (Shankar, Chung, & Frank, 2017).

- About 21.0% of U.S. households reported some degree of food insecurity in 2017, representing approximately 40 million people.
- Approximately 15.7% of households with children were food insecure, and of those headed by single women with children, 30.3% reported food insecurity (USDA, 2018).

A national study by Lee, Scharf, and DeBoer (2018) suggests that there is an association between food insecurity and obesity in school-age children (kindergarten through 3rd grade). A study by Rongstad, Neuman, Pillai, Birstler, and Hanrahan (2018) provide additional validation that there is a significant relationship between food insecurity and chronic diseases such as obesity and metabolic syndrome, ADHD, and anemia.

Undernutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful undernutrition. Because prepubertal children often exhibit a period of adiposity before a growth spurt, they are at risk for developing eating disorders. Along with childhood obesity, prevention of eating disorders is also a high priority in this age group.

- Some sources find pediatric eating disorders to be more prevalent than T2DM, and minority groups, boys, and younger children have higher rates. An estimated 5.4% of children between 13 and 18 years will suffer from an eating disorder. Of children with a lifetime prevalence of an eating disorder, 3.8% will be female and 1.5% will be male ([James, 2017](#)).
- The 2017 Youth Risk Behavior Survey indicates that 47.1% of students are trying to lose weight. The prevalence of trying to lose weight was higher in females than males, and higher among Hispanic students than White or Black students ([CDC, 2017d](#)).
- [Yilmaz et al. \(2017\)](#) indicated that there is increased prevalence of disordered eating among adolescents with ADHD. Authors recommend health care providers monitor youth with ADHD for disordered eating symptoms and early identification of eating disorders.

Research also indicates that youth with a history of obesity are at a higher risk of disordered eating. Signs of disordered eating include food rituals, refusal to eat foods once enjoyed, avoiding meals, overexercising, secret eating, preoccupation with food, calorie counting, fear of becoming fat, binge eating, and food phobias. Other concerning behaviors include depression, irritability, sudden mood changes, and anxiety around food and eating. Parents and health care providers alike should be aware of symptoms and seek evaluation of the child or adolescent ([Dawson, 2017](#)).

- School nurses and C/PHNs should be aware of signs and symptoms of this disorder, noting that T1DM children may be at higher risk, and watch for unexplained weight loss, stunting of normal growth patterns, concerns about body image, delayed puberty, and abnormal or restrictive eating.
- They can provide families with necessary information to promote healthful eating and exercise, as well as provide guidance for parental and child support ([Dawson, 2017](#)). Some school districts include BMI screening programs as part of healthy lifestyle promotion.
- The CDC recommends that schools have a series of safeguards in place before launching a BMI measurement program. This includes fostering a safe and supportive environment for all students and a comprehensive program to prevent and reduce obesity ([CDC, 2017f](#)).

## *Inactivity*

An association between poor eating habits and physical inactivity has been found in numerous research studies. More television watching, fewer family meals eaten together at home, and living in an unsafe neighborhood were shown to be associated with overweight ([Williams et al., 2018](#)).

- The YRBS revealed that approximately 70% of children surveyed who were enrolled in physical education classes did not attend class on a daily basis.
- In addition, fewer than 15.4% of respondents stated that they were physically active for 60 minutes daily.
- About 22% watched 3 or more hours of television daily and 43% used a computer (other than for schoolwork) or played a video game on a daily basis ([CDC, 2017d](#)).

School nurses and C/PHNs can work with families to increase their levels of physical activity and to encourage limited television viewing for school-age children. They can also advocate for increased physical education in the school setting and for increased safe recreational opportunities in all neighborhoods.

## *Dental Caries*

Dental caries is thought to be the most prevalent chronic childhood infectious disease.

- Caries affect 45.8% of children between the ages of 2 and 19 years with 84.7% of children age 2 to 17 years with a dental visit in the past year.
- Hispanic children have the highest rates of decay and non-Hispanic Black youth have the highest prevalence of untreated caries ([Fleming & Afful, 2018](#)).

The prevalence of dental caries in school-age children has decreased significantly since the early 1970s because of community fluoridation projects and the use of fluoride toothpaste. Fluoridated drinking water, the availability of school-provided fluoride rinse or gel, and dental sealant programs are cost-effective, proven methods of reducing dental caries in school-age children ([National Institute of Dental & Craniofacial Research, 2018](#)).

The peak incidence of dental caries is found among school-age children and adolescents, although the effects of decay are observed in adulthood as caries activity recurs or various restorations fracture or wear out and must be replaced.

- In 2016, 84.7% of children aged 2 to 17 years visited a dentist in the past year; but for children living in poverty, the percentage remains lower ([FCFS, 2019e](#)).
- Over time, these rates have improved with coverage through the State Children's Health Insurance Program and preventive programs such as community water fluoridation and the expansion of sealant programs.

- In a nationally, representative study of children and adolescents, [Slade, Grider, Maas, and Sanders \(2018\)](#) reaffirm the importance of fluoridated drinking water. Their study results support the continuation of community water fluoridation (CWF) policies and provide evidence for CWF as a key public health intervention.

Yet, access to dental care is still problematic. Barriers to dental care are more prevalent among the poor. Financial barriers, lack of education, and limited numbers of dentists accepting Medicaid lead to poor dental health values and adversely affect the appropriate use of early dental services and conscientious personal oral health care ([Simmer-Beck, Wellever, & Kelly, 2017](#)).

- A recent strategy for improving oral health of low-income children provided preventive services by registered dental hygienists in school-based clinics. Both adults and children are seen at the clinic; however, during school hours, at least 80% of the appointments were for children.
- Success of the program suggests that changes in licensing policies provide increased RDH autonomy in the public health setting ([Simmer-Beck et al., 2017](#)).

C/PHNs and other community health nurses working with school-age children and families can promote good dental health through education and advocacy, as well as through collaboration to provide adequate dental services to uninsured children and promotion of fluoridation and sealant programs.

# ADOLESCENT HEALTH

Adolescence is a time of self-discovery, movement toward self-reliance, increasing opportunities, and pivotal choices that can affect the remainder of an individual's life.

- Adolescence generally begins with puberty and encompasses the ages between 10 and 24; it consists of early adolescence (aged 10 to 14), middle adolescence (15 to 17), and late adolescence (18 to mid-20s).
- Adult society largely segregates adolescents and often has ambiguous expectations for them. Adolescents are part of a subculture, one with its own language, dress, social mores, and values.
- The tasks of adolescence remain fairly constant: adolescents must become autonomous, come to grips with their emerging sexuality and the skills necessary to attract a mate, and acquire skills and education that can prepare them for adult roles, all while resolving identity issues and developing values and beliefs (ODPHP, 2018; Office of Adolescent Health, 2017a).
- The search for and expression of developing identity, along with the strong drive for social acceptance, are evident in the personal home pages and blogs of adolescents on social networking Internet sites such as Twitter and Facebook (Nesi, Choukas-Bradley, & Prinstein, 2018).

Adolescents and young adults make up 22% of the nation's population. Adolescents are generally healthy, but multiple health-related behaviors and social problems begin during this stage of development. Examples include mental health disorders, substance abuse, tobacco use, nutrition-related disorders, sexually transmitted diseases, unintended pregnancy, homelessness, homicide, suicide, and motor vehicle crashes (ODPHP, 2018).

- The leading causes of morbidity and mortality for U.S. youth are related to health risk-taking behaviors. Six health-related adolescent and young adult behaviors are monitored by the Youth Risk Behavior Surveillance System (YRBSS). These include behaviors contributing to unintentional injuries and violence; tobacco use, alcohol use, and substance abuse; sexual behaviors including unintended pregnancy and sexually transmitted diseases; dietary behaviors; and physical activity.

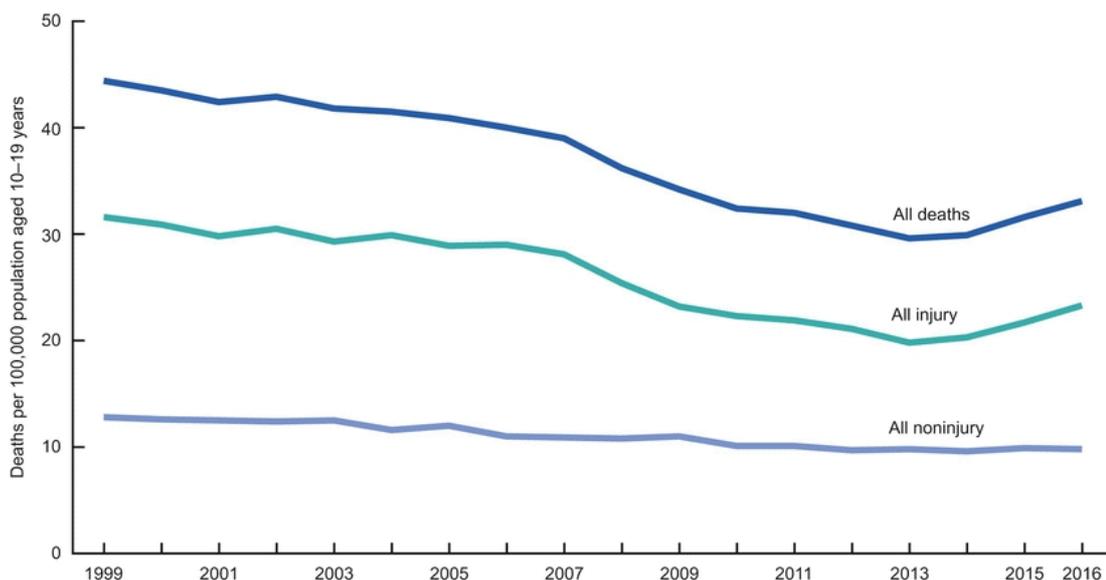

During the period that generally encompasses the teen years, adolescents encounter many complex changes physically, emotionally, cognitively, and socially. Rapid and major developmental adjustments create a variety of

stresses with concomitant problems that have an impact on health and risk-taking.

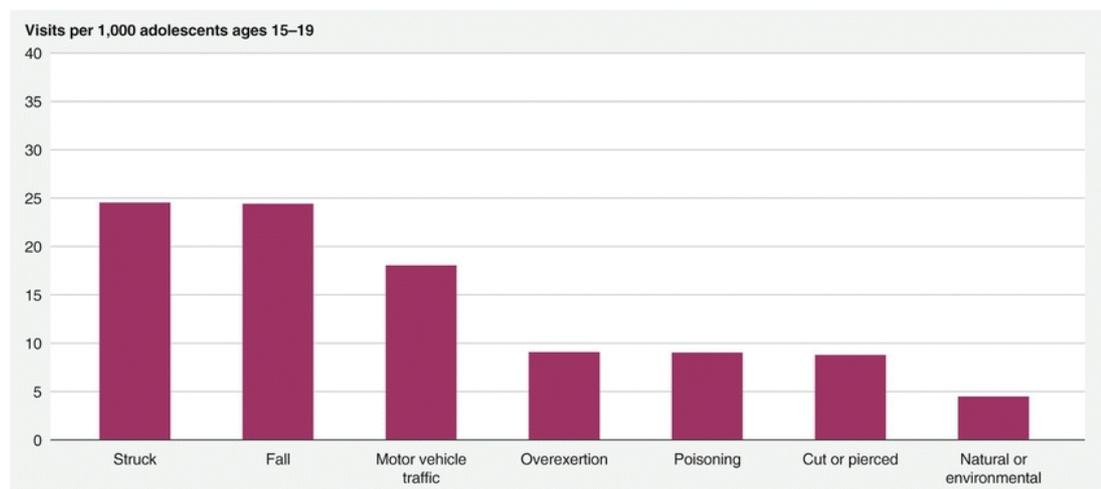

- Because the amygdala influences adolescent brains more than the frontal cortex, teens base their decisions more on emotion—solving problems differently than adults. As a result, it is important to guide adolescents through the decision-making process before they engage in risky behaviors.
- The [U.S. Office of Adolescent Health \(2018a\)](#) explains that in stressful situations, adolescents are more likely to:
  - Think one way but act or feel differently
  - Misinterpret social cues
  - Participate in risky behaviors

Unintentional injuries were the leading cause of death in the 10-to 24-year age group. Most deaths in this adolescent/young adult age group are due to preventable causes.

- In 2016, 74% of adolescent deaths related to injury, with motor vehicle collision (MVC) accounting for approximately 22% of deaths, unintentional injuries (20%), suicide (17%), and homicide (15%).
- Although MVC deaths have decreased, they remain a significant cause of injury with adolescents and young adult drivers disproportionately represented in the data ([Figs. 20-4 and 20-5](#)). Teen males are two times more likely to be involved in an MVC than female adolescents are.
- In 2017, 5.5% of U.S. students reported using alcohol while driving, 13% of students reported using marijuana while driving, and 39.2% of students reported texting or e-mailing while driving a car ([Kann et al., 2018](#)).

**FIGURE 20-4** Total injury and noninjury death rates for children and adolescents aged 10 to 19 years: United States, 1999 to 2016. (Reprinted from CDC. [2018]. Recent increases in injury mortality among children and adolescents aged 10 to 19 years in the United States, 1999–2016. Retrieved from [https://www.cdc.gov/nchs/data/nvsr/nvsr67/nvsr67\\_04.pdf](https://www.cdc.gov/nchs/data/nvsr/nvsr67/nvsr67_04.pdf))

**FIGURE 20-5** Emergency department visit rates for adolescents ages 15 to 19 by leading cause of injury, 2014 to 2015. (Reprinted from [https://www.childstats.gov/americaschildren/phys\\_fig.asp#phy8b](https://www.childstats.gov/americaschildren/phys_fig.asp#phy8b))

Public health interventions are key to reducing teen injuries. A recent study investigated the effectiveness of the Save A Life Tour (SALT) program implemented in high schools. SALT is a safe-driving awareness program designed to educate about the harmful effects of distracted driving and drunk driving. Researchers concluded that that annual education regarding teen driving while intoxicated or distracted might reduce the morbidity and mortality associated with MVC. Key components of the program were to deliver a clear message of dangers and provide ongoing education (Layba, Griffin, Jupiter, Mathers, & Mileski, 2017).

Unintentional injuries also cause the greatest level of adolescent morbidity; the largest cause being transportation (drivers and passengers, bicyclists, pedestrians). Other causes include being struck by/against something, falling, poisoning, overexertion, and cutting/piercing.

- Emergency rooms treat approximately 22,000 children daily for nonfatal injuries. These injuries are highest among adolescents aged 15 to 19 years and can have a lasting effect for the children, their families, and society.

- The most common cause of unintentional injury for 10-to 19-year-olds (250,000 youth) is assault—being struck by/against, sexual assault, cut/pierce, and firearms. It is important to note that disparities exist between race/ethnicity.
- Black youth are significantly more at risk of homicide. This may be related to social determinants of health such as poverty, neighborhood crime, limited educational and occupational opportunities, and racism (Ballesteros, Williams, Mack, Simon, & Sleet, 2018).

Social stressors and strained relations with peers and parents are also linked to adolescent health complaints.

- Common complaints of adolescents include sleep deprivation, fatigue, chronic insomnia, acne, and concerns about weight and body image (Hockenberry et al., 2019). As children become adolescents, their sleep patterns change—they move from early risers/sleepers to staying up later and sleeping in later or catching up on sleep over weekends. This transition becomes more apparent through high school.
- Scientists believe that these changes in circadian and homeostatic sleep regulation support this delayed sleep phase, and there are concerns about consistent lack of sleep (Hale & Troxel, 2018).
- Recent studies confirm the support for delaying adolescent school start times and indicate several health risks associated with sleep deprivation including being overweight, drinking alcohol, using drugs and tobacco, and poor academic performance (CDC, 2018e).
- A review of literature showed support for delayed start time for adolescents with improvement seen in attendance and tardiness, less falling asleep in class, improvement in grades, and reduction in MVA (Wheaton, Chapman, & Croft, 2016). Even modest delay times can be beneficial for student outcomes and supports development of evidenced-based policies for school districts and communities. Hale and Troxel (2018) suggested that, based on confirming research, later school times are also a social justice issue.

In the past, routine health care visits by adolescents were not commonplace. Newer recommended vaccines and better awareness of the health needs of adolescents have led to improvement, but concerns remain.

- In 2016, only 19.4% of 12-to 17-year-olds had a health care provider visit within the past year (CDC, 2017g). Reasons for underutilization of health care services may be related to lack of transportation, lack of parental support, past experience with health care system, lack of health care insurance, and cost.
- Research has also identified trust of health care providers as a possible reason for low or inconsistent use of health care services. In a cross-

sectional, descriptive study regarding reasons for low use of health care systems by rural adolescents, [Hardin, McCarthy, Speck, and Crawford \(2018\)](#) founded that many of the barriers regarding adolescent access to care were resolved by a school-based health clinic.

Health literacy during adolescence is another important consideration. Teens are frequent users of mass media (Internet, television, radio, text messaging), and specific health-related educational interventions can be targeted to them by using these media. Although social media offers benefits such as health education, it can also put youth at risk for exposure to violence and risky behavior examples, opportunistic bullying, sexually explicit material, sexual solicitation, and Internet addiction.

- Research estimates that 92% of teens are online daily, with 88% belonging to at least one social networking site, and 88% having access to a cell phone.
- Increased use of social media designates it as a unique context that shapes an adolescent's behavior and life experience ([Nesi et al., 2018](#)).
- C/PHNs can help young people find reliable sources of information, as well as work with families to ensure proper monitoring of social media use.

## Health Objectives for Adolescents

*Healthy People 2030* objectives are focused on improving the health of all Americans. Goals and objectives for adolescent health have been developed (Box 20-7). Because much of the mortality and morbidity in this age group stems from risk-taking behaviors, many objectives addressing alcohol-related unintentional injuries, violent behaviors, and suicide and mental health issues, as well as more responsible reproductive health behaviors, are included throughout the document under Substance Abuse, Mental Health, *etc.* As of 2017, eight of the Healthy People 2020 objectives had been met with the objective to reduce the proportion of adolescents who have been offered, sold, or given an illegal drug on school property being met for the first time (Kann *et al.*, 2018).

### BOX 20-7 HEALTHY PEOPLE 2030

#### Objectives to Improve the Health and WellBeing of Adolescents

##### Core Objectives

AH-01	Increase the proportion of adolescents who had a preventative health care visit in the past year
AH-02	Increase the proportion of adolescents who speak privately with a provider at a preventative medical visit
AH-03	Increase the proportion of adolescents who have an adult they can talk to about serious problems
AH-05	Increase the proportion of 4th-graders with reading skills at or above the proficient level
AH-06	Increase the proportion of 4th-graders with math skills at or above the proficient level
AH-07	Reduce chronic school absence among early adolescents
AH-08	Increase the proportion of high school students who graduate in 4 years

##### Developmental Objectives

AH-D01	Increase the proportion of trauma informed early childcare settings and elementary and secondary schools
EMS-D04	Increase the proportion of children and adolescents who get appropriate treatment for anxiety or depression
EMC-D05	Increase the proportion of children and adolescents who get appropriate treatment for behavioral problems

##### Research Objectives

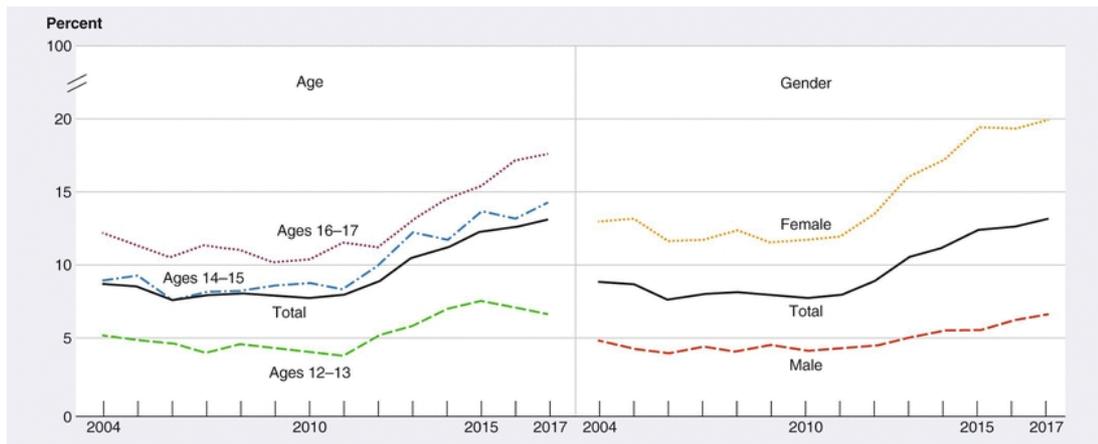

AH-R02	Increase the proportion of adolescents in foster care who show signs of being ready for adulthood
AH-R04	Increase the proportion of 8th-graders with reading skills at or above the proficient level
AH-R05	Increase the proportion of 8th-graders with math skills at or above the proficient level
AH-R06	Increase the proportion of youth with special health care needs, ages 12–17, who receive services to support their transition to adult health care
AH-R07	Increase the proportion of secondary schools with a start time of 8:30 AM or later
AH-R08	Increase the proportion of secondary school with a full-time registered nurse
AH-R09	Increase the proportion of public schools with a counselor, social worker, and psychologist

## Emotional Problems and Suicide

The adolescent years are a time of rapid growth and change. Complex developmental changes physically, emotionally, cognitively, and socially may cause a teen to be emotional and unpredictable at times ([Office of Adolescent Health, 2018a](#)). The influence of peers increases, and peer pressure may influence behavior. Teens test family rules and generally search for their own identity and individuality apart from the family. Most parents and teens ride out this period with love and understanding and no long-term negative effects. For some children, however, a real or perceived lack of emotional support can lead to temporary or permanent emotional problems. Additionally, increased risk behaviors such as suicide, risky sexual behavior, and mental health disorders are associated with child and adolescent maltreatment. Because adolescents have less contact with the health care system than children, many conditions may go undetected. The transition from high school into early adulthood is often difficult and individuals with mental health issues often have worse outcomes than those with physical conditions ([Jordan et al., 2018](#); [Office of Adolescent Health, 2018a](#)).

- Depression, anxiety disorders, and eating disorders may first appear during adolescence. It is estimated that one in five adolescents have mental health disorders with depression being the most commonly reported diagnosis.
- Prevalence rates of depression vary ([Fig. 20-6](#)). About 35% of high school students report feelings of sadness or hopelessness every day for longer than 2 weeks. Of those reporting symptoms, 41.1% are female and 21.4% are male.
- Anxiety disorders such as OCD, posttraumatic stress disorder, social anxiety disorders, and phobias are reported by approximately 32% of students between ages 13 and 18 years. Of concern is research indicating that the percentage of youth using alcohol after a major depressive episode is double that of youth not experiencing a major depressive episode ([Office of Adolescent Health, 2018a](#)).

**FIGURE 20-6** Percentage of youth ages 12 to 17 who had at least one major depressive episode in the past year by age and gender, 2004 to 2017. (Reprinted from [https://www.childstats.gov/americaschildren/health\\_fig.asp#health4a](https://www.childstats.gov/americaschildren/health_fig.asp#health4a))

Many adolescents are reluctant to seek help for emotional problems, or help may not be readily available to them. Most mental health disorders are treatable; however, in 2016, only 41% of adolescents experiencing depression received treatment. Barriers to treatment may include social stigma, cultural norms, and lack of qualified providers.

- Survey results indicate that 12.7% of youth aged 12 to 17 have been given some type of mental health services, but the usual disparities apply (e.g., ethnicity, income level, rural vs. urban locale).
- Treatment for serious mental health problems may include hospitalization or placement in a group home. Use of a team-based Collaborative Care program has improved mental and physical health outcomes.
- Mental health disorders experienced during adolescence may persist into adulthood, becoming more difficult to treat. It is critical to identify negative adolescent mental health behaviors, provide access to services, and educate teens about healthy physical and mental health skills (Office of Adolescent Health, 2018a).

The presence of major depressive disorder (MDD) is common in children and teens; it is associated with suicide and self-injury. It is more common in adolescents with chronic disease and can result in obesity, suicidal thoughts and attempts, and academic performance.

- Major depressive disorder is most commonly associated with lifetime prevalence of adolescent suicidal ideation, plans, and attempts. Health

care providers can play an integral part in identifying adolescent depression and those at risk for suicide.

- Recent stressful events and preoccupation with suicide, as well as substance use, are also important to note. Being bullied, a history of sexual or physical abuse, aggressive conduct disorders, and personality disorders are risk factors for adolescent suicide attempts. When evaluating adolescent mental health, the broader context of school, social, and family influences needs to be considered ([Diamond et al., 2017](#)).

Suicide is the second leading cause of death in 10-to 19-year-olds.

- Between 2007 and 2015, suicide deaths increased by 130% in the 10-to 14-year-old group and 46% in the 15-to 19-year-old age group.
- Overall, male suicide rates are higher than female rates, and American Indian and Alaskan Native adolescent suicide rates are the highest. Ethnic disparity may result from social and environmental factors such as discrimination, exposure to others' suicides, and inadequate health care system access ([Ballesteros et al., 2018](#)).
- In 2017, 17.2% of high school students reported that they seriously considered suicide in the previous 12 months, and 7.4% made at least one suicide attempt. Approximately 2.4% made an attempt that required medical attention. Suicide attempt rates for adolescent female versus male students were higher (9.3% vs. 5.1%) ([CDC, 2018f](#)).

School-based programs to educate adolescents about depression and suicide prevention have been useful. C/PHNs and school nurses often participate in the development or administration of these types of programs.

- Suicide prevention programs and direct intervention by counselors or school nurses to determine an adolescent's suicide intentions may be effective school-based interventions. It is important for counselors to identify markers for attempted suicide, such as a precipitating event, intense affective state, suicide ideation or actions, deterioration in social or academic functioning, or increased substance abuse.

C/PHNs and community mental health counselors may serve as consultants to schools in the development of sound prevention programs.

- Hallmarks of good prevention programs include student education on suicide awareness and intervention; coping and problem-solving skills training; skill building by reinforcement of strengths and protective factors while dealing with risk-taking behaviors; and teaching about the association between suicide and mental health (especially depression).

Suicide screening is often thought to be effective in reducing suicidal ideation (Bhatta, Champion, Young, & Loika, 2018).

Youth suicide has been of great concern over the past several decades. Communities across the nation have been urged to implement effective school-based suicide prevention programs. There is some evidence that universal school-based programs decrease the number of adolescent suicide attempts.

- The SOS Signs of Suicide program is an evidence-based school-based intervention that educates adolescents about poor mental health, suicide, and coping mechanisms. It has been shown to decrease self-reported suicide attempts.
- Skills training programs that target a broader range of problems (e.g., depression, anxiety, negative self-perceptions) have been effective in teaching adolescents how to monitor feelings, identify triggers, and avoid and reframe negative thoughts. Relaxation skills training, learning how to seek out help from others, and promoting healthier responses to stress have also been successful in impacting internalizing behaviors.
- The Substance Abuse and Mental Health Services Administration (SAMHSA) awards grants in support of youth suicide prevention programs. SAMHSA has also developed a suicide prevention toolkit to help school around the nation implement programs (available online at <https://store.samhsa.gov/product/Preventing-Suicide-A-Toolkit-for-High-Schools/SMA12-4669>) (County Health Rankings & Roadmaps, 2018).

A behavior that can sometimes accidentally result in suicide is *self-injury* or *cutting* (Fig. 20-7). Adolescents with this abnormal behavior who overdose, head bang, cut, burn, brand, mark, or otherwise dangerously harm themselves are attempting to find relief from profound psychological pain. The physical injury distracts them from these painful emotions, often giving them a feeling of control or providing a means of feeling emotions when they are cut off from them.

**FIGURE 20-7** An adolescent girl with evidence of “cutting” self-injury.

- Emergency room visits for adolescents with nonfatal injuries have significantly increased in the United States since 2009. CDC research indicates that self-inflicted injuries among male adolescents remained stable, while female adolescents have increased about 8.4% each year between 2009 and 2015.
- For female youth aged 10 to 14, the percentage increased by 18.8% each year. This behavior most often begins in early adolescence or late childhood and can continue into adulthood.
- It is more common in those with a family history of suicide, self-injury, or maternal depression. Isolation, neglect, or abuse may predispose an adolescent to this behavior. Depression, poor quality of relationships, excessive seeking of reassurance, and eating disorders are often associated with self-injury ([Stockwell, 2018](#)).

C/PHNs and school nurses can provide education to adolescents and families about this condition and can work with schools to promote prevention strategies, such as early detection and referral to mental health providers.

## Violence

Youth violence is defined as “the intentional use of physical force or power to threaten or harm others by young people ages 10–24” (CDC, 2020h). The physical, emotional, and social effects of youth violence can be severe and long lasting. Youth violence affects entire communities and has become a leading cause of death for U.S. youth. The Youth Risk Behavior Surveillance Survey—United States, 2017, indicated that:

- 15.7% of high school students carried a weapon at least 1 day within 30 days of the survey.
- Male students (24.2%) carried a weapon more than female students (7.4%), with prevalence higher among White male students (29.0%), followed by Hispanic male students (18.4%), and Black male students (15.3%).
- In 2017, 3.8% of students did not go to school on at least 1 day prior to the survey because of safety concerns (Kann et al., 2018).
- It is not uncommon for children (0 to 17 years) to be exposed to more than one type of violence. Within the past year, approximately 37% of children were physically assaulted and 5% were sexually victimized (FCFS, 2019a).
- Homicide is a leading cause of death for adolescents and youth (aged 15 to 24). It is the leading cause of death for African American youth, the second leading cause of death for Hispanic youth, and the third leading cause of death for American Indian/Alaska Native (CDC, 2020h).
- Unfortunately, in the United States, more than 33% of homicide victims are young adults, meaning that approximately 13 adolescents are murdered each day.

Gangs are often associated with teen violence. In the United States, with a rise in gang membership to approximately 750,000 members, gangs are found in all 50 states.

- Gang participants are often young, male, and Black or Hispanic. Authorities believe that gangs are responsible for up to 13% of homicides, in addition to other crimes and drug sales. A survey of some of the largest city police departments in the United States indicated “significant criminal activity by youth gangs or gang-like groups of young people” (United States Department of Justice, 2018).

Multiple successful antigang programs have been implemented in communities including Gang Resistance Education and Training (G.R.E.A.T.). The G.R.E.A.T. program is taught by local law officials to students in middle and high schools. The goal of the program is to teach

students how to avoid violence, resist gang pressure, and improve positive attitudes about law enforcement. This promising program has shown promising results as it successfully meets its goals ([Bureau of Alcohol, Tobacco, Firearms, and Explosives \[ATF\], 2018](#)).

Although gang members may engage in violence and intimidation, other instances of school violence have captured greater media attention. Incidents of high school shootings are of great concern to parents, teachers, communities, and the nation. These high-profile events are becoming more common and bring attention to the need for change ([University of Virginia, 2018](#)).

School violence has been linked to bullying and the overall school environment and should be addressed quickly.

- Bullying can result in depression, social anxiety, internalizing and psychosomatic symptoms, loneliness, and poor school performance ([Jordan et al., 2018](#)).
- In 2017, bullying incidents were reported by 19% of students in public schools, cyberbullying was reported by 14.9% of students, and 6.7% of students did not feel safe going to school.
- In 2017, 6.0% of adolescents reported being threatened or injured with a weapon; this statistic has decreased significantly since 2007.
- Males were more likely to be involved in carrying weapons and fighting. Another form of violence found among adolescents and young adults is dating violence.
- In 2017, 8.0% of high school students reported physical violence while dating. This is significantly higher than the percentage reported in 2013 ([CDC, 2018f](#)).

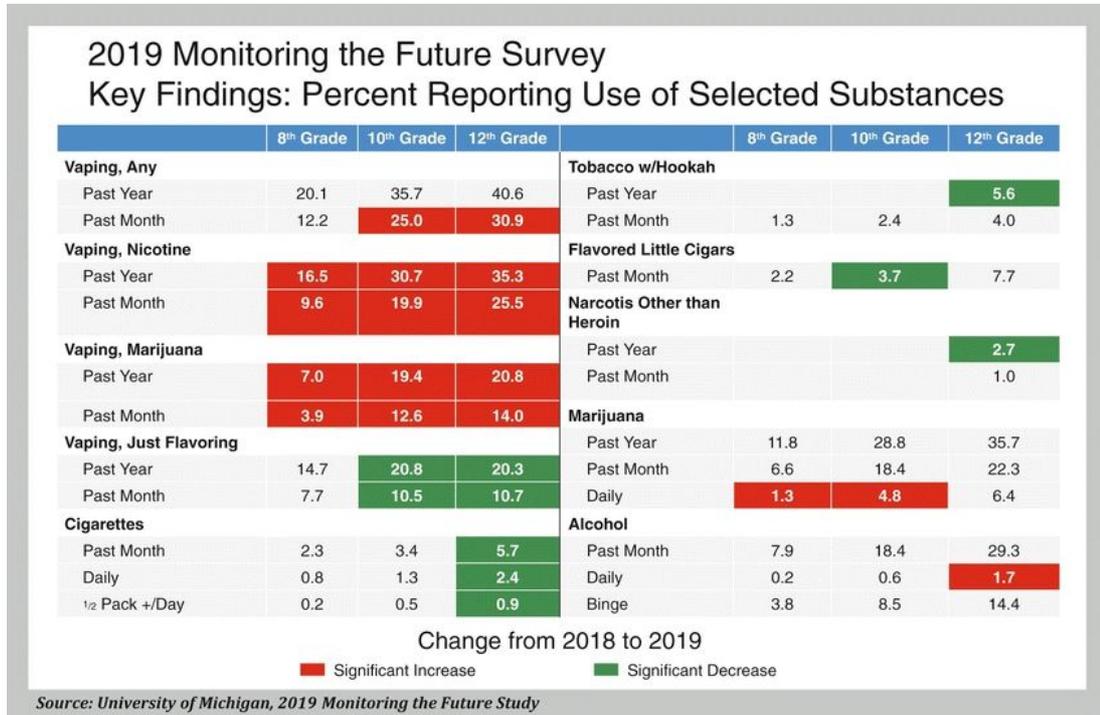

Of recent concern is the growing prevalence of school shootings and the effects this can have on students' wellbeing. Many students and their parents fear a shooting could occur in their school; nonwhite teens expressed a higher level of concern than white counterparts, and girls a greater concern than boys ([Pew Research Center, 2018](#)). School-aged children have become involved in the debate surrounding gun violence, where proposals focus on addressing mental illness, assault-style weapon ban, and the use of metal detectors in schools. To address this issue, researchers examined the relationship between 36 high schools' shootings and student achievement in 14 states and found that academic achievement was associated with standardized test scores in math and English, which were lower in affected schools 3 years following a deadly shooting ([Beland & Kim, 2016](#)). In addition, students' parents were likely to change their school selection due to a shooting; enrollment dropped for 9th grade students following a deadly shooting. Graduation and suspension rates showed no significant impact, despite a reduction in students' standardized test scores.

Cultural and environmental influences on youth include the violence to which children and adolescents are exposed. Increased aggressive behavior among children and teens has been attributed to violence in the environment, the home (spousal and child abuse), and the community, as well as to what children see on television and in movies. The effects of family violence (domestic violence, child maltreatment) can lead to internalizing and externalizing behaviors among youth.

- Personally experiencing or witnessing violence as a child is a risk factor for adolescent behaviors such as school dropout, running away from home, attempting suicide, and delinquency (Fix, Alexander, & Burkhart, 2018).
- School climate is important in reducing the levels of violence in this age group, as is adequate parental support. Family cohesion can also be a mediating factor for delinquency as a consequence of childhood effects of violence.
- The Functional Family Therapy (FFT) 3-month program used with adolescents with behavioral issues such as delinquency, and drug and alcohol abuse, has been adapted for adolescents with gang involvement and those at risk for gang involvement. A study found that prevention of gang involvement, subsequent delinquency, and decreased substance abuse were all positive outcomes of the program (Gottfredson, Thornberry, Slothower, & Devlin, 2018).

# Substance Abuse

Why do adolescents turn to alcohol or illicit drugs? Substance abuse is one of the greatest threats to adolescent health (Fig. 20-8).

**FIGURE 20-8** 2019 Monitoring the Future Survey key findings: percent reporting use of selected substances. (Reprinted from <https://www.drugabuse.gov/publications/drugfacts/monitoring-future-survey-high-school-youth-trends>)

- In 2017, 14.0% of high school students reported using illicit drugs including cocaine, inhalants, heroin, methamphetamines, hallucinogens, or ecstasy. This is a significant decrease over the past 10 years in the United States (CDC, 2018f).
- There are many influences associated with adolescent substance use including influence and monitoring by parents and guardians, family structure, history of physical abuse and maltreatment, adult example and parental substance use, and teen peer influence.
- Some research indicates that friend and peer influences become an even stronger predictor of substance abuse as teens age (Henry, Fulco, Agbeke, & Ratcliff, 2018).
- Depression has also been linked to alcohol and substance use. Increased emphasis on family values was noted to be a protective factor for alcohol use. This includes not only the parenting style of the

adolescent's parents but also the parenting influences of the teen's friend's parents ([Office of Adolescent Health, 2018b](#)).

Alcohol is the most frequently used substance for U.S. adolescents—it is often their first drug of choice. As adolescents get older, they are more likely to drink. Although rates of adolescent drinking have decreased since 2002, in 2017, 33% of 12th grade students report drinking, as compared to 20% of 10th grade students, and 7% of 8th grade students ([Office of Adolescent Health, 2018b](#)).

- The teen brain is very susceptible to the damaging effects of alcohol and a number of social, physical, and academic are associated with its use. Early drinkers more often report damaged family relationships, academic problems, problems with concentration and memory, use of other substances, and delinquent behavior in middle and high school.
- Early use of alcohol, even sipping/tasting with parental permission, was found to be a marker for increased alcohol use later in and the associated alcohol-related behaviors/problems ([Colder, Shyhalla, & Frndak, 2018](#)). It is important to stress education and prevention in late childhood to delay the initiation of alcohol use ([Box 20-8](#)).
- Family drinking, perceived family norms, and neighborhood societal contexts related to drinking have been found to affect adolescents' perceptions of the benefits of drinking. This perception, in turn, predicts their drinking behavior. Parenting practices (e.g., monitoring, discipline, enforcing rules related to alcohol use) have also been found to have an influence on adolescent drinking behavior ([Cambron, Kosterman, Catalano, Guttmanova, & Hawkins, 2018](#); [Colder et al., 2018](#)).

**BOX 20-8 Population Focus Using Evidence-Based Practice to Design Substance Abuse Prevention Strategies for Adolescents**

School nursing runs in my family. In the 1980s, when my mother was a school nurse in a small, rural school district located in an agriculturally dependent county, there was only one high school in the small

**town of about 10,000 people. School personnel were aware of some “keg parties” after football games and the occasional alcohol-related fight on school property between some of the rougher students, but they were not fully aware of the substance abuse problems. The school psychologist conducted an anonymous survey and found, much to the surprise of teachers and administrators, that most of the teens involved in alcohol and drug abuse were the athletes and cheerleaders. They had assumed that the lower-income, trouble-making kids were much more involved, but this was not necessarily the case. My mother worked with the psychologist to implement health education classes in the high school and eventually the middle school and elementary schools to address this issue and health promotion in general.**

I am a school nurse at a suburban, larger school district serving over 30,000 students with four high schools, a charter high school and a continuation high school. Each high school has a full-time school nurse, and the middle schools have one most of the week. We utilize evidence-based practice as school nurses, and there are many resources available to us. We are aware of national surveys on substance use among

adolescents (e.g., YRBSS) and have conducted some ourselves to better understand our students' needs. Although alcohol is still a concern, drug use has increased since my mom's school nursing experience. A national survey found that 14.0% of high school students use some type of illicit drugs (CDC, 2018f).

The district school nurses met with our advisory board, parent groups, school administration, and eventually the school board to discuss the problem and address potential interventions. We discussed our population demographics, our various cultural and ethnic influences, and our community statistics. After examining the best research-based methods, we found screening, brief interventions (SBI), and referral to treatment is key to delaying and decreasing substance abuse in teens. Additionally, family-focused prevention programs often provide skills to parents (e.g., parenting, helping children develop social resistance skills, monitoring/rule setting). Parental education and family-centered interventions have been found to be most effective in preventing risk behaviors and promoting self-regulation among teens and early adults (Stormshak, DeGarmo, Chronister, & Caruthers, 2018).

Based on the evidence, our school district decided to implement SBIRT and a family-based prevention program for upper elementary students and their parents. I hope we can eventually encourage a more community-based approach to population health for our children and adolescents. I feel that with the resources we have today, we can really make a difference in the lives of our students and their families. I know my mother is proud of the work I am doing, and I hope my daughter considers carrying on the family tradition!

*Holly, age 30, school nurse*

Source: Centers for Disease Control and Prevention (CDC) (2020l); Lunstead *et al.* (2017); Stormshak *et al.* (2018).

Adolescents who are engaged emotionally and connected to school usually have better outcomes. Positive parenting practices such as open communication, monitoring adolescent activities, and teaching methods of self-control have also been associated with a reduction in adolescent alcohol use.

- Family mealtimes have been shown to promote family cohesion and problem-and emotion-focused coping by encouraging parents to help their children feel part of the family and allowing them valuable time to coach them in effective methods for dealing with daily stresses and problems. The benefits of family mealtime include improved self-esteem, improved mental health, decreased alcohol and substance abuse, and decreased depression (Youth.Gov, n.d.). To promote the health and

welfare of adolescent children, it is vital to stress to families with young children the continued importance of family meals throughout adolescence.

Marijuana is the most commonly used illicit drug among 14-to 17-year-olds—35.6% of high school students reported ever using marijuana (Fig. 20-9).

**FIGURE 20-9** Marijuana use is common among adolescents.

- Marijuana use during adolescence has been associated with a much greater likelihood of drug abuse and dependency, poorer mental health, poorer academic performance, increased delinquency, and neurocognitive deficits (D'Amica, Rodriguez, Tucker, Pedersen, & Shih, 2018).
- Marijuana use has negative health effects, including anxiety, panic attacks, increased heart rate, frequent respiratory infections, impaired memory and learning, and tolerance. Regular marijuana smokers often have respiratory complications similar to those of tobacco smokers—cough, phlegm, respiratory infections, and airway obstruction (National Institute of Drug Abuse for Teens, 2017a).

Inhalant abuse is very common and frequently used by young teens. Inhalant use begins in early adolescence—more 12- and 13-year-olds reported using inhalants than any other illicit drug.

- The most commonly reported inhalants used were shoe polish, glue or toluene, spray paints, and lighter fluid or gasoline.
- Other inhalants commonly used include amyl nitrite “poppers”; locker room deodorizers or “rush”; cleaning fluid, degreasers, or correction fluid; halothane, ether, or other anesthetics; lacquer thinner or other

paint solvents; butane or propane gases; nitrous oxide or “whippets”; and other aerosol sprays.

- Inhalant abuse can result in severe nervous system damage or death. Control of legal products, such as spray paint, lighter fluid, household solvents, gasoline, and glue, is difficult, making this problem almost impossible to monitor adequately ([National Institute of Drug Abuse for Teens, 2017b](#)).

Other drugs that are used by adolescents and young adults include “club drugs” such as MDMA (Ecstasy), a synthetic drug with amphetamine and hallucinogenic properties, and its purer form “Molly” often glamorized by singers and musicians. Visits to the ED and deaths have occurred from the use of many of these drugs. Cocaine and heroin use has significantly decreased since 1999 with 1.2% of teens using cocaine and <0.03% of teens using heroin in the last month. Methamphetamine use is also down with <0.03% of teens using in the last month and 0.06% use in a year ([National Institute of Health, 2017](#)). Methamphetamine labs are a public health hazard. Prolonged exposure to methamphetamine can result in cognitive deficits and psychosis ([National Institute of Drug Abuse for Teens, 2017c, 2017d](#)). C/PHNs should be aware of this when making home visits.

Another drug used by adolescents is anabolic steroids. The illicit use of anabolic steroids is difficult to monitor; however, 0.6% of 8th graders, 0.7% of 10th graders, and 1.1% of 12th graders reported using steroids in a national survey ([National Institute of Drug Abuse for Teens, 2017e](#)). The Youth Risk Behavior Surveillance—United States, 2017 noted that use was higher in males, and more prevalent among Hispanic (3.5%) than White (2.2%) students.

- The prevalence of nonprescription steroid use increased between 1991 and 2001 and then decreased during 2001 to 2017 ([Kann et al., 2018](#)).
- Adverse effects of illicit steroid use include irritability, increased risk-taking behavior, extreme mood swings, paranoia, jealousy, and euphoria, as well as psychiatric conditions that may be intensified or induced ([National Institute of Drug Abuse for Teens, 2017e](#)).
- Because steroids are often readily available through Internet pharmacies, policymakers, health educators, and parents must make adolescents aware of the dangers, such as altered serotonin levels and increased aggression.

Adolescents are becoming more involved with prescription drugs, often found in their parents' medicine cabinets, purchased on the Internet or bought from friends at school. Secondary too marijuana and alcohol, they are the most commonly abused substances by teens. Medications are often mixed with alcohol, and adolescents often mistakenly believe prescription

medications are safer than street drugs when used to produce a high. The Youth Risk Behavior Surveillance—United States, 2017 indicated that adolescent misuse of prescription drugs ranges from 7.8% to 19.3% across 36 states (Kann et al., 2018). Prevalence of prescription drug misuse by 12th grade students decreased significantly between 2014 and 2017; however, this remains one of the most commonly abused substances by all Americans aged 14 years and older (National Institute of Drug Abuse for Teens, 2017f).

Tobacco products are also easily acquired, often from parents. Approximately 28.9% high school seniors report ever trying a cigarette.

- Between 1991 and 2017, the overall rates of adolescents currently using cigarettes significantly decreased from 27.5% to 8.8%.
- In 2017, 1.6% of teens reported using smokeless tobacco such as chewing tobacco, snuff, dip, snus, or dissolvable products, and 8% of students reported smoking cigars.
- Electronic cigarettes (e-cigarettes) are becoming increasingly used in the adolescent population. In 2017, 42.2% of adolescents reporting that they had ever used an electronic vapor product, and 13.2% reported using e-cigarettes in the past 30 days (Kann et al., 2018).
- Research regarding adolescent e-cigarette use indicates an association between e-cigarette use and the subsequent use of tobacco (Soneji et al., 2017; Wills et al., 2017).

Social disapproval and heightened perception of health risks are thought to help contribute to the downward trend of smoking and smokeless tobacco use, along with price increases and advertising bans. But tobacco marketing continues to be problematic, as the tobacco industry has joined with convenience stores to more prominently display tobacco products, and even though state and federal taxes comprise about half the cost of a pack of cigarettes, states have not always sufficiently invested these funds in adolescent tobacco prevention (Cruz et al., 2018). Flavored nicotine products are marketed to youth luring children with such flavors as bubble gum and cotton candy (Tobacco Free Kids, 2017).

- Risk factors associated with cigarette smoking include being an older adolescent, male, and white. Also, having parents without college education and adolescent lack of college education plans (Office of Adolescent Health, 2017b).

Primary health care providers do not always question adolescents about smoking, drinking, and use of other substances. Some evidence highlights the effectiveness of brief interventions by health care providers in encouraging smoking cessation and improvement in other risk behaviors.

Research recommends that health care professional counseling be provided as a preventive measure to adolescent tobacco users.

- Important to note is research indicating that education regarding the harmful effects of tobacco use are more effective than messages about the benefits of not smoking. This research may prove influential regarding the risk warning on tobacco products and in social media (Mays, Hawkins, Bredfeldt, Wolf, & Tercyak, 2017).
- C/PHNs and community health nurses can provide information to teens about smoking cessation programs and promote primary prevention by educating children and adolescents to choose not to smoke or engage in other health risk behaviors. They can also encourage physicians and parents to question and monitor adolescents about smoking and the use of tobacco products.

## Teen Sexuality and Pregnancy

Teenage pregnancies, sexually transmitted diseases (STDs), and HIV/AIDS are public health concerns associated with the sexual activity of adolescents.

- In the 2017 YRBSS, 39.5% of high school students reported ever having sexual intercourse, and 53.8% used a condom during their last sexual intercourse.
- About 10% reported having had sexual intercourse with four or more persons, and 20.7% used birth control pills to prevent pregnancy ([Kann et al., 2018](#)).

Adolescent birth rates differ by age, racial and ethnic group, and country region. The downward trend in teen birth rates has continued over the past 25 years; however, the rate in the United States remains higher than many other developed countries.

- In 2016, teens (aged 15 to 19) experienced 209,809 pregnancies, with 74% of all teen births occurring to 18-to 19-year-olds.
- Teen births are more prevalent among Hispanic and Black females, although this rate has decreased in recent years.
- Preventive teenage pregnancy factors include being engaged in learning and after school activities, having a positive attitude toward learning and school, academic excellence, and living in a wealthier neighbor with higher income levels ([Office of Adolescent Health, 2017c](#)).

Teenage pregnancy is associated with increased health risks to both the mother and the child. These risks include increased risk of illness and death, increased risk of mother's death from violence, and increased developmental concerns of the child. In addition, young mothers are more likely to live in poverty and to be delayed in their own education. The children of teen mothers are at risk of several social and health challenges, including lower academic achievement, health problems, incarcerations during adolescence, teenage pregnancy, and young adult unemployment ([CDC, 2019g](#)).

- By 19 years of age, 39.5% of males and females have had sexual intercourse. Approximately 3.4% of teens have had sex by age 13.

As such, it would be appropriate for U.S. society to provide effective sexuality education. There is often debate about the virtues of comprehensive versus abstinence-only educational programs. Despite the controversy about the subject, in 2014, 72% of private and public schools in the United States taught pregnancy prevention as part of required health education. Most adolescents (aged 15 to 19) received education about STDs and abstinence

(76%), 61% were taught about contraceptives, and 35% were taught how to use a condom. Many sexually active teens have no instruction on contraception before their first sexual experience (40% girls, 45% boys) (Guttmacher Institute, 2017). Teaching about contraception has not been shown to increase the risk of adolescent sexual activity or STIs, but it may decrease the risk of pregnancy. A systematic review and meta-analysis assessing the effectiveness of school-based programs found that sex education, of any type, when compared to no education was associated with delayed adolescent sexual intercourse. Research, however, was divided regarding effectiveness in preventing teen pregnancy (Marseille et al., 2018). Besides formal education through schools, adolescents note that peers, the media, and parents are also sources of information on sexual health. Between 70% and 78% of teens report talking with a parent about sex, although girls more often talk with parents about how to say no to sex or use birth control (Guttmacher Institute, 2017).

Pregnancy prevention programs can be effective in reducing teen pregnancy and birth rates (Fig. 20-10), as well as in reducing the number of second births to teenage mothers. Research regarding the effectiveness of a multicomponent, community-wide teen pregnancy prevention (TPP) program focusing on 15-to 19-year African American and Latino/Hispanic youth found that key elements influenced the success of a community mobilization program. Learnings included:

**FIGURE 20-10** Pregnancy prevention programs can be helpful in decreasing rates of adolescent pregnancy.

1. Communities are generally willing to “‘face’ the issue of teen pregnancy.”
2. Support of the program by key stakeholders was critical to success.
3. Collaboration of health and human service agencies strengthened the program.
4. Education of and establishing trust within the community was essential.
5. Engagement of youth teams and extensive training for youth leaders was imperative.

Review of the TPP intervention research by project coordinators was positive, “*The model was important in creating a network of community partners and concerned citizens—including the youth of the community—who would contribute to normalizing TPP within their communities*” (Saunders, 2018). Health promotion professionals were important allies throughout the TPP community mobilization program through direct service, community advocacy and networking, and being actively involved in health promotion (Saunders, 2018).

Primary care providers often miss opportunities to provide counseling on prevention of pregnancy, HIV, and STDs, as well as other risk factors for unintentional injury. Nurses can provide information and counseling on birth control and emergency contraception to adolescent clients and collaborate with schools to promote effective pregnancy prevention programs. It is important for C/PHNs to provide education and health counseling on these subjects. A recent study by [Rabbitte & Enriquez \(2018\)](#) demonstrated the importance of nursing collaboration in high school sexual education and counseling, stating “*If implemented correctly, sex education teaches students about anatomy and physiology, healthy relationships, hygiene, positive self-image, how to handle uncomfortable situations, and about health resources available to them. School nurses are in a unique position to play a critical role in policy change with regard to sex education*” (p. 10).

# Sexually Transmitted Infections

STI and HIV infections are epidemic among adolescents worldwide ([WHO, 2018a](#)). More than 20 diseases can be transmitted sexually; only the most common are reportable.

- Each year, about half of the STD cases occur among the 15-to 24-year-old age group, even though they represent only 27% of the population of sexually active individuals. These diseases include syphilis, gonorrhea, *Chlamydia*, HPV, and herpes simplex virus.
- Almost all sexually active people will get an HPV infection in their lifetime. HPV infections can lead to several types of cancer in both men and women and other health-related problems ([CDC, 2018g](#)).

*Chlamydia*, gonorrhea, and syphilis are other STDs/STIs found in the adolescent population.

- Of the 19 million new cases of STDs annually, about half are among adolescents (15 to 24 years old), and 21% of 13-to 24-year-olds in reporting states had a new HIV infection in 2016.
- In the adolescent population, STIs are more common among those engaging in sexual risk behaviors. In 2017, 40% of high school students reported ever having sexual intercourse and 30% were active within the previous 3 months.
- About 10% had sex with four or more partners, and 54% used a condom with their last sexual contact ([CDC, 2020i](#)).
- Gonorrhea is the most commonly reported STD (70%), followed by *Chlamydia* (63%), HPV (49%), genital herpes (45%), HIV (26%), and syphilis (20%) ([CDC, 2018g](#)).

About one in four sexually active adolescent females have an STD. Compared with adults, adolescents (10 to 19 years) and young adults (20 to 24 years) are at increased risk for acquiring STDs. Reasons for this may include a greater likelihood of multiple sex partners, unprotected intercourse, and selection of higher-risk partners. Immature biology makes adolescents more vulnerable to infection and earlier sexual initiation.

- Barriers to prevention and care include social and cultural conditions such as lack of health insurance and transportation, concerns about confidentiality, and lack of quality STD prevention services.
- Adolescent girls also have a physiologically amplified susceptibility to *Chlamydia* infection because of increased cervical ectopy.
- Serious complications from STDs include pelvic inflammatory disease (PID), sterility, increased risk of cancers of the reproductive system,

and, with syphilis, blindness, mental illness, and death. There are also complications for the unborn children of those infected with STDs (CDC, 2018g).

Even though death rates from HIV/AIDS have dramatically fallen, new HIV infections reported annually do not reflect the same steep decline.

- It is estimated that as many as 51% of youth with HIV are not aware of their infection. Adolescents and young adults (aged 13 to 24) comprised 21% of all new cases of HIV infection in 2016 and young gay and bisexual men accounted for 81% of the new cases.
- As a result, in 2017, the CDC granted approximately \$11 million per year/5-year community-based organizations for HIV testing of young gay and bisexual men. The goal of these grants is to identify undiagnosed HIV infections and connect those diagnosed with HIV to appropriate health care resources (CDC, 2020j).

As noted earlier, sex education is effective at both delaying the onset of sexual activity and possibly increasing the use of contraception in adolescents who are already sexually active. It is also effective in increasing safer sex practices, knowledge of birth control method efficacy, and overall sexual knowledge when that content is taught (Rabbitte & Enriquez, 2018; Saunders, 2018). Prevention strategies identified by the CDC to reduce sexual risk behaviors included:

- Targeting behaviors that are most easily amenable to change (e.g., condom use, decreased number of sexual partners, abstinence)
- Tailoring programs to the target population, using theory as a guide in development of programs (e.g., modeling discussions with partners about condom use, skill building by role-playing situations, increasing self-efficacy)
- Addressing a broader content than just STI/HIV prevention education (e.g., problem-solving, social skills, gender pride, capacity building)

Evidence-based prevention interventions are the most effective (CDC, 2018h). See Chapter 28 for the school nurse's role with STD/HIV.

## Acne

Acne is a skin disease that primarily affects adolescents going through puberty.

- The prevalence of acne in the adolescent population is nearly 95%. The precise cause of acne is not fully understood. It is often related to several factors. Genetics play a part (there is often a family history of acne), hormonal influences are also a factor (especially an increase in male hormones), and greasy cosmetics may plug cells of follicles, producing a plug.
- Acne usually begins during puberty (10 to 12 years of age) with the increase in circulating male hormones that stimulate sebaceous glands in the skin. It often affects adolescent men more than females ([Skroza et al., 2018](#)).

Common acne treatment includes skin cleansers, peelers, and medications to decrease sebaceous gland activity. Topical retinoids are the first-line drugs of choice because of their anti-inflammatory properties. Benzoyl peroxide is used to kill bacteria on the skin and in the pores. It may be sold over the counter (OTC) or by prescription. Other OTC medications include salicylic acid and resorcinol. Retin-A (a topical vitamin A ointment), glycolic acid, and alpha-hydroxy acids help to peel the impacted cells from the pores. Antibiotics (oral or topical), such as tetracycline or doxycycline, may be prescribed to help control bacteria on the skin. Isotretinoin reduces the size and activity of sebaceous glands but can cause liver or kidney dysfunction. Because of an extremely high risk of birth defects, female adolescents taking Isotretinoin are prescribed oral contraceptives and must participate in a Food and Drug Administration–approved risk management program. Corticosteroids may be injected directly into the comedones. Some adolescents choose to try complementary therapies such as tea tree oil, fish oil, or brewer's yeast, as well as biofeedback and traditional Chinese medicine ([Cao et al., 2017](#)).

The best preventive measures are keeping the skin clean, eating a balanced diet that includes fresh fruits and vegetables, drinking lots of water, and getting adequate sleep. It is important for male adolescents to shave carefully and for all teens with acne to avoid touching their faces or picking at their blemishes. They may want to use skin and hair products that are noncomedogenic. Adolescents with severe acne may need to be referred to dermatologists who specialize in this skin disorder ([Mayo Clinic, 2017](#)).

## Poor Nutrition and Eating Disorders

Poor nutrition and obesity are common among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. The nutritional needs of adolescents increase as their growth rate and body composition changes with puberty. Many things, from psychosocial factors, family and peers, availability of fast-food, and mass media marketing, influence the eating behaviors of adolescents. Research indicates that two thirds of adolescents are not aware of dietary needs, sources of nutrients, and diet–disease relationship ([Demory-Luce & Motil, 2018](#)).

- Girls are more at risk for problems with nutrition for several reasons: they tend to diet inappropriately, to have more finicky eating habits, and to be less physically active than teenage boys.
- Approximately 5.4% of adolescents (13 to 18 years) suffer from an eating disorder, with the majority being female. Issues with body image and control are at the heart of anorexia nervosa and bulimia nervosa, common problems for adolescent girls.
- **Anorexia nervosa** is an eating disorder with an emotional etiology that is characterized by body image disturbance (i.e., girls see themselves as fat, although they may be extremely thin), an intense fear of becoming fat or gaining weight, and refusal to maintain adequate body weight.
- **Bulimia nervosa** is an eating disorder characterized by recurrent episodes of binge eating with repeated compensatory mechanisms to prevent weight gain, such as vomiting (purging type) and fasting or exercise (nonpurging type) ([National Institute of Mental Health, n.d.b](#)).
- **Binge eating**, also a recognized eating disorder, involves recurrent episodes of binge eating without fasting, self-induced vomiting, or other compensatory measures. Self-esteem, depressive symptoms, and emotional eating are very sensitive predictors of binge eating. Low levels of support from peers can also be linked to binge eating, and binge eating is associated with an increased risk of becoming overweight or obese ([National Institute of Mental Health, n.d.b](#)).

These diseases affect both male and female adolescents. Research indicates that they are caused by multiple factors including genetics, biological, behavioral, psychological, and social elements. Nutrition education, psychological counseling, and cognitive–behavioral techniques that teach clients how to control stimuli, substitute alternative behaviors, and use positive visualization are all part of treatment; development of a support network is also important. Family and individually based treatments are most often used for severe cases of adolescent eating disorders and have been

studied most often. Medications (e.g., antidepressants) have been used to treat some adolescents with eating disorders, when co-occurring illnesses exist ([National Institute of Mental Health, n.d.b](#)).

# **HEALTH SERVICES FOR SCHOOL- AGE CHILDREN AND ADOLESCENTS**

A number of programs serve the health needs of school-age children and adolescents. Community health nurses play a major and vital role in delivering these services. Such programs fall into three categories that approximate the three practice priorities of community health nursing practice: illness prevention, health protection, and health promotion.

## Preventive Health Programs

Among programs to prevent physical illness and other health problems among adolescents are immunizations and TB testing, as well as school- and community-based education, and support programs. Private and public counseling programs and other social services are also geared to promote health and prevent illness.

### *Immunizations and Tuberculosis Testing*

C/PHNs are deeply involved in each of the preventive activities of immunizations and tuberculosis testing. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws are helpful in carrying out these preventive services, but recent survey results reveal that not all adolescents are fully covered.

- A national immunization survey revealed mixed results for adolescent vaccination. There were significant increases in vaccination rates for varicella, tetanus/diphtheria/acellular pertussis (Tdap), and meningococcal conjugate vaccine. HPV coverage also increased with 65.1% of females and 56% of males being vaccinated ([Walker et al., 2017](#)).

It is important for adolescents, as well as adults, to get a single dose of Tdap to protect themselves and infants who may be around them from whooping cough. Although pertussis in adolescents or adults often manifests as an upper respiratory infection with a chronic cough, for infants who have not yet been fully immunized, it can lead to serious complications.

In the recent past, adolescents were only given “catch-up” vaccinations (those missed in childhood), except for a tetanus/diphtheria booster. Recommended immunizations now include Tdap, meningococcal vaccine, pneumococcal polysaccharide vaccine, both hepatitis A and B, influenza vaccine, and HPV vaccine for both boys and girls. Additionally, any missed vaccines such as polio and varicella are recommended (for immunization tables, see [thePoint](#) ).

Often, school nurses and community health nurses work with nurse volunteers to provide immunization clinics at elementary and middle schools; these are convenient for adolescents and their parents. School-based clinics are also great places to catch adolescents who need updated immunizations. There is some evidence that adolescent vaccinations are becoming more available at retail pharmacies. Researchers note, however, that higher levels of medical and health needs are met when children and adolescents have an annual visit with a health care provider ([Office of](#)

[Adolescent Health, 2018c](#)). Routine visits give the health care provider an opportunity to discuss risk behaviors and health concerns with adolescents and to intervene early as problems arise. Annual tuberculosis (TB) testing is often recommended for children and adolescents from high-risk populations. Targeted TB skin testing identifies adolescents and children at risk for latent TB who could benefit from treatment to prevent progression of the disease ([CDC, 2018h](#)). See [Chapter 8](#) for more on TB skin testing.

## *Education and Social Services*

The health education of school-age children and adolescents includes a wide variety of approaches and can range from the basics of handwashing for elementary school students to health risk behavior for adolescents. Parental support services are commonly available through many public and private agencies, including churches. These services can have long-range effects on the health of school-age children, because emotionally healthy parents and stable families offer a healthful environment and support system for children and can facilitate their progress in school. In most states, community health nurses provide teaching and counseling services to parents in their homes and in groups. School nurses, school mental health counselors, and school psychologists also organize parent support groups in local schools. This is particularly important during periods of transition (e.g., from elementary to middle school, from middle to high school). Discussing parenting concerns and increasing parents' understanding of normal child growth and development help to allay fears and prevent problems. Through such efforts, family violence and abuse can be averted. Reduction in rates of divorce and the attendant consequences may also be a benefit of strengthening family resilience.

Family planning programs, often stationed strategically in inner cities, near schools, or in school-based clinics, provide birth control information and counseling to young people.

- In some communities, the school-based clinic dispenses condoms. In many states, adolescents have the right to consent for sexual and reproductive health care without parental permission. It is important that health care providers be aware of local and regional options for counseling.
- C/PHNs, in collaboration with an interdisciplinary team, are usually the primary care providers in these programs. Their major goals are to prevent teenage pregnancy, educate teens about reproduction and contraception, and encourage responsible sexual behavior.
- Schools can foster evidence-based health education and create healthy, safe, and nurturing school environments, especially when implementing

policies and programs regarding reproductive health and health risk behaviors.

- Collaborative efforts by the student, family, school, community, and society are essential to promoting adolescent health. Developing healthy and safe health education environments will influence adolescent health and academic achievement ([CDC, 2019h](#)).

Children and adolescents can be influenced by adults' smoking in the home.

C/PHNs should educate parents about the effects of smoking in the home and its relationship to adolescent smoking. Youth tobacco use is also associated with peer approval, mental health (strongly associated with depression, anxiety, and stress), lower socioeconomic status, lower academic achievement, accessibility, and tobacco advertising.

- Multiple programs to reduce and prevent teen smoking have been implemented in recent years. Successful activities include higher tobacco costs, indoor smoking prohibition, raising minimum age of tobacco sales, social media, and community antitobacco programs ([CDC, 2019i](#)).

It is essential that C/PHNs work with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay the use of tobacco products. Information on smoking cessation and resources to help prevent tobacco use by children and adolescents is available through the CDC and the Foundation for a Smokefree America.

## Health Protection Programs

### *Safety and Injury Prevention*

Accident and injury control programs serve a critical role in protecting the lives of school-age children and adolescents. They are cost-effective: seat belt laws, child safety seats, and helmet laws have saved millions of dollars in medical care. Efforts to prevent motor vehicle accidents, a major cause of adolescent death, include driver education programs, better highway construction, improved motor vehicle design and safety features, and continuing research into what causes various types of crashes.

- Injury prevention and reduction have been addressed through multiple strategies. These include state laws requiring the use of safety restraints; installation of driver and front passenger airbags; substitution of other modes of travel (air, rail, or bus); lower speed limits; stricter enforcement of drunk driving laws; graduated drivers licenses (GDLs) for teenagers; safer automobile design; and helmets for motorcyclists, bicycle riders, and skaters ([Ballesteros et al., 2018](#)).
- In developing interventions, community health nurses need to recognize that adolescents are prone to risk-taking/novelty-seeking behaviors as a result of their cognitive, physical, and psychosocial developmental stage ([Nesi et al., 2018](#)).
- A campaign from the CDC, “Parents are the Key,” focuses on the influence of parents, pediatricians, and communities as safety features for teens ([CDC, 2017h](#)). Communities can also work with law enforcement officials to ensure compliance with mandatory seat belt laws and to promote safe speeds and appropriate driving behaviors near schools.

Safety programs also seek to protect school-age children and adolescents from the hazards of poisonings, ingestion of prescription or OTC drugs, product-related accidents (unsafe toys, bicycles, skateboards, skates, playground equipment, and furniture), and recreational accidents, including drowning and sports-related injuries. Safety services assume various forms. Poison control centers in many localities offer information and emergency assistance. Whereas the federal Consumer Product Safety Commission monitors the safety of products, education programs in schools or through local fire or police departments teach school-age children about bicycle and water safety, fire dangers, and hazards related to poisoning. Generally, the community health nurse can educate families to recognize potentially hazardous situations and encourage efforts to eliminate them. Working with

school nurses and school district officials to reduce playground hazards can contribute to the reduction of school-related injuries.

Environmental hazards and other dangers await school-age children and adolescents in the workforce.

- There were approximately 19.3 million workers under age 24 in 2016, and 403 workers under age 24 died from a work-related injury in 2015. Hospitals treated nearly double the number of workers aged 15 to 19 years, as compared to workers over age 25; it is necessary to reduce the number of occupational-related injuries among 15-to 19-year-olds ([The National Institute for Occupational Safety and Health \(NIOSH\), 2018](#)).
- C/PHNs can join with occupational health nurses and school nurses to teach parents and children about the dangers and risks inherent in the workplace, and they can work with local employers to ensure safe working conditions and reasonable hours of employment that do not interfere with school.

### *Infectious Disease Prevention*

Programs that protect school-age children and adolescents against infectious diseases encompass such efforts as closing swimming pools that have unsafe bacteria counts, conducting immunization campaigns in conjunction with influenza or measles outbreaks, and working with hospital pediatric units to reduce the incidence and threat of iatrogenic disease. Prevention of community-acquired MRSA is a new challenge for public schools, and C/PHNs may work with school nurses or others to provide educational programs covering a variety of infectious diseases. Epidemiologic investigations, especially with school sports teams, may be necessary to determine the cause of outbreaks ([CDC, 2019f](#)).

### *Child Protective Services*

The Children's Bureau collects and analyzes information on child abuse and neglect, serves as an information clearinghouse, publishes educational materials on the subject, offers technical assistance, and conducts research into the problem ([Administration on Children and Families \[ACF\], 2018a](#)).

- In 2016, an estimated 4.1 million referrals were made alleging child abuse and/or neglect of approximately 7.4 million children.
- Approximately 58% of these referrals were screened, and almost 3.5 million cases had an investigation or alternative response. This reflects a Child Protective Services (CPS) response increase of 9.5% since 2012.
- Most victims suffered from neglect (74.6%), approximately 18.2% were physically abused, and 8.5% were sexually abused.

- There were 2.36 deaths per 100,000 children, and 70% of children were under age 3. More than 70% of deaths were attributed to neglect or a combination of neglect and another form of maltreatment.
- Nearly 45% of deaths were attributed to physical abuse or a combination of physical abuse and another form of maltreatment. Most perpetrators of child abuse and maltreatment (78%) were biological parents ([ACF, 2018b](#)).

Consequences for affected children include lower self-esteem, depression, suicide, self-abuse, substance abuse, eating disorders, less empathy for others, antisocial behavior, delinquency, aggression, violence, low academic achievement, and sexual maladjustment. Long-term emotional, social, cognitive, and physical consequences are well documented, and often follow abused children into adolescence and adulthood. Posttraumatic stress disorder, poor attachment and problems with trust, difficulties with language development and abstract reasoning, high-risk health behaviors, and abusive or violent behavior may be seen later in life ([CDC, 2020k](#)). These findings were first noted in a large-scale, landmark research study, the Adverse Childhood Experiences study ([Felitti et al., 1998](#)).

In some areas, C/PHNs are working together with social workers, mental health workers, and substance abuse counselors as part of a team that provides services to families. Improved training of mandated reporters, such as teachers and physicians, has led to better reporting of abuse; as professionals and the public become more aware of the problem, an increase in reporting has occurred. Child abuse prevention programs can be found in many public health departments and through some school districts as a primary preventive intervention. Primary prevention of child maltreatment can also occur through home visiting programs utilizing C/PHNs. These visits can also help to connect high-risk families to the community and promote better child outcomes when an appropriate curriculum is followed ([Matone et al., 2018](#)). Programs that target at-risk families, especially adolescent mothers and young couples prone to partner violence or harsh parenting practices, may help to prevent later child abuse. C/PHNs and school nurses must be vigilant for signs of family stress, harsh parenting practices, family violence, and other risk factors for child abuse and neglect, and must provide resources and respite as needed (for additional information, see [Chapters 18 and 19](#)).

## *Oral Hygiene and Dental Care*

Fluoridation of drinking water, school-provided fluoride rinse or gel, and dental sealant programs are cost-effective and can reduce dental caries.

- Fluoride makes teeth less susceptible to decay by increasing the resistance of tooth enamel to the bacterially produced acid in the mouth. School-based programs that provide fluoride rinses and dental sealants and promote tooth brushing and nutrition education for dental health can be found in most areas of the country.
- Fluoridation of community water supplies is considered the most effective, safe, and low-cost means of protecting the dental health of children and adolescents.
- Although most dental care is focused on children, adolescents remain in need of dental health services. In addition to regular dental care, good nutrition, and proper oral hygiene, C/PHNs can promote public water fluoridation as an important program for protecting children's dental health. Nurses can also recommend that parents talk with their primary health care provider and dentist about fluoride varnish or supplements ([CDC, 2019j](#)).

## **Health Promotion Programs: Nutrition and Exercise**

Nutrition and weight control programs form another important set of health promotion services. Children need to learn sound dietary habits early in life to establish healthy lifelong patterns. Being overweight during childhood or adolescence may persist into adulthood and may increase the risk for some chronic diseases later in life.

- A number of weight control programs for overweight children and adolescents are available through schools, health departments, community health centers, health maintenance organizations, and private groups ([Geria & Beitz, 2018](#); [Williams et al., 2018](#)).
- Children and adolescents are particularly vulnerable to media and peer pressures with regard to their food choices. Because of increased rates of childhood obesity and a greater awareness of the need for better nutrition in adolescence, district-level policies to increase the availability of healthy foods at public schools is growing ([Micha et al., 2018](#)).

The C/PHN, through nutrition education and reinforcement of positive practices and policy advocacy, plays a significant role in promoting the health of children.

# SUMMARY

- The physical and emotional health of children and adolescents can affect not only their academic achievement but also the future of society. Children and adolescents need the guidance and direction provided by community health nurses.
- Poverty is a significant social determinant of health that has been shown to contribute to many physical, psychological, and behavioral problems in children and adolescents. There is concern that government assistance programs are not sufficiently meeting the needs of poor children and adolescents.
- Health problems that affect learning and achievement in school-age children include chronic diseases, behavioral and learning problems, disabilities, injuries, communicable diseases, dietary and physical activity concerns, and poor dental health.
- The federally and state-mandated immunization program for school-age children and adolescents is one measure to prevent communicable diseases. Among vaccines given on schedule throughout childhood are those that prevent polio, smallpox, diphtheria, tetanus, typhoid, and many other diseases.
- Mortality rates for children and adolescents have decreased dramatically since the early 1900s, but morbidity rates remain high. Children and adolescents are vulnerable to many illnesses, injuries, and emotional problems, often as a result of a complex and stressful environment.
- Violence against children and deaths because of homicide occur in the United States at alarming rates. Unintentional injuries, suicide, and homicide are the leading threats to life and health for adolescents.
- Other health problems include alcohol and drug abuse, unplanned pregnancies, STIs and HIV/AIDS, and poor nutrition. All of these problems create major challenges for the community health nurse who seeks to prevent illness and injury among children and adolescents and to promote their health.
- *Healthy People* objectives for children and adolescents provide key goals for reduction of alcohol-related unintentional injuries; declines in violent behaviors, suicide, mental health issues; and more responsible reproductive health behaviors. Barriers to achieving these goals vary and include economic inequities; lack of sufficient immunization, educational, and community-supported health programs; and the presence of risk behaviors typical among developing youth.
- Community health nurses play a large role in promoting the health of adolescents, their families, and communities, through education

programs and by developing strategies to support healthy growth and development and prevent risky behaviors that lead to injury, teen pregnancy, and sometimes death.

- Health services for children and adolescents span three categories: prevention, health protection, and health promotion. The community health nurse plays a vital role in each.
  - Preventive services may include immunization programs, parental support services, family planning programs, services for those with STIs, and alcohol and drug abuse prevention programs.
  - Health protection services often include accident and injury control, programs to reduce environmental hazards and control infectious diseases, and services to protect children and adolescents from child abuse and neglect.
  - Health promotion services may include programs in nutrition and weight control, along with HIV/AIDS prevention and smoking, alcohol, and drug abuse education.
- C/PHNs are integral to the health and wellbeing of children and adolescents, through their work with families, schools, and other community agencies.

# ACTIVE LEARNING EXERCISES

1. You are a community health nurse assigned to work at a school. You learn that more than 20% of the students in this school district are receiving medications for treating attention deficit hyperactivity disorder (ADHD). Why is this significant? Explain your reasoning. What evidence-based information will you use to prepare an individualized health care plan for each child?
2. You are working in a rural health department and are researching the leading causes of death among children and adolescents. Where can you find national and state data for your search? What evidence-based public health interventions have been successful in preventing childhood deaths? Select one intervention for children or adolescents and describe how you and a group of community health professionals might develop effective preventive measures.
3. A 14-year-old girl from a middle-class family and a 14-year-old girl from a poor family both come to the health department clinic where you work. The girls have similar symptoms that suggest gonorrhea. Would your assessment and intervention be the same for the two girls? What personal assumptions or biases might influence your plan of care? Compose a sexually transmitted infections prevention instruction document for this population group.
4. Your school district is searching for ways to improve adolescent nutrition and diet. What influencing factors should you consider (e.g., student behaviors, environment/cultural influences, school policies)? What key stakeholders should you include as you research and develop a health improvement plan? Describe an evidence-based program that you could implement to increase physical activity and improve nutrition for school-age children and adolescents.
5. You are assigned to work with a rural elementary school with repeated outbreaks of head lice and limited access to health care. Search credible online resources for causes of recurrent head lice infestations and effective over-the-counter treatment products. Describe two head lice treatments and the supporting evidence. What are the advantages and disadvantages of each treatment?
6. Apply “Utilize Legal and Regulatory Actions” (1 of the 10 essential public health services; see [Box 2-2](#) ), to the following: Your school district allows personal exemptions for vaccination (i.e., parents can refuse to get mandatory vaccinations for their children based on personal, not solely religious, beliefs). The public health department has informed you that there is a measles epidemic in your county.

What information do you need to promote a safe and healthy school environment? Outline your concerns and formulate a health intervention for your school.

# CHAPTER 21

## *Adult Health*

*“Male and female represent the two sides of the great radical dualism. But in fact, they are perpetually passing into one another. Fluid hardens to solid, and solid rushes to fluid. There is no wholly masculine man, no purely feminine woman.”*

—Margaret Fuller (1810–1850), *Woman in the Nineteenth Century*, 1845

## KEY TERMS

Adult

Anorexia nervosa Binge eating Bisexual

Bulimia nervosa Cancer

Cardiovascular disease (CVD) Chronic lower respiratory disease (CLRD)

Diabetes mellitus Erectile dysfunction (ED) Life expectancy Menopausal

hormone therapy (MHT) Menopause Myalgic encephalomyelitis/chronic

fatigue syndrome (ME/CFS) Osteoporosis Perimenopause Prostate

Substance use disorder (SUD) Transgender Unintentional injuries

## LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

1. Identify key demographic characteristics of women and men throughout the adult life span.
2. Discuss the concepts of life expectancy, health disparities, and health literacy and how they apply to adult women and men living in the United States.
3. Discuss the major chronic illnesses found in adult women and men in the United States.
4. Compare and contrast the manifestations of chronic illnesses in adult women and men.
5. Discuss factors affecting the health of adult women and men in the United States.
6. Identify primary, secondary, and tertiary health promotion activities designed to improve the health of women and men across the life span.
7. Identify the *Healthy People 2030* objectives for adult women and men.
8. Describe the role of the community health nurse in promoting the health of adult women and men across the life span.

# INTRODUCTION

Mrs. Anderson is a relatively healthy middle-aged woman, with no chronic health conditions. Her family history is positive for type 2 diabetes mellitus, cardiovascular disease, and colon cancer. She tries to eat healthy, but her moderately stressful career and busy family make it difficult to find time to cook and exercise. Over the past few years, she has noticed weight gain and is concerned that this, along with her family history, may lead to the development of chronic disease. What are considerations for Mrs. Anderson based on her age, risk factors, and current health status? What preventative services and screenings might she need?

Community and public health nurses (C/PHN) are in a key position to educate clients like Mrs. Anderson on health promotion and disease prevention and inform them of U.S. Preventative Services recommendations. This teaching impacts community health by improving the health of individuals.

The term *adult* has many different meanings in society. To children, an **adult** is anyone in authority, including a 14-year-old babysitter. As people age, they tend to redefine the term upward. It is not unusual, for example, to hear an older person describe a couple in their mid-30s as “kids.” The U.S. criminal justice system distinguishes between adults and juveniles for purposes of delimiting types of crimes and possibilities for punishment, and labor legislation provides different protections for children than for adult workers. Even hospitals and health care systems vary somewhat as to the ages at which they distinguish pediatric and geriatric clients from middle-aged adults.

How would you characterize an adult? Does your definition rest solely on age or is it influenced by other factors, such as marital status, employment status, financial independence, amount of responsibility for self and others, and so on?

- For the purposes of this chapter, an adult is defined as anyone 18 years of age or older. Obviously, there are tremendous differences in health profiles and health care needs as people age.
- As adults enter their middle years (35 to 65), they experience many normal physiologic changes. However, some changes are the result of disease, environment, or lifestyle and can be modified through behavior change.

Throughout history, the health care needs of women and men have differed more often than shown similarities (Fig. 21-1). Many health promotion and health protection programs are designed specifically for women or for men, as the examples below illustrate.

**FIGURE 21-1** Health care needs of men and women of varying ages are often different.

- Mammography screening programs and prenatal clinics are designed with women's health in mind.
- Teaching about testicular self-examination (TSE) and prostate cancer screening is typically included in health promotion programs for men.
- Programs in many areas, such as cardiac rehabilitation, stress management, and dating violence prevention, may have initially targeted one gender but are now established as programs for both genders.

Despite areas of overlap in women's and men's health, morbidity and mortality statistics, historical development of research foci, and workforce changes require that the health care needs of women and men be examined separately. This chapter focuses on the health of women and men across the adult life span. A physical profile of middle-aged adults is organized by body systems and can be found on [thePoint](#) .

# DEMOGRAPHICS OF ADULT WOMEN AND MEN

Examining mortality statistics provides key information to understanding changes in the health and well-being of a population. In 2016, a total of 2,744,248 people died in the United States. The age-adjusted death rate was 728.8 per 100,000 for all ages (Kochanek, Murphy, Xu, & Arias, 2017). Causes of death varied by age, gender, and ethnicity, but the 10 leading causes of death for all people in rank order are shown in Table 21-1.

**TABLE 21-1 The 10 Leading Causes of Death for All Ages in 2017**

Cause of Death (in rank order)	Number of Deaths
1. Diseases of the heart (heart disease)	647,457
2. Malignant neoplasms (cancer)	599,108
3. Unintentional injuries (accidents)	169,936
4. Chronic lower respiratory diseases	160,201
5. Cerebrovascular diseases (stroke)	146,383
6. Alzheimer's disease	121,404
7. Diabetes mellitus (diabetes)	83,564
8. Influenza and pneumonia	55,672
9. Nephritis, nephritic syndrome, and nephrosis (kidney disease)	50,633
10. Intentional self-harm (suicide)	47,173

Source: National Center for Health Statistics (2017).

Since the beginning of the 21st century, the major causes of death have remained fairly consistent. This was a major shift from the turn of the 20th century, when communicable diseases, such as tuberculosis and pneumonia, were leading causes of death. The shift from communicable to chronic illness can be attributed to the significant advances in public health, prevention, technology, pharmacotherapy, and biomedical research (see [Chapters 1 and 7](#)).

- In 2016, 74% of all deaths in the United States were attributed to the 10 leading causes ([Heron, 2018](#)).
- Diseases of the heart and malignant neoplasms are the top two causes of death for both men and women and accounted for 44.9% of deaths in 2016.

Differences included the following:

- Cerebrovascular diseases (stroke) were the third leading cause of death for women.
- Unintentional injuries (accidents) were the leading cause of death for all adults aged 25 to 44 years and the third leading cause of death for men.
- Cancer was the leading cause of death in adults aged 45 to 65 years ([Heron, 2018](#); [National Center for Health Statistics \[NCHS\], 2019](#)).

# LIFE EXPECTANCY

**Life expectancy** is the average number of years that an individual member of a specific cohort (usually a single birth year) is projected to live. It is another standard measurement used to compare the health status of various populations and is typically calculated based on age-specific death rates. Health statistics often report life expectancy figures at birth and at 65 and 75 years of age (Table 21-2).

**TABLE 21-2 Life Expectancy at Birth and 65 Years of Age According to Sex: United States, Selected Years, 1900–2017**

Year	At Birth			At 65 Years		
	Both Sexes	Male	Female	Both Sexes	Male	Female
1900	47.3	46.3	48.3	—	—	—
1950	68.2	65.6	71.1	13.9	12.8	15.0
1960	69.7	66.6	73.1	14.3	12.8	15.8
1970	70.8	67.1	74.7	15.2	13.1	17.0
1980	73.7	70.0	77.4	16.4	14.1	18.3
1990	75.4	71.8	78.8	17.2	15.1	18.9
2000	76.8	74.1	79.3	17.6	16.0	19.0
2010	78.7	76.2	81.0	19.1	17.7	20.3
2016	78.7	76.2	81.1	19.4	18.0	20.6
2017	78.6	76.1	81.1	19.4	18.0	20.6

—, data not available.

Reprinted from National Center for Health Statistics (NCHS). (2019). *Health, United States 2017*. Retrieved from [https://www.cdc.gov/nchs/data/nvsr/nvsr68/nvsr68\\_07-508.pdf](https://www.cdc.gov/nchs/data/nvsr/nvsr68/nvsr68_07-508.pdf)

- In the United States, life expectancy increased consistently over time until 2015, when for the first time in 25 years it decreased for both males and females (Xu, Murphy, Kochanek, & Arias, 2018).
- Women have a higher life expectancy than men, but the gap has narrowed from 7.0 years in 1990 to 5.0 years in 2016.
- There also continue to be differences in life expectancy based on race and ethnicity in the United States. In 2016, individuals of Hispanic origin had a life expectancy of 81.8 years, whereas the life expectancy for Whites was 78.5 years and for Blacks was 74.8 years, indicating a disproportionate burden of morbidity and mortality (NCHS, 2019).

Globally, life expectancy in the United States trails that of many countries (Table 21-3). Japan reports the highest life expectancy for males

and females. In all countries, disparities exist between male and female life expectancy. The smallest disparity can be found between women and men living in Iceland, at 2.6 years (NCHS, 2019).

**TABLE 21-3 Life Expectancy at Birth for Selected Countries by Sex, 2015**

	Female	Male	Disparity
Japan	87.1	80.8	6.3
France	85.5	79.2	6.3
Switzerland	85.1	80.8	4.3
Spain	85.8	80.1	5.7
Australia	84.5	80.4	4.1
Iceland	83.8	81.2	2.6
Germany	83.1	78.3	4.8
Greece	83.7	78.5	5.2
Korea	85.2	79.0	6.2
United States	81.1	76.3	4.8

# HEALTH DISPARITIES

The overarching goal of the *Healthy People* initiative is to eliminate health disparities and improve the health of all Americans. A health disparity is defined as a difference in health status that occurs by gender, race/ethnicity, education or income, disability, geographic location, or sexual orientation (Orgera & Artiga, 2018). Health disparities occur when one segment of the population has a higher rate of disease or mortality than another or when survival rates are less for one group when compared with another (National Institutes of Health [NIH], 2019a). Often, persons with the greatest health burden have the least access to health care services, adequate health care providers, information, communication technologies, and supporting social services. Interdisciplinary, collaborative, public, and private approaches as well as public–private partnerships are needed to develop strategies to address the health disparity goal of *Healthy People 2030*. Chapter 23 discusses health disparities in more detail.

# HEALTH LITERACY

Health literacy is defined as the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health-related decisions. The ability to read and understand health information is key to managing health problems. Low health literacy contributes to health disparities and has been documented as an increasing problem among certain racial and ethnic groups, non-English-speaking populations, and persons over 65 years of age in the United States. Low health literacy is directly associated with ([Health Resources & Services Administration, 2019](#); [NIH, National Library of Medicine, n.d.](#)):

- Poorer health outcomes
- Higher use of emergency service
- More frequent hospitalizations
- Increased risk of death

See [Chapter 10](#) for additional information on health literacy.

# MAJOR HEALTH PROBLEMS OF ADULTS

Morbidity and mortality among adults vary substantially by age, gender, and race/ethnicity. Several leading causes of death are presented in this section. Heart disease is the first-leading cause of death in adults and is presented along with stroke. Malignant neoplasms, chronic lower respiratory diseases (CLRDs), unintentional injuries, and diabetes mellitus are among the top 10 leading causes of death and are discussed separately. Other selected major causes of death are covered in detail in other chapters: suicide ([Chapter 25](#)), Alzheimer's disease ([Chapter 22](#)), and homicide ([Chapter 18](#)).

## Coronary Heart Disease and Stroke

**Cardiovascular disease (CVD)** describes a group of heart and blood vessel disorders including hypertension, coronary heart disease (CHD), stroke, arrhythmias, valvular heart disease, peripheral vascular disease, and cardiomyopathies ([World Health Organization \[WHO\], 2019](#)). Over the last three decades, cardiovascular mortality in the United States has declined by about 50%. These gains are attributed to increased use of evidence-based medical therapies for secondary prevention and reduction in risk factors associated with lifestyle and environment ([Box 21-1](#)). Despite these gains, approximately one third of all deaths in the United States are still due to CVD. Currently, an estimated 92.1 million adults are living with one or more types of CVD and over half of these individuals are 60 years of age or older. It is estimated that every 36 seconds, an American will die from CVD, accounting for 2,300 deaths each day ([Fig. 21-2](#); [Benjamin et al., 2018](#); [Centers for Disease Control and Prevention \[CDC\], 2017a](#)).

### **BOX 21-1 Evidence-Based Practice**

#### **Landmark Research on Cardiovascular Disease**

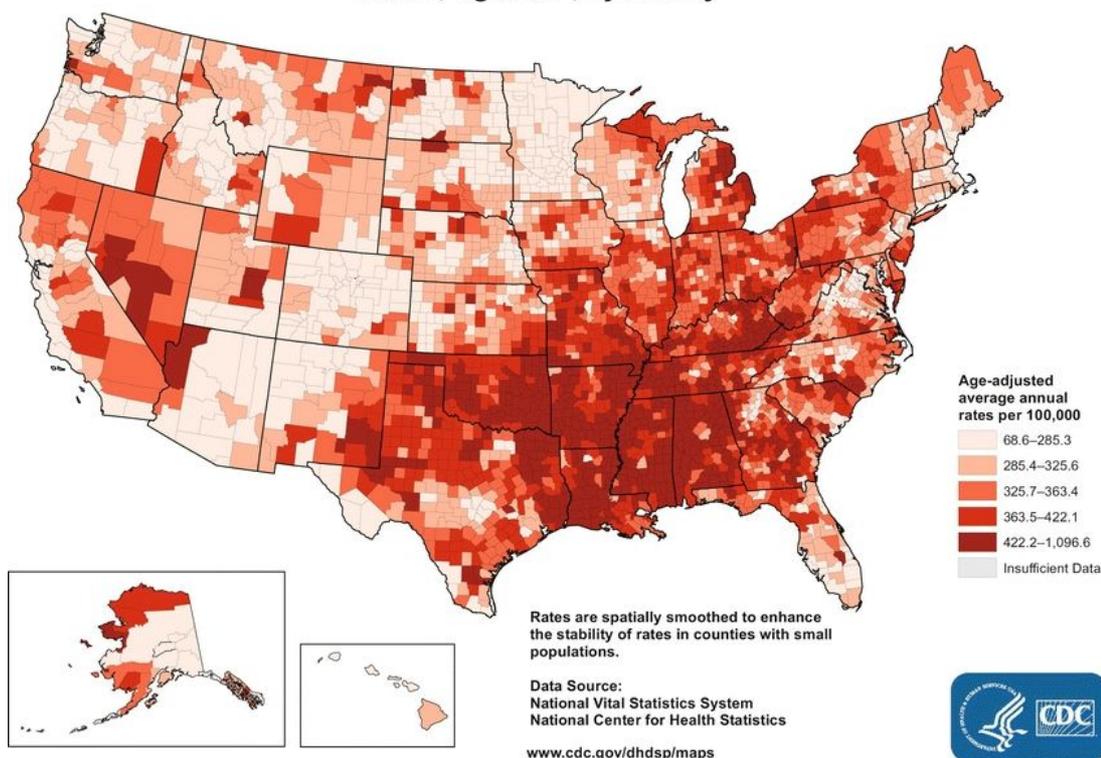

**The hallmark Framingham Heart Study identified major risk characteristics associated with the development of CVD and the effects of related factors such as blood triglycerides, gender, and psychosocial issues. The study began in 1948 under the direction of National Heart Institute, now known as the National Heart, Lung, and Blood Institute (NHLBI). At that time, the death rates from CVD were rising, but little was known about the general causes of heart disease and stroke. The Framingham Heart Study researchers recruited 2,336 men and 2,873 women between the ages of 30 and 62 in an effort to identify common factors or characteristics that contribute to CVD. All participants lived in the town of**

**Framingham, Massachusetts. Every 2 years, these individuals were scheduled for an extensive medical history, physical examination, and laboratory tests. In 1971, the study enrolled 5,124 of the original participants' adult children and their spouses (offspring cohort) ([Framingham Heart Study, 2018](#)).**

In an effort to reflect the changing demographics that occurred in the town of Framingham since the original cohort was enrolled, researchers implemented a new study in 1994. This study included individuals of Black, Hispanic/Latino, Asian, Indian, Pacific Islander, and Native American origin (Omni cohort). In 2002, a third generation (the children of the offspring cohort) was recruited and a second group of Omni participants was enrolled in 2003. Over the last several years, investigators expanded their research into the role of genetics and CVD. The Framingham Heart Study celebrated its 70th anniversary in 2018, with 15,447 participants covering three generations and 3,698 peer-reviewed research articles since it began in 1948. Fortunately, findings from the Framingham Heart Study will continue to make important scientific contributions about the causes and treatment of CVD and related health issues ([Framingham Heart Study, 2018](#)).

Source: [Framingham Heart Study \(2018\)](#).

Heart disease death rates, 2015–2017  
adults, ages 35+, by County

**FIGURE 21-2** Heart disease death rates, 2015–2017 adults, ages 35+ by county. (Source: Centers for Disease Control and Prevention, Division for Heart Disease and Stroke Prevention. (2019). *Quick maps of heart disease, stroke, and socioeconomic conditions*. Retrieved from [http://www.cdc.gov/dhdsp/maps/national\\_maps/hd\\_all.htm](http://www.cdc.gov/dhdsp/maps/national_maps/hd_all.htm))

In the United States, racial/ethnic minority populations continue to encounter more barriers to CVD diagnosis and care, receive lower-quality treatment, and experience worse health outcomes. Such disparities are linked to complex factors such as income and education, genetic and physiological factors, access to care, and communication barriers. Although it appears as though the disparity gap may be declining, this is likely not due to gains made by racial/ethnic minority populations, but worsening cardiovascular health in Whites (Brown et al., 2018). To tackle inequalities in CVD morbidity and mortality, actions that focus on the social determinants of health are needed. This includes development and implementation of health and social policy interventions that improve access to and quality of health care services and a reduction in poverty and unemployment (Dong, Fakeye, Graham, & Gaskin, 2018).

According to the American Heart Association (AHA), risk factors for CVD can be separated into three categories: major risk factors that cannot be changed, modifiable risk factors, and contributing risk factors (2016).

- Major risk factors that cannot be modified or treated include heredity (family history, race), increasing age, and gender (male).
- Risk factors that can be modified, treated, or controlled include high blood cholesterol, high blood pressure, smoking tobacco, physical inactivity, diabetes, and obesity/overweight.
- Risk factors that are known to contribute to heart disease are stress, alcohol consumption, and diet and nutrition.

About half of all Americans (49%) have at least one of the three key risk factors for heart disease: high blood pressure, high cholesterol, and cigarette smoking. The likelihood of heart disease or stroke multiplies with the increasing number of risk factors present ([CDC, 2019a](#)).

Stroke ranks fifth among all causes of death in the United States and is a leading cause of serious physical and cognitive long-term disability in adults ([Box 21-1](#)).

- Approximately 795,000 Americans experience a new or recurrent stroke each year—610,000 of these are first attacks and 185,000 are recurrent attacks. On average, someone in the United States has a stroke every 40 seconds.
- Disparities exist among people who are at risk for having a stroke. For example, women have a higher lifetime risk of having a stroke compared with men, with approximately 55,000 more women than men experiencing a stroke each year.
- The risk of having a first stroke is nearly twice as high for Blacks than Whites, and Blacks are more likely to die following a stroke than are their White counterparts. The risk for stroke among Hispanics/Latinos falls between that of Whites and Blacks, with stroke mortality increasing in this population since 2013.
- In the Southeastern United States (the “Stroke Belt”), stroke death rates are higher than in any other part of the country. Strokes cost the United States about \$34 billion each year. This total includes the cost of health care services, medications, and missed days of work ([Benjamin et al., 2018](#); [CDC, 2020a](#)).

# Cancer

**Cancer** is a major chronic illness and remains the second leading cause of death in the United States ([Xu et al., 2018](#)).

- The National Cancer Institute's (NCI) Surveillance, Epidemiology, and End Stage Program (SEER) ([2020](#)) estimated that, in 2015, there were approximately 15.1 million Americans living with cancer.
- It was estimated that in 2018, 1,735,350 new cancer cases would be diagnosed, and of these cases, 609,640 persons were expected to die.
- Approximately 87% of all cancers are diagnosed in persons 50 years of age and older, and as individuals age, they are more likely to develop cancer.
- Among ethnic groups, Blacks are more likely to develop and die from cancer.
- Over their lifetime, men living in the United States are more likely to develop cancer than women.
- The Agency for Healthcare Research and Quality estimated the total expenditures for cancer in 2015 at \$80.2 billion ([American Cancer Society \[ACS\], 2019](#); [NCI, 2020](#)).

Cancer is caused by internal and external factors.

- Internal factors are inherited gene mutations, hormones, immune conditions, and gene mutations that occur from metabolism.
- External factors include tobacco and alcohol use, chemicals, radiation, infectious organisms, and poor lifestyle choices.
- These factors can occur in isolation or together to initiate illness.
- Screenings can reduce the cancer mortality rate, especially malignancies associated with the breast, colon, rectum, cervix, and lung ([ACS, 2019](#)).

While the lung cancer death rate continues to decline, it remains the number one cause of cancer deaths among adults in the United States. In 2018, there were an estimated 234,030 new lung cancer cases and 154,050 deaths, attributing to more than 25% of all cancer deaths in the United States ([ACS, 2019](#)).

Cigarette smoking is the predominant risk factor for lung cancer. The quantity of cigarettes smoked and the number of years a person smoked both increase an individual's risk of developing lung cancer. Other risk factors include occupational or environmental exposure to secondhand smoke, radon, or asbestos; genetic susceptibility (disease at an early age); and a history of tuberculosis. Annual screening for lung cancer using low-dose computed tomography scan is recommended for individuals 55 to 74 years of

age who currently smoke or have smoked in the past 15 years and have at least a 30-pack history. Shared decision-making in screening and smoking cessation counseling for current smokers are key factors in the success of screening and prevention ([Smith et al., 2018](#); [Wood et al., 2018](#)).

Colon and rectal cancers are the third most common cancers in adults. In 2018, an estimated 97,220 cases of colon and 43,030 cases of rectal cancers were expected to occur, resulting in 50,630 deaths ([ACS, 2019](#)).

- The risk of developing colorectal cancer increases with age, and 90% of all cases are diagnosed in individuals 50 years of age or older.
- There are several modifiable factors associated with the increased risk of colorectal cancer. These factors include obesity, physical inactivity, a diet high in red or processed meat, alcohol consumption, long-term smoking, and low intake of whole grains, fruits, and vegetables.
- Other risk factors include certain inherited genetic mutations, personal or family history of polyps or colorectal cancer, and personal history of chronic inflammatory bowel disease.
- The U.S. Preventative Services Task Force ([USPSTF, 2016a](#)) recommends that screening for colon and rectal cancer should begin at age 50 years for men and women who are at average risk (see Screenings and Checkup Schedule for Women and Men on [thePoint](#) ).

## Chronic Lower Respiratory Diseases

**Chronic lower respiratory disease (CLRD)** comprises three major conditions: chronic bronchitis, emphysema, and asthma. CLRD is the third leading cause of death in the United States. The term chronic obstructive pulmonary disease (COPD) includes emphysema and chronic bronchitis. COPD is a leading cause of death, affecting over 16 million adults in the United States. The COPD National Action Plan identified educational interventions to inform the public on ways to prevent, diagnose, and treat this disease ([NIH, National Heart, Lung, and Blood Institute \[NHLBI\], 2019](#)). By 2020, the annual cost of medical care for adults living with COPD will be more than \$49 billion ([CDC, 2018a](#)).

- Cigarette smoking is the major risk factor for developing COPD, accounting for 85% to 90% of cases. Pipe, cigar, and other types of tobacco smoke also can cause COPD, especially if the smoke is inhaled.
- The remaining COPD cases are attributable to environmental exposures and genetic factors ([American Lung Association \[ALA\], 2020a](#)).
- Since 2000, the number of women dying from COPD has surpassed the number of men. Women are more vulnerable to lung damage from cigarette smoke and other pollutants because their lungs are smaller, and research has found that estrogen plays a role in worsening the disease ([ALA, 2020a](#)).
- The exact cause of asthma is unknown, but research indicates that both genetic and environmental factors contribute to its cause. In the United States, approximately 20.4 million adults have been diagnosed with asthma and 6.1 million children under 18 years of age have asthma. The prevalence of asthma is higher in women (10.7%) than in men (6.5%), respectively ([ALA, 2020b](#); [CDC, 2016](#)).

## Unintentional Injuries

**Unintentional injuries** refer to any injury that results from unintended exposure to physical agents, including heat, mechanical energy, chemicals, or electricity. They are the fifth leading cause of death overall and the leading cause of death for persons 44 years of age and younger. The top three causes of unintentional injuries include motor vehicle crashes, poisoning, and falls. Approximately 214,000 Americans die from injury each year—one person every 3 minutes (Fig. 21-3; CDC, 2017a, 2017b).

**FIGURE 21-3** Unintentional injuries such as falls are the leading cause of death for those aged 44 years and younger.

- In 2015, 2.8 million people were hospitalized due to injuries and 27.6 million were treated in emergency departments. The costs associated with fatal injuries were \$214 billion, whereas nonfatal injury costs were over \$457 billion.
- Males account for the majority of fatal injury costs (78% or \$166.7 billion), as well as nonfatal injury costs (63% or \$287.5 billion; CDC, 2017a, 2017b, 2020b).
- Drugs, both pharmaceutical and illicit, cause the vast majority of poisoning deaths in the United States, and the number of drug-related deaths continues to increase. Two out of three deaths from drugs involve opioids.
- Overdose deaths from opioids have increased more than six times since 1999. In 2017, 47,000 people died from an opioid death in the United States (CDC, 2020c).

The CDC advocates for preventing opioid overdose by improving opioid prescribing, reducing exposure to opioids, preventing misuse of opioids, and improving treatment modalities for opioid use disorder (CDC, 2017c). See [Chapter 25](#) for more on substance use.

In the United States, motor vehicle accidents are a leading cause of death. In 2015, more than 2.5 million individuals were treated in emergency rooms due to injuries from motor vehicle accidents.

- The costs of medical care and productivity losses due to motor vehicle accidents in a 1-year period exceeded 63 billion dollars (CDC, 2020d).
- Efforts to decrease motor vehicle injuries are directed toward prevention of motor vehicle crashes through education and policies related to seat belts, impaired driving, distracted driving, older adult drivers, teen drivers, and motorcycle and bicycle safety (2017f).

# Diabetes Mellitus

**Diabetes mellitus** is the seventh leading cause of death in the United States. This chronic health condition puts individuals at risk for other serious health conditions, including heart disease, stroke, hypertension, blindness, kidney disease, and nervous system disease (i.e., neuropathy, which is a loss of sensation or pain in the feet or hands).

- According to the [CDC \(2017g\)](#), over 30 million Americans have type 1 or type 2 diabetes. Of these, 9.2 million have not been diagnosed yet.
- Additionally, more than 84 million adults have prediabetes and are at risk to develop type 2 diabetes.
- Risk factors for type 2 diabetes include family history, being overweight, age >45 years, not getting enough physical activity, and history of gestational diabetes.
- Races/ethnicities at increased risk for developing type 2 diabetes are African American, Hispanic/Latino, American Indian, and Alaska Native ([Table 21-4](#); [CDC, 2020e, 2020f](#)).
- The [American Diabetes Association \(2018\)](#) recommends screening for diabetes for all people beginning at age 45 years and repeated every 3 years if test results are normal and for asymptomatic adults who are overweight and/or obese. Individuals with more than one risk factor may need to be screened more frequently.

**TABLE 21-4 Estimated Diagnosed and Undiagnosed Diabetes Among People Ages 18 Years or Older, United States, 2020**  
**Source: [Center for Disease Control \(2020e\)](#).**

Group	Number Who Have Diabetes and Rate per 1,000
Ages 18–44 years old	4.2%
Ages 45–64 years old	17.5%
Ages 65 years or older	26.8%
Men	14%
Women	12%

## Arthritis

Arthritis is a common term used to describe joint pain or joint disease; there are, in fact, more than 100 types of arthritis conditions, with the most common being osteoarthritis, rheumatoid arthritis, and psoriatic arthritis ([Arthritis Foundation, n.d.](#)). Over 54 million or 23% of all adults have some type of arthritis, with the condition occurring more often in women and more frequently as we age. Symptoms include swelling, pain, stiffness, and decreased range of motion; however, symptoms come and go and may be mild, moderate, or severe ([CDC, 2019b](#)). Arthritis may cause visible permanent joint changes such as knobby finger joints or may be less visible and detected only through x-ray ([Arthritis Foundation, n.d.](#)). The disease may occur with other conditions such as diabetes, heart disease, and obesity ([CDC, 2019b](#)). Arthritis can affect daily life including a person's ability to work, walk, or climb stairs. Over 140 billion is spent on medical costs related to this disease each year. Approaches to reducing arthritis pain and managing independence may include ([CDC, 2019b](#)):

- Being active
- Maintaining a healthy weight
- Protecting your joints
- Staying educated
- Pharmacological and nonpharmacological treatment options

Staying active is an important part of mitigating health issues such as arthritis. The CDC works with national organizations such as the YMCA to provide fitness classes that reach over 200,000 adults; efforts to address health disparities includes bringing classes to low income and underserved communities ([CDC, 2019b](#)).

## Obesity

Obesity is defined as having a body mass index (BMI) of 30 or greater and is recognized as a national health threat and a major public health challenge in the United States. This condition is a major risk factor for CVD, along with certain types of cancer, type 2 diabetes, obstructive sleep apnea, and premature death (CDC, 2020g).

- According to the *National Health and Nutrition Examination Survey*, in 2015–2016, the prevalence of obesity among adults was 39.8%. Middle-aged adults (40 to 59 years old) had a higher prevalence of obesity at 42.8% than young adults (20 to 39 years old) at 35.7%. The prevalence of obesity in adults over age 60 years was 41.09% (Hales, Carroll, Fryar, & Ogden, 2017).
- Some groups have higher rates of obesity than others. Adults from lower socioeconomic and education levels have a higher prevalence of obesity, as do non-Hispanic Black and Hispanic adults (CDC, 2017c; Hales et al., 2017).
- Additionally, certain geographic regions have higher obesity rates than others in the United States. The South (32.4%) and Midwest (32.3%) have the highest prevalence of obesity, and at least 35% of adults in Alabama, Arkansas, Iowa, Louisiana, Mississippi, Oklahoma, and West Virginia are obese (CDC, 2019c).

Being obese can have serious health consequences; it is the leading cause of death in the United States and worldwide (CDC, 2019d), and it is associated with reduced quality of life and poorer mental health outcomes. In addition, those that are obese are at increased risk for mortality, hypertension, elevated LDL, dyslipidemia, stroke, type 2 diabetes, gallbladder disease, osteoarthritis, CHD, sleep apnea, some cancers, and difficulty with physical functioning (CDC, 2019d). There are also economic and societal consequences from obesity, including medical costs associated with related health issues and productivity concerns related to absenteeism, as well as premature mortality and morbidity (CDC, 2019d). Healthy behaviors that include healthy diet patterns and regular physical exercise should be incorporated into lifestyle habits. Community environment that are safe and offer healthy food and places for physical activity are also necessary (CDC, 2019d).

*Healthy People 2030* has several objectives targeting obesity, some of which are shown in [Box 21-2](#).

### **BOX 21-2 HEALTHY PEOPLE 2030**

## Select Objectives Related to Obesity

OA-01	Increase the proportion of older adults with physical or cognitive health problems who get physical activity
NWS-03	Reduce the proportion of adults with obesity
NWS-05	Increase the proportion of health care visits by adults with obesity that include counseling on weight loss, nutrition, or physical activity
PA-02	Increase the proportion of adults who do not have enough aerobic physical activity for substantial health benefits
PA-04	Increase the proportion of adults who do enough muscle-strengthening activity

Reprinted from [U.S. Department of Health & Human Services \(USDHHS\). \(2020\). Healthy People 2030: Browse objectives.](#)  
Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

According to current guidelines, adults should receive a minimum of 150 minutes (2.5 hours) of moderate intensity or 75 minutes of vigorous aerobic exercise every week, in addition to 2 days muscle-strengthening exercises ([USDHHS, 2018](#)). Community health nurses play an important role in combatting obesity through educating adults on the importance of maintaining a healthy weight, or weight reduction if indicated, through physical activity and proper nutrition.

## Substance Use

- In 2017, 30.5 million people aged 12 years or older used an illicit drug, or about 1 in 9 Americans. In 2017, illegal drug use was marked primarily by marijuana use and the misuse of prescription pain relievers. Smaller numbers of individuals were current users of cocaine, hallucinogens, methamphetamine, inhalants, or heroin or were misusers of prescription stimulants or sedatives ([Substance Abuse and Mental Health Services Administration \[SAMSHA\], 2017a](#)).
- Men are more likely than women to use illegal drugs and have higher rates of use or dependence on illicit drugs and alcohol than do women ([National Institute of Drug Abuse \[NIDA\], 2018](#)). Not all people who abuse illegal drugs, however, develop a substance abuse disorder (see [Chapter 25](#)).

According to [SAMHSA \(2019\)](#), a **substance use disorder (SUD)** occurs when the recurrent use of alcohol and/or drugs causes clinically and functionally significant impairment such as health problems, disability, and failure to meet major responsibilities at work, school, or home. SUD is a serious and continuing problem among adult women and men living in the United States. Women are just as likely as men to develop a SUD ([NIDA, 2018](#)).

- In 2017, an estimated 19.7 million people aged 12 or older had a SUD related to their use of alcohol or illicit drugs in the past year in the United States.
- The abuse of opioids, leading to opioid use disorder, has become a national epidemic and public health concern. Approximately 2.1 million people had an opioid use disorder, including 1.7 million people with a prescription pain reliever use disorder and 0.7 million people with a heroin use disorder ([SAMSHA, 2017a](#)).
- The medical diagnosis of alcohol use disorder (AUD) refers to a chronic relapsing brain disease characterized by compulsive alcohol use, loss of control over alcohol intake, and a negative emotional state when not using. To be diagnosed with AUD, a person must meet certain criteria as delineated in the Diagnostic and Statistical Manual of Mental Disorders (DSM).

Under the current version of the DSM (DSM-V), anyone meeting 2 of the 11 criteria during the same 12-month period can be diagnosed with AUD. The severity of AUD is outlined as mild, moderate, or severe based on the number of criteria met ([National Institute on Alcohol Abuse and Alcoholism \[NIAAA\], 2017](#)). In the United States, it is estimated that 16 million people

have AUD. Approximately 15.1 million adults in the United States ages 18 and older had AUD in 2015. This includes 9.8 million men and 5.3 million women. Adolescents can also be diagnosed with AUD. In 2015, an estimated 623,000 adolescents ages 12 to 17 years had AUD (NIAAA, 2018).

Tobacco use is another major public health problem and the leading cause of preventable diseases and deaths in the United States.

- More than 16 million Americans are living with a disease related to smoking.
- Smoking causes cancer, heart disease, stroke, lung diseases, diabetes, and COPD. Cigarette smoking is responsible for more than 480,000 deaths per year in the United States, including more than 41,000 deaths resulting from secondhand smoke exposure. This is about 1,300 deaths every day (CDC, 2020h).
- In 2017, an estimated 48.7 million people aged 12 years or older were current cigarette smokers, including 27.8 million people who smoked cigarettes daily (NIAAA, 2018). When examining cigarette smoking based on gender, men (17.5% of males) are more likely to smoke cigarettes than women (13.5% of females).
- The total economic cost of smoking is more than \$300 billion a year, including approximately \$170 billion in direct medical care for adults and \$156 billion in lost productivity due to premature death and exposure to secondhand smoke (CDC, 2020h).
- E-cigarettes (also known as e-cigs, e-hookahs, mods, vape pens, vapes, tank system, and electronic nicotine delivery systems) are used by 2.8% of adults in the United States; the product is largely used by young adults. The product produces an aerosol by heating liquid, which usually contains nicotine; users then inhale this aerosol. E-cigarettes are not considered safe because they contain “harmful and potentially harmful substances, including nicotine, heavy metals like lead, volatile organic compounds, and cancer-causing agents” (CDC, 2020h, para. 2). Adults may use e-cigarettes to reduce craving for regular cigarettes, but the FDA has not approved e-cigarettes as an aid to quit smoking (CDC, 2020i).

Because of the significance of the problem, 28 of the *Healthy People 2030* objectives are related to tobacco use.

The illegal use of prescription opioids, synthetic opioids (fentanyl), and heroin is a major public health concern in the United States. A serious national crisis exists due to the abuse and addiction of opioids.

- Every day, 130 people die due to opioid overdose in the United States. In 2017, 47,600 individuals died from an overdose of opioids and an estimated 1.7 million people experience the disease (NIDA, 2019).

- This rise in opioid overdose deaths is due to increased prescribing of opioids in the 1990s, the rise in heroin use beginning in 2010, and synthetic opioid (such as fentanyl) abuse stemming from 2013 ([CDC, 2017c, 2019e](#); [NIDA, 2019](#)).
- The economic aftermath of prescription opioid misuse in the United States is estimated at \$78.5 billion a year, including the costs of health care, lost productivity, addiction treatment, and criminal justice involvement ([NIDA, 2019](#)).

The full extent of the damage of the opioid crisis goes beyond economics, influencing family and community life and placing an extreme strain on community resources, including first responders, emergency rooms, hospitals, and treatment centers.

In response to the opioid crisis, the USDHHS is focusing efforts on:

1. Improving access to treatment and recovery services
2. Promoting use of overdose-reversing drugs
3. Strengthening understanding of the epidemic through improved public health surveillance
4. Providing support for innovative research on pain and addiction
5. Initiating better practices for pain management

In 2018, the NIH launched HEAL (Helping to End Addiction Long-term) Initiative, an aggressive, trans-agency effort to increase scientific solutions to positively impact the national opioid public health crisis ([NIH, 2018](#)).

# WOMEN'S HEALTH

Women have not been the focus of medical attention throughout history. Health benefits achieved by women were incidental compared with those of men. Advances in women's health are very recent and primarily an advantage for women living in Western countries, where the women's or feminist movement has made major inroads (Fig. 21-4).

**FIGURE 21-4** Women's health has not historically been the focus of health care research.

## Overview of Factors Influencing Women's Health

Women's rights in the United States started in the second half of the 19th century and over time addressed issues directly or indirectly impacting the health of women: voting rights, labor laws, reproductive rights, and violence against women ([International Women's Day, n.d.](#)). This section of the chapter examines women's health concerns over the adult life span, the major causes of acute and chronic illness and death, and the issues, trends, and policies that have affected and currently affect women. For a discussion of how research in genomics and pharmacogenomics is being applied to women's health, see [Box 21-3](#).

### **BOX 21-3 Evidence-Based Practice**

**Genomics and Pharmacogenomics An individual's genome consists of their entire set of DNA, including all genes. Genomics considers how a person's genes interact with each other, the individual's environment and their behaviors, such as diet and exercise, to influence growth, development, and health ([WHO, n.d.](#)). This is different than genetics, which considers the function and composition of a single gene. Discoveries made in the field of genomics allow health care providers to translate research to clinical practice. For example, genomics has increased understanding of why individuals with the same disease may not respond similarly or have the same treatment outcomes, guiding individualized treatment. It also assists in the identification of individuals with increased risk for the development of certain diseases based on gene mutation, gene interaction, and environment, to**

**develop individualized prevention and treatment strategies. These advances in science and technology have allowed health care to increase its focus on the delivery of individualized care and prevention, known as precision medicine (CDC, 2020n; NIH, 2019b; NIH, NCI, 2017).**

Nurses and other health care providers use genomics routinely in practice. In the community setting, the nurse may educate women about breast cancer and risk factors, providing information about genetic testing for women with a family history. Health care providers partner with women who have BRCA1 or BRCA2 gene mutations to individualize breast and ovarian cancer prevention and screening. The same is true for those with a strong family history of heart disease. Careful family and personal health histories may guide health care providers to recommend testing for Familial Hypercholesterolemia (FH). Individuals with gene mutations causing FH need targeted treatment to prevent adverse cardiac events. Nurses play a key role in patient education to assist the individual with FH in reducing or eliminating modifiable risk factors that could also contribute to cardiovascular disease.

Another important aspect of genomics is pharmacogenomics, which considers information about an individual's genome to guide decision-making in medication and dose selection. The utilization of pharmacogenomics to guide treatment has become routine for some disease states and/or medications. Examples of utilizing pharmacogenomics to guide treatment include:

- Avoiding primaquine and other medications known to cause acute hemolytic anemia in individuals with G6PD deficiency, caused by an alteration of the G6PD gene.
- Choosing an HIV medication other than abacavir for individuals with an HLA-B\*57:01 allele due to increased risk for developing a severe hypersensitivity reaction.
- Adjusting warfarin dose in individuals with CYP2C9 or VKORC1 gene variations to avoid increased bleeding risk (Dean, 2018; FDA, 2018b; NORD, 2017).

Individualizing patient care based on genomics and pharmacogenetics will continue to increase as the availability of

genomic data expands. It is essential for nurses to have an understanding of genomics and pharmacogenomics in order to answer questions appropriately and provide appropriate and individualized health promotion and disease prevention education.

Source: Centers for Disease Control and Prevention (2020n); Dean (2018); Food and Drug Administration (FDA) (2018b); National Institutes of Health (NIH) (2019b); National Institutes of Health, National Cancer Institute (NIH, NCI) (2017); National Organization for Rare Diseases (NORD) (2017); World Health Organization (WHO) (n.d.).

Women's health is still overlooked in much of the world. Only in the past few decades has the health of women been a formidable issue in the United States, coming not so coincidentally with the modern women's feminist movement that began in the 1960s.

- The landmark 1963 publication *The Feminine Mystique* helped launch the modern women's movement by critically examining the role of women in American society (Foster, 2015; Friedan, 2013). The Boston Women's Health Book Collective's *Our Bodies, Ourselves* (initially released in 1973) represented the first book to explore women's health issues, exclusively written by and for women. In addition, this publication served as a model for women who wanted to learn about themselves, communicate their findings with doctors, and challenge the medical establishment to change and improve the care that women received (*Our Bodies Ourselves*, n.d.).
- To further expand the dialogue regarding women's health, consumer activists created the National Women's Health Network in 1975, primarily to shape health policy and support consumer health decisions (National Women's Health Network, 2018). These historical occurrences likely contributed to more female researchers and women as participants in research.
- Feminists paved the way for women to have their voices heard on many health, social, and political issues. Women sought out higher-education opportunities in greater numbers and entered workplaces once solely occupied by men, especially during and after World War II.
- These positive changes escalated women toward greater equality, and with equality came the freedom—and pressure—for women to compete with men in their social and work settings. Issues related to women's health were discovered as a result of research that now more regularly includes women.
- The importance of women's health research was reaffirmed in the NIH's Revitalization Act of 1993, Subtitle B—clinical research equity regarding women and minorities to “identify projects for research on women's health that should be conducted or supported by the national research institutes; identify multidisciplinary research relating to

research on women that should be so conducted or supported ...” (NIH, 1993, section 486).

## Women's Health Research

In response to changing priorities, researchers have designed and implemented major studies that focus exclusively on women. Five significant studies have provided and continue to provide important health information about women:

- The *Women's Health Initiative* (WHI) was a major research program addressing the most common causes of death, disability, and poor quality of life in postmenopausal women—CVD, cancer, and osteoporosis ([WHI, n.d.](#)).
- The *Women's Health Study* (WHS) evaluated the effects of vitamin E and low-dose aspirin therapy in primary prevention of CVD and cancer in apparently healthy women ([WHS, n.d.](#)).
- The *Nurses' Health Study (NHS) I* involved investigating risk factors for cancer and CVD, and the *NHS II* researched diet and lifestyle risk factors in a population younger than the original NHS cohort ([NHS, 2016](#)).
- The *NHS III* is currently investigating women's health issues related to lifestyle fertility/pregnancy, environment, and nursing exposures ([NHS, 2016](#)).

The WHI addressed CVD, cancer, and osteoporosis and was one of the largest prevention studies of its kind in the United States, starting in 1991 and spanning 15 years. This study was sponsored by the NIH and the NHLBI, involved 161,808 women ages 50 to 79 years, and was considered to be one of the most far-reaching clinical trials for women's health ever undertaken. To date, more than 616 publications have been associated with findings from this study, which address coronary artery calcium, breast cancer risk, colorectal cancer, venous thrombosis, peripheral arterial disease risk, risk of CHD, dementia and cognitive function, and the effects of estrogen alone in reducing the risk of CHD ([National Center for Biotechnology Information, 2017](#); [WHI, n.d.](#)).

The WHS was a randomized, double-blind, placebo-controlled clinical trial sponsored by the NHBLI and the NCI. It was the first large clinical trial to study the use of low-dose aspirin to prevent heart attack and stroke in women 45 years of age and older. This study began in 1991 and continued through March 2009 for additional observation and follow-up of the original 28,345 participants. Findings indicated that low-dose aspirin does not prevent first heart attacks or death from cardiovascular causes in women; however, stroke was found to be 17% lower in the aspirin group. More than 110 professional articles are associated with this investigation. Recent publications address the association of dietary fat intake with risk of atrial

fibrillation in women and the novel protein glycan biomarker and future CVD events (WHS, n.d.).

The NHS (three separate phases) represents the longest running study related to women's health in the world, investigating factors that influence the health of women.

- The *NHS I*, a prospective study that began in 1976, enrolled registered nurses aged 30 to 55 years. Every 2 years, participants received a follow-up questionnaire with questions about diseases and health-related topics including smoking, hormone use, and menopausal status. Later in the study, questions regarding diet and nutrition and quality of life were added.
- The *NHS II* represented women who started using oral contraceptives in adolescence, a population with long-term exposure during early reproductive years. Women, aged 25 to 42 years, were enrolled and followed forward in time. Every 2 years, participants received a follow-up questionnaire and were surveyed about diseases and health-related topics including smoking, hormone use, pregnancy history, and menopausal status.
- The *NHS III* began recruitment in 2010 and will continue until 100,000 nurses (registered and licensed practical, 22 to 45 years of age) are enrolled. Also, nurses from Canada are participants and the study aims to be more representative of the diverse backgrounds of nurses. These studies are supported by major nursing organizations, with more than 280,000 participants to date (NHS, 2016).

## Women's Health Promotion Across the Life Span

What health care needs do women have that are different from those of men? Is there a need to look at health promotion throughout the life cycle of adult women? How is the health of an 18-year-old different from that of a 50-year-old woman? Most of us would have no trouble agreeing that women have different health care needs that must be considered and that these concerns vary with age. Knowing what the needs are is essential to knowing how to help women promote their health.

### *Healthy People 2030 Goals for Women*

As a nation, we have been focusing on improving the health of all citizens through the *Healthy People* initiatives, commencing with the 1979 Surgeon General's report, *Healthy People: The Surgeon General's Report on Health Promotion and Disease Prevention*, providing measurable population objectives. *Healthy People 2000* set a standard for change and improvement in objectives that were met or exceeded in some areas and were far from being reached in others. In that initiative, objectives in 14 areas focused specifically on women's health. *Healthy People 2010* focused on two overarching goals: increasing the quality of life and eliminating health disparities, containing 25 objectives relating to women. *Healthy People 2020* reaffirmed the goals of *2010* and added two additional goals: quality of life, healthy development, along with healthy behaviors across the life span and creating social and physical environments that promote good health (USDHHS, 2015). In the nation's fourth generation of health planning, 35 objectives pertain to the health of women (Box 21-4). As the community health nurse works with women at various stages in the life cycle, the objectives in *Healthy People 2030* can give structure to program planning and services offered to women in the community at the primary, secondary, and tertiary levels of prevention.

## **BOX 21-4 HEALTHY PEOPLE 2030**

### **The Objectives for Women**

### Core Objectives

C-04	Reduce the female breast cancer death rate
C-05	Increase the proportion of females who get screened for breast cancer
C-09	Increase the proportion of females who get screened for cervical cancer
MICH-04	Reduce maternal deaths
MICH-05	Reduce severe maternal complications during delivery hospitalizations
MICH-06	Reduce cesarean births among low-risk women with no prior births
MICH-07	Reduce preterm births
MICH-08	Increase the proportion of pregnant women who receive early and adequate prenatal care
MICH-10	Increase abstinence from cigarette smoking among pregnant women
MICH-11	Increase abstinence from illicit drugs among pregnant women
MICH-12	Increase the proportion of women of childbearing age who get enough folic acid
MICH-13	Increase the proportion of women who had a healthy weight before pregnancy
FP-01	Reduce the proportion of unintended pregnancies
FP-02	Reduce the proportion of pregnancies conceived within 18 months of a previous birth
FP-09	Increase the proportion of women who get needed publicly funded birth control services and support
FP-11	Increase the proportion of women at risk for unintended pregnancy who use effective birth control
STI-01	Increase the proportion of sexually active female adolescents and young women who get screened for chlamydia
STI-03	Reduce the syphilis rate in females
STI-04	Reduce congenital syphilis
STI-06	Reduce the proportion of adolescents and young adults with genital herpes
STI-07	Reduce pelvic inflammatory disease in female adolescents and young women
HIV-03	Reduce the number of new HIV diagnoses

### Developmental Objectives

FP-D01	Increase the proportion of publicly funded clinics that offer the full range of reversible birth control
MICH-D01	Increase the proportion of women who get screened for postpartum depression
MICH-D02	Reduce the proportion of women who use illicit opioids during pregnancy

Reprinted from U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives.

## *Young Adult Women (18 to 35 Years)*

Women in the earlier years of adulthood have different tasks to accomplish and issues to address than women in later adulthood, and the transition from adolescence to adulthood can be stressful. There are major developmental tasks that young women need to accomplish such as forming an identity and the development of intimacy. Behaviors associated with young adulthood include completing postsecondary education, choosing and establishing a career (Fig. 21-5), choosing a significant other for the long term, establishing a household, and planning for children by using a variety of parenting models (childbirth, adoption, foster parenting). During this time, women also develop a personal philosophy that encompasses meaningful and comforting spiritual beliefs that are consistent with day-to-day living (Berk, 2018).

**FIGURE 21-5** Choosing a career path is one developmental task for young adults.

Women in this age group tend to be healthy. Unfortunately, during this period, many women engage in health risk behaviors such as physical inactivity, eating poorly, participating in unprotected sexual intercourse, and smoking (Box 21-5). Some, if not all, of these behaviors may have been established in adolescence and represent modifiable behaviors. If not addressed, poor lifestyle choices can contribute significantly to the leading causes of morbidity and mortality: diseases of the heart and vascular systems, cancers, chronic respiratory diseases, and diabetes (CDC, 2019f). The majority of health concerns for many women in this age group are related to eating disorders, reproductive health and sexually transmitted infections (STIs), physical activity, mental health and mood disorders, and substance use.

## **BOX 21-5 What Do *You* Think?**

**Fad Diets Each year, approximately 45 million Americans begin a diet. Fad diets have been around for centuries and don't seem to be going anywhere. Every year new diets promise results, but do they work and are they safe?**

In 2018, the ketogenic diet (keto) made its way back into mainstream. This is a high-fat, low-carbohydrate diet that eliminates sugar, grains/starches, fruits, beans/legumes and encourages high-fat foods such as eggs, nuts, meats/fish, full-fat dairy and cheeses, and healthy oils. Low-

carb vegetables are also encouraged. The goal is to reach ketosis by replacing dietary carbs with fats. Benefits may include weight loss and decreased glucose and insulin levels. There are conflicting studies reporting benefits and risks of the ketogenic diet. While individuals adhering to this diet lose weight, once carbohydrates are re-introduced, the resulting side effect is often weight gain. Research has shown both increase and decrease in LDL cholesterol, as well as the development of insulin resistance, and nonalcoholic fatty liver disease.

The paleolithic diet is known by a few different names and continues to be a popular option among individuals trying to lose weight. This is a low-carbohydrate, high protein diet that encourages high consumption of lean meats and vegetables, moderate consumption of fruits, nuts, and seeds, and abstinence from dairy, legumes, and grains. While it has many of the same attributes of keto, it is higher in protein and lower in fat. Evidence suggests that maintaining a low carbohydrate diet, such as the paleo or ketogenic diet, long term may increase mortality from cardiovascular disease, stroke, and cancer, when compared to higher carbohydrate diets. However, the source of carbohydrate intake, whole-food versus highly processed, must be considered and whole-food sources recommended as an individual's main carbohydrate intake.

The plant-based, or vegan, diet has gained momentum in recent years and eliminates all animal products including meat, eggs, and dairy. It is rich in fruits, vegetables, nuts, seeds, legumes, and plant proteins. While there are variations of veganism, such as whole-food plant-based or raw, there are many vegan “junk foods” or processed vegan replacement foods that can cause more harm than good. Adherence to a plant-based diet that is not heavily based on processed vegan foods may reduce weight and help manage or eliminate chronic disease.

Other recent dieting trends include intermittent fasting, juicing, detoxing, and gluten-free diet. Whether individuals ask about the health benefits or adverse effects of diets they are following or considering, it's important to encourage them to research potential nutritional deficiencies certain diets may cause. This allows for intentional monitoring for dietary deficiencies and supplementation if needed. For example, individuals following a ketogenic diet may not be consuming sufficient amounts of fiber or vitamins and minerals found in fruits and vegetables. Vegans may need to supplement or be intentional about consuming vitamins B12 and D3, omega-3 fatty acids, iron, and calcium.

Do you know someone who seems to always be trying the latest diet? Is that person successfully losing weight or in a constant weight loss/weight gain cycle? As a C/PHN, how would you approach this subject?

## *Eating Disorders*

Eating disorders are complex, chronic illnesses primarily affecting young women. There is no single cause of these disorders; however, several things may contribute: culture, personal characteristics, emotional disorders, stressful events, biology, and families. The three most common are anorexia nervosa, bulimia nervosa, and binge eating.

- **Anorexia nervosa** is characterized by marked weight loss, emaciation, a disturbance in body image, and a fear of weight gain. Persons affected lose weight either by excessive dieting or by purging themselves of ingested calories. This illness is typically found in industrialized nations and usually begins in the teen years. Young women are 10 to 20 times more likely than young men to experience anorexia. Refusal to maintain body weight can be life threatening due to electrolyte disturbances, anemia, and secondary cardiac arrhythmias. Low body weight can impair insulin production, leading to amenorrhea (absent menstrual periods) and decreased bone density ([National Institute of Mental Health, 2016, 2018](#); [Office on Women's Health, 2018a](#)).
- **Bulimia nervosa** is characterized by recurrent episodes of binge eating, self-induced vomiting and diarrhea, misuse of laxatives or diuretics, excessive exercise, strict dieting or fasting, and an excessive concern about body shape or weight. Females in cultures where emphasis is placed on a certain ideal of beauty, individuals who have been sexually abused or come from families with a history of eating disorders, and individuals with low self-esteem and a history of not being “in control” or with communication and emotional difficulties are at greater risk ([Office on Women's Health, 2018b](#); [SAMHSA, 2017b](#)).
- **Binge eating** is the most common eating disorder in the United States, with typical onset in late adolescence and early 20s. It is characterized by repeated episodes of uncontrolled eating including eating large amounts quickly, when not hungry, and until comfortably full. Many individuals with this disorder have difficulty expressing their feelings, have difficulty controlling impulses and stress, and feel depressed about overeating. Obesity is common because purging is not a characteristic of this disorder. This disorder results in increased risk for type 2 diabetes, high cholesterol, osteoarthritis, kidney disease or renal failure, heart disease, and hypertension ([Office on Women's Health, 2018c](#); [SAMHSA, 2017b](#)).

In general, females have a higher rate of eating disorders than males. However, millions of men and boys battle all forms of this illness. The community health nurse can play a vital role in identifying affected persons and refer these individuals to appropriate health care providers, mental health counselors, and self-help groups. Screening tools that may help identify individuals requiring referral for further assessment are available ([National Eating Disorder Association, 2018](#)).

## *Reproductive Health*

During the reproductive years, it is important for both women and men to be as healthy as possible ([Fig. 21-6](#)). During this time, healthy habits can be initiated, and unhealthy habits resolved to ensure the best health during the years individuals focus on having children. Preconception health is important for all women of reproductive age, not just those planning to become pregnant, because it focuses on getting healthy and staying healthy ([CDC, 2020j](#)).

**FIGURE 21-6** Good health is important during pregnancy.

Although preconception care is addressed in *Healthy People 2030*, many of the preconception objectives are related to family planning and maternal health. The CDC has developed a checklist for women of reproductive age to commit to healthy preconception activities including ([CDC, 2020j](#)):

- Make a plan and take action
- See a health care provider
- Take 400 µg of folic acid every day
- Stop smoking, using drugs, and drinking excessive amounts of alcohol
- Avoid toxic substances
- Reach and maintain a healthy weight

- Get help for violence
- Learn family history
- Get mentally healthy
- When ready, plan pregnancy

Community health nurses have been at the forefront of maternal and child health care for decades, and they must continue to strive to incorporate components of preconception care into their practices. Nurses must also advocate for clients to influence public policy, which has the potential to improve access to care for many women and improve pregnancy outcomes.

Sexual health and STIs are important health concerns for young women. Sexual activity typically commences in adolescence and continues throughout the life span. STIs are epidemic in the United States, especially among young adults (see [Chapter 8](#)).

- Human papillomavirus (HPV) is the most common STI in the United States. Approximately 79 million Americans are infected with HPV, resulting in 10,800 cases of cervical cancer and 300,000 high grade cervical lesions annually. Gardasil 9 is a two or three dose vaccine that can prevent 90% of cervical cancers, as well as anogenital warts. Gardasil 9 is now approved for individuals 9 to 45 years old ([CDC, 2019g](#); [FDA, 2018a](#)).
- Chlamydia and gonorrhea are also common STIs affecting women. Rates for both these STIs have increased in women in recent years. Chlamydia is the most reported nationally notifiable disease in the United States, with more than 1.7 million cases in 2017.
- The rate of gonorrhea is lower than chlamydia, but in 2017, there were 555,608 cases reported, making it the second most nationally reported notifiable disease in the United States. Both chlamydia and gonorrhea are underdiagnosed, which can have deleterious consequences for women. If treatment is delayed, women can develop pelvic inflammatory disease, chronic pelvic pain, ectopic pregnancy, and infertility ([CDC, 2017d, 2018b](#)). See [Chapter 8](#) for more information on communicable diseases.

Routine screening recommendations for STIs in women include the following:

- HPV: screen women 30 to 65 years old every 5 years with high-risk HPV testing (alone or with cytology screening; [USPSTF, 2018a](#))
- Chlamydia and gonorrhea: annual screening for women under age 25 years or older women with risk factors ([CDC, 2017d](#); [USPSTF, 2016b](#))
- HIV: screen individuals aged 15 to 65 years; annual screening if high risk; younger or older depending on risk factors ([USPSTF, 2018b](#))

Community health nurses working with adult women should provide factual information to increase women's knowledge of STI risk. This information should be a part of frank discussions regarding condom use, sexual partners (male and female), type of sexual activity (oral, anal, vaginal), life-threatening consequences of an undiagnosed STI, and undesirable pregnancy outcomes. Outside of abstinence, condom use is the first line of prevention against STIs. See [Chapter 8](#) for more on communicable diseases.

### *Adult Women (35 to 65 Years)*

Women in the adult age group of 35 to 65 years have established themselves into patterns of living that have served them well or ill. During this period, the results of years of choices may present themselves in the form of chronic illnesses. Nevertheless, many women in this age group have time to change health habits to possibly reverse encroaching chronic illnesses ([Fig. 21-7](#)). For other women, lifestyle choices and undetected diseases have shortened their life spans, and large numbers of women in this age group are dying prematurely.

**FIGURE 21-7** Menopause is transitional period in a woman's life, and healthy diet and exercise are important.

Adult women demographics are shifting. An increasing number of educated women are having children, and they are having them later in life; they are also spending more time in the work force before they have children. Births within the United States are decreasing; however, foreign-born births are increasing. In the United States, one in four mothers is solo mother, raising children on their own. Typical stereotypes are also shifting as working women face pressure to be more involved as mothers, while men are

more involved in childcare and housework than in the past ([Pew Research Center, 2020a](#)). Women in the developmental stage between 35 and 65 years of age may face many challenges including:

- Caring for aging parents
- Supporting young adult children
- Family–work role conflict
- Economic burden for single mothers
- Gender gap
- Parenting pressure ([Pew Research Center, 2020b](#))

## *Menopause and Hormone Replacement Therapy*

- **Perimenopause**, or menopausal transition, is the period of time leading up to the last menstrual cycle and is characterized by cycle changes and irregularity. Women typically begin to notice symptoms of perimenopause in their 40s. Menstrual flow may be light or heavy, and spotting may occur, depending on varying estrogen and progesterone levels. Women may also have vasomotor symptoms such as hot flashes (flushes) or night sweats and climacteric symptoms such as experience sleep disturbances and vaginal and urinary tract changes ([American College of Obstetricians and Gynecologists \[ACOG\], 2018a](#); [Martin & Barbieri, 2019](#)). The average length of perimenopause is 4 years but may last up to 10 years.
- **Menopause** is a time that marks the permanent cessation of menstrual activity (last menstrual period). The average age is 51 years (range = 45 to 58); however, it can occur earlier ([Office on Women's Health, 2018d](#)). Natural menopause is defined as cessation of menstrual periods for 12 consecutive months, with no other apparent cause.
  - Menopause symptoms differ among women and may last months to years. They range from hardly noticeable in some women to very severe in others. Symptoms include nervousness or anxiety, hot flashes (flushes), chills, excessive sweating (often at night), excitability, fatigue, mood disorders (apathy, mental depression, crying episodes), insomnia, palpitations, vertigo, headache, numbness, tingling, myalgia, urinary disturbances, and vaginal dryness ([ACOG, 2018a](#); [Office on Women's Health, 2018d](#)).
  - According to the *Study of Women's Health Across the Nation* (SWAN), hot flashes and some of the other menopausal symptoms last an average of 7.4 years, persisting 4.5 years once menopause is reached. However, these symptoms may persist for longer, particularly in African American women and those who are overweight or obese ([Santoro, 2016](#)).

The Endocrine Society recommends diagnosis of menopause based on the cessation of menstruation for 12 consecutive months. Recommendations for women in the menopausal transition include discussions about menopausal symptoms, osteoporosis, cancer screening, and assessment for CVD; along with a determination of the need for appropriate **menopausal hormone therapy (MHT)** (Stuenkel et al., 2015). For women under age 60, or who are <10 years past onset of menopause, with bothersome menopausal symptoms, MHT may be an appropriate treatment option. Health care providers must take patient risk for CVD, venous thromboembolic events, and breast cancer into account when considering initiation or continuation of MHT and should use a shared decision-making approach (Martin & Barbieri, 2019). At this time, ACOG recommends against the use of MHT as primary or secondary prevention of heart disease or osteoporosis (ACOG, 2018b). Women who are not candidates for oral MHT may be able to use transdermal routes or nonhormonal therapies to relieve symptoms, depending on risk factors and contraindications.

- Some women choose to use bioidentical hormone therapy—chemically similar hormones derived from plants—that may (e.g., micronized estradiol and progesterone) or may not be approved (e.g., Triest, Biest, pregnenolone) by the Food and Drug Administration (FDA).
- Current evidence does not support the use of bioidentical hormone therapy over conventional MHT (ACOG, 2018c; Martin & Barbieri, 2019).
- Women may also choose natural products (e.g., phytoestrogens, black cohosh, DHEA, dong quai, vitamin E) for symptomatic relief. Women choosing natural or herbal supplements should be counseled on lack of evidence supporting efficacy and long-term safety, as well as potential side effects and drug interactions (National Center for Complementary and Integrative Health, 2018).
- Other complementary health approaches women may choose for menopausal symptom relief includes hypnotherapy, meditation, yoga, and acupuncture.

## *Osteoporosis*

- A gradual loss in bone density is known as **osteoporosis**. Typically, bone mass stops increasing around age 30 years. As women age, bones may weaken and easily fracture as estrogen levels decrease.
- In the United States, 1 in 4 women over the age of 65 years has *osteoporosis* (CDC, 2020k). Therefore, it is important for women to build strong bone early. Bone density is influenced by many factors such as heredity, race/ethnicity, physical activity, and nutrition. It is

important for women of all ages to maintain a healthy diet that is rich in calcium and vitamin D, engage in physical activity, and avoid smoking.

- There are several classes of medications that can be used to treat osteoporosis: bisphosphonates (helps build bone mass), selective estrogen receptor modulators (slows rate of bone loss), calcitonin (slows rate of bone loss), and teriparatide (helps build up new bone).
- The USPSTF recommends screening for osteoporosis in women over the age of 65 years, or in postmenopausal women under age 65 years with increased risk for osteoporosis-related fractures ([USPSTF, 2018b](#)). See [Chapter 22](#) for more on osteoporosis in older women.

## *Heart Disease*

- Heart disease is the number one killer of women, causing the death of 295,995 females in 2016 ([Xu et al., 2018](#)). The most common heart problem, CHD, is underdiagnosed, undertreated, and under-researched in women.
- In addition, women have a higher mortality rate after heart attack and poorer outcomes than do men, and this may be related to delayed diagnosis and treatment.
- Risk factors for heart disease in women are age, family history, race/ethnicity, physical inactivity, sleep apnea, obesity, diabetes mellitus, high blood pressure, high cholesterol, and cigarette smoking ([Office on Women's Health, 2018e](#)).

Family history, race/ethnicity, and advancing age cannot be changed, but women can make lifestyle changes to alter other risk factors. The remaining risk factors are issues that the community health nurse can discuss with female clients in this age group. Community health nurses can help raise awareness regarding heart disease when working with women at the individual, family, or aggregate levels. Some important facts that can be shared are as follows:

- Heart disease accounts for 1 in 5 female deaths in the United States ([CDC, 2019c](#)).
- In the United States, approximately 1 in 16 Black, White, and Hispanic women over the age of 20 years have CHD ([CDC, 2019c](#)).
- The average age for first heart attack in females is 72.0 years ([Benjamin et al., 2018](#)).
- In all age groups, mortality rate for women following a heart attack is higher than in men ([Office on Women's Health, 2018d](#)).
- Almost two thirds of women who suddenly die from heart disease have had no previous symptoms ([CDC, 2019c](#)).

- Heart disease is sometimes thought of as a “man's disease,” but about the same number of women and men die each year of heart disease (CDC, 2019c).
- Women may have atypical heart symptoms or less acute chest pain, which may delay them from seeking care (Office of Women's Health, 2019).
- MHT may increase risk of heart attack, stroke, and blood clots (Office of Women's Health, 2018f).
- Nine out of 10 women have at least one risk factor for heart disease (NIH, NHLBI, 2019).

An excellent lay resource is “*Go Red for Women*,” a public awareness program of the AHA to help improve knowledge (AHA, 2018). Also, *Well-Integrated Screening and Evaluation for Women across the Nation* (WISEWOMAN), a CDC program that helps women with little or no health insurance reduce their risk for heart disease, stroke, and other chronic diseases (located in 21 sites across 19 states), can be helpful. The program assists women ages 40 to 64 in improving their diet, physical activity, and other behaviors (Fig. 21-8). This program also provides cholesterol tests and other screening (CDC, 2020K, 2020L ).

**FIGURE 21-8** A healthy diet is an important part of health promotion.

## *Cancer*

- Cancer is the second leading cause of death for women, estimated to kill 286,010 females in the United States in 2018. The majority of cancers (87%) occur in persons 50 years of age and older.

- An estimated 38% of women in the United States will develop cancer in their lifetime. To help address this disparity, community health nurses can provide more opportunities for education and screening for this population. Screening has reduced the deaths for cancers of the breast, colon, rectum, and cervix (ACS, 2019).
- Breast cancer is the most common cancer among women; however, more women die of lung cancer. In 2018, it is estimated that 40,920 deaths related to breast cancer will occur (SEER, n.d.a).

Overall, the death rates from breast cancer have declined since 1990, and the biggest decline was among women under 50 years of age (Table 21-5). This can be attributed to early detection and improvements in treatment. The sooner breast cancer is discovered, the more successfully it is treated. By obtaining regular clinical breast exams and mammograms, eating a diet low in fat and high in fruits and vegetables, breast-feeding (if possible), and avoiding prolonged use of MHT, a woman is doing what she can to promote breast health.

**TABLE 21-5 Breast Cancer Death Rates Among All Women: 2013–2017**

Women	Rate
<i>Age-Adjusted Rates per 100,000</i>	
All races	20.3
Black	27.6
White	19.8
American Indian/Alaska Native	14.6
Hispanic	14.0
Asian/Pacific Islander	11.4

Source: Cancer Statistic Center (2018); Surveillance, Epidemiology, and End Stage Program (SEER) (n.d.a).

- Although breast self-examination (BSE) is no longer a routine screening recommendation, it is important that women are familiar with their breasts. This allows them to recognize any overt changes in their breasts, especially changes related to size, shape, symmetry, and nipple

discharge. The community health nurse has many resources available to provide information and to teach women breast awareness in their homes, small groups in clinics, or in various other community settings to enhance knowledge of breast health (ACS, 2020a). See [Chapters 11 and 12](#) for more on breast cancer screening.

Breast cancer screening is important for early detection when tumors are likely to be smaller and confined to the breast. Early detection is associated with better prognosis for survival. The USPSTF (2016c) published the following breast cancer screening recommendations for women of average risk:

- Women, age younger than 50 years: should be an individual decision and the patient's context (risk for disease) should be taken into account (Grade C).
- Women, aged 50 to 74 years: biennial screening with mammography (Grade B).
- Women, aged 75 years and older: evidence is insufficient to assess the benefits and harms of screening mammography (Grade I; USPSTF, 2016c).
- Women who have a first-degree relative with breast cancer (mother, sister), have a breast cancer gene (*BRCA1* or *BRCA2*), or have had previous breast cancer are at a higher risk for developing the disease than other women in the general population. Therefore, these individuals need to consult their physicians regarding timelines for screenings (ACS, 2020a).

Cervical cancer screening has improved early detection and prevention of cervical cancer dramatically. Both the incidence and the death rates for cervical cancer have declined in recent decades because of treatment of pre-invasive cervical lesions. The major risk factors for this disease are infection with certain types of HPV, unprotected intercourse at an early age, and multiple sex partners. In 2018, it is estimated that 13,240 new cases of invasive cervical cancer will be diagnosed in the United States, contributing to 4,170 deaths among women from this disease. The 5-year survival rate for this cancer, if prompt treatment is initiated, is 66.2% for all stages and 91.7% for local infiltration, making it one of the most successfully treated cancers (SEER, n.d.b). The USPSTF published the following cervical cancer screening recommendations:

- Women younger than 21 years: recommend against screening (Grade D)
- Women age 21 to 29 years: every 3 years with cervical cytology (Grade A)
- Women age 30 to 65 years: every 3 years with cervical cytology alone, or every 5 years with high-risk human papillomavirus testing (hrHPV),

- or every 5 years with hrHPV and cytology combination (Grade A)
- Women older than 65 years: recommend against screening with adequate screening previously and not at high risk (Grade D) ([USPSTF, 2018c](#))

C/PHN can continue to improve screening and early diagnosis through education and advocating for low-cost screening, which will allow at-risk low-income and rural women access to regular cervical cancer screenings. In addition to screening, educating women about the HPV vaccine is an important strategy to reduce the incidence of cervical cancer. The Gardasil 9 vaccine protects against 9 HPV virus types that may cause cervical cancer and anogenital warts. It is started as early as age 9 and given as two (age 9 to 13) or three doses (age 14 and older) over 6 months. Previously, the HPV vaccine was only available for individuals age 9 to 26; however, in 2018, the FDA approved the expanded use of Gardasil 9 to also cover males and females age 27 to 45 years ([FDA, 2018a](#); [Merck Sharp & Dohme Corporation, 2018](#)).

- Ovarian cancer contributes to more deaths than any other cancer of the female reproductive system and accounts for 5% of cancer deaths among women. In 2018, a total of 22,240 cases were anticipated and 14,070 deaths were expected.
- The primary risk factor for this disease is heredity, or a strong family history of breast or ovarian cancer. The 5-year survival rate is 47.4% compared to cervical (66.2%) and breast (89.9%) cancers.
- The USPSTF recommends against routine screening for ovarian cancer in women who do not have symptoms. However, women considered at high risk should receive a pelvic exam, a transvaginal ultrasound, and a blood test for the tumor marker CA 125. Therefore, C/PHNs need to continue to stress the importance of early detection ([SEER, n.d.c](#); [Torre et al., 2018](#); [USPSTF, 2018d](#)).

## *Myalgic Encephalomyelitis/Chronic Fatigue Syndrome*

- **Myalgic encephalomyelitis/chronic fatigue syndrome (ME/CFS)** is a chronic and debilitating disease characterized by fatigue lasting for 6 or more months, worsening of symptoms after exertion and unrefreshing sleep. Other symptoms may include cognitive impairment, orthostatic intolerance, frequent sore throat, headache, painful muscles, and joint pain. It is estimated that between 836,000 and 2.8 million persons in the United States have ME/CFS, with women affected up to four times more than men.

- Symptoms may last for months or years, waxing and waning and are difficult to validate objectively, but they are subjectively debilitating. Because the cause is unknown, there is no specific treatment and no prevention suggestions.
- Treatment is focused on supportive care for the associated pain, depression, and insomnia. The Solve ME/CFS Initiative provides support and information for women and is one of seven organizations that contributed to *Impact of Chronic Overlapping Pain Conditions on Public Health and the Urgent Need for Safe and Effective Treatment*, a report that raises awareness of chronic pain conditions that disproportionately impact women.

The community health nurse can assess activity level and degree of fatigue, emotional response to the illness, and coping ability. Emotionally supportive family members and health care providers are helpful. Referring women to mental health counseling or a local support group is useful for many women and within the role of the community health nurse ([CDC, 2019h](#); [Chronic Pain Research Alliance, 2015](#); [Institute of Medicine, 2015](#); [Solve ME/CFS Initiative, 2018](#)).

# MEN'S HEALTH

Gender is among the numerous factors that influence health. More male neonates die at birth, and men are more likely to die earlier from a chronic illness than women (Fig. 21-9). This is evidenced by the difference in life expectancy between men and women in the United States; women survive an average of 5 years longer than men (CDC, 2017e; Xu et al., 2018).

**FIGURE 21-9** Men have different health care needs at various stages of life.

## **Overview of Factors Influencing Men's Health**

Masculinity is an influencing factor in men's health. Men are socialized to be independent and conceal their vulnerability. Therefore, even when they are aware of personal physical or mental health problems, they are less likely to access the health care system. How the male identity is maintained can include activities that are hazardous to their health, and the result is a high death rate from unintentional injuries among young men. Examples of these activities include substance use, use of firearms, excessive alcohol consumptions, and smoking (CDC, 2017e; Xu et al., 2018).

# Men's Health Promotion Across the Adult Life Span

In the early years of young adulthood (between 18 and 35 years), men continue to grow and mature. Adult men aged 35 to 65 years have reached maturity, the peak of their physical and intellectual development, and their greatest earning power. What specific needs do men in these age groups have? Are their needs being met through provided services?

## *Healthy People 2030 Goals for Men*

*Healthy People 2030* addresses men's health through family planning, STD, LGBT, and adult health issues such as mental health, substance abuse and opioids, tobacco, nutrition, physical activity, chronic diseases, and cancer (Box 21-6).

## **BOX 21-6 HEALTHY PEOPLE 2030**

### **The Objectives for Men**

#### **Core Objectives**

C-07	Increase the proportion of adults who get screened for colorectal cancer
C-08	Reduce the prostate cancer death rate
STI-05	Reduce the syphilis rate in men who have sex with men
HIV-03	Reduce the number of new HIV diagnoses
LGBT-01	Increase the number of national surveys that collect data on lesbian, gay, and bisexual populations
LGBT-02	Increase the number of national surveys that collect data on transgender populations
PA-02	Increase the proportion of adults who do enough aerobic physical activity for substantial health benefits
TU-01	Reduce current tobacco use in adults
SU-03	Reduce drug overdose deaths
SU-13	Reduce the proportion of people who had alcohol use disorder in the past year
SU-15	Reduce the proportion of people who had drug use disorder in the past year
NWS-03	Reduce the proportion of adults with obesity
MHMD-08	Increase the proportion of primary care visits where adolescents and adults are screened for depression

Reprinted from [U.S. Department of Health & Human Services \(USDHHS\). \(2020\). Healthy People 2030: Browse objectives.](#)

Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objective>

## *Young Adult Men (18 to 35 Years)*

The young adult male has many tasks to accomplish including:

- Acquisition of training/education leading to a personally and financially rewarding career
- Selecting a compatible companion and establishing a life together (Fig. 21-10)
- Practicing and internalizing a belief and value system that brings comfort and meaning to existence
- Actively planning for having (or not having) children
- And participating in the betterment of the greater community

**FIGURE 21-10** Choosing a significant other is a developmental task of young adulthood.

Young men may choose work that involves physical labor, office work, or a variety of other endeavors, including active duty military. They may also be veterans of military service.

Young men engage in risk taking behaviors without thinking about the consequences. Depending on his attitudes and practices before a man enters young adulthood, he may or may not be enticed to experiment or continue with the use of tobacco, alcohol, or illicit drugs. Experimentation or usage of these substances can occur while in college, the military, or working at a full-time job. In addition, young men respond to challenges such as drag racing and exceeding speed limits. This is an important age group for the C/PHN to reach with health information because decisions made in these formative years affect how young men live the rest of their lives. The nurse can meet with young adult men in work settings, college campuses, military bases, health clubs and bars, and at single-adult groups sponsored by religious communities and other organizations.

Another issue to address during the early years is the young man's attitudes and beliefs toward sex and sexual experimentation. Young men may question their sexuality as they mature. During this stage, some men come to

the realization that they are homosexual—a person who has sexual interest in or sexual intercourse exclusively with members of his or her own gender. Some men who have sex with men (MSM), women, or both often do not consider themselves to be **bisexual**. When taking a sexual history, community health nurses must ask men if they have sex with women, men, or both, and they should be aware of issues affecting the lesbian, gay, bisexual, and transgender (LGBT) population.

**Transgender**, another term associated with sexuality, describes individuals who experience and/or express their gender differently and often does not correspond with the person's apparent or birth gender. An example is when a presumed male chooses to put on makeup and clothes that a female would traditionally wear. Some transgender individuals define themselves as *female to male* or *male to female* and may take hormones and/or undergo medical procedures to enhance or make permanent their gender selection, including gender reassignment surgery. Others prefer to simply be called *male* or *female*—the gender they present to others, whether or not they have undergone permanent gender reassignment.

Sexual experimentation, whether heterosexual or homosexual, can place young men at risk for diseases that affect long-term health or is life threatening. Men who are sexually active can reduce the possibility of being infected with an STI by limiting the number of sexual partners and using condoms consistently and correctly. Condoms also serve as a form of birth control for men. *Monogamy*, having sex with only one partner and abstinence can further reduce or eliminate the chance of contracting an STI. Public health nurses can serve as a resource for young men and can help them obtain free or low-cost condoms and treatment for STIs.

## *Human Immunodeficiency Virus*

From 2012 through 2016, the rates of diagnoses of HIV infection in the Northeast and the Midwest decreased. The rates in the South and the West remained stable. In 2017, rates were 16.1 in the South, 10.6 in the Northeast, 9.4 in the West, and 7.4 in the Midwest (CDC, 2017f). Because the percentage of persons diagnosed with HIV varies by geographic region, it is important that prevention, testing, and treatment interventions be tailored for each area's distinctive needs.

<https://www.cdc.gov/hiv/statistics/overview/geographicdistribution.html>

- Despite advances in the prevention and treatment of human immunodeficiency virus (HIV), the disease continues to disproportionately impact men in the United States.
- In 2016, the rate of HIV infected men was 570.1 per 100,000 compared to 169.9 in females. Of the 754,218 infected males in 2016, 72% of infections were attributed to male-to-male sexual contact (CDC, 2017f).

- The highest rate of new infection was seen in blacks/African Americans, followed by Hispanics/Latinos.
- HIV new infection was most prevalent in persons aged 25 to 29 years followed by those persons aged 20 to 24 years (CDC, 2019i).
- When examining trends in the disease based on race/ethnicity and age, the burden of the disease is highest among men of color and young adults.

Alcohol and illicit drug use are known to decrease social inhibitions and increase the risk for HIV transmission through risky sexual behaviors (e.g., lack of condom use) and the sharing of needles or other injection equipment (CDC, 2019i). Community health nurses must be able to talk openly and nonjudgmentally with men about their use of substances and their sexual relationships. These conversations can be challenging, but they have to occur if the number of HIV infections is to be reduced.

### *Testicular Cancer*

- The risk for testicular cancer is a health problem that young men should be aware of even before early adulthood. The disease occurs most often in men between 20 and 34 years of age.
- A few risk factors have been identified that increase a young man's chance of developing testicular cancer including a personal history of an undescended testicle, abnormal testicular development, family history of testicular cancer, race/ethnicity (White), and age, (ACS, 2018).
- It is a rare form of cancer and is not on the list of objectives for men in *Healthy People 2030*. However, if detected early, this cancer is highly curable.
- According to the [Testicular Cancer Society \(2020\)](#), it may be beneficial to the overall health of a young man to know how to perform a testicular self-exam. For more information on TSE, visit the following Web site of the [Testicular Cancer Society](https://testicularcancersociety.org/pages/self-exam-how-to):  
<https://testicularcancersociety.org/pages/self-exam-how-to>

The choices a young adult man makes during these years establish healthy eating, work, rest, and exercise habits that will benefit him for a lifetime. A man should follow the dietary food guidelines that are recommended by [U.S. Department of Agriculture \(2016\)](#). Establishing a pattern of rest that allows his body to recover and refresh from a day full of meaningful activities will help him look forward to each day. He should establish an exercise routine that meets his personal needs, fits his skills and talents, and includes some physical activities that involve his family ([Fig. 21-11](#)). These choices provide him with the knowledge that he is doing everything he can to keep himself healthy and to prevent the two major

killers of men—heart disease and cancer. Typically, young adult clients have few interactions with health care providers in any given year. It is important for people in this age group to have regular health checkups, be assessed for early signs of disease, and engage in health promotion activities.

**FIGURE 21-11** Adult men are encouraged to maintain good health through eating a healthy diet and getting regular exercise.

### *Adult Men (35 to 65 Years)*

Men in the developmental stage between 35 and 65 years of age face many challenges including:

- Caring for their own families and children
- Caring for aging parents and in-laws
- Economic burdens of putting children through college
- Adjusting to the reality that their career path is probably set, and many life choices have been made

The term “midlife” is applied to the first half of this age period, 35 to 49 years during which many men experience a “midlife crisis.” This period of time can be a difficult stage of life due to:

- Reappraisal of values, priorities, and personal relationships
- Doubt and anxiety realizing that his life is half over
- Beliefs he has not accomplished enough
- Struggles to find new meaning or purpose in his life
- Boredom with his personal life, job, or partners
- Desires to make life changes in personal life, job, or partners

In fact, men in midlife are at higher rates for suicide behavior than the general population (SAMHSA, 2018).

The later years in this stage, ages 50 to 64, involve preparation for retirement. In anticipation of retirement, these years are marked by:

- Expanded social relationships
- Pursuit of new hobbies to fill increased leisure time
- Finishing a career and accumulation of the best retirement benefits
- Making life altering decisions
- Potential health problems
- Loss of loved ones, particularly a spouse or long-term companion

Successful navigation of this stage can be fulfilling but may require a man to enhance his self-care skills. This includes having a positive attitude toward aging, one that examines the benefits of maturity, finds a balance between work and home, and maintains a healthy lifestyle by eating balanced meals and obtaining regular exercise. The community health nurse can provide anticipatory guidance to men approaching this stage and provide them with information on ways to manage life more effectively.

## *Reproductive Health*

As mentioned earlier in this chapter, during the reproductive years, both women and men should strive to be as healthy as possible. During this stage, especially when a man has decided that his family is complete (Fig. 21-12), he may choose a permanent form of birth control through a surgical procedure called *vasectomy*. A vasectomy entails:

**FIGURE 21-12** Reproductive health is an important consideration for men.

- Removal of all or a segment of the vas deferens
- Sperm cannot be released

- Routinely conducted on an outpatient basis
- Minimally invasive
- Takes about 30 minutes ([CDC, 2017g](#))

Compared to tubal ligation (a surgical form of contraception for women), vasectomy is equally effective in preventing pregnancy, but vasectomy is simpler, faster, safer, and less expensive. A vasectomy is not protective against STIs and almost all can be reversed ([NIH, 2016](#)). Because these methods, however, are intended to be irreversible, all women and men should be counseled about the permanency of these procedures ([CDC, 2017g](#)).

Erection problems are common among men of all ages but especially in men as they age. **Erectile dysfunction (ED)**, sometimes called *impotence*, is the repeated inability to get or keep an erection firm enough for sexual intercourse. The word *impotence* may also be used to describe other problems that interfere with sexual intercourse, such as lack of sexual desire and problems with ejaculation or orgasm. Using the term *erectile dysfunction* makes it clear that these other issues are not involved ([AUA, 2018](#); [Urology Care Foundation, 2018](#)). Because an erection requires a specific sequence of events, ED can occur when any of the associated events are disrupted. The sequence includes nerve impulses in the brain, spinal column, and areas around the penis, as well as response in muscles, fibrous tissues, veins, and arteries in and near the corpora cavernosa. Damages to nerves, arteries, smooth muscles, and fibrous tissues, often as a result of disease, are the most common causes of ED. Comorbidities such as diabetes, kidney disease, chronic alcoholism, multiple sclerosis, atherosclerosis, vascular disease, and neurologic disorders are primary health risk factors for ED ([AUA, 2018](#); [Urology Care Foundation, 2018](#)).

Lifestyle choices that contribute to heart disease and vascular problems also increase the risk of ED. Smoking, being overweight, and lack of exercise are possible causes of ED. Surgery (especially radical prostate and bladder surgery for cancer) can injure nerves and arteries near the penis, causing ED. Injury to the penis, spinal cord, prostate, bladder, and pelvis can lead to ED by harming nerves, smooth muscles, arteries, and fibrous tissues of the corpora cavernosa. In addition, many common medicines—antihypertensive, antihistamines, antidepressants, tranquilizers, appetite suppressants, and cimetidine—can produce ED as a side effect. In diagnosing ED, the medical provider will do a thorough health history including a lifestyle assessment. Specific questions related to the cardiovascular system and the nature of ED will be addressed ([AUA, 2018](#); [Urology Care Foundation, 2018](#)).

Drugs for treating ED can be taken orally, injected directly into the penis, or inserted into the urethra at the tip of the penis. Current medical treatment consists of approved sildenafil citrate (Viagra), the first pill to treat ED. Since

then, vardenafil hydrochloride (Levitra [oral], Staxyn [sublingual]), tadalafil (Cialis), and avanafil (Stendra) have been created and belong to a class of drugs called phosphodiesterase (PDE) type 5 inhibitors. These medications are currently the first line of therapy for treating ED. The drugs work by relaxing smooth muscles in the penis during sexual stimulation and allow increased blood flow. They can be taken as needed before sexual activity, up to once a day. Low-dose daily dosing rather than “on-demand” dosing has been found to be beneficial for some couples ([Urology Care Foundation, 2018](#)).

## *Cardiovascular Disease*

Heart disease is the leading cause of death in men across most racial/ethnic groups. Despite a decline in the overall death rate from CVD, the burden of disease among men remains high.

- In 2013, CVD caused 310,000 deaths in men ([CDC, 2020m](#)).
- Approximately 70% to 89% of sudden cardiac events occur in men, and 50% of these men have no previous symptoms of disease.
- The average age for a first heart attack among men is 66 years.
- About 8.5% of White men, 7.9% of Black men, and 6.3% of Mexican American men have some coronary disease.
- The rate of a first cardiovascular event rises from 3 per 1,000 men at 35 to 44 years of age to 74 per 1,000 men at 85 to 94 years of age.
- It is interesting to note, if all forms of major CVD were eliminated, life expectancy among all persons would increase by almost 7 years ([CDC, 2020m](#)).

Major risk factors for heart disease in men include hypertension, hyperlipidemia (high LDL), tobacco use, diabetes, obesity/overweight, lack of physical activity, excessive alcohol consumption, stress, and low daily fruit and vegetable consumption ([Box 21-7](#)). When working with adult men, the community health nurse should educate men about the importance of modifying factors that increase their risk of developing CVD ([CDC, 2020m](#)). C/PHNs should discuss the signs and symptoms of a heart attack and how to access emergency medical treatment with adult males.

### **BOX 21-7 Evidence-Based Practice**

**Church-Based Blood Pressure Interventions for Young Black Males Hypertension is a significant disorder among Black males in the United States who experience early-onset and**

**multiple comorbidities. Black males are less likely to engage in healthy lifestyles and seek medical advice and treatment. Interventions directed at young black males to decrease the incidence and severity of hypertension are limited.**

A community-based participatory research study was conducted (Carter-Edwards et al., 2018) in the southeastern United States to explore using the church as a venue to offer blood pressure interventions for young black men. Focus group participants consisted of 19 men, 9 were aged 18 to 35 years and 10 were aged 36 to 50. Focus group questions explored lifestyle and self-management behaviors related to hypertension. The analysis of the focus group data revealed that most lifestyle behaviors were perceived to be manageable although participants admitted to added stress in managing busy work and family-related activities. Interestingly, another major theme generated was understanding hidden sodium.

Although the findings confirm persistent challenges of engaging young black men for blood pressure interventions, the results imply that programs should utilize the church infrastructure as a means to disseminate information and implement health care interventions. Prayer, supportive family systems, church leaders, mentors, and peers may help young black men increase their knowledge and achieve optimal lifestyles related to their blood pressure (Carter-Edwards et al., 2018).

Nurses were not included in the study, yet community health nurses would be an invaluable resource, as they can form partnerships to educate young black males on healthy lifestyles. Nurses are in a key position to recognize concerns touching the health and well-being of patients, determine health configurations across patient populations, connect patients with community resources and social services, and develop comprehensive interventions (Bachrach & Thomas, 2016).

Source: Bachrach and Thomas (2016); Carter-Edwards et al. (2018).

## *Prostate Health*

Prostate health is another concern that may occur later in this life stage. The **prostate** is a doughnut-shaped gland located at the bottom of the bladder, about halfway between the rectum and the base of the penis. The prostate encircles the urethra. The walnut-sized gland produces most of the fluid in

semen. Men can experience infection (prostatitis), prostate enlargement (benign prostatic hyperplasia [BPH]), and prostate cancer ([ACS, 2020b](#)).

- BPH is very common among men.
- The primary risk factor for developing BPH is age. Nearly 50% of men over 50 years of age report symptoms that are related to prostate gland enlargement.
- Symptoms of BPH are caused by an obstruction of the urethra and gradual loss of bladder function, which results in incomplete emptying of the bladder. The most commonly reported symptoms of BPH involve lower urinary tract symptoms (LUTS), such as hesitant, interrupted, or weak urinary stream, urgency or leaking of urine, and more frequent urination, especially at night.
- Men often report the symptoms of BPH before the physician diagnoses it through a digital rectal examination (DRE).
- Treatment for BPH can include medication or surgery to reduce the size of the prostate ([Urology Care Foundation, 2019](#)).

Prostate cancer is the most frequently diagnosed cancer in men and the second leading cause of cancer death.

- According to the ACS, 1 man in 7 will get prostate cancer during his lifetime and 1 man in 38 will die from the disease.
- However, most prostate cancers grow slowly and do not cause any health problems in men who have them.
- More than 2.9 million men in the United States who have been diagnosed with prostate cancer at some time in their lives are still alive today.
- Prior to age 40, prostate cancer is very rare, but the chance of having prostate cancer rises rapidly after age 50.
- About 6 cases in 10 are diagnosed in men 65 years of age and older.
- Age is the strongest risk factor for prostate cancer, but family history and ethnicity also need to be considered.
- Prostate cancer occurs more often in Black men than in men of other races and occurs less often in Asian and Hispanic/Latino men.

The reasons for these racial and ethnic differences are not clear. Starting at age 50, all men should talk to their health care provider about the pros and cons of screening for prostate cancer. This discussion should start at age 45 if a man is Black or has a father or brother who had prostate cancer before age 65. Men with two or more close relatives who had prostate cancer before age 65 should talk with their health care provider about screening for prostate cancer at age 40 ([ACS, 2020b](#); [CDC, 2019j](#)). The effectiveness of the screening test, prostate-specific antigen (PSA), has been brought into

question, and the USPSTF (2015) has outlined a framework for further study and review.

Treatment for prostate cancer depends on the man's age, overall health status, and stage of disease ([Tabayoyong & Abouassaly, 2015](#)).

- Treatment options include surgery to remove all or part of the prostate (prostatectomy), radiation, and hormone therapy.
- Surgery, radiation, and hormone therapy all have the potential to disrupt sexual desire and performance, temporarily or permanently.
- Urinary dysfunction and incontinence are common side effects that occur after surgery or radiation.
- Rather than immediate treatment, watchful waiting or active surveillance is an option that may be appropriate for older men with limited life expectancy and/or less aggressive tumors ([Filson, Marks, & Litwin, 2015](#)).

A community health nurse can reinforce or clarify information shared with the man by his health care provider, discuss his treatment options with him and his family, and provide the support they may need if prostate cancer is diagnosed.

# ROLE OF THE COMMUNITY HEALTH NURSE

The community health nurse works with adults in all age groups using the three levels of prevention—primary, secondary, and tertiary—as a guide. Interventions are conducted at the individual, family, group, and aggregate levels to make progress toward the *Healthy People 2030* objectives (Box 21-8).

## BOX 21-8 Levels Of Prevention Pyramid

### Breast Cancer SITUATION: Breast cancer.

**GOAL:** Using the three levels of prevention, avoid or promptly diagnose and treat negative health conditions and restore the fullest potential.

Tertiary Prevention		
Rehabilitation	Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Recovery at home with return to activities of daily living within 2 wk</li> </ul>	<ul style="list-style-type: none"> <li>Maintains periodic follow-up with health care provider, follow-up mammogram at 6 and 12 mo, and as recommended by health care provider</li> <li>Education regarding risk for other cancers (cervical, ovarian, uterine, etc.)</li> </ul>	<ul style="list-style-type: none"> <li>Practice breast awareness and receive mammograms as recommended; receives screening for ovarian cancer—transvaginal ultrasonography and blood test for tumor marker CA 125</li> </ul>

Secondary Prevention	
Early Diagnosis	Prompt Treatment
<ul style="list-style-type: none"> <li>Identification of lump in left breast, appointment made with health care provider for evaluation</li> <li>Receives mammogram and sonogram</li> </ul>	<ul style="list-style-type: none"> <li>Needle aspiration of lump followed by cytologic studies</li> <li>Lumpectomy with removal of two suspicious lymph nodes</li> <li>Low-dose radiation</li> </ul>

Primary Prevention	
Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Education regarding breast awareness and mammograms, as needed</li> <li>Education regarding environmental exposure and breast cancer (smoking, alcohol, chemicals)</li> <li>Education regarding low-fat diet and maintaining a body mass index &lt;29</li> </ul>	<ul style="list-style-type: none"> <li>Avoidance of environmental exposures that may contribute to cancer</li> <li>Maintains breast awareness and obtains mammogram when appropriate</li> </ul>

Client teaching by the community health nurse is a major factor in preventing and managing chronic diseases. The challenge to the nurse is to

be prepared to discuss issues, backed up with knowledge of and access to the appropriate community resources, to meet client needs. What the nurse can accomplish can be quite dramatic in terms of reducing days in the hospital because of chronic disease, improving quality of life for the chronically ill person, and preventing a combination of unhealthy habits from becoming causative factors in new cases of chronic disease. A nursing care plan matrix can guide the community health nurse in discussing areas of health promotion and protection with the client. An example of a nursing care plan matrix for young adults can be found in [Box 21-9](#).

## **BOX 21-9 Nursing Care Plan Matrix for Health Promotion, Young Adults: 18 to 35**

Community health nurses can use this matrix to individualize teaching, services, and/or care to young adult clients. Use the questions to stimulate the development of an individualized approach that is client focused and client driven with the community health nurse acting as the catalyst. In any or all of these areas, the community health nurse may (1) discuss issues and commend the client for positive attitudes and behaviors (e.g., when the client is making healthful decisions, such as condom use for his/her health and the health of significant others); (2) discuss the issues and guide the client to resources that will enhance more positive behaviors and decisions (e.g., flu shot clinic or healthy lifestyle program for adults); or (3) discuss the issues and inform the client that immediate changes must be made to protect the health of self or others and inform/utilize the appropriate resources as soon as possible (e.g., follow-up for symptoms related to suspected STI).

1. *Life partner*. Ascertain whether the client is looking for a life partner or is choosing to live a single life. Discuss how the single life is satisfying for the client and ways to make it richer. Discuss settings in which client can meet others (male or female, based on sexual preference) with similar interests, philosophy, and outlook, such as work settings, school settings, faith communities, recreational communities, and the like. Discuss what the client is looking for in a potential life partner, expectations for the relationship, what the client contributes, how the client compromises and resolves conflict, and other issues. If in a relationship, what is good, what needs improving, and how to initiate change.
2. *Life's work*. How is the client preparing for his/her life's work (education, formal training, on the job training)? Will the life's

work provide resources for client's life plans? Will the work choice provide long-term satisfaction? Is the work choice a “stepping stone” to another work role? How will/does he/she handle work and rearing children? What needs changing or can be improved in the work/children arrangement?

3. *Planning for children.* What knowledge does he/she have about family planning? What methods fit best with his/her philosophy, religious beliefs, and lifestyle? What are the long-term effects of the choices? How many children is the client planning to rear? Has he/she thought through the ramifications of this number? If choosing not to have (or unable to have) children, how will he/she deal with this? Does he/she want alternative suggestions for raising a child (adoption, foster parenting) or information about interacting with children (volunteering)?
4. *Maintaining physical and mental health.* In this area, the community health nurse needs to explore all areas of health promotion and protection. This will include discussions regarding primary and secondary prevention. Primary prevention discussions could include:
  - Diet and nutrition
  - Physical and leisure activities
  - Safe sex practices
  - Periodic health examinations
  - Personal safety—seat belts, protective helmets, dating violence, *etc.*
  - Immunizations
  - Regular use of sunscreen
  - Stress reduction activitiesSecondary prevention discussions could include:
  - Screening for sexually transmitted infections
  - Testicular self-examination
  - Smoking cessation
  - Pelvic exams and Pap smears
  - Counseling and support at times of stress
5. *Developing a life's philosophy.* Discuss client's personal life satisfaction, which may include religiosity and spirituality, living in congruence with cultural/ethnic/family beliefs and expectations, and coming to a comfortable level of satisfaction with life choices, having few regrets.

## Primary Prevention

- Primary prevention activities focus on education to promote a healthy lifestyle. Much of the community health nurse's time is spent in the educator role.
- When working with individuals, the C/PHN should encourage routine health examinations, healthy eating habits, adequate sleep, moderate drinking, and no smoking. Among aggregates, the community health nurse focuses on community needs for services and programs that will keep that population healthy, such as providing flu vaccine clinics, teaching sexual responsibility, and preventing STIs.

The community health nurse may collaborate with community leaders and other stakeholders in designing programs, work with committees to secure funding, or approach the state legislature to lobby for needed changes to state laws and policies governing the health of adults. At other times, the nurse works with small groups of adults who could benefit from making healthy choices in diet, relaxation, and physical activity. Likewise, it is not unusual for the C/PHN to work with an individual to promote healthy living. An example of available resources on smoking cessation to those working with the veteran population is shared in [Box 21-10](#).

### **BOX 21-10 Population Focus**

**Public Health and the Veteran Population** The Office of Patient Care Services within the Veterans Health Administration provides a public health focus on health promotion and disease prevention for the veteran population. The mission is accomplished through education and outreach, public health policy development, population-based surveillance, performance measurement and improvement, clinical guidelines, and research. Current focus areas for the veteran population include reducing complications from military exposures, hepatitis C, HIV/AIDS, influenza, women's

**health issues, and tobacco cessation. The veteran population is disproportionately affected by smoking-related illnesses. Many veterans began using tobacco during military service or deployment. The U.S. Department of Veterans Affairs Mental Health Web site “Tobacco and Health” was developed specifically for the veteran population to provide evidence-based information and helpful resources for veterans interested in improving their health by quitting the use of tobacco. The Web site is resource rich and can be accessed by any veteran or health care professional at <http://www.mentalhealth.va.gov/quit-tobacco/index.asp>. Two particularly meaningful resources for the veteran population are the SmokefreeVET (a text messaging program utilizing daily advice and support) and Stay Quit Coach (a mobile app to help Veterans deal with issues arising in tobacco cessation).**

—Cory, VA Staff Nurse

Source: [Veterans Health Administration, U.S. Department of Veterans Affairs \(2019\)](#).

## Secondary Prevention

- Secondary prevention focuses on screening for early detection and prompt treatment of diseases. Throughout the life span, screening tests can help adults identify disease early (see Screenings and Checkup Schedule for Women and Men on [thePoint](#) ).
- A significant amount of the community health nurse's time is spent in assessing the need for planning, implementing, or evaluating programs that focus on the early detection of diseases.
- This is followed with teaching to prevent further damage from the disease in progress or to prevent the spread of the disease, if it is communicable. Examples of secondary prevention programs include establishing mammography clinics, teaching breast and TSE, and screenings—blood pressure, blood glucose, BMI, and cholesterol. Wherever adults gather in groups, this is a good place to provide both primary and secondary health care and prevention services.

## Tertiary Prevention

- The tertiary level of prevention focuses on rehabilitation and preventing further damage to an already compromised system. Many adults with whom a community health nurse works have chronic diseases, conditions resulting from another disease, or long-standing injuries with resulting disability.
- Ideally, negative health conditions can be prevented. If not, the next best thing is for them to be diagnosed early, without damage to an individual's health. But if negative health conditions have not been treated or brought under control, then the individual is at a tertiary level of prevention. At this level of prevention, the nurse focuses on maintaining quality of life.

Depending on the client's age, tertiary prevention can be simple or very complex. A 19-year-old man who breaks his leg while skiing needs information about using crutches safely, a reminder to eat protein foods for bone healing, and an appointment to return to his health care provider if he experiences various symptoms and to get the cast removed. He generally needs no additional help from others. Tertiary prevention in this case is uncomplicated. On the other hand, a 62-year-old woman who is 70 lb overweight with out-of-control blood glucose levels, symptoms of congestive heart failure, and difficulty walking more than 20 ft has much to accomplish in order to feel healthy. Can the nurse help the woman lose weight? Will weight loss bring her diabetes under control and alleviate congestive heart failure symptoms? With some weight reduction, will she be able to walk more easily? Or, will the woman feel better with physical therapy and a different medication regimen? Is there a quicker, safer, and better approach? On assessment, the nurse discovers that the woman has been as much as 80 lb overweight for 40 years. Will this information alter the nurse's approach to helping this woman? What additional information does the nurse need?

Caring for people at the tertiary level of prevention can become quite complicated because many body systems may be involved. In addition, all people function within many social systems, which may include family expectations, roles people have within the family, expected behaviors, community system knowledge and involvement, personal expectations, motivation, and support. Working at the tertiary level involves all of the nurse's skills in addition to community resources and a client who can be or wants to be motivated.

# SUMMARY

- The 20th century saw a shift in the leading causes of death, from communicable to noncommunicable diseases. Currently, the five leading causes of death in adults are diseases of the heart, malignant neoplasms, unintentional injuries, CLRDs, and cerebrovascular diseases—none of which are communicable.
- The health care needs of adults are of great concern. Many needs are the same for both women and men, but the important differences were addressed in this chapter.
- Adults have health care needs that change as they age. Diet and exercise, obesity, substance use, safety, and healthy lifestyle choices are issues that adults must consider throughout their lives.
- Genomics refers to how a person's genetic makeup and environment predispose an individual to the development of disease. Understanding a person's genetic risk and environmental factors that may further influence and increase risk allows community health nurses to provide targeted education on disease prevention. Heart disease and cancers remain important concerns for both men and women, and health decisions made as a young adult can have a major impact on persons as they age.
- Chronic illness is an issue of increasing concern for both men and women as life expectancies increase. C/PHN should use the three levels of prevention to promote health across the life span. Primary prevention activities focus on education to promote a healthy lifestyle. Secondary prevention focuses on screening for early detection and prompt treatment of diseases.
- The C/PHN role at this stage is to assess needs; to plan, implement, or evaluate programs that focus on the early detection of diseases; and to educate clients to prevent further damage from or spread of disease. The tertiary level of prevention focuses on rehabilitation and prevention of further damage to an already compromised system. At this level of prevention, the nurse focuses on maintaining quality of life.

# ACTIVE LEARNING EXERCISES

1. Using journals or online sources, select three articles that relate to a preventable chronic disease. For each article, summarize the content, identify the likely cause, and describe how the disease may have been prevented.
2. You are asked to offer a weight control program for 12 young adults who are residents in an apartment complex that has monthly programs related to health and wellness. The ages of the intended participants range from 20 to 30. What steps would you take to develop a successful program? What would be important to emphasize with this age group? What resources (e.g., smartphone apps, online information) might be useful to them in adhering to a healthy diet and exercise program?
3. Apply “Assess and Monitor Population Health” (1 of the 10 essential public health services; see [Box 2-2](#) ) as follows: Using nursing and other health care databases, research a chronic disease associated with men or women aged 35 to 65. In a small group discussion with your classmates, identify selected concerns and discuss both personal responsibility and societal responsibility regarding management of this health problem.
4. In a small group, determine screening recommendations for a male and female at 50 years of age. Which recommendations are similar? Which are different?
5. Complete a health history on an adult, including medical, family, social history, and environmental history. Based on the information collected, determine the individual's personal risk factors. Which risk factors are modifiable? Which are not modifiable? Which chronic diseases is he or she at risk for developing? What education would you provide to help the individual reduce his or her risk?

# CHAPTER 22

## *Older Adults*

*“In the end, it's not the years in your life that count. It's the life in your years.”*

—President Abraham Lincoln (1809–1865)

## **KEY TERMS**

Age dependency ratio Ageism

Aging in place Alzheimer's disease (AD) Arthritis Assisted living Beta-amyloid Case management Chronic conditions Continuing care retirement communities (CCRCs) Custodial care Elder abuse

Geriatrics Gerontological Hospice

Long-term care Nursing home Osteoporosis Palliative care Polypharmacy Respite care Senility

Tau protein Universal design

## **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Describe the global and national health status of older adults.
2. Identify and refute at least three common misconceptions about older adults.
3. Describe characteristics of healthy older adults.
4. Provide an example of primary, secondary, and tertiary prevention practices in the older adult population.
5. Identify four chronic conditions most commonly found in the older adult population.
6. Describe initial steps for reporting elder abuse.
7. Describe various types of living arrangements and care options as older adult's age in place.
8. Describe the importance of integrating palliative care into aspects of care for older adults.

# INTRODUCTION

Ms. Barbara is still in the apartment she and her husband shared for many years after they retired. At 94, Ms. Barbara tends her parakeet, Bert, and visits her neighbors regularly. Because she does not drive anymore, she orders her groceries online for delivery. Her apartment has a universal design with safety bars and a pull string for quick assistance. She loves card games and plays bridge and Scrabble regularly with others in the retirement community. Her health has had its ups and downs, but with the support of an automated pill box and frequent visits from her daughter, Ms. Barbara is able to remain independent in her apartment.

Older adults constitute a large and rapidly growing population group in the United States, one that you will join eventually. Perhaps your parents or grandparents are part of that group now. Improved medical care, advances in public health standards, and a focus on prevention have contributed to dramatic increases in life expectancy in the United States. A child born in 2016 could expect to live 78.6 years, about 30 years longer than a child born in 1900 ([Administration for Community Living, 2019b](#)). A second reason for the huge growth in the number of older adults began in 2011 as the baby boomers (people born after World War II between the years of 1946 and 1964) reached age 65. One out of four of these baby boomers will live past age 90 ([Administration for Community Living, 2019b](#)). Older adults represent 15.2% of the U.S. population or about one in every seven Americans (over 50 million); this number is expected to double by 2060, when older adults will outnumber young children.

Racial and ethnic minority populations will increase to approximately 28% of older adults by 2030 ([U.S. Department of Health and Human Services, 2020b](#)). The health status of racial and ethnic minorities of all ages lags far behind that of nonminority populations. For a variety of reasons, older adults may experience the effects of health disparities more dramatically than any other population group.

Looking forward to these changing health needs of the nation, *Healthy People 2030*, the road map for health in the United States, lists five overarching goals, all of which focus on healthy aging:

1. Attain health and wellbeing, free from preventable disease, disability, injury, and premature death.
2. Eliminate disparities, and achieve health equity for all.
3. Create environments that promote full potential for health for all.
4. Promote healthy development and healthy behaviors across all life stages
5. Engage leadership, constituents, and the public to take action

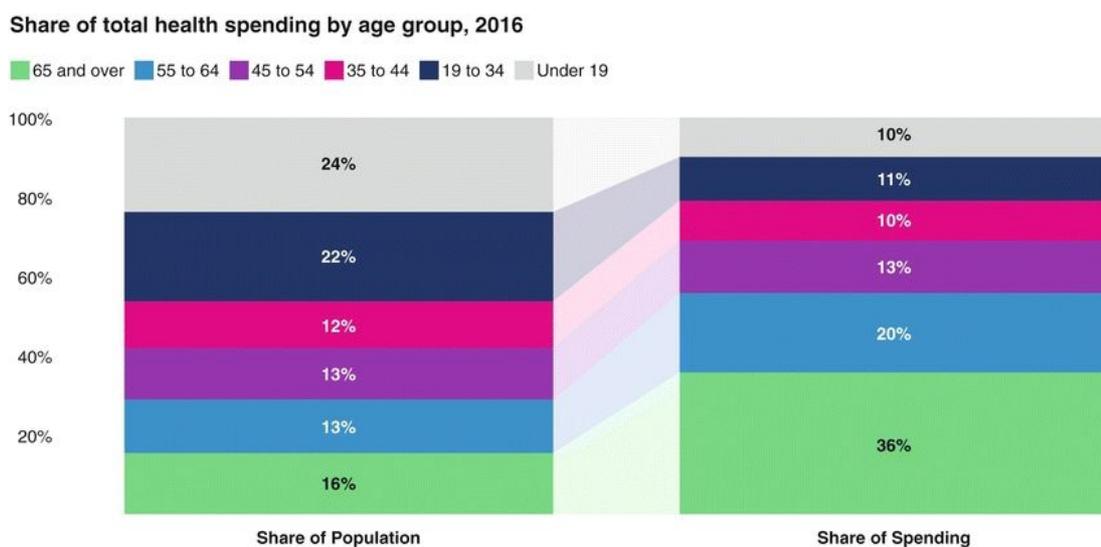

to improve health for all (ODPHP, 2020).

The future older population is expected to be better educated than the current one. The increased levels of education may accompany better health, higher incomes, more wealth, and consequently a higher standard of living in retirement.

Baby boomers bring much to the conversation about retirement, including an interest in the solvency of Medicare and Social Security programs and an interest in **aging in place** in their communities. At the end of the 2008 recession, which impacted many retirement plans, about one half of working adults aged 50 to 64 years reported that they were not prepared to retire and were delaying retirement, according to a national survey by the [Pew Research Center's \(2016\)](#).

In addition to financial preparation for retirement and older age, many older adults view marriage through a different lens than older generations before them. Given that many baby boomers are divorced or have never been married, they have a different opinion about the definition of family, including how obligated they feel about taking care of an older family member ([Reuters, 2017](#)). Single adults may not have the same preparation for retirement that married adults do.

Another factor affecting the health of the current generation of older adults is ever-rising health care costs in the United States ([Fig. 22-1](#)). These costs have a disproportionately greater impact on older adults because the cost of providing health care for an American 65 years or older is three to five times greater than the cost for someone younger ([Peterson-Kaiser Health System Tracker, 2016](#)).

**FIGURE 22-1** Share of total health spending by age group and share of the population. (Peterson-Kaiser Health System Tracker. (2016). *How do health expenditures vary across the population?*)

Retrieved from [https://www.healthsystemtracker.org/chart-collection/health-expenditures-vary-across-population/?sf\\_data=results&\\_sft\\_category=spending&sf\\_paged=2#item-whites-have-higher-health-spending-in-most-age-categories-than-people-in-other-groups\\_2016](https://www.healthsystemtracker.org/chart-collection/health-expenditures-vary-across-population/?sf_data=results&_sft_category=spending&sf_paged=2#item-whites-have-higher-health-spending-in-most-age-categories-than-people-in-other-groups_2016))

The growth of the aging population presents opportunities for public health nurses to work with communities to strengthen and expand programs and services targeted to seniors, to advocate for the needs of the aging population with government agencies and other organizations, and to assure access to quality health care services that address their unique and complex problems (United Nations, 2017).

This chapter first examines the characteristics of the aging population in the United States and the global challenge of an aging society. Ageism is discussed in the context of misconceptions about older adults. Next, the primary, secondary, and tertiary health needs of older adults are explored. Diseases common among older adults are reviewed, with a focus on Alzheimer's and other dementias. Elder abuse is reviewed with a focus on financial abuse and abuse reporting. Finally, population-based health services and nursing interventions applied to the health of the aging population are discussed in light of cost containment and comprehensive care.

# GERIATRICS AND GERONTOLOGY

Nurses trained in the specialty of gerontological nursing are needed to care for our aging population. **Gerontological** nursing encompasses all aspects of the aging process, including economic, social, clinical, psychological, and spiritual factors. Gerontological nursing focuses on promoting and improving the health of older adults. This holistic approach includes evaluating the impact of these factors on the older adult and society. Health is defined by the person and may include the ability to age in place or sustain maximum functioning.

In contrast, **geriatrics** is a medical specialty. Like other medical specialties, geriatrics focuses on abnormal conditions and the treatment and cure of those conditions. A geriatrician is a medical doctor with specialized training in geriatrics.

A C/PHN works with older adults at the individual, family, and group levels. In one instance, the nurse may work to promote and maintain the health of a vigorous 80-year-old man who lives alone in his home. However, a community/public health perspective must also concern itself with the aggregate of older adults. There are many groups of seniors with whom the nurse may choose to work, such as those who attend a memory day care center, those who belong to a retirement community, those who live in a nursing home, or members of a caregiver support group. Other groups include residents of a senior citizens' apartment building; those with cognitive, vision, or hearing impairments; homeless men and women; and veterans. Work with clients can also involve political advocacy. The possibilities for C/PHNs to work with older adults are vast and ever expanding.

# HEALTH STATUS OF OLDER ADULTS

People are living longer as a result of improved health care, eradication and control of many communicable diseases, use of antibiotics and other medicines, healthier dietary practices, safer global water supplies, regular exercise, and accessibility to a better quality of life via education and social services. Increased life expectancy reflects, in part, the success of public health interventions. However, community/public health programs must now respond to new challenges, such as the following: the growing burden of chronic illness, physical and cognitive impairments, increasing concerns about future caregiving, coordinating care across providers and settings, and rapidly rising health care costs.

Chronic diseases, often referred to as **chronic conditions**, affect older adults at a disproportionately higher rate. They contribute to disability, diminish quality of life, and increase health care costs. Two out of three older Americans have multiple chronic conditions, with treatment for this group resulting in 66% of the U.S. health care budget ([Centers for Disease Control and Prevention \[CDC\], 2017a](#)).

C/PHNs have the opportunity to address key challenges faced by the older population. They can work to meet the long-term needs of individuals with cognitive and physical impairments, coordinate care across providers, oversee the adequacy of services, and support family caregivers in the plan of care. In this way, C/PHNs can help older adults live in the communities, a more cost-effective and desirable outcome.

## Global Demographics

The unprecedented growth in the number of older adults is not limited to the United States but is happening worldwide. In 2010, an estimated 524 million people were aged 65 years or older—8% of the world's population. By 2050, this number is expected to nearly triple, to about 1.5 billion, representing 16% of the world's population ([United Nations, 2017](#)).

Life expectancy at birth around the world now is 67. A child born in Myanmar or in Brazil can expect to live 20 years longer than one born 50 years ago. And in Iran, only 1 person in 10 is currently older than 60 years, but in 35 years' time, this will change to 1 in 3 ([Beard et al., 2016](#)).

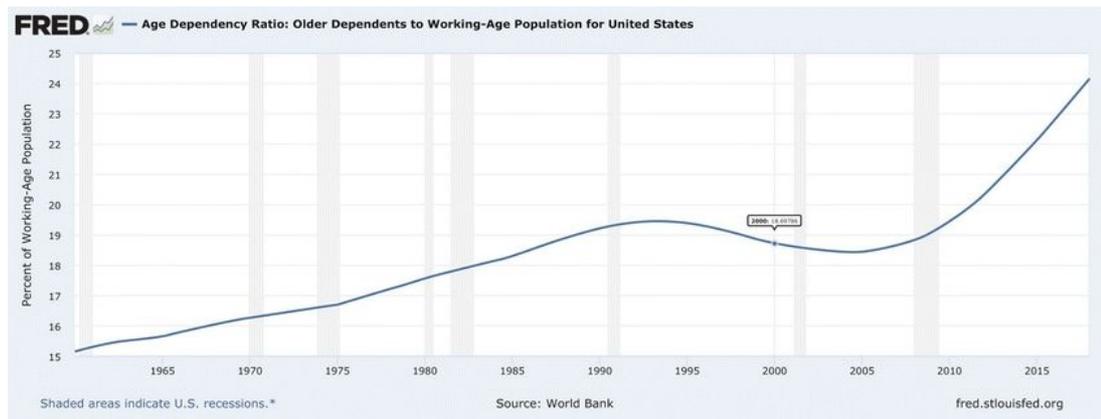

Although more developed countries have the oldest population profiles, the vast majority of older people—and the most rapidly aging populations—are in less developed countries. Between 2010 and 2050, the number of older people in less developed countries is projected to increase more than 250%, compared with a 71% increase in developed countries ([United Nations, 2017](#)).

Because of this demographic shift, along with altered societal expectations, changes in attitudes and social policies worldwide are needed. Many countries have few or no social programs, pensions, or health care services available for their older adult populations.

## National Demographics

As a result of demographic transitions, including declining infant and childhood mortality, lower fertility rates, and improvements in adult health, the shape of the global age distribution is changing. The age distribution in developed countries, such as the United States, includes a larger proportion of older adults than does the age distribution in less developed countries.

By 2025, the United States is expected to have 80% more older adults than in 2000, but the number of working-age adults will grow by only 15% (Ortman, Velkoff, & Hogan, 2014). This is often represented by an **age dependency ratio**. By looking at Figure 22-2, you can see that over the years, an increasing number of younger, working-age adults are needed to provide support for older adults (15 working-age persons for 1 older adult in 1960 vs. 23 in 2015). However, the age dependency ratio does not take into consideration that many older adults may still be working or have other sources of income.

**FIGURE 22-2** World Bank, Age Dependency Ratio: Older Dependents to Working-Age Population for the United States [SPPODPNDOLUSA]. (Retrieved from FRED, Federal Reserve Bank of St. Louis; <https://fred.stlouisfed.org/series/SPPODPNDOLUSA>, January 24, 2019. FRED® chart provided courtesy of the Federal Reserve Bank of St. Louis. © 2019 Federal Reserve Bank of St. Louis. All rights reserved.)

Despite the overall trend toward increased life expectancy, disparities exist among various subgroups in the population. Life expectancy is highest for White Americans and lowest for Black Americans, who have the highest

death rates of any of the racial and ethnic groups in the United States. The Hispanic, Black, and Asian populations have been expanding and are projected to grow substantially through 2025 (U.S. Census Bureau, 2015). Although the older population is not expected to become majority–minority in the next four decades, it is projected to be 42% minority in 2050, up from 20% in 2010 (U.S. Census Bureau, 2015).

The health status of racial and ethnic minorities of all ages lags behind that of nonminority populations. For a variety of reasons, older adults may experience the effects of health disparities more dramatically than any other population group (Box 22-1). To help address these health disparities, the Racial and Ethnic Approaches to Community Health (REACH) (CDC, 2020b) program supports community-based coalitions in the design, implementation, and evaluation of innovative strategies to reduce or eliminate health disparities among racial and ethnic minorities. The goal of REACH is to achieve health equity, eliminate disparities, and improve the health of all groups (CDC, 2020b).

### **BOX 22-1 Evidence-Based Practice**

**Health Risks Faced by Older Adults Below are three examples of research findings related to health risks faced by older adults that are relevant to community/public health nurses (C/PHNs).**

**Suicide Assessment of older adults for suicide risk is an important consideration for community health nurses and C/PHNs. Although suicide attempts are less frequent in older adult populations, the completion rate is high, with 25% of older adults, both male and female, succeeding. Nurses need to**

**understand the known risk factors for suicide, such as depression, anxiety, and bipolar disorder. However, many older adults may not have diagnosable symptoms and may not be assessed for mental illness. C/PHNs need to understand the losses that may contribute to suicidal ideation, such as the loss of a spouse or friend or physical problems with vision, hearing, or untreated pain. They should also know of key supports for older adult: supportive family and friends, spiritual practices, and connection to the community. This article discusses assessment, screening, and reducing risk by connecting clients to resources.**

**Health Complications Related to Homelessness** The proportion of homeless who are older adults is increasing by virtue of the aging of

**the general population. According to the research study indicated below, conducted in Oakland, California, one half of single homeless adults are aged 50 years or older and have the kinds of chronic conditions that typically occur in housed adults aged 75 years or older. This study considers participants who stayed in four primary environments: unsheltered, shelters, and homeless hotels, with family or friends, and in rentals following a period of homelessness. Nearly 40% had problems with at least one activity of daily living, and 25% had cognitive impairment. Many had vision and hearing problems and urinary incontinence. This study highlights the needs of older homeless adults who do not have supportive living environments to meet their needs.**

**Chronic Illness and Functional Disabilities Consider the influence of Programs that offer All-Inclusive Care for the Elderly (PACE) sites in communities and what occurs after a PACE site closed. PACE activities are organized around a day center that provides medical and social services to avoid institutionalization of older people with chronic illnesses and functional needs. Outcomes of PACE site closures lead to higher numbers of emergency department visits, hospitalizations, and nursing home placements. C/PHNs need to learn about comprehensive programs such as PACE, which can be effective in reducing health care costs.**

Source: [Diggle-Fox \(2016\)](#); [Brown et al. \(2017\)](#); [Meunier et al. \(2016\)](#).

Growth in the number of older adults will significantly affect health care resources, housing options for older adults, and national longevity statistics. As the number of older people increases, so, too, will their need for assistance with activities of daily living (ADLs) and other services, especially those persons with Alzheimer's and other dementias. Many will serve as caregivers to family members who need assistance in attending to

ADLs such as dressing, eating, toileting, and bathing, and researchers are seeking effective methods for providing respite to caregivers and reducing costs. Laws pertaining to health care and social services are being passed to better address the needs of older adults, most of whom will remain in the community. The Administration on Community Living, along with the National Family Caregivers Support Project Program (NFCSP), provides grants to states and territories to provide five types of services ([Administration for Community Living \[ACL\], 2019a](#)):

- Information to caregivers about available services
- Assistance to caregivers in gaining access to the services
- Individual counseling, organization of support groups, and caregiver training
- Respite care
- Supplemental services, on a limited basis

These services are designed to work with other state-and community-based services to provide a coordinated set of supports. Studies have shown that these services can reduce caregiver burnout and stress and keep them healthy, delaying the need for costly **assisted living** or **nursing home care** ([Administration for Community Living, 2019b](#)).

Many older adults live in poverty; over 4.5 million older adults (9%) were below the federal poverty level in 2016. This poverty rate represents a statistically significant increase from the poverty rate of 8.5% in 2013 ([Kaiser Family Foundation, 2018](#)). However, in 2017, the Supplemental Poverty Measure (SPM) from the U.S. Census Bureau, which was adjusted for regional costs of living and nondiscretionary expenses, revealed a poverty level for older adults of 14.1% (over 5% higher than the official 9% rate). This increase is mainly due to adding medical out-of-pocket expenses, which were not included in the original poverty level calculations ([U.S. Census Bureau, 2018](#)).

The education level of the older population is rising. Between 1970 and 2016, the percentage of older persons who had completed high school increased from 28% to 85%. In 2014, about 28% had a bachelor's degree or higher. Considerable racial and ethnic differences were found in the proportion completing high school (i.e., 90% of non-Hispanic Whites, 80% of Asians, 77% of African Americans, 71% of American Indian/Alaska Natives, 54% of Hispanics). In comparison, only 30% of older Whites and 9% of older African Americans had high school diplomas in 1970 ([Administration for Community Living, 2019b](#)). With higher levels of education come broader health consumerism and improved quality of life.

# DISPELLING AGEISM

**Ageism** is negative stereotyping of older adults and discrimination because of older age. These stereotypes often arise from negative personal experiences, myths shared over time, and a general lack of current information. A majority of older adults report having experienced ageism in the form of being patronized, ignored, or treated as if they were incompetent (Applewhite, 2016).

By becoming more aware of the myths and realities of older age, C/PHNs can improve the health and quality of life of the growing population of older adults. C/PHNs must guard against ageism in their practice by dispelling common myths and misconceptions (Table 22-1).

Myth	Reality
Senility: <i>It's normal for older adults to become confused, childlike, and forgetful. They become "senile."</i>	Certain parts of the brain do shrink, and some blood flow is reduced. Regardless, many older adults continue to think well. <b>Senility</b> and dementia are often equated. However, not all older adults develop dementia. Alzheimer's dementia is the most common of all dementias (Alzheimer's Association, 2020).
Rocking chair: <i>As age increases, older adults withdraw, become inactive, and cease being productive.</i>	People live longer, work later, and live well with chronic conditions. People over 50 are firing up the longevity economy with "encore careers" (AARP, 2017a).
Homogeneity: <i>As older adults age, they lose their individual differences and become progressively more alike.</i>	"Young" and "Old" are helpful when one considers living a long or a short period of time. However, despite looking different, older people feel about the same inside as they did when young. The move to slow or stop aging may not be helpful.
The old benefitting at the expense of the young: <i>Older people are pulling down the economy. We cannot afford longevity.</i>	The economy profits more from the wisdom of older workers than ever before (AARP, 2017a). Many grandparents care for their children and grandchildren, and Medicare and Medicaid keep older adults independent during the time that younger people are raising their own families. The federal government established an advisory council to help older adults raising grandchildren in the Supporting Grandparents Raising Grandchildren Act (2018). Organizations on aging concur that we can provide for health care and retirement if we use our resources wisely (Lindland, Fond, Haydon, & Taylor-Kendall, 2015).
Inability: <i>Older adults are unable to learn new things and are set in their old ways of doing things.</i>	Learning is a lifetime ability that continues into old age. Although older adults may experience some difficulty with short-term (or working) memory as they get older, their long-term memory generally remains sound. People at any age can learn new information and skills. Although some are slower to adopt technology, once older adults join the online world, they use their technology most every day (Narushima, Liu, & Diestelkamp, 2018).

The aging process among older adults is individual, subtle, gradual, and lifelong. One can see remarkable differences among individuals in the rate of aging. Even in a single individual, various systems of the body age at different rates. Therefore, chronologic age cannot readily be a reliable indicator of health needs. Methods for calculating your "real" or biological age can give you a better picture of your body's true state of health (see <http://www.biological-age.com/about.html> for a calculator you can use for yourself and your clients). For information on how to make a healthy transition into older age, see **Box 22-2**.

## **BOX 22-2 Levels of Prevention Pyramid**

**SITUATION: Making a healthy transition into a satisfying old age**

**GOAL: Using the three levels of prevention, prevent or delay chronic diseases, promptly diagnose and treat conditions, and restore the fullest possible potential.**

### **Transitioning to Older Age**

<b>Tertiary Prevention</b>		
<i>Rehabilitation</i>	<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>Adapt to changed roles with spouse and significant others.</li> <li>Maintain health while assessing increasing dependency needs, including alternative housing, modifications in transportation, and changing health care needs.</li> </ul>	<ul style="list-style-type: none"> <li>Periodically review and update will, insurances, and other important documents as needed.</li> <li>Keep beneficiaries or executors aware of changes in and location of documents and personal wishes regarding end-of-life care and funeral/burial arrangements.</li> </ul>	<ul style="list-style-type: none"> <li>Review medications, prescription and over-the-counter, on a regular basis.</li> <li>Explore and provide community resources as needs change.</li> </ul>

<b>Secondary Prevention</b>	
<i>Early Diagnosis</i>	<i>Prompt Treatment</i>
<ul style="list-style-type: none"> <li>See Chapter 21 recommendations for screenings for adults.</li> <li>Follow the U.S. Task Force Recommendations for regular screening of potential health problems (USPSTF, 2018a).</li> <li>Focus on results of the Medicare Annual Wellness Visit (Cordell et al., 2013) results or screen for cognitive impairment and depression symptoms.</li> <li>Assess for social engagement: volunteerism, faith-based activities, family, and support of others.</li> <li>Assess for caregiver health and burden levels.</li> </ul>	<ul style="list-style-type: none"> <li>Provide resources for social engagement: healthy, satisfying, and enriching activities.</li> <li>Follow up on any abnormal findings, keeping any family or caregivers informed.</li> <li>Manage vision, hearing problems.</li> <li>Provide strategies for behaviors resulting from cognitive problems.</li> <li>Provide community resources to prevent caregiver burnout.</li> </ul>

<b>Primary Prevention</b>	
<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>Begin preparations early—emotional, spiritual, and financial.</li> <li>Plan ahead for changes in health status and potential need for long-term care.</li> <li>Complete documents, such as a will and a living will.</li> </ul>	<ul style="list-style-type: none"> <li>Regularly assess health status.</li> <li>Follow the recommended schedule for immunizations of the Centers for Disease Control and Prevention (2020c; <a href="https://www.cdc.gov/vaccines/schedules/hcp/adult.html">https://www.cdc.gov/vaccines/schedules/hcp/adult.html</a>).</li> <li>Medicare Wellness visit.</li> <li>Include oral examination in routine medical and nursing visits.</li> <li>Implement a health-promoting regimen that includes diet and exercise.</li> <li>Assess living environment for comfort and safety hazards.</li> </ul>

# MEETING THE HEALTH NEEDS OF OLDER ADULTS

Many factors contribute to healthy aging, including a lifetime of healthy habits and circumstances, a strong social support system, and a positive emotional outlook. Most people recognize a healthy older person when they meet one.

What is healthy old age? Would you consider Minerva Blackstone in [Box 22-3](#) to have a healthy old age? The vast majority (94%) of older adults in the United States, even those with chronic diseases or other disabilities, are living outside institutions and are relatively independent. Good health in the older adult means maintaining the maximum possible degree of physical, mental, and social vigor. It means being able to adapt, to continue to handle stress, and to be active and involved in life and living. In short, healthy aging is being able to function, even when disabled, with the assistance of others as needed.

## **BOX 22-3 STORIES FROM THE FIELD**

**Minnie Blackstone I am a public health nurse (PHN) and live next door to Minerva Blackstone, affectionately called Minnie by her friends. Minnie is a lively 87-year-old woman who enjoys life. Every day, except in bad weather, she walks a half mile to visit her granddaughter Karen. There, she works on the quilt she is making for Karen. Twice a week, Minnie takes the city bus to the senior citizens' center to join her friends in an exercise class. Minnie has noticed that her vision and her hearing are not what they used to be. She can no longer crochet in the evening with low**

**lighting but has found a bright magnifying lamp to help her continue her hobby. As for her hearing, Karen has set up an appointment with the audiologist. Do you know how much hearing aids will cost Minnie? Will Medicare pay for them?**

Minnie is a happy person but is not content unless she is up on the latest political developments. She never misses the news and talks about current events at every chance. She has a good appetite and generally sleeps well. Minor arthritis does not hamper her activities nor does the hypertension that she controls by independently taking her medication daily. Right now Minnie is enjoying a healthy old age. What planning needs to be made for Minnie when and if her arthritis or other chronic conditions disable her?

Carole, District PHN

Wellness among the older population varies considerably. It is influenced by many factors, including personality traits, life experiences, current physical and cognitive health, current societal supports, and personal health behaviors. Areas of focus for Healthy People 2030 for older adults (USDHHS, 2020a) include the following:

- Increase physical activity for those who have reduced physical and cognitive function
- Reduce pressure ulcer–related hospital admissions
- Reduce emergency department visits due to falls
- Reduce inappropriate medication use
- Reduce hospital admissions due to diabetes
- Reduce hospital admissions for pneumonia
- Reduce hospital admissions for urinary tract infections

In 2016, the category dementias, including Alzheimer's disease (AD), was added to Healthy People 2020 topics and objectives and is in the objectives for Healthy People 2030 (USDHHS, 2020a). This chapter discusses AD in depth (see Diseases and Conditions Common in Old Age). Important steps for the care of those with dementia and their caregivers include earlier diagnosis, reduction of severity of both cognitive and behavioral symptoms, and supporting caregivers (Healthy People 2020, 2020b; USDHHS, 2020a).

Other actions that can increase healthy aging include addressing health disparities among older adults, encouraging people to plan for end-of-life care and communicate their wishes through advance directives, improving oral health and increasing physical activity among seniors by promoting environmental changes, increasing adult immunization levels, and preventing falls. Some older adults demonstrate maximum adaptability, resourcefulness, optimism, and activity. Others, often those from whom we tend to draw our stereotypes, have disengaged and present a picture of dependence and resignation. Most older adults are somewhere in between these two extremes. Although the level of wellness varies among older adults, that level can be raised.

The goals in community health nursing are to maximize the wellness potential of older adult clients and to support their highest level of functional ability. Nurses must analyze and build on an older person's strengths rather than focus on the difficulties or deficits.

# **LEVELS OF PREVENTION**

Older adults, like any age group, have certain basic needs: physiologic and safety needs, as well as the needs for love and belonging, self-esteem, and self-actualization. Their physical, emotional, and social needs are complex and interrelated. The following sections discuss these needs according to primary, secondary, and tertiary prevention activities.

## Primary Prevention

Primary prevention activities involve those actions that keep one healthy. Such primary prevention activities as health education, follow-through of sound personal health practices (e.g., flossing, seat belt use, exercise), recommended routine screenings, and maintenance of an appropriate immunization schedule ensure that older adults are doing all that they can to maintain their health.

### *Nutrition and Oral Health Needs*

People who have maintained sound dietary habits throughout their life have little need to change in old age. Adults aged 80 years and over had the lowest rate of obesity, 26.7%, from 2013 to 2016 ([Healthy People, 2020b](#)). The U.S. Department of Agriculture ([USDA, n.d.](#)) replaced the food pyramid with MyPlate as a visual to guide the food intake of Americans. Tufts University has modified MyPlate for older adults ([Fig. 22-3](#)). The modifications include an emphasis on drinking plenty of fluids, including water, tea, and coffee, and consuming a diet high in fiber. Although multivitamins are not meant to replace food as a source of nutrients, taking them as a supplement to food to achieve recommended intakes may be a good idea ([Tufts University, 2015](#)).

**FIGURE 22-3** MyPlate for older adults. (Reprinted with permission. Available at <https://hrca.tufts.edu/myplate/> (“My Plate for Older Adults” Copyright 2016 Tufts University, all rights reserved. “My Plate for Older Adults” graphic and accompanying website were developed with support from the AARP Foundation. “Tufts University” and “AARP Foundation” are registered trademarks and may not be reproduced apart from their inclusion in the “My Plate for Older Adults” graphic without express permission from their respective owners.)

It is generally believed that older people need to maintain their optimal weight by eating a diet that is low in fats, moderate in carbohydrates, and high in proteins with a daily calorie count of 1,200 to 1,600 (Fig. 22-4). Older adults need less vitamin A but more calcium and vitamin D (for healthy bones), more folic acid, and more vitamins B<sub>6</sub> and B<sub>12</sub> (for cognitive health) than younger adults. Many communities offer meals to seniors, either at senior centers or by way of Meals on Wheels, through grants provided by the Older Adult Nutrition Program ([Administration for Community Living, 2020](#)).

**FIGURE 22-4** Healthy nutrition for older adults. Preparing and eating meals should be an uncomplicated, natural process, best shared with others.

Oral health is integral to general health and wellbeing throughout one's life. Major advances in the field of oral health—including community water fluoridation, advanced dental technology, better oral hygiene, and more frequent use of dental services—have had a substantial impact on the number of older adults who retain their natural teeth. The percentage of older adults who have lost all their natural teeth has declined to 18%, surpassing the *Healthy People 2020* target of no more than 20% (CDC, 2017b). The percentage of adults aged 65 or over with a dental visit in the past year was 60.6% (CDC, 2017b). Healthy People 2030 guidelines addresses oral health and maintenance, with a focus for older adults on receiving treatment for root decay (USDHHS, 2020a).

Poor oral health has been associated with peripheral vascular disease, diabetes, and risk for death caused by pneumonia in nursing homes ([Almirall, Serra-Prat, Bolibar, & Balasso, 2017](#)). Even those with dentures must be vigilant in maintaining oral health, as they are still at risk from inflammatory processes leading to diseases such as pneumonia. Many older adults, especially those who are disadvantaged or have limited incomes, have decreased nutritional and fluid intake, changes in gums, and increased periodontal disease, as well as a higher incidence of dry mouth.

Fluid intake and oral hygiene are appropriate topics for anticipatory guidance from C/PHNs working with older adults. Take the time to assess the older adult's oral cavity, including mucosa, denture fit, and any complaints about chewing or swallowing.

In addition to maintaining a healthy diet, older adults are cautioned to limit the use of alcohol. Any person can have a problem with alcohol, and it is not unusual for older adults to have an alcoholic drink. Use of alcohol can lead to falls or car crashes ([National Institute for Aging \[NIA\], 2020a](#)). As with all adults, older persons should avoid tobacco, drink fluoridated water or use fluoride toothpaste, practice good oral hygiene, and have regular dental checkups ([CDC, 2017b](#)). They should also avoid the habitual use of laxatives, instead adding more fluids, fiber, and bulk to their diet with fresh fruits and vegetables. Also, inadequate fluid intake can contribute to bowel and bladder problems. Increased physical activity and exercise help maintain regularity of bowel function in older adults.

## *Exercise Needs*

Older adults need to exercise; in fact, they thrive when exercise is incorporated into their daily routine ([National Institute on Aging, 2020b](#)). Research demonstrates that exercise and increased physical activity have multiple benefits for the older adult, including:

- Arthritis relief, restoration of balance and reduction of falls, strengthening of bone, proper weight maintenance, and improvements in glucose control, cognitive and brain function, and overall mortality ([Macera, Cavanaugh, & Belletiere, 2017](#))
- A healthy state of mind, improved sleep, and reduced risk of heart disease ([Roitto et al., 2018](#))
- Decreased incidence of osteoporotic fractures due to a reduced risk of falling, with an exercise routine that includes activities to improve strength, flexibility, and coordination, even among the very old

The C/PHN should explore the kinds of activity that appeal to older adults, including walks. A wide variety of activities are appropriate for and benefit older adults:

- In one study, older adults who were informed about the benefits of walking walked more than those who were reminded of the negative consequences of not walking (Notthoff & Carstensen, 2017).
- Exercise may occur with others in connection with such activities as homemaking chores, gardening, hobbies, or recreation and sports.
- Resistance training (with small dumbbells or resistance bands), along with either Tai Chi or regular walking, has been shown to increase muscle strength, stability, and functional ability among seniors (Healthfinder.gov, 2020).
- Physical disabilities need not be a barrier to exercise, as there are specialized exercise programs (e.g., chair aerobics, wheelchair fitness).

## *Sleep*

Sleep is another area of focus in *Healthy People* and is important to older adults for the following reasons:

- In older adults, adequate sleep is necessary to fight off infection and support the metabolism of sugar to prevent diabetes or to work effectively and safely.
- Sleep timing and duration affect a number of endocrine, metabolic, and neurological functions that are critical to the maintenance of individual health.
- Untreated, sleep disorders and chronic short sleep are associated with an increased risk of depression, heart disease, high blood pressure, obesity, diabetes, and all-cause mortality (Gulia & Kumar, 2018).

Some changes in sleep are natural with aging, such as:

- Decreased slow-wave or deep sleep due to the body producing lower levels of growth hormone
- Altered circadian rhythms (the internal clock that tells one when to sleep and when to wake up), causing the older adult to want to go to sleep earlier in the evening
- Nighttime wakefulness and interrupted sleep due to pain, the need to void, medications, and snoring, which may worsen with age (Gulia & Kumar, 2018)

The C/PHN can assess and help older adults having sleep challenges by:

- Asking them to keep a sleep journal
- Investigating their nighttime voiding patterns
- For men, assessing for the possibility of an enlarged prostate, which can cause problems with complete bladder emptying and may need treatment

Objectives for Healthy People 2030 focus on reduction of accidents due to driving while drowsy, providing treatment for those with obstructive sleep apnea, and sufficient sleep ([USDHHS, 2020a](#)).

## *Economic Security Needs and Poverty*

Economic security is a major need for older adults. Many older adults work beyond retirement age for reasons of enjoyment and purpose, but they may also be concerned about having financial stability through the rest of their lives. Factors affecting economic security in older adults include the following:

- Having to spend retirement resources caring for elderly parents or grandchildren
- Limited income and reliance on Social Security and Supplemental Security Income, with half of all people on Medicare in 2016 having incomes of <\$26,200 ([Kaiser Family Foundation, 2018](#))

Fearing the potential cost of major illness and wanting to avoid being a burden on family or friends, many older people conserve their limited finances by practices that may threaten their health:

- Adopting frugal eating patterns
- Skipping or taking only partial doses of medications
- Limiting the use of home heating and cooling
- Spending little on themselves, in general

For older adults today who have lived many years past retirement without sufficient financial security to maintain them throughout these additional years, fears are not unfounded. More than a quarter of Hispanic older adults and nearly a quarter of Black older adults lived in poverty in 2016, compared with around 1 in 10 White adults aged 65 or older ([Kaiser Family Foundation, 2018](#)).

Many older adults are not aware that there are important preventive health measures and community-based programs that can maximize function and help older adults maintain health at a higher level ([U.S. Preventive Services Task Force \[USPSTF\], 2018b](#)). C/PHNs should be familiar with and share with their clients local support services that may provide housing, food, and utilities for older people in need, which can do much to help relieve the source of that stress and anxiety.

## *Psychosocial and Spiritual Needs*

All human beings have psychosocial needs that must be met for their lives to be rich and fulfilling. Typically, aging is seen as a time of loss and decline, and much research focuses on the physiological and psychological impact of multiple losses and decline. However, some research indicates that older adults actually pay attention to and remember positive information and memories more than younger people do ([American Psychological Association, 2020](#)). There may be biological and psychological reasons for this:

- The amygdala in the brain reacts to emotions, and biological research indicates that older adults may not react at a brain level to negative information in the way the younger adults do ([Mather, 2016](#)), meaning that they may be more likely to gather and hold onto only their good memories.
- For many, old age may be a time of life reflection, review, and reevaluation of what gives meaning and satisfaction in life. Knowing that they have limited time, older adults may choose to focus on positive emotions.

However, with a lack of healthy relationships with other people, life can be very lonely and diminished in quality for older people.

Holistic nursing is a hallmark of community and public health nursing. This means a focus on the body, mind, and spirit. The word spirit comes from the Latin meaning “breath” and refers to the core of an individual, the part that gives meaning to life ([New World Encyclopedia, n.d.](#)). Although related, religion and spirituality are distinct concepts:

- A spiritual component exists in all people but not everyone is religious.
- Religion is generally recognized to be the practical expression of spirituality or the organization, rituals, and practice of one's beliefs.
- Religion includes specific beliefs and practices, whereas spirituality is far broader.

According to the Pew Forum, belief in God continues to be very important to older adults, including the younger baby boomers, even though religious practices vary ([Pew Research Center, 2018](#)). Whereas other sources of wellbeing decline, religion may become more important over time. Individuals within different cultures have varying philosophies and practices of spirituality but derive similar positive outcomes.

Faith-based nursing is one of the community nursing roles that epitomizes this holistic approach of caring for one's clients, many of whom are older adults. See [Chapter 29](#) for an in-depth discussion of faith community nursing.

## *Coping With Multiple Losses and Suicide*

Older adults may experience multiple losses, including loss of income and purpose from a career once practiced, loss of the economic stability of employment, and loss of space due to replacement of a larger residence, where the older adult may have raised a family. The loss of a spouse after 50 years of marriage may have a huge impact on the remaining partner. Short-or long-term declines in health may result in pain or limited mobility and may necessitate multiple moves, such as a move to a child's home, a move to an assisted living facility, and a move to a skilled living facility. Repetitive losses occur as significant others, relatives, friends, and acquaintances die. There is no right or wrong way to grieve, but there are healthy and unhealthy ways to cope with the pain. Assisting older adults with handling these losses is an important role of the public health nurse. To do this, C/PHNs need to be aware of some of the facts about grief.

As [Kübler-Ross \(1969\)](#) stated in her classic work, there are five stages of grief: denial, anger, bargaining, depression, and, finally, acceptance. Inadequate coping with the compounding losses can make an older person believe that life holds no meaning. Depression may be a difficult problem for older adults. Social and emotional withdrawal can often occur, as can suicide.

- Among the risk factors for suicidal behavior in older adults are the loss of a spouse; having other mental disorders, such as dementia and depression; physical illnesses or decline; and social isolation.
- Although older populations have a much lower rate of suicide attempts than younger age groups do, the rate of completed suicide is high ([Conejero, Olie, Courtet, & Calati, 2018](#)). The rates of suicide may be underreported, given the negative stigma around suicide, especially in older adults.

Community health nurses should be observant of risk factors and be prepared to ask questions, including whether the client is suicidal, as older adults are not likely to talk about the subject ([Diggle-Fox, 2016](#)). Asking someone whether he or she is suicidal does not put the idea in the person's head. This is a myth. Most people are grateful that they have been asked. If you think someone is suicidal, do not let them be left alone; seek further services for the older adult.

Older adults who have maintained good health and developed a supportive system of family and friends have more fulfilled lives ([Fig. 22-5](#)). Churches, universities, and senior service programs often have volunteers who regularly meet with isolated seniors either in their homes or **long-term care** facilities, increasing social support for those who have no family members nearby.

**FIGURE 22-5** A supportive system of family and friends helps older adults meet their psychosocial needs.

Explore the senior services available in your community on the Internet. Good examples are the local Area Agency on Aging (AAA), the local health department, senior community centers, and the YMCA. Some counties have a senior resources guide. The Eldercare Locator, available at <https://eldercare.acl.gov/Public/Index.aspx>, can provide current information on local caregiver services and resources.

### *Maintaining Independence*

The need for autonomy—to be able to assert oneself as a separate individual—is important for all people. Independence helps to meet the need for self-respect and dignity. Older adults need to have their ideas and suggestions heard and acted upon, and they ought to be addressed by their preferred names in a respectful tone of voice. Respect for the older adult is not a strong value in American society, but it is highly valued in Asian, Italian, Hispanic, and Native American cultures. Older people represent a rich resource of wisdom, experience, and patience that is often unacknowledged in the United States.

Older adults who are in poverty, minorities, or veterans and who experience poorer health need support at home to remain independent. Communities work with local, state, and federal agencies to create programs to provide support to older adults who need assistance but want to remain in their home communities. A good example of a program supporting older veterans at home is the Veteran in Charge program in Colorado Springs, Colorado. This program allows veterans to receive community-based services to continue living in their homes as long as possible and gives them control of the who, what, when, and how much related to the care (<https://www.theindependencecenter.org/veterans/>).

## *Interaction, Companionship, and Purpose*

Baby boomers, who started to reach the retirement age of 65 in 2011, have changed the face of aging. Nearly 75% of boomers feel that full-time retirement is not for them. This may be, in part, because they are not financially prepared to live another 20 years past retirement ([AARP, 2016](#)). As the largest and healthiest aging cohort, they may also be the most engaged.

However, not everyone will be employed after the age of 65. Some may be challenged with physical or mental impairments or caring for spouses or parents. A new phrase in our language is “Grand families.” It is possible that grandparents and even great grandparents may be cutting into their own finances to care for grandchildren whose parents may have been deployed or are struggling with substance abuse.

Programs exist to support older adult caregivers. Examples include the federally supported Foster Grandparents and Senior Companions programs, which engage millions of Americans in service ([Fig. 22-6](#)). These older adults work part-time offering companionship and guidance to handicapped children, the terminally ill, and other people in need ([Corporation for National & Community Service, n.d.](#)).

**FIGURE 22-6** Volunteering can be a rewarding experience for older adults.

In cases where family and social networks have weakened, C/PHNs and others can help to improve their psychosocial health by working at individual, family, and community levels. The problem is of greatest significance for women, who outnumber men considerably in the later years and who more frequently live alone. Take time to explore skills that older

adults can do from home: letter writing, volunteer phone calling, or crafting for others who are ill.

### *Safety and Health Needs*

Safety issues are a major concern for older adults and the C/PHNs who work with them. Several areas of focus are discussed here: personal health and safety, home safety, and community safety.

Personal health and safety includes three major areas: immunizations, home safety and prevention of falls, and drug safety ([Box 22-4](#)).

## **BOX 22-4 C/PHN USE OF THE NURSING PROCESS**

**Nursing Care Plan For Community Older Adults: Example of Risk For Falls: Ms. Belmont** Ms. Belmont lives with the companionship of an elderly Dalmatian dog. She goes out with her daughter occasionally for lunch and for appointments. Generally she and her dog are at home. At 94 years old, she states that she isn't as strong as she used to be and has mentioned concern that she may trip over her dog.

### **Problem Statement**

- Fall prevention

### **Desired Outcomes**

- No falls
- No fall-related injuries
- Can demonstrate preventive measures (take up any loose rugs, remove electric cords, etc.)
- Implements strategies to prevent falls at home (e.g., coaches the dog verbally to stay in front of her walker, locks the cellar door to remind herself to avoid the stairs)

## Contributing Factors

- Altered mobility and physical impairments: osteoporosis, neuropathy, impaired balance
- Sensory and cognitive impairments: profound hearing loss, macular degeneration, mild cognitive impairment
- Sleep problems
- Home safety: dog in the way
- Environmental concerns: bathroom and bedroom setup, distance to kitchen

Nursing Interventions	Rationale
Assess for conditions that increase risk: changes in mental status; medication changes; worsening vision, hearing, or cognition; poor hydration or nutrition status.	Proper assessment is key to prevention.
Consider a safety bracelet/necklace/device to call for assistance should a fall occur.	A safety device would mitigate the risk of being independent with her companion at home.
Review the dog safety issue: is the training adequate to keep the dog out of Ms. Belmont's way?	The dog is family, supporting psychosocial needs.
Educate about medications and other fall risk issues.	Identification of drug interactions and side effects can improve safety.
Integrate Ms. Belmont's daughter into the safety planning.	The presence of family can provide an early alert system as well as protect Ms. Belmont from activities that increase her risk of falls.

## *Immunizations*

Older adults are at increased risk for many vaccine-preventable diseases. Preventable illnesses cause substantial morbidity and mortality in older patients, who tend to have more medical comorbidities and are at higher risk for complications. Acute respiratory infections, including pneumonia and influenza, are the eighth leading cause of death in the United States, accounting for 56,000 deaths annually (CDC, 2019a).

Nonetheless, vaccination rates in the United States do not meet targets for vaccination against flu and pneumonia, such as the *Healthy People 2020* target of 90%. Healthy People 2030 objectives target a reduction in hospital admissions due to pneumonia by older adults (USDHHS, 2020a). Although influenza does kill an estimated 36,000 people per year, in older adults, it is the exacerbating effect it has on other conditions (e.g., pneumonia, congestive heart failure, or chronic obstructive pulmonary disease [COPD]) that is of greatest concern (National Foundation for Infectious Diseases, 2018).

Racial and ethnic disparities exist among older adults receiving influenza and pneumonia vaccines; therefore, it is important to engage in outreach efforts to these populations, such as culturally targeting communication, reaching out to those providers serving this population, and offering vaccination clinics in underserved sections of the community. The CDC regularly updates immunization guidelines for older adults (CDC, 2020c).

Attempts to improve immunization coverage involve changing provider knowledge, attitudes, and behavior through reminders and standing orders, so that “missed opportunities” when seeing clients are prevented. Additional opportunities for vaccinating people exist beyond the primary care setting, as C/PHNs are well aware. Regardless of the site, a method for tracking and communicating vaccinations is needed so that vaccination information may be documented and shared with the elder's primary care provider.

Shingles is caused by the varicella–zoster virus (VZV); this is the same virus that causes chickenpox. Anyone who has had chickenpox can develop shingles because VZV remains in the nerve cells of the body after the chickenpox infection clears, and VZV can reappear many years later causing shingles. Shingles is a very painful localized skin rash, often with blisters. The disease most commonly occurs in people 50 years or older, people who have medical conditions that keep the immune system from working properly, or people who receive immunosuppressive drugs. A new shingles vaccine called Shingrix (recombinant zoster vaccine) was licensed by the U.S. Food and Drug Administration (FDA) in 2017. The CDC recommends that healthy adults aged 50 years or older get two doses of Shingrix, 2 to 6 months apart (CDC, 2018a ). Shingrix provides strong protection against shingles, and C/PHNs should advise clients about this vaccine.

## *Fall Prevention*

According to the CDC STEADI fact sheet, every 20 minutes an older adult dies from a fall, and one in five falls causes a serious injury, such as a head trauma or a fracture. Furthermore, fewer than half of fallers talked to the primary provider about the fall. Medicare costs for fall injuries total over \$31 billion dollars annually (CDC, 2019b). In fact, falling once can double your chances of falling again. In 2017, medical costs for falls exceeded 50 billion dollars, with Medicare and Medicaid responsible for 75% of these costs (CDC, 2017c). Although not all falls cause serious injuries, effects from falls, such as decreased mobility and excessive bleeding due to taking medications such as blood thinners, lead to additional concerns (CDC, 2017c).

Environmental hazards (e.g., lack of nonslip surfaces and handrails) and host conditions (e.g., poor vision, problems with balance) are often the causative factors in falls. Falls are a preventable problem. The CDC STEADI initiative has a toolkit that includes screening tools and other clinician and patient resources to guide you in preventing falls in older adults (2019b).

We have all heard stories about older adults who have fallen and fractured a hip and who were not wearing technology that could have helped them call for assistance, such as a pendant alert. Today, more than in any other time, older adults can be safer and more comfortable at home or in a facility as the result of smart home technology and wearable monitoring. Smart homes may include environmental, activity, and physiological sensors, with more affordable systems being developed in a rapidly expanding market (Boxes 22-5 and 22-6; Majumder et al., 2017). Smart homes have been purported as a method to safeguard senior safety through alerts and notification related to falls, first aid, and detection of unattended cooking (Wong, Skitmore, & Buys, 2017). One study looked at the use of smart home technologies in older individuals in Hong Kong. Seniors reported concerns related to confidence in the use of machines specifically, technical problems, and the inability to fix a problem. However, seniors did like automation processes such as reminders, because this reduced the need for outside assistance (Wong et al., 2017).

## **BOX 22-5 Guidelines for Assessing the Safety of the Environment**

### **Illumination and Color Contrast**

- Is the lighting adequate but not glare producing?
- Are the light switches easy to reach and manipulate?
- Can lights be turned on before entering rooms?
- Are night-lights used in appropriate places?

- Are there working flashlights close by (bedroom, kitchen, bath, living room)?
- Is color contrast adequate between objects such as a chair and floor?

## **Hazards**

- Are there throw rugs, highly polished floors, or other hazardous floor coverings?
- If area rugs are used, do they have a nonslip backing and are the edges tacked to the floor?
- Are there cords, clutter, or other obstacles in pathways?
- Is there a pet that is likely to be running underfoot?

## **Furniture**

- Are chairs the right height and depth for the person?
- Do the chairs have armrests?
- Are tables stable and of the appropriate height?
- Is small furniture placed well away from pathways?

## **Stairways**

- Is lighting adequate?
- Are there light switches at the top and bottom of the stairs?
- Are there securely fastened handrails on both sides of the stairway?
- Are all the steps even?
- Are the treads nonskid?
- Should colored tape be used to mark the edges of the steps, particularly the top and bottom steps?

## **Bathroom**

- Are grab bars placed appropriately for the tub and toilet?
- Does the tub have skid-proof strips or a rubber mat in the bottom?
- Has the person considered using a tub seat?
- Is the height of the toilet seat appropriate?
- Has the person considered using an elevated toilet seat?
- Does the color of the toilet seat contrast with surrounding colors?
- Is toilet paper within easy reach?

## **Temperature**

- Is the temperature of the room(s) comfortable?
- Can the person read the markings on the thermostat and adjust it appropriately?
- During cold months, is the room temperature high enough to prevent hypothermia?
- During hot weather, is the room temperature cool enough to prevent hyperthermia?

## **Overall Safety**

- How does the person obtain objects from hard-to-reach places?
- How does the person change overhead light bulbs?
- Are doorways wide enough to accommodate assistive devices?
- Do door thresholds create hazardous conditions?
- Are telephones easily accessible, especially for emergency calls?
- Would it be helpful to use a cordless portable phone or a cellular phone?
- Would it be helpful to have some emergency call system available?
- Does the person wear sturdy shoes with nonskid soles?
- Are smoke alarms present and operational?
- Is there a carbon monoxide detector (if the house has gas appliances)?
- Does the person keep a list of emergency numbers by the phone?
- Does the person have an emergency exit plan in the event of fire?

## **Bedroom**

- Is the height of the bed appropriate?
- Is the mattress firm at the edges to provide enough support for sitting?
- If the bed has wheels, are they locked securely?
- Would side rails be a help or a hazard?
- When side rails are in the down position, are they completely out of the way?
- Is the pathway between the bedroom and bathroom clear of objects and adequately illuminated, particularly at night?
- Would a bedside commode be useful, especially at night?
- Does the person have sufficient physical and cognitive ability to turn on a light before getting out of bed?
- Is furniture positioned to allow safe use of assistive devices for ambulation?
- Is a telephone situated near the bed?

## Kitchen

- Are storage areas used to the best advantage (e.g., are objects that are most frequently used in the most accessible places)?
- Are appliance cords kept out of the way?
- Are nonslip mats used in front of the sink?
- Are the markings on stoves and other appliances clearly visible?
- Does the person know how to use the microwave oven and other appliances safely?

## Assistive Devices

- What assistive devices are used?
- Is a call light available, and does the person know how to use it?
- Would the person benefit from any assistive devices that are not being used?
- Are assistive devices being used safely and properly, or do they present additional hazards?

Source: [Miller \(2019\)](#).

## BOX 22-6 QSEN: Focus on Quality

### Safety for Older Adults

**Safety:** *Minimizes risk of harm to patients and providers through both system effectiveness and individual performance (Cronenwett et al., 2007, p. 126).*

(See [https://qsen.org/competencies/pre-licensure-ksas/#quality\\_improvement](https://qsen.org/competencies/pre-licensure-ksas/#quality_improvement) for the knowledge, skills, and attitudes associated with this QSEN competency.) Nurses must deliver safe and effective care. Not only must they be vigilant in the safety of the care they provide, they are also tasked with proving a safe environment for the patient. In the community setting this can be difficult, because patients and families may need assistance or education regarding home safety. C/PHNs may be able to identify issues or concerns based on home visits and discussions with patients and their families and are positioned to provide support and education.

For example, a C/PHN working in a metropolitan city makes a home visit to Margaret, a 90-year-old woman living alone, following her hospitalization for a fall. The nurse discovers that despite using a walker, “Maggie” is spry, alert, and attentive. In the 900-square-foot home, the nurse notes many small rugs scattered around and furniture cluttered within every

room, limiting walking space. Maggie states that she has lived in this house for 70 years and is not moving. The daughter is present for the home visit, and the son lives two blocks away; both check in on their mother daily.

1. *What risks are presented in this situation?*
2. *How would you address safety for the patient and her family?*

Source: Cronenwett *et al.* (2007); Dolansky and Moore (2013).

Risk factors for falls include (CDC, 2017c, para, 4) the following:

- Difficulty with walking and balance
- Vitamin D deficiency
- Medications that effect balance such as tranquilizers, sedative, or antidepressants
- Vision problems
- Poor footwear
- Hazards such as throw rugs, clutter, and uneven steps

## *Medications*

Medications are often prescribed to control the effects of chronic conditions. A significant safety issue for the older adult arises from the use of prescription and over-the-counter (OTC) drugs. Problems can arise from a single difficulty or a combination of issues such as:

- Number of medications taken daily
- Absorption rate of medications
- Drug interactions
- Side effects

In addition, the more medications taken daily, the higher the rate of nonadherence to the schedule (Chou, Tong, & Brandt, 2019). This problem is compounded when older adults have visual or cognitive impairments. Older adults often have multiple chronic diseases for which they take prescription medications. It is not unusual for older people to be taking four to six medications daily. The use of multiple drugs, called **polypharmacy**, is defined as using from 5 to 10 prescription drugs (Golchin, Frank, Vince, Isham, & Meropol, 2015). For example, an older adult with two chronic diseases, such as heart failure and COPD, is likely to take more than five medications.

Older adults often receive multiple prescriptions from multiple providers and sometimes from multiple pharmacies, including mail-order pharmacies. They are less likely to see the pharmacist in person, and these circumstances put older adults at risk of receiving the same or similar medications in error. For example, an older adult living in the community has arthritis and heads

to the pharmacy for pain management. Many of the pain medications the older adult considers contain acetaminophen (Tylenol). However, this older adult is already taking prescribed pain medication that contains acetaminophen and thus is at risk of overdosing.

Medication side effects or drug interactions can lead to falls and further disability. Older adults need education about the drugs they take and their possible effects. They also need proper supervision of their overall medication intake, including complementary and alternative therapies (e.g., herbal treatments) and OTC drugs. It is also important for all seniors to keep a list of their current medications and doses and to have this available in the event of an emergency. This is an area in which the community health nurse can intervene very effectively (Box 22-7).

## **BOX 22-7 Preventing Polypharmacy in Older Adults Below are some strategies you can use to help patients reduce the risk of polypharmacy.**

### **Recommendations**

- Use the correct medication, at the correct dose, and for the shortest duration.
- AMOR
  - Assess medications and review for interaction.
  - Minimize nonessential medications.
  - Optimize by noting duplication.
  - Reassess patient for function, cognition, clinical status, and medical adherence.
- *Start low and go slow* is recommended for medication prescriptions of older adults.

### **Nurse's Role**

- Look for duplications in drugs—same category or drug classification.
- Are the medication dosages therapeutic?
- Are there any interactions such as drug–drug, drug–food, or drug–disease?
- Are any nondrug therapies being used?

Source: [Smith and Kautz \(2018\)](#).

Research evidence indicates that polypharmacy in older adults is being addressed by the use of appropriate screening tools such as the Beer's criteria and STOPP Screening tool (<https://consultgeri.org/try-this/general-assessment/issue-16>). C/PHNs can help by doing a thorough medication review with older adults (Box 22-7).

## *Safety in the Community*

Safety can involve many things, such as pedestrian and driving issues, crime and fear of crime against older adults, and environmental factors such as sun exposure, pollution, heat, and cold.

Because of age-related changes in vision, hearing, and mobility and the effects of polypharmacy, older adults are at risk in the community as pedestrians and as drivers. Automobile crashes and pedestrian injuries can be life-threatening events when elders are involved. As pedestrians, older adults must be increasingly vigilant to traffic patterns, sidewalk irregularities, and the possibility of being a victim of street crime.

Often out of necessity and pride, older people may drive longer than their abilities permit. The C/PHN may recommend resources for families who need to talk about driving safety <https://www.aarp.org/auto/driver-safety/we-need-to-talk/> (AARP, n.d.).

Although many older adults are fearful of being victims of crime, rates of nonfatal violent crime and property crime against the elderly are lower than in all younger age groups. See Box 22-8 for actions the C/PHN can take to assist elders with a fear of crime.

### **BOX 22-8 Simple Steps to Prevent Crime and Identity Theft**

- Never open the door automatically; always keep doors and windows locked.
- Use neighborhood watch to keep an eye on your neighborhood.
- Don't leave notes on the door when going out.
- Let someone know when you are away and cancel deliveries.
- Keep the lights on at night and use a timer.
- Keep an inventory of serial numbers and photographs of valuable items; keep copies in a safe place.
- Ask for proper identification of delivery persons or strangers. Do not let a stranger in your home.
- Never give out information on the phone letting someone know you are alone.

- Use direct deposit as much as possible, and keep valuables in a safe deposit bank box.
- Be wary of unsolicited offers to fix your home. It could be a scam. If it happens, report it to the police right away.

## Secondary Prevention

Secondary prevention focuses on early detection of disease and prompt intervention (see [Chapter 1](#)). Much of the C/PHN's time is spent in educating the community on preventive measures and positive health behaviors. This includes encouraging individuals to obtain routine screening for diseases such as hypertension, diabetes, or cancer, which, if identified early, can be treated successfully. Many nurses, working in collaboration with community agencies, are in positions to establish screening programs based on the desires and demographics of the community and agency focus, making them accessible to the population being served.

Older adults need to be encouraged to follow the routine health screening schedule prescribed by their clinic or health care provider. See [Chapter 21](#) for information on adult screenings (see <http://www.cdc.gov/vaccines/schedules/hcp/imz/adult.html> for a recommended immunization schedule for older adults).

### *Diseases and Conditions Common in Old Age*

Four of five older adults experience at least one chronic condition, and many suffer multiple chronic conditions as they progress into older age. Cardiovascular disease, cancer, diabetes, and obesity are common to all adults and are discussed in depth in [Chapter 21](#). AD is covered in this chapter as a disease of older adults, as well as arthritis, sensory loss, depression, and osteoporosis. Common chronic conditions seen in older adults are as follows:

- Alzheimer's disease
- Arthritis
- Cardiovascular disease
- Depression
- Diabetes
- Hearing loss
- Obesity
- Osteoporosis

The prevalence of chronic disease and resulting disability in older adults require health promotion behaviors and guidance. [Chapter 21](#) covers appropriate preventive services recommended for older adults (see Screenings and Checkup Schedule for Women and Men in on [thePoint](#) of [Chapter 21](#)).

### *Alzheimer's Disease*

- **Alzheimer's disease (AD)** is the most common form of dementia in older adults, first described in 1907 by Dr. Alois Alzheimer, who depicted many of the symptoms that are now known as Alzheimer's dementia. AD is the sixth leading cause of death and the only disease among America's top 10 that cannot be prevented or cured.
- Ethnically diverse older adults face a higher risk: African Americans are twice as likely and Hispanics one and one-half times more likely to develop AD than Whites (Mayeda et al., 2016).

Although much is still unknown about this devastating age-related disease, the Alzheimer's Association (AA, 2020a) annually releases a report of the current scientific findings. To identify AD, a comprehensive examination is needed (see Box 22-9). AD causes more deaths than breast and prostate cancer combined. Yet less than half of those diagnosed with AD or their caregivers report being told of their diagnosis, in contrast to 90% of persons with any of the four most common types of cancer being told.

**BOX 22-9 Annual Cognitive Assessment**  
Although there is no single test to identify Alzheimer's disease (AD) (AA, 2020b), annual cognitive assessment recently became a mandatory component of the Annual Wellness Visit (AWV) required for all Medicare and Medicaid enrollees (Borson et al., 2013; Scott & Mayo, 2018). It is recommended that health care providers offer a comprehensive examination during this AWV (Wiese & Williams, 2015). A complete health and family history—including cognitive, behavioral, and psychiatric, physical exam, lab tests, neurologic, functional, and mental status

**assessments—are essential. A comprehensive assessment is needed because many conditions, including some that are treatable or reversible (e.g., thyroid disease, depression, brain tumors, drug reactions), may cause dementia-like symptoms.**

C/PHNs are well positioned to initiate a discussion about memory with their clients and family members as the first step of assessment for cognitive decline, followed by a brief 5-minute screening using one of several methods recommended by an AA workgroup (Cordell et al., 2013; Scott & Mayo, 2018), such as Borson's (2013) MiniCog, which involves a clock-drawing test and recall of three words. Another tool is the Quick Dementia Rating Scale (Galvin, 2015), which asks family members 10 questions regarding the client's functional ability; the patient's responses give a clear indication of dementia risk. If an AD diagnosis is given, the nurse can provide anticipatory guidance on managing potential behavior changes and help the family to plan for future care needs. Early and accurate diagnosis could save up to 7.9 trillion in care costs by 2050 (AA, 2020b).

Dr. Lisa Wiese, Assistant Professor, Florida Atlantic University

Between 2017 and 2025, every state is expected to see at least a 14% rise in the AD prevalence (AA, 2020b). Because of this growth, *Healthy People 2020* designated dementias, including AD, as a focus area ( *Healthy People 2020, 2020c* ). *Healthy People 2030* guidelines highlight the need for early identification, reduction in preventable hospitalizations, and communication with a provider regarding care and treatment (USDHHS, 2020a).

The occurrence of AD is not a normal development in the aging process. Damage to the brain from AD can begin 20 years prior to the onset of symptoms (AA, 2020b). One of the major contributors to AD is the slow accumulation of “plaques and tangles” that interfere with brain function. A concentration of **tau proteins** result in tangles and block the transport of essential nutrients inside the neurons. Plaques result from an excess amount of **beta-amyloid**, which are thought to interrupt the neuronal communication at brain synapse. The increased presence of tau proteins and beta-amyloid activates the production of microglia, which are charged with clearing these

toxins. Unfortunately, the microglia are overwhelmed by the amount of proteins and debris left by dying cells, and a harmful chronic inflammatory response ensues. The result is even more cell death and brain atrophy. Another contributor to decreased brain function is the consequent decreased ability of the brain to metabolize its main fuel, glucose. Persons with diabetes and cardiovascular disease were recently found to have a higher risk for AD and related dementias (ADRD). This led to the additional findings that a combination of a person's health, environmental factors, and lifestyle choices in addition to age-related and genetic factors influence the onset and progression of AD (AA, 2020b).

- There is a simple means of describing the difference between the normal forgetfulness of aging and AD. We may forget where we have placed our keys, but upon finding them, we remember why we needed the keys, whereas a person with AD loses immediate recall.
- People in the preclinical Alzheimer's stage eventually notice that they are forgetting recent activities or events, or names of familiar things or people (AA, 2020b).
- In the mild stage, persons may be able to work, drive, and participate in well-known activities but may become lost or forget commonly used words. A typical sign of Alzheimer's is the difficulty in creating new memories, as the limbic system where memories are stored is often the area affected first by beta-amyloid plaques and neurofibrillary tangles.
- As the disease advances, the symptoms become serious enough to cause people with AD or their family members to recognize that things are “not right” and that help is needed. The moderate stage is characterized by struggles to complete routine tasks, wandering, and behavior and personality changes. Persons may become agitated, experience paranoia, and begin to lose the ability to complete ADLs.
- Persons in the severe stage of Alzheimer's dementia become bedbound and cannot communicate in words that can be understood by others (AA, 2020b).
- On average, a person with AD lives 4 to 8 years after diagnosis but can live as long as 20 years, depending on other factors (AA, 2020b). Contrary to the myth, persons with AD are still the same person they once were, but their current reality is different.

Several medications have been approved for use with persons diagnosed with Alzheimer's dementia. Medications called cholinesterase inhibitors are prescribed for mild to moderate AD. Memantine is prescribed for moderate to severe stages, often in combination with donepezil. However, these drugs only delay the progression of symptoms for a limited time. At best, available medications “turn back the clock somewhat” with the disease worsening at a

slower rate, or the drugs control some of the client's behaviors that jeopardize safety, thereby promoting caregiver management.

How does this disease impact the role of the C/PHN? First, the C/PHN can conduct family teaching regarding health behaviors that may reduce the risk of ADRD, such as staying active, exercising, healthy eating habits, adequate sleep, and managing cardiovascular risk factors (diabetes, smoking, obesity, and hypertension (AA, 2020b)). The C/PHN can stress the importance of completing the Medicare Annual Wellness Visit, including routine cognitive screening to detect early signs and symptoms of MCI, which provide the opportunity to investigate other possible causes of decline. Early detection benefits also include the following:

- Effective management of coexisting conditions
- Appropriate use of available treatment regimens and holistic modalities
- Pursuing health-promoting activities; brain games, exercise, improved nutrition, and sleep patterns
- Coordination of care between all members of the health care team, including providers and caregivers
- Encouraging the client and family to participate in activities that bring joy/are meaningful
- Accessing support services, day centers, and caregiver support groups

Learning about the illness and ADRD management that will decrease care costs is essential, where nearly one in every five Medicare dollars is spent. Average per person Medicare spending for those with ADRD is three times higher than average per person spending across all other seniors. Medicaid payments are 19 times higher (AA, 2020b). These 2018 figures did not include caregivers, who provide 83% and over 18 billion hours of unpaid care to those with ADRD, valued at \$232 billion (Black et al., 2018).

- The person with dementia often exhibits depression, agitation, sleeplessness, and anxiety, which disrupt the caregiver's normal routine, greatly adding to caregiver stress. Caregiver burden is multiplied by new or worsening illness, creating a further demand on health care resources. Caregivers experience twice the rate of anxiety and depression as other caregivers (Zhu et al., 2015).
- In many situations, the main caregiver is an aged spouse. The C/PHN can make a difference in health outcomes for both the person with ADRD and their caregiver by helping to connect families to community resources (Box 22-10).

## **BOX 22-10 C/PHN Use of the Nursing Process Resources for Managing**

# Alzheimer's Disease Assessment

Mr. and Mrs. Boxwell are in their early 80s and have lived modestly on a fixed income since Mr. Boxwell's retirement. However, their budget has been strained this year as they have had \$300 to \$400 a month in out-of-pocket expenses for prescription medications. Mrs. Boxwell confessed to you (the C/PHN visiting them after receiving a referral from the senior center) that during some months, they will skip medication doses to “make ends meet.” Mrs. Boxwell is diabetic, Mr. Boxwell has heart failure, and they both take medications for hypertension. They live in a small, older home, and their older model car is seldom driven as they report “the traffic is getting worse” and they have “come close to having a car crash two times” lately. They are receptive to your suggestions and are trying to stay healthy and independent.

## Problem Statements

1. Health status altered as a result of insufficient finances to purchase needed medications for chronic diseases
  2. Altered safety and diminished driving skills
- Plan and Implementation

### *Problem Statement 1*

The C/PHN will explore the clients' eligibility for Medicare Part D and Medicaid. It is possible that these clients are eligible, yet unaware of these programs. The nurse will look at Benefits CheckUp, a service of the National Council of Aging that has information on benefits programs for older adults ([benefitscheckup.org](http://benefitscheckup.org)).

The C/PHN will consult with the clients' primary health care provider and ask for a change in prescriptions from brand names to generic. Also, ordering some medications in larger doses that come in scored tablets may be less expensive, and the client can safely break the larger pills in half. Mrs. Boxwell will check with her present distributor of diabetic supplies about getting larger quantities, generic brands of syringes, alcohol pads, *etc.*

### *Problem Statement 2*

Mr. Boxwell will look into selling the car and exploring the bus schedule and other senior shuttle services that can be used to travel to the doctor and grocery store. Mr. and Mrs. Boxwell's daughter spends a day with them monthly and takes them wherever they want to go, as long as it is “a fun outing,” and they will look into coordinating errands with her.

## Evaluation

The couple is eligible for Medicare Part D, and this will help defray the out-of-pocket costs for medications. They have reduced medication costs as much as possible and report not missing any prescribed medications.

They sold their car and are negotiating the bus in good weather and using a taxi in the winter or when it is raining (they figured they save \$1,000 a year in auto insurance, auto maintenance, and gasoline, whereas the bus and taxi cost them about \$22 a month).

Because the couple is receptive to the help you have provided, you initiate a discussion regarding their long-term plans for housing needs as they get older. They are not opposed to a senior housing option and have been talking about it with their daughter. They are going to talk with a realtor about selling their house, explore some senior apartments with their daughter on her monthly visits, and review their budget.

## *Arthritis*

- **Arthritis** encompasses more than 100 diseases and conditions that affect joints, surrounding tissues, and other connective tissues and is the leading cause of disability for adults in the United States ([CDC, 2018b](#)).
- Types of arthritis include osteoarthritis (OA), rheumatoid arthritis (RA), gout, and fibromyalgia. With OA, the number of cartilage cells diminishes, cartilage becomes ulcerated and thinned, and subchondral bone is exposed. The bony surfaces rub together resulting in joint destruction with subsequent pain and stiffness ([National Institute of Arthritis and Musculoskeletal and Skin Diseases \[NIAMS\], 2019](#)).

Gentle exercise is helpful for clients with OA, following treatment for pain. Acetaminophen is the first drug of choice; however, clients often find a combination of medications and daily routines that helps them the most. The nurse can best assist these clients by assessing the safety of a particular regimen and suggesting treatment changes as new research becomes available: new medications, surgical options for joint replacement, and dietary changes, such as vitamins and foods high in essential fatty acids ([NIAMS, 2017](#)).

RA is a progressive chronic condition that begins during young adulthood and becomes disabling as the disease continues, attacking tissues of the joints and causing systemic damage in the later years ([NIAMS, 2017](#)). This form of arthritis is an autoimmune disease that causes inflammation, deformity, and crippling. RA is treated with anti-inflammatory agents, corticosteroids, antimalarial agents, gold salts, and immunosuppressive

drugs. Joint discomfort is often relieved by gentle massage, heat, and range-of-motion exercises.

The C/PHN needs to be aware of the major differences between these two prevalent forms of arthritis. Recommended treatments, including physical therapy, diet, and medication, change as more evidence-based research is conducted on arthritis (NIAMS, 2017).

## *Depression*

Depression is not a normal part of growing older, yet it is common among older adults (CDC, 2017d). Health care providers can miss depression and mistake it for a natural response to grief/loss or illness.

The nurse needs to keep in mind the many potential causes of depression. Medical conditions, such as stroke, cancer, vitamin B<sub>12</sub> deficiency, diabetes, chronic pain with dependence on prescription painkillers, or insomnia, may lead to depressive symptoms. Many prescription drugs can trigger or exacerbate depression. These include blood pressure medications, sleeping pills, calcium channel blockers, ulcer, and pain medications. Screening for depression is within the scope of responsibility of the C/PHN. The Geriatric Depression Scale (GDS) is available and revised for 2019 (<https://consultgeri.org/try-this/general-assessment/issue-4.pdf>).

C/PHNs can help elders prevent the overwhelming signs and symptoms of depression related to losses by working with community groups. Through senior centers, adult housing units, senior day care centers, or men's and women's groups at religious centers, the C/PHN can meet with seniors to offer support, teach strategies to improve the quality and quantity of support systems, invite mental health speakers to discuss the topic of depression prevention, and generally assess the holistic health status of the elders in that setting.

## *Osteoporosis*

**Osteoporosis** is a disease of aging bone in which the amount of bone is decreased and the strength is reduced. Osteoporosis means “porous bone,” meaning that the condition enlarges the holes, and the bones become brittle.

- Researchers estimate that one in five women in the United States has osteoporosis and that half of the women over 50 will have a fracture of the hip, wrist, or vertebrae; it is considered a major public health threat for approximately 44 million U.S. adults over age 50 (International Osteoporosis Foundation, n.d.).

Proper diet and weight-bearing exercise throughout life are now recognized as the most effective measure to maintain bone health. There is

growing evidence that calcium and vitamin D supplementation can help lower rates of fractures and reduce bone loss in the elderly. Higher protein intake may also help prevent bone loss ([International Osteoporosis Foundation, n.d.](#)). There are many FDA-approved drugs to treat osteoporosis that can be prescribed by a primary care provider. Therefore, identification of risk factors and regular screenings is essential to prevent the progression of this debilitating disease ([International Osteoporosis Foundation, n.d.](#)).

## *Sensory Loss*

Older adults complain about losing their “taste buds” and have deficits in smell. This is why it is not unusual for older adults to over-salt their food or reach for sweet foods they can taste.

- The prevalence of hearing loss (as high as 75%) and vision impairments (18%) is high in adults >70 years old ([Correia et al., 2016](#)). Most hearing loss happens slowly over time, and the older adult may not recognize their hearing problem. These losses of hearing and vision are correlated with depression, social isolation, physical function, cognitive impairment, and quality of life ([Contrera, Wallhagen, Mamo, Oh, & Lin, 2016](#)).

C/PHNs can assess for hearing and vision loss using simple tests. For vision, a simple reading of text from a book or newspaper with glasses can suffice. Problems like macular degeneration or glaucoma can cause blindness and need medical care, while presbyopia can be solved with drugstore readers. For hearing, check to see if the older adult uses well-fitted hearing aid, and that they have a good supply of batteries. A family member may be able to supply information about how well the older adult is hearing, but a referral to a clinic may be helpful. Cost for hearing aids is significant in the decision for improvement of hearing. Some amplification help can be found with smartphone application or necklace type amplifiers. But these and hearing aids are not yet paid for by Medicare ([Contrera et al., 2016](#)) and can be quite expensive. Medicaid will pay for some hearing solutions, should the older adults have dual eligibility.

## Tertiary Prevention

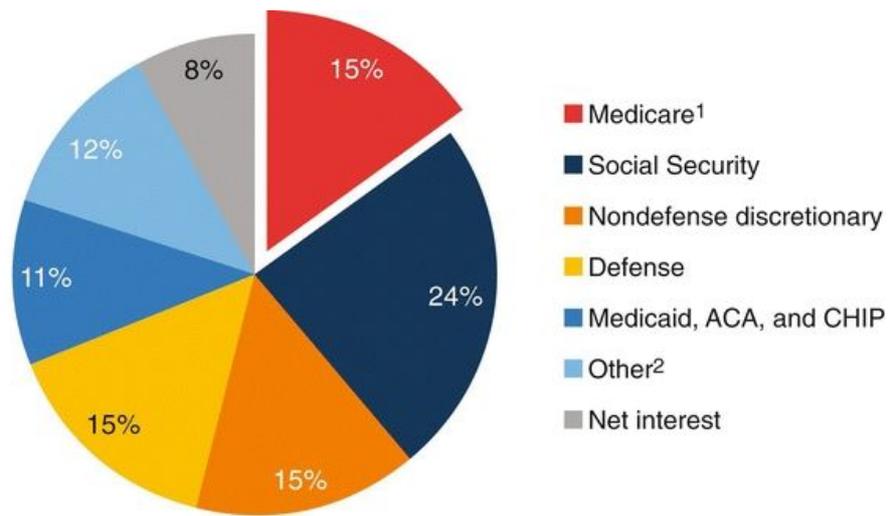

Tertiary prevention involves follow-up and rehabilitation after a disease or condition has occurred or been diagnosed and initial treatment has begun. Chronic diseases that are common among older adults, such as heart failure, stroke, diabetes, cognitive impairment, or arthritis, cannot always be prevented but can frequently be postponed into the later years of life through a lifetime of positive health behaviors. However, when they occur, the debilitating symptoms and damaging effects can be controlled through healthy choices encouraged by the C/PHN and recommended by the primary care practitioner.

- Although many older adults are considered generally healthy, 80% have at least one chronic condition and 50% have at least two ([National Council on Aging \[NCOA\], 2018](#)).
- A small proportion suffer more disabling forms of disease, such as COPD, cerebral vascular accidents (CVAs), cancer, or DM, with some requiring extensive care and ongoing medical management.

Heart disease and cancer pose their greatest risks as people age, as do other chronic diseases and conditions, such as stroke, chronic lower respiratory diseases, AD, and diabetes. Influenza and pneumonia also continue to contribute to older adult deaths among older adults, despite the availability of effective vaccines. While the risk for disability from disease clearly increases with advancing age, poor health is not the inevitable outcome of aging. Many older adults manage chronic conditions well throughout the remainder of their lives.

# HEALTH COSTS FOR OLDER ADULTS: MEDICARE AND MEDICAID

As the number of older adults grows, so do costs for health care (see [Chapter 6 Medicare and Medicaid](#)). Older adults generally pay about 13% of health care from out of pocket, and the rest comes from insurances, especially Medicare. There is a concern that older adults, especially those with low incomes, will have much higher out-of-pocket costs ([Hatfield, Favreault, McGuire, & Chernew, 2018](#)). See [Figure 22-7](#) for total federal outlays for Medicare spending in 2017. With the addition of Social Security, Medicaid, ACA, and CHIP, half of the pie is spent annually ([Kaiser Family Foundation, 2017](#)).

Total Federal Outlays, 2018: \$4.1 trillion  
 Net Federal Medicare Outlays, 2018: \$605 billion

NOTE: All amounts are for federal fiscal year 2018.<sup>1</sup> Consists of mandatory Medicare spending minus income from premiums and other offsetting receipts.<sup>2</sup> Includes spending on other mandatory outlays minus income from offsetting receipts. ACA is Affordable Care Act. CHIP is Children’s Health Insurance Program.  
 SOURCE: KFF analysis of federal spending from Congressional Budget Office, The Budget and Economic Outlook, 2019 to 2029 (May 2019).

**FIGURE 22-7** Total Federal outlays for Medicare Spending in 2018. (Reprinted with permission from the Kaiser Family Foundation. Retrieved from <https://www.kff.org/medicare/issue-brief/the-facts-on-medicare-spending-and-financing/#:~:text=Medicare%20spending%20was%2015%20percent,same%20as%20the%202018%20projection>)

Medicare or Medicaid does not cover all health care costs for older adults. It is predicted that by 2050, the numbers of older adults, especially those over 85 years of age and those with cognitive impairment, will need support with ADLs. Most of care is done by informal unpaid caregivers. This is often done at a heavy physical and financial cost, including lost opportunities for employment, health insurance, and retirement savings. Services for older adults are very expensive.

## Medicare

Although Medicare does cover many services for older adults, there can be significant out-of-pocket costs. Some are surprised that Medicare does not cover long-term or custodial care, most dental care and dentures, eye examinations for prescribing glasses, and hearing aids and examinations ([Medicare.gov](https://www.medicare.gov), n.d.).

Medicare Part A covers inpatient care and rehabilitation expenses, hospice care services, and some home health care services. Hospitalizations and rehospitalizations are a significant expense for the Medicare program. A major theme of health care reform was the prevention of hospitalizations by providing more supportive care at home.

Medicare Part B covers outpatient and primary care visits. When enrolling for Medicare Part B, older adults will pay 20% of the monthly expenses. Medicare premiums for medical insurance (Part B) are \$11,608 per person per year for most beneficiaries and are higher for those with incomes above \$85,000 ([Medicare.gov](https://www.medicare.gov), 2018). See [Chapter 6](#) for more details on Medicare.

## Medicaid

Although the majority of people enrolled in Medicaid are children and families, most Medicaid spending goes for services provided to people aged 65 years and over and people with disabilities ([Kaiser Family Foundation, 2018](#)) (see [Fig. 22-7](#)).

Most people believe that Medicaid is a program for the poor, whereas Medicare is for those who are financially secure. In FY 2010, 14% of all Medicaid beneficiaries—9.6 million—were “dual eligible” seniors and younger persons with disabilities who are covered by Medicare as well. One of every five Medicare beneficiaries is a dual eligible client. Dual eligible beneficiaries are very poor, and many have high health and long-term care needs. Medicaid assists them with their Medicare premiums and cost sharing and covers full Medicaid benefits for a large majority of them—most importantly, long-term services and supports at home or in a care facility, which Medicare does not cover ([Kaiser Family Foundation, 2018](#)). See [Chapter 6](#) for more details on Medicaid.

# ELDER ABUSE

**Elder abuse** or mistreatment (i.e., abuse and neglect) is defined as intentional actions that cause harm or create a serious risk of harm to a vulnerable elder by a caregiver or another person who stands in a trust relationship with the older adult.

Signs of elder abuse may be missed by professionals working with older adults because of lack of training on elder mistreatment or lack of reporting. In addition, older adults themselves may be unwilling to speak up for fear of retaliation, physical inability to report, cognitive impairment, or they do not want to get the abuser (90% of whom are a family member) in trouble. See [Chapter 18](#) for comprehensive discussion of all types of elder abuse and mistreatment.

It is notable that financial abuse often accompanies one of the other forms of abuse (see [Box 22-11](#)). The financial abuse of seniors is a growing problem, often called the “crime of the 21st century.” A senior can be financially stable and living independently and may suddenly become destitute and forced out of the home as a result of financial abuse. The most common perpetrators of elder abuse are spouses or partners of elders, often in a relationship with long-term domestic violence. Family members account for 76% of reported mistreatment. Abusers, particularly adult children, are often dependent on the victim for financial assistance, housing, or because of personal problems such as mental illness, alcohol, or drug abuse ([NIA, 2020c](#)).

Various state, local, and county agencies investigate and enforce elder abuse laws. The first agency to respond to a report of elder abuse in most states is APS. In some states, certain professionals are required or encouraged to report elder abuse; there are generally doctors and nurses, psychologists, police officers, social workers, and employees of banks and other financial institutions. In 2017, APS in Texas received funding to improve elder abuse reporting by using telehealth to connect virtually with clients who were reported to the state as suspected victims of elder abuse. In the first 8 months, 300 clients were referred for assessments by a team of physicians that provided mental health assessments, guardianship filings, employee misconduct reviews, and other medical assessments. This approach reaches older adults in rural and hard-to-reach areas ([Burnett, Dyer, Clark, & Halphen, 2018](#)).

## **BOX 22-11 What Do *You* Think?**

**Mrs. Stetson's Story** The C/PHN has been visiting Mrs. Stetson for a wound dressing for the past few weeks. After Mr. Stetson passed away, her son, John, offered to help her with the finances. She was no longer able to see well enough to do the bank deposits. John took her to the bank to be added as a signer on the account. When Mrs. Stetson's daughter from out of town arrived several months later for a visit, she wanted to do some Christmas shopping with her mother for the grandchildren. Upon arrival to the bank with her daughter, Mrs. Stetson found that her checking account and substantial amount of her savings were drained. She shared this information with the C/PHN. What should the C/PHN do? Review the steps for reporting elder abuse in your state: What is your professional responsibility?

# **APPROACHES TO OLDER ADULT CARE**

As we noted in the introduction to this chapter, the United States and the world is experiencing unprecedented growth in the number of aging older adults. Current costs of care in facilities, price of long-term care insurance, and the limits on amounts of support in community services will demand new or improved models of care. Case management can focus on primary, secondary, and tertiary services to enhance the quality of care by decreasing fragmentations, maximizing resources, and providing the highest quality of care possible.

## Case Management and Needs Assessment

**Case management** involves assessing needs, planning and organizing services, and monitoring responses to care throughout the length of the caregiving process, condition, or illness. Nurses have stepped into the case management role to coordinate and manage patient care across the continuum of health services. Following the nursing process, nurses as case managers assure quality outcomes and cost containment as well as coordination of care. They work with the health care team including social work as each discipline has "...different training, different skills, and see patients from a different perspective" ([Christie 2018](#), para, 4).

Social workers use case management to address their clients' social needs, including their financial problems. Provisions of the Affordable Care act support home and community-based services by providing Medicaid coverage for home services coordinated by a case manager. This funding is available through states who opt in to the ACA Community First Choice ([Medicaid.gov, 2015](#)). When covered by a community program like the First Choice option, case managers and C/PHNs can support the family members of an older adult who will be paid for caregiving for their family member, a great cost saving when compared with a nursing home.

The C/PHN is part of the case management team and should be prepared to assess the needs of older adults with valid instruments:

- The Older Americans Resources and Services Information System (OARS), developed by Duke University Center for the Study of Aging and Human Development ([Duke University, 2014](#)), utilizes two sections of one tool—OARS Multidimensional Functional Assessment Questionnaire (OMFAQ)—to determine levels of functioning in five areas (mental health, physical health, economic resources, social resources, and ability to perform ADLs).
- The Katz Index of ADLs is based on an evaluation of the functional independence or dependence of clients with respect to bathing, dressing, toileting, and related tasks ([Katz, 1963](#)).
- The Lawton Instrumental ADLs Scale looks at an older adult's ability to perform such activities as using the telephone, shopping, doing laundry, and handling finances ([Graf, 2008](#)).
- Times Up and Go Test (TUG) is a measurement of the time in seconds for a person to rise from sitting from a standard armchair, walk 10 ft, turn, walk back to the chair, and sit down. The person wears regular footwear and walking supports (cane, walker). The test is predictive of falls in older adults ([Kang et al., 2017](#)).
- Cognitive Screens: to screen for the need for further testing, should the client or family be worried. Open this link and try the MiniCog

(<https://consultgeri.org/try-this/general-assessment/issue-3.1>).

- Vision and hearing screens: The test is familiar to older adults. A simple test of reading with corrective lenses if used will suffice to know if the older adult can read directions, pill bottles. This would not screen for eye problems like macular degeneration. For hearing, the Whisper Test may be used, with hearing aids if the older adult uses them (<https://geriatrics.ucsf.edu/sites/geriatrics.ucsf.edu/files/2018-06/whispertest.pdf>).
- Spiritual assessment: Spiritual needs can be assessed using many different instruments or questionnaires. Try FICA (Faith, Importance, Community, Address) for example (Dameron, 2005).

# HEALTH SERVICES FOR OLDER ADULT POPULATIONS

How well are the needs of older adults being met? To answer this question, other questions must be raised. Do health programs for older adults encompass the full range of needed services? Are programs both physically and financially accessible? Do they encourage clients to function independently? Do they treat older people with respect and preserve their dignity? Do they recognize older adults' needs for companionship, economic security, and social status? If appropriate, do they promote meaningful activities instead of overworked games or activities such as bingo, shuffleboard, and ceramics? Are health care services and other social services provided based on evidence and research? Effective services for older adults should be comprehensive, coordinated, and accessible and demonstrate evidence-based quality.

## Criteria for Effective Service

Several criteria help to define the characteristics of an effective community health service delivery system. Four, in particular, deserve attention. In order to be effective, it should be *comprehensive*. Many communities provide some programs, such as limited health screening or selected activities, but do not offer a full range of services to more adequately meet the needs of their senior citizens (see [Box 22-12](#)). A comprehensive set of services should provide the following:

### **BOX 22-12 What Do *You* Think?**

**Services in your Community** Have you wondered whether or not you should intervene if you see an older adult in a situation where they might need help? Or perhaps a neighbor will tell you about someone who might be in trouble. As a nurse, these kinds of situations come to our attention regularly. Silver Key SOS of Colorado Springs, Colorado offers an SOS (Senior Outreach Service). Anyone can contact Silver Key if there is a concern about an older person who may need help (<https://www.silverkey.org/services/senior-assistance/silverkey-sos/>). The reporting person need not be identified to the referred older adult. Once notified, a case manager will contact the older person and connect them with appropriate services, if the older adult is willing. Services include counseling for many problems, community resources, treatment for depression or misuse of drugs or prescriptions, teach your peers and family to recognize some warning signs: confusion,

## **physical problems, signs of home/person neglect, social isolation, and economic problems.**

Look for these kinds of services in your community. Do they exist under city services? Perhaps the County Health Department? How would you go about connecting families or older adults to services?

1. Affordable housing options
2. Adult day and memory care programs
3. Access to high-quality health care services (prevention, early diagnosis and treatment, rehabilitation)
4. Health education (including preparation for retirement) and centralized resources for information
5. In-home services that promote aging in place
6. Recreation and activity programs that promote healthy nutrition and socialization
7. Specialized transportation services
8. Safe and outdoor spaces that promote activity and enjoyment

A second criterion for a community service delivery system is *coordination*. A good example of efforts toward effective and coordinated services is the Age Friendly Cities and Communities programs ([AARP, 2019a](#)). Communities that apply for Age-Friendly demonstrate that the community addresses the above listed services. In 2018, 301 communities are designated age-friendly ([AARP, 2020a](#)).

A coordinated information and referral system provides another link. Most communities need this type of information network, which contains a directory of all resources and services for the older adult and includes the name and telephone number of a contact person with each listing. An example of this network is 2-1-1. This number connects the caller to services, and many communities have their own. San Diego 2-1-1 is a good illustration (<https://211sandiego.org/>).

A third criterion is *accessibility*. Too often, services for seniors are inconveniently located or are prohibitively expensive. Some communities are considering multiservice community centers to bring programs and services for low-income elderly closer to home. The Program of All-Inclusive Care of the Elderly (PACE) is one example of this ([National PACE Association, 2020](#)). Comprehensive services are offered to eligible nursing home patients, including personal, health care, and housing. Other services such as transportation, in-home services (home health aides, homemakers, grocery and meal delivery) may further solve accessibility problems for many older adults.

Finally, an effective community service system for older people should promote *quality* programs. This means that services should truly address the needs and concerns of a community's senior citizens and be based on

evidence of good outcomes. A range of housing types, from luxurious retirement communities with all amenities for the active and wealthier senior to secure and more modestly priced or low-income apartments for independent senior living, are being built in most communities. However, affordable rental apartments and homes for older adults and low-income families are in short supply in many communities, putting some older adults in homeless situations. Age-friendly communities are focusing on this problem with an array of solutions, including “tiny houses,” “granny flats,” and redesigning current homes to **universal design**, that is, usable by anyone of any age, whether a disability or not (e.g., wider door frames, less steps up).

## Services for Older Adults by Level of Care Required

There is increased emphasis on providing needed services for older people at home, the essence of aging in place. Today's emphasis on cost control gives added support for providing services at home. Given the increase in longevity, the potential for cost savings appears significant if care for dependent older people can be supported where they live (see [Table 22-2](#)).

**TABLE 22-2 Senior Residential and Home Health Care Service Comparison**

Senior Living facilities types	Assisted Living Can be a few residents or a large building, great variety in types and services	Skilled Nursing Facility (SNF) Skilled rehabilitation	Custodial Care (Nursing Home/Facility) about 4.2% of > 65 years old live in nursing homes CDC (2020a)	Home Health Care

Maintaining functional independence should be the primary goal of services for the older population. Assessment of needs, ability to function, and the use of assessment tools to form the basis for determining appropriate services is necessary. Although many well older people can assess their own health status, some are reluctant to seek help. Therefore, outreach programs serve an important function in many communities, as they locate people in need of health or social assistance and refer them to appropriate resources.

- Independent living is a general term for any housing arrangement designed exclusively for seniors. Types of independent living facilities include subsidized senior housing, retirement communities, Continuing Care Retirement Communities, and age-restricted apartments (55+). The senior housing industry is rethinking these older models to come up with intergenerational community models, as baby boomers tend to be less interested in senior-only communities.
- The concept of **continuing care retirement communities (CCRCs)**, sometimes referred to as total life care centers, allows older people to “age in place,” with flexible accommodations designed to meet their health and housing needs ([AARP, 2019b](#)). CCRCs are the most expensive long-term care solution available to seniors; however, they provide all levels of living, from total independence to the most dependent.
- Assisted living communities provide care to residents who need support with ADLs (these could include eating, dressing, bathing, mobility, toileting, grooming, and assistance with medications). These communities typically provide cooked meals in a shared dining hall, housekeeping, laundry, and transportation. Some communities include additional services such as salon/barbershops, art/activities, or a theater ([Dementia Care Central, 2019](#)).
- Memory care units are for individuals with dementia who require skilled care and supervision. These units or living spaces provide 24/7 supervision by staff who are specifically trained to care for patients with memory loss ([Dementia Care Central, 2019](#)).

Residents entering CCRCs sign a long-term contract that provides for housing, services, and nursing and dementia care. Many seniors enter into CCRC contracts while they are healthy and active, knowing they will be able to stay in the same community and receive nursing care should this become necessary. Currently, CCRCs are redesigning their homes and apartments to fit the needs of the baby boomers, who want more of a village feel. Dedicated memory care units in long-term and assisted living are part of the redesign. Older adults who invest in a CCRC need to have financial means to support the entrance and monthly fees. Entrance fees can be as high as \$1,000,000 ([AARP, 2019b](#)).

- The growing *Village Concept* is a relatively new, self-supporting solution for independent living in which older adults live in their own homes, in a neighborhood, or in some cases high rise city apartment buildings. Neighbors share services such as transportation, grocery shopping, or helping with household chores provided by village providers, either professional or volunteer. The village encourages socialization with a wide offering of activities among the members, and

some hold wellness activities. This option requires a membership fee, on average, about \$450 a year to provide services ([AARP, 2017b](#)).

Older adults who remain in their homes or apartments may rely on smart home technology to improve their autonomy ([Majumder et al., 2017](#)). Other older people may live with family members or participate in home sharing (<https://www.seniorhomeshares.com/about>). They may attend an adult or memory day care center during the day. Sometimes being able to stay home or return home includes short-term living arrangements. This could be a rehabilitation hospital for recovery and physical therapy related to a hip fracture, or respite care, which gives the usual caregiver a much-needed rest from 24-hour-a-day caregiving and helps prevent “burnout” (see [Box 22-13](#)).

### **BOX 22-13 Family Caregiving Concerns**

**Finances Taking time off from work to care and loss of income; most caregivers are working women who will not be contributing to their own retirement accounts for possibly long periods of time. The Credit for Caring Act is proposed legislation that would create a \$3,000 tax credit for caregivers who work and care for their parents ([AARP, 2019d](#)).**

**Payment for Caregiving Caregivers are often not paid. Medicaid eligible and veterans may get assistance, which varies by state. Long-term care insurance is often out of the financial reach of many families.**

**Hospice and End-of-Life Guidance This concern centers on how to have the conversations with family members.**

**Caregiver Life Balance This concern involves the daily work of caregiving, especially when it**

**falls on one family member, can result in depression, anxiety, fatigue, guilt, and anger.**

**Resources These include adult day programs, support groups, dementia care, and respite care.**

**Safety as We Age These concerns include aging parents driving as well as home safety ([AARP, 2020d](#)).**

Many nurses do not know the difference between an SNF and a **custodial care** nursing home. They often exist within the same building.

- SNFs are reimbursed for 30 days by Medicare for rehabilitation for conditions such as post stroke, spinal cord injury, IV therapy, and PT, OT, and Speech ([CMS, 2020](#)).
- When an older adult has a long-term chronic condition that cannot be managed in the community, a nursing home is an option. There is 24-hour nursing and nursing assistant care in both SNF and nursing homes, but the payment model is quite different (see [Table 22-2](#)).

Nursing home reform was legislated in the late 1980s, putting increased demands on facilities to provide competent resident assessment, timely care plans, quality improvement, and protection of resident rights ([Omnibus Budget Reconciliation Act, 1987](#)). This increased complexity of services has resulted in increased costs in these facilities. Staffing needs increase as care becomes more complex and the resident population grows. Licensed personnel must be knowledgeable decision-makers, managers of unskilled staff, staff educators, and role models, as well as efficient and effective administrators in an essentially autonomous practice setting. And, as the population grows, the need for greater numbers of both licensed and attendant staff becomes more evident.

# END OF LIFE: ADVANCE DIRECTIVES, HOSPICE, AND PALLIATIVE CARE

A final need of older adults is preparing for a dignified death. In her classic work, *On Death and Dying*, Elisabeth Kübler-Ross (1969) described death as the final stage of growth and one that deserves the same measure of quality as other stages of life.

- Although death is a natural part of life, many older people fear death as an experience of pain, humiliation, discomfort, or financial concern for loved ones. Sometimes, very aggressive and heroic medical treatments are offered to those near the end of their lives, often at the urging of family members.
- Planning for a dignified death is an important issue for many older people, and C/PHNs can facilitate conversations among family members and provide necessary information and resources. Look up [www.theconversationproject.org](http://www.theconversationproject.org), a very helpful toolkit to help individuals and families have the conversation about wishes for end of life.

The C/PHN will need to be aware of the laws around physician-assisted suicide and patient self-determination around death. The Death with Dignity Web site is very helpful: <https://www.deathwithdignity.org/learn/access/>. In addition, there are personal and professional decisions around this topic and nursing practice that a C/PHN might want to think about (Stokes, 2016).

## Advance Directives

Living wills and advance health care directives (AHCDs), sometimes referred to as *advance directives*, are legal documents that instruct others about end-of-life choices should an individual be unable to make decisions independently. The forms for advance directives are available for every state online through [AARP \(2020b\)](#).

An AHCD only becomes effective under the circumstances specified in the document. This document allows for appointment of a health care agent who will have the legal authority to make health care decisions on behalf of the patient and for specific written instructions for future health care in the event of any situation in which the patient can no longer speak for himself or herself. Examples include the following:

- The use of dialysis and breathing machines
- Use of resuscitation if breathing or heartbeat stops
- Tube feeding
- Organ or tissue donation

Having such documents prepared and making them known to significant others can ensure that wishes will be honored. These documents can provide clear directions for families and health care professionals and are gaining more recognition and importance as a result of increasing ethical dilemmas and challenges brought on by advances in technology ([American Medical Association, 2020](#)). Advance directives can be revoked or replaced at any time, as long as the individual in question is capable of making his or her own decisions. It is recommended that these documents be reviewed every 2 years or so, or in the event of a change in health status and revised to ensure that they continue to accurately reflect an individual's wishes.

Projections indicate that by 2030, close to one half of older adults greater than the 85 years of age will have dementia and may not have a spouse or family living with them ([Meunier et al., 2016](#)). C/PHNs and other health care professionals will be faced with choices around end-of-life decisions. The education and decisions need to come far in advance for older adults.

## **Hospice**

**Hospice** is an option that takes a multidisciplinary approach to end-of-life care and needs. Hospice is more a concept of care than a specific place, although some hospice organizations provide individuals with a place to die with dignity if they have no home or choose not to die at home. Hospice is an option for people with a “projected” life expectancy of 6 months or less and often involves palliative care (pain and symptom relief) as opposed to ongoing curative measures.

[Chapter 30](#) details hospice care. The C/PHN can be a helpful resource in connecting clients with hospice services before end of life in imminent, and hospice is most beneficial for all.

## **Palliative Care**

**Palliative care** consists of comfort and symptom management and does not provide a cure. For most chronic ongoing health conditions—such as diabetes, high blood pressure, congestive heart failure, arthritis, and COPD—there are no cures, only symptom relief. Palliative care should not be viewed as synonymous with hospice or end-of-life care. Rather, palliative care should be viewed as any care primarily intended to relieve the burden of physical and emotional suffering that may accompany illness associated with aging. Palliative care should be a major focus of illness care throughout the life span and in any community setting, regardless of whether a client is a hospice patient or not ([National Consensus Project, 2020](#)). There is an excellent summary of palliative care in [Chapter 30](#).

# CARE FOR THE CAREGIVER

The burden of caregiving is receiving more attention in recent years because it is such a demanding and costly role. An increasing number of older people are cared for in their home by a spouse or other family member, often referred to as an informal caregiver, on an unpaid basis.

Almost 75% of persons receiving care at home rely exclusively on informal caregivers, usually women between the ages of 45 and 64 ([Schultz & Eden, 2016](#)). The demands of caregiving exact a toll on the caregiver, who not only may miss important screening and health care visits for self but also often give up a social life. Because of the toll of caregiving on their own health, caregivers for those with AD and dementia had \$7.9 billion in additional health care costs ([AARP, 2020c](#)). Their own decline in health compromises their ability to be a caregiver unless they get some relief (see Chapter 32 ; [Box 22-13](#)).

**Respite care** is a service that is receiving increasing attention. Although there are different approaches to respite care, all have the same basic objective: to provide caregivers with planned temporary, intermittent, substitute care, allowing for relief from the daily responsibilities of caring for the care recipient ([AARP, 2020c](#)). Long-term care insurance may cover some costs of respite care. The 2000 Older Americans Act Amendments provided funding for states to work through NFCSP to address respite care specifically on the local level ([ACL, 2019a](#)).

# THE COMMUNITY HEALTH NURSE IN AN AGING AMERICA

C/PHNs can make a significant contribution to the health of older adults. The nurse may function as a collaborator, case manager, advocate, and educator to assist older adults and their families to maintain or improve health. Because these nurses are in the community and already have contact with many seniors, they are in a prime position to carry out a comprehensive needs assessment, culminating in a nursing diagnosis and holistic plan for the health care needs of this group. Case management is often a critical aspect of the nurse's role because the C/PHN must know what resources are available and when and how to make referrals for these older clients (see [Box 22-14](#)).

## **BOX 22-14 STORIES FROM THE FIELD**

### **Case Management: Role of the C/PHN**

Mr. Jessup is 94 years old and lives with his wife, age 86, in a small mobile home on some acreage in a rural area of our county. He is hard of hearing, but he only needs glasses for reading. Mr. Jessup was diagnosed with prostate cancer 20 years ago and has some bowel incontinence as a result of radiation treatments; he manages this well with pull-up protective underwear. They have one son who lives in the same town; they speak by phone every other day, and he comes by to visit when he can. Their three grandsons are all away at college and they rarely see them.

Mrs. Jessup has recently been having memory lapses, and some difficulty remembering to turn off the stove and close the refrigerator door. She has trouble with a number of daily tasks. She likes to have someone bring them fast-food as a treat every week, and they are beginning to require assistance with errands and housekeeping tasks.

Recently, Mr. Jessup noticed that he was having more difficulty doing his outside chores. He seems more “weak” and “tired” and he has recently had quite a bit of “nausea and vomiting.” The Jessup's son took them for an appointment with his urologist, and it was determined that his prostate-specific antigen (PSA) was elevated.

You are a district C/PHN and have recently been assigned to the Jessup family to assess their functional limitations and provide them with information on resources they might need over the next few months.

1. *How would you begin your visit?*
2. *What assessments could be helpful (social, spiritual, mental/cognitive, etc.)?*
3. *What resources and services might be helpful to them?*

# SUMMARY

C/PHNs work with older adults and families in many settings, wherever they find them, and with whatever health needs are present. While the priority of community/public health nursing is health promotion and disease prevention, community nurses work with older adults with chronic health conditions who are aging in place to help them achieve their maximal health potential. Because the trend for older adults is to remain in community, C/PHNs need to assess their living situations and find out as much as possible about the community's support systems, available resources, and gaps in services.

- As the number of older adults in America grows, the need for health care services and health professionals that serve older people in communities will escalate.
- Healthy longevity is the goal for the aging population and is a focus of *Healthy People*. This means being able to function as independently as possible; maintaining as much physical, mental wellness, and social engagement as possible while adapting to chronic conditions and functional impairments.
- Through advocacy, education counseling, case management, and collaboration with clients, families, and health services and providers, the community health nurse can be effective in improving quality of care and social conditions for older adults.
- Older adults prefer to age in place and live independently in the community. Public health nurses deliver health care services to a large and rapidly growing segment of the population.
- Alzheimer's dementia is the sixth leading cause of death and the only disease among America's top 10 that cannot be prevented or cured. Between 2017 and 2025, every state is expected to see at least a 14% rise in the AD prevalence (AA, 2020b). The C/PHN will support families and caregivers who need support caring for older adults with this devastating disease.
- A variety of living arrangements and care options are available from which to choose and can be tailored to the older person's desires and needs. These include continuing care communities, villages, day and memory care centers, PACE programs, assisted living, skilled and SNF long-term care centers, and hospice.
- The community health perspective includes a case management approach that offers a centralized system for assessing the needs of older people and then matching those needs with the appropriate services. The C/PHN should also seek to serve the entire older

population by assessing the needs of the population, examining the available services, and analyzing their effectiveness. The effectiveness of programs can be measured according to four important criteria (targeted to the specific needs of the population): comprehensiveness, effective coordination, accessibility, and quality.

# ACTIVE LEARNING EXERCISES

1. On the Internet, search for and download instructions for filling out your own advance directive. Complete the form for your state and discuss your wishes with someone who is likely to be involved in your health care.
2. Picture an older adult you know well or know a great deal about. Make a list of characteristics that describe this person. How many of these characteristics fit your picture of most senior citizens? What are your biases (ageisms) about them?
3. As part of your regular community health nursing workload, you visit a senior day care center one afternoon each week. You take the blood pressures of several people who are taking antihypertensive medications and do some nutrition counseling. The center accommodates 60 senior clients, and you would like to serve the health needs of the aggregate population. List five potential health needs of this group. What actions might you consider taking at an aggregate level? With whom would you consult as you plan programs at the center?
4. Using “Strengthen, Support, and Mobilize Communities and Partnerships” (1 of the 10 essential public health services; see [Box 2-2](#)), discover examples of innovative community programs for elders at the primary, secondary, and tertiary levels of care. Determine whether such programs could work in your own community. Discuss with C/PHNs and local stakeholders or key informants.

# **UNIT 6**

## **Vulnerable Populations**

# CHAPTER 23

## *Working With Vulnerable People*

*“How far you go in life depends on your being tender with the young, compassionate with the aged, sympathetic with the striving, and tolerant of the weak and the strong—because someday you will have been all of these.”*

—George Washington Carver (1860–1943), Botanist and Scientist

### **KEY TERMS**

Differential vulnerability hypothesis Empowerment strategies  
Environmental resources  
Health disparities  
Human capital  
Marginalized populations Racial/ethnic disparities Racism  
Relative risk  
Social capital  
Social determinants of health Socioeconomic gradient  
Socioeconomic resources  
Vulnerability  
Vulnerable populations

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Describe the term “vulnerable populations.”
2. Discuss the effects of vulnerability and relative risk.
3. Differentiate between the concepts of social capital and human capital.
4. List three of the most common factors related to vulnerability.
5. Identify two strategies to solicit and evaluate input from vulnerable populations when planning health care programs and services.
6. Explain the socioeconomic gradient in health.
7. Describe three types of health disparities.
8. Describe four C/PHN roles or behaviors that help promote client empowerment.

# INTRODUCTION

The concept of **vulnerability** is an important one for nurses because of its implications for health, no matter where they practice. Often, vulnerable populations are subpopulations, such as ethnic or racial minorities, the uninsured, those with HIV/AIDS, children, older adults, the poor, and those who are homeless ([American Public Health Association, 2017](#); [Stafford & Wood, 2017](#)). These subpopulations often have higher morbidity and mortality rates, less access to health care (and disparities in outcomes of health care), shorter life expectancy, and an overall diminished quality of life compared with the population in general ([Agency for Healthcare Research and Quality \[AHRQ\], 2015](#); [American Public Health Association, 2017](#)).

In this chapter, we examine popular models and theories of vulnerability, important concepts, and contributing factors. We also briefly discuss health disparities that are more common among vulnerable members of society and the role of C/PHNs working with these groups. This chapter provides an overview of this subject and lays the foundation for other chapters.

# **THE CONCEPT OF VULNERABLE POPULATIONS**

In this section, we consider several key models and theories related to vulnerability, the criteria used to determine who is considered vulnerable, and causative factors linked to vulnerability.

## Models and Theories of Vulnerability

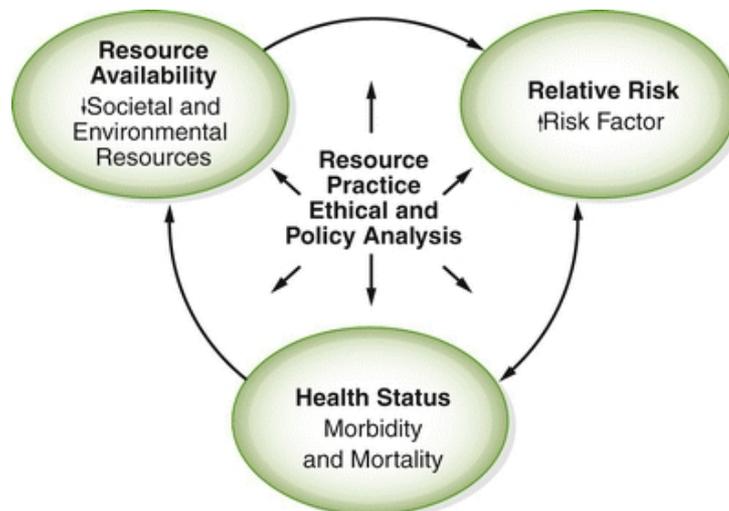

Key models and theories of vulnerability that have been proposed include the vulnerable populations conceptual model developed by Flaskerud and Winslow in 1998 (Box 23-1; Fig. 23-1), the Behavioral Model for Vulnerable Populations (Box 23-2; Fig. 23-2), the differential vulnerability hypothesis (Kessler, 1979; Box 23-3), the concept of social capital (Fig. 23-3), a general model of vulnerability, and Maslow's Hierarchy of Needs.

**BOX 23-1 Vulnerable Populations Conceptual Model (Flaskerud & Winslow, 1998)** Flaskerud and Winslow (1998) developed a popular conceptual framework of vulnerability (see Fig. 23-1) that contains three related concepts: resource availability, relative risk, and health status. The model provides evidence of the link between poor health status and socioeconomic resource availability through the loss of income, jobs, and health insurance. The following concepts are supported by this model:

- Lack of resources (e.g., socioeconomic and environmental) increases a population's exposure to risk factors and reduces individuals' ability to avoid illness.
- **Socioeconomic resources** include **human capital** (e.g., jobs, income, housing, education), social connectedness or integration (e.g., social networks or ties; social support or the lack of it, characterized by marginalization), and social status (e.g., position, power, role).

- **Environmental resources** deal mostly with access to health care and the quality of that care.
- Limited access or lack of access to care can arise from many sources, including crime-ridden neighborhoods, insufficient transportation systems, lack of adequate numbers and types of providers, limited choices of health care plans, or no health insurance.
- **Relative risk** refers to exposure to risk factors identified by a substantial body of research as lifestyle, behaviors and choices (e.g., diet, exercise, use of tobacco, alcohol and other drugs, sexual behaviors), use of health screening services (e.g., mammogram, colonoscopy), and stressful events (e.g., crime, violence, abuse, firearm use).

Source: Flaskerud and Winslow (1998).

**FIGURE 23-1** Vulnerable populations conceptual model. (Adapted from Flaskerud, J. H., & Winslow, B. J. (1998). Conceptualizing vulnerable populations health-related research. *Nursing Research*, 47(2), 69–78.)

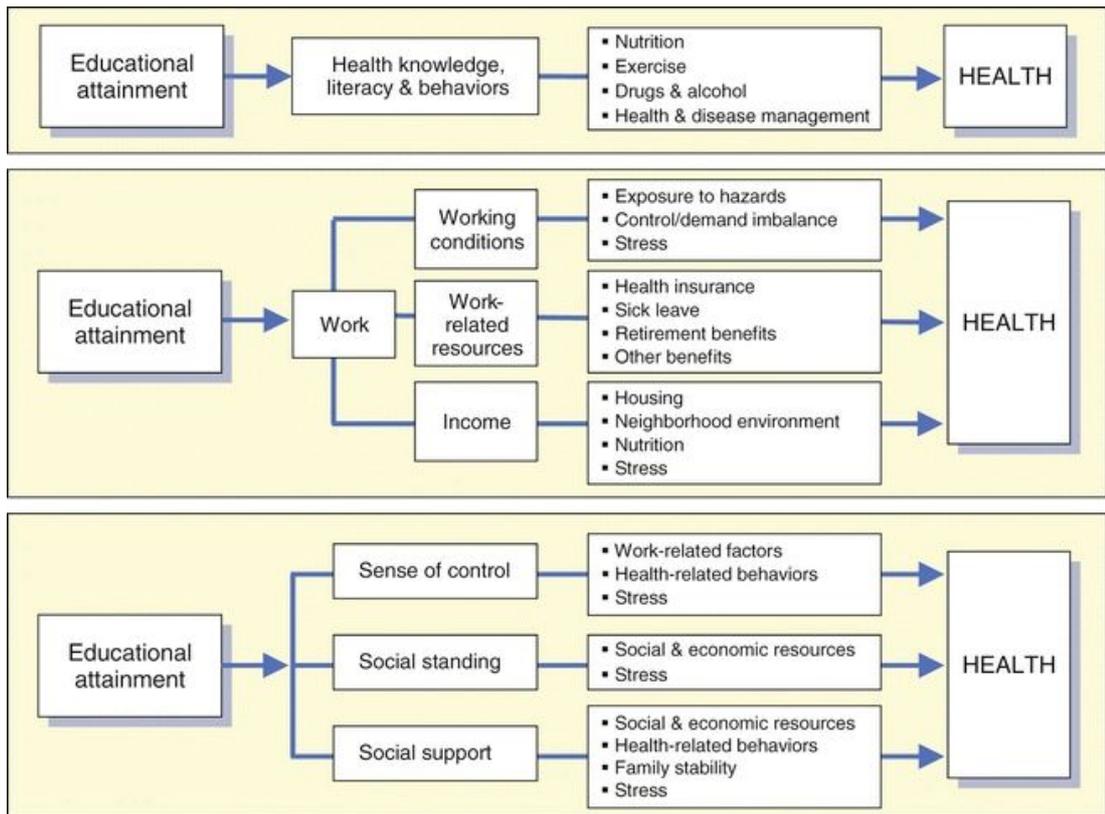

**BOX 23-2 The Behavioral Model for Vulnerable Populations (Gelberg, Andersen, & Leake, 2000)** Gelberg *et al.* (2000) advanced another classic model, the Behavioral Model for Vulnerable

**Populations; this model looks at population characteristics (predisposing and enabling factors and needs) as an explanation for health behaviors and eventual health outcomes (Burg & Oyama, 2016). The following concepts are supported by this model:**

- Predisposing factors included demographic variables (e.g., gender, age, marital status), social variables (e.g., education, employment, ethnicity, social networks), and health beliefs (e.g., values and attitudes toward health and health care services, knowledge of disease).
- Social structures (e.g., acculturation and immigration), sexual orientation, and childhood characteristics (e.g., mobility, living conditions, history of substance abuse, criminal behavior, victimization, or mental illness) were also considered predisposing factors.
- Enabling factors included personal and family resources, as well as community resources (e.g., income, insurance, social support, region, health services resources, public benefits, transportation, telephone, crime rates, social services resources).
- Perceived health needs and population health conditions also were considered, as were health behaviors including diet, exercise, tobacco use, self-care, and adherence to care.
- The use of health services (e.g., ambulatory and inpatient care, long-term care, alternative health care) and personal health practices (e.g., hygiene, unsafe sexual behaviors, food sources) combined with the other factors to produce outcomes such as perceived and evaluated health and general satisfaction with health care services.

The model has been used in research with homeless adults (Doran *et al.*, 2014) and in examining barriers to interconceptual care (Rhoades *et al.*, 2014), with mixed results. See [Figure 23-2](#), interrelated pathways linking education to health.

Source: Burg and Oyama (2016); Doran *et al.* (2014); Gelberg *et al.* (2000); Rhoades *et al.* (2014).

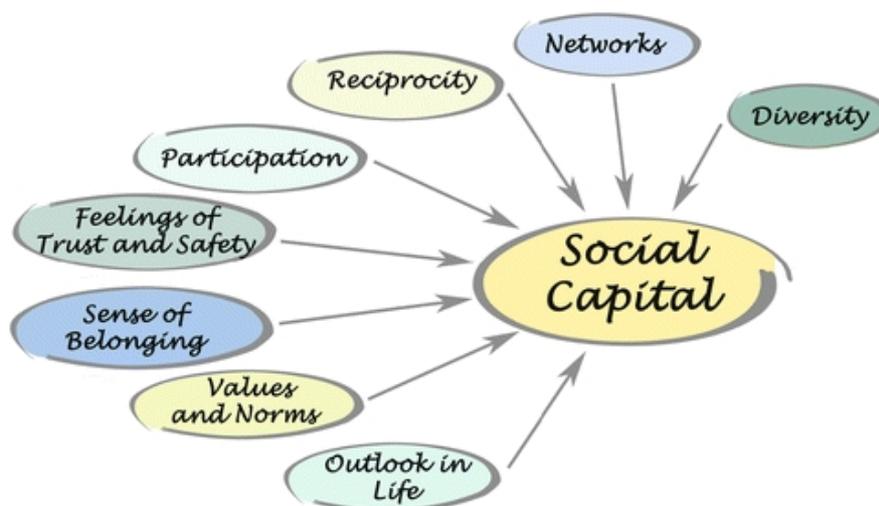

**FIGURE 23-2** Interrelated pathways linking education to health. (From Braveman, P., Ergerter, S., & Williams, D. R. (2011). The social determinants of health: Coming of age. *Annual Review of Public Health*, 32, 381–398, used with permission.)

**BOX 23-3 The Differential Vulnerability Hypothesis (Kessler, 1979)** Kessler's (1979) differential vulnerability hypothesis states that there is a relationship between social status and psychological distress; a person's psychological distress is determined by the impact of the stressor event as influenced by social status (this includes class, sex, marital status, and rural vs. urban). The formula  $P_i = V_i (S)_i + a_i$  is

defined as (Kessler, 1979, p. 101): “(P) Psychological distress is the result of varying exposure to environmental stress events or situations (S) acting on individuals who possess varying vulnerabilities to stress (V); (a) represents the residual influence of constitutional makeup of the mental health of person (i) independent of any environmental stresses he/she might experience” (Kessler, 1979, p. 101).

The hypothesis has been used in research with racial inequity (Roxburgh & MacArthur, 2014; Wickrama, Bae & Walker, 2016).

Source: Kessler (1979); Roxburgh and MacArthur (2014); Wickrama *et al.* (2016).

**FIGURE 23-3** Social capital is a network of relationships where one lives and works.

The importance of **social capital** is sometimes missed, as it can be subtle and less obvious than the lack of money or jobs (Fig. 23-3). But the presence of friends and family or someone to rely on in case of an emergency can be invaluable in assisting individuals through many of life's difficulties. Social

support, or a close confidante, can promote social and psychological health and help counteract the effects of stressful events. In our mobile society, many people live great distances from family members and have difficulty establishing new friendships. Those who live alone or who are socially isolated are at greatest risk of vulnerability, increased morbidity and mortality, and decreased overall health (Lubben, Gironda, Sabbath, Kong, & Johnson, 2015); thus, C/PHNs should be aware of this and strive to provide additional support and resources.

A general model of vulnerability helps to explain individual and community risk factors that lead to vulnerability, as well as problems with access to care and quality of care received that impact health outcomes on both an individual and community level, as described in a seminal article by Shi, Stevens, Lebrun, Faed, and Tsai (2008). According to this model, vulnerable populations often experience clusters of risk factors, and these are viewed as cumulative. The specific combinations of risks (e.g., low income, low education) are more detrimental to health outcomes, as is the greater number of risk factors that accumulate over time.

Most nursing students are familiar with Maslow's Hierarchy of Needs (Maslow, 1987), with physiological needs (e.g., water, food, air) as the base of a pyramid, and the needs for safety, belonging, esteem, and self-actualization building from the basic needs. Chronic poverty, environments of crime and violence, or disenfranchisement, racism, and discrimination (vulnerability) can keep people from meeting the higher needs (Bates, 2016). **Racism** is largely defined as believing that race is the primary factor of our capacities and traits as humans and that any racial differences result in feelings of either superiority or inferiority.

## Who Is Considered Vulnerable?

In her classic book, [Aday \(2001\)](#) included the following factors and populations in the description of who is considered vulnerable:

- Income and education
- Age and gender
- Race and ethnicity
- Chronic illness and disability
- HIV/AIDS
- Mental illness and disability
- Alcohol and substance abuse
- Familial abuse
- Homelessness
- Suicide and homicide risk
- High-risk mothers and infants
- Immigrants and refugees
- Military personnel

Other authors considered the uninsured and underinsured as **vulnerable populations** because of their difficulties with health care access and the potential for poor health outcomes, as well as victims of bullying and crime, children in foster care, those in the gay and lesbian community, veterans and returning military personnel, and victims/survivors of torture and terrorism ([Hong, Pequero, & Espelage, 2018](#); [Koven, 2018](#); [Mohatt et al., 2018](#); [Scherrer et al., 2018](#)).

- Although many segments of the population may be considered vulnerable at some point in their lives, some population segments are more often identified as vulnerable because of their long-term situations ([de Chesnay & Anderson, 2016](#)). The very young and the very old have particular risk factors that increase their chances of poor health, as well as unique issues with access to health care.
- An extensive body of research substantiates the reality of higher morbidity and mortality rates for racial and ethnic minorities than for the White population, thus demonstrating **racial/ethnic disparities** in health ([Gwede, Quinn, Green, 2016](#); [Institute of Medicine \[IOM\], 2003](#); [Neumayer & Plümper, 2015](#)).

## Prevalence of Vulnerable Populations and Causative Factors

Root causes of vulnerability, such as low socioeconomic status (SES), lack of insurance coverage, racism, and discrimination, have been widely researched. Which cause or causes are considered most important? The exact weight of the interaction of these causes has been difficult to ascertain. The current approach to understanding the complex interrelationships among the causes and factors related to vulnerability is to examine multiple determinants of health (Brantley, Kerrigan, German, Lim, & Sherman, 2017; Gwede et al., 2016); this chapter focuses on the social determinants of health (Box 23-4).

### BOX 23-4 STORIES FROM THE FIELD

**Teen Pregnancy** Teen pregnancy is viewed as a social issue that impacts families for generations. Although the teen pregnancy rate has been declining over the past few decades, the United States still has the highest teen pregnancy rate among developed nations (Watson & Vogel, 2017). Teen mothers are less likely to receive prenatal care and more likely to live in poverty and have more than one child before age 20, and their children are more prone to behavioral issues (Watson & Vogel, 2017).

One teenage mother describes being a teenage mother at school as follows: “I feel like an ant ... traveling the whole world. I have to get around the world by trying to get a boat to get across the water, trying to get some food so I don't fall over and die. .... [I]t's the hardest battle you're ever going to face.” (Watson & Vogel, 2017)

1. *Discuss vulnerable populations. What risk factors apply to this situation?*

*2. What primary, secondary, and tertiary interventions can be applied to this scenario?*

Source: [Watson and Vogel \(2017\)](#).

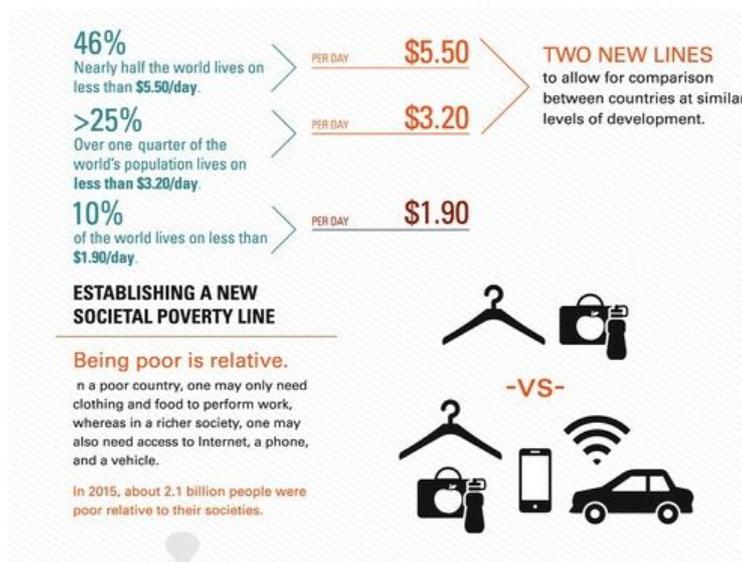

## *Poverty*

If only one indicator is measured—poverty—it is evident that vulnerability touches a large segment of the global population and the population in the United States (see [Fig. 23-4](#)):

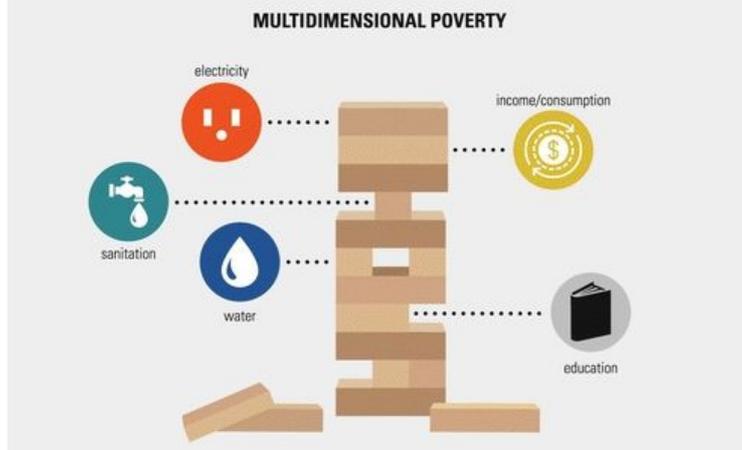

**NEW STANDARDS FOR A GROWING WORLD**

Half of the countries for which the World Bank monitors poverty have now reduced extreme poverty to below 3%, but that doesn't mean poverty is nonexistent in these countries.

**BEYOND MONETARY POVERTY**

Poverty isn't just about money. It's about measuring people's well-being—not just their income or consumption.

**FIGURE 23-4** Infographic: Poverty and Shared Prosperity 2018: Piecing together the poverty puzzle. (Adapted with permission from World Bank. (2018). Retrieved from

<https://www.worldbank.org/en/news/infographic/2018/10/17/infographic-poverty-and-shared-prosperity-2018-piecing-together-the-poverty-puzzle>). See [thePoint](#) for the complete infographic.

- According to the latest figures from the [World Bank \(2015\)](#), an estimated 767 million people are living in extreme poverty (living on \$1.90 or less a day), and 2.1 billion are living in moderate poverty (living on between \$1.90 and \$3.10 a day).
- The official poverty rate in the United States is 12.7%, which represents an estimated 43.1 million people ([Center for Poverty Research, University of California Davis \[UCD\], 2017](#)).
- Poverty thresholds in the United States are \$12,486 for a single individual under age 65, \$14,507 for a household of two people with a householder 65 years or older with no children, and \$24,339 for a family of four with two children under age 18 ([Center for Poverty Research, UCD, 2017](#)).
- According to the [National Center for Children in Poverty \(2017\)](#), 36% of the children in poverty are Black, or African American, 33% American Indian, 30% Hispanic or Latino, 12% White, and 12% Asian or Pacific Islander.

How does poverty make one vulnerable to poor health outcomes? The answer to this question is complex:

- One supposition is that having less money means being less able to afford most aspects of a quality life, including adequate housing in a safe neighborhood. This living situation may lead to fewer opportunities for exercise, especially if walking outside puts one at risk of becoming a victim of violence.
- Fewer community resources are usually available, such as grocery stores, quality schools, recreation facilities, and health care providers. Lower income level is associated with lower levels of education and often results in a person having to work at jobs where he or she is exposed to higher risks (e.g., mining), or the need to work at more than one job to make ends meet, and often without health insurance coverage ([Centers for Disease Control & Prevention \[CDC\], 2015a](#)).

Data from the National Health Interview Survey showed that from 2013 to 2015, the percentage of adults aged 18 to 64 years ([Martinez & Ward, 2016](#)):

- Who were uninsured decreased for poor (40.0% to 26.2%), near-poor (37.8% to 23.9%), and not-poor (11.7% to 7.7%) adults
- Who had a usual place to go for medical care increased for poor (66.9% to 73.6%) and near-poor (71.1% to 75.9%) adults

- Who had seen or talked to a health professional in the past 12 months increased for poor (73.2% to 75.8%) and near-poor (71.9% to 75.9%) adults
- Who did not obtain needed medical care due to cost at some time during the past 12 months decreased for poor (16.8% to 12.4%), near-poor (14.6% to 11.0%), and not-poor (4.9% to 3.8%) adults

Research has shown that those groups with the lowest income and least education were consistently less healthy than were those with the most income and education ([World Health Organization, 2020a](#)). Poverty and race/ethnicity are often intertwined, but SES is considered a consistent and robust variable related to health and death ([Brantley et al., 2017](#); [Montez, Zajacova, & Hayward, 2017](#); [Montez, Zhang, Zajacova, & Hamilton, 2018](#); [Neumayer & Plümper, 2015](#); [Williams, Priest, & Anderson, 2016](#)):

- Low-income minority neighborhoods with poor access and poor walkability to fresh fruits, vegetables, and lean proteins are associated with a significant increase in cardiovascular disease mortality and type 2 diabetes ([Gaglioti et al., 2018](#); [Haynes-Maslow, Ammerman & Leone, 2017](#)). Many of these neighborhoods are termed food deserts due to the lack of available supermarkets ([Fig. 23-5](#)).
- Research has shown that fast food restaurants are more prevalent in low-income neighborhoods, and this prevalence has been shown to have a positive correlation with obesity and type 2 diabetes ([Michimi & Wimberly, 2015](#); [Rummo et al., 2017](#)).

**FIGURE 23-5** Income and race/ethnicity influence access to healthy food.

Another risk factor for vulnerability that is associated with poverty is exposure to pollution and smoking:

- One finding indicates that the highest amount of pollution is most often found in neighborhoods where there is more poverty, lower education levels, and higher rates of unemployment ([CDC, 2015a](#)).
- Others note an association between SES and poorer respiratory health, often due to living conditions, such as ambient air pollution and smoking ([Berry, Nickerson, & Odum, 2017](#)), and because of a higher smoking prevalence among those with lower SES ([Lowe et al., 2018](#)).
- Also, research has shown that lower SES groups are as likely as higher ones to attempt smoking cessation but are less likely to be successful ([Perelman et al., 2017](#)). The lower success in the ability to quit smoking is being examined to find more effective evidence-based treatment for low-income populations ([Evans et al., 2015](#)).

At the population level, increases in total income and reductions in poverty levels are “strongly associated with subsequent improvements in population health” ([Aday, 2005](#), p. 190). This is proven out in a systematic review of maternal mortality outcomes. Financial barriers and lack of

maternal health education for the mother and partner were shown to negatively impact maternal-child outcomes ([Banke-Thomas, Banke-Thomas, & Ameh, 2017](#)). Income affects health, and poor health can affect the income of an individual as well as that of a nation (see [Chapter 6](#)).

### *Uninsured and Underinsured*

If the uninsured are also classified as a vulnerable population, even more Americans join the ranks, because the majority of those without health insurance are working adults who are not eligible for Medicaid or Medicare.

- The percentage of uninsured in 2013 was estimated at 16.7%. In 2016, 10.3% of people in the United States were without health insurance ([Kaiser Family Foundation, 2019](#)).
- The decline in the percentage of uninsured is attributable in great part to the Patient Protection and Affordable Care Act (ACA), signed into law by President Barack Obama on March 23, 2010. This law requires most U.S. citizens and legal residents to have health insurance coverage, along with many other provisions ([Knickman & Kovner, 2015](#)). See [Chapter 6 & 13](#) for more on the ACA.
- Although the improvement in health insurance coverage is encouraging, disparities in access to health care continue.
  - In 2014, 31 million people were underinsured in the United States, which was unchanged from 2010.
  - In 2003, only 1% of privately insured adults had a deductible of \$3,000 or more, but that increased to 11% in 2014 ([Collins, Rasmussen, Beutel, & Doty, 2015](#)) and 13% in 2016 ([Commonwealth Fund Report, 2017](#)).
- Also, most health care experts feel that there will still be disparities in quality, access, and outcomes for those who are more vulnerable ([Gwede et al., 2016](#)).

How does having inadequate or no health insurance lead to poor health outcomes? As explained in [Chapter 6](#), those with few or no resources in this area do not use early screenings and preventive measures, and they delay getting treatment in an effort to save money. Those without health insurance receive care only for the problem at hand and not always for underlying causes. They do not get regular physical examinations and may be inadequately immunized against common diseases. Thus, they are at risk for poorer general health. Also, when examination and subsequent treatment are delayed, diseases, such as cancer or cardiovascular illness, may result in earlier death.

### *Race and Ethnicity*

The United States is a multiracial, multiethnic country. About one third of the population belongs to a racial or ethnic minority group, and this proportion will continue to increase, as minorities are projected to constitute more than half of all children by 2023 (Frey, 2018; Laun, 2019).

- Hispanics represent the largest minority group (16% of the total population, up from 13% in 2000 census), and they are also the fastest-growing group, with a lifetime average number of children per woman of 2.53, compared with 1.71 for White women (Pew Research Center, 2015).
- Blacks in the United States account for a higher proportion of new HIV diagnoses, those living with HIV, and those who have ever received an AIDS diagnosis, compared with other races and ethnicities (CDC, 2015b). In 2016, Blacks accounted for 44% of HIV diagnoses, though they comprise only 12% of the U.S. population (CDC, 2015b).
- There is a disparity in the prevalence of preterm births in the United States, with 12.7% of infants born to Black mothers being premature compared with only 8.0% among White mothers (McKinnon et al., 2016).
- Infant mortality is much higher among African Americans at 10.9% when compared with 4.9% among White Americans (U.S. Department of Health and Human Services, 2019).
- Hypertension increases the prevalence of cardiovascular disease outcomes, such as stroke, congestive heart failure, kidney failure, and cognitive impairment/dementia, and Blacks are disproportionately more affected by hypertension and its comorbid conditions. In the United States, the prevalence of hypertension is 40% to 50% in African Americans compared with 25% to 30% in Whites (Osei & Gaillard, 2017).
- Blacks have higher prevalence of heart failure, by twofold, stroke, by twofold to fourfold, and kidney failure, by twofold to fourfold, in the United States (Osei & Gaillard, 2017).

Why does simply being a member of a racial or ethnic minority group make someone vulnerable? The reasons are complex and just beginning to be understood. Williams *et al.* (2016) found in a review of the scientific research that racism affects the health of minority racial populations in multiple ways.

- Institutional racism in policies and procedures reduced access to housing, neighborhood and educational quality, employment opportunities, and other societal resources.
- Cultural racism affects economic status and health by creating a policy environment adverse to equal policies.

- Experiences of racial discrimination are a type of psychosocial stressor that can increase health risks.

Recent immigrants have healthier exercise and dietary patterns than do those born inside the United States.

- A systematic review of acculturation, obesity, and health behaviors among recent migrants showed that there was evidence across multiple studies for a positive association between acculturation (measured with standard measures or as duration of stay) and obesity ([Alidu & Grunfeld, 2017](#)).
- Others note the generational link between minority group membership and low educational attainment (e.g., father's education level) and the tie between education and health ([Hahn & Truman, 2015](#)).
- A majority of Hispanics and Blacks have spent a lifetime at a lower level of educational attainment and continue to lag behind in most areas.
- One bright spot is that the percentages of Hispanics and African Americans enrolled in college have increased significantly over the past two decades. From 1997 to 2016, for instance, the percentage of Black young adults enrolled in college has increased by 6% and the percentage of Hispanic young adults has increased by 17% ([Digest of Education Statistics, 2016](#)).

# **VULNERABILITY AND INEQUALITY IN HEALTH CARE**

Various social factors, known as the social determinants of health, including SES, affect a person's vulnerability to poor health. Specific areas in which inequities in health outcomes result from these social factors are known as health disparities.

## Social Determinants of Health

The World Health Organization has defined the **social determinants of health** as “...factors such as where we live, the state of our environment, genetics, our income and education level, and our relationships with friends and family all have considerable impacts on health...” including the available health system (World Health Organization, 2020b, para. 1). Commonly acknowledged factors, such as social norms or attitudes (e.g., discrimination, racism); exposure to crime, violence, and social disorder; and concentrated poverty, are associated with health outcomes and are recognized as social determinants of health (CDC, 2015a; USDHHS, n.d.). The connection between social inequalities and health is illustrated in the Bay Area Regional Health Inequalities Initiative (BARHII) conceptual framework: <http://barhii.org/framework> (BARHII, 2015).

The unequal distribution of these factors among certain groups is thought to contribute to health disparities that are persistent and pervasive. The IOM report *For the Public's Health: The Role of Measurement in Action and Accountability* called for addressing the underlying factors, not only the data, related to morbidity and mortality (2010). When we address health disparities, we must consider these social determinants and work on all levels—individual, aggregate, community, and population—to reduce them.

Social determinants of health are related to both morbidity and mortality. Quantified deaths that could be attributed to social factors in the United States were reported:

- The authors found that life expectancy in the United States for the top and bottom 1% of the income distribution varies by 15 years for men and 10 years for women (Price, Khubchandani, & Webb, 2018).
- Moreover, it is estimated that only 10% to 15% of the increase in length of life in Western nations can be attributed to improved medical care, according to Raphael's classic treatise (2003).
- Between 2001 and 2014, life expectancy increased by 2.34 years for men and 2.91 years for women in the top 5% of the income distribution, but by only 0.32 years for men and 0.04 years for women in the bottom 5% (Chetty et al., 2017).
- Life expectancy for low-income individuals varied substantially across local areas. In the bottom income quartile, life expectancy differed by approximately 4.5 years between areas with the highest and lowest longevity (Chetty et al., 2017).
- Geographic differences in life expectancy for individuals in the lowest income quartile were significantly correlated with health behaviors such as smoking. Life expectancy for low-income individuals was correlated

with the local area fraction of immigrants, fraction of college graduates, and government expenditures (Chetty et al., 2017).

- Life expectancy can also be linked to where you live as predicted through zip code (Robert Wood Johnson Foundation, 2018a, 2018b).

To improve the health of disadvantaged groups, early public health efforts addressed determinants of health such as sanitation and poverty, along with living conditions and other environmental issues, as noted in Chapters 3 and 9. The present need to address underlying social conditions to improve health status is borne out by current research on race and socioeconomic class (Hahn & Truman, 2015). It is now widely acknowledged that to truly have an impact on the health of the population, there is a need to improve social conditions (Bharmal, Derose, Felician, & Weden, 2015; CDC, 2018). Political action and participatory action research are vital tools in reducing the effects of these conditions, as are methods of community empowerment (World Health Organization, 2020b; see Chapters 4 and 13). Healthy People 2030 addresses the context to which people's lives influence their health (see the social determinants of health in Box 23-5).

## **BOX 23-5 HEALTHY PEOPLE 2030**

### **Social Determinants of Public Health**

- Economic stability
- Education access and quality
- Health care access and quality
- Neighborhood and built environment
- Social and community context

## Socioeconomic Gradient of Health

In a series of large-scale, longitudinal studies in England, the now classic Whitehall studies, British civil servants were divided into socioeconomic groups based on their occupational status, from executives to unskilled workers. What the investigators discovered was an improvement in mortality and morbidity rates as the level of one's occupation and pay increased. Those at the lowest levels had the poorest health, but as they moved up the salary scale and occupational level, their health improved. What makes this so interesting is that all of the workers had basic health insurance coverage and free medical care—no real problems with access to health care existed. Although less pronounced, even when the researchers adjusted for diet, exercise, and smoking, the gradient persisted (Marmot, Ryff, Bumpass, Shipley, & Marks, 1997; Marmot & Wilkinson, 2006). The investigators of one study found higher prevalence of heart disease for all participants at the lower end of the social stratus. The researchers also found death rates for diabetic participants to be about 200% higher in the lowest social group when compared with the highest (Chaturvedi, 1998).

A U.S. study, following up on children of Framingham study subjects, found an association between lower socioeconomic position and coronary heart disease. A later study found higher odds of smoking, excess consumption of alcohol, and obesity, which “may contribute to adult cardio metabolic disease” by the predisposition of these unhealthy behaviors (Loucks et al., 2009; Non et al., 2016, para. 5).

This direct relationship between social class or income and health has been termed the **socioeconomic gradient** (Hajizadeh, Mitnitski, & Rockwood, 2016). It has been found in populations around the world, although not always unfailingly, and has been related to

- Poor health outcomes regarding cardiovascular disease in European countries (Lenhart, Wiemken, Hanlon, Perkett, & Patterson, 2017)
- Cancer incidence, mortality, and survival in Western countries (Olver & Roder, 2017)
- Injury rates, such as blunt and penetrating injuries (Chikani et al., 2015)
- Increased burden of chronic illness among Kenyan, South African, and Indian citizens (Mendenhall, Kohrt, Norris, Ndeti, & Prabhakaran, 2017)
- Outcomes of adult asthma, chronic obstructive pulmonary disease, and rhinitis (Torres-Duque, 2017)
- Behaviors, such as smoking, that are highest among those who are from the working class and who have low-income and low educational levels (Psaltopoulou et al., 2017)

- Chronic conditions in older adults, with individuals in the poorest neighborhoods in Canada being more likely to have more chronic conditions and die as a result of those conditions ([Lane, Maxwell, Grunier, Bronskill, & Wodchis, 2015](#))
- Higher rates of in-hospital mortality in U.S. pediatric patients and Iranian acute coronary syndrome patients ([Abbasi et al., 2015](#))
- Lower levels of education and income being associated with higher rates of low birth weight, whereas higher levels of occupation and income being associated with lower rates of infant mortality ([Elder, Goddeeris, & Haider, 2016](#))

## Health Disparities

**Health disparities** are differences in the quantity of disease, burden of disease, and other adverse health conditions present in different groups (Zhang et al., 2017).

- Health disparities may be unavoidable, such as health-damaging behaviors that are chosen by an individual despite health education and counseling efforts, but most are thought to be due to inequities that can be corrected (Mueller, Purnell, Mensah, & Cooper, 2015).
- A long-held belief about health inequities, adopted by the World Health Organization (2017), is that they are unnecessary and avoidable as well as unjust and unfair, so that the resulting health inequalities also lead to inequity in health.
- Health disparities can be objectively viewed as a disproportionate burden of morbidity, disability, and mortality found in a specific portion of the population in contrast to another.
- The topic of social determinants of health was added to *Healthy People 2020* (Office of Disease Prevention and Health Promotion, 2020a). The *National Healthcare Quality and Disparities Report* revealed that disparities persist, but several racial disparities in rates of childhood immunizations and adverse events associated with procedures have been eliminated (AHRQ, 2015).
- Reported disparities exist in the areas of quality of health care, access to care, levels and types of care, and care settings; they exist within subpopulations (e.g., elderly, women, children, rural residents, disabled) and across clinical conditions.
- Promoting healthy choices does not eliminate health disparities; action must be taken to improve the conditions within people's environments. That is why Health People 2030 has increased its focus on SDOH (USDHHS, n.d.). In fact, one of Healthy People's 2030 goals focuses on SDOH: "Create social, physical, and economic environments that promote attaining the full potential for health and well-being for all" (USDHHS, n.d., para 4).

Poor access to quality care and overt discrimination are examples of disparities. Discrimination can occur during service delivery if health care providers are biased against a specific group or hold stereotypical beliefs about that group. Providers may also not be confident about providing care for a racial or ethnic group with whom they are unfamiliar. Language may be a problem, as can cultural values and norms that are unfamiliar to providers. Patients can also react to providers in a way that promotes disparities;

patients may not trust the information given to them and may not follow it as explained, leading to inadequate care (Mueller et al., 2015).

## *Access to Care*

The landmark IOM (2003) report *Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care* noted a large body of research highlighting the higher morbidity and mortality rates among all racial and ethnic minority groups when compared with Whites. This report drew attention to an issue that continues today and remains relevant. Differences in health care access were also explained, whether due to inadequate or no health insurance, problems getting health care, poorer quality of care, fewer choices in where to go for care, or the lack of a regular health care provider. For instance, because there are fewer numbers of health care providers in minority neighborhoods, finding a primary care provider is more difficult for those living in these areas. Providing low-cost or free clinics within low-income neighborhoods has been shown to improve the management of chronic conditions and decrease rates of hospitalization (Hutchinson et al., 2018).

Progress in this area has remained slow. The Institutes of Medicine's Progress Report highlights the following mechanisms to address 21st century health care needs: better coordination of care, nurses to practice to the full extent of their license, increased educational levels of nurses (including more doctorate and bachelor's prepared nurses), increased workforce diversity, and nurse engagement in leadership roles (National Academy of Sciences, 2019).

Residential segregation, although illegal, still exists and can play a role in health disparities. Many vulnerable populations, especially racial and ethnic minority groups and low-income populations, find health care at safety-net hospitals and community clinics where they are at the mercy of balanced budgets and vast bureaucratic systems (AHRQ, 2015). However, more recent data showed that the ACA is improving access for uninsured individuals to safety-net clinics in states with expanded Medicaid coverage (Angier et al., 2015).

Other geographic factors can affect access to health care services. For example, a classic study by O'Mahony et al. (2008) found that only 25% of pharmacies in non-White neighborhoods, compared with 72% in predominately White neighborhoods, stocked sufficient opioid drugs to meet the needs of palliative care patients in different New York neighborhoods.

Health care access is also problematic for other vulnerable groups. For example, services and resources for the mentally ill and substance abusers are often fragmented and inadequate, as are those for abusing families and homeless persons. Refugees and immigrants may have difficulty finding affordable and easily accessible health care, largely because of their lack of

health insurance and the need to find care at free clinics or emergency rooms (Richard et al., 2016). When vulnerable individuals cannot get appropriate health care or treatment for illness or disease, for whatever reason, they are more likely to have health deficits.

### *Quality of Care*

Quality of care is another area in which health disparities persist. One aspect of quality care is the comfort level patients have with their providers. Research indicates that racial and ethnic minority clients feel more comfortable and satisfied with care from a health care provider who comes from the same racial and/or ethnic group (Fig. 23-6; AHRQ, 2015). However, a shortage of ethnically diverse health care providers exists. Despite racial and ethnic minorities constituting 37% of the U.S. population, only 19% of registered nurses are from minority racial and ethnic groups (American Association of Colleges of Nursing, 2015).

**FIGURE 23-6** Racial and ethnic minority clients often prefer health care providers from the same racial and ethnic background.

Lack of quality health care services is common among racial and ethnic minority groups. A recent study on Black and White older adult Medicare general surgical patients showed that Blacks had higher 30-day mortality, in-hospital mortality, in-hospital complications, and failure-to-rescue rates, longer length of stay, and more 30-day readmissions (Silber et al., 2015). The researchers suggested that poorer health of Blacks on surgical presentation was a major contributing cause for the disparities (Silber et al., 2015).

Communication can also be a factor in poor quality of care. Marginalized vulnerable populations, such as substance abusers, at-risk mothers and infants, abusing families, suicide-and homicide-prone individuals, and the

mentally ill or disabled, may feel they are treated as “second-class citizens,” and cultural barriers and misunderstandings can lead to a discontinuation of recommended regimens. Poor health outcomes may result as effectiveness of health care for vulnerable populations is not often considered or even well defined ([Hutchinson et al., 2018](#)).

# WORKING WITH VULNERABLE POPULATIONS

Through the day-to-day provision of care and participation in larger efforts in the community, the nurse can help improve health outcomes for vulnerable populations (see [Box 23-6](#)).

## **BOX 23-6 QSEN: Focus On Quality**

**Patient-Centered Care for Working With Vulnerable Populations**  
**Patient-Centered Care: Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient's preferences, values, and needs (Cronenwett et al., 2007, p. 123).**

(See [https://qsen.org/competencies/pre-licensure-ksas/#quality\\_improvement](https://qsen.org/competencies/pre-licensure-ksas/#quality_improvement) for the knowledge, skills, and attitudes associated with this QSEN competency.) C/PHNs work with many vulnerable groups, including the homeless population. Vulnerable groups within the community may be marginalized and lack access to quality health care services. To build rapport and trust, nurses must provide respectful understanding and care while focusing on the needs of the client. How do the QSEN competencies assist nurses in demonstrating patient-centered care to the homeless?

Students in a community health clinic spent time working with homeless clients and their families in a homeless center. Some students had limited previous exposure to diverse populations and were aware only of stereotypes and misconceptions regarding this population. Homeless women heads-of-household and their children made up 60% of the population using this facility. Students were unaware of the variance of demographics and backgrounds regarding this vulnerable group.

In conjunction with the homeless center, student identified clients' needs and provided an educational health fair. Local agencies supplied free needed items; education stations were then created to support health issues surrounding the donated items (e.g., an oral health education station provided free travel-size toothbrushes).

While offering health education, students engaged with clients and their families, which gave them the opportunity to learn about vulnerability. One

student had a conversation with a mother about how she became homeless. The woman shared that after her husband died, she had no family or support systems for herself or her child with severe asthma. The woman lost her home and insurance, so she was unable to pay for her child's medical bills. Another student talked with a man about how long he had been homeless. This man was a veteran and suffered from PTSD and drug misuse; alienated from his family and friends, he had been homeless for several years.

In speaking with clients, students identified issues that prevented use of shelters by some clients, such as lack of privacy or rules prohibiting pet dogs. Students learned valuable skills related to working with a vulnerable group and breaking through fears related to stereotypes and biases.

Source: [Cronenwett et al. \(2007\)](#).

## The Role of Public Health Nurses

C/PHNs can work to improve the health of vulnerable populations by empowerment, facilitating external support from patient's family and friends, and engaging in evidence-based practice.

### *Empowerment*

Because vulnerability often equates with feelings of powerlessness, the actions of C/PHNs can either promote engagement or destroy chances for rapport. C/PHNs can use **empowerment strategies** in their work with clients once trust and rapport have been established (Box 23-7). The personal values, experiences, characteristics, and actions of both nurses and clients influence the speed at which this process takes place and the eventual level of connection. Helping clients identify their fears and clearly defining the C/PHN role with the client and family are also important.

**BOX 23-7 Community/Public Health Nurse Actions to Promote Client Empowerment** Which community/public health nursing activities/actions are most effective in promoting empowerment among nurses' vulnerable clients? In Falk-Raphael's (2001) well-known qualitative study of public health nurses (C/PHNs) and their clients, several themes were noted as components of the C/PHN role:

- *Empowerment* is “an active, internal process of growth” that is reached by actualizing the full potential inherent within each client, and this occurs “within the context of a nurturing nurse–client relationship” (p. 4). C/PHNs describe the process of empowerment as a two-way street with clients not only gaining knowledge and skills and “acting on informed choices” but also further

empowering the nurse to continue the work of the empowerment (p. 6).

- *Having a client-centered approach*, denoted by flexibility in dealing with clients, for example, “meeting them where they are,” “communicating at their level,” and “backing off and following client's agenda” (p. 6)
- *Developing a trusting relationship* based on mutual respect and dignity, for example, clients as active partners with the C/PHN assuming more or less responsibility as needed; being empathetic, nonjudgmental, and “creating a safe environment” (p. 7)
- *Employing advocacy*, both at an individual level as well as political advocacy, for example, using their role and power as a professional to cut through bureaucratic red tape, connecting clients with available community resources, supporting clients in reaching their health goals, making their expertise available, and being a client resource as someone who is open and “available” (p. 8)
- *Being a teacher and role model*, using a variety of strategies and providing opportunities for clients to safely practice new skills. For example, using strategies such as teaching classes, providing individual coaching, providing positive reinforcement and support, demonstrating skills such as assertiveness, and encouraging community action/participation are helpful
- *Capacity building* through encouraging and supporting of clients' work toward attaining health goals, for example, “reflective listening and an empathetic approach” focusing on strengths, not limitations; facilitating client “self-exploration” and providing encouragement for them to “act on their choices” while being “realistic about barriers to success”; or having expectations for client accountability regarding their decisions and actions (p. 9)

Source: [Falk-Raphael \(2001\)](#).

Building and preserving relationships with clients is a central focus of C/PHN home visits. It requires building trust and rapport and helping them to feel accepted, engaged, and ready. The building phase involves working with individual clients to improve their social connections, build their strengths, and work toward their goals. Building self-efficacy, motivation, and health literacy are essential in this stage, as are helping them with coping skills and giving encouragement as they build resilience.

Extending strategies include helping clients to use new strategies and apply them in other situations. Phone calls and other methods of checking in with clients are used to help them change behaviors and access services. Negotiation and teamwork approaches are helpful in this stage. Keeping a focus on solutions rather than problems helps build client strengths. Six

principles of solution-focused nursing, built on mental health nursing concepts, are helpful (McAllister, 2010):

- Focus on the person, not the problem.
- Do not focus solely on problems. Begin with an emphasis on strengths, as this can build client hope and self-confidence.
- Resilience is just as important as vulnerability.
- Work to change unjust societal and cultural forces.
- Nurses should assist clients as they adapt and grow and not focus solely on care and illness.
- Encourage a proactive approach that uses the three stages of client involvement: joining, building, and extending.

These solution-focused nursing principles of client empowerment are exemplified in a study directed by the American Academy of Nursing. In examining the commonalities of nurse-designed models of health care, the authors of this study found four common elements (Mason, Jones, Roy, Sullivan, & Wood, 2015, p. 548):

- Health holistically defined
- Individual-, family-, and community-centric approaches to care
- Relationship-based care
- Group and public health interventions (Box 23-8)

## BOX 23-8 PERSPECTIVES

**A C/PHN's Viewpoint on Community/Public Health Nursing I have been a C/PHN for many years and been fortunate enough to work with various populations. I remember a case when I learned that although experience is a valuable asset, sometimes this contributes to assessment miscues. I had an established relationship with a socioeconomically disadvantaged postpartum client, who was experiencing anxiety, feelings of**

**being overwhelmed, and insomnia. The interventions that I had successfully used for so many other moms in similar situations with postpartum depression had failed with this client. It was not until I inquired about a picture of my client, Nancy, in her military uniform that she shared with me that she had served for a few years in the Middle East. She further stated that she did not like to discuss her past, she regretted not being physically able to continue her military career, and she just wanted to “get some sleep.” Long story short, we were able to get Nancy into a Veteran's Administration (VA) residential treatment program for substance abuse and medical treatment for traumatic brain injury (TBI). I learned through this encounter that experience coupled with a patient-centered assessment, minus my internal preconceptions, results in the best outcomes for patients. Nancy had more than the usual stressors affecting her, and I was glad that I was finally able to pick up on those clues and address her needs more completely.**

—Tessa, C/PHN

While empowering clients, nurses should also remember to empower themselves through collaboration with others and self-care. Working with disadvantaged populations can be challenging and exhausting. Often, novice community health nurses feel overwhelmed and suffer “compassion fatigue” when confronted with the crushing realities that their vulnerable, disenfranchised clients face on a daily basis. Feelings of guilt sometimes surface when nurses contrast their own life experiences with those of their

clients. To be effective in working with vulnerable populations, it is often more helpful to donate money and items on a group level rather than an individual level and to work for substantial changes in community attitudes and policies. Also, it is vital to remain grounded to continue to have the necessary energy and compassion (Box 23-9).

## **BOX 23-9 Evidence-Based Practice**

**Caring and Compassion Dmytryshyn, Jack, Ballantyne, Wahoush, and MacMillan (2015), studying public health nurses (C/PHNs) working with a Nurse–Family Partnership program, found that compassion fatigue could be problematic for nurses working with vulnerable young mothers in this long-term home visiting program (described in more detail in Chapter 4). C/PHNs generally found the nurse–client relationship rewarding but needed to adapt their philosophy and definition of client success to see clients as the experts of their own individual lives. In this qualitative study, C/PHNs expressed personal costs of worrying about clients and doubting their own effectiveness in their ability to address concerns of clients. When they were able to shift the focus to the client, they reported greater satisfaction in the nurse–client relationship and in watching the successes of their clients over time.**

Source: Dmytryshyn *et al.* (2015).

In one study, outcomes of empowerment for clients included increased self-esteem and confidence, improved self-efficacy, and the ability to “reframe situations in a positive way” (Falk-Raphael, 2001, p. 10). Clients

also subsequently made better choices regarding their health and used resources more appropriately. They were better able to seek information and services and became more politically active. Clients' focus became more proactive than reactive, and they felt that they could communicate more effectively to define boundaries or express feelings. Consequently, clients were also better able to collaborate with their health care providers, becoming more trusting partners in care by demonstrating ownership for their actions and their health. Some clients noted a newfound ability to see their communities in a more holistic way and looked for ways to change things for the better. A large part of C/PHN practice is to work with the vulnerable and encourage them to become more self-reliant and responsible for their health.

### *Facilitating External Support*

The degree of external support clients have, along with their temperament and other individual factors, affects their ability to cope with stress and adverse situations. The support can be from family members, neighbors, friends, teachers, or others. C/PHNs can help clients establish external support at both the individual and population levels (Boxes 23-10 and 23-11). (For an interactive map that provides information on the degree to which specific U.S. communities are affected by external stresses on human health, see the CDC's Social Vulnerability Index at <https://svi.cdc.gov/>.)

## **BOX 23-10 STORIES FROM THE FIELD**

**A View of Disasters When disaster strikes the communities of those who are struggling to survive, the effects are devastating, and the recovery is long and challenging. Communities with poorly built homes, without strong foundations or storm windows, are less safe during tornadoes and hurricanes. Floods impact low-lying, low-income neighborhoods the hardest (Lowrey, 2019). The high cost of living in California has encouraged low-income individuals to migrate to less expensive and remote fire-prone areas (Lowrey, 2019).**

In 2018, the most destructive fire in California history incinerated the town of Paradise within a matter of hours. The poor were the hardest hit, and 2 months after the disaster, because of inadequate housing for the poor, there were still hundreds living in shelters. Many of those impacted were elderly and disabled, living in trailer homes. Local hospitals and other health care facilities were also incinerated, impacting access to health care. A nurse who was interviewed after the disaster, referring to the struggling poor impacted by the devastating fire, likened the incident to a house of cards; when removing a card, the whole house collapses (Lowrey, 2019).

In 2017, Hurricane Harvey caused catastrophic flooding and many deaths in Houston, Texas. The New York Times interviewed a survivor of this disaster 1 year later. She spoke about the experience of losing her home and living in a trailer. The survivor had no savings to use for recovery, and the support she received from the government, nonprofit groups, and volunteers was not enough for her and her family to return to a sense of normalcy. The survivor and her family were left feeling sad, broken, and confused (Fernandez, 2018).

In 2005, Hurricane Katrina broke through the levee system in New Orleans, Louisiana, causing massive flooding. Many of the poor residents did not flee because they did not have a car, and they didn't have money to pay for a hotel and other necessities. Health issues related to the aftermath of the hurricane included concerns about contamination of local waters with solid waste, pesticide use for vector control from an abundance of mosquitoes, and reduction in air quality from mold and dust. The poor bore the brunt of the disaster, and the few facilities that existed to quickly help the victims became miserable and dangerous places (Schake, Sommers, Subramanian, Waters, & Arcava, 2019). Moving from large shelters to trailer homes negatively affected the mental health of some survivors and caused a great strain on family relationships. A Hurricane Katrina survivor who was born and raised in a housing project in New Orleans was relocated, as many were, to Houston, where she had no family, social support, nor means of transportation (Voice of a Witness, 2019).

Source: Fernandez (2018); Lowrey (2019); Schake *et al.* (2019); Voice of a Witness (2019).

**BOX 23-11 Foundational Public Health Services (FPHS) Model The FPHS model is a conceptual framework describing the capacities and programs that state and local health departments**

**should be able to provide to all communities and for which costs can be estimated.**

## **Foundational Public Health Service**

### **Foundational Areas**

- Environmental Health<sup>a</sup>
- Chronic Disease
- Injury Prevention
- Maternal, Child Health
- Access Linkage
- Communicable Disease

### **Foundational Capabilities**

- All Hazards
- Communications
- Policy Development
- Assessment
- Community Partnership
- Organizational Competencies

### **Other Health/Services**

- Critical Care
- Environmental Protection<sup>a</sup>
- Behavioral Health
- Disability Related
- Other Services

<sup>a</sup>“Environmental Health” refers to prevention (permitting, education, regulation) activities. “Environmental Protection” refers to remediation and environmental quality.

Adapted with permission from Resnick, B. A., Fisher, J. S., Colrick, I. P., and Leider, J. P. (2017). The foundational public health services as a framework for estimating spending. *American Journal of Preventive Medicine*, 53(5), 646–651.

*Using Evidence to Reduce Vulnerability*

Community health nurses can help vulnerable populations, communities, individuals, and families reduce their vulnerability by using evidence from research, expert opinion, and best practices (see [Chapter 4](#) on evidence-based practice). Often, evidence is embedded in policies, procedures, and clinical guidelines. Thus, the first place to locate evidence for practice is in the specific agency documentation for nursing practice. Sometimes, a community need is discovered that requires creative thinking and evidence-based interventions ([Box 23-12](#)).

## **BOX 23-12 Population Focus**

**Improving Health Care Professionals' Caring for LGBTQ Persons**  
**Karen and Lisa had been together for 17 years. They lived in a state where same sex marriage is not legal but they were registered domestic partners. Together they had three children ages 9, 11, and 15. Their children were conceived through artificial insemination. Two of the children were conceived by Lisa and one by Karen.**

For their summer vacation, they decided to visit a well-known amusement complex for a week. Three days into their vacation, Karen suddenly complained of a severe headache and within minutes, was unresponsive. She was taken by ambulance to a local hospital.

When Lisa arrived at the hospital with their children, she was stopped by the emergency room admissions clerk, who said she needed her insurance information. After providing the information, she asked to see her partner. The admissions clerk found the charge nurse who asked Lisa what her relationship was to Karen. When Lisa told her they were partners, the charge nurse told her that only immediate family would be allowed in to see her and she was not considered family. Lisa tried to explain that she was Karen's only immediate family, that both her parents were dead and that they had been together for 17 years. Again, the charge nurse refused to allow her in. Lisa spent the next couple hours on the phone with friends back home, sending one of them to their home to find their official domestic partnership paperwork.

After the paperwork had been faxed to the admissions clerk, Lisa approached the charge nurse again asking to see Karen. In a condescending tone, the charge nurse told Lisa that her paperwork is not

recognized in this state and she again refused to allow her to see Karen. She did, however, agree to allow the 9-year-old daughter (the only one of the children Karen gave birth to) to come into the emergency room, but Lisa was concerned that this would be too traumatic for her since she could not go with her nor could her older siblings.

Karen had been intubated immediately upon arrival to the emergency room and underwent CT imaging, which revealed a massive intracranial hemorrhage, likely from an AV malformation. Four hours after her arrival at the hospital, Karen died. Alone.

1. *How do you define family?*
2. *How would you react to this policy?*
3. *What would you do to meet the needs of the patient and the patient's family?*

Source: [National LGBT Health Education Center \(2015, 2016, n.d.\)](#); [The Fenway Institute \(2015\)](#).

—Marla Seacrist, PhD, RN

Many areas for improvement of the lives of vulnerable populations lie in areas related to prevention and health promotion, as described above. Primary prevention is readily available in the form of immunizations for children, adolescents, and adults. Nursing activities to promote increasing immunization levels among vulnerable people will result in greater economic and social returns for the whole community. Similar is the involvement of nurses in smoking prevention and smoking cessation activities. Also, some vulnerable subpopulations require additional insight and experience, such as veterans ([Box 23-13](#)) and victims of human trafficking ([Box 23-14](#)).

## **BOX 23-13 Population Focus**

**Veterans Health Veterans are a unique and diverse population in the community. There are approximately 20 million veterans living in the United States, with almost 2 million of those being women ([VetPop, 2016](#)). Veterans are older in comparison to non-Veterans ([NCVAS, 2018](#)), have shorter life expectancy, lower amounts of education, and household income when**

**compared to the general U.S. population (NCVAS, 2017). The military culture (deployments, service commitments, training, and battlefield exposure) and the subsequent impact on the health of veterans and their families can only be experienced by this population. The current veteran population is diverse, with representation from varying gender and sexual orientations, ethnicities and races, ages, and geographies (Veterans Health Administration, 2018). These characteristics have historically resulted in greater health disparities and therefore constitute veterans as a vulnerable population. Veterans can experience long-lasting negative effects because of their time in the military. These negative effects are often the result of traumatic stress and can create vulnerabilities that result in mental health disorders, alcoholism, substance abuse, dysfunctional relationships, homelessness, depression, and unemployment (Koven, 2018).**

Traumatic exposures can lead to posttraumatic stress disorder (PTSD). PTSD has been associated with an increased risk for depression, anxiety, attachment avoidance, obesity, type 2 diabetes, and substance abuse (Scherrer et al., 2018). PTSD has been associated with a nearly 200% increase in hospitalizations among active duty service members between 2006 and 2012, and it is a leading diagnosis in the U.S. Department of Veterans Affairs medical settings (Armenta et al., 2018). These statistics may underestimate the impact of PTSD because many service members in need of treatment might not seek care.

- Symptoms of PTSD and depression overlap significantly (Sher, Braqualais, & Casas, 2012).

- Common features of depression include diminished interest or participation in significant activities, irritability, sleep disturbance, difficulty concentrating, restricted range of affect, and social detachment (Sher et al., 2012).
- Veterans who live in rural communities are more socially isolated and are 20% more likely to commit suicide than veterans who live in urban areas (Mohatt et al., 2018).
- Obesity is twice as common in patients with PTSD compared to those without PTSD and those with PTSD were 30% more likely to report being diagnosed with type 2 diabetes than those without traumatic exposure (Scherrer et al., 2018).
- Traumatic brain injuries have resulted in frontal lobe deficits that are linked to impulsive behaviors such as aggression and violence (Kois, et al., 2018; Mohatt et al., 2018).

Source: Armenta et al. (2018); Kois et al. (2018); Koven (2018); Mohatt et al. (2018); NCVAS (2017, 2018); Scherrer et al. (2018); Sher et al. (2012); Veterans Health Administration (2018); VetPop (2016).

Cory Church, PhD, RN-BC

**BOX 23-14 Human Trafficking Each year, approximately 14,500 to 17,500 women, men, and children are trafficked into the United States for the purposes of forced labor or sexual exploitation (American Civil Liberties Union, 2018). The Global Slavery index (2018) estimates that on any given day in 2016, there were 403,000 people living in conditions of modern slavery in the United States, a prevalence of 1.3 victims of modern slavery for every thousand.**

Human trafficking has significant effects on both physical and mental health. Victims of human trafficking rarely come forward to seek help because of language barriers, fear of the traffickers, and/or fear of

law enforcement. Traffickers use force, fraud, or coercion to lure their victims and force them into labor or commercial sexual exploitation. Traffickers look for people who are susceptible for a variety of reasons, including psychological or emotional vulnerability, economic hardship, lack of social safety net, natural disasters, or political instability.

Victims of human trafficking often have untreated medical problems, including physical injuries associated with abuse and torture (e.g., burns, lacerations, missing or broken teeth), malnutrition, dehydration, substance use disorders, depression, anxiety, and PTSD (Nursing for Women's Health, 2016; Richards, 2014). It is estimated that 80% human trafficking victims are women and girls (Nursing for Women's Health, 2016). Female victims are at increased risk for gynecologic and obstetric problems, including persistent or untreated sexually transmitted infections, unintended pregnancies, repetitive abortions or miscarriages, trauma to the rectum or vagina, and infertility (Nursing for Women's Health, 2016; Richards, 2014).

Nurses are ideally positioned to screen, identify, care for, provide referral services for, and support victims of human trafficking. It is imperative for nurses who provide care to human trafficking victims to have knowledge of local organizations specializing in working with trafficked women; free health services (general practice, reproductive health, hospital, and mental health); sources of advice on housing and other social services; legal aid/immigration advice services; local churches/community support organizations; language training centers; and nongovernmental organizations in the victim's home country (U.S. Department of the State, 2018). Screening patients for human trafficking in private, safe, health care settings and, if needed, utilizing professional interpreter services are imperative in providing care to this vulnerable group of people. During interviews and care encounters with these victims, it is key for nurses to be respectful and nonjudgmental.

Source: American Civil Liberties Union (2018); Nursing for Women's Health (2016); Richards (2014); U.S. Department of the State (2018).

Veterans who have experienced trauma may not recognize dysfunctional coping styles such as social isolation and mistrust of others as symptoms of mental health disorders but as functional coping strategies. Increase in alcohol and substance use has been shown to parallel and increase in PTSD symptoms (Koven, 2018). Military sexual trauma (MST) increases PTSD symptoms and attachment anxiety, causing issues with intimacy and trust (Holiday, et al., 2018). MST is defined by the Veterans Health Administration as sexual assault and repeated, threatening sexual harassment occurring during military service (Veterans Health Administration, 2018).

The prevalence of MST among veterans is estimated to be 21.5% among women and 1.1% among men ([Kimmerling et al., 2007](#)).

Along with physical and psychological injuries, war has the capacity to affect veterans spiritually and morally. Veterans exposed to combat can experience moral injury. Moral injury has been defined as “perpetrating, failing to prevent, bearing witness to, or learning about acts that transgress deeply held moral beliefs and expectations” ([Drescher et al., 2011](#), p. 10). Some of the symptoms reported among combat veterans with PTSD in the literature that arguably might be related to moral injury include ([Drescher et al., 2011](#))

- Negative changes in ethical attitudes and behavior
- Change in or loss of spirituality, including negative attributions about God
- Guilt, shame, and forgiveness problems
- Anhedonia and dysphoria
- Reduced trust in others and in social/cultural contracts
- Aggressive behaviors
- Poor self-care or self-harm

A greater understanding of the emotional scars experienced by veterans and their greater risk for comorbidities will help improve and direct care, resulting in better outcomes.

Women veterans are also increasing in the community and are the fastest-growing population within the veteran community ([U.S. Department of Veterans Affairs \[USDVA\], 2015](#)). In the last 10 years, women enrolled in health care service through the Veterans Health Administration have doubled. Women veterans are younger and more racially and ethnically diverse in comparison with male veterans ([Northern Center for Veteran's Analysis and Statistics \[NCVAS\], 2016](#)). Higher numbers of female veterans have experienced MST ([USDVA, 2010](#)). The Veterans Health Administration is working to address strategic priorities in the areas of primary care, health education, and reproductive health. Each Veterans Health Administration health care system contains an MST coordinator and a Women Veterans Program manager to advise and advocate for female veterans' health care services. Nurses in both acute and primary care areas can seek out these services for their patients.

It is evident that Veterans have multiple determinants that affect health and access to care. The Veterans Health Administration health care system is working to improve disparities among vulnerable populations and increase access to care ([USDVA, 2016](#)). Nurses in all care settings can call the Veterans Health Administration to determine access and benefits for

veterans. It is equally important for nurses to assess military service in patients and the impact of service on one's health.

The *Military Health History Pocket Card for Clinicians* (USDVA, 2017) provides an easy guide for clinicians to understand veterans' unique medical problems and concerns associated with military service. Nurses can ask, "Would it be ok if I talked with you about your military experience? Did you have any illnesses or injuries while in the service?" The pocket card can help nurses understand if veterans are seeking compensation and benefits for their care, or the current living situation of a veteran. These questions help a nurse determine the level of care needed for veterans in the community. Finally, the pocket card can help establish rapport and collaborative relationships with veterans (Box 23-15).

## BOX 23-15 PERSPECTIVES

**An Emergency Room Nurse's Viewpoint on Community/Public Health Nursing** I have been an emergency room nurse for several years and been fortunate enough to work with various populations. As a beginning emergency nurse, I did not understand that I would advocate for services and resources of patients that sought care in the emergency department. I remember a patient who was experiencing depression, anxiety, and having suicidal ideation came to the local county hospital. Fortunately, I read through the patient's social and medical history only to find that the patient had prior military experience and posttraumatic stress disorder. I brought up the patients' military experience, and this was a way for us to establish a nurse–patient relationship.

**After speaking with the veteran, I was able to determine that he wanted to seek mental health care through the Veterans Health Administration (VHA), but the nearest hospital was several hours away. Through collaboration with the nursing case manager, we were able to establish transportation to the VHA hospital for inpatient mental health treatment. I learned through this encounter that assessing military history in patients is key, especially in individuals in the community with mental health concerns. I was finally able to understand my role in advocating for resources and help for individuals in the community.**

—Cory Church, PhD, RN-BC

## Improving Health Literacy

In addition to immunizations, smoking cessation, and other preventive interventions, the following topics are highlighted as evidence-based concepts shown to improve the health status of vulnerable populations: health literacy, access to nursing services, and policy.

People living in low-income communities often have low educational levels that are related to low literacy and low health literacy levels. An estimated 80 million Americans have limited health literacy. Because clients have difficulty obtaining, processing, and understanding health information, it is not surprising that low health literacy is associated with poorer health outcomes and poorer use of health care services. A systematic review found that low health literacy was associated with more emergency care use, higher hospitalization rates, fewer instances of influenza vaccine and mammography, poorer ability to read labels and interpret health messages, and greater inability to demonstrate appropriate medication administration, as well as higher mortality and poorer overall health status among senior citizens ([AHRQ, 2015](#)).

Assisting vulnerable groups and communities to improve health literacy is one approach for reducing vulnerability and improving health outcomes. Many cities have literacy programs that use volunteers to provide tutoring. This is an excellent way for nurses to give back to the community. Literacy training contributes to health literacy by improving reading, writing, and comprehension skills. A crucial aspect of improving health literacy is improvements in public schools so that more students graduate with adequate skills for higher education and employment. See [Chapters 10](#) and [11](#) for more on health literacy.

## Improving Access to Nursing Services

The benefits of home health are well known (Olds et al., 1997). Home visiting can be provided from almost any setting that provides services to communities. The usual settings are local health departments, home health care agencies, community-based hospice agencies, and visiting nurse associations. In addition, school nurses, ambulatory nurses, parish or faith-based nurses, and other nurses have recently provided limited home visiting services to clients or families seen in a variety of settings, including outpatient clinics, Head Start programs, places of worship, and health centers. Expanding home visiting to all vulnerable groups holds promise for improving the health of many individuals and communities (Fig. 23-7).

**FIGURE 23-7** Home visiting has been shown to have positive outcomes for a variety of vulnerable populations. Results from over three decades of research have demonstrated that home visiting by registered nurses is effective in improving outcomes for low-income women and children.

School-based health centers (SBHCs) are considered one of the most effective strategies for delivering preventive care, especially for difficult-to-reach populations such as adolescents. Numerous evaluations have shown that SBHCs achieve marked improvements in adolescent health care access when compared with that in other settings ([Shackleton et al., 2016](#)). These clinics are included in health care reform funding, largely because of their proven track record for accessibility and quality.

Nurse-led clinics (NLCs) have also increased access to care for communities and provided care that is more affordable, convenient, and with reduced patient waiting times. The nursing role in such clinics involves patient assessment, admission, health-related education, treatment and monitoring, discharge, and referral to other health care professionals. Findings indicate that NLCs were well received by patients, with positive experiences reported by patients ([Randall, Crawford, Currie, River, & Betihavas, 2017](#)). See [Chapters 28](#) and [29](#). Improving access to nursing care in the community has been shown to have benefits for population and individual health.

## Improving Health and Public Policy

Policies to reduce vulnerability for individuals, families, and communities have been shown to be effective at all levels: local, state, and national. Policy based on evidence is an important component of reducing vulnerability for communities and individuals. This section addresses health and public policy, including policy in schools, cities, counties, and health care settings. Policy includes social, economic, environmental, and health aspects. See [Chapter 13](#) for an expansive discussion of policy.

Small changes in policy can make a big difference in outcomes for vulnerable communities. For example, policies to provide healthy foods in school vending machines provide healthier choices for all students, not just those considered vulnerable. Mandatory physical activity time for school children contributes to preventing obesity and enhancing learning in all children and it is essential that future research and policy makers continue to recognize the school environment as a way to improve health for all ([Cisse-Egbuonye et al., 2016](#); [Owen, Kerner, Newson, & Fairclough, 2017](#)).

Communities that lack safe places for physical activities need to have attention directed to the appropriate governing bodies, such as the city council or the department of recreation. Community residents can be effective in bringing about change that improves a total community ([Hood, Gennuso, Swain, & Catlin, 2016](#)). One model that addresses both individual and social determinants of health is the County Health Rankings Model ([Fig. 1-3](#) ; [Robert Wood Johnson Foundation, 2018a](#)).

# SOCIAL JUSTICE AND PUBLIC HEALTH NURSING

Social justice occurs when a society provides for the overall health and well-being of all people by treating people fairly. It involves an equal societal bearing of burdens and reaping of benefits, and it is a widely held view that social justice is the foundation of public health nursing ([Box 23-16](#); [Matwick and Woodgate, 2017](#)).

- Community health nurses who practice social justice have broad and holistic views of health; they have strong convictions that health care is a basic human right and that improving the health of communities is an example of social justice.
- Social justice ensures the distribution of resources that benefits **marginalized populations** and holds in check the self-interest of more privileged populations. Impartiality is the goal.
- For instance, C/PHNs concerned with social justice include socially marginalized and vulnerable populations (e.g., criminal justice involved, undocumented residents) in their influenza pandemic planning processes. Not to do so would constitute discrimination and would be morally indefensible.

## BOX 23-16 Population Focus

### Challenges for Community/Public Health Nursing Related to Refugee Resettlement

*“A refugee is a person who has had to flee his or her country of origin due to a well-founded fear of persecution due to war, race, religion, ethnicity, nationality, political opinion, or association with a particular group.” (UNHCR, 1951 Refugee Convention)*

Currently, there are large numbers of displaced people worldwide. The United Nations High Commission for Refugees (UNHCR) registered 70.8 million displaced persons, 25.9 million refugees, and 3.5 million asylum seekers in its database for the year 2019 ([UNHCR, 2020](#)). Refugees granted resettlement in the United States are among the most vulnerable refugee cases, including single mothers, children, the elderly, survivors of violence and torture, and people with acute medical needs.

Refugee women, in particular, have been exposed to extreme levels of poverty, deprivation, violence, and trauma, which often remain unaddressed after resettlement (COE, 2020). Displacement from one's home and country of origin, loss of family through civil unrest or other traumatic events, as well as loss of familiar cultural norms are enormous challenges for this population (UNHCR, 2020). Further stressors include concerns about poor job opportunities and a fear of poverty. Low literacy skills, language barriers, differences in cultural practices, and lack of knowledge about health care limit access to physical and mental health care services (Riggs, Yelland, Duell-Piening, & Brown, 2016). A lack of culturally appropriate mental health services, providers, and psychosocial programs to address these issues further complicate provision of care for this population.

When assessing the needs of a local population, nurses need to take into consideration both the traumatic events that individuals have experienced as well as the resiliency that they demonstrate in adapting to their new homes. Innovation and creativity are key in developing appropriate interventions for delivery of care to the resettled refugee population. To be effective, community interventions and quality improvement programs must be designed in collaboration with local refugee resettlement organizations that have expertise in working with this population. Appropriate nurse-led interventions might include psychosocial support groups (Felsman, 2016), health literacy programming for English as a Second Language (ESL) classes, individual health coaching for persons with chronic illness, and doula services for pregnant refugee women.

**The Story of Ester (name changed for privacy) Rebels kidnapped Ester's husband in the Democratic Republic of Congo during the civil war one evening. Soon after, rebel forces came back, took her and her children to the forest, and attempted to rape her and her daughter. When she resisted, the rebels shot her in the hip, crippling her. The rebel leader kidnapped her**

**daughter and took her as his wife. Her son, niece, and nephew ran into the forest. She was rescued and taken to a hospital by a kind person on a bicycle. She eventually made her way to a UNHCR refugee encampment, where she registered as an official refugee and lived for many years.**

Ester now lives in the United States in a small city, learning how to negotiate a new language, culture, foods, and health care system. She did eventually find her son and speaks to him by phone when she can. Wheelchair bound, she struggles to make a living; her goal is to reunite her family in America, but it will take a lot of money.

- *What is the best plan of care for Ester as a new refugee?*

# SUMMARY

- Vulnerable populations are at risk for poor health outcomes, including increased risk for morbidity and mortality.
- Various models or theoretical frameworks examine personal and environmental resources and risks relative to vulnerability.
- Leading factors that make aggregates vulnerable are poverty, age, gender, race or ethnicity, being uninsured or underinsured, being a single parent, and having little or no education.
- Social determinants of health are factors strongly associated with health outcomes and include social norms or attitudes, such as discrimination and racism; exposure to crime, violence, and social disorder; and concentrated poverty.
- The socioeconomic gradient, a direct relationship between social class/income and health, has been repeatedly demonstrated in research conducted around the world.
- Health disparities are defined as differences in access to quality health care and in health outcomes, particularly along income/class and racial/ethnic lines, and are usually characterized as avoidable and unfair.
- To be effective, C/HNs must establish a sense of trust and rapport with their clients by finding common ground.
- Empowerment strategies with individual clients can help them to meet their full potential while also providing empowerment to the nurses working with them.
- Community health nurses can provide individual support as well as support and leadership for vulnerable communities.
- Nurses can use evidence-based practice when addressing health disparities among vulnerable populations.
- C/PHNs should be concerned with improving the health literacy, access to health care, and health outcomes through political action.
- C/PHNs must be aware of the value of cultural, racial, and socioeconomic differences and that these differences are often turned into discrimination in health care services and policies. With a focus on social justice, they must be determined to ensure equitable access to care for all.

# ACTIVE LEARNING EXERCISES

1. Identify at least four vulnerable groups within your community. Using one of the models of vulnerability depicted in this chapter, determine the health status for each of these groups. Describe the relative risk for each group.
2. Using “Communicate Effectively to Inform and Educate” (1 of the 10 essential public health services; see [Box 2-2](#) ), find available community resources for each of the groups you identified in exercise 1. Where are the resources located? How easily accessible are they? What outreach services do they provide for the vulnerable population they serve? Describe some socioeconomic resources. What areas are most deficient?
3. Talk to two expert C/PHNs and discuss the concept of empowerment with them. What strategies have they used with clients? Ask them to share examples of when they felt that they made a real difference in the lives of their clients. Note any similarities between these nurses' responses and the roles and behaviors of C/PHNs and client empowerment strategies described in this chapter.
4. Check with the health department about any interagency groups or committees that may be addressing the needs of vulnerable populations in your community. What issues are most important to this group? Who are the members? Note the agencies represented. Are there any community members present? If possible, attend a meeting or access minutes of a recent meeting and determine the types of issues being discussed. Is there a sense of community involvement and participation?
5. Search for a current evidence-based article on vulnerable populations based on ideas from this chapter. Discuss the main points of each article and how they may relate to vulnerable populations (e.g., health disparities, socioeconomic gradient), as well as individual clients you may be seeing in your clinical rotations (e.g., empowerment, health literacy). Based on the research findings, what interventions might be most helpful? Are they feasible in your area? With your specific populations?

# CHAPTER 24

## *Clients With Disabilities*

*“I choose not to place ‘DIS,’ in my ability.”*

—Robert M. Hensel (1969–, Disability Advocate)

### **KEY TERMS**

Activity limitations American Sign Language Americans with Disabilities Act (ADA) Assistive devices and technology Disability Environmental factors Family and Medical Leave Act Impairments Individuals with Disabilities Education Act (IDEA) International Classification of Functioning, Disability, and Health (ICF) National Council on Disability Participation restrictions Respite care Secondary conditions Social Security's Supplemental Security Income (SSI) Temporary Assistance for Needy Families (TANF) Universal design

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Discuss the national and global implications of disabilities.
2. Describe the economic, social, and political factors affecting the well-being of individuals with disabilities and their families.
3. Provide an example of primary, secondary, and tertiary prevention practices for individuals with disabilities.
4. Describe the laws that protect individuals with disabilities, such as the Americans with Disabilities Act.
5. Discuss the benefits of universal design for all persons.
6. Explain the role of the community health nurse when working with clients with disabilities.

# INTRODUCTION

Currently, an estimated 61.4 million (25.7%; [Fig. 24-1](#)) of noninstitutionalized American adults live with **disabilities**, consisting of vision, hearing, mobility, self-care, cognitive, and independent living deficits ([Centers for Disease Control and Prevention \[CDC\], 2018](#); [Okoro, Hollis, Cyrus, & Griffin-Blake, 2018](#)). Disability is an overarching term to describe limitations in activities, impairments, and restrictions in one's ability to participate; “Disability refers to the negative aspects of the interaction between individuals with a health condition (such as cerebral palsy and depression) and personal and environmental factors (such as negative attitudes, inaccessible transportation and public buildings, and limited social supports)” ([WHO, 2011](#), p.7). Conditions such as an aging population and a higher risk for disabilities in older people, as well as a global increase in chronic health conditions, have led to a greater prevalence in disabilities.

# Disability Impacts ALL of US

COMMUNITIES

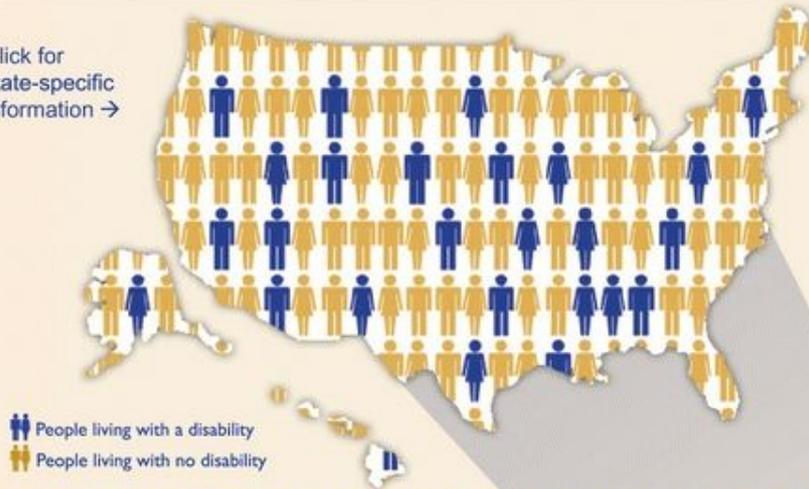

HEALTH

ACCESS

61 million adults in the United States live with a disability

Click for  
state-specific  
information →

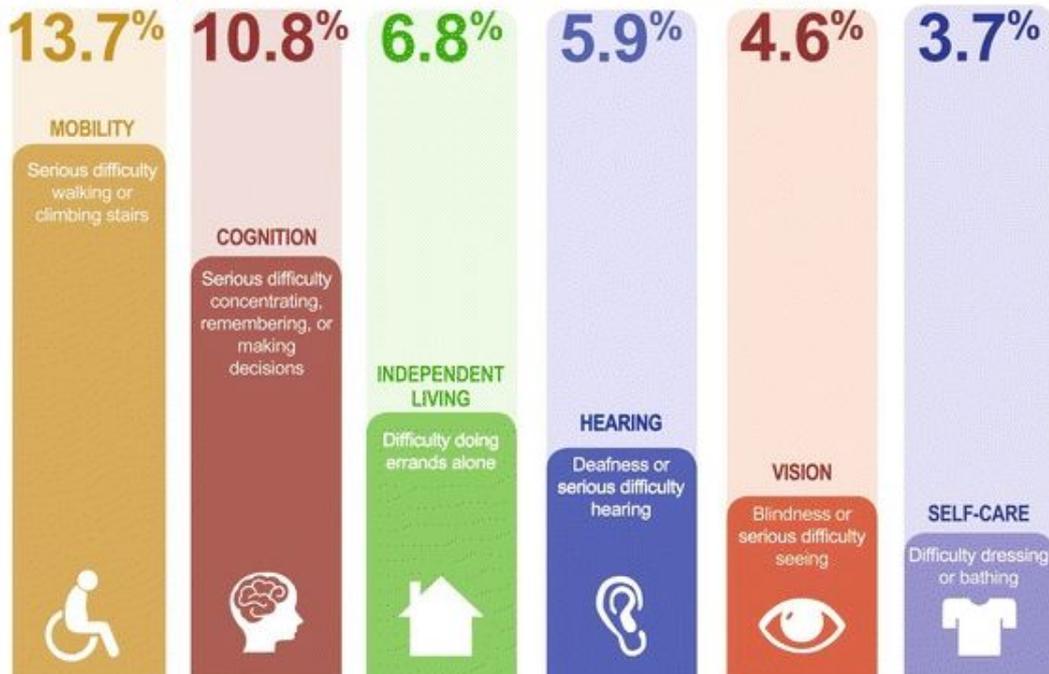

**26%** of adults in  
the United States  
have some type  
of disability  
(1 in 4)

The percentage of people  
living with disabilities is  
highest in the South

## Percentage of adults with functional disability types

**FIGURE 24-1** Disability impacts ALL of us. (Reprinted from Centers for Disease Control and Prevention. (n.d.). *Disability Impacts All of US*. Retrieved from [https://www.cdc.gov/ncbddd/disabilityandhealth/documents/disabilities\\_impacts\\_all\\_of\\_us.pdf](https://www.cdc.gov/ncbddd/disabilityandhealth/documents/disabilities_impacts_all_of_us.pdf).)

*Across the world, people with disabilities have poorer health outcomes, lower education achievements, less economic participation and higher rates of poverty ... partly because people with disabilities experience barriers in accessing services..., including health, education, employment, and transport as well as information. These difficulties are exacerbated in less advantaged communities (WHO, 2011, p. 5).*

According to the Census Bureau, disability status is determined by difficulties in these six areas: hearing, vision, cognitive, ambulatory, self-care, and independent living; children 5 to 14 can have difficulty in hearing, vision, ambulatory, and self-care; and children <5 can have difficulties in hearing and vision (American Community Survey, 2015). Among young adults, cognitive disabilities were the most common, whereas mobility disabilities were more prevalent in those over the age of 45 (Okoro et al., 2018). Overall, disabilities related to mobility were the most prevailing (Kraus, Lauer, Coleman, & Houtenville, 2018; Okoro et al., 2018). The primary physical causes for limitations included back and neck pain and arthritis, whereas depression and anxiety were the leading psychiatric causes (Kennedy, Wood, & Frieden, 2017). In 2015, one of every five adults in the United States had been diagnosed by a health care provider with arthritis, most commonly osteoarthritis.

More than one third of those over the age of 65 have a disability (Kraus et al., 2018). As our populations age, these numbers will increase. There is little difference in gender in the likelihood of a disability, yet by race, American Indian/Alaskan Natives (17.7%) and Whites (14.1%) were more likely to report a disability (Pew Research Center, 2019). Some states are more likely to have people with disabilities than other states. Among the 50 states, Utah had the lowest percent of the population with disabilities at 9.9%, whereas West Virginia had the highest percent at 20.1% (Kraus et al., 2018). With population growth and an aging population, by 2030, the number of adults with arthritis is expected to increase to 67 million (CDC, 2019b).

Globally, 15% of the world's population has a disability (World Health Organization [WHO], 2019a). Worldwide, nonfatal injuries result in temporary or permanent disabilities in likely thousands of people yearly. In the adolescence age group, depression is the number one cause

of disability and anemia is the number three cause of disability. Twenty percent of years lost to disability are due to mental illness (WHO, 2015). Disabilities in children and adults over 60 years were more common in low-to middle-income countries (Banks, Kuper, & Polack, 2018). Adult hearing loss and vision problems were the highest cause of disabilities worldwide. Mental illnesses, such as depression, bipolar disorder, schizophrenia, and alcohol use disorders, were in the top 20 causes of disabilities worldwide (GBD 2015 Disease and Injury Incidence and Prevalence Collaborators, 2016).

In addition to the human burden of disability, the related financial costs of direct medical care and associated indirect costs had significant impact on public and private payers of health and social insurance. Those living with disabilities are at a greater risk of poverty due to the high cost of medical care directly related to the disability, as well as the costs associated with secondary conditions, lower educational attainment, and a higher rate of unemployment or low-paying employment (American Psychological Association, 2019). Costs related to disabilities vary depending on the severity of the disability, the individual's age, and household composition (Mitra, Palmer, Kim, Mont, & Groce, 2017). Employment status varies depending on the type of disability. Individuals with hearing disabilities have the highest percent of employment, and those with self-care disabilities have the lowest rate of employment (Kraus et al., 2018). In 2016, 35.9% of those with disabilities were employed compared with 76.6% of persons without disabilities. Individuals with disabilities make a median income of \$10,000 less than persons without disabilities (Kraus et al., 2018).

This chapter begins with an overview of disabilities, followed by a discussion of current national and global trends in addressing these issues. The various organizations that focus on improving the well-being of those affected by disabling conditions, the impact of these disabilities on families, and the role of the C/PHN in addressing the related needs of individuals, families, and aggregates are discussed. The benefits of universal design and issues of easy access for all ages and abilities are introduced.

# PERSPECTIVES ON DISABILITY AND HEALTH

People with disabilities daily face negative societal views and stereotypes of disability, and many, along with their families, allies, and advocates, have challenged these views. New and more positive approaches continue to emerge that view individuals and their needs from a more person-centered, holistic standpoint. The diverse personal narratives of those living with disabilities emphasize the individual circumstances and unique responses to disability, and social support and potential inclusive care for the individual have a positive impact on engaging those with disabilities in settings such as work (Cook, Foley, & Semeah, 2016).

Individuals living with a disability must be included in clinical and population health strategies to prevent acquisition of additional chronic diseases or threats to their health (Mahmoudi & Meade, 2015; Reichard, Gulley, Rasch, & Chan, 2015). A literature review conducted on the benefits of park-based physical activities found improvement in the three domains of health: physical, social, and psycho-emotional and spiritual (Saitta, Devan, Boland, & Perry, 2019). In the landmark U.S. Surgeon General's *Call to Action to Improve the Health and Wellness of Persons with Disabilities* placed the health of persons living with disabilities equal in importance to the health of the nation, and today, disability remains a priority for the nation, as reflected in *Healthy People 2030* (Box 24-1; U.S. Department of Health and Human Services, 2020).

## **BOX 24-1 HEALTHY PEOPLE 2030**

### **Disability and Health—Objectives**

## Disability and Health—Objectives

### Core Objectives

- |       |   |
|-------|---|
| DH-01 | Reduce the proportion of adults with disabilities who delay preventive care because of cost   |
| DH-02 | Reduce the proportion of adults with disabilities who experience serious psychological distress   |
| DH-03 | Reduce the proportion of people with intellectual and developmental disabilities who live in institutional settings with 7 or more people |
| DH-04 | Increase the proportion of homes that have an entrance without steps  |
| DH-05 | Increase the proportion of students with disabilities who are usually in regular education programs                                       |

### Research Objectives

- |        |  |
|--------|--|
| DH-R01 | Increase the proportion of national surveys with questions that identify people with disabilities                              |
| DH-R02 | Increase the proportion of state and DC health departments with programs aimed at improving health in people with disabilities |

Reprinted from U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives. Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

One area in which further development is needed to better meet the needs of people with disabilities is that of health and wellness apps, such

as medical text messaging or mHealth. Although mHealth apps are helpful for those with chronic conditions such as hypertension or diabetes, they are limited in usefulness for persons with disabilities (Jones, Morros, & Deruter, 2018). Accessibility necessitates redesign of these apps for use by those with vision or hearing impairment, poor fine motor skills, or cognitive disabilities (Jones et al., 2018).

Another potential area of development is the use of technology to enhance the integration of persons with disabilities into society. Manzoor & Vimarlund (2018) completed a literature review on the use of digital technology to improve social inclusion. Results revealed that none of the articles discussed the level of user knowledge needed to use the technology or the cost associated with the technology. Only a few articles discussed technology that could assist in the job market, participation in social events, and accessing educational opportunities (Manzoor & Vimarlund, 2018). As technology advances, hopefully new and innovative solutions addressing these needs will emerge.

## Healthy People 2030

In the United States, *Healthy People* is the most influential series of planning documents that seek to address health promotion and disease prevention as a basis for improving the health of all Americans (U.S. Department of Health and Human Services, 2020). *Healthy People* strives toward a vision of a society in which all people live long, healthy lives. Through its clearly delineated, science-based, and measurable objectives, the decennial *Healthy People* has had far-reaching influences on national and state health initiatives, health care policy, research priorities, and funding since its first efforts in 1979. The evolving American perspectives on disability and on chronic illness have been reflected in the changing focus of the *Healthy People* series. A comparison among *Healthy People* plans since its inception underscores the emergence of new approaches to both identifying priority areas and planning to improve the health of individuals with disabilities and chronic illness. In *Healthy People 2000*, only one priority area was devoted to disability and chronic illness: “Diabetes and Chronic Disabling Conditions” (USDHHS, 2016). One of the most influential aspects of the decade of *Healthy People 2010* was to promote a change in thinking within the health care community about the health promotion and disease prevention needs of people with disabilities. This shift was essential to remedy the lack of existing health promotion and disease prevention activities for this population. Misconceptions of those with disabilities include the following: (1) all people with disabilities have poor health or may have chronic pain; (2) those with disabilities should be treated as different and special; (3) public health activities need to focus only on preventing disability; (4) people with disabilities are similar; (5) there is no need for a clear definition of “disability” or “people with disabilities” in public health practice; and (6) environment does not play a significant role in the disability process (Together We Rock, n.d.).

In *Healthy People 2020*, the section “Disability and Health” further strengthens *Healthy People's* approach to disability to emphasize the principles of health promotion and disease prevention for those currently experiencing disabilities and/or chronic illnesses. Rather than narrowly defining individuals with disabilities and/or chronic illnesses through their limiting conditions, *Healthy People 2020* developers understand that individuals with disabilities and/or chronic illnesses have the potential to meet and exceed health promotion and disease prevention goals set for the nation's population as a whole. This approach is

consistent with the multifaceted national goal of improving parity across all groups and among all individuals. For example, the goal of “Disability and Health” in *Healthy People 2020* is to engage those with disabilities of all ages to maintain the optimal state of health and prevent chronic conditions so that the highest quality of life can be maintained (ODPHP, 2016). For Healthy People 2030, 62 main objectives are identified across the following five broad categories:

- health conditions
- health behaviors
- populations
- settings and systems
- social determinants of health (U.S. Department of Health & Human Services, 2020)

These objectives reflect a growing emphasis on holistic approaches that recognize that life satisfaction is just as important to human health and well-being as are preventive services. In addition, Healthy People 2030 indicates a growing realization that healthy life-years for persons with disabilities equate to decreased health costs at local, state, and national levels, just as they do for persons without disabilities (ODPHP, 2016; Box 24-2).

## BOX 24-2 PERSPECTIVES

**Focus on Persons With Disabilities Recent events from the COVID-19 pandemic and rolling electrical outages in California to prevent wildfires highlight the isolating effect events can have on the health and well-being of those with a disability, specifically those with limited mobility. Living independently can be difficult for those using wheelchairs and**

**walkers and for those relying on care providers. The recent pandemic provided other aspects of care to consider such as good hygiene, cleaning and disinfecting, and preventing the spread of infection, as well as having plans for if the direct support provider gets sick, ways to ensure enough prescription medication is on hand, and how to obtain assistance with purchasing household items and groceries. Electrical outages required patients in the community to have backup medical equipment, generators, batteries, nonperishable food, and flashlights or lanterns. It is imperative that clients with mobility limitations have a plan in place to support their care and well-being during these isolating events. A C/PHN's disaster preparedness plans must address such crises and provide resources for clients and their families so they are not forgotten.**

Mark, a C/PHN case manager in the field

Halfway between *Healthy People 2010* and *Healthy People 2020*, the 2005 *Midcourse Review* analyzed changes since implementation of *Healthy People 2010*. It recognized the issue with accommodations for those with disabilities in disaster management and disaster settings (USDHHS, 2016). The United States experienced a great deal of natural disasters in 2018 with the fires and mudslides in California, flooding in Maryland, and hurricane Florence in the Carolinas. Man-made disasters included mass shooting devastated the country in Thousand Oaks California in which 12 people were killed, mainly young adults, and in Pittsburgh Pennsylvania where a gunman killed 11 people in a synagogue. Smith and Notaro (2015) found individuals with disabilities

are significantly less likely to be prepared for disasters than persons not disabled, and those with activity limitations or severe mental health illness are especially at risk of unpreparedness. The [U.S. Department of Home Land Security \(2018\)](#) met with individuals with disabilities and local agencies and advocacy groups for feedback on ways to improve disaster relief to the population with disabilities. Issues addressed included improved communication, involve persons with disabilities in the emergency planning, ensure shelters are accessible to all, and improve FEMA resources. Universities provide training to staff, faculty, and students on actions to take if an active shooter comes on campuses. This training meant to assist the population on what to do should an event occur may have unexpected outcomes for individuals with disabilities ([Box 24-3](#)).

## BOX 24-3 PERSPECTIVES

### **A Community Member Viewpoint on Active Shooter Response by Persons With Disabilities**

**I went to the “Active Shooter Response” workshop at work to stir things up. As a wheelchair user, I knew the currently popular “Run. Hide. Fight.” model didn't take people like me into consideration. I was prepared to draw attention to every point that didn't apply to people with various disabilities and put the facilitator on the spot for alternative solutions. I wanted to make people think, but I quickly realized I had a lot of thinking to do myself.**

The facilitator shared some interesting tactics that seemed useful, like creating obstacles between yourself and the shooter, finding a hiding

place, and the difference between cover and concealment. Then it was time to test our new skills. I felt surprisingly good about adapting what I'd learned.

The first drill began with a police officer rushing in, screaming for everyone to “get down.” I stood out like a spire when everyone else collapsed to the ground. My glaring vulnerability felt like a gut punch. I could drop out of my chair, but then I'd be stranded. My only hope to save myself is to stay in my chair, but where does that leave me with the officer? I'm at the mercy of his training and ability to quickly evaluate the situation.

We reset and drilled again. The “shooter” stormed in, and my colleagues ran from the room slinging furniture behind them, slowing down the faux assailant...and me! Their impromptu barricades effectively trapped me with an armed aggressor.

In that moment, my cautious optimism melted into terror. The well-intentioned light I meant to shed on the need for inclusive emergency preparedness seemed so petty when people were running for their lives. The A.D.A, accessibility, inclusion, even the kindness of strangers, all the social strategies I had come to rely on for helping me navigate life were suddenly off the table, and I can't even be upset.

My friends and neighbors have families they desperately want to go home to and lives they want to go on living just like I do. You can't really know how a person will react in a crisis, and I have no right to expect anyone to put themselves in danger for me. I don't even want that. In a world where active shooter drills have become necessary, and weather events are becoming more and more extreme, have I finally met my match?

My fellow disabled citizens and I will continue to keep an eye out for ways to disappear in a wheelchair and fight off attackers with crutches and canes, but we all must learn how to be aware of the people around us and create protocols that give everyone at least a chance to survive.

Amanda Timpson, who was diagnosed with bilateral spastic diplegia cerebral palsy as a toddler and became a wheelchair user at the age of 22 due to a car accident

The health of people with disabilities is influenced by many social and physical factors. Using the ICF and the WHO principles of action for

addressing health determinants, *Healthy People 2020* identified three areas for public health action. These areas are listed below ([ODPHP, 2020](#)):

1. Promote full potential of health and well-being.
2. Eliminate health disparities among people with disabilities and those without disabilities.
3. Address determinants of health and address health equity for people with disabilities.

# International Classification of Functioning, Disability, and Health

The **International Classification of Functioning, Disability, and Health (ICF)** supports the more positive, emerging approaches to understanding disabling conditions (WHO, 2019b). The ICF (WHO, 2019b) is a universal classification system using standardized language that views the domains of health from a holistic viewpoint. It takes into account body functions and structures, activities and participation, environmental factors, and personal factors. This multidimensional approach supports a complex evaluation of an individual's circumstances in terms of functioning, disability, and health. By combining the “medical model” with the “social model,” the ICF provides a biopsychosocial approach for assessing people with disabilities. Its approach emphasizes that no two people with the same disease or disability have the same level of **functioning**. The aims of the ICF are to provide a scientific basis for understanding and research, improve communication among providers and those with disabilities, allow for data comparisons, and provide a coding system for health information systems (WHO, 2019b).

The following concepts and related definitions further clarify the ICF view of health:

- **Body functions:** physiologic functions of body
- **Body structure:** anatomic parts of the body
- **Impairments:** problems in body function or structure
- **Activity:** task or action
- **Participation:** to be involved in a life situation
- **Activity limitations:** difficulty an individual may have with an activity
- **Participation restrictions:** limitations in involvement
- **Environmental factors:** the physical and social environments where people live and conduct their lives (WHO, 2019a)

For public health nursing practice, application of the ICF reinforces that disability and disease are additional factors to be considered in planning and implementing a care plan for individual clients and for population groups in the community. For individual clients, the ICF guides and facilitates assessment across a wide range of variables. Although two individuals may have the same apparent disability, such as

a below-the-knee amputation, their health status and personal well-being can be quite different. One may have a more positive outlook, more social supports, or fewer additional health issues that complicate rehabilitation than another. The C/PHN must always consider the totality of the situation, including the biologic, psychological, sociocultural, and environmental realms of the whole person.

## The World Health Report

World Report on Disability ([WHO, 2011](#)) addresses the barriers for those with disabilities and the role of the environment in facilitating or restricting participation for those with disabilities. The barriers include inadequate policies and standards, negative attitudes, lack of provision of services, problems with service delivery, inadequate funding, lack of accessibility, lack of consultation and involvement, and lack of data and evidence ([WHO, 2011](#), pp. 9–10). According to the report, when those with disabilities encounter barriers, results may include poorer health outcomes, lower educational achievements, less economic participation, higher rates of poverty, and increased dependency and restricted participation. The WHO challenged the global community to address barriers and inequalities for those with disabilities in regard to health, rehabilitation, support and assistance, environments, education, and employment ([WHO, 2011](#)). In addressing the barriers to health care, the following provide for a more patient-centered care approach for the disabled: use of equipment with universal design, communication of information in appropriate formats, and using alternative models of service delivery provides. In addition, health service providers must have education and training to know how to provide care to those with disabilities. Services for care should focus on efficiency and effectiveness; increasing access to assistive technology increases independence and participation and may reduce costs. Those that are disabled must be empowered to manage their health and advocate on their own behalf. Additionally, policy responses must emphasize early intervention, the benefits of rehabilitation, and provision of services close to where people live ([WHO, 2011](#)).

In the seminal report by the, World Health Report (WHR) ([WHO, 2002b](#)) emphasized that health care providers worldwide should broaden their clinical and population health practices, rather than continue to focus narrowly on acute illness. Changes in lifestyles and behaviors that have key impacts on increasing healthy years of life should be emphasized. The 10 leading health risks identified by the WHO are as follows:

- air pollution and climate change;
- noncommunicable diseases;
- global influenza pandemic;
- fragile and vulnerable settings;
- antimicrobial resistance;

- ebola and other high-threat pathogens;
- weak primary health care;
- vaccine hesitancy;
- dengue; and
- HIV ([WHO, 2019c](#)).

Across the globe, these 10 health risks affect low-and middle-income countries; low levels of socioeconomic status are correlated to poor health and lower quality of life ([WHO, 2019c](#)). For those with disabilities, individuals and their families “...are at increased risk for poor health and quality-of-life outcomes when their disability status affects their socioeconomic standing” ([American Psychological Association, 2019](#), para 6).

Environment now plays a role in the health of individuals, with drought, famine, conflict, and population displacement creating protracted crisis situations and contributing to lack of care, chronic illness, disability, and premature death ([WHO, 2019c](#)). Of the leading 10 health risks (above), six are directly related to pathogens:

- ebola
- global influenza pandemic

Vaccine hesitancy and increase in vaccine preventable diseases, dengue, HIV, and antimicrobial resistance ([WHO, 2019a](#)). Diabetes, cancer, and heart disease are responsible for over 41 million deaths each year and can be attributed to the use of tobacco, alcohol, unhealthy diets, and air pollution. Children are most at risk when unable to access basic health care. In addition, children in vulnerable settings may face famine, drought, and lack access to vaccinations. Malnutrition and deficits of important nutrients can lead to a wide array of preventable disabilities. For example, the leading cause of acquired blindness in children is vitamin A deficiency ([Vijayaraghavan, 2018](#)), and the leading cause of intellectual disability and brain damage is iodine deficiency ([Georgieff, 2017](#)).

## **The United Nations Convention on the Rights of Persons With Disabilities**

An estimated 1 billion people across the globe live with disabilities, with 110 to 190 million (2.2% to 3.8%) people 15 years and older having significant difficulties in functioning (WHO, 2016). Factoring in the over 2 billion family members affected by disability, the WHO stressed that almost one third of the world population is directly impacted by disabilities. The sheer magnitude of this issue and the recognition that people with disabilities are significantly overlooked across the world led to the 2006 United Nations (UN) Convention on the Rights of Persons with Disabilities (CRPD). To date, 160 countries have signed the Convention or its Optional Protocol (UN, 2016). This document remains the standard for considering the rights of those with disabilities, regardless of age, race, gender, or other demographic considerations. Some of the key principles include respect for dignity and autonomy, nondiscrimination, inclusion into society, acceptance and

- respect for differences, equality of opportunity, accessibility, gender equality, and respect for children's capacities and preserving their identity (UN, 2016).

More information is located on their website: <https://www.un.org/development/desa/disabilities/convention-on-the-rights-of-persons-with-disabilities.html>.

Although the U.S. Congress passed legislation in support of the U.N. CRPD in 2009, this positive effort proved symbolic, because the effort fell short of the needed step to ratify the Convention. This happened because only Congress can ratify treaties. Despite a wide variety of successful legislation and program development at the national level (see Civil Rights Legislation, below), the United States has been unable to ratify the UN CRPD. As of January 2019, the CRPD is still pending in the U.S. Senate (U. S. Department of State, 2019).

## The World Report on Disability

In 2011, the WHO and the World Bank reassessed global progress on disability since the 2006 CRPD (UN, 2016). The *Convention* provided guidance to governments globally and communicated that it was their responsibility to improve the lives of individuals and families living with disability. Citizens of every country must and need to participate in their country's development. People living with disabilities must advocate for the removal of barriers that prevent their full participation in their communities, including access to health, education, employment, transportation, and information services. To assure full participation of people with disabilities in their communities, stakeholders in each country—and globally—must establish an inclusive world characterized by enabling environments, rehabilitation and support services, adequate social protection, and relevant policies, programs, standards, and legislation (WHO, 2019a).

Specific recommendations include:

- Address unmet health care needs.
- Assess health risks for those with disabilities (such as comorbidities or engagement in health-risk behaviors).
- Advocate for those who have barriers to care (WHO, 2019a).

Citizens of every country, including Americans at every level, can become engaged in translating the World Health Organization into action. Even though government at every level must play a significant part, operationalizing the recommendations affords important roles for service providers, academic institutions, the private sector, communities, and especially people with disabilities and their families (WHO, 2019a).

# **HEALTH PROMOTION AND PREVENTION NEEDS OF PERSONS WITH DISABILITIES**

Two ways that CHNs and other health care providers can better address the health care needs of people with disabilities are to take advantage of every opportunity to promote their quality of life and to work to eliminate disparities between their level of health care access and quality and that of people without disabilities.

## Missed Opportunities by Health Care Providers to Affect Quality of Life

All of us, whether with or without disabilities, require basic elements to maintain health, including clean air and water, a safe place to live, sunshine, exercise, nutritious food, socialization, and the opportunity to be successful in life's pursuits. As self-evident as these health-promoting elements may seem, for the millions of persons who deal with disability, such basic needs too often take second place to other issues. It is equally problematic that health promotion and disease prevention measures, most notably at the primary and secondary levels, are often nonexistent or lacking (Fig. 24-2). Individuals with disabilities are more likely to experience difficulties accessing health care, dental services, mammograms, Pap tests, and fitness activities and are more likely to use tobacco, be overweight or obese, have hypertension, and have lower employment rates (ODPHP, 2016). Key to addressing these barriers is for people with disabilities to have an opportunity to participate in public health activities, receive appropriately timed health interventions, engage with the environment without restrictions, and be able to participate in life without limitations (Fig. 24-3; ODPHP, 2020).

**FIGURE 24-2** Preventive services, such as immunizations, are sometimes forgotten among the disabled population.

**FIGURE 24-3** A disabled rugby player.

The CDC is making an effort to reduce health disparities among persons with disabilities. Surveillance, or use of surveys, helps to determine the needs and problems that people with disabilities experience, and research programs help to prevent the development of secondary conditions. **Secondary conditions** include mental, emotional, social, medical, or family/community issues that may be experienced as a result of having a disabling condition. For instance, inadequate transportation was reported by 31% of adults with disabilities compared with only 13% of adults without disabilities; poverty is also a concern, as 26% of adults with disabilities report an annual income of under \$15,000 compared with 9% of those without disabilities (CDC, 2020). The focus of the health care delivery system is increasingly skewed toward secondary and tertiary prevention efforts, and limited emphasis is placed on the primary prevention needs of this population. Health care providers often fail to address many issues related to health promotion and prevention with people with disabilities that they do cover with those without disabilities, which is a grave concern (CDC, 2020). For example, issues such as sexuality are often not explored with individuals with disabilities. Holland-Hall and Quint (2017) discovered that sexual health education was frequently ignored in the adolescent population with mild-to-moderate disabilities even though their sexual activity is equal to that of their peers.

Disability often serves as the presenting reason for an individual's encounter with the health care community, including the C/PHN. As a result, the disability often drives the selection of prevention efforts, to the possible exclusion of other, equally important health issues. [Box 24-4](#)

offers several examples of missed opportunities in the areas of primary and secondary prevention. It is of particular concern to the practice of community/public health nursing that the broad range of health promotion and prevention needs of all clients be addressed.

## **BOX 24-4 Missed Opportunities**

### **Example 1**

A 60-year-old woman, blind since birth, self-sufficient, and active all of her life, has developed severe arthritis. She encounters a health care system that far too often focuses on her “disabilities” and not her “abilities.” The focus is placed squarely on her tertiary health promotion needs, often at the expense of health-promoting or lifestyle-enhancing needs. The result is a failure to recognize that the “disability” of arthritis is likely no less and no more an issue for her than for a sighted person. She receives the same medication therapy as does a sighted person but may not be offered a physical therapy program because of her disability. Her need for physical therapy is no less important, but locating an appropriate, safe, and easily accessible program requires some additional work on the part of her provider. At issue is that options potentially discussed with a sighted person are more apt to be omitted completely, which may negatively affect the client's overall health and well-being.

### **Example 2**

A 20-year-old man with learning disabilities, who is employed at a local factory, receives a regularly scheduled physical examination with a new provider. He lives in a congregate care facility, which is an out-of-home facility that provides housing for people with disabilities in which rotating staff members provide care for 16 or more adults or any number of children/youth younger than 21 years of age. It excludes foster care, adoptive homes, residential schools, correctional facilities, and nursing facilities ([U.S. Department of Health and Human Services \[USDHHS\], 2016](#)). The major finding of the examination is that he is due for a tetanus booster and should also begin the series for hepatitis A, because he lives in a high-risk area of the western United States. He takes the referral slip and leaves the office. One year later, at his regularly scheduled visit, it becomes clear that he never received his immunizations. Apparently, he didn't know what he was supposed to do with the

paper, because he has difficulty reading, and he had no idea where to go to get his “shots.” The primary prevention elements were provided, but clearly not in a manner appropriate for this individual. With additional explanation and follow-up, perhaps the outcome would have been quite different.

### **Example 3**

A 34-year-old woman, who has been severely obese since the birth of her last child (4 years ago), has not had a gynecologic examination since that birth. She is aware of the need to have regular examinations, yet she cannot bring herself to make an appointment. The reason is that she knows she will have to be weighed, and this terrifies her, especially because it is done in an open area where others can see. She finally gets the courage to call for an appointment and tells the clerk that she does not want to be weighed. The clerk's response is less than helpful, and she is essentially told that it is “policy.” She makes the appointment but does not keep it. This situation could have been handled in a compassionate manner, recognizing the painful experience that weighing is for many individuals and suggesting alternatives, one of which could have been simply to bypass the scales until after the interview and examination. At that point, the woman may have been more amenable to the measurement and a more discrete area could have been offered. In this case, the opportunities to provide primary, secondary, and tertiary prevention were lost.

[Gofine, Mielenz, Vasan, and Lebwohl \(2018\)](#) documented the risk of missed opportunities for clinical preventive services among people with mobility disability. Americans 50 to 75 years old with a mobility disability were less likely to receive routine colorectal cancer screening. The researchers also discovered that age, comorbidities, and the severity of the disability played a role. Additionally, [Na et al. \(2017\)](#) determined that the care for chronic diseases and preventive care such as annual visits to the primary care provider, vision exams, and mammograms for women decreased as activity limitation increased for older adults receiving Medicare. Furthermore, women with intellectual and development disabilities were less likely to receive routine cervical cancer screenings, even if they had been sexually active, as evident by previous pregnancies ([Brown, Plourde, Ouellette-Kuntz, Vigod, & Cobigo, 2016](#)). In light of the *Healthy People 2030* guidelines, these studies indicate a need to focus concerted efforts on improving

preventive health screenings and services for those with disabilities ([U.S. Department of Health and Human Services, 2019](#)).

## Health Care Disparities

Individuals living with disabilities, along with their families and advocates, have embraced concerns about the type and quality of the health-related services to which they have access and the referral process they face. They also have concerns about the care they receive being appropriate to their individual circumstances. Lack of access to individualized, quality health care can result in increased illness and disability, as well as potentially decreased quality or length of life. It is important to consider the impact that access to care can have in the continuum of health and the **health care disparities** between those with disabilities and those without disabilities, such as the risk for unmet care needs. For example, the inability to access medical, dental, and prescription drug care is 57% to 85% higher in those with disabilities than in those without disabilities (Mahmoudi & Meade, 2015). The recent opioid epidemic also touches those with disabilities. When compared with adults without disabilities, adults with disabilities were prescribed opioids more frequently, misused opioids at a higher rate, misused the drug for pain, and received less treatment for opioid misuse (Lauer, Henly, & Brucker, 2019). This study highlights the need for health care providers to improve services and referrals for this population. Additional disparities may exist in services received by those with disabilities.

A **medical home** should provide care that is family centered and coordinated with a permanent health care provider, have any easy referral process, and be the usual source of care (Rosen-Reynoso et al., 2016). Ideally, services provided should be prompt and easy to navigate. However, only 43% of children with special health care needs and emotional, behavioral, or developmental disabilities had a medical home (Rosen-Reynoso et al., 2016). Several factors were found to negatively impact needed services: non-English speakers, male child with disability, severity of disability, at or below 200% of poverty level, uninsured, Black or Hispanic race, and single-parent households (Rosen-Reynoso et al., 2016). Reducing health disparities between those with disabilities and those without disabilities provides an opportunity for maximal health of those with disabilities, as well as for the general U.S. population.

Primary, secondary, and tertiary prevention activities are essential aspects of quality care for all persons. According to a recent literature review, researchers found that individuals with disabilities face four obstacles in accessing preventive care:

- the physical environment of the provider's office not being large enough for a wheelchair;
- transportation challenges, including expense, poor access, and late pick-ups;
- health care providers having a negative demeanor; and
- financial concerns (Marrocco & Krouse, 2017).

Those with disabilities require specialized attention to needs resulting from or related to their disabilities, yet they also require preventive care to attain healthier outcomes (Marrocco & Krouse, 2017). C/PHNs are in a prime position to advocate for needed changes for those with disabilities. Such changes include increased attention to health promotion and disease prevention needs, accessible and appropriate delivery of those services, and specialized treatment plans that incorporate the latest knowledge of a specific illness or disability (Box 24-5).

## BOX 24-5 PERSPECTIVES

**A Nurse's Viewpoint on Community Health Nursing** I have worked supporting people with disabilities, different roles, such as home health, C/PHN home visitor, and public health nursing manager. As C/PHN, assessment and screening are essential interventions when interacting with disabling individuals and their families. Listening to parents and caregivers could make a difference to assess for early services. For example, I received a referral to check a toddler's development. Mom was concerned that something was wrong with her child. The

**initial biopsychosocial assessment of the toddler and family did not show any red flags, but the mother needed health teaching, parenting, and connection with resources available for children zero to five.**

Further developmental screenings identified caution in gross and fine motor skills that required a referral to the regional center, early intervention program. Through on-going case management, consulting with the medical providers, and advocating for specialty services due to lack of improvement, this toddler was finally connected with specialty services and diagnosed with a degenerative muscle disorder. The family applied to social security disability program to meet their child and family needs, find transportation, and modify the environment to accommodate a wheelchair, hospital bed, homeschooling, therapies, and medical services among others. The C/PHN interventions for this child and family, as a home visitor case manager, included collaboration with staff from multiple agencies, advocacy, and coordination with the children services' C/PHN care manager. Parents learned to voice their concerns, got involved with the community, and advocated for their child until the end of her life, several years later.

As C/PHN, we need to assess the needs of people with disabilities at the individual, family, community, and system level. C/PHN needs to keep in mind the developmental stages of people with disabilities and aspects of sexual health to prevent sexual, physical, and emotional abuse. Across the life span, people with disabilities have sexual health needs finding partners and forming their own family, which could be challenging and requires C/PHN interventions and referrals to agencies, including child and adult protective services. When working with people with disabilities, advocacy is one C/PHN intervention that is a common denominator. People with disabilities and their families need a voice, support, information, guidance, encouragement to get services from basic human needs of food and shelter to complex health care to maintain health and wellness, be active, surrounded, and supported by the community.

—Claudia Pineda Benton, Supervising Public Health Nurse for  
Community Health Nursing Field and Maternal Child Adolescent  
Health Programs

# CIVIL RIGHTS LEGISLATION

Legislation is vital to ensure that every individual's rights are protected and that there is legal recourse to secure needs that have been denied. As is often true for other issues of equality, legislation is only one of many steps that must be taken. The movement to achieve civil rights for persons with disabilities in this country has gained momentum and continues to seek the influence and public attention that will improve the health and lives of those with disabilities and **handicaps**. The **Americans with Disabilities Act (ADA)** was signed into law in 1990 to protect the civil liberties of Americans living with disabilities and continues to be updated, as recently as 2017, when movie theaters were required to provide captioning and audio description for movies that are produced with those features ([United States Department of Justice \[USDOJ\], n.d.](#)). This legislation and others, such as Section 504 of the Rehabilitation Act of 1973 and Individuals with Disabilities Education Act in 1990, resulted from a long and difficult struggle ([Landmark, Zhang, Ju, McVey, & Ji, 2017](#)). Individuals with disabilities and their advocates made their voices heard by repeatedly demanding an end to inferior treatment and lack of equal protection under the law, which have impeded their daily lives. The ADA has set the standard for a number of subsequent laws that, together with pre-ADA legislation, have become a broad spectrum of protections for people with disabilities. These laws, which are listed in [Table 24-1](#), cover a variety of issues, including telecommunications, architectural barriers, and voter registration.

TABLE	24-1	Disability	Rights	Laws
Law	Summary	Contact		
Americans with Disabilities Act (ADA) (1990)	Prohibits discrimination in 1. employment 2. state and local government 3. public accommodations, commercial facilities, transportation, and telecommunications	<ul style="list-style-type: none"> <li>• U.S. Equal Opportunity Commission</li> <li>• Civil Rights Division</li> <li>• U.S. Department of Justice (USDOJ)</li> <li>• Office of Civil Rights, Federal Transit Administration</li> </ul>		
Telecommunications Act of 1996	Telecommunication equipment and services are accessible	Federal Communications Commission (FCC)		
Fair Housing Act (amended 1988)	Prohibits housing discrimination	U.S. Department of Housing and Urban Development (HUD)		
Air Carrier Access Act (1990)	Prohibits discrimination in air transportation by domestic and foreign carriers	U.S. Department of Transportation (DOT)		
Voting Accessibility for the Elderly and Handicapped Act of 1984	Requires polling places to be physically accessible for federal elections	USDOJ, Civil Rights Division		
National Voter Registration Act of 1993	"Motor Voter Act"—makes it easier to vote by increasing low registration rates by minorities and persons with disabilities	USDOJ, Civil Rights Division		
Civil Rights of Institutionalized Persons Act (CRIPA) 1997	Right to receive care in the least restrictive setting	USDOJ		
Individuals with Disabilities Education Act (1990)	Make available free public education in the least restrictive environment for all children with disabilities	U.S. Department of Education, Office of Special Education Programs		
Rehabilitation Act (1973)	Prohibits discrimination in all federal programs or programs receiving federal financial assistance	<ul style="list-style-type: none"> <li>• Employer's Equal Employment Opportunity Office</li> <li>• U.S. Department of Labor, Office of Federal Contract Compliance Programs</li> <li>• USDOJ</li> </ul>		
Architectural Barriers Act (1968)	Buildings constructed or altered with federal funds must meet federal accessibility standards	U.S. Architectural and Transportation Barriers Compliance Board		
Accessible Design (2010 Standards)	Standards required for new construction and alterations under Title II and Title III	U.S. Architectural and Transportation Barriers Compliance Board		
Revision of the ADA Title II and Title III regulations to implement the requirements of the ADA Amendments Act of 2008 (2016)	To clarify the meaning and interpretation of the ADA definition of "disability"	Civil Rights Division, U.S. Department of Justice (USDOJ)		
Provide appropriate auxiliary aids and services for people with disabilities (2017)	Movie theaters provide closed captioning and audio description when showing a digital movie.	Civil Rights Division, U.S. Department of Justice (USDOJ)		

Source: [U.S. Department of Justice Civil Rights Division, Disability Rights Section \(2020\)](#).

This federal law protects those with a disability, which is defined as "...a person who has a physical or mental impairment that substantially limits one or more major life activities, a person who has a history or record of such an impairment, or a person who is perceived by others as having such an impairment. The ADA does not specifically name all of the impairments that are covered" (USDOJ, 2009, page 2). The ADA does not list specific diagnoses but focuses on the impact the disability has on daily living, such as on the ability to care for self, perform manual tasks, see, hear, eat, sleep, walk, stand, lift, bend, speak, breathe, learn, read, concentrate, think, communicate, and work. Despite this specificity, there remains a broad range of interpretations and legal challenges with respect to who is actually covered by the ADA.

In addition to the uncertainty about who is actually protected by the ADA, there can also be confusion about who is required to comply with the provisions of the Act and what specific remedial actions are necessary. The ADA currently applies to all employers with 15 or more employees (including religious organizations), and all activities of state and local governments irrespective of their size. Public transportation, businesses that provide public accommodation, and telecommunication entities are also required to provide access for individuals with

disabilities. It is important to note that the ADA does not override federal and state health and safety laws (U.S. Department of Labor [USDOL], n.d.a).

Individuals who believe that their legal rights under the ADA have been violated may seek remedy by filing a lawsuit or submitting a complaint to one of four federal offices, depending on the specific type of alleged violation: (1) the USDOJ, Civil Rights Division; (2) any U.S. Equal Employment Opportunity Commission field office; (3) the Office of Civil Rights, Federal Transit Administration; or (4) the Federal Communications Commission. The process for filing a complaint is not a simple task, and many seek the assistance of attorneys, legal aid societies, or various private organizations, some of which are discussed later in this chapter (Box 24-6).

**BOX 24-6 Office of Civil Rights: Compliance With the Americans With Disabilities Act** The responsibility of the U.S. Department of Justice, Office of Civil Rights (OCR), is to investigate complaints of alleged violations of the Americans with Disabilities Act (ADA). An example of one of those complaints involved a 22-year-old Connecticut woman with cerebral palsy. She had been placed in a nursing home because of changes in her living situation and health care status, but wanted to move back into the community. The OCR intervened to ensure that the woman secured

appropriate housing and that counseling and intensive case management services were in place when she moved back into the community. Another example involved a man with traumatic brain injury (TBI) who was told he must remain in a hospital when he requested home health care services. OCR intervened and secured physical, occupational, and speech therapy for the client, as well as physical modifications needed for his home. A 32-year-old quadriplegic man had lived independently in his own apartment with a health aide's assistance, but suddenly lost his apartment and was transferred against his will to a facility. He was able to get a wheelchair accessible apartment but could not get health aide services. OCR intervened on his behalf and secured a personal care assistant so that he could live in his

**new apartment. Without the protection afforded under the ADA, the outcome could have been much different.**

Source: [USDHHS, Office for Civil Rights \(September 2006\)](#).

The USDOJ published *A Guide to Disability Rights Laws* (2009). The guide provides information on federal civil rights laws for those with disabilities and is available in large print, CD, and Braille. The laws included are

- Americans with Disabilities Act (ADA)
- Telecommunications Act
- Fair Housing Act
- Air Carrier Access Act
- Voting Accessibility for the Elderly and Handicapped Act
- National Voter Registration Act
- Civil Rights of Institutional Persons Act
- **Individuals with Disabilities Education Act (IDEA)**
- Rehabilitation Act
- Architectural Barriers Act

The most challenging aspect of providing services for persons with disabilities is to alter the perceptions and misunderstandings of others about people with disabilities ([Yee, 2016](#)). The perspective of one community member offers one such example ([Box 24-7](#)).

## BOX 24-7 PERSPECTIVES

**A Community Member Viewpoint on Hearing Loss I lost my hearing as a young adult. By the time I was 28 years old, I had no natural**

hearing left. I received a cochlear implant when I was 32. Around the time I decided to have the implant, I was struggling so much to survive in the hearing world (phone usage, conversations with hearing people, etc.). The decision to receive a cochlear implant changed my life. I could now communicate with the hearing world again. While the cochlear implant has some amazing benefits, there are some negatives still. For one, I still do not have perfect hearing. I have enough hearing, though, for people to not realize I am deaf. This “hidden disability” can be problematic. Many people assume I am just stupid. It happens all the time. What they don't know is that I am actually well educated and very intelligent. Often, I hear my friends, family, and fellow students talk about how smart I am, but when I don't hear something I sound stupid. I might mishear the beginning of a conversation and respond with something totally off topic. This particular trait should be a red flag that the person may have a hearing loss. It is very demoralizing for people to treat you like you are stupid, when the reality is you just can't hear well. Another very difficult thing about having a cochlear implant is that when you can't wear it for some reason (dead battery, loss, medical procedure, etc.) you feel absolutely powerless, and often fearful, in the

**hearing world. I've most often experienced this in the health care environment. When I had to have surgical procedures that required removing my implant, I could not hear the instructions provided to me in preop. I could not hear the words that were intended to calm or comfort me. Instead, I was in a constant state of panic wondering if I was missing important information related to my health and safety. Hearing people should also realize that deaf people are extremely tuned to the visual world. We see your frustrated eye rolls, side glances, and facial expressions very acutely. It is very hurtful and frustrating to see this and not be able to do anything about it. Like many "hidden disabilities," imagining yourself in someone else's shoes would probably facilitate a more beneficial and pleasant interaction.**

Veronica Russell

The [National Council on Disability \(n.d\)](#) is an independent federal agency charged with advising the President, Congress, and other federal agencies regarding policies, programs, practices, and procedures that affect people with disabilities. Its policy areas include civil rights, cultural diversity, education, emergency management, employment, financial assistance and incentives, health care, housing, international issues, long-term services and support, technology, transportation, and youth issues. NCD's Web site has publications dating back to 1986 on civil rights. Information can be found at <https://www.ncd.gov/policy/civil-rights>.

# **FAMILIES OF PERSONS WITH DISABILITIES**

Families that include a member with a disability face many challenges. Below we consider factors affecting families' ability to cope with the disability and the impact of caregiving on families.

## Factors Affecting the Family's Ability to Cope

The parents of a child with disabilities must come to grips with many unknowns. [Shenaar-Golan \(2017\)](#) studied subjective well-being in parents of children with disabilities. Often times their financial stability is depleted and parents express concern for the future well-being of their child, especially as the parents age. The study found that the parents' level of hope and perception of the disability and the parental relationship affected their subjective well-being ([Shenaar-Golan, 2017](#)). The child's transition from a minor to an adult and the child's leaving the school setting, which provides a routine for the child, may cause anxiety for parents and the child. Parents may not have the necessary knowledge to ensure a smooth transition. Researchers found that a structured training period for parents of soon-to-be-adult children with autism increased their knowledge of services such as SSDI, housing, and Medicaid and made them feel more comfortable in advocating for their children and more empowered ([Taylor, Hodapp, Burke, Waitz-Kudla, & Radideau, 2017](#)). Families may also have little understanding of what services they are entitled to because of language barriers, difficult agency policies, or disjointed service delivery. These challenges may be magnified when a family member is newly diagnosed with a disability.

The C/PHN is usually not the first health care professional that the family encounters. They may already have been through a lengthy struggle to receive assistance. In these circumstances, the nurse may be confronted with a frustrated family, reluctant to trust yet another health care provider. Nurses must earn the trust and confidence of the family by practicing consistency, following through with promised actions, and always being truthful. Not all problems that the family faces can be remedied, and even for problems that do have solutions, time and effort may be needed to obtain the desired result. [Nageswaran and Golden \(2018\)](#) uncovered four themes in the relationship between the caregivers (parents) and the home health nurse:

- the relationship developed over time;
- trust and communication were crucial;
- boundaries were difficult to maintain; and
- a good working relationship between the nurse and the caregiver decreased caregiver stress, lowered stress for the health care provider, and improved care of the child.

Additionally, when working with an older child and the family, the CHN needs to remain respectful to both parties. The child is a separate entity, and the child's wishes need to be considered as much as possible (Cureton & Silver, 2017).

## The Impact of Caregiving on Families

Caring for a family member who is disabled, whether a child or an adult, is stressful. High levels of anxiety, stress, depression, and illness are often reported in these families (Dykens, 2015). Caregiver strain is common in families caring for a member with disabilities. These caregivers have multiple roles, associated with employment, caring for other children in the family, the parents' relationship, and providing care for the child with needs (Pilapil, Coletti, Rabey, & DeLaet, 2017). Caregiving affects the parents' physical and/or psychological health, financial status, and family function (Pilapil et al., 2017).

Hamilton, Mazzucchelli, and Sanders (2015) also examined parental support for children with disabilities. In the adolescent years, the needs of the child dramatically shift, as parenting styles that worked at a younger age are no longer effective. Parents report struggling to understand these needs and making accommodations for the transitions of their adolescent children, and this frustration leads to increased stress and feelings of grief. The study suggested that a targeted, evidence-based parenting program should be tailored for this special population. Nurses should be prepared to provide parenting support and referrals to parental support groups and educational programs that can assist the parents in providing the best care possible to their children with disabilities.

Nurses should also be aware of the physical needs of parents caring for children with disabilities. In a study by Garip *et al.* (2017), the researchers noted that mothers of children with cerebral palsy reported depression and lower quality of life associated with a high level of fatigue. Nurses should assess the mother's fatigue level and be watchful for signs and symptoms of depression to assure that the parent is able to provide the care needed for the child.

Caregivers of older adults tend to be spouses or adult children. One study found an average of 30 hours per week of care was provided (Wolff *et al.*, 2018). Although caregivers reported less emotional, financial, and physical difficulties between 1999 and 2015 (Wolff, 2018), many suffer from poor physical health, depression, and anxiety (Riffin, Van Ness, Wolff, & Fried, 2019). Over half of caregivers reported caregiver burden related to the recipient's dementia (Riffin *et al.*, 2019). Fewer than 10% of caregivers use supportive services or attend training on best practices in providing care (Riffin *et al.*, 2019). C/PHNs working with this population should provide caregivers with community resource

referrals such as in respite care, support services, and local classes for training.

Children and adults with disabilities are at risk of abuse due to many factors. The exact number of children with disabilities who are abused remains unknown. The abuse could be triggered by the parents being stressed with the obligations of caring for a disabled child or frustrated with the child's difficult behavior (CDC, 2018). Other risk factors for abuse include inadequate social support for the parents, financial burdens, and time constraints in caring for a child with disabilities (Prevent Child Abuse America, 2019).

Categories of elder abuse or dependent adult abuse include physical abuse, psychological abuse, neglect, and financial abuse. Platt *et al.* (2017) discovered that over 63% of men and 68% of women with developmental disabilities had been abused as adults. More women than men had been sexually abused, but for other types of abuse, there was no difference between genders (Platt *et al.*, 2017). Health care providers may find it difficult to detect intimate partner violence (IPV) in women with disabilities. Health care staff need to be educated on communication skills with women who have experienced IPV to detect and treat these women (Ruiz-Pérez, Pastor-Moreno, Escribà-Agüir, & Maroto-Navarro, 2018). In a study conducted by Ballan, Freyer, and Powledge (2017), researchers discovered that men with disabilities experienced IPV at a higher rate than men or women without disabilities. More than 71% of the men described physical abuse as the most severe type of abuse and nearly half had seen a medical provider. Yet, fewer than 16% of these men had been referred to IPV assistance (Ballan *et al.*, 2017). Clearly more needs to be done to protect this population from abuse.

Geographic differences were noted in a national survey of therapy services provided to infants and toddlers with developmental disabilities. Magnusson and McManus (2017) found that states differ in their ability to meet the needs of these children for physical, occupational, and speech therapy. IDEA requires states to provide early intervention services but allows the individual states to set their own criteria. Children living in states with narrow early intervention eligibility had a significant level of unmet therapy needs. Furthermore, children of racial/ethnic minorities had higher levels of unmet needs (Magnusson & McManus, 2017). Paying for needed resources places a financial burden on many families. Parents of children with special needs are more likely to be single, unemployed, or underemployed and to have incomes of <\$50,000 per year (McRee, Maslow, & Reiter, 2017). The cost of care of a child with special needs is high and a financial burden to families even when

considering only the obvious costs, such as health care provider and hospital bills, diagnostic testing, medical treatments, and prescription medicines (Price & Oliverio, 2016). However, the care often includes many less obvious costs, such as 24-hour supervision for activities of daily living, and these costs often do not end when these children reach the age of 18, but last for their lifetimes. Therapy, health care professionals, financial planners, support group facilitators, educational advocates, special education attorneys, and other professionals may be required for care.

Although *Healthy People 2030* directly addresses delays in receiving primary and preventative care, obstacles to obtaining **assistive devices and technologies** may still be encountered (U.S. Department of Health and Human Services, 2019). **Temporary Assistance for Needy Families (TANF)**, **Social Security's Supplemental Security Income (SSI)**, and Medicaid are three government assistance programs nurses should familiarize themselves with. TANF is a time-limited federal program that provides assistance to families that cannot meet basic needs. Each state determines how to use the funds (U.S. DHHS, n.d.). SSI is a federal program that provides income to persons with disabilities who have little or no income to meet their basic needs (Social Security Administration, 2018). Lastly, Medicaid provides affordable coverage as well as services not normally covered by provider insurance (Musumeci, 2018). Those with disabilities and their families often are unaware of eligible programs and confused about the rules and regulations of each program. CHNs working with this population need to educate themselves on government resources and nonprofit agencies that assist the family in attaining equipment and supplies. Advocating for our clients and providing case management provide a welcome relief to families.

**Respite care** is another resource of great importance for families. Due to the constant demands of providing care 24 hours per day, 7 days per week and the stress associated with numerous demands, respite offers relief and hope in regaining normalcy, not only for the primary caregiver, but for the siblings, as well (Whitmore & Snethen, 2017). When focus is placed on the needs of one family member, other children may feel that their own needs are not as important, which can lead to behavioral and health-related problems (Box 24-8). Although more spouses and adult children who care for older adults with disabilities are using respite care, only 15% of caregivers currently use it (Wolf et al., 2018). Respite care is vital to the family's health and should be considered a priority in the overall treatment plan. ARCH National Respite Network and Resource Center provides a list of respite services nationwide.

## **BOX 24-8 C/PHN Use of the Nursing Process**

### **Supporting a Family With a Child With Autism**

#### **ASSESSMENT**

The local public health department received a referral from the school nurse requesting a home visit on the Smith family. The family recently moved to the area with three small children. The school nurse expressed concern because the children are late to school every morning, their clothes are dirty, and they arrive to school hungry. The C/PHN arrives to the home unannounced in order to assess the home life. Both parents are home but the father retreats into the bedroom when the nurse arrives. The mother of the children, Joanne, is 25 years old and has recently lost her job at a small boutique. The father, Richard, is 26 and has started working two jobs to pay the bills. The family recently moved to a new town 100 miles away from the wife's family who provided emotional support and help with childcare. The one-bedroom apartment is cluttered and dirty. The apartment is void toys and family photos. James the 5-year-old was diagnosed with autism at the age of two. He is seen hitting his head against wall and throwing clothes. Joanne is attempting to calm her son and is yelling to Richard to help without success. The other children are playing videos ignoring their mother's request for help. Joanne expresses being overwhelmed since the family moved away from her family and friends. The family has not connected with a medical home yet, finances are insufficient to pay bills, and they have no social support in the new neighborhood. The two older children ages 7 and 10 are sick with colds and have productive coughs. They have missed 4 days of school and are falling behind in their studies. The mother appears unconcerned about her children's health issues. The family does not have a medical home and the mother expresses being overwhelmed with the children's health issues, especially James. The C/PHN notices the lack of affection between members.

#### **PROBLEM STATEMENTS**

1. Ineffective parenting skills

## 2. Support for a healthy family management plan

### **PLAN/IMPLEMENTATION**

#### **Problem Statement 1**

The C/PHN will:

- Assess the family support systems and refer the parents to support groups of children with disabilities.
- Provide resources for sliding scale family counseling and other governmental or private organizations.
- Provide information regarding respite care for parents to have time for themselves and the other children.
- Encourage parenting classes and role model communication techniques with children.
- Continue to assess parents stress level and assess for possible abuse.
- Schedule monthly follow-up visits to provide a resource and support to the parents.

#### **Problem Statement 2**

The C/PHN will:

- Assist the family in finding a medical home.
- Educate the parents in healthy behaviors such as exercise and proper nutrition.
- Assess health literacy of parents and provide information that best meets their needs and understanding.
- Acknowledge each family member's health concerns.

### **EVALUATION**

The C/PHN conducted follow-up visits every 2 weeks to check on family progress. After 1 month, the C/PHN reported the family had a medical home that provided antibiotics for the older children's sinus infection. The two older children and the parents had gone to the park twice using a free respite service provided through a local church. The children are attending school and are doing well. The parents have joined support group for parents with children with disabilities and have made friends with group members. The mother

is observed playing with children. The home while still cluttered is clean. The C/PHN informs the parents they are doing wonderful and will decrease her visits to monthly. She encourages the parents to contact her if they have any questions or concerns.

The issue of employment is generally of great significance to families, as employment options may be quite limited when a family member has special needs. The family may have to remain in a particular location to access needed health and social services, reducing the possibility of increased earning potential at a different location or in another field of employment. Although some legal protections are provided under the **Family and Medical Leave Act** of 1993, it does not apply in all situations. For instance, it is only available in companies with more than 50 employees and is most often used for birth and care of a newborn or newly adopted child or for temporary care of a family member with a serious health problem (spouse, parent, or child). More importantly, it allows only for time off; it does not mandate that employers continue a salary during those periods ([USDOL, n.d.b](#)). Family members may have to choose between taking unpaid time off and continuing to work while dealing with the needs of the family member as best they can. Some individuals choose to work part-time or not to work at all so that they can care for family members ([Baillargeon, Bernier, & Normand, 2011](#)). At a time when many families have two wage earners to help meet financial commitments, families engaged in caregiving may have to rely on only one income. Limitations in income are particularly challenging considering the myriad needs of those who are disabled, needs that may not be covered by any insurance.

[Falk \(2016\)](#) explored the relationship between welfare status and health. The researcher noted that families receiving TANF often were eligible for many programs and that the different policies and requirements are difficult for families to navigate.

Caregiver health needs and mental health status are another area of concern for families. The mental health of the mother as caregiver is documented to be an area of concern, and the expression of depression in this population is concerning ([In Sook & Hyun Sook, 2015](#); [Yamaoka et al., 2015](#)). Although research often focuses on the mental health of the mother as caregiver, a line of research exploring paternal mental health when caring for a child with an intellectual disability is growing. This research suggests that the child's behavior problems, father's daily stress, low parenting satisfaction, and childcare needs are the biggest predictors for the father's mental health difficulties ([Giallo et al., 2015](#)). A study

exploring family health of parents caring for a child with disabilities indicated that parent caregivers who experienced activity restriction and low social support and those families in the lowest quartile of monthly expenditure were more likely to experience psychological distress (Yamaoka et al., 2015). It is important for nurses to provide detailed information about the child's health needs, disease, disability, medical services available, and social support available to meet the needs of the child to decrease parental mental health stress and disorders. Recognizing that caregivers within a family are at increased risk for poor health outcomes, it is important that the C/PHN select appropriate interventions to address the health needs of all family members.

Families may experience financial difficulties, poor physical or mental health, and a variety of other challenges. For instance, a classic study on loss of family income related to having a child with autism spectrum disorder found an average decrease in annual income of 14% for these families (Montes & Halterman, 2008). Families are often ill prepared to deal with the complicated systems that must be accessed to obtain needed care. The C/PHN is in an optimal position to interpret those systems to the families and to advocate for the needed care, services, and equipment (Fig. 24-4). The nurse must view the family holistically, recognizing additional needs that may develop as a result of the situation currently faced, and include an assessment of caregiver and family work patterns when caring for families with a family member who is disabled.

**FIGURE 24-4** Public health nursing support for families with children with disabilities can be critical in helping them access resources and services.

## Organizations Serving the Needs of Individuals With Disabilities and Their Families

Many governmental and privately funded organizations are dedicated to serving individuals with disabilities and their families as well as educating the public on disabilities. These organizations provide nurses with a starting point for exploring specific topics pertinent to practice. As clients and families may also be accessing online content through personal or public internet access, it is important for nurses to prescreen and make recommendations to clients and families about reliable and accurate sites. Numerous organizations provide Web sites to assist individuals with disabilities and their families; a few key Web sites are listed in [Table 24-2](#).

**TABLE 24-2 Web sites to Assist Those With Disabilities and Their Families**

Organization	Description	Website
Disabled World	Provides lists of disabled services within the United States	<a href="https://www.disabled-world.com/disability/foundations/us-organizations.php">https://www.disabled-world.com/disability/foundations/us-organizations.php</a>
American Deafness and Rehabilitation Association (ADARA)	National organization that assists and educates those who work with the deaf and hard of hearing	<a href="https://www.adara.org/">https://www.adara.org/</a>
American Council of the Blind (ACB)	Mission is to increase independence and quality of life for the blind and visually impaired; has had a historical presence in state   local chapter since the 1880s	<a href="https://www.acb.org">https://www.acb.org</a>
The Arc	Works to support and protect the rights of those with intellectual and developmental disabilities	<a href="https://thearc.org/">https://thearc.org/</a>
National Organization on Disabilities	Works to increase employment opportunities for working-age disabled Americans	<a href="https://www.nod.org/">https://www.nod.org/</a>
Easterseals	A resource for individuals with disabilities providing programs, services, early intervention, workforce development, and adult day care	<a href="https://www.easterseals.com">https://www.easterseals.com</a>
Special Olympics	Uses sports and activities to inspire and reach those with disabilities	<a href="https://www.specialolympics.org/">https://www.specialolympics.org/</a>
United Cerebral Palsy	Provides family assistance, education, financial assistance, and resources for those with a spectrum of disabilities	<a href="http://ucp.org/">http://ucp.org/</a>
Special Needs Alliance	National organization of attorneys who specialize in public benefits law and assist those with disabilities	<a href="https://www.specialneedsalliance.org/">https://www.specialneedsalliance.org/</a>
National Center on Disability and Journalism	Provides links to many resources and services	<a href="https://ncdj.org/resources/organizations/#neurological-disorders-and-injury">https://ncdj.org/resources/organizations/#neurological-disorders-and-injury</a>

The C/PHN student is encouraged to explore these resources and to learn more about specific disabilities that can impact clients and their

families. For example, parents may not realize their child has a hearing loss. It may take an outside family member, a neighbor, a teacher, or a nurse to notice a child who is not talking at an age-appropriate level or who does not turn to the source of a sound. Children born prematurely and the elderly are at risk for hearing loss. Genetic syndromes and accidents can also cause unexpected loss of hearing. In fact, one out of every eight people in the United States has a hearing loss (CDC, 2019a). Luckily, there are screening tools, treatments, and interventions for those that are deaf or hard of hearing. In addition to technology such as hearing aids and cochlear implants, many people learn alternate ways to communicate such as sign language. [Box 24-9](#) offers a brief summary of the purpose and use of **American Sign Language** and other signed languages, and [Box 24-10](#) discusses Braille.

## BOX 24-9 Sign Language in Brief

- Sign language is the use of “handshapes” and gestures to communicate ideas or concepts.
- American Sign Language is a unique language with its own rules of grammar and syntax.
- American Sign Language is primarily used in America and Canada and is the natural language of the deaf community; in Britain, British Sign Language (BSL) is used.
- Sign languages are not universal.
- International Sign Language (Gestuno) is composed of vocabulary signs from various sign languages for use at international events or meetings to aid communication.
- Systems of Manually Coded English (i.e., Signed English, Signing Exact English) are not natural languages but systems designed to

represent the translation of spoken language word for word.

## **BOX 24-10 What Is Braille?**

Braille takes its name from Louis Braille, an 18-year-old blind Frenchman who created a system of raised dots on paper for reading and writing by modifying a system used on board sailing ships for night reading. The six raised dots of each Braille “cell” vary to form palpable letters and punctuation. Persons experienced in Braille can read at speeds of 200 to 400 words per minute, comparable to print readers. Braille text can be written (1) by hand with a slate and stylus; (2) with a Braille writing machine; or (3) with specialized computer software and a Braille-embossing device attached to the printer.

Source: [National Federation of the Blind \(n.d.\)](#) Note: More information about Braille is available at: <http://nfb.org/search/node/braille>.

# UNIVERSAL DESIGN

For those living with a disability or chronic disease and their family members, the issue of access is of utmost importance. **Universal design** is the concept of purposely creating environments in a way that they are accessible to all without the need for modifications. The term universal design has been attributed to Ron Mace, founder of the Center for Universal Design, based out of North Carolina State University. Mace, who had polio as a child, died suddenly in 1998, leaving behind a long legacy of advocacy on behalf of accessibility in design ([Center for Universal Design, 2016](#)). Universal design is at the core of the ADA, and it is important to note the relationship between inclusiveness and reduction of barriers to access ([Hums, Schmidt, Bocak, & Wolff, 2016](#)). Universal design is for everyone, not solely for those with disabilities.

The issue of accessibility is not new. The ADA, as discussed earlier, addresses issues of access in employment, governmental building, and public accommodations. The Fair Housing Accessibility Guidelines, effective beginning in 1991, provide for design and construction of multifamily dwellings (four or more units) in accordance with accessibility requirements ([United States Department of Housing and Urban Development, n.d.](#)). Provisions mandate that doorways be wide enough to accommodate wheelchairs, dwellings be readily accessible to and usable by persons with handicaps, and accessible routes be throughout buildings ([Figs. 24-5, 24-6, 24-7; Fair Housing Accessibility First, n.d.](#)). The specific provisions may be found at <https://www.fairhousingfirst.org>.

**FIGURE 24-5** Ramps are needed for those using wheelchairs to gain access to buildings.

**FIGURE 24-6** Recommended height of electrical outlet for ease of access for wheelchair-seated person. (From CDC Image Library. Retrieved from <http://phil.cdc.gov/Phil/quicksearch.asp>.)

**FIGURE 24-7** Handicap access shower. (CDC Image Library. Retrieved from <http://phil.cdc.gov/Phil/quicksearch.asp>.)

For those with existing disabilities and as the population ages, ensuring easy accessibility to all in businesses, housing, and places of recreation is of paramount importance. Having the opportunities for healthy participation in physical activity may forestall or prevent the development of illness. For the community, having an environment that promotes rather than restricts a healthy lifestyle can be economically advantageous (Fig. 24-8). A healthier population may be achieved with attention to the environmental barriers that impede healthy lifestyles for all persons, including those with disabling conditions.

**FIGURE 24-8** Planned, mixed-use development with curb cuts, well-marked crossings, sidewalks, and accessible commercial and public spaces. (Source: Center for Universal Design. CDC Image Library.)

# THE ROLE OF THE COMMUNITY/PUBLIC HEALTH NURSE

This section considers the various roles of the C/PHN working with this population. It is important to review these roles in the context of multilevel practice: the individual, the family, and the community. [Chapter 2](#) first examined the broad spectrum of roles that the C/PHN assumes within the community (i.e., clinician, educator, advocate, manager, collaborator, leader, researcher), as well as the 10 essential services of public health. Consider an example of the variety of roles with respect to a 55-year-old female client who uses a wheelchair. The client has difficulty obtaining a gynecologic examination because of the lack of accessible examination tables at the local clinic; as a result, she has not had an examination for more than 20 years. Recognizing the need for a complete examination, the C/PHN arranges with the clinic to find appropriate alternatives that will aid the client in receiving the needed examination, possibly by ensuring that additional personnel are provided. The C/PHN is an advocate at the individual level providing the essential services of monitoring health. Because this solution is temporary and less than optimal, the nurse contacts a number of clinics in neighboring communities and finds one that has appropriate equipment for people who have difficulty transferring to a standard examination table. Unfortunately, this clinic is 1 hour away. The nurse then contacts a number of other C/PHNs and discovers that they also have a significant number of women clients with this problem who have not received a gynecologic examination in many years. The C/PHN discovers a need at the community level through research. Essential services provided include monitoring health and diagnosis and investigation at the community level.

Through a coordinated effort, the nurse is able to develop partnerships with a local transportation company and the clinic to arrange a twice-yearly gynecologic screening program for women in the community who require special accommodations. Acting as an advocate and coordinator at the community level, the C/PHN mobilizes community partnerships, develops policy, and links the population to needed services. Information sheets that discuss the need for annual

gynecologic examinations and advertise the program are distributed to area C/PHNs, employers, and health clinics. Functioning in the educator role at the community level, the C/PHN is providing the essential services of informing, educating, and empowering others. Data collection on examinations provided over the next few years shows a 65% increase in the number of women with special needs who have received a gynecologic examination within the past year. Continuing in the role of researcher at the community level, the C/PHN practices the essential services of evaluating the services and reaching new solutions.

This is not an uncommon scenario in the practice of community/public health nursing. Often, the needs of an individual may open the door to areas of concern for many in a community and provide a basis for intervention that can benefit a larger population. The complexity of issues surrounding these conditions requires creativity, tenacity, honesty, and, most of all, knowledge. C/PHNs who are informed about the issues that affect those with disabilities at local, state, and national levels are prepared to offer assistance to their clients and to their communities.

Although successes at the individual level are laudable, the extent to which the health and well-being of those affected are improved must be the ultimate goal. Forming partnerships within the community places the C/PHN in a prime position to initiate and support efforts to improve the health status of those populations.

It is important for C/PHNs to consider population health among those with disabilities. As [Grady \(2011\)](#) reminds us, our U.S. population is living longer, is suffering multiple chronic illness and disabilities, and needs nurses trained to meet the requirements of this aging population. Population health promotion and prevention of secondary disabilities are also public health concerns across age groups and conditions ([Ouellette-Kuntz, Cobigo, Balogh, Wilton, & Lunsky, 2015](#)). Community-based interventions that help support all populations with self-management skills, improve health behaviors, and prevent secondary disabilities have been shown to be popular and can result in cost savings as well as improved health outcomes ([Ravesloot et al., 2016](#)).

# SUMMARY

- The issues of disability are of growing importance in public health and to community/public health nursing, both nationally and internationally.
- Through the efforts of the WHO, the international community has been challenged to provide increased attention to health promotion and disease prevention.
- The aging of the U.S. population and the rise in lifestyle-related illnesses such as diabetes and obesity are often linked with increasing rates of disability. Health disparities and differing access to services are a focus of *Healthy People 2030*.
- *Healthy People* has placed increasing focus on individuals' well-being, helping those with disabilities to get support and services within the health care system, at work, home, and school. To improve quality of life, accessibility in our homes, schools and workplaces is essential.
- Legislation is but one step toward equality for those affected by disabilities and chronic illnesses. The IDEA and ADA secured many improvements in accessibility and specific legal protections for the disabled, but it is only the beginning.
- C/PHNs are in a prime position to advocate for the health needs of the disabled and chronically ill. With a long history of serving those who are most vulnerable, C/PHNs can help make needed changes at the individual, family, and community levels.

# ACTIVE LEARNING EXERCISES

1. Interview an individual with a disability (e.g., hearing, vision, mobility) about the challenges that he or she has faced in interactions with nondisabled persons and in everyday activities.
2. Using “Utilize Legal and Regulatory Actions” (1 of the 10 essential health services), how does legislation effect the health and well-being of a disabled client and their family? Looking at disability rights, how would you address the essential services specific to Developing Policies and Enforcing Laws?
3. Take an inventory of your house or apartment and make a list of modifications you would need to make if you had a disability. Would you even be able to stay in your current residence (e.g., are you living in a second-floor apartment in a building that does not have an elevator)?
4. What resources are available in your community to assist disabled individuals and families?
5. Address health promotion activities for clients and their families in your community health clinical course who are either disabled or have a chronic illness. Examples of health promotion activities could include healthy eating, physical activity, and leisure-time activities. Does the public health department have any outreach services for disabled clients to encourage them to obtain routine preventable services? Ask some of your clients with disabilities and chronic illnesses about their experiences and feelings about preventive services.

# CHAPTER 25

## *Behavioral Health in the Community*

*“Mental health and mental disorders are not opposites, and mental health is not just the absence of mental disorder.”*

—World Health Organization

### **KEY TERMS**

At-risk alcohol use Behavioral health Integrated behavioral health Mental disorders Mental health Substance-related disorders

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Identify key mental disorders and describe their effect on individuals and the community.
2. Identify commonly used substances and their effect on health.
3. Follow the steps of the nursing process in detection of at-risk alcohol use and management of that risk.
4. Use prevalence data to inform the development of individual-and community-level interventions to address mental health and substance use disorders.
5. Use the Strategic Prevention Framework to guide the implementation of sustainable prevention activities to promote the behavioral health of the community.

# INTRODUCTION

This chapter provides an overview of behavioral health, a term used to refer to both mental health and substance use. A comprehensive approach to behavioral health recognizes a continuum of care, from promotion to prevention, treatment, and recovery. Community/public health nursing practice is discussed, with a focus on individual-, community-, and policy-level interventions. The community/public health nurse has a key role in working with individuals, families, and communities to promote optimal behavioral health and thereby decrease the prevalence and incidence of mental and substance-related disorders (Box 25-1).

## BOX 25-1 Behavioral Health Terminology

- **At-risk alcohol use:** Thresholds for alcohol use are based on healthy individuals and those adults 21 years or older. Alcohol consumption that causes risk to a person's health or increases risk to others is unsafe. Health conditions and activities may indicate a lower level of alcohol consumption (Mahmoud, Finnell, Savage, Puskar, & Mitchell, 2017).
- **Behavioral health:** This term, which is used to refer to both mental health and substance use, looks at a comprehensive approach, recognizing a continuum of care, from promotion to prevention, treatment, and recovery.
- **Integrated behavioral health:** Integrated care blends medical and behavioral health factors in one setting. The advantage of an integrated system is coordination of care, and team communication of all health care providers as they work toward person-centered health goals (Agency for Healthcare Research and Quality, 2012a, 2012b).
- **Mental health:** *Healthy People 2030* addresses increased treatment for those with mental health. In addition, screening and early identification is essential for all including youth and the homeless (U.S. Department of Health and Human Services [USDHHS], 2020).
- **Mental disorders:** “Health conditions that are characterized by alterations in thinking, mood, and/or behavior that are associated with distress and/or impaired functioning. Mental disorders contribute to a host of problems that may include disability, pain,

or death” (Office of Disease Prevention and Health Promotion, 2020)

- **Substance-related disorders:** Use of 10 separate classes of drugs that, when taken in excess, activate the brain reward system, resulting in neglect of normal everyday activities. This system influences the reinforcement of behaviors and the production of memories (American Psychiatric Association, 2013).

Source: Agency for Healthcare Research and Quality (2012a, 2012b); American Psychiatric Association (2013); Mahmoud *et al.* (2017); U.S. Department of Health and Human Services (USDHHS) (2018, 2020).

# CONTEMPORARY ISSUES

From concerns over the opioid crisis and alcohol use and controversies over supervised injection sites and the legalization of marijuana to the integration of behavioral health services and the emergence of antistigma strategies, behavioral health issues have undeniably preoccupied the United States in recent years.

## Opium Crisis

A total of 63,632 Americans died of drug overdoses in 2016, and two thirds of these deaths involved a prescription or illicit opioid (Centers for Disease Control and Prevention [CDC], 2018a). As the supply of prescription opioids has been reduced, rates of deaths from heroin and fentanyl have rapidly increased (Hall & Farrell, 2018). Community and public health nurses (C/PHNs) have crucial roles to play in addressing this public health problem, including identifying persons at risk because of opioid use and providing education, support, and resources for this population (Fig. 25-1).

**FIGURE 25-1** CDC's efforts to prevent opioid overdoses and other opioid-related harms. (Reprinted from Centers for Disease Control and Prevention. (2019). Retrieved from [https://www.cdc.gov/opioids/pdf/Strategic-Framework-Factsheet\\_Jan2019\\_508.pdf](https://www.cdc.gov/opioids/pdf/Strategic-Framework-Factsheet_Jan2019_508.pdf))

## Supervised Injection Sites

Supervised injection sites, also known as safe consumption sites, have been found to mitigate overdose-related harms and unsafe drug use as well as facilitate the acceptance of treatment and other health services (Kennedy, Karamouzian, & Kerr, 2017). These services are available in Europe, Australia, and Canada and are beginning to emerge in the United States. The first supervised injection sites in North America were established in Vancouver, Canada, and the experience gained from them has informed the expansion of this harm reduction approach elsewhere. Proponents of these services view them as beneficial to public health and the community. Opponents believe these sites do nothing to deter drug use or help individuals stop opioid use. Contentious legislative battles are ensuing as federal law prohibits these services, and if such sites are opened, they will face action by the United States Department of Justice to close them. Box 25-2 identifies some of the tensions between harm reduction and public safety. Informed by the evidence related to health outcomes for persons who use these services and areas in which they are situated, C/PHNs will be able to advocate for best practices to promote the health of this population and society.

### **BOX 25-2 Safe Consumption Sites: Tensions Between Harm Reduction and Public Safety**

#### **Harm Reduction**

- Do safe consumption sites reduce drug overdose deaths?
- Do safe consumption sites encourage people who use opioids to seek help/treatment?

#### **Safety Concerns**

- Do safe consumption sites create social problems in neighborhoods?
- Do safe consumption sites encourage more people to use drugs?

Source: [European Monitoring Centre for Drugs and Drug Addiction \(2018\)](#).

and methods of use. Educating individuals or the public with this information does not imply endorsement of marijuana use, but rather is an essential role that C/PHNs should assume.

Some also suggest that there may be a therapeutic role of cannabis in opioid use treatment.

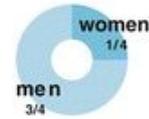

- A study by [Sociás and colleagues \(2018\)](#) concluded that at least daily cannabis use was associated with higher retention in opioid treatment when compared with less than daily consumption.
- Yet, this emerging area of research calls for further exploration because previous studies reported mixed results on this association ([Timko & Cucciare, 2018](#)).
- C/PHNs need to stay abreast with the trends in the care of persons with opioid use disorder and critically evaluate novel approaches to improve engagement in care for this population.

## **Alcohol Use**

The emphasis on the opioid crisis has in some ways overshadowed concerns over alcohol use, which, according to the World Health Organization (WHO), contributes to 3 million deaths annually ([WHO, 2018a](#)). C/PHNs can provide evidence-based strategies to address this significant problem and help achieve the WHO goal of 10% reduction in the harmful use of alcohol globally by 2025 ([WHO, 2018b](#)) and the alcohol-related Healthy People goal of reducing alcohol use in the United States ([Fig. 25-3](#)).

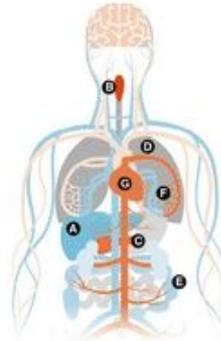

# Alcohol and health World Health Organization

**3 million** **deaths** every year  
6 deaths every minute  
 from harmful use of alcohol

## Harmful use of alcohol causes

-  **100%** of alcohol use disorders
-  **18%** of suicides
-  **18%** of interpersonal violence
-  **27%** of traffic injuries
-  **13%** of epilepsy

- A** **48%** of liver cirrhosis
- B** **26%** of mouth cancers
- C** **26%** of pancreatitis
- D** **20%** of tuberculosis
- E** **11%** of colorectal cancer
- F** **5%** of breast cancer
- G** **7%** of hypertensive heart disease

## Reduce harmful use of alcohol

Best buy interventions

-  **Regulate alcohol distribution**
-  **Restrict or ban advertising**
-  **Increase prices**

More key interventions

Prevent and treat alcohol use disorders

Raise awareness of alcohol-attributable health burden

Support community action to prevent and reduce the harmful use of alcohol

Implement drink-driving policies

Provide consumer information on alcohol containers

Regulate informally produced alcohol

Develop surveillance systems for alcohol consumption health consequences and policy

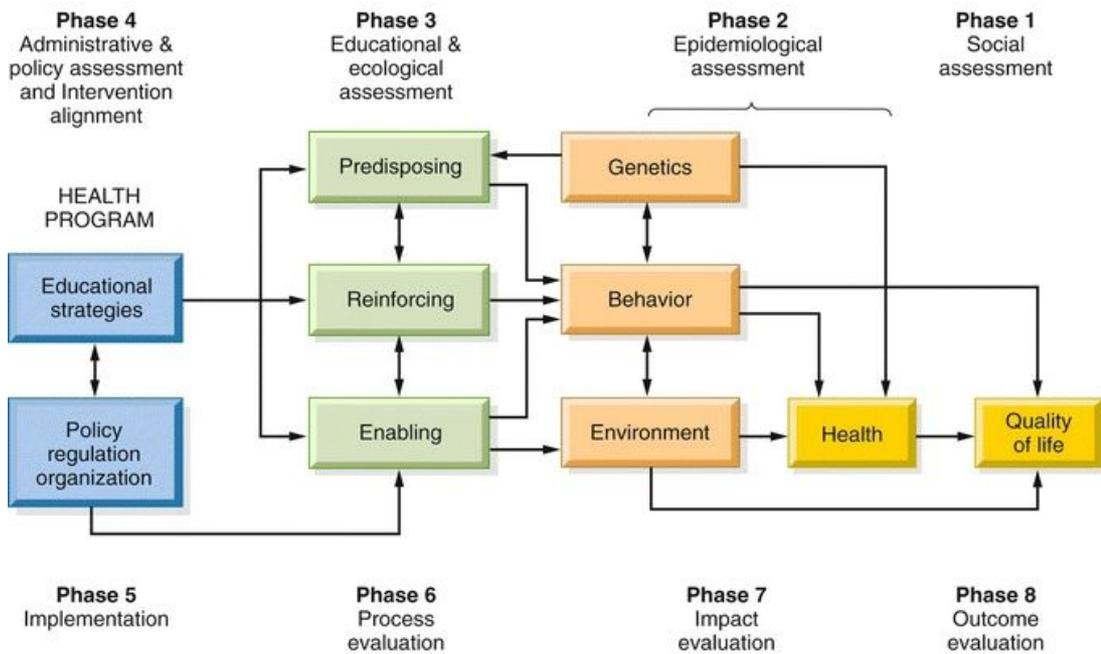

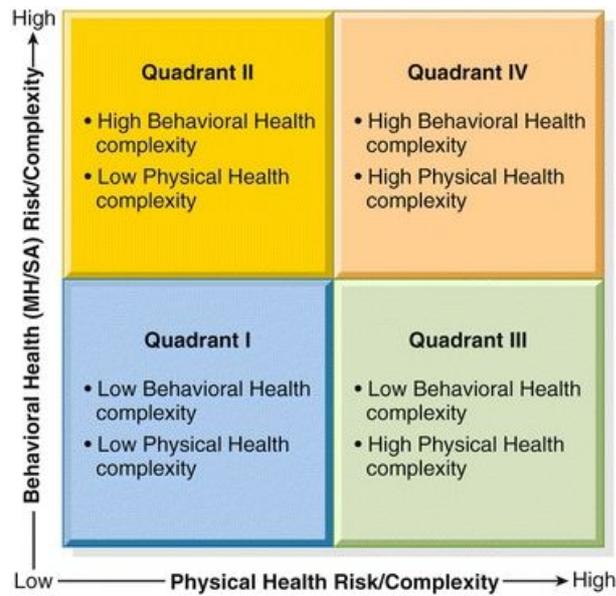

**10% reduction in the harmful use of alcohol by 2025**

**FIGURE 25-3** Alcohol and health. (Reprinted with permission from World Health Organization. (2018). *Global status report on alcohol and health*. Geneva, Switzerland: Author. Retrieved from [http://www.who.int/substance\\_abuse/infographic\\_alcohol\\_2018.pdf?ua=1](http://www.who.int/substance_abuse/infographic_alcohol_2018.pdf?ua=1))

## **Integration of Behavioral Health Services**

For decades, primary care, mental health, and substance use services have been separated, requiring patients to seek services among multiple sites and providers to obtain comprehensive care. Recognizing that the needs of persons with mental health problems, substance use, and physical conditions were not being adequately met, provider organizations began to design and implement integrated services in their practice and communities. These model services provided primary care in **behavioral health** clinics or behavioral health services in primary care. **Integrated behavioral health** models of clinical integration guide the providers in addressing the need for populations based on the behavioral risk/complexity and the physical health risk/complexity. The Four Quadrant Clinical Integration Model by the National Council for Behavioral Healthcare (2009) serves as a guide for C/PHNs to determine broad approaches to meet the needs of individuals and populations. [Figure 25-4](#) depicts the relative balance between the complexity of behavioral health needs and the complexity of physical health needs.

**FIGURE 25-4** Four Quadrant clinical integration model. (Adapted with permission from National Council for Behavioral Health. (2009). *Behavioral health/primary care integration and the person-centered healthcare home*. Washington, DC: Author. Retrieved from [https://www.samhsa.gov/sites/default/files/programs\\_campaigns/samhsa\\_hrsa/four-quadrant-model.pdf](https://www.samhsa.gov/sites/default/files/programs_campaigns/samhsa_hrsa/four-quadrant-model.pdf))

## Antistigma Strategies, Peer-Based Support, and Naloxone

Stigma is a key barrier to seeking treatment for behavioral health conditions for many who could benefit from it (Knaak, Mantler, & Szeto, 2017), yet there is a lack of research on this topic. Corrigan and Nieweglowski (2018) proposed antistigma strategies that could be incorporated into public health programs targeting opioid stigma. Such strategies may be relevant for C/PHNs to help resolve stigma that has persisted for decades. Stereotypes, prejudice, and discrimination underlie stigma, factors that, in part, can be confronted through education that dispels myths with facts.

- A study by Mahmoud and colleagues (2019) reported that after receiving education on how to detect and manage alcohol and opioid use, nursing students' stigma-related perceptions were favorably changed.
- Further, as these nursing students engaged with this patient population in the clinical setting, their attitudes toward working with these patients exhibited positive changes (Mahmoud et al., 2019).
- Contact with persons who are in treatment or in recovery may be a good addition to education programs that are meant to reduce stigma (Corrigan & Nieweglowski, 2018).
- C/PHNs are in key positions to apply these antistigma strategies when providing education to the public and engaging people in recovery.

Peer-based recovery support services provided by persons who have a lived experience and experiential knowledge of substance use disorders have proliferated over the past decade. These peer roles are garnering increased support in the face of the opioid epidemic.

Another trend is the increasing public availability of naloxone, an opioid-reversing drug (USDHHS, 2018). Given their presence in community settings, The C/PHN has a key role in the fight against the opioid epidemic (see Box 25-3). C/PHNs can and should carry and use naloxone as a key part of the public health response to the opioid crisis.

**BOX 25-3 The C/PHN's Role in the Fight Against the Opioid Epidemic**  
Prescription of opioid pain medications has increased since the 1990s, with

**assurance from pharmaceutical companies that risk of addiction was low (Gale, 2016). Subsequently, overuse of both prescription and nonprescription opioids occurred with associated increase in overdose events of 30% to 70% from 2016 to 2017 (Vivolo-Kantor et al., 2018).**

The Department of Health and Human Services (HHS) declared a public health emergency and proposed strategies to combat this opioid epidemic (Hargan, 2017). The accompanying community burdens associated with the loss of life, productivity, and health care treatment dollars as well as increased demands on criminal justice systems were deemed unsustainable. In response, the American Nurses Association (ANA) emphasized the nurse's role in assessment and formulation of plans to decrease the impact of this epidemic while still advocating for appropriate treatment for painful conditions (ANA, 2018).

As frontline caregivers to the opioid-using population, Cleveland Clinic nurses have taken lead roles in the opioid task force established in early 2017. The task force has multiple focus areas designed to change harmful behaviors (Consult QD, 2017).

First, nurses are studying the clinical settings, and describing patterns of those addicted to opioid medications. Integral to improvement of clinical care is incorporating alternative treatments to chronic pain as well as the provision of rescue medications in cases of overdose (Consult QD, 2017).

Next, health policy and laws that impact the availability of naloxone to first responders and pharmacists are addressed. In addition, policy is needed to facilitate treatment of addicted pregnant women and address associated child custody matters (Consult QD, 2017).

Finally, nurses provide prevention education in the community with nurse-led information sessions within public gathering facilities. In addition, nurses develop curricula and educate peers how to avoid “compassion fatigue,” which frequently develops when providing care for those with substance abuse and addiction (Consult QD, 2017).

Source: American Nurses Association (ANA) (2018); Consult QD (October 16, 2017); Hargan (2017); Vivolo-Kantor *et al.* (2018).

# PREVENTION OF SUBSTANCE USE AND MENTAL DISORDERS

Relevant to behavioral health, the Healthy People 2030 leading health indicators focus on mental health and mental disorders, substance abuse, and tobacco ([U.S. Department of Health and Human Services, 2020](#)). The overarching goals are to:

- Improve mental health through prevention and by ensuring access to appropriate quality mental health services
- Reduce substance abuse to protect the health, safety, and quality of life for all, especially children
- Reduce illness, disability, and death related to tobacco use and secondhand smoke exposure

Across these three major priority areas, C/PHNs can use evidence-based interventions to address the targeted outcomes. Interventions can be categorized according to the three levels of preventive behaviors, as shown in [Box 25-4](#).

## **BOX 25-4 Levels of Prevention Pyramid**

### **The C/PHN Works With High-Risk Populations for Mental Disorders and Substance Abuse**

**SITUATION:** Community and public health nurses play a key role in affecting the social determinants of health in vulnerable populations. The main goal of the C/PHN is to improve the population's health through highlighting prevention and addressing the determinants of health within that population.

**GOAL:** To provide examples of the three levels of prevention when working with high-risk populations for mental disorders and substance use. These examples are meant to provide a starting point for the C/PHN

practice and will vary based on the population served. The first step in working with any aggregate is the development of trust.

**Tertiary Prevention**

- Provide classes on mental health and mental disorders to individuals and families.
- Provide resources and referrals to communities affected by substance use.
- Develop community partnerships to address these issues.
- Focus on the strengths of the community when developing interventions.

**Secondary Prevention**

**Early Diagnosis**

- Provide screening programs for the early detection of mental health concerns such as depression, suicidal thoughts, and substance use.
- Ensure that all adolescents receive screenings in schools.
- Increase referrals to inpatient and outpatient treatment programs.
- Provide harm reduction by needle exchange programs.

**Prompt Treatment**

- Provide referrals and treatment that are culturally sensitive and in native language of the client.
- Provide anticipatory guidance and ensure referrals are operational.
- Provide educational material that is culturally sensitive and literacy-appropriate.
- Offer clinic hours that meet the needs of the community such as after-work hours or weekends.

**Primary Prevention**

**Health Promotion and Education**

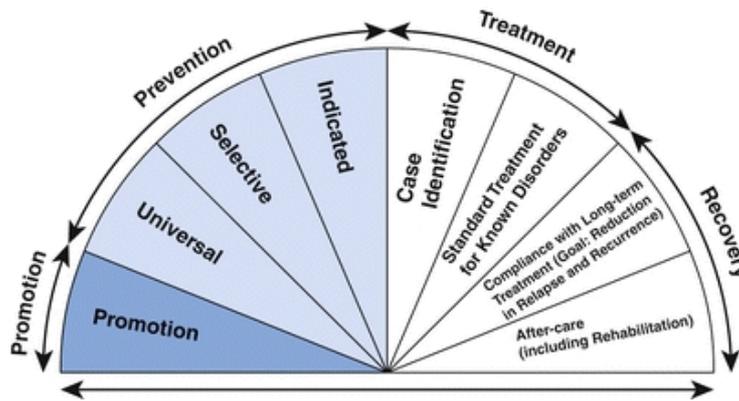

- Ensure that educational material and health promotion take into account the health literacy level of the population and the individual.
- Provide education and health promotion activities in partnership with the community members. Education topics should be relevant to the intended age group and community need. Topics may include coping skills, nutrition, exercise, wellness tips, mental health, and stress reduction.

**Health Protection**

- Assess the community's social determinants of health and how they affect mental health.
- Hold town meetings to gain insight into the needs to the community.
- Meet with community partners to decrease number of liquor stores in lower income neighborhoods.
- Assist the population in navigating sign-ups for a medical home.
- Achieving higher education has been shown to improve health and decrease poverty. Provide mentoring to middle-school and high-school students.
- Nurse-run clinics in areas with low percentage of health care providers.

Charlene Niemi PhD, RN, PHN, CNE.

A comprehensive approach to behavioral health means seeing prevention as part of an overall continuum of care. The Behavioral Health Continuum of Care Model ([Wisconsin Behavioral Health Association, n.d.](#)), depicted in [Figure 25-5](#), recognizes multiple opportunities for addressing behavioral health problems and disorders. The components of the model include promotion, prevention, treatment, and recovery.

**FIGURE 25-5** Behavioral health continuum of care model. (Reprinted with permission from Louis, L. *Oppor of parents lead*. Retrieved from <http://www.parentslead.org/sites/default/files/ContinuumofCareModel.pdf>)

- Promotion strategies reinforce the entire continuum of behavioral health services. These strategies are designed to create the environments and conditions that support behavioral health and help individuals overcome challenges.
- Prevention strategies, as characterized by [Gordon \(1983\)](#) in a classic article on prevention, may be grouped into three different categories, according to the level of risk that each addresses: universal, selective, and indicated.
  - *Universal prevention* includes those strategies delivered to broad populations wherein the benefits outweigh the costs and risks for everyone. Examples of this include public health campaigns related to suicide prevention, legislation related to impaired driving, and a minimum age for purchase of alcohol.
  - *Selective strategies* are indicated when a person's risk of becoming ill is elevated. Through detection of risk, vulnerable subgroups of individuals can be identified. As a result, programs and practices can be provided to reduce the risk.
  - *Indicated strategies* address specific risk conditions, focusing efforts on individual risk factors or behaviors that put individuals at high risk for developing a behavioral disorder.
- Treatment begins with case identification, which entails the ability to correctly identify those individuals who have a behavioral disorder with minimal false positives. Once identified, individuals who are at risk need to be referred for evidence-based treatments.
- Recovery focuses on promoting a high-quality and satisfying life in the community for all people. By engaging with individuals in recovery, C/PHNs can provide support and help them achieve their recovery

goals, monitor progress toward and recognize when they are moving away from goals, and support their transitions throughout the recovery process. C/PHNs can foster activities that contribute to wellness and a meaningful life, enhancing ways that persons in recovery can connect with others in their communities.

# MENTAL HEALTH

Improving **mental health** is a key goal of Healthy People 2030 (Box 25-5). Mental health is essential to personal well-being, family and interpersonal relationships, and the ability to contribute to community or society (U.S. Department of Health and Human Services, 2020). C/PHNs should understand the risk factors that challenge and undermine the health of individuals across the lifespan, such as adverse childhood experiences (Merrick et al., 2018) and social determinants of health (Walker & Druss, 2018). Early and regular mental health screenings are important for detecting emerging mental health problems. C/PHNs can engage the community in health-promoting activities and help establish community conditions to support health behaviors. These strategies are important for the prevention of **mental disorders**, which are associated with significant distress or disability in social, occupational, or other activities (American Psychiatric Association [APA], 2013).

## BOX 25-5 HEALTHY PEOPLE 2030

### Selected Mental Health and Mental Disorders Objectives

#### Core Objectives

MHMD-01	Reduce the suicide rate
MHMD-02	Reduce suicide attempts by adolescents
MHMD-03	Increase the proportion of children with mental health problems who get treatment
MHMD-04	Increase the proportion of adults with serious illness who get treatment
MHMD-05	Increase the proportion of adults with depression who get treatment
MHMD-06	Increase the proportion of adolescents with depression who get treatment
MHMD-07	Increase the proportion of people with substance use and mental health disorders who get treatment for both
MHMD-08	Increase the proportion of primary care visits where adolescents and adults are screened for depression

#### Developmental Objectives

MHMD-D01	Increase the number of children and adolescents with serious emotional disturbance who get treatment
----------	--

#### Research Objectives

MHMD-R01	Increase the proportion of homeless adults with mental health problems who get mental health services
----------	---

Reprinted from U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives.

Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

## Suicide

Two Healthy People 2030 objectives related to mental health improvement are to (1) reduce the suicide rate and (2) reduce suicide attempts by adolescents ([U.S. Department of Health and Human Services, 2020](#)). Suicide is a leading cause of death in the United States. According to the CDC WISQARS data ([CDC, 2020a](#)), in 2018, suicide was the tenth leading cause of death overall, claiming the lives of 48,344 people, and by age groups, suicide was ranked as the

- Second leading cause of death for persons aged 10 to 34 years
- Fourth leading cause of death for persons aged 35 to 54 years
- Eighth leading cause of death for persons aged 55 to 64 years

The National Violent Death Reporting System collects data regarding violent deaths, including those resulting from suicide. Recognizing at-risk groups is an important first step in reducing suicide rates. C/PHNs can use report summaries to develop, implement, and evaluate programs and policies to prevent suicides and other violent deaths. For example, the report by [Ertl and colleagues \(2019\)](#) provides information related to the circumstances preceding suicides reported in 32 states in 2016. The most common precipitating circumstances included substance use and current depressed mood in the individual. More than one fourth of these individuals were receiving mental health treatment at the time of their death ([Ertl et al., 2019](#)). Demographic characteristics are also important considerations for suicide prevention. Based on deaths occurring in 2016, the overall suicide rate for males was nearly 3.5 times the rate for females, and non-Hispanic American Indian/Alaska Natives had the highest rates of suicide ([Ertl et al., 2019](#)).

The method of suicide and location of the injury can also be important data for C/PHNs developing prevention strategies. Firearms have been reported to be used in nearly half (49.4%) of suicides, followed by hanging/strangulation/suffocation (27.8%) and poisoning (14.4%) ([Ertl et al., 2019](#)). [Houtsma, Butterworth, and Anestis \(2018\)](#) discussed strategies to mitigate the risks related to firearms, including decreasing their availability through removal and safe storage and educating professionals and individuals within the firearm community so that they can, in turn, disseminate knowledge about safe handling and storage of firearms. C/PHNs can reach out to at-risk individuals in the community and increase safety for those who may be capable of firearm suicide, as well as assess the rates of such suicides to determine the impact of their efforts.

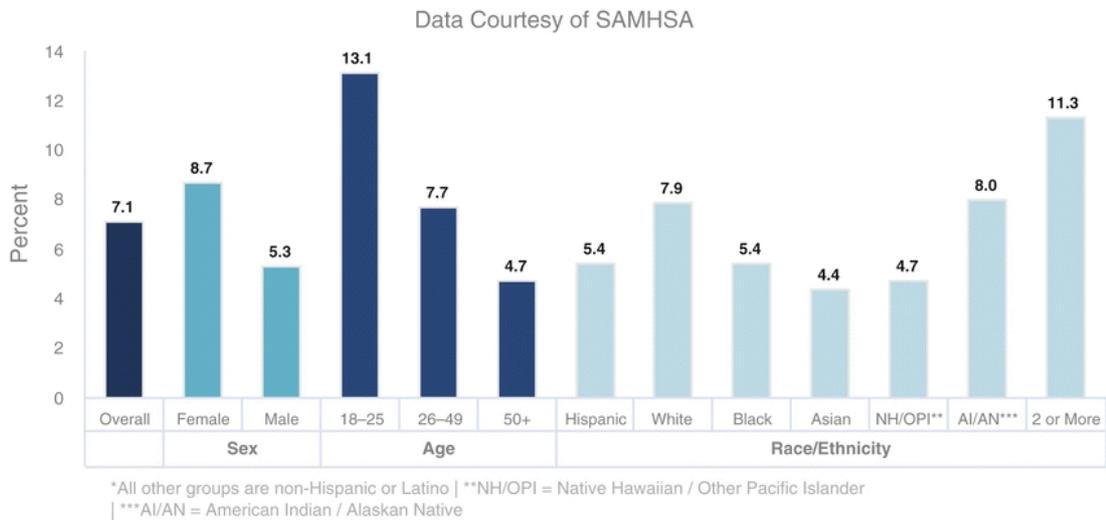

Results from the 2017 Youth Risk Behavior Surveillance System highlight the need for reducing suicide attempts by adolescents. [Kann and colleagues \(2018\)](#) reported that 17.2% of high school students in the United

States had seriously considered attempting suicide in the previous 12 months and that 13.6% of students surveyed had made a plan about how they would attempt suicide. The CDC has developed a technical package that provides evidence-based strategies for preventing suicide (Stone et al., 2017). C/PHNs can lead programs to provide children, youth, and adults with skills to resolve problems and negative influences that are associated with suicide. Evidence-based strategies discussed by Stone et al. (2017) include the following:

- Strengthen economic supports.
- Strengthen access and delivery of suicide care.
- Create protective environments.
- Promote connectedness.
- Teach coping and problem-solving skills.
- Identify and support people at risk.
- Lessen harms and prevent future risk.

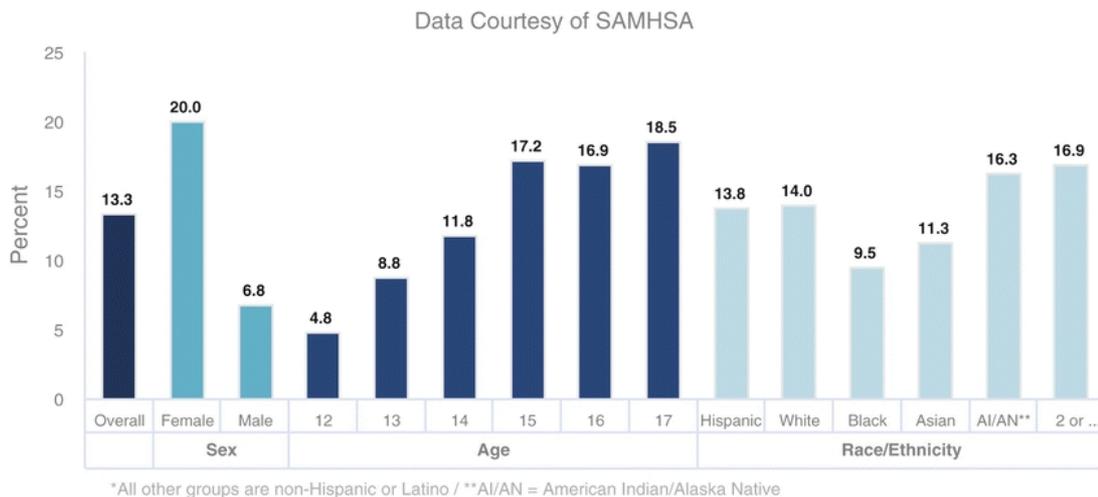

# Major Depressive Episode

In 2018, about 17.7 million U.S. adults (those aged 18 years or older) reported experiencing at least one major depressive episode; of those, 37% reported that they received no treatment (SAMHSA, 2019a). As seen in Figure 25-6, the prevalence was higher among adult females than males, in individuals aged 18 to 25 years, and among adults reporting two or more races.

**FIGURE 25-6** Past year prevalence of major depressive episode among US adults (2017). (Reprinted from NIMH. (2017). *Major depression. Past year prevalence of major depression episode among US adults (2017)*. Retrieved from <https://www.nimh.nih.gov/health/statistics/major-depression.shtml>)

Among adolescents, 14.4% of the U.S. population aged 12 to 17 years reported at least one major depressive episode (SAMHSA, 2019a). As seen in Figure 25-7, the prevalence was higher among adolescent females than males, with increasing prevalence from age 12 to 16 years and highest among White adolescents and those reporting two or more races. Of adolescents with major depressive episode, nearly 60% reported that they received no treatment (SAMHSA, 2019a).

**FIGURE 25-7** Past year prevalence of major depressive episode among US adolescents (2017). (Reprinted from NIMH. (2017). *Major depression. Past year prevalence of major depression episode among US adolescents (2017)*. Retrieved from <https://www.nimh.nih.gov/health/statistics/major-depression.shtml>)

What can C/PHNs do to help reduce the proportion of persons who experience major depressive episodes and increase the proportion who receive treatment?

- A systematic review and meta-analysis by [Deady and colleagues \(2017\)](#) reported that a range of eHealth cognitive behavioral programs have small, but positive effects on symptoms reduction for depression at both indicated/selective and universal prevention levels. The authors suggest that eHealth has potential for more reach with fewer resources than more traditional approaches because it is better able to overcome a range of financial, geographic, and time barriers ([Deady et al., 2017](#)).
- Technology-supported interventions for depression, such as Step-by-Step, developed by the WHO, are feasible to deliver to communities, adaptable, evidence based, and scalable in multiple settings ([Carswell et al., 2018](#)). This online psychological intervention is directed toward people with depression, includes informational and interactive exercises, and is designed to be a minimally guided self-help intervention ([Carswell et al., 2018](#)).
- C/PHNs could have a valuable role in providing support to end users to help them overcome any barriers to using or navigating through the content of such applications and encouraging their engagement by sending personalized messages and feedback ([Fuller-Tyszkiewicz et al., 2018](#)).

National Depression Screening Day is held annually during Mental Illness Awareness Week in October (<http://screening.mhanational.org/screening-tools>). C/PHNs can be actively involved by hosting an event in the community, conducting screenings, and providing information to help youth and adults identify the signs and symptoms of depression in themselves, their family members, and their peers. The Patient Health Questionnaire is the most commonly used depression screening instrument in the United States (O'Connor et al., 2016). Because the U.S. Preventive Services Task Force recommends there be adequate systems in place to ensure accurate diagnosis, effective treatment, and appropriate follow-up (Siu et al., 2016), C/PHNs should document a list of resources in the community where adults and adolescents can be evaluated and treated for major depression.

# SUBSTANCE USE

The *Diagnostic and Statistical Manual of Mental Disorders* 5th Edition (*DSM*; [APA, 2013](#)) provides diagnostic criteria for **substance-related disorders** encompassing 10 classes of drugs: alcohol; caffeine; cannabis; hallucinogens; inhalants; opioids; sedatives, hypnotics, and anxiolytics; stimulants; tobacco; and other or unknown substances. A departure from the previous edition of the *DSM*, the fifth edition shifted from categorizing the severity as “abuse” or “dependence” to recognizing substance use along a continuum from “mild” to “moderate” to “severe” based on the corresponding symptoms that are reported ([APA, 2013](#)). For some, substance use may increase the risk of harm to their health or well-being and/or increase the risk of harm to others ([Mahmoud et al., 2017](#)), and as such, they may not meet the criteria for a substance use disorder diagnosis. Healthy People 2030, as shown in [Box 25-6](#), focuses on substance use. C/PHNs should know how to detect the level of risk associated with alcohol and other drug use and the skills to intervene accordingly. The sections below address the scope of the problem associated with each substance, how to screen for risk, and how to intervene accordingly. For commonly used substances, signs of use, and associated health risks, see [https://www.drugabuse.gov/sites/default/files/Commonly-Used-Drugs-Charts\\_final\\_June\\_2020\\_optimized.pdf](https://www.drugabuse.gov/sites/default/files/Commonly-Used-Drugs-Charts_final_June_2020_optimized.pdf) and <https://www.drugabuse.gov/drug-topics/commonly-used-drugs-charts>

## **BOX 25-6 HEALTHY PEOPLE 2030**

### **Selected Substance Use Objectives**

### Core Objectives

SU-01	Increase the proportion of people with a substance use disorder who got treatment in the past year
SU-02	Reduce cirrhosis deaths
SU-03	Reduce drug overdose deaths
SU-04	Reduce the proportion of adolescents who drank alcohol in the past month
SU-05	Reduce the proportion of adolescents who used drugs in the past month
SU-06	Reduce the proportion of adolescents who used marijuana in the past month
SU-07	Reduce the proportion of adults who used drugs in the past month
SU-08	Reduce the proportion of adults who use marijuana daily or almost daily
SU-09	Reduce the proportion of people under 21 years who engaged in binge drinking in the past month
SU-10	Reduce the proportion of people aged 21 years and over who engaged in binge drinking in the past month
SU-11	Reduce the proportion of motor vehicle crash deaths that involve a drunk driver
SU-12	Reduce the proportion of people who misused prescription drugs in the past year
SU-13	Reduce the proportion of people who had alcohol use disorder in the past year
SU-14	Reduce the proportion of people who had marijuana use disorder in the past year
SU-15	Reduce the proportion of people who had drug use disorder in the past year

### Developmental Objectives

SU-D01	Increase the number of admission to substance use treatment for injection drug use
SU-D02	Increase the proportion of people who get a referral for substance use treatment after an emergency department visit

### Research Objectives

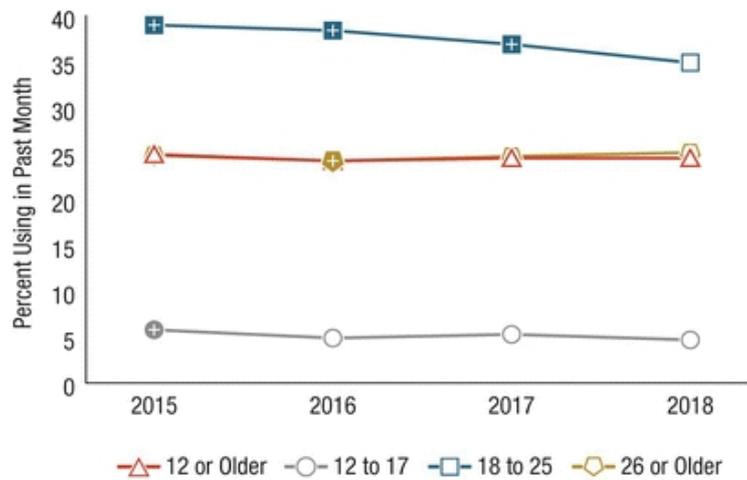

SU-R01	Increase the proportion of adolescents who think substance abuse is risky
--------	---

U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives.

Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

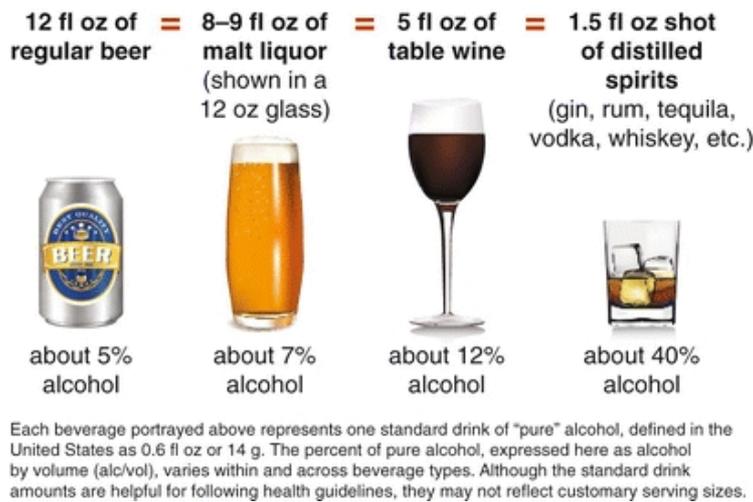

## Alcohol Use

Although the opioid crisis continues to loom and rightfully command attention, alcohol contributes to the death of more than 3 million people each year (WHO, 2018). The 2018 National Survey on Drug Use and Health (NSDUH) collected information from persons in the United States aged 12 years or older on past month alcohol use, binge alcohol use, and heavy alcohol use (SAMHSA, 2019a). Figure 25-8 displays the prevalence for each category and its definition.

**FIGURE 25-8** Past month binge and heavy alcohol use: percentages (2015 through 2018) for people aged 12 years or older, by age group. (Reprinted from Substance Abuse and Mental Health Services Administration. (2019). *Key substance use and mental health indicators in the United States: Results from the 2018 National Survey on Drug Use and Health* (HHS Publication No. PEP19-5068, NSDUH Series H-54). Rockville, MD: Center for Behavioral Health Statistics and Quality, Substance Abuse and Mental Health Services Administration. Retrieved from <https://www.samhsa.gov/data/sites/default/files/cbhsq-reports/NSDUHNationalFindingsReport2018/NSDUHNationalFindingsReport2018.pdf>)

The percent of alcohol varies by beverage. In screening for alcohol use, it is important to explain the definition of a standard drink. A graphic depiction of a standard drink available from the [National Institute on Alcohol Abuse and Alcoholism \(n.d.a\)](#) is useful for providing this information (Fig. 25-9).

**FIGURE 25-9** What is a standard drink? (Reprinted from National Institute on Alcohol Abuse & Alcoholism (NIAAA). (n.d.a). *What is a standard drink?* Retrieved from <https://www.niaaa.nih.gov/alcohol-health/overview-alcohol-consumption/what-standard-drink>)

The National Institute on Alcohol Abuse and Alcoholism (n.d.b) has established low-risk alcohol consumption limits for healthy adults based on sex (Fig. 25-10). There are no safe limits for youth, and various health conditions and activities may warrant lower limits or no alcohol consumption at all. For example, alcohol consumption is contraindicated at any time during pregnancy (CDC, 2018b).

No amount of alcohol or drug is safe if driving, pregnant, or a possible substance use disorder.

**FIGURE 25-10** Low-risk alcohol consumption limits. (Reprinted from National Institutes of Health (NIH). (2016). *Rethinking drinking: Alcohol and your health*. Retrieved from [https://pubs.niaaa.nih.gov/publications/RethinkingDrinking/Rethinking\\_Drinking.pdf](https://pubs.niaaa.nih.gov/publications/RethinkingDrinking/Rethinking_Drinking.pdf))

Grounded in an understanding of the nursing process, the definition of a standard drink, and recognition of the alcohol consumption limits for healthy adults, C/PHNs can promote the reduction of alcohol use by delivering evidence-based interventions. **Box 25-7** illustrates the application of the nursing process to care of a patient with alcohol use disorder, including the standard steps of screening, brief intervention, and referral to treatment (SBIRT). This example illustrates how SBIRT can be used in public health nursing to help meet the Healthy People 2030 goal of reducing substance use. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) publications, *Planning Alcohol Interventions Using NIAAA's CollegeAIM* (NIAAA, n.d.c) and *Alcohol Screening and Brief Intervention for Youth: A Practitioner's Guide* (NIAAA, 2020), provide step-by-step guidance and tools for the delivery of this set of clinical strategies.

## BOX 25-7 C/PHN Use of the Nursing Process

### Detection and Management of At-Risk Alcohol Use

Component	Definition	Assessment	Planning	Implementation	Evaluation
Screening	A method of identifying people who use alcohol at a level that is harmful to their health or increases their risk for future harm	Are you using an established measure for screening, such as recommended by the National Institute on Alcohol Abuse and Alcoholism, "How many times in the past year have you had five (men) or four (women or patients over age 65) drinks or more in a day?" or the Alcohol Use Disorders Identification Test?  Can you provide the definition of a standard drink or provide a graphic when administering the screen?	Have screening measure available for administration.  Determine if you will screen all people or specific groups.  Prepare to employ best practices during the screening process.	Perform screening based on best practices:  <ul style="list-style-type: none"> <li>• Explain that it is a part of the standard practice.</li> <li>• Ask their permission to screen.</li> <li>• Interact in a nonjudgmental manner.</li> <li>• Convey empathic verbal and nonverbal behaviors during screening.</li> <li>• Thank the patient for answering the questions.</li> </ul>	Evaluate the person's response to screening.  Ensure that you were neutral in your responses to the person's questions or statements that may have been challenging of the process.
Brief Intervention	A motivational, awareness-raising, shared agenda-setting conversation with a person whose alcohol use puts him or her at risk and potentially creates problems with health and wellness.	Are you prepared to provide feedback based on the results of the screening?  Do you know the recommended alcohol limits for healthy adults based on sex and age?  Are you prepared to discuss alcohol limits for persons with other health conditions including those on alcohol-interactive medications?	Develop your motivational interviewing skills.  Practice those skills in a simulated environment and/or with experts.	Engage in the brief intervention based on best practices:  <ul style="list-style-type: none"> <li>• Ask permission to provide feedback about their alcohol use and screening results.</li> <li>• Use reflection and open-ended questions during the conversation.</li> <li>• Provide feedback about the risks associated with their alcohol use.</li> <li>• Negotiate a goal with the person based on the steps the person is willing to take.</li> <li>• Demonstrate the motivational interviewing spirit by: <ul style="list-style-type: none"> <li>• Providing summary statements of the person's stated reasons for change</li> <li>• Negotiating a treatment plan in a collaborative manner</li> </ul> </li> <li>• Affirming the person's strengths, ideas, and/or successes</li> </ul>	Determine if a goal was established and accepted by the person.  Evaluate your ability to convey the true spirit of motivational interviewing as opposed to using it as a technique.

Referral to Treatment	Establishing a clear method of follow-up with persons who may benefit from ongoing care because of risk or who need specialized treatment	Are you aware of your own limitations in terms of knowledge, skills and scope of practice to provide ongoing care for the person who is at high risk because of alcohol use? Do you know referral sources within and outside of your health care system?	Establish a list of potential resources for further assessment and/or treatment. Ensure that you are prepared to address questions about those resources, including access, cost, and what is provided. Engage in a discussion about potential barriers to acceptance of the referral and discuss ways to overcome them. Provide a warm handoff to the referral source or otherwise make a direct introduction of the person to the specialist provider.	Did you follow best practices below? <ul style="list-style-type: none"> <li>Recognize the person's need for alcohol treatment based on their screening score and/or medical/behavioral factors.</li> <li>Suggest the use of specific community and specialty resources.</li> <li>Arrange appropriate follow-up for ongoing evaluation.</li> </ul>	Evaluate if the person is accepting of the recommendation for referral. At follow-up, ascertain if the person followed through with the referral, and if so, the outcome.
-----------------------	---	--	--	---	---

Source: [Babor et al. \(2001\)](#); [Pringle et al. \(2017\)](#).

At the community level, C/PHNs can organize and actively engage in the National Alcohol Screening Day. This annual event, an initiative of the National Institutes of Health, is conducted to provide information about alcohol and health as well as free anonymous screening (<https://nationaldaycalendar.com/national-alcohol-screening-day-thursday-of-first-full-week-in-april/>). C/PHNs can help identify and address gaps in the treatment system by surveilling the types of specialty treatment that are provided in the community and assessing the time to access treatment as well as other factors affecting one's ability to receive timely and affordable treatment.

## Drug Use

The annual NSDUH for persons in the United States aged 12 years or older obtains information on drugs including marijuana, cocaine, heroin, hallucinogens, inhalants, and methamphetamine (SAMHSA, 2019a). C/PHNs should remain up to date on the prevalence of drug use in the community. The SBIRT clinical strategies can be used to identify and address drug use, including the use of a psychotherapeutic drug that is not as directed, including without a prescription of one's own. A single screening question begins the process (Smith, Schmidt, Allensworth-Davies, & Saitz, 2010); a positive response to that question triggers the administration of the Drug Abuse Screening Test (DAST; Skinner, 1982; Yudko, Lozhkina, & Fouts, 2007). To view the DAST, go to <https://cde.drugabuse.gov/instrument/e9053390-ee9c-9140-e040-bb89ad433d69>. The intervention is provided based on the level of risk per the DAST score.

### *Marijuana*

The drug that survey respondents most commonly reported as having used in the past month is marijuana, used by 43.5 million people aged 12 years or older (SAMHSA, 2019a). Marijuana use was reported by 43.5 million, or 15.9%, of Americans aged 12 years or older reported in 2018; this percentage of use was higher than any of the percentages of use from 2002 to 2017 (SAMHSA, 2019a). With the emerging context of legalization of marijuana, it will be important for C/PHNs to continue to monitor the prevalence of marijuana use in their communities. Given the adverse health effects and harms associated with marijuana use (Memedovich, Dowsett, Spackman, Noseworthy, & Clement, 2018), C/PHNs need to educate the public on its impact on health. (See Boxes 25-8 and 25-9.)

## **BOX 25-8 QSEN: Focus on Quality**

### **Patient-Centered Care for Behavioral Health: Adolescent Access to and Use of Marijuana**

*Evidence-Based Practice: Integrate best current evidence with clinical expertise and patient/family preferences and values for delivery of optimal health care (Cronenwett et al., 2007, p. 123).*

(See [http://qsen.org/competencies/pre-licensure-ksas#quality\\_improvement](http://qsen.org/competencies/pre-licensure-ksas#quality_improvement) for the knowledge, skills, and attitudes associated with this QSEN competency) More states are permitting commercial production and sales of recreational, or retail, marijuana. A public health concern is a potential

increase in adolescents' access to and use of marijuana given the evidence of negative health effects on this population. The National Survey on Drug Use and Health (NSDUH; <https://nsduhweb.rti.org/respweb/homepage.cfm>), conducted annually, asks questions about marijuana use for Americans ages 12 and older. Information from the NSDUH is used to support prevention and treatment programs, monitor substance use trends, estimate the need for treatment, and inform public health policy. In Colorado, the commercialization of medical marijuana allowed the proliferation of consumable marijuana products including candies, lozenges, baked goods, and beverages, with little attention paid to standardized dosing levels, guidance for novice users, food safety, and contamination issues. The legalization of marijuana cultivation for dispensaries has impacted growing conditions and horticultural practices with the goal of increasing the supply and the potency of the psychoactive ingredient tetrahydrocannabinol (THC).

1. *What are the harms associated with marijuana use among adolescents? How would you incorporate that evidence in educating the public?*
2. *Are strategies used to prevent unintentional poisoning transferrable to children and youth related to edible products and access to marijuana? If so, how would those be used in public health messages?*
3. *What data are needed to monitor impaired driving and risks of fatalities associated with marijuana use? Are limits for drivers' THC levels warranted?*
4. *What areas of the health care system should be under surveillance to monitor the impact of increased access to marijuana? How would data collected from those systems be used to inform public awareness campaigns or support policies and regulations to protect children, youth, and the community at large?*

Source: [Cronenwett et al. \(2007\)](#).

**BOX 25-9 Marijuana Use in the United States According to a 2018 Gallup poll, 66% of Americans favor legalizing the recreational use of marijuana (McCarthy, 2018). It is estimated that 43.5 million Americans between the ages of 12 and older used marijuana in 2018**

**(SAMHSA, 2019). *Delta-9-tetrahydrocannabinol* (THC) is the main psychoactive chemical found in the *Cannabis sativa* plant. Although usually smoked, it can be brewed in tea or mixed in foods called *edibles*. The THC content has steadily increased since 1976, when marijuana had an average of THC content of 0.72% (Marijuana Break, 2018). In 2014, this rose to 50% to 80% in some samples (NIDA, 2018).**

Marijuana use disorders (MUD) account for about 30% of all users. Frequent users prior to age 18 are at a four to seven times greater risk of developing MUD. Roughly 4 million people in the United States have MUD (NIDA, 2018). Academic difficulties occur with use, including increased risk of skipping college classes, poorer grades, and poorer graduation rates (Arria, Caldeira, Bugbee, Vincent, & O'Grady, 2015), and cognitive difficulties were significantly related to the minutes of marijuana use (Conroy, Kurth, Brower, Strong, & Stein, 2015). Judgment and attention are impaired (NIDA, 2018).

Frequent use is associated with mental health problems including depression, increased anxiety with use (Keith, Hart, McNeil, Silver, & Goodwin, 2015), panic, fear, and paranoia (NIDA, 2018). When used in large doses, acute psychosis may occur.

THC affects several parts of the brain, including the hippocampus and the orbitofrontal cortex, causing impaired thinking and difficulty in absorbing new information. A 25-year study found that those with a lifetime exposure to marijuana had lower scores in verbal memory. The effects on the cerebellum and basal ganglia result in poor balance and coordination as well as slowed reaction time (NIDA, 2018).

THC stimulates the mesolimbic system to release a high level of the neurotransmitter dopamine producing the "high." When compared to nonusers, in marijuana users there was a higher incidence of other drug use such as alcohol (use including binge drinking), almost half used cocaine, and 30% used amphetamines (Keith et al., 2015).

Currently, 14 states and the District of Columbia have legalized recreational use of marijuana ([National Conference of State Legislatures, 2020](#)). Teens and young adults' perception of the risks of the drug have decreased partially due to the legalization of the drug for medical and recreational use in some states ([NIDA, 2018](#)). Research continues to shed light on the benefits and dangers of marijuana use. C/PHNs need to stay up-to-date on the community trends and research in order serve their communities.

Source: [Arria et al. \(2015\)](#); [Conroy et al. \(2015\)](#); [Keith et al. \(2015\)](#); [Marijuana Break \(2018\)](#); [McCarthy \(2018\)](#); [National Institute on Drug Abuse \(NIDA\) \(2018\)](#); [Substance Abuse and Mental Health Services Administration \(2017, 2019a\)](#); [WHO \(2020\)](#).

Charlene Niemi, PhD, RN, PHN, CNE

## *Cocaine and Crack*

In 2018, 2% (5.5 million) of 5.5 people aged 12 years or older reported current use of cocaine and 0.3% who reported current use of crack cocaine. Among those aged 12 to 17 years, 0.4% (11,200) used cocaine and fewer than 0.1% (4,000) used crack ([SAMHSA, 2019a](#)).

## *Heroin*

Heroin use has increased in recent years. Roughly 800,000 people aged 12 years or older reported heroin use in 2018 ([SAMHSA, 2019a](#)). Until 2002, methadone was the primary medication used to treat individuals with heroin use disorder and was dispensed through licensed treatment facilities. The introduction of buprenorphine in 2002 allowed for an additional medication option and also increased access to treatment because this medication could be prescribed by physicians in their office or clinic setting. Access to buprenorphine was further increased with the passage of the Comprehensive Addiction and Recovery Act (P.L. 114-198), which allowed nurse practitioners to prescribe buprenorphine. The SUPPORT for Patients and Communities Act ([Congress.gov, 2018](#)) expanded access to this medication even further by allowing Certified Nurse Specialists, Certified Nurse Midwives, and Certified Nurse Anesthetists to prescribe buprenorphine for a 5-year period ([American Academy of Physician Assistants \[AAPA\], 2018](#)).

## *Hallucinogens*

In 2018, about 5.6 million people aged 12 years or older reported the use of hallucinogens, or 2% of the population. Compared with all other age groups, the highest percentage of use was reported by people aged 18 to 25 years at 6.9% ([SAMHSA, 2019a](#)).

## *Inhalants*

Respondents of the NSDUH survey are asked to report the use of inhalants to get high, but not to include accidental inhalation of a substance. In 2018, approximately 2 million people aged 12 years or older reported use of inhalants. Use was more common among adolescents aged 12 to 17 years than among people in other age groups ([SAMHSA, 2019a](#)).

## *Methamphetamine*

Most of the methamphetamine in the United States is produced and distributed illicitly, creating a serious public health and safety problem in the United States. Some suggest that the lull in the methamphetamine epidemic, at its peak in 2005, is swiftly ending, as this drug now accounts for 11% of the total number of opioid deaths ([The Lancet, 2018](#)). In 2018, about 1.9 million people aged 12 years or older reported current use of methamphetamine ([SAMHSA, 2019a](#)). About 43,000 adolescents aged 12 to 17 years reported methamphetamine use, or 0.7% of adolescents. The next-largest age group were 273,000 young adults aged 18 to 25 years who reported use in 2018; 1.6 million adults aged 26 years or older reported methamphetamine use also in 2018 ([SAMHSA, 2019a](#)).

## *Prescription Drugs*

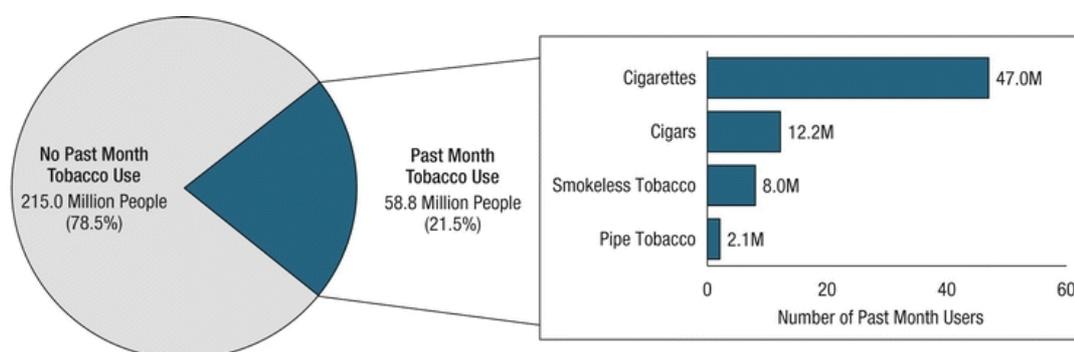

In the NSDUH, respondents are asked to report on any use of a prescription drug that is not used as directed, including use without a prescription of one's own. In 2018, this type of prescription drug use was reported by 16.9 million of the population aged 12 years or older. In 2018, among four different prescription drug categories, pain relievers were the most commonly reported, with 9.9 million persons aged 12 years or older reporting having used them in the past month, followed by prescription tranquilizers and sedatives (6.4 million), and prescription stimulants (5.1 million) ([SAMHSA, 2019a](#)).

Of greatest concern are prescription opioid analgesics (e.g., morphine, oxycodone), which along with heroin and fentanyl contribute to opioid-involved deaths. In 2018, close to 70% of the over 67,000 drug overdose deaths in the United States involved an opioid ([CDC, 2020b](#)). Various strategies have been undertaken to prevent overprescribing of opioids ([Dowell, Haegerich, & Chou, 2016](#)), improve drug monitoring programs ([Bao et al., 2018](#)), increase access to naloxone for opioid overdose reversal ([Kerensky & Walley, 2017](#)), increase linkages to harm reduction services and treatment ([Hawk & D'Onofrio, 2018](#)), and provide fentanyl test strips ([Peiper et al., 2019](#)). C/PHNs can assume important roles in promoting these

strategies in the community and providing education to the public on the crisis and ways to mitigate it.

# TOBACCO USE

Across the United States, tobacco consumption was the leading risk factor in terms of disability-adjusted life years (DALYs) for the years 1990–2016 (Mokdad et al., 2018). In 2016, about 63.4 million people aged 12 years or older reported tobacco use in the past month, the majority of whom smoked cigarettes (Fig. 25-11).

Note: The estimated numbers of current users of different tobacco products are not mutually exclusive because people could have used more than one type of tobacco product in the past month.

**FIGURE 25-11** Past Month Tobacco Use among People Aged 12 or Older: 2018. (Reprinted from Substance Abuse and Mental Health Services Administration. (2019). *Key substance use and mental health indicators in the United States: Results from the 2018 National Survey on Drug Use and Health* (HHS Publication No. PEP19-5068, NSDUH Series H-54). Rockville, MD: Center for Behavioral Health Statistics and Quality, Substance Abuse and Mental Health Services Administration. Retrieved from <https://www.samhsa.gov/data/sites/default/files/cbhsq-reports/NSDUHNationalFindingsReport2018/NSDUHNationalFindingsReport2018.pdf>)

The use of electronic cigarettes is rapidly emerging among adolescents, along with concerns about its impact on the health of both the individual and the public. A literature review by Perikleous, Steiropoulos, Paraskakis, Constantinidis and Nena (2018) reported as risk factors for e-cigarette use among adolescents the following: being male, being an older adolescent, being able to afford e-cigarettes, being a regular or heavy smoker, and having peers who smoke. With e-cigarette use rising among high school students in 2018 to 3.05 million (U.S. Food and Drug Administration, 2020), C/PHNs

need to be attentive to the attraction of this mode of tobacco use and provide educational initiatives targeting youth and young adults.

The [U.S. Preventive Services Task Force \(2017\)](#) recommends screening and providing brief intervention for tobacco use as part of standard routine health care for adults and women who are pregnant. The U.S. Department of Health and Human Services clinical practice guideline provides information about screening and interventions that can be provided based on the individual's willingness to quit. It is recommended that all patients be asked whether they use tobacco and, if so, whether they want to quit.

The [Agency for Healthcare Research and Quality \(2012a\)](#) recommends five major components for treating tobacco use and dependence:

- “Ask” about tobacco use
- “Advise” to quit
- “Assess” willingness to make a quit attempt
- “Aid” the person in quitting
- “Arrange” for follow-up

C/PHNs are encouraged to adopt these 5As as part of their standard care to address this major health problem in the United States and globally. Strategies for various populations are provided on the [smokefree.gov](#) Web site, including strategies for those who are willing to quit, those unwilling to quit, those who have recently quit, and specific populations (e.g., veterans, women, teens, those 60 years and older, and Spanish speakers).

# COMMUNITY-AND POPULATION-BASED INTERVENTIONS

Interventions to promote behavioral health at the community level begin with a community assessment to establish a community diagnosis, followed by interventions that can address the specific public health issue identified in the diagnosis. The *Healthy People 2030* objectives serve as a starting point in the development of an intervention. Community interventions move beyond single interventions and outcomes at individual levels of health behavior change.

Depicted in [Figure 25-12](#), the five steps of SAMHSA's A Guide to SAMHSA's Strategic Prevention Framework (SAMHSA, 2019b) can guide C/PHNs in a comprehensive process for addressing the behavioral health problems facing communities.

**FIGURE 25-12** A guide to SAMHSA's Strategic Prevention Framework. (Reprinted from Substance Abuse and Mental Health Services Administration. (2019). *A guide to SAMHSA's strategic prevention framework*. Retrieved from <https://www.samhsa.gov/sites/default/files/20190620-samhsa-strategic-prevention-framework-guide.pdf>)

Table 25-1 provides descriptions of each step of the process.

**TABLE 25-1 Strategic Planning Framework: Step-by-Step Guidance for the C/PHN**

Step	Description	Questions to Address	Information That Can Help Address the Questions
1. Assess	Assess the problem and related behaviors including risk and protective factors.	What substance misuse problems occur in the community? How often, where, and to which populations is this occurring?	State and local data collected within the community Identified risk and protective factors within the community Identify gaps given current community resources and their capacity.
2. Capacity	Build local capacity to address prevention.	Who are your stakeholders, and what information do they need? How can they be motivated to be involved? Who should be part of the prevention team? Can partnerships be created?	Identify all possible stakeholders within the community to raise awareness and support.
3. Plan	Formulate a plan and prioritize risk and protective factors.	How are risks and protective factors prioritized? Does the community have the resources to address the problem?	Create a plan that aligns to your logic model.
4. Implement	Delivery of evidence-based interventions and programs.	Can the community provide evidence-based solutions for required levels and needs within the community? What support is necessary for implementation?	Create evidence-based program and treatments that meet the needs of your community.
5. Evaluate	Conduct a process evaluation, looking at both process and outcomes.	How successful were the programs and practices? What was the effect of the program? Did changes occur, and if so, what were those changes? Were stakeholders included in the evaluation process with respect for all groups?	Create report based on process and outcomes of programs. Evaluation designs, instruments, and methods of evaluation used.

Source: Substance Abuse and Mental Health Services Administration (SAMHSA) (2019b).

Community coalitions that have used the Strategic Prevention Framework include the following:

- Iowa Department of Public Health substance abuse program (<https://idph.iowa.gov/substance-abuse/programs/spfrx/about>): A program designed to raise awareness about the dangers of sharing medications and to work with the pharmaceutical and medical communities to communicate the risks of overprescribing to youth
- Kansas Prevention Coalition (<http://kansaspreventioncollaborative.org/Coalitions/Strategic-Prevention-Framework>): Using the Strategic Prevention Framework, offers community programs and resources on prevention (the Web site provides an overview of the framework, and the New and Highlights section of the Web site provides links to numerous community programs and resources)
- SAMHSA provides a *Collaborative Approach to the Treatment of Pregnant Women with Opioid Use Disorder*, offering communities

guidance in developing interagency policies and practices to assist pregnant women and their infants in the health, safety, and recovery (SAMHSA, 2016).

- *Screening and Assessment of Co-occurring Disorders in the Justice System* provides direction and guidance to communities to assess and address symptoms of mental health and substance abuse disorder in offenders (SAMHSA, 2019c).
- *Medication-Assisted Treatment Programs in Criminal Justice Settings* are exemplified in New Jersey and Rhode Island. In an effort to stabilize individuals over the course of their sentences and after release, medications are prescribed to treat opioid use disorder (OUD) (SAMHSA, 2019d).
- Kentucky and Massachusetts use a relapse prevention focus, where criminal offenders with OUD are provided naltrexone before and after release to avoid the risk of relapse after reentry into the community (SAMHSA, 2019d).

# SUMMARY

- Substance use disorders are linked to health problems. Healthy People 2030 focuses on strategies to prevent and access to treatment to mitigate health problems and deaths.
- At the individual level, C/PHNs can detect the person's level of risk via screening instruments, assess the individual, and intervene accordingly.
- The Strategic Prevention Framework serves to guide C/PHNs in community-level interventions to address behavioral health problems.

# ACTIVE LEARNING EXERCISES

1. Develop your skills in assessing health education materials. Select a Healthy People 2030 objective related to mental health and mental disorders, substance use, or tobacco use. Search for accessible health education materials related to that behavioral health problem. Select one health education flyer, brochure, booklet, or Web site. Evaluate the material using the Suitability Assessment of Health Education Materials Scoring Sheet available at <http://aspiruslibrary.org/literacy/SAM.pdf>. Provide a summary narrative of your scoring and justification, based on the literature for your evaluation. Provide a list of the references used in your analysis of the health education materials.
2. Using “Enable Equitable Access” (1 of the 10 essential public health services; see [Box 2-2](#) ), identify services for behavioral health in your community or state. What services are available, and how accessible are those services?
3. Examine the evidence related to safe consumption spaces. Assume a position on the pro or the con side and conduct a literature search to support that perspective.
4. Identify a health promotion topic based on one of the Healthy People 2030 objectives related to a behavioral health problem. Develop a 5-minute presentation on the topic preparing no more than 20 PowerPoint slides. The presentation can be in person or by creating an Ignite presentation that can be delivered online. Whichever format you select, the following resources will be useful in developing your talk.
  - <https://www.youtube.com/watch?v=yGENcskRGRk&feature=youtu.be%2F>
  - <https://speakingaboutpresenting.com/content/fast-ignite-presentation/>
  - <http://www.lauramfoley.com/ignite/>
5. Research behavioral health issues in your community. Gather data from local, state, and national agencies to determine incidence and prevalence of behavioral health concerns and morbidity and mortality rates. One source might be the CDC's Web-based Injury Statistics Query and Reporting System (WISQARS). Begin by going to the Web site: <https://www.cdc.gov/injury/wisqars/index.html>.
  - Select “Fatal Injury and Violence Data.”

- Select “Fatal Injury Reports 1981–2018.”
- Review the following areas and make selection(s) for each:
  - Year Range/Census Region
  - Intent or manner of the injury
  - Cause or mechanism of the injury
- Complete the “Select-specific options” that are of interest for your report.
- Submit the request to see the results.
- Click “Download Results in a Spreadsheet CSV) File.”

# CHAPTER 26

## *Working with the Homeless*

*“We have come dangerously close to accepting the homeless situation as a problem that we just can't solve.”*

—Linda Lingle (1953), American Politician

### **KEY TERMS**

Chronically homeless  
Continuum of care  
Deinstitutionalization  
Doubling up  
Homeless  
Housing First  
Literally homeless  
Period prevalence counts  
Point-in-time counts  
Single-room occupancy (SRO) housing  
Survival sex  
Trauma-informed care  
Unaccompanied youth  
Unsheltered (hidden) homeless

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Define the concept of homelessness.
2. Describe the demographic characteristics of the homeless living in the United States.
3. Discuss factors predisposing persons to homelessness.
4. Compare and contrast the unique challenges confronting selected subpopulations within the homeless community.
5. Explain the effects of homelessness on health.
6. Analyze the extent and adequacy of public and private resources to combat the problem of homelessness.
7. Assess your beliefs and values toward homelessness.
8. Propose community-based nursing interventions to facilitate primary, secondary, and tertiary prevention in addressing the problem of

homelessness.

# INTRODUCTION

What was once considered unthinkable in a prosperous nation is now an expected occurrence in towns and cities across the United States. Drive through an inner city or suburban community on any given day, and you will see people on street corners holding signs stating “Hungry and homeless.” Where is the public outcry in response to this scene? Has the American conscience been anesthetized to this form of human suffering? Or is the need simply too overwhelming and the problems too far reaching to mount an effective campaign to prevent such a tragedy?

The purpose of this chapter is to define the concept of homelessness, examine the factors contributing to homelessness, analyze the major issues confronting the homeless, and examine the role of the community health nurse (CHN) in addressing the needs of the homeless.

The McKinney-Vento Homeless Assistance Act (Title 42 of the U.S. Code) defines as **homeless** a person who lacks a fixed, regular, adequate nightly residence; this definition includes as homeless those who stay in supervised public or private shelters that provide temporary accommodations. Homeless individuals may also reside in institutional settings providing temporary shelter or in public or private places that are not designed for or used as a regular long-term sleeping accommodation for human beings (e.g., cars, parks, campgrounds; [Fig. 26-1](#)). Such individuals are often referred to as **literally homeless**. Incarcerated individuals are not considered homeless under this definition ([McKinney-Vento Homeless Assistance Act, 1987](#)).

**FIGURE 26-1** A row of tents and belongings of some of the over 30,000 homeless people who live in Los Angeles. Homeless

individuals often struggle to find shelter.

The education subtitle of the McKinney-Vento Homeless Assistance Act expands on the definition of homelessness when addressing homeless children and youth. The Act includes as homeless those children who share housing with others because of economic hardship or loss of housing, are abandoned in hospitals, are awaiting placement in foster care, or are living in motels, trailer parks, or camping grounds. However, children awaiting foster care placement were removed from the definition of homeless in 2016 ([National Center for Homeless Education, n.d.](#)).

The U.S. Department of Housing and Urban Development (USDHUD) defines homeless people as those living on the streets, in vehicles, in shelters or parks, or in transitional housing; unaccompanied youth or families with children who are defined as homeless under other federal statutes; or individuals facing imminent eviction (within 14 days; [National Health Care for the Homeless Council \[NHCHC\], 2018](#)). Although this definition may be appropriate for the urban homeless, who are more likely to live on the street or in shelters, persons living in rural areas tend to cohabit with relatives or friends in overcrowded, substandard housing ([Housing Assistance Council \[HAC\], 2016](#)). [Box 26-1](#) outlines selected *Healthy People 2030* goals that relate to the homeless population.

## **BOX 26-1 HEALTHY PEOPLE 2030**

### **Objectives Related to Homelessness**

Objective	Description
MHMD-R01	Increase the proportion of homeless adults with mental health problems who get mental health services
HIV-01	Reduce the number of new HIV infections
<b>Related Access to Care Objectives</b>	
AHS-01	Increase the proportion of people with medical insurance
AHS-04	Reduce the proportion of people who can't get medical care when they need it
AHS-06	Reduce the proportion of people who can't get prescription medicines when they need them
AHS-07	Increase the proportion of people with a usual primary care provider
AHS-08	Increase the proportion of adults who get recommended evidence-based preventative health care
AHS-09	Reduce the proportion of emergency department visits with a longer wait time than recommended
AHS-R01	Increase the ability of primary care and behavioral health professional to provide more high-quality care to patients who need it

Reprinted from U.S. Department of Health and Human Services (USDHHS). (2020). *Healthy People 2030: Browse objectives*. Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

# SCOPE OF THE PROBLEM

It is difficult to estimate the number of people who are homeless, because homelessness is a temporary condition. Rather than trying to count the number of homeless people on a given night, or **point-in-time counts**, it may be more prudent to gauge the number of people who have been homeless over a longer time frame, such as over the course of a year, or **period prevalence counts** ([Ontario Ministry of Housing, 2017](#); [USDHUD, 2017b](#)).

It is also difficult to locate and account for homeless people. Most estimates of homelessness are based on the number of people served in shelters or soup kitchens or the number of people who can easily be located on the streets. People who spend time at places that are difficult to reach (e.g., cars, campgrounds, caves, boxcars, wooded areas) are considered **unsheltered (hidden) homeless**. Many people are unable to access shelters because of overcrowding and limited capacity ([Box 26-2](#)). In rural areas, there are fewer housing options and resources for the homeless. As a result, people may be forced to live temporarily with friends or family (a practice known as **doubling up**). Although still experiencing homelessness, these individuals are not always counted in homeless statistics or considered eligible for homeless services ([NHCHC, 2019](#)).

## BOX 26-2 Population Focus

### Tent Cities and Solutions for the Homeless

After the Great Recession of 2007 to 2008, tent cities began springing up across many larger cities in the United States, some of them with mutually determined codes of conduct and social structures. These temporary communities were a similar phenomenon to the shantytowns of the Great Depression, and many cities have responded to these temporary encampments by criminalizing them, citing concerns for public health and safety ([Herring, 2015](#); [National Law Center on Homelessness and Poverty \[NLCHP\], 2017](#)).

Imagine a world where it is illegal to sit down. Could you survive if there were no place you were allowed to fall asleep, store your belongings, or to stand still? Homeless people, like all people, must engage in activities such as sleeping or sitting down in order to survive. Yet in communities across the nation, these harmless, unavoidable behaviors are treated as criminal activity under laws that criminalize homelessness ([NLCHP, 2017](#)).

Between 2007 and 2016, the number of homeless encampments reported by the media has increased 1,342% (NLCHP, 2017). Encampments have been reported in every state across the nation and in the District of Columbia. Most of these temporary communities are illegal and under constant threat of eviction. The dramatic increase in encampments is a reflection of the growth in homelessness and the lack of accessible shelter.

Why do people live in tent cities? Most cities in the United States do not have sufficient shelter beds to accommodate the number of homeless in need of shelter. Many shelters limit admission based on gender. Others do not allow children. Some shelters do not allow personal belongings or have no provision for their safe storage. Other shelters lack accommodations for persons with disabilities. Many shelters have strict curfews that may make it difficult to hold down a job. Very few shelters allow pets (NLCHP, 2017).

Some states have adopted more tent city–friendly policies. Innovations in addressing the tent city crisis include hosting permanent encampments with colocated service centers, engaging religious organizations to temporarily host tent cities on their properties, and providing permits for temporary encampments on city property (NLCHP, 2017).

1. *Have you seen tent cities in your community? How do you feel when you see them?*
2. *What do you think could be done to address some of the issues raised by the proliferation of tent cities? Debate the issue with classmates.*
3. *How could C/PHNs be involved in helping to design feasible population-focused interventions?*

Source: Herring (December 2015); NLCHP, 2017.

The USDHUD, in its *Annual Homeless Assessment Report to Congress*, publishes the latest counts of homelessness nationwide. In 2017, on a single night in January, there were an estimated 553,742 sheltered and unsheltered homeless people across the nation (Fig. 26-2). Approximately 48% of people experiencing homelessness were in unsheltered locations. The number of homeless people in the nation decreased by 14% from 2007 to 2017, with the number of people in unsheltered locations declining by 25% and the number of people in sheltered locations declining by 8%. From 2016 to 2017, the number of homeless increased in major cities but declined elsewhere in the United States. From 2007 to 2017, the rate of homelessness has declined across all categories except for the sheltered homeless, which has increased by 4% in major cities (USDHUD, 2017b).

requiring improved resources to reduce the rate of homelessness ([United States Conference of Mayors, 2016](#)).

## Demographics

Poverty is directly linked to homelessness (Fig. 26-3). Demographic groups more likely to be poor are also at greater risk of becoming homeless.

**FIGURE 26-3** Volunteers sharing food with homeless people. Raising awareness about homelessness is an important step in seeking community solutions.

### *Age*

- In 2017, 88% of individuals experiencing homelessness were adults over 24 years of age, 10% were 18 to 24 years old, and only 1% were under 18 years of age.
- Among the unsheltered homeless, 87% are over 24 years old and 1.6% are under 18 years of age ([USDHUD, 2017b](#)).

### *Gender*

- The majority of homeless individuals are unaccompanied adult men. Men are more likely than women to be unsheltered.
- Approximately 61% of people experiencing homelessness are men and 39% are women ([USDHUD, 2017b](#)).
- From 2016 to 2017, homelessness declined by 1% among women but increased by 1% among men.
- Fewer than 1% of homeless individuals identify themselves as transgender or as not male, female, or transgender ([USDHUD, 2017b](#)).

## *Ethnicity*

The racial and ethnic makeup of the homeless population varies based on geographic location.

- Nationally, 47% of people experiencing homelessness are non-Hispanic white, whereas approximately 41% are African American and 22% are Hispanic or Latino.
- Persons in sheltered situations are more likely to be African American, whereas those in unsheltered settings are more likely to be white ([USDHUD, 2017b](#)).
- Compared with the U.S. population, the sheltered homeless are more likely to be unaccompanied adult males, African Americans, and disabled ([USDHUD, 2017c](#)).

## *Families*

- Families with children represented 33% of the homeless population in the United States in 2017.
- Over 20% of people experiencing homelessness are children.
- Approximately 59% of homeless people in families are children (under 18 years of age).
- More than 90% of homeless people in families reside in shelters.

The number of homeless people in families declined by 21% from 2007 to 2017. The number of homeless families declined by 26%, with the majority of the decline being in families with children in unsheltered locations ([USDHUD, 2017b](#)).

Although nearly 78% of adults experiencing sheltered homelessness as part of families with children are women, men are increasingly being represented in sheltered homeless families ([USDHUD, 2017c](#)). During recessions and periods of economic decline, more two-parent families and families headed by single fathers are likely to become homeless ([Fig. 26-4](#)). Because organizations serving homeless families are generally geared to serving single women with children, it may be difficult for intact families and families headed by men to access shelter ([Zobel, 2016](#)).

**FIGURE 26-4** Homeless family sitting on the street. Families with children represent about one third of the homeless population in the United States.

## Contributing Factors

Persons are predisposed to homelessness because of a complex array of factors that result in individuals having to choose between necessities of daily living. Scarce resources limit choices. What would you do if you had to choose between eating and buying your child's medication? Housing consumes a huge portion of one's income and is often the first asset to be lost. Many families find they are only a paycheck away from homelessness (Boxes 26-3 and 26-4).

### BOX 26-3 PERSPECTIVES

#### **A Homeless Couple's Viewpoint on Living in Their Car**

My name is Sally. Sam and I are in our fifties and have been homeless for 2 years. We became homeless when my husband's company downsized, and he lost his job. I had to go on medical disability because of my brittle diabetes. I could no longer work, and the medical bills just kept piling up. Eventually, we were unable to pay our rent and were evicted from our home. We have been living in our car. We park in the local SuperMart lot at night. This place is great. It is located in a safe area of town, and it is open 24 hours a day, so we always have access to restroom facilities. We stayed in a county shelter for a while. The social worker there tried to help us find housing, but we were afraid to go into the parts of town where the subsidized housing was located. The criminal activity there was so pervasive that we just figured we would be safer living in our car. We have been married for over 30 years, but we were separated at the shelter and told we could not demonstrate any physical affection. When we tried to apply for food stamps, we were told we needed to produce our rent and gas and electric bills, or we would be ineligible to receive this benefit. I kept telling them that we live in our car. We don't pay rent! We don't have a gas and electric bill! Many times, we were turned down from housing and other benefits, because we did not meet the eligibility criteria. We were not single parents. We had no children. We did not suffer from a severe mental health or addiction disorder. We were not veterans. It is so frustrating. There are resources, but there are so many barriers to accessing them.

## BOX 26-4 What Do *You* Think?

### Street or Shelter? Which Would You Choose?

Many people wonder why so many homeless individuals choose not to use shelters. Walker (2018) discussed the following reasons why homeless persons may be reluctant to utilize shelter services: (1) lack of sufficient beds and overcrowding (many shelters require you to arrive at prescribed times and to wait in line to secure a space at night; if you have a job, you cannot always arrive in time, or you may work at night and need a place to sleep during the day); (2) fear of communicable diseases (e.g., bedbugs and other contagious diseases); (3) fear of having your belongings stolen; (4) having to leave your pets behind; (5) fear for one's safety and concerns regarding being attacked or abused; (6) fears of being proselytized or coerced to adopt particular faith perspectives; (7) having to be separated from one's spouse or loved ones, including older male children (who may not be allowed in a family shelter); and (8) difficulty adhering to sobriety requirements (for individuals who are active in their addiction).

1. *What do you think might be other reasons an individual would choose to sleep outside rather than in a homeless shelter?*
2. *How could some of these issues be effectively addressed?*
3. *How does your city address these issues and the overall problem of homelessness?*

Source: Walker (2018).

## *Poverty*

In 2016 (Semega, Fontenot, & Kollar, 2017):

- Nearly 41 million people (or 12.7% of the U.S. population) were living in poverty.
- Eighteen percent of children (under 18 years old) lived in poverty.
- Poverty rates were highest among single female heads of household.

Factors impacting poverty include declining wages, loss of jobs that offer security and carry benefits, an increase in temporary and part-time employment, erosion of the true value of the minimum wage, a decline in manufacturing jobs in favor of lower-paying service jobs, globalization and

outsourcing, and a decline in public assistance. As wages drop, the potential to secure adequate housing wanes (NCH, 2018c, 2019d).

Compounding the problem are a lack of affordable housing (particularly **single-room occupancy [SRO] housing** or housing units intended to be occupied by one person) and limited funding for housing assistance. A household seeking to afford a two-bedroom rental home in the United States must earn at least \$21.21 per hour. This figure is nearly \$14 higher than the federal minimum wage of \$7.25 (NLIHC, 2018). The Raise the Wage Act of 2017 is expected to gradually raise the minimum wage to \$15 per hour by 2024 (Economic Policy Institute, 2019).

When rental costs increase and the number of available low-rent units declines, the housing gap widens. Moreover, federal support for housing assistance is unable to keep pace with the high demand for housing (NCH, 2018a). As a result, many persons must pay high rents to obtain shelter. This situation leads to overcrowding and substandard housing. Because the demand for housing assistance exceeds federal housing assistance resources, there are often long waiting lists. Waiting lists may close when demand for housing exceeds the supply of subsidized units available for occupancy (NCH, 2019c; USDHUD, n.d.).

### *Lack of Affordable Health Care*

In the absence of affordable health care coverage, a serious illness or disability can lead to job loss, savings depletion, and even eviction. In 2016, nearly 28 million Americans (9% of the population) were without health care coverage (Kaiser Family Foundation, 2020).

The Affordable Care Act has expanded Medicaid coverage to millions of previously uninsured people, reducing the number of uninsured in the United States from 44 million in 2013 to <28 million in 2016 (Kaiser Family Foundation, 2019).

The uninsured are less likely to receive preventive care or care for chronic health conditions. They are more at risk for preventable hospitalizations and missed diagnoses. Nearly half of all bankruptcies in the United States are due, in part, to medical debts (Kaiser Family Foundation, 2019). Those who are able to qualify for medical assistance may be reluctant to seek employment, fearing termination of benefits. Many others have limited coverage that requires higher co-pays or deductibles and does not cover major catastrophic illnesses. A catastrophic adverse health event can plunge one into a homeless condition.

### *Employment*

Low-income wage earners may hold jobs with nonstandard work arrangements. Temporary employees, day laborers, independent contractors, and part-time employees are examples of those with work arrangements that tend to pay lower wages, offer few or no benefits, and have less job security.

For persons with few or no job skills, it is virtually impossible to compete for jobs that offer a living wage. Barriers to employment among the homeless include a lack of education or job skills; a lack of transportation, childcare, or other supportive services; a lack of access to technology; and disabilities that make it difficult to pursue or retain employment. To overcome homelessness and maintain employment, one must not only obtain a job that pays a living wage but also have access to supportive services such as childcare and transportation (NCH, 2018c).

## *Domestic Violence*

Domestic violence is a major cause of homelessness among women. For victims of domestic violence, the choice is often between living in an abusive situation and leaving to face life on the streets. More than one third of domestic violence survivors report being homeless following separation from their intimate partners.

Victims of domestic violence are often isolated from social support networks and financial resources, rendering them especially vulnerable. They may lack a steady income or a stable employment record and often experience anxiety, depression, panic disorder, or substance abuse disorders. A major challenge facing service providers of homeless domestic violence victims is the need to ensure a safe and secure environment and to protect client confidentiality (NAEH, 2020b, 2020c).

## *Mental Illness*

- Untreated mental illness may precipitate homelessness, and homelessness is a significant risk factor for poor mental health (Stafford & Wood, 2017).
- Approximately 112,000 homeless persons across the United States reported a severe mental illness in 2017 (USDHUD, 2017a).
- In January 2016, 20% of people experiencing homelessness had a serious mental illness (Substance Abuse and Mental Health Services Administration [SAMHSA], 2017a).

**Deinstitutionalization** (being released from institutions into the community) has contributed to the number of severely mentally ill persons represented in the homeless population (Howell, 2017). Some mentally ill persons self-medicate their disturbing symptoms using street drugs, placing

them at increased risk of addictions and diseases transmitted through injection drug use. Mental illness and substance abuse are often comorbid conditions, which, coupled with poor physical health, makes it especially difficult to secure employment and safe, affordable housing (SAMHSA, 2017a).

### *Addiction Disorders*

Rates of alcohol and drug abuse are disproportionately high among the homeless. In January 2016, 20% of people experiencing homelessness had a serious mental illness, and a similar percentage had a chronic substance use disorder (SAMHSA, 2017a).

For persons already at risk for homelessness, the behaviors associated with an addictive disorder can create instability and jeopardize family and employment support nets. Once homeless, persons may resort to drugs or alcohol to dull the pain of being homeless and ease the feelings of hopelessness that accompany such a desperate state. They may also turn to chemical substances to self-medicate the disturbing symptoms of an untreated mental illness. Fragmentation of services, limited access to care, lack of transportation, social isolation, and complex treatment needs make it difficult to receive the services needed to achieve a successful recovery (NAEH, 2020f).

Many shelters require sobriety to access services. There may be long waiting lists for addiction treatment, and homeless people who do not have a phone and are difficult to locate may be dropped from the waiting list. Lack of transportation and lack of documentation needed to access programs (i.e., birth certificates, social security cards) further exacerbate the problem. Denial of Supplemental Security Income or Social Security Disability Insurance to persons with substance abuse-related disabilities creates a huge barrier to achieving recovery support, proper medical care, and housing and income assistance. Moreover, the federal programs targeting homelessness, mental health, and addictions services (Box 26-5) lack the funding necessary to effectively address this problem on a national level.

## **BOX 26-5 PERSPECTIVES**

### **A C/PHN's Viewpoint on Caring for the Homeless**

I can't believe I am sitting around this table. What am I doing here? How did I end up on the Board of Directors of an organization that houses one of the largest residential addiction recovery programs for homeless men in the country? I have been a public health nurse for years. I know how to take care of homeless patients. But this is a whole different ball game. I'm looking at budgets and learning about capital campaigns. I even testified before a gubernatorial commission to advocate for funding for homeless services. And now I am chairing a Board level committee that is analyzing census tract data to determine the impact of its wellness center on public health. We are looking at emergency department utilization rates and rates of hospitalization for substance-related illnesses to see if our Wellness Center has an impact on our clients and the surrounding community. If we can demonstrate that our programs reduce hospitalizations and emergency room visits, we may be eligible to apply for population health funding and to partner with local hospitals in much bigger ways to make a positive impact in our community. This is exciting stuff!

Stan, C/PHN

### *Additional Variables*

Additional variables impacting homelessness include personal and financial crises, natural disasters, immigration and refugee crises, and personal choice. For example, natural disasters or immigration crises may displace previously independent and self-sufficient individuals and families, rendering many homeless and in need of emergency shelter. See more on disasters and their aftermath in [Chapter 17](#).

## Homeless Subpopulations

Although many of the struggles the homeless face are universal, there are subpopulations within the homeless community that are uniquely vulnerable. Often, these groups face additional burdens because of their special needs and challenges.

### *Homeless Men*

Approximately 61% of people experiencing homelessness are men ([USDHUD, 2017b](#)). The majority of homeless men are single adults.

Some men find themselves in a cycle of intermittent homelessness as they move back and forth between prisons, treatment centers, shelters, temporary housing, and the streets. Other men are at risk for becoming **chronically homeless**. Nearly one quarter of the homeless population in the United States is chronically homeless ([USDHUD, 2017b](#)). A chronically homeless adult is someone who has been homeless for long periods of time or has experienced repeated episodes of homelessness.

These individuals have a diagnosed disability such as mental illness, substance abuse, or a chronic medical condition and have been homeless for at least a year or have experienced at least four episodes of homelessness in the past 3 years. In 2017, the Annual Homeless Assessment Report to Congress recorded nearly 87,000 chronically homeless individuals in its point-in-time count (an 18% decline since 2010). Nearly 70% of these individuals were unsheltered (i.e., living on the street or in places not fit for human habitation; [USDHUD, 2017b](#)).

Homeless men are more likely to be treated with disdain than other homeless subgroups. Some people perceive the homeless male as largely to blame for his plight, believing that he is able bodied and should be able to work. Moreover, homeless men may have disabilities that are not severe enough to warrant eligibility for health and social services. Often health and social programs give priority to women and children ([Myrick, 2016](#)).

### *Homeless Women*

Women, as single parents, lead most homeless families in the United States ([Fig. 26-5](#)). Nearly 80% of sheltered homeless families are led by women ([USDHUD, 2017c](#)). Domestic violence is a major cause of homelessness among women ([USDHHS, 2016](#)).

**FIGURE 26-5** Homeless poor woman and her daughter asking for help. Most homeless families are headed by single female heads of household.

Lack of affordable housing forces many women to choose between living in an abusive home and facing life on the streets. Domestic violence victims often have poor credit and employment records due to the disruption caused by family violence. If violence is discovered in the home, landlords may evict tenants, forcing the family onto the streets ([Family & Youth Services Bureau, 2016](#)). Once on the street, a woman faces the risk of greater abuse. Moreover, the increased risk for exposure to violence and sexual assault on the streets increases the risk for sexually transmitted infections and traumatic injuries.

### *Homeless Children*

- In 2017, there were nearly 41,000 unaccompanied homeless children and youth (those under the age of 25 years) in the United States, of whom 12% were under the age of 18 years ([Fig. 26-6](#)).
- One in 20 children under 6 years of age was homeless in 2014 and 2015 ([USDHHS, 2017](#)).
- From 2007 to 2016, the number of children in families living in poverty increased by 13% ([USDHUD, 2017c](#)).

**FIGURE 26-6** A young homeless boy sleeping on a bridge.

The majority of homeless children and youth live in shelters, share housing with friends or relatives, or live in motels or campgrounds. Compared with their housed counterparts, homeless children are more likely to become ill, go hungry, and experience emotional and behavioral disorders (Fig. 26-7). They are also more likely to experience developmental delays and learning disabilities. Children in homeless families are more likely to experience parental separation, by being placed in either foster care or the care of friends or relatives. More than 25% of homeless children have witnessed violent acts ([American Institute on Research, 2020](#); [Child Trends Data Bank, 2015](#)).

**FIGURE 26-7** A 3-year-old homeless girl. Homeless children are more likely to go hungry than their housed counterparts.

Education is compromised when one is homeless. Homeless children are more than twice as likely to repeat grades in school as other children and

more likely to drop out or be suspended or expelled ([Child Trends Data Bank, 2015](#); [NAEH, 2020a](#)). They are also less likely to graduate from high school or college than their housed counterparts ([Hayes, 2016](#)). Barriers to education include transportation to and from the shelter, lack of academic and medical records required for registration, unstable living arrangements necessitating multiple moves, and urgent needs for food and shelter that take priority over education ([Family & Youth Services Bureau, 2016](#)).

Homeless children are more likely to get sick than other children. Not only are acute and chronic health problems more severe in homeless children, but these children are less able to access medical and dental care. Asthma, hyperactivity/inattention disorders, and behavioral problems are more prevalent in homeless children than in the general population ([Child Trends Data Bank, 2015](#)).

### *Homeless Youth*

On a single night in January 2016, nearly 36,000 unaccompanied youth were experiencing homelessness in the United States ([USDHUD, 2017c](#)). **Unaccompanied youth** are defined as persons under 25 years of age who are not accompanied by either a parent or guardian and are not themselves a parent ([USDHUD, 2017b](#)).

These youths may have run away from home or been evicted by their parents. There may be conflicts in the home that make it dangerous for them to return home. Many have been victims of abuse and have spent time in foster care. They may be overlooked during homeless counts because they are often difficult to locate ([Child Trends Data Bank, 2015](#)). For more information on the road to youth homelessness, see [Figure 26-8](#).

**FIGURE 26-8** The road to youth homelessness. (Retrieved from <https://nationalhomeless.org/wp->

<content/uploads/2014/12/Infographic1-FINAL.jpg>. Used with permission.)

In a national survey, nearly one third of youth experiencing homelessness had experiences with the foster care system and nearly half had been incarcerated or in juvenile detention (Morton, Dworsky, & Samuels, 2017). Foster care placement is associated with homelessness among youth. Moreover, some youth who are discharged from residential or foster care with inadequate housing or income support may find themselves homeless (Ahmann, 2017).

Homeless adolescents may have difficulty accessing emergency shelter because of shelter policies that prohibit older youth from the facility or because of a lack of bed space. Due to lack of education or job training skills, many resort to prostitution or **survival sex** (exchanging sex for food, shelter, or other basic necessities). As a result, homeless youth are at higher risk for sexually transmitted infections. Homeless youth also suffer disproportionately from mental health disorders (Cima & Parker, 2017; NCH, 2019b; Oppong Asante, Meyer-Weitz, & Petersen, 2016).

It is not uncommon for homeless youths to be arrested for running away, breaking curfews, or being without supervision. As young people age out of the foster care system, they find themselves on the street with inadequate support systems and little opportunity for housing or employment (Box 26-6; Ahmann, 2017).

## **BOX 26-6 STORIES FROM THE FIELD**

### **Crisis Shelter Intake of Roberto, a Homeless Youth**

I sat across from Roberto in a darkened, gritty community room at the homeless teen drop-in center located in an edgy part of downtown. He had just gone through an hour-plus worth of intake questions from the shelter staff; he was tired of questions, though grateful to get one-to-one time with a caring adult and *very happy* to have food in his belly. The intake questionnaire painted a picture of how he landed in this shelter as a 16-year old: a history of being in foster care while in elementary school; a diagnosis of anxiety disorder; a housing history mostly living with a loving, single parent who struggled to pay for a place in this gentrified city; and an academic record moving from school to school with four siblings whom he cared about a lot. Still, he told the intake

workers of wishes and hopes of going to college, continuing with his love of art, and finding his own housing “to take the burden of having another kid at home” off his mom.

I ran through his HEADDSS assessment screening tool and a brief PHQ-9 to understand the background and status of his physical and mental health. Roberto told me about his extended family whom he loved very much but couldn't live with right now. He liked school and got decent grades, though he worried about paying for college. He played soccer as an extracurricular, but rarely stayed at a school long enough to become a starter on the varsity teams. He stayed away from drinking and drugs because his father had been a drunk and left the family while he was young. And despite having an on-again, off-again girlfriend, says he adheres to his Catholic faith and has never had sex. On his PHQ-9, he scored “moderate depressive” symptoms and noted his anxiety has been “pretty high” the past couple weeks, and especially today being in this new place, not knowing anyone in the shelter. He repeatedly says “thank you” as staff walk by to welcome him to the center and shows extreme gratitude to me as we wrap up our discussion.

1. *What are some other critical pieces of information would you like to know about Roberto before you take him back to the housing staff for case management planning?*
2. *What 1 to 2 health or social concerns do you want to address with him right now using motivational interview techniques? What are Roberto's top health concerns you would like to include in his case management plan for this shelter stay?*

Scott Harpin, PhD, MPH, RN, APHN-BC, FSAHM

## *Homeless Families*

Poverty and the lack of affordable housing place families at risk of becoming homeless. Declining wages, changes in welfare programs, unstable employment, domestic violence, and a struggling economy have all contributed to the rise in family homelessness. Racial disparities and the challenge of single parenting also contribute to the growing trend in family homelessness (NAEH, 2020a).

Homelessness often breaks up the family unit. Families may be separated by shelter policies that prohibit admission to older boys or men. Sometimes, parents are forced to leave their children with family or friends or to place them in foster care to shelter them from becoming homeless (Child Trends Data Bank, 2015; United States Interagency Council on Homelessness, 2018).

A child is at greater risk for homelessness if the child's father becomes injured or ill, experiences a job loss, has a substance abuse issue, or becomes involved with the criminal justice system. Fifty percent of fathers of homeless children are unemployed, and 43% have problems with drugs or alcohol. Homeless children are at a high risk of being placed in foster care, and a personal history of foster care predicts family homelessness during adulthood. To assist homeless families, attention must be focused on promoting affordable housing; supporting education, job training, and childcare for parents; promoting access to school; expanding violence prevention and treatment services; and preventing unnecessary separation of families ([American Institute on Research, 2020](#); [Lenz-Rashid, 2017](#); [NCFH, 2014](#); [United States Interagency Council on Homelessness, 2018](#)).

## *Homeless Veterans*

- According to the 2017 Annual Assessment Report to Congress, 9% of homeless adults are veterans ([USDHUD, 2017b](#)).
- Female homeless veterans represent approximately 9% of the homeless veteran population ([Box 26-7](#); [USDHUD, 2017c](#)).
- Homelessness among veterans declined 45% from 2009 to 2017 ([USDHUD, 2017b](#)).
- In 2009, the U.S. Department of Veterans Affairs established a goal to end homelessness among veterans by 2015.

## BOX 26-7 PERSPECTIVES

### **A Homeless Female Veteran's Viewpoint**

I am a female veteran, recently discharged from active duty service during which I was deployed to Iraq. I am now homeless. I am one of thousands of veterans who sleep on the streets of America every night. I did not know that I was at risk for homelessness when I joined the military; in fact, I thought a military career or enlistment would help me be successful in life. I did not know that women veterans are three to four times more likely to become homeless than nonveteran women. Or, that posttraumatic stress disorder (PTSD) is twice as likely to be diagnosed in women as in men. Considering that 14% of all deployed military personnel to Iraq and

Afghanistan are women, I guess I should have known this was a possibility for me. But I was not prepared for what happened to me.

I am also a victim of sexual trauma, which is a trigger for PTSD, and this has profoundly impacted my ability to return to a normal life as a veteran.

Now, I never feel safe and I am not able to trust anyone or anything. I know you look at me and wonder why I am in this position. I am sure that you don't understand why I do not seem to be able to change my situation. Believe me, I have tried.

1. *What resources are available in the community for homeless female veterans?*
2. *Are there barriers to accessing these resources for certain veterans?*
3. *What are some of the common assumptions and stereotypes circulating in your community about homeless veterans?*
4. *What would you want to include in your assessment in order to identify risks and to implement treatment planning for homeless veterans like Sarah?*

Sarah, a veteran

The U.S. Department of Veterans Affairs administers programs that provide long-term care, emergency shelter, 2-year transitional housing, group homes, and work therapy for homeless veterans. These programs provide case management, residential treatment, and other services to homeless veterans and improve housing, employment, and access to care for the homeless veteran population. Unfortunately, the programs are often unable to keep pace with existing needs ([NCH, 2019a](#); [National Coalition for Homeless Veterans, n.d.](#)).

### *The Rural Homeless*

Because there are fewer shelters in rural areas, homeless persons living in rural areas are less likely to live in shelters or in the streets and more likely to live in cars, substandard housing, or “doubled up” with friends and family. As a result, they may not be considered “homeless” for reporting purposes. Moreover, the communities in which they live may not be able to access as much federal funding, because the statistics do not adequately reflect the magnitude of the problem.

Families with single mothers and children compose the largest segment of the rural homeless population. Native Americans and migrant workers are more likely to be among the rural homeless.

Like urban homelessness, rural homelessness is largely a result of poverty and lack of affordable housing. Although housing costs are lower in rural areas, incomes are also lower (HAC, 2016; 2017; National Advisory Committee on Rural Health and Human Services, 2014). Homelessness in rural areas may be precipitated by structural or physical housing problems that force families to relocate to safer but more expensive housing (Fig. 26-9). In addition, the lack of job opportunities, the distance between low-income housing and job sites, the lack of transportation, rising rents, geographic isolation, and the lack of resources compound the problem. To address the needs of the rural homeless, the definition of homelessness needs to be expanded to include people living in temporary or substandard housing (HAC, 2016, 2017; National Advisory Committee on Rural Health and Human Services, 2014).

**FIGURE 26-9** Rural housing may be structurally unsound or substandard.

### *The Older Homeless*

- Only 4.7% of sheltered homeless individuals were 62 years or older in 2016 (USDHUD, 2017c).
- Even so, as the population ages, many more adults are aging into poverty (Goldberg, Lang, & Barrington, 2016).
- Although the percentage of older individuals in shelters is low, it has increased from 2.9% in 2007 to 4.7% in 2016 (USDHUD, 2017c).
- The percentage of individuals aged 51 to 61 years who are housed in shelters also increased from nearly 14% in 2007 to nearly 18% in 2016 (USDHUD, 2017c).
- Some researchers define the “older homeless” as homeless persons 50 years or older because of the declining physical health that accompanies

street living (NCH, 2012b).

Many older people live on a fixed income. At the same time, housing has become increasingly more unaffordable. Moreover, the cost of health care continues to rise, leaving older adults at higher risk of poverty. Their restricted income renders them more vulnerable to unexpected financial crisis and even homelessness. The Social Security benefits to which many are entitled are inadequate to cover housing costs. Moreover, the waiting list for affordable housing for seniors is often 3 to 5 years (Goldberg et al., 2016; NCH, 2018b). Isolation also contributes to homelessness. Many older people live alone and lack a support network.

Homeless adults 50 years and older have health issues similar to those of housed adults who are 15 to 20 years older. Homeless older adults, compared with the general population, are more likely to experience difficulty in activities of daily living at a younger age. Shelter conditions, such as the use of bunk beds and shared bathing facilities, can also increase the risk of falls and injury.

### *Lesbian, Gay, Bisexual, and Transgender Homeless*

Lesbian, gay, bisexual, transgender, and questioning (LGBTQ) persons often experience difficulty finding shelters that accept them. They are sometimes required to identify themselves as a particular gender. Transgender individuals may be turned away from shelters or subjected to physical, sexual, or verbal abuse. They are more likely to be victims of violence, abuse, and exploitation than their gender-conforming peers (NCH, 2018e).

Transgender youth account for 2% of the unaccompanied homeless youth population (USDHUD, 2017b). LGBTQ youth have a 120% increased risk of becoming homeless compared with youth who identify as heterosexual or cisgender (Morton et al., 2017).

# HEALTH CARE AND THE HOMELESS

Acute and chronic health problems are prevalent among the homeless population, and they contribute to and result from homelessness. Conditions such as HIV/AIDS, diabetes, and heart disease are three to six times more prevalent in the homeless population than among the general population ([NAEH, 2020d](#)). Chronic health conditions require ongoing monitoring and are often difficult to treat in a population that is transient and lacks stable housing ([NCH, 2018d](#); [NHCHC, 2019](#)).

Persons with HIV/AIDS are at higher risk of homelessness, because HIV-related illness can impact job stability. Moreover, health care costs associated with treating the illness can exact an enormous financial burden on a low-income family. Insufficient funds to adequately house the poor with HIV/AIDS may also contribute to homelessness among HIV-infected individuals. Substance abuse and sexual exploitation among the homeless increases the risk of HIV infection. Moreover, it is difficult to maintain adherence to complex HIV/AIDS medication regimens without access to good food, bathrooms, refrigeration, and clean water ([Aidala, et al., 2016](#); [NCH, 2012a](#)).

Poverty, substance abuse, poor nutrition, and coexisting medical and psychiatric illnesses also predispose the homeless to severe oral health problems. Persons with poor access to dental treatment and preventive services have higher rates of oral disease. Poor oral health is also associated with lower levels of education and income ([United States Department of Health and Human Services, 2019](#)).

It is difficult for the homeless to adhere to complex treatment regimens. For example, where would a homeless person find a refrigerator to store insulin? Where would someone keep supplies for dressings? How could someone with no access to transportation keep regular appointments with health care providers? How does a homeless person keep track of multiple appointment dates? How is a shelter resident who receives the typical shelter diet high in carbohydrates, fats, and sodium to adhere to a low-salt or diabetic diet?

“Health Care for the Homeless” was a model for homeless health care developed through a 19-city demonstration project funded by the Robert Wood Johnson Foundation and the Pew Memorial Trust. In 1987, federal legislation (the McKinney-Vento Homeless Assistance Act) was passed that authorized federal funding for these programs. Grants are awarded to

community-based organizations that deliver high-quality health care to homeless populations. Health Care for the Homeless projects exist across the nation to provide comprehensive primary care and supportive services, including substance abuse treatment, to medically underserved populations (Box 26-8; NHCHC, 2018).

## **BOX 26-8 Evidence-Based Practice**

### **Impact of Cell Phone Use on Coping and Social Connectedness Among Homeless Youth**

Tyler and Schmitz (2017) examined the impact of cell phone data collection use on maintaining social connectedness and informational awareness among homeless youth in two mid-western cities in the United States. Participants completed a baseline interview and were then given a disposable cell phone that was activated for 28 to 30 days. Text questions were sent to them from an automated system. Participants were asked to respond to the text questions (11 texts per day) and received cash and/or gift cards for their participation.

A follow-up in person interview was used to assess benefits and cell phone usage patterns. Data revealed that the youth reported using the study phones to seek employment and housing and to schedule appointments. The phones also served as a source of comfort for them, as they had a lifeline for communicating with others in the event of an emergency. The cell phones also enhanced the participants' feelings of independence and autonomy and promoted a greater sense of emotional and social connectedness. The researchers concluded that cell phone ownership among homeless youth can promote positive mental health, improve coping skills, strengthen social support systems, and promote access to vital resources.

1. *What creative outreach approaches might the community health nurse (CHN) develop to improve coping skills, enhance communication and connectedness, and promote greater access to resources for the homeless?*
2. *What new technologies or communication devices might be used to enhance outreach efforts?*
3. *How can creative approaches be used to improve, not only health care delivery, but the delivery of other supportive services?*
4. *How might the CHN use research evidence to make a case for funding technologies that enhance communication and service delivery in the homeless population?*

Source: Tyler and Schmitz (2017).

# **RESOURCES TO COMBAT HOMELESSNESS**

Both public and private sectors have promoted a variety of initiatives to address the problem of homelessness. These initiatives are intended to impact homelessness on the local, state, and national levels and to ensure a coordinated, comprehensive, and systematic approach to addressing the problem of homelessness.

## Public Sector

The McKinney-Vento Homeless Assistance Act (PL100-77) was the first and only major piece of federal legislation intended to address the problem of homelessness on a national level. This landmark legislation Act, passed by Congress in 1987, originally consisted of 15 programs to address the major, pressing needs of the homeless. These needs included emergency shelter, transitional and permanent housing, job training, primary health care, education, and housing (NCH, 2006; NLIHC, 2019).

The current Act has been amended over the years to expand its scope and strengthen its impact. In particular, the amendments made to the Act in 1990 represented significant milestones in advocating for the needs of the homeless. These amendments included the creation of the Shelter Care Plus program, which provided for housing assistance for persons with disabilities, mental illness, AIDS, and drug and alcohol addiction. Another amendment created a demonstration program within the Health Care for the Homeless program to provide primary care and outreach to at-risk and homeless children. In addition, the Community Mental Health Services Program was amended and retitled: the Projects for Assistance in Transition from Homelessness.

Finally, the amendments made in 1990 strengthened access to public education for homeless children and youth. The McKinney-Vento Act authorized the U.S. Department of Education to administer the Education for Homeless Children and Youth program, which provides grants to schools to assist in identifying children who are homeless and to provide services to help them succeed in school (NLIHC, 2019). States are required to provide grant funding to local educational institutions to insure access to a free, appropriate education for homeless youth and children (NCH, 2006; NLIHC, 2019).

Over the years, Congress has appropriated funding to enable implementation of this federal legislation. The extent of federal funding has fluctuated over the years. Moreover, rising rental housing costs limit the impact of these limited resources. Although homeless advocates acknowledge that the Act was an important step in addressing homelessness, the lack of adequate funding over recent years threatens its impact on a national level (NLIHC, 2019).

The USDHUD oversees a number of programs established in the McKinney-Vento Act that provide rental, homeownership, and supportive housing for older, low-income, and disabled persons. The Department also manages grants for community development initiatives and helps to strengthen the housing market (NLIHC, 2019).

In many communities, this housing assistance is based on a **continuum of care** model, in which programs are developed to assist persons to transition from emergency to transitional to permanent housing. Emergency shelters provide temporary overnight shelter, whereas transitional housing provides up to 24 months of housing and supportive services. Rapid rehousing programs provide short-term rental assistance and supportive services, whereas permanent housing provides long-term housing and supportive services (NAEH, 2020h).

In recent years, a **Housing First** philosophy has guided much of the publicly funded housing initiatives. In a Housing First approach, housing is viewed as an immediate priority. The goal of Housing First is to end homelessness by providing stable, permanent housing as soon as possible and to provide supportive services to enable people to maintain their housing. Housing or supportive services are not contingent upon adherence to rigid rules or policies or to the maintenance of sobriety (NAEH, 2020h). See Box 26-2 on tent cities and successful approaches to Housing First.

The Homeless Emergency Assistance and Rapid Transition to Housing (HEARTH) Act of 2009 increased funding for McKinney-Vento programs that provide emergency, transitional, and permanent housing and supportive services to the homeless and resources to local school districts to coordinate services for homeless children (NCFH, 2014). The HEARTH Act also consolidated homeless programs at USDHUD and made the homeless assistance system more performance based (NLIHC, 2019).

On March 23, 2010, President Barak Obama signed into law the Affordable Care Act, federal legislation that extends health insurance coverage and gives states the option to expand Medicaid coverage to low-income individuals regardless of disability or family status. This landmark legislation enabled homeless individuals in many states to secure health care coverage (NAEH, 2020g). See Chapter 6.

Another significant milestone in federal initiatives to reduce homelessness occurred in 2001 when the federal government adopted the goal of ending chronic homelessness in 10 years. To meet this goal, annual funding was appropriated to create new permanent supportive housing. These resources helped to stimulate the production of housing. Many communities followed the lead of the federal government and developed their own 10-year plans (Burt, 2006; McEvers, 2016).

In 2010, the U.S. Interagency Council on Homelessness published the nation's first comprehensive federal strategic plan to prevent and end homelessness. The document, entitled "Opening Doors," outlined a comprehensive and ambitious plan aimed at eliminating homelessness on a national level. The goals of the plan included ending chronic homelessness in 10 years, preventing and ending homelessness for families, youth, and

children in 10 years, preventing and ending homelessness among veterans in 5 years, and establishing a path to end all types of homelessness (USICH, 2015). This plan was updated and amended in 2012 and 2015. Progress reports on the plan attest to the effectiveness of this federal, coordinated initiative in reducing homelessness across the nation (USICH, 2017). Table 26-1 summarizes the nine titles of the McKinney-Vento Act. Table 26-2 presents selected federally sponsored programs for addressing the needs of the homeless.

**TABLE 26-1 McKinney-Vento Homeless Assistance Act Titles I to IX**

Title I	Statement of findings by Congress and definition of homelessness
Title II	Establishes the Interagency Council on Homelessness, a council composed of 15 heads of federal agencies to address the needs of homeless populations
Title III	Authorizes the Emergency Food and Shelter Program, administered by the Federal Emergency Management Agency (FEMA)
Title IV	Authorizes the emergency shelter and transitional housing programs administered by the Department of Housing and Urban Development (HUD) including the Emergency Shelter Grant Program, the Supportive Housing Demonstration Program, Supplemental Assistance for Facilities to Assist the Homeless, and Section 8 Single Room Occupancy Moderate Rehabilitation
Title V	Requires federal agencies to make available federal land and buildings for states and local governments to use to assist the homeless
Title VI	Authorizes programs to provide health care services to the homeless, including Health Care for the Homeless program, Community Mental Health Services Block Grant Program, and two demonstration programs providing substance abuse and mental health treatment services to the homeless
Title VII	Authorizes the Adult Education for the Homeless Program, the Education of Homeless Children and Youth Program (administered by the Department of Education), the Job Training for the Homeless Demonstration Program (administered by the Department of Labor), and the Emergency Community Services Homeless Grant Program (administered by the Department of Health and Human Services)
Title VIII	Amends the Food Stamp Program to facilitate access by the homeless and expands the Temporary Emergency Food Assistance Program (administered by the Department of Agriculture)
Title IX	Extends the Veterans Job Training Act

Source: National Association for Education of Homeless and Youth (2018); National Coalition for the Homeless (2006).

**TABLE 26-2 Federally Sponsored Programs for the Homeless**

Program	Description
The U.S. Interagency Council on Homelessness	The United States Interagency Council on Homelessness coordinates the federal response to homelessness and creates a national partnership with public and private sectors to reduce and end homelessness in the United States. The Council is responsible for reviewing the effectiveness of federal initiatives and programs to assist the homeless, promoting better coordination of services between programs, and informing state and local governments and private sector organizations about sources of federal homeless assistance ( <a href="http://www.usich.gov">www.usich.gov</a> ).
Substance Abuse and Mental Health Services Administration Center for Mental Health Services	The Center for Mental Health Services, a center of the federal Substance Abuse and Mental Health Services Administration (SAMHSA), supports states in facilitating access to mental health services and supports outreach and case management for the homeless mentally ill (SAMHSA, 2019). The Center for Mental Health Services also operates the Homelessness Resource Center, which provides resource information and information on the latest research and best practices for addressing the problem of homelessness (SAMHSA, n.d.a, n.d.b).
Projects for Assistance in Transition from Homelessness (PATH)	PATH is a SAMHSA grant program created under the McKinney Act to provide treatment and supportive services to persons with severe mental illnesses, including those who are homeless or at risk of becoming homeless. The grants support outreach, mental health and substance abuse treatment, and rehabilitation for the severely mentally ill (SAMHSA, 2017a, 2017b).
Health Care for the Homeless (HCH)	The HCH program (a provision of the McKinney Act) awards grants to community-based organizations that seek to provide quality, accessible health care to the homeless. The HCH program is administered by the United States Department of Health and Human Services Health Resource and Service Administration Bureau of Primary Care. HCH projects provide comprehensive primary care and supportive services to low-income populations in medically underserved communities (NHCHC, 2018).
The U.S. Department of Housing and Urban Development (HUD)	HUD provides funding for supportive housing for low-income individuals and families, including low-income elderly and disabled. Funds can be used for housing development or rental assistance. Grants are also provided to public housing agencies to renovate or replace dilapidated public housing. ( <a href="http://www.hud.gov">www.hud.gov</a> )

Source: NHCHC (2018); SAMHSA (n.d.a, n.d.b, 2016, 2017a, 2017b).

## Private Sector

The private sector has made a concerted effort to organize communities in the battle against homelessness by forming coalitions, alliances, and memberships that champion the causes of the homeless. These organized efforts are carried out at the national, state, and local levels to positively impact the problem of homelessness in communities across the nation. [Table 26-3](#) presents a list and descriptions of selected resources in the private sector to combat homelessness.

**TABLE 26-3 Private Sector Initiatives to Combat Homelessness**

Initiative	Description
National Coalition for the Homeless (NCH)	The National Coalition for the Homeless is the nation's oldest advocacy and direct service organization for the homeless. The mission of the Coalition is to prevent and end homelessness while ensuring the immediate needs of the homeless are met and their civil rights protected. ( <a href="http://nationalhomeless.org">http://nationalhomeless.org</a> )
The National Center on Family Homelessness (NCFH)	The National Center on Family Homelessness seeks to prevent and end family homelessness by advancing knowledge gained from research, programs, trainings, and collaborations with homeless shelter and service providers. The organization seeks to raise awareness of the causes and effects of homelessness and to inform local, state, and national solutions for the problem of homelessness. See <a href="http://www.familyhomelessness.org">http://www.familyhomelessness.org</a> .
National Coalition for Homeless Veterans	The National Coalition for Homeless Veterans is a 501(c)(3) nonprofit organization that provides resource and technical assistance to service providers and local, state, and federal agencies that provide assistance to homeless veterans. The Coalition advocates for the needs of homeless veterans and for increased funding for federal homeless veteran assistance programs. See <a href="http://www.nchv.org">http://www.nchv.org</a> .
National Alliance to End Homelessness (NAEH)	The National Alliance to End Homelessness seeks to end homelessness by advocating for policies that promote solutions to homelessness, providing technical assistance to local communities, and advancing data and research on best practices and solutions for combating homelessness. See <a href="http://www.endhomelessness.org">http://www.endhomelessness.org</a> .
Commission on Homelessness and Poverty, American Bar Association	This Commission is committed to educating the public and the legal community about the issue of poverty and homelessness and trains members of the legal community on how best to advocate for those in need. The Commission also advocates for public policies that protect and provide for the needs of the poor and homeless. See <a href="http://www.americanbar.org/groups/public_services/homelessness_poverty/about_us.html">http://www.americanbar.org/groups/public_services/homelessness_poverty/about_us.html</a> .
National Low-Income Housing Coalition	The National Low-Income Housing Coalition is dedicated to establishing housing stability and expanding the supply of low-income housing in America. A major priority of the coalition is to promote public policy that provides funding for housing for extremely low-income people. See <a href="http://www.nlihc.org">http://www.nlihc.org</a> .

# ROLE OF THE C/PHN

C/PHNs maintain a long tradition of providing care to vulnerable populations and play a vital role in addressing the health needs of the homeless. Settings for care include shelters, clinics, soup kitchens, churches, community centers, social service agencies, and even the streets.

Trust is an essential ingredient in the development of a therapeutic relationship with the homeless. However, it is sometimes difficult to establish trust with clients who have experienced negative encounters with the health care system. Often these negative perceptions are intensified by limited resources, inadequate access to care, or prejudicial views. As with other vulnerable populations, the homeless struggle with feelings of powerlessness, loss of control, and low self-esteem.

This lack of trust and self-esteem among the homeless often comes from experiencing disproportionately harsh consequences for violating the law. Behaviors that would ordinarily be considered lawful in the privacy of one's home become criminal activity when they are exhibited in public. For example, the homeless can be arrested for loitering, sleeping, urinating, or drinking alcohol in public. These behaviors can trigger a criminal record, thereby jeopardizing future employment or housing opportunities. Moreover, parents can be incarcerated for failing to pay child support ([National Conference of State Legislators, 2018](#)). Consider a man who is laid off from a low-wage job. He is unable to pay child support and is arrested. His violation generates a criminal record and compromises his ability to secure employment in the future. He becomes trapped in a cycle of poverty and homelessness that is difficult to escape.

To effectively address the multifaceted problems associated with homelessness, a comprehensive and holistic approach is needed ([Boxes 26-9, 26-10, 26-11](#)). As such, the CHN is responsible for implementing primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services ([Box 26-12](#)).

## **BOX 26-9 QSEN: Focus on Quality**

### **Quality Improvement for Homeless Populations**

**Quality Improvement:** Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems ([Cronenwett et al., 2007](#), p. 123).

(See [https://qsen.org/competencies/pre-licensure-ksas/#quality\\_improvement](https://qsen.org/competencies/pre-licensure-ksas/#quality_improvement) for the definition and knowledge, skills, and attitudes associated with this QSEN competency.)

It is likely that you evaluate the quality of the care given to your patients in the acute care setting every day you are in a patient care environment. Biomarkers such as improvements in blood pressure and hemoglobin A1C levels, reduction in pain, or changes in function such as improvement in activities of daily living may serve as indicators of success when measuring the effectiveness of one's nursing interventions. But how is success measured when one is caring for large and diverse population groups such as the homeless?

To measure change in this context, one must first define what is meant by “success.” For example, what are the markers for success when working with a population of homeless teen mothers? What about a population of homeless men with decade long histories of active addiction? Literature reviews, surveys, or focus groups may help point to measures of success. Interviews with key stakeholders also provide insight as to the most important measures for evaluating program effectiveness in a population.

Lashley (2018) examined the impact of length of stay among homeless men in recovery from chemical addiction in a faith-based recovery program on four quality of life indicators. A time series design was used to measure changes at program admission and at 3-, 6-, and 9-month intervals. Nicotine dependence, self-esteem, depression, and physical activity were evaluated at distinct times throughout the 1-year program to determine whether length of stay in the program impacted these measures. Each variable was measured using standardized instruments. The researcher found that self-esteem, depression, and physical activity all improved over time. Nicotine dependence scores also declined but not at a rate that was statistically significant. The author concluded that time spent in this recovery program had a significant impact on three of the four quality of life indicators.

1. *What outcomes do you believe are most important to track when caring for homeless populations?*
2. *How might you engage a target population to actively participate in the evaluation process?*

Source: Cronenwett *et al.* (2007); Lashley (2018).

## **BOX 26-10 What Do *You* Think?**

## Reflecting on Personal Beliefs and Values About Homelessness

Every nurse encounters new situations with prior assumptions, biases, and preunderstandings. When considering work with the homeless, it is important to clarify one's own beliefs and values about poverty, homelessness, addictions, and mental disorders.

1. *What has been your experience with the homeless?*
2. *Have you ever observed a homeless individual asking for money or holding up signs at a busy intersection?*
3. *What thoughts and feelings do encounters such as these provoke?*

It may be helpful to interview people who work with the homeless or to visit clinics, shelters, or other settings where the homeless congregate or access services.

1. *How are homeless people treated?*
2. *What is a typical day like for someone who is homeless?*
3. *How often do homeless persons hear their names?*
4. *How often are they touched in a way that is therapeutic, respectful, and affirming?*

By reflecting on your personal values and by allowing yourself to get closer to the people and places that are a part of the experience of homelessness, you will gain a deeper understanding of the homeless condition and be better equipped to serve those suffering from homelessness.

### BOX 26-11 PERSPECTIVES

#### A Nurse's Viewpoint on Working With the Homeless

When I first decided to visit the homeless men's shelter, I was scared to death. Here I was, a veteran nurse with over 20 years of experience, but I was afraid. But, I thought to myself—afraid of what? I couldn't tell you. I

suppose I harbored the stereotypes that most of us associate with homeless addicts. I remember passing this shelter years ago, looking out at the men hanging out on the street corner, and thinking to myself “Please God, don't let my car break down!” I remember thinking, “I would never step foot in a place like that.”

Well, I believe God has a sense of humor. He was equipping me for work I could not have ever imagined. My views about homelessness were challenged to the core when I peered into the faces of those men, heard their stories, and began to feel their pain. Theirs were stories of broken lives and lost hope but also of courage in the face of suffering and the will to survive in the midst of great adversity. These men were as diverse as their stories. They were from all walks of life. They possessed incredible gifts and talents. They were musicians, artisans, businessmen, writers, and poets.

So here I am. Doing what I can to bring hope and healing. The irony is I came to bring hope and yet I am the one who is being healed. Healed in the broken areas of my life. I am so grateful to God for giving me this unique opportunity. It is a great privilege to serve these men.

Rita, C/PHN

## **BOX 26-12 C/PHN USE OF THE NURSING PROCESS**

### **An On-Site Nursing Clinic for Homeless Women and Children**

Sheila Hendricks, a public health nurse for the Manchester City Health Department, and her colleagues were brainstorming ideas for how to reach the growing population of homeless women and children in their jurisdiction. They arranged a meeting with the director of a local rescue mission in the area. The mission provided emergency shelter to 100 homeless women and children each night. The community health nurses negotiated with the rescue mission to establish an on-site nursing clinic twice a week that would provide health education, screenings, and referrals on a drop-in basis.

#### **Assessment**

After the clinic was in operation for 2 weeks, Sheila identified poor nutrition, lack of primary care services, depression, high rates of sexually transmitted infections, and addictions as priority health issues in the population.

## **Plan**

Problem statement (in order of priority):

- Client does not have access to health and social services due to transportation, no insurance and community resources.
- Family difficulties with coping from addiction, mental health, intimate partner violence, and hazards associated with street living.
- Client has not meet nutritional requirements due to addiction, chronic health issues, and limited resources for nutritional foods.

**GOAL:** To promote access to care by linking clients to essential health and social services

**RATIONALE:** If clients are able to access needed services, the other diagnoses can potentially be addressed (i.e., need for counseling, health care, housing, education).

## **Implementation**

- Primary care services provided by nurse practitioner at the shelter
- HCH Clinic referrals made for more extensive follow-up
- Social worker engaged to assist clients in applying for housing and public assistance
- Referrals to local community mental health center for counseling
- Nurse-led health education and counseling sessions and on-site screenings with referrals to health department clinic as needed

## **Evaluation**

90 days after the clinic had been in operation:

- 65 women and 28 children had frequented the clinic over the past 3 months. All 65 women received health promotion teaching and a resource packet for further reference.
- 80% of clients who required referrals to outside agencies were successful in accessing care.
- 25 women and 15 children were under the care of the nurse practitioner for acute or chronic health conditions.
- 10 cases of latent tuberculosis (TB) infection identified through TB testing with referrals to the City Health Department TB clinic for follow-up treatment.
- 7 abnormal PAP smears identified, and 8 clients diagnosed with sexually transmitted infections.
- 15 clients diagnosed HIV positive. 15 referrals to City Health Department or the local Health Care for the Homeless Clinic for

treatment.

- 40 women applied for social service benefits. Awaiting receipt of benefits.

## Primary Prevention

Primary prevention includes advocating for affordable housing, employment opportunities, and better access to health care to prevent the downward spiral into homelessness. Strategies for preventing homelessness may include financial counseling to assist clients to better manage their money, assistance in locating sources of legal or financial aid to prevent eviction (i.e., loans or grants for emergency funds to help pay for rent, utilities), or assistance in accessing social services, temporary housing, or health care to avoid a housing, health, or family crisis ([Anderson & McFarlane, 2018](#)).

Health education that addresses primary prevention may focus on positive parenting skills, violence prevention, anger management, coping skills, healthy eating, or principles of basic hygiene. Immunization programs can help to prevent communicable disease in this high-risk population. Counseling victims of intimate partner violence and helping them to locate safe shelter can also aid in the prevention of homelessness ([Anderson & McFarlane, 2018](#)). Addiction treatment is also important to prevent the likely consequences of untreated addiction: death, incarceration, institutionalization, or homelessness.

## Secondary Prevention

The focus of secondary prevention measures is on the early detection and treatment of adverse health conditions. This requires a thorough assessment of client needs, including the need for housing, health care, education, social services, and employment (Box 26-13). Clients also benefit from secondary prevention measures such as screening for communicable and chronic diseases (i.e., hepatitis, tuberculosis, sexually transmitted infection, HIV, hypertension, diabetes, cancer).

### BOX 26-13 PERSPECTIVES

#### A C/PHN's Holistic Approach to Homelessness

I got a referral from our communicable disease coordinator regarding a homeless client with a lesion on his lower leg (wound botulism). I quickly learned that he had a long history of drug abuse, suicide attempts (13 known), and repeated hospitalizations for this wound. He was discharged from the hospital each time because he had no insurance, and he was also misdiagnosed.

I finally located him living on a friend's property in a disheveled travel trailer with a leaky roof and broken windows. It was a rainy week; during the winter months, and he and his small dog were trying to keep warm and dry. He used the oven for heat and a nearby field as his bathroom. His only relatives lived out of state, and he dumpster dived for food. He ate food from expired cans, when he could find them. He knew about the local food lunch program and health care at our county clinic, but he was seldom able to utilize these services, because of lack of transportation and difficulties with ambulation related to his leg wound.

As a C/PHN, your view of the patient is holistic and goes beyond the diagnosis. My C/PHN partner and I did the following:

- Reviewed his wound care.
- Assisted him in getting his medication, with money from the local Coordinating Council and Ministerial Association.
- Referred his case to two churches who provided him with assistance from their food pantries and a Pizza Hut gift card for his birthday (to

cheer him up).

- Obtained tarps for his trailer, and a sleeping bag from a local service group.
- Assisted him with a disability application.
- Connected him to a mobile mental health unit and; updated his immunizations.
- We arranged for transport to another hospital for treatment, as the patient refused to go back to the original hospital that had misdiagnosed him and kept discharging him.

I remember that, after I graduated with my BSN, someone asked me why I was leaving the recovery room to go into public health nursing. At that time, I told the person “I didn't want my varicose veins popping out of my support hose before I retired.” But, I love public health nursing and am so glad that I made this choice. And, as I am planning my retirement, I can truly say, “It's been quite a ride”!

Susan, a District C/PHN

Barriers to accessing services and the extent of community resources available to the homeless also need to be assessed ([Anderson & McFarlane, 2018](#)). Resources such as shelters, soup kitchens, medical clinics, social service agencies, and supportive housing should be readily accessible to the homeless population. Providers servicing homeless populations should be educated in **trauma-informed care**, a homeless service delivery model that recognizes the traumatic experiences associated with homelessness and the traumatic events that led to living on the streets. Strength-based interventions and skill building are used to assist homeless clients in regaining control of their lives ([Davies & Allen, 2017](#)).

Lack of transportation can be a major barrier to accessing care. Some programs have responded to this need by adopting mobile health vans that provide care on street corners and in neighborhoods ([Yu, Hill, Ricks, Bennett & Oriol, 2017](#)). Clinics have also been established in shelters to facilitate client access ([Chatterjee et al., 2017](#)). These clinics are often managed by nurses. Nurse-run community-based clinics are an effective means of promoting optimum care among disenfranchised populations ([Randall, Crawford, Currie, River & Betihavas, 2017](#)). Nursing students also play an important role in promoting access to care for the homeless.

The CHN should also consider the role of faith-based communities in providing physical and spiritual support to the homeless. Many places of worship have responded to the crisis of homelessness by offering food, shelter, counseling, medical care, and social services within the context of

the faith community. Clinics have been built within faith communities to promote access to care (Box 26-14).

## **BOX 26-14 STORIES FROM THE FIELD**

### **Faith-Based Outreach**

As a faith community nurse working in a large church congregation, you are invited to develop an outreach program to minister to the needs of an inner-city mission that is receiving financial support from the church. Approximately 500 homeless men in recovery from chemical addictions frequent the mission daily. Staff and residents have expressed concerns regarding a recent outbreak of boils among residents.

Assessment data reveal the following issues:

- Approximately 80% of clients have a history of injection drug use.
- Clients sleep in dormitory-style accommodations and share bathroom facilities.
- An on-site barbershop operated by the residents provides haircuts for a nominal fee.
- Clients have access to a small recreational area with donated exercise equipment.
- Laundry is typically washed in cold water, and at times the laundry runs out of detergent.

Consider the following questions:

1. *What additional data would you wish to gather to address the outbreak of boils at the shelter? How would you collect these data?*
2. *What host, agent, and environmental factors may have contributed to the outbreak of boils?*
3. *Discuss appropriate nursing interventions to address the outbreak. Consider the following levels of prevention: primary, secondary, and tertiary.*
4. *What advocacy role might the community health nurse play in addressing this issue?*

## **Tertiary Prevention**

Tertiary preventive measures attempt to limit disability and to restore maximum functioning. The goal is to provide rehabilitative care and support to clients who are already experiencing the consequences of homelessness. Often, homeless individuals have chronic health conditions that have gone untreated for long periods of time. This neglect in attending to health needs results in significant disease morbidity. Treating complications of advanced disease, providing rehabilitative and respite care, and offering counseling and support are important tertiary preventive strategies.

## **Case Management**

At each level of prevention, the C/PHN functions as a case manager and coordinator of care to ensure seamless delivery of services as people transition from one level of care to another. It is often difficult for the homeless to keep track of multiple appointments, negotiate the bureaucracy of multiple agencies and services, and maintain communication with providers through follow-up phone calls, letters, or visits. With no permanent address or phone, homeless clients encounter obstacles to adhering to recommendations to follow up on test results or to notify their provider if symptoms persist or worsen. The C/PHN can help to bridge these gaps in service delivery and promote more effective adherence to therapeutic regimens.

## Advocacy

Advocacy is a vital dimension of the C/PHN's role in working with the homeless. Advocacy entails working with different sectors of the community to develop innovative models for responding to the crisis of homelessness. Advocacy creates the broader system-wide changes needed to end homelessness (NCH, 2019e). The C/PHN acts as an advocate at each level of prevention to effect positive change (Box 26-15). For example, the nurse may advocate for mental health and substance abuse services to promote mental health and prevent homelessness (primary prevention). Alternatively, he or she may advocate for legislation to fund supportive housing, health care, or social services to benefit the homeless chronically mentally ill (tertiary prevention). The C/PHN can also assume an advocacy role by becoming involved in local, state, or national coalitions or organizations devoted to protecting the rights of the homeless or by speaking out on legislation that impacts the homeless (NCH, 2019e; NLIHC, 2019).

### **BOX 26-15 Levels Of Prevention Pyramid**

#### **Preventing Illness Among Homeless Male Addicts**

**SITUATION:** Promoting health and preventing illness among homeless male addicts

**GOAL:** To apply the three levels of prevention to avoid adverse health conditions, promptly diagnose and treat disorders, and assist the homeless male addict population to maintain or regain optimal health

##### **Tertiary Prevention**

- Provide case management of chronic health conditions.
- Advocate for expansion of counseling, rehabilitative services, and addictions treatment programs for the homeless.
- Advocate for supportive and transitional housing to enable homeless residents with addiction disorders to successfully transition back into the community.

##### **Secondary Prevention**

- Conduct mass screenings for diseases commonly found in homeless male population (tuberculosis, HIV, hepatitis, prostate cancer, colorectal cancer).

- Develop programs for health screening and early diagnosis and treatment in the community that are culturally sensitive and accessible to the homeless (i.e., mobile vans, faith community, or shelter-based clinics).

<b>Primary Prevention</b>	
<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>▪ Support employment and job training opportunities that assist clients to obtain jobs with livable wages and benefits.</li> <li>▪ Advocate through housing coalitions and legislative efforts to promote affordable housing, employment opportunities, and better access to health care.</li> <li>▪ Develop culturally sensitive health education programs that promote healthy coping, positive parenting, communication and relationship building, mental health, and injury and illness prevention.</li> <li>▪ Promote programs that offer counseling and support to prevent continued high-risk behaviors as a result of untreated addiction.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Advocate for legislation to protect citizens from environmental toxins and industrial wastes common to low-income areas.</li> <li>▪ Provide immunization services to prevent communicable disease transmission.</li> <li>▪ Counsel clients on proper nutrition, exercise, and basic hygiene to promote healthy lifestyles and prevent disease transmission</li> <li>▪ Advocate for funding for nutrition programs for the homeless and for homeless shelters that would allow for the purchase of nutritious foods.</li> </ul>

# SUMMARY

- A homeless person is one who lacks a fixed, regular, adequate nightly residence; this definition includes as homeless those who stay in supervised public or private shelters that provide temporary accommodations.
- Although accurately estimating the number of homeless in the United States is challenging, a count performed on one night in 2017 indicated that there were 553,742 sheltered and unsheltered homeless people across the nation.
- Poverty, a lack of affordable health care, low-income and low-benefit employment, domestic violence, mental illness, addictions, personal and financial crisis, natural disasters, immigrant and refugee status, and personal choice are factors that may predispose persons to homelessness.
- Each subpopulation within the homeless community faces its own unique challenges with homelessness, including men, women, children, youth, families, veterans, rural homeless, older persons, and LGTB persons.
- Acute and chronic health problems plague the homeless and are difficult to treat because of the challenges associated with being homeless.
- Both the public and private sectors have launched concerted efforts to combat the problem of homelessness through the passage of federal legislation and through the formation of national, state, and local coalitions and alliances to champion the cause of the homeless.
- The C/PHN delivers primary, secondary, and tertiary preventive measures to prevent homelessness or to assist those who are homeless to obtain needed services.
- The C/PHN serves as a case manager to coordinate care and to assist clients to negotiate the bureaucracy of multiple agencies and services.
- The C/PHN acts as an advocate to promote the rights of the homeless and to speak out on legislation impacting homelessness.

# ACTIVE LEARNING EXERCISES

1. Reflect in writing on the meaning of “home.” Share your reflections with classmates either face to face or online. How similar are your responses?
2. Interview a homeless person regarding the most difficult choices he or she has had to make. What were the conditions surrounding these choices?
3. Volunteer to work at a soup kitchen or homeless shelter. Observe carefully the faces, sounds, attitudes, and activities. What is it like there? What would it be like to receive rather than give service?
4. Using “Assess and Monitor Population Health” (1 of the 10 essential public health services; see [Box 2-2](#) ), analyze online census data to determine the rates of homelessness in your county, state, or region. How many people are homeless? What is the age and gender distribution? What policies exist to address the issue of homelessness in your community? Consider how you might address these issues in a letter or visit to your local city, county, or state legislator.
5. Perform a windshield survey in a low-income community. What resources are lacking? Where is the nearest bank, school, grocery store, or health clinic? What are the conditions of the roads, homes, and other buildings? How do you feel as you drive through the community? What do you think it would be like to live there?

# CHAPTER 27

## *Rural, Migrant, and Urban Communities*

“No city should be too large for a man to walk out of in a morning.”

—Cyril Connolly (1903–1974), British Critic

“Globalization is exposing new fault lines—between urban and rural communities, for example.”

—Ban Ki-moon, United Nations Secretary General

### KEY TERMS

Built environment

Critical access hospitals (CAHs) Federally qualified health centers Frontier area

Health professional shortage areas (HPSAs) In-migration

Medically underserved areas Medically underserved population Migrant farmworkers

Migrant streams

Nomadic migrant workers

Out-migration

Population density

Rural

Rural health clinics

Seasonal farmworkers

Sustainable communities

Urban

Urban health

Urbanized area

Urban planning

Urban sprawl

### LEARNING OBJECTIVES

Upon mastery of this chapter, you should be able to:

1. Define the terms *rural*, *frontier*, *migrant*, and *urban*.
2. Discuss the population characteristics of rural residents.
3. Describe five barriers to health care access for rural clients.
4. Describe the lifestyle of migrant farm workers and their families.

5. Identify at least three health problems common to migrant workers and their families.
6. Discuss barriers and challenges to migrant health care.
7. Identify common health disparities found among rural and urban populations.
8. Propose intervention strategies at the aggregate or community level to assure a healthier *built environment* in both rural and urban areas.
9. Explain the concept of *social justice* and how it relates to public health nursing in rural and urban areas.
10. Compare and contrast the challenges and opportunities related to rural and urban community health nursing practice.

# INTRODUCTION

As a community/public health nurse (C/PHN), I enjoyed making home visits to see Alison. She was quiet at first, but slowly she would open up about herself when she knew I was there to help her and not judge. Alison lived in a small duplex in a big city in California surrounded by dense housing, a busy street that never slept, and constant noise—babies crying, sirens, and people's voices. She was used to the noises now, but it wasn't always that way, she said. Over 60 years ago, Alison moved here as a young bride of 20; the city provided opportunity for her and her husband to find work and raise a family. Many young families had moved there from the country. It was full of people even then, though not nearly the population it was when I spoke with her. Alison and her husband Jim moved from one of the rural communities further south. They left their families to start their own with hopes and dreams. Alison sighed as she shared stories of her childhood, staring off into the distance as she remembered the time her sister almost died because the family had to drive 90 minutes to a hospital as none existed in their small community. Although Alison said she missed the slow pace of a small community, she stated she might not have advanced her education had she not had access to a college in the big city.

Alison's story illustrates how different rural and urban life can be. About half of the population live in what is known as the suburbs, but the remainder live in one of two diametrically opposed areas: rural or urban (Fig. 27-1). There is a good chance that many of you reading this book live either in very densely populated, bustling urban areas or in sparsely populated, somewhat isolated rural areas. Public health nursing in urban and rural areas requires not only general public health nursing knowledge and skills but also a unique understanding of how these distinctive environments affect the health of the populations living there. Where you live can and does markedly affect your health outcomes, with rural and urban areas having distinctive problems and issues.

**FIGURE 27-1** The Denver Tech Center skyline.

Rural nursing practice offers many opportunities. Nurses are respected community members—their judgment and opinions count. Rural nurses are key members of the health care team. They can make a difference in the lives of their neighbors, friends, and community. Rural C/PHNs often struggle with helping clients gain access to quality health care and the inherent transportation problems found in isolated areas. The challenges are many, but the rewards are great.

Urban C/PHNs often specialize in particular areas of interest. They deal with different types of problems, such as homelessness, overcrowding, bioterrorism threats, and violent crime. They are often called upon to advocate for their most vulnerable clients, and they develop collaborative relationships with other professionals. Urban community health nursing can also be very rewarding and satisfying.

An aggregate at risk, migrant workers suffer higher frequency of illness, greater complications, and more long-term debilitating effects. Exacerbated by a magnitude of environmental and work stressors, the health of migrant families is also compromised by limited access to health care, mobility, language and cultural barriers, low educational levels, and few economic and political resources. Because migrant health needs are largely manageable within community settings, C/PHNs are ideal health providers. C/PHNs must advocate for the health of migrant workers, who have very little economic or political power, and also guide them through the complexities of a changing health care system.

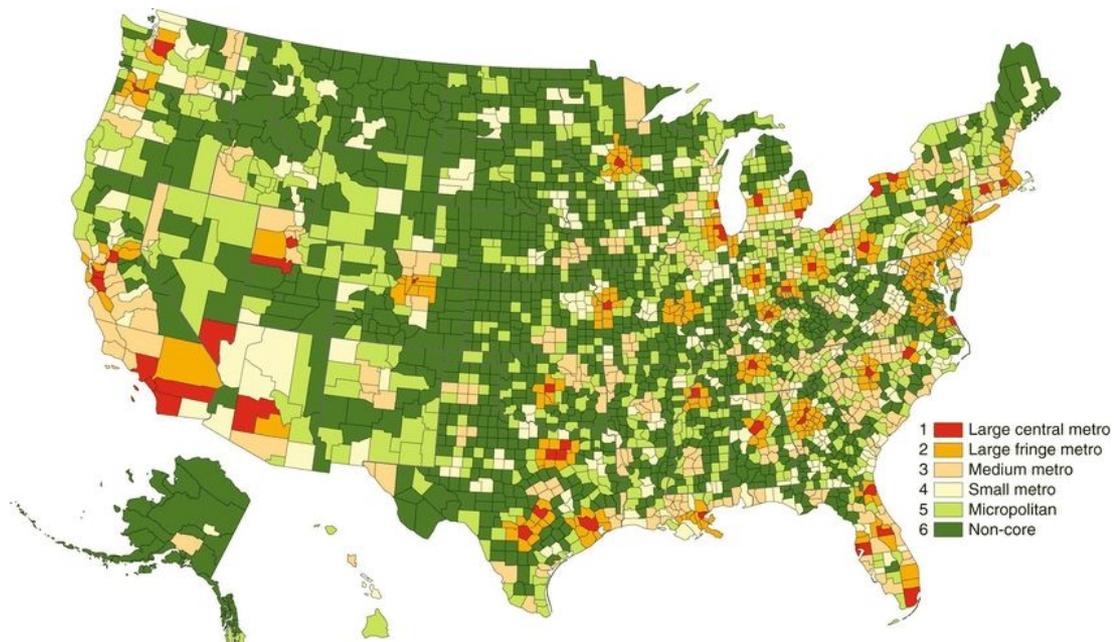

This chapter addresses the special health needs and concerns of rural, migrant, and urban clients and the ways in which a community health nurse can address those needs. After reading the chapter, you may come to appreciate the many advantages that rural nurses enjoy and consider rural nursing as a practice choice or you may find that being a C/PHN in an urban area offers you more opportunities for specialization and networking. Either

way, your contributions can improve the health of populations living at both extremes.

# DEFINITIONS AND DEMOGRAPHICS

## *Definitions*

The U.S. government provides several definitions of rural. It is important to understand the terms and how they are used in federal programs and grant funding. The [U.S. Department of Agriculture \(USDA\) \(2020\)](#) rural–urban continuum examines metropolitan and nonmetropolitan areas on the basis of counties, and this provides different data apart from census reports ([U.S. Census Bureau, 2016a](#)). Nonmetropolitan areas have some type of combination that includes “open countryside,” rural towns (<2,500 people), and **urban** areas (2,500 to 49,999 people; [Fig. 27-2](#)). State and federal agencies recognize county-level jurisdictions and governments and depend upon employment, income, and population data that are available on an annual basis. Many states have offices of rural health or other agencies dealing with issues specific to rural populations.

**FIGURE 27-2** 2013 urban–rural classification schemes for counties, 2017. (Reprinted from Centers for Disease Control and Prevention, National Center for Health Statistics. (2020). Retrieved from <https://www.cdc.gov/nchs/images/popbridge/URv3.png>)

- For the purposes of this chapter, **rural** is defined as *communities with fewer than 10,000 residents and a county population density of <1,000 persons per square mile*. This definition of rural is arbitrary because rural clients do not merely consider population density or community size when defining their *ruralness*.  
They have a multitude of reasons for defining their community as rural, such as distance from a large city, major occupations in the area (e.g., agriculture), or number of students in the local schools. If you have access to a small community, ask some of the residents the reasons why they consider their community to be urban or rural (USDA, 2019a; Fig. 27-3).
- The term **frontier area** is used to designate sparsely populated rural places that are isolated from population centers and services, but specific definitions vary (Rural Health Information Hub [RHIH], 2018a). A common definition of a “frontier and remote area” (FAR) is one with six or fewer persons per square mile, but others include not only population density but also distance and travel time to market service areas.  
For instance, 60 miles or 60 minutes of driving on paved roads to the nearest 75-bed (or greater) hospitals could constitute a frontier area. The USDA (2019b) has developed FAR codes, based upon urban–rural census data and delineated by ZIP codes.
- There are four levels of FAR codes; level one includes a good number of people living far from city areas where higher-level goods are available (e.g., regional airport hubs, stores with major household appliances, advanced medical care), whereas level four includes fewer people with a more significant level of remoteness (e.g., decreased access to stores selling gas or groceries, or basic medical care).
- The other two levels may also have access to movie theaters, car dealerships, and clothing stores. This is helpful to researchers and public health agencies in determining rural–urban status and designing programs to meet specific needs. Rural–urban commuting area (U.S. Census Bureau, 2019) is also used to designate remote areas (RHIH, 2020a).
- It is estimated that 3 million people (4% of population) live in frontier areas that comprise 56% of the U.S. land areas. States with more than 10% of their population in a frontier area include Idaho, Nebraska, Maine, Arkansas, Oklahoma, Alaska, Arizona, Montana, Wyoming, New Mexico, Colorado, North Dakota, and South Dakota (National Center for Frontier Communities, 2019).

**FIGURE 27-3** Change in rural and urban population size: 1910 to 2010. (Reprinted from U.S. Census Bureau. (2020). *Measuring America: Our changing landscape*. Retrieved from <https://www.census.gov/library/visualizations/2016/comm/acs-rural-urban.html>)

Health issues of concern in rural areas may be of even greater concern for frontier areas. Sparsely populated areas may be less able to attract health care professionals.

- The term **health professional shortage areas (HPSAs)** is used to identify urban or rural geographic areas, population groups, or facilities with chronic shortages of medical, dental, or mental health professionals. The federal government determines which areas are HPSAs. As of 2015, there were 15,557 in the United States. Over 59 million people live in areas that have been designated as HPSAs for primary care, representing about 60% of need met. Over 90.3 million live in mental health HPSAs, and 47.4 million are in areas with shortages of dentists ([Health Resources and Services Administration \[HRSA\], 2020](https://www.hrsa.gov/); see also <https://www.kff.org/other/state-indicator/primary-care-health-professional-shortage-areas-hpsas/?activeTab=map&currentTimeframe=0&selectedDistributions=total-primary-care-hpsa->

[designations&sortModel=%7B%22collId%22:%22Location%22,%22sort%22:%22asc%22%7D](#)).

- In **medically underserved areas**, residents experience a shortage of health services; these areas are determined by the federal government using a score based on the shortage of primary care physicians, high infant mortality rates, high percentage of the population living below the poverty level, and a high proportion of residents over age 65.
- A **medically underserved population** includes those with economic and cultural/linguistic barriers to primary health care services ([Fig. 27-3](#); [HRSA, 2020](#)).

## Population Statistics

The number of persons living in urban areas of the United States tripled since the mid-1800s, to almost 60 million in 2000, and grew 10.8% from 2000 to 2010 (Table 27-1). About 81% of the total population can be found in urban areas (U.S. Census, 2016b).

**TABLE 27-1 A National Rural Health Snapshot: Rural Versus Urban**

National Rural Health Snapshot	Rural	Urban
Percentage of population	19.3%	80.7%
Number of physicians per 10,000 people	13.1	31.2
Number of specialists per 100,000 people	30	263
Population aged 65 years and older	18%	12%
Average per capita income	\$45,482	\$53,657
Non-Hispanic White population	69%–82%	45%
Adults who describe health status as fair/poor	19.5%	15.6%
Adolescents who smoke	11%	5%
Male life expectancy in years	76.2	74.1
Female life expectancy	81.3	79.7
Percentage of dual-eligible Medicare beneficiaries	30%	70%
Medicare beneficiaries without drug coverage	43%	27%
Percentage covered by Medicaid	16%	13%

All information in this table is from the Health Resources and Services Administration and Rural Health Information Hub.

National Rural Health Association. (2018). *About rural health care*.

Retrieved from <https://www.ruralhealthweb.org/about-nrha/about-rural-healthcare>

- California, Arizona, and Texas showed the largest growth in suburbs of large metropolitan cities. During the same period, rural population growth was 4.5% with 46% to 60% of rural counties losing residents.
- An all-time high of 51% of the population live in the suburbs.
- Only 16% of the U.S. population is characterized as rural, the lowest ever. The primary cause for this shift is thought to be children leaving home for larger cities with better employment opportunities.
- Rural areas are caught in a vicious cycle, because of individuals moving away to find jobs and businesses reluctant to relocate to rural areas because of a smaller pool of potential workers. States with the largest percentage of rural population are Maine (61%), Vermont (61%), Mississippi (51%), and West Virginia (51%) (U.S. Census Bureau, 2016b).

- Rural areas have lower rates of poverty (11.7% compared to 14% for urban) but were less likely to have a bachelor's degree (19.5% compared to 29% for urban); however, compared with urban households, rural households had lower median income ([U.S. Census, 2016b](#)).

Rural employment has grown slower than urban employment and was the slowest to recover from the recession in 2007. Many Americans living in rural communities continue to face barriers that prevent them from attaining the quality of life they deserve. Access to adequate transportation is difficult for many rural Americans. Insufficient access to medical care can lead to health problems; this can be exceptionally hard to overcome for Americans living in rural areas. In addition, too many rural Americans do not have necessary broadband access needed to engage in the modern economy ([Council of Economic Advisors, 2018](#)).

- For instance, as of 2014, 39% of the rural population lacked access to broadband at speeds necessary for advanced telecommunications and data transfer capability. This e-connectivity gap not only prevents rural Americans from participating in the global marketplace but also limits urban Americans.
- Rural e-connectivity supports economic development for the whole nation through access to capital and global markets, job training and workforce development, innovation and technology, and enhanced quality of life ([USDA, 2017](#)).
- In addition, there is also a higher percentage of elderly and those living in poverty, along with higher rates of chronic illness (about half have one chronic illness or more) and more rural residents reporting poor to fair health ([Seright & Winters, 2015](#)).

Rural residents are less likely to receive recommended preventive services, and they make fewer visits to health care providers. They also have fewer physicians (10% of total), and there is continuous concern about recruitment of health care professionals in rural areas of the United States and other countries beyond what incentives (e.g., scholarships, forgivable loans) can offer ([Rural Health Information Hub, 2018b](#)). Specialized medical care is rarely found in rural areas. Of the 2,000 rural hospitals, 75% of them have 50 or fewer beds; most are designated **critical access hospitals (CAHs)** as they have 25 or fewer beds ([Rural Health Information Hub, 2018a](#)). CAHs must provide 24-hour emergency care, with either MD on site or RN on site with MD on call and able to arrive within 30 minutes. They must also have 25 beds maximum and be over 35 miles from the next hospital or 15 miles if the terrain is difficult ([Seright & Winters, 2015](#)).

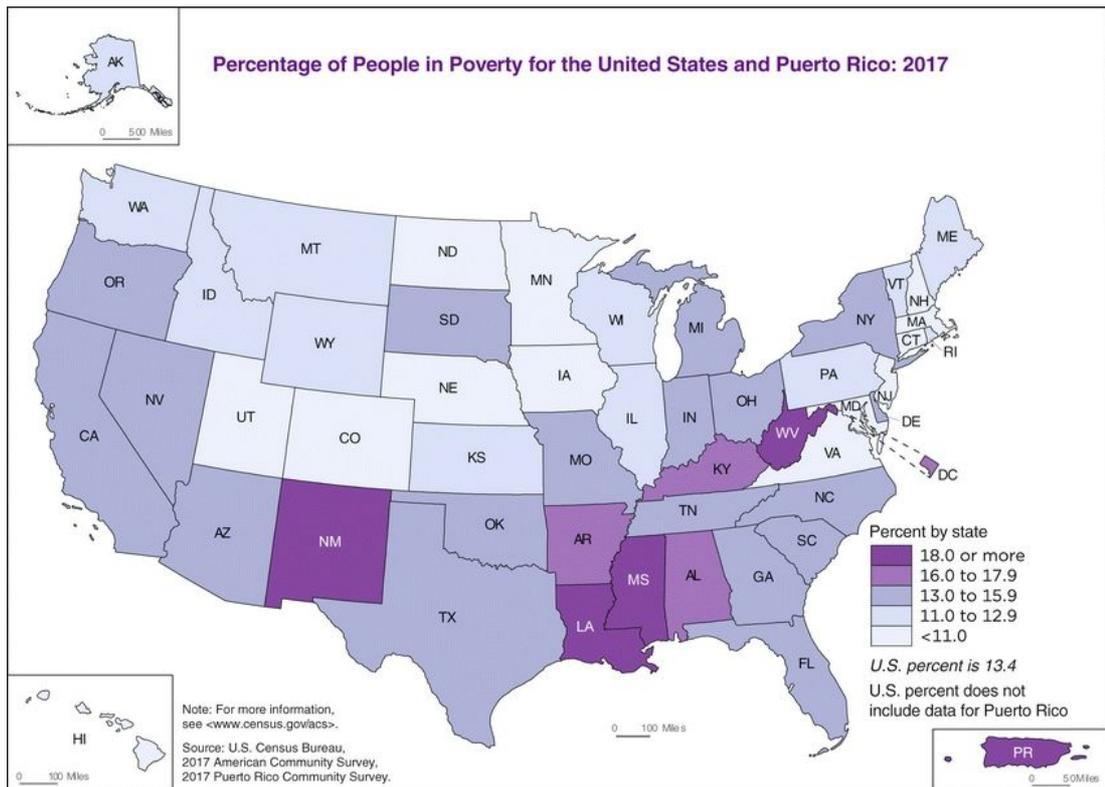

Recent solutions have been formulated to address these issues:

- The National Health Service Corp (NHSC) Program addresses long-standing primary care health professional shortages by providing physicians, APRNs, and other health professionals with scholarships and repayments of student loans in return for at least 2 years' service in communities facing shortages.
- Area Health Education Centers (AHECs) were developed by Congress in 1971 to recruit, train, and retain health care professionals committed to underserved populations, which includes rural areas. There are over 56 AHECs with more than 235 centers operating in almost every state. Many work collaboratively with medical schools, nursing programs, and allied health schools to improve health for underserved and underrepresented populations.
- **Federally qualified health centers** make up one of the largest health care systems for rural America and are frequently the only source of primary and preventive services in their communities. Fifty-three percent of these community health centers are located in rural and frontier areas. Nurses play a central role in all three of these initiatives, providing both direct primary and preventive care ([Rural Health Information Hub, 2018a](#)).

## Changing Patterns of Migration

- Population changes in rural areas are usually related to natural increase through births or decrease through **out-migration**, the process of residents moving out of rural communities and into urban places. When America was a more rural country, there was more natural increase than out-migration, which caused continued growth in the rural population. Since the beginning of the 21st century, more rural counties have experienced out-migration, and rural towns in some areas have disappeared; this trend has slowed but continues overall (USDA, 2019a).
- The lack of **in-migration** is related to a decrease in retirees moving to rural areas, problems recruiting professionals and managers for local manufacturing companies, poverty, and low quality of life (USDA, 2017). Population trends have many implications for the health services needed by rural people. The patterns of rural migration change like shifting sand, adding to the challenge of planning resources for rural communities (U.S. Census Bureau, 2019).

Although other sectors of the American economy have largely recovered from the Great Recession (Fig. 27-4), rural America has lagged in almost every indicator (Fig. 27-5). Today, rural areas are more economically diverse than in the past, reflecting the national trend to greater reliance on service jobs. While traditional rural occupations such as agriculture, mining, and manufacturing employ less of the rural population than before, they continue to anchor the economies of more than half the U.S. counties (USDA, 2017).

**FIGURE 27-4** Percentage of people in poverty for the United States and Puerto Rico: 2017. (From the U.S. Census Bureau. (2018). *Poverty: 2016 and 2017. Geography of poverty*. Retrieved from <https://www.census.gov/content/dam/Census/library/publications/2018/acs/acsbr17-02.pdf>)

**FIGURE 27-5** A farm in rural Utah.

## *Demographics*

Migrant farmworkers constitute a mobile population with shifting composition, and it is difficult to precisely determine their number or origins. These estimates also vary because of the influx of illegal and undocumented workers. A large number of seasonal and migrant farmworkers reside in the United States, 33% are U.S. citizens, and others have permanent resident status. Most of the estimated 3 million migrant (42%) and seasonal (58%) farmworkers tend to be either newly arrived immigrants, with few connections, or established legal residents, with limited opportunities and skills, who rely on farm labor for survival (NCFH, 2018a). In addition to male workers, who make up the majority, you may also see mothers bring infants and young children to work with them, and the children spend their days strapped to their mother's back or playing among the pesticide-laden fields.

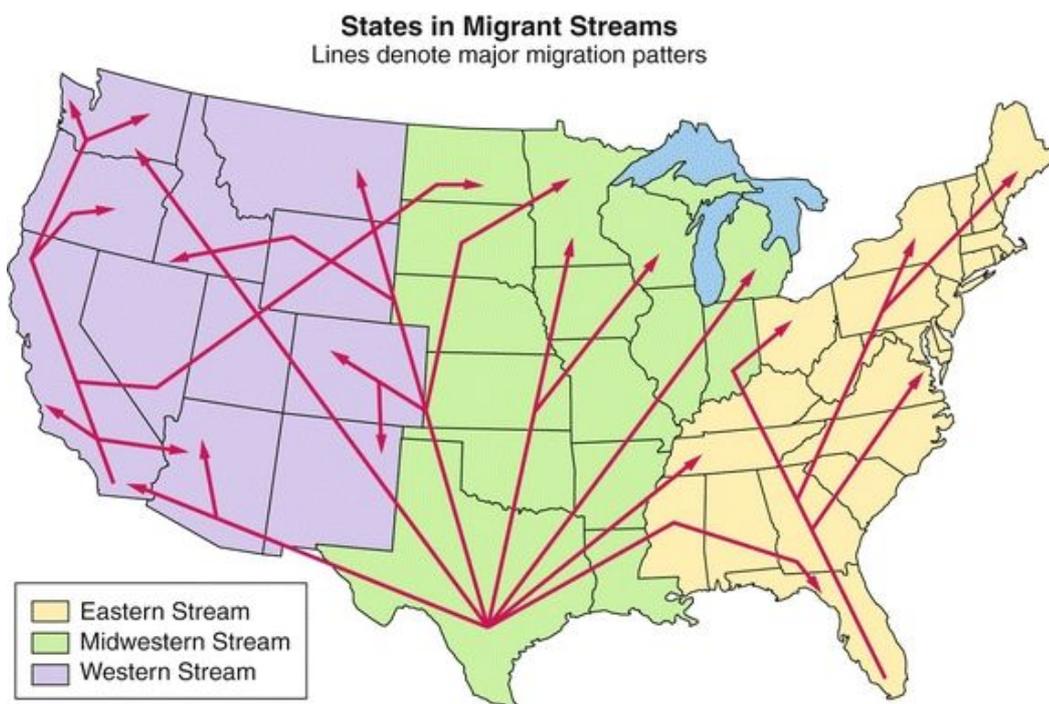

- **Seasonal farmworkers** generally live in one geographic location and are temporarily employed in agriculture, whereas migrant farmworkers meet that classification while moving to find agricultural work throughout the year, usually from state to state, and establishing temporary residences (Migrant Clinicians Network, 2017a).
- Some live apart from their families, forming groups of single men; others travel with their entire families. The average migrant farmworker spends from June to September doing seasonal harvesting, with about 8 weeks on the road traveling from farm to farm for work, and is then unemployed unless other work, such as hauling or canning, is found.
- Work days begin before dawn and often last 12 hours or longer. Farmworkers cannot be paid for overtime, as federal laws exclude this category of work. Seventeen states do not require workers' compensation insurance for agricultural workers, 14 states require workers' compensation for all agricultural workers and the remainder requires it but provide exceptions for small employers (NCFH, 2018a).

Migrant farmworkers represent some of the most economically disadvantaged people in the United States. According to the 2013 to 2014 National Agricultural Workers Survey (NAWS) survey results, 30% of migrant worker families had total family income levels below the national poverty guidelines. The same survey found that 83% of these workers said that they were paid by the hour, 9% were paid by the piece, and 8% were salaried or had other payment methods. Using piece rate as a basis for payment is common in agricultural work when the crop being picked is easily weighed and measured, motivating workers work faster during such a short window of seasonal crop harvesting (NCFH, 2018a). Farmworkers paid at a per piece rate may earn as little as 40 cents for a bucket of tomatoes or sweet potatoes, therefore needing to pick approximately 2 tons of produce (125 buckets) to earn 50 dollars (Student Action Farmworkers [SAF], 2011–

2019). In addition to low wages, agricultural workers rarely have access to worker's compensation, occupational rehabilitation, or disability compensation benefits.

### *Migrant Streams and Patterns*

Migrant farmworkers usually have their permanent residence, or *home base*, in states with a traditionally high number of immigrants, like California, Texas, Florida, Washington, Oregon, and North Carolina (SAF, 2011–2019). From their home base, migrant farmworkers move to locations where new crops are ready for harvest, following the harvest seasons as they move from place to place along predetermined routes called **migrant streams** (Fig. 27-6). Some migrant farmworkers are multigenerational; their families have been farmworkers for several generations, traveling the same streams for many years. It is common for migrant farmworkers to send money back home to family members in other countries, like Mexico, China, India, and the Philippines. In fact, an estimated \$625 billion dollars was sent by migrants to individuals in their home countries in 2017, a 7% increase from 2016. More specifically, more than 30 billion dollars was sent from the United States to Mexico by migrant workers (Pew Research Center, 2020). Of farmworkers in the United States, 75% were born in Mexico and 60% live apart from their immediate family members. Immigrant farmworkers often leave their home country to seek a better life for their families (SAF, 2011–2019).

**FIGURE 27-6** Migrant streams. (Source: Migrant Head Start Program, USHDHUD.)

Three principal streams formulate the agricultural routes that migrant laborers follow.

- The *eastern stream* originates in Florida, where most of their time is spent, and extends up the East Coast through North Carolina, Tennessee, Kentucky, Virginia, and other states east of the Mississippi, as far as north as Ohio, New Jersey, New York, Connecticut, Massachusetts, New Hampshire, Vermont, and Maine.
- The *midwestern stream* begins in southern Texas or northern Mexico and fans out across the United States, ending in the Northwestern and Midwestern states bordering Canada, both east and west of the Mississippi.
- The *western stream* originates in California and moves up the West Coast to all Western states and from central California into Oregon and Washington (NCFH, 2018a).
- California, Florida, and Texas are regarded as *sending states*, as they are often home states with long growing seasons where migrant streams begin and end (Fig. 27-7). Male workers may travel with the crops and leave their families in these home states (USDHUD, 2016). Workers move from areas with cotton, tree fruits and nuts, and vegetable crops to other areas where they harvest cherries, watermelons, cantaloupes, or potatoes.

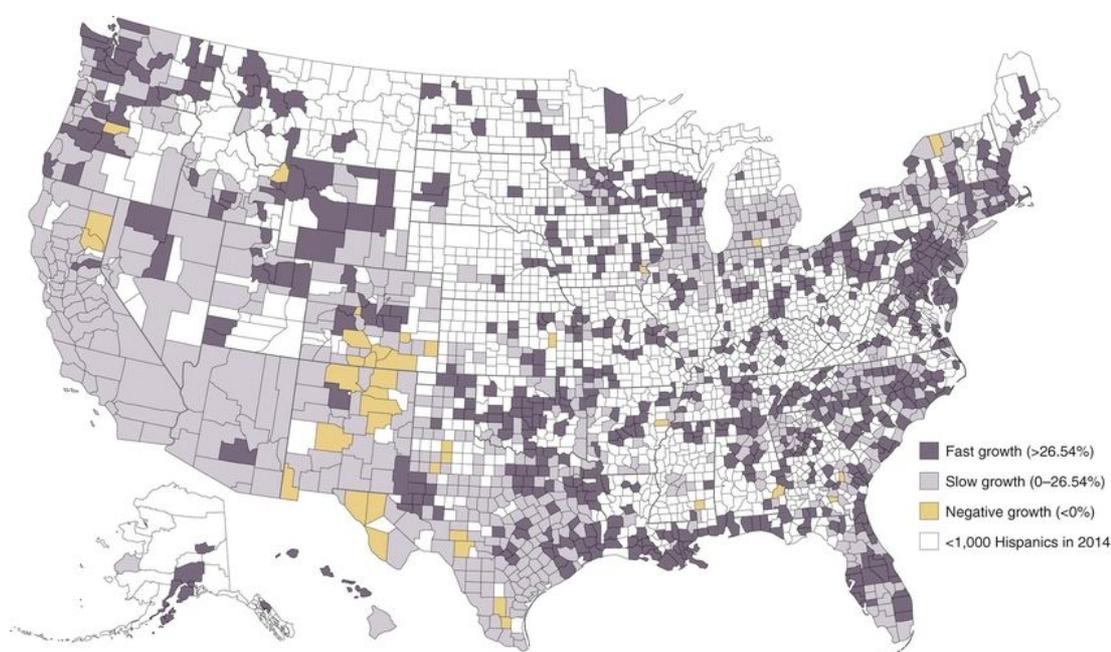

**FIGURE 27-7** Migrant farm workers pick and package crops (strawberries) directly into boxes in the Salinas Valley of central California.

**Nomadic migrant workers** travel away from home for several years, working from farm to farm and crop to crop and relying on word of mouth about job opportunities. Some of these workers eventually settle in the areas to which they have migrated, whereas others return to their home base. A given ethnic group usually follows its own particular stream and pattern of migration. New growth states, like Utah, Minnesota, Wisconsin, Nebraska, Kansas, Tennessee, and Arkansas, have seen immigrant population's increase. Some migrant workers find work in service sector jobs and others labor in construction or landscaping, thus ending their need to constantly move with the crops. Married men, not living with their families, are more likely to migrate than those living with their families, often because of the need to send money back home.

# RURAL HEALTH

Rural areas have historically had less racial diversity than urban areas. However, that is rapidly changing. More recently, rapid Hispanic growth areas are found in the South and Metropolitan areas (Fig. 27-8; Pew Research Center, 2018). California, Texas, and Florida are home to 55% of the U.S. Hispanic population, with 14.4 million living in California. In rural counties, the white population has decreased, and other ethnic groups have increased in size, but still only 11% of rural counties are majority nonwhite (Pew Research Center, 2020).

**FIGURE 27-8** The fastest-growing Latino counties between 2007 and 2014 were largely located in the South and metropolitan areas. (Reprinted with permission from Stepler, R., and Lopez, M. H. (2016). *U.S. Latino population growth and dispersion has slowed since onset of the Great Recession*. Pew Research Center: Hispanic Trends. Retrieved from [http://www.pewhispanic.org/2016/09/08/latino-population-growth-and-dispersion-has-slowed-since-the-onset-of-the-great-recession/ph\\_2016-09-08\\_geography-06/](http://www.pewhispanic.org/2016/09/08/latino-population-growth-and-dispersion-has-slowed-since-the-onset-of-the-great-recession/ph_2016-09-08_geography-06/))

Urban and rural disparities have changed over time. The National Rural Health Association (2019) identifies life expectancy to have shifted with those in rural areas living slightly longer than those in urban areas (Table 27-

1). Health concerns of populations in rural areas are related to the environment, occupations, injuries, and distance from health care providers. Population trends have a direct relationship to the kinds of health services that are needed in rural communities. Growing families with young children need maternity, pediatric, and family health medical services, along with dental care and mental health services. They also can benefit from health promotion and disease prevention activities. The elderly, on the other hand, need health care to manage increased number of chronic health conditions. Rural communities need to provide access to nursing homes and rehabilitative services, as well as to hospitals, clinics, and health promotion programs that serve the elderly and the entire community.

**BOX 27-1 Locating a Rural Home Health Client** It can be difficult to locate a patient in the rural community. Directions may include structures such as barns, fences, and trees, or identification of stores that are familiar to the patient and their family but not the nurse. In addition, living quarters may be on long unmarked dirt roads or be an additional structure to an already existing address. Once I received directions from a patient who told me to "...take the second dirt road on the right after you get off the highway (after the Dairy Queen), you'll see a big oak tree with a swing. Continue down that road for about 5 maybe 6 minutes and turn right again at the red one-story house. Drive to you see the green barn, don't

**turn there, but turn left at the next barn. You'll see our house over the hill.” Additional time may be needed to navigate rural residents because GPS systems may not be of assistance in these rural areas.**

## The Built Environment in Rural Areas: Relationship to Health

Even with the advances of medicine and genomics, and the staggering percentage of our gross domestic product (GDP) spent on health care, scientists feel that we will not be able to significantly improve our overall health and quality of life without addressing how we plan our living spaces.

As discussed in [Chapter 9](#), the **built environment** consists of the development of housing, highways, shopping areas, and other man-made features added to the natural environment.

As populated areas expand, stresses are placed on natural habitats, water supplies, and air quality. The built environment is inextricably related to health. Substantial scientific evidence gained in the past decade has shown that various aspects of the built environment can have profound, directly measurable effects on both physical and mental health outcomes, particularly adding to the burden of illness among ethnic minority populations and low-income communities ([Hansen, Umstattd Meyer, Lenardson, & Hartley, 2015](#)).

**Urban sprawl** is a concern in some rural areas, as people move from urban centers to more suburban environments. Urban encroachment into agricultural areas creates problems with air and water pollution, access to health care, and heat islands. *Heat islands* occur when green areas are exchanged for asphalt, resulting in temperature and ecosystem changes that can extend to more rural areas ([Trivedi et al., 2015](#)). Ozone levels are often highest just outside the city, because “ozone is formed relatively slowly by the action of sunlight on oxides of nitrogen and hydrocarbons” (p. 72). Urban sprawl also causes problems with water pollution and the availability of water. Encroachment of housing areas into natural habitats or farmlands can lead to wider human exposure to pesticides, herbicides, and other hazards such as mosquito-borne illnesses. Mass transit is not often available in suburban areas and almost never found in rural areas. Opportunities for healthpromoting behaviors are often more limited in rural areas. Deteriorating (or no) sidewalks can be a barrier to walking in rural areas. Exercise or fitness facilities, bike paths, jogging trails, and other incentives for physical activity are also often lacking in rural communities.

- [Trivedi and colleagues \(2015\)](#) examined data from a large national survey and found that rural adults were 1.19 times more likely to be obese when compared to urban adults. The prevalence was 35.6% in rural residents versus 30.4% for urban residents, and that difference was also found for both males and females (37.7% vs. 32.5%; 33.4% vs. 28.2%).

- Exercise levels were lower among rural adults than for those in urban areas (Trivedi et al., 2015). Obesity is prevalent in rural areas, and the physical environment, along with diet, plays a role in this epidemic (Lenardson, Hansen, & Hartley, 2015).
- Eating out, especially at buffets, fast-food restaurants, and cafeterias, instead of cooking at home, as well as not participating in physical activity have been associated with higher rates of obesity (Lenardson et al., 2015). In fact, Bhutani, Schoeller, Walsh, and McWilliams (2018) found that for every 1-meal/week increase in fast-food and sit-down restaurant consumption was associated with an increase in BMI by 0.8 and 0.6 kg/m<sup>2</sup>, respectively.

Rural roads are another concern because they are often narrow, without streetlights, and poorly maintained. More fatalities occur on rural roads and highways. While 19% of the country's population lived in rural areas in 2012, 54% of all road fatalities occurred there (National Highway & Traffic Safety Administration, 2018). Speeding, failure to use safety restraints, and alcohol are common causes of fatal crashes in rural areas. Over half of fatal crashes occurred during daylight hours in rural areas; the opposite is true in urban areas. Fifty-five percent of all fatal alcohol-related crashes occurred in rural areas, and 65% of rural occupant deaths in pickup trucks were not using restraints. Slow-moving farm equipment traveling on rural roads, along with speeding and failure to use safety restraints, are often fatal conditions for drivers in rural areas.

## Self, Home, and Community Care in Rural Areas

Historically, self-management of health care problems has been the most common way for rural people to cope with illness (Fig. 27-9). This can be viewed as a type of strength, or it may be seen as a limitation.

**FIGURE 27-9** Life in a rural area may seem idyllic, but there are some significant risks of a rural lifestyle.

- Rural residents are often viewed as hardworking, traditional, hardy, self-reliant, and resistant to accepting help or services from outside agencies regarded by them as welfare-type programs.
- Many rural clients are considered individualistic, independent, and resourceful. They often take care of illnesses or injuries on their own or have a supportive network to help them get their health needs met.
- Small communities commonly have strong social networks, but this type of familiarity may lead to problems with privacy and confidentiality, as well as stigma regarding mental health or substance abuse treatment.
- Because cost, travel, weather, and distance are barriers to obtaining health services from formal health care providers, rural clients may employ a variety of folk treatments and home remedies before consulting a nurse or a physician; such clients tend to visit providers at a much later stage than do people in urban areas.
- Rural residents may utilize physicians who are more likely to provide care that is outside their specialty areas.
- Compared with hospitals that are less rural, CAHs have been found to have significantly higher patient mortality rates.

- Patients living in rural areas are known to have higher risk for poor health outcomes, more likely to smoke and consume less healthy diets. These factors may contribute to higher mortality rates.
- Social determinants of health for rural dwellers, such as living environment, community health supports, distance to providers, and local economic prospects, can contribute to the mortality disparity (Heath, 2017).
- The low population density in rural areas makes service delivery more difficult, especially for those with special health needs. The greater treatment barriers when living in an isolated area are geography and lack of adequate transportation.
- Home health care (HHC) is particularly difficult in sparsely populated areas, for both patients and nurses. Locating addresses in very rural areas often takes additional skills. (See Box 27-1 for the story of a home health nurse trying to locate a client's home.) The benefits of HHC are worthwhile; it allows people to stay at home, supports their hardiness, and compensates for the long distance between home and formal health care.

## Major Health Problems in Rural Communities

Among major health problems affecting individuals in rural areas are cardiovascular disease (CVD), diabetes, and COPD. Geography, economics, and rural lifestyle factors may account for the higher rate of these major health problems.

### *Cardiovascular Disease*

CVD is a leading cause of death in the United States (42%), and the total direct and indirect costs of CVD and stroke were estimated at over \$351.3 billion in 2015 ([American Heart Association, 2020](#)). Research demonstrates that geography may play a role.

- Mortality because of heart disease is highest in the South, especially following the path of the Mississippi River ([Bolin et al., 2015](#)). Regional variations have been noted in prevalence of CVD and stroke. Studies have found increased stroke mortality in the South (stroke belt), and many researchers are focusing on the possible underlying risk factors related to geographical variations. One group of researchers wanted to better understand the effect of length of time living in the stroke belt and age at first exposure.
- Rural areas usually have less high-tech health care equipment available, which may affect outcomes for patients with cardiovascular emergencies. Being within 60 minutes of a Primary Stroke Center (PSC) can determine outcome for many patients. C/PHNs can advocate for better access to care and promote healthy lifestyle choices as well as population-targeted interventions to reduce stroke and CVD.
- Rural residents may ignore early cardiovascular symptoms and give little heed to preventive interventions such as exercise and low-fat diets.
- Several models of care are being implemented to address rural CVD. In Maine, community-based education is targeting the specific needs of low-income residents with CVD with attention given to socioeconomic status, and residents' local culture and education level. In Montana, pharmacists are working with rural clients to discuss medication management, nutrition, and other risk factors such as smoking with good success. In rural east Colorado, community health workers meet clients in local community facilities such as libraries and schools to provide screenings, referrals, services, and education ([Rural Health Information Hub, 2019a](#)).

### *Diabetes*

Rural populations are disproportionately affected by diabetes and CVD (8.6% and 38.8%, respectively); the prevalence is generally greater in rural areas, and this is even more pronounced among Hispanics and Blacks. Mortality rates for diabetes were higher in the rural regions within the south and Midwest with 21% of deaths per 100,000 compared to 15.1% per 100,000 in the northwest and west (HRSA, 2018). Overall, the prevalence of diabetes is 15% to 17% higher in rural areas than in urban (HRSA, 2018).

- Rural areas have been cited as promoting obesity on a population level because of fewer opportunities for walking, as residents spend a great deal of time commuting to work or driving to essential services, and rural residence was positively correlated with BMI, distance to retail food, and commute times, among other things (Calancie et al., 2015).
- Lower physical activity rates and greater barriers to physical activity are commonly found in rural populations, as opposed to populations living in urban settings (Bolin et al., 2015).
- Rural populations also face greater barriers in diagnosis, treatment, and follow-up care. Some compliance issues with prescribed medication regimens may relate to the lack of health insurance and low-income levels in rural areas but could also be due to lower health literacy and education levels.
- Other problems with accessing care may involve transportation and weather. A lack of access to quality health care services has been a long-standing problem for rural Americans because of the significant difference in access to health care (HRSA, 2020).

Anderson, Saman, Lipsky, and Lutfiyya (2015), in a comparison study of people living in rural counties versus nonrural counties, found that rural residents had statistically lower scores in areas such as clinical care, morbidity factors, and general health behavior. For instance, a classic study by Krishna, Gillespie, and McBride (2010) highlighted the extreme complications encountered by rural residents who often have to travel great distances to access services for diabetes care, such as basic follow-up with podiatrists for diabetic foot care, ophthalmologists for retinal health, and nutritionists and health educators, as well as routine laboratory blood tests, to guide lifestyle choices. C/PHNs, especially in rural and frontier areas, often provide follow-up for diabetic clients who may be unable to regularly access their health care providers because of problems with distance or transportation. Home visits to check on their diet/exercise, blood glucose monitoring, and foot care are important safeguards for this population. Also, interventions targeted to behavior change can be helpful.

## *Chronic Obstructive Pulmonary Disease*

Prevalence of COPD in rural counties is twice that of urban areas (8.2% vs. 4.7%) with high concentrations occurring in the Appalachia and the southern geographic regions (DHHS, 2018). Medicare beneficiaries aged 65 years and over in rural regions had higher COPD-related hospitalization than urban (13.8 to 11.4 per 100,000). Lack of access to care, limited transportation, decreased specialty services, and treatment options increase the disparity of COPD in rural versus urban areas. Environmental exposures can also affect COPD patients in rural communities (DHHS, 2018). Typical rural occupations expose people to very dusty or dirty air, chemicals, environmental pollutants, and occupational activities such as farming and coal mining. Even nonagricultural rural workers are much more likely to be exposed on the job to high levels of gases, dust, and fumes (27%) than urban workers (15%). In addition, a higher percentage of rural than urban people smoke, including exposure to secondhand smoke. Smoking among teen-agers is decreasing but remains considerably higher among rural young people. Other causative factors for high mortality rates from COPD include difficulties for rural people getting to basic and specialized medical care. Rural individuals may have to travel longer distances to received care and treatment (DHHS, 2018). Small rural hospitals may not have the equipment to measure and track changes in a person's breathing over time and may not have respiratory therapists to teach patients better ways to live with their damaged lungs (Myers, 2018). Environment issues particularly relate to agriculture and the health risks that accompany farming and other rural lifestyles.

## Agriculture and Health

Although farming is not characteristic of all rural areas where agricultural production occurs, both direct and indirect effects on health can exist.

- In a classic summary sponsored by the Institute of Medicine ([Merchant, Coussens, & Gilbert, 2006](#)), it is noted that pesticides and fertilizers can affect water, air, and soil, and dust created from plowing for crops can affect the air quality. For instance, an “estimated 70% of antibiotics are used for nontherapeutic purposes in intensive livestock production,” placing workers at risk for developing antibiotic-resistant infections (p. 4).
- [Donham and Thelin \(2016\)](#) focused their research on diseases commonly seen in agricultural workers, mainly arthritis (rheumatoid and osteoarthritis), injuries of the musculoskeletal system, skin cancer, burns, rural roadway crashes, and zoonotic diseases. Neurotoxicity can develop due to exposure to industrial chemicals and pharmaceuticals, leading to report of neuropsychiatric disorders, such as attention deficit hyperactivity disorder (ADHD) and autism.
- Exposure to these substances during early development may lead to adverse behavior effects manifested at a later time of life. Pesticides are a wide group of chemicals that are still actively used, and residues are found in the environment and in food products ([Lee, Eriksson, Fredriksson, Buratovic, & Viberg, 2015](#)).
- Pesticides are linked to disease and environmental risks through various routes (e.g., residues in food and drinking water). These hazards range from short term (e.g., skin and eye irritation, headaches, dizziness, and nausea) to chronic problems (e.g., cancer, asthma, and diabetes). Further, their risks are difficult to explain due to the involvement of various factors (e.g., period and level of exposure, type of pesticide) ([Kim, Kabir, & Jahan, 2017](#)).
- Lawsuits have been filed in California, Delaware, Florida, Hawaii, and Missouri against Monsanto over its popular herbicide, Roundup, with its active ingredient now thought to be a “probable human carcinogen” ([Gillam, 2016](#), para. 8). The World Health Organization's International Agency for Research on Cancer has called glyphosate a “probable human carcinogen,” and in 2017, the state of California added this weed killer to its list of cancer-causing chemicals ([Cone, 2019](#)).

Many rural residents depend on their own well water for drinking, and water quality is monitored only sporadically by well owners and then usually only for nitrates and coliform bacteria ([Lee et al., 2015](#)). About 30% of rural residents obtain drinking water from very small water systems, without the

monitoring and regulations associated with large urban water suppliers. Testing of small water systems should be done at regular intervals in order to get a true picture of water quality (Wedgworth et al., 2015). In addition, agricultural-related morbidity and mortality are relatively high. Agriculture, forestry, and underground mining are ranked high in the rate of occupational injuries (U.S. Department of Labor, 2017).

It is estimated that 33,000 injuries to children are farm related, and approximately 100 of them are fatal. Of the fatal injuries to youth, 23% were machinery related (often tractors), 19% were vehicle related (including ATVs), and drowning was to blame in 16% of fatalities. Most fatalities (34%) were in the 16-to 19-year age group (Occupational Health & Safety Administration [OSHA], n.d.). Farming injuries can result from tractor rollovers, suffocations in grain bins, exposure to harmful substances, falls, fires or explosions, accidents with other farm equipment, and on-or off-road collisions. Some injuries result in permanent disability, and worker training programs to recognize hazards and prevent injuries are rare in rural areas. See Box 27-2 for farming accidents.

## **BOX 27-2 Agricultural Accidents**

**Farm Tractor Accidents** In the old days before mechanical equipment, a farmer might be injured by one of his horses or mules, or accidentally stabbed with a pitchfork. Today, tractors are involved in the majority of injuries and deaths. ROPS, or a roll cage over the tractor seat, can save lives; they were standard on every tractor manufactured in the country since 1985 (1959 in Sweden). If a farmer uses the seat belt and the tractor equipped with ROPS turns over, there is a good chance that he will survive the accident. Sadly, many farmers don't use seat belts, and many use older tractors without ROPS protection. There are many potential hazards on farms (e.g., falling bales of hay, heat stroke, dangerous equipment

**like hay balers, choppers, combines), but tractor rollovers and children falling from tractors are much too common and can often be prevented.**

**Death on the Farm Agricultural deaths are not uncommon, elderly men, youths, and hired hands are the most affected. Agriculture industry has the highest fatal occupational injuries with 23.2 per 100,000 and nonfatal injuries 58,300 in 2016. Tractor rollovers are preventable; ROPS along with seatbelt use can eliminate these injuries. Engineering controls along with policies, practices, and protective equipment can control agricultural workplace accidents. Currently, there are 4.2 million tractors in use with all new equipment manufactured with ROPS. As of 2006, 59% of tractors were equipped with ROPS. Due to longevity of equipment, retrofitting of equipment is an option, but cost, special**

**clearance, tractor housings, and personal preferences are barriers for many farmers.**

## Access to Health Care in Rural Areas

### *Insurance, Managed Care, and Health Care Services*

Health insurance in today's market is costly, especially for individual purchasers. Some people, therefore, forego health insurance for themselves and their families. Depending on their income, people may or may not be eligible for Medicaid or State Children's Health Insurance Programs (SCHIPs). Even people who are eligible for government health assistance may not apply because of their belief that it is a sign of weakness to accept a handout. Historically, a traditional fee-for-service model delivered health care in rural and urban communities (see [Chapter 6](#)). However, that is changing, and it is challenging for rural providers to deliver the cost-effective, complex health care that rural persons need in small practices.

- Rural patients often utilize family practice clinics.
- The managed care model, which attempts to control costs and improve health care delivery, has slowly diffused into rural communities. In addition, rural practitioners are reluctant to become part of organizations that negotiate to reduce their payments, as many of them already see a disproportionate number of Medicaid and uninsured patients that impact their bottom line.
- Low population density makes this type of health care insurance less profitable.
- More states are moving to Medicaid managed care models, and Medicare offers this option to beneficiaries. This puts rural residents at a disadvantage, as they may have poor access to services because of distance and travel time.

Building provider networks in rural communities is both time- and effort-intensive because rural providers are often inexperienced with managed care organizations (MCOs). The federal government provides support for **rural health clinics** in areas designated as underserved and nonurban; differences in effectiveness and efficiency have been noted in larger clinics versus smaller clinics ([RHIH, 2020a](#)). These clinics have served rural clients for more than 30 years, and they are an important source of health care.

- Rural areas are characterized by a lack of core health care services (e.g., primary care, hospital care, emergency medical services, long-term care, mental health and substance abuse counseling services, dental care, and public health services).
- Shortages were noted for physicians, with urban areas having 263 specialists for every 100,000 residents and rural areas having 30

specialists for every 100,000 residents (Lahr, Neprash, Henning-Smith, Tuttle, Hernandez, 2019).

- In the United States, 56% of all rural counties do not have a pediatrician affecting the health status of children (Rural Health Information Hub, 2019a).
- Population health services in rural areas may be covered by a combination of public health departments, physicians in private practice, local hospitals, as well as various community agencies.
- In some rural or frontier areas, state health departments may offer services, as no local infrastructure may be present. Many rural residents depend heavily on public health department services. Seventeen percent of local health departments (LHDs) serve small towns (populations under 10,000), and 44% serve communities with populations between 10,000 and 49,999.
- These LHDs are less likely than larger health departments to provide environmental health services, but they often provide many of the other services (e.g., primary prevention, health services, epidemiology/surveillance) found in larger health departments (National Association of County and City Health Officials, 2016).
- Numerous states have sizable rural areas; this geographic isolation may restrict access to health care for vulnerable groups, especially minorities and those with disabilities. To adequately address health disparities, rural areas need to be better incorporated into discussions of geographic and racial inequality (Caldwell, Ford, Wallace, Wang, & Takahashi, 2016). See Box 27-3 for a hard lesson learned by one C/PHN student.

## BOX 27-3 PERSPECTIVES

**A Nursing Student Viewpoint On Rural Transportation** I live in a relatively large city of 450,000 people. When I started my community health nursing rotation, I was assigned to a rural county public health department in an adjoining county over 50 miles from my house. When I arrived for my first clinical day, my professor told

**me that I was assigned to see clients in an isolated community another hour away from the health department! There was nothing but farmland between the county seat and this small town.**

After I got over my frustration about traveling such long distances, I began to visit some of my families and started to actually enjoy my time with them. They were so appreciative and open to my suggested interventions. I really seemed to be making a difference. One older gentleman, Armando, was a diabetic who spoke very little English. He lived with his wife of 50 years, who spoke almost no English. Their children had moved away in order to go to school and get better jobs. His diabetes was not well controlled, and the rural health clinic FNP suggested that he see a specialist (actually an internist) in the largest city in the county. I helped him make arrangements with the doctor for an early afternoon visit and made sure that he could catch the county bus that ran between the smaller communities and the county seat.

When I came back for a follow-up visit the next week, I was shocked to learn that Armando's appointment had been pushed back to 4:30 PM because of the doctor's involvement in hospital emergencies, and by the time Armando was finished with his appointment, the county bus service had ended. Armando, with no money and no one to call for a ride, began walking back to his home—over 52 miles away! About halfway home, a farm truck driver gave him a lift to the large cotton farm a few miles from his home. I never realized how difficult it was for rural people to get to their medical appointments. I thought that the bus would not be a problem, but I learned my lesson. Now, I make sure that the physician's office understands the patient's circumstances and the importance of getting them back to the bus stop in time to make the last bus.

Andrea, senior nursing student

Unpredictable weather adds to potential barriers for rural clients. Snow, ice, wind, flash floods, and rain can make travel dangerous, even over short distances.

- Parents may decide not to risk driving on poorly maintained roads to get their children immunized or to have their own hypertension evaluated (Fig. 27-10).
- Elderly people may choose to delay health care when long travel times, especially in isolated rural areas, are involved.

- Rural populations have disproportionately high injury mortality rates, much of which is due to motor vehicle accidents (APHA, 2018).
- In a more recent study by Chaiyachati *et al.* (2018), offering complimentary ridesharing services to Medicaid patients did not reduce rates of missed primary health care appointments. The acceptance of free rides was low, and rates of missed appointments remained unchanged at 36%. Study results indicated that efforts to reduce missed appointments due to transportation barriers may require more targeted approaches.
- Historically, rural communities have been somewhat overlooked in the transportation planning process. In fact, because of the way in which transportation dollars are allocated, rural states often receive less funding than more densely populated states (APHA, 2018).
- Inadequate phone service, dead zones in cell coverage, and the lack of adequate contact information for emergency physicians on staff are all problems frequently encountered in rural areas (Bolin *et al.*, 2015).

**FIGURE 27-10** A railroad crossing along a dirt road across farmland on a winter day without snow in northern Illinois.

### *New Approaches to Improve Access*

The *Healthy People 2030* document mandates improvements in access, health education, health screening, immunizations, environmental health, and disease morbidity for the United States. Creative ways of delivering these and other services to rural clients need to be explored. Access to care is a social justice issue: clients who live in rural areas should receive quality health care, regardless of where they choose to live. The *Healthy People 2030* plan of action includes investment in health and well-being for all individuals. The first three overarching goals of *Healthy People 2030* focuses

on the elimination of health disparities, improving health access, and creating healthy environments.

- Attain healthy, thriving lives and well-being, free of preventable disease, disability, injury, and premature death
- Create social, physical, and economic environments that promote attaining full potential for health and well-being for all ([USDHHS, 2020a](#)).

*Faith-based* nursing has been a staple in rural areas, as well as with some urban communities, but is gaining momentum as more formal interventions are developed, for instance, mental health promotion for rural Latino immigrants ([Stacciarini et al., 2016](#)). Even informal support from other church members and friends may provide a compassionate environment for needed behavioral changes such as healthy diet and increased physical activity. See more on faith-based nursing in [Chapter 29](#). Results indicate that perceived improvements in church nutrition environments were most strongly associated with decreases in unhealthy food consumption and stronger intentions to use physical activity resources at church. Perceived changes in the physical activity environment were unrelated to church or general behavior ([Jacob et al., 2016](#)).

One approach that has been successful in numerous rural areas is the use of *mobile clinics*. These clinics bring health care providers to remote places for health screenings, immunizations, dental care, mental health visits, and other services.

- Mobile health clinics are frequently staffed by NPs and can improve access to health care for low-income residents.
- They often are available to residents on evenings and weekends and offer culturally sensitive and bilingual outreach, as well as care for uninsured clients.
- Although the aim of the Affordable Care Act (ACA) includes increasing the number of insured individuals in the United States and overcoming health disparities, it has no provisions for mobile medical clinics, which appear to serve as an important component of health care delivery, especially to vulnerable populations.
- In addition, mobile dental clinics provide an innovative solution to providing dental to improve physical access to dental care for medically underserved population in poor urban and remote rural communities.
- Many mobile clinics provide existing dental clinics services at lower or no cost to the user.

*School-based clinics* can improve access for schoolchildren (and sometimes their families) but may be less prominent in rural areas (see more

on school-based clinics in [Chapter 28](#)). These clinics provide available, community-based, affordable, and culturally acceptable care to well and sick children. Often, grant-supported, school-based clinics facilitate the receipt of health education and primary care by children who are otherwise without easy access to health services. More than 66% of school-based health centers offer primary care and behavioral health services. In addition, school-based health centers are associated with improved educational status, including higher grade point averages and higher rates of high school completion ([National Conference of State Legislatures, 2020](#)).

Telehealth, another approach to increasing access to care, provides electronically transmitted clinician consultation between the client and the health care provider. This option is especially useful for connecting home health nurses with their patients who need close monitoring at home. It is also useful for patient and professional health education, public health applications, and health administration. Specialty health care also may be accessed, with patients and providers connected via two-way audiovisual transmission over telephone lines or the Internet, thus obviating the need for patients to leave their residences. Streaming media, video conferencing, and store-and-forward imaging are just some of the applications commonly utilized ([HRSA, 2020](#)).

- Telehealth interventions for speech–language services to rural children were found by parents to be both feasible and acceptable. Parents found the teletherapy to be more frequent and consistent services, which in turn promoted their confidence and skill in assisting their children to achieve their speech and language goals ([Fairweather, Lincoln, & Ramsdeb, 2016](#)).
- Online counseling and remote counseling link rural clients with urban behavioral health services. Counseling services can also be provided online in Spanish ([Rural Health Information Hub, 2020b](#)).
- Telehealth is especially critical in rural and other remote areas that lack sufficient health care services, including specialty care. The range and use of telehealth services have expanded over the past decades, along with the role of technology in improving and coordinating care. Grants and other funding are available to promote the use of this technology ([HRSA, 2020](#); [RHIH, 2019b](#)). See [Chapter 10](#).

## *Healthy People 2030 Goals*

The five overarching goals of *Healthy People 2030* are to:

- Attain healthy, thriving lives and well-being, free of preventable disease, disability, injury, and premature death

- Eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all
- Create social, physical, and economic environments that promote attaining full potential for health and well-being for all
- Promote healthy development, healthy behaviors, and well-being across all life stages
- Engage leadership, key constituents, and the public across multiple sectors to take action and design policies that improve the health and well-being of all (USDHHS, 2020a, para. 11)

Because of the unique health issues facing rural America, *Healthy People 2030* identifies broad areas of concern such as access to health services, environmental health, and health communication/information technology (Box 27-4). Using surveys, literature reviews, and other methods of data collection and analysis, top priorities for rural health have been used, allowing rural stakeholders to reflect on and measure progress in meeting previous Healthy People rural goals (Bolin et al., 2015). In addition, there are data to substantiate continued problems with access to health care and insurance, as well as emergency services, in rural areas. And there is a higher rate of CVD and diabetes, along with obesity and tobacco use among rural populations (NRHA, 2019).

## BOX 27-4 HEALTHY PEOPLE 2030

### Health Issues in Rural America

#### Access to Health Services

AHS-01	Increase the proportion of people with health insurance
AHS-02	Increase the proportion of people with dental insurance
AHS-05	Reduce the proportion of people who can't get the dental care they need when they need it
AHS-08	Increase the proportion of adults who get recommended evidence-based preventative health care
AHS-R02	Increase the use of telehealth to improve access to health services
ECBP-D06	Increase the number of community-based organizations providing population-based primary prevention services

#### Diabetes

D-09	Reduce the rate of death from any cause in adults with diabetes
D-D01	Increase the proportion of eligible people completing CDC-recognized type 2 diabetes preventative programs

#### Environmental Health

EH-06	Reduce the amount of toxic pollutants released into the environment
-------	---

#### Health Communication and Health Information Technology

HC/HIT-06	Increase the proportion of adults offered online access to their medical record
-----------	---

#### Heart Disease and Stroke

HDS-01	Improve cardiovascular health in adults
--------	---

- A large longitudinal study of maternal and infant health in Maine revealed that access to prenatal care, along with pregnancy care and outcomes, was similar for rural and urban women over an 11-year period (Harris, Aboueissa, Baugh, & Sarton, 2015). Rural mothers had higher BMIs prior to pregnancy and were generally younger, less well educated, unmarried, and living in low-income households. They were also more likely to smoke, but less likely to drink alcohol, and were not often sure of their pregnancies until later than urban mothers, but they still accessed prenatal care at similar times (Harris et al., 2015).
- Access to quality care is linked to availability of health insurance. Rural residents, when compared to urban counterparts, have higher rates of uninsured, higher out-of-pocket costs, and higher proportions of emergency room visit costs; they are also less likely to be covered through group health insurance or managed care plans and less likely to have prescription drug coverage (Bolin et al., 2015).
- Also, insurance instability (gaps in coverage) is correlated with increased use of emergency rooms, and this is particularly significant for rural residents who often have less access (Fields, Bell, Moyce, & Bigbee, 2015). Because of lower rates of insured rural residents, their preventive health care is often lacking (e.g., lower rates of mammograms, colonoscopies, vision examinations).
- Approximately 65% of primary care professional shortages occur in rural counties. Rural residents are also less likely than urban residents to have a usual source of primary care (Rural Health Information Hub, 2019a).
- Problems more commonly seen in rural areas include oral health and cigarette and smokeless tobacco use. Sixty percent of rural counties are considered professional shortage areas for dental health, and more dentists are over age 55 in rural areas (42% vs. 38% in urban) (Rural Health Information Hub, 2019a). Rural populations are less likely to have annual dental examinations. They are also more likely to have tooth or gum disease, often because of higher rates of cigarette and smokeless tobacco use, and they are more likely to use the emergency room because of dental caries than urban residents (Bolin et al., 2015).
- Rural teens have a higher rate of tobacco and alcohol use than their urban counterparts (Rural Health Information Hub, 2019a).
- Unintentional overdose deaths due to nonmedical use of prescription drugs disproportionately impact rural over urban settings in the United States. Specific geographic areas, such as Appalachia, parts of the West and the Midwest, and New England, have seen higher prevalence than

other areas ([United States Department of Health and Human Services, 2018](#)).

- Drug overdose rates in the Central United States have grown dramatically over the last decade. Missouri, Oklahoma, and Wyoming have rates of overdose nearly double the rates of New York, California, Texas, or Virginia and nearly double the rates of Eastern rural states. Unfortunately, some central states still do not make naloxone available to the public, nor have they passed “Good Samaritan” laws protecting bystanders who report overdose incidents to emergency services, or who administer naloxone to someone who has overdosed. Some Central U.S. states with high levels of overdose have taken action to make overdose deaths less likely by making naloxone more available and its use in an emergency more protected ([Dombrowski, Crawford, Khan, & Tyler, 2016](#)).
- Prescription opioid use and abuse is increasingly becoming a public health crisis across the United States. Over the last two decades, opioid-related deaths have increased dramatically to become a serious public health concern. Opioid-related mortality rates have reached epidemic levels in rural areas of the United States, such as Appalachia, New England, and the Mountain West with rural counties having an 87% higher chance of receiving an opioid prescription compared to persons living in large metropolitan areas ([Mundell, 2019](#); [Rigg, Monnat, & Chavez, 2018](#)).
- Rates of opioid-related inpatient hospital stays, emergency room visits, and mortality are high in predominantly rural states like Maine, Kentucky, and West Virginia, but rates are lowest in other largely rural states such as Iowa and Nebraska ([Weiss et al., 2017](#)).
- Newer and less addictive types of pain control are needed ([Dryden, 2016](#)).

Cancer disparities are found in rural populations. Rural women are less likely to receive screening mammograms and Pap smears than urban women. In one study, cancer incidence was 447 cases per 100,000 in metropolitan counties and 460 per 100,000 in nonmetropolitan counties. Cancer mortality rates were 166 per 100,000 in metropolitan counties and 182 per 100,000 in nonmetropolitan counties. Higher incidence and mortality in rural areas were observed for cervical, colorectal, kidney, lung, melanoma, and oropharyngeal cancers ([Blake, Moss, Gaysynsky, Srinivasan, & Groyle, 2017](#)). Rural populations also have a lower proportion of colonoscopies to screen for colorectal cancer. Further, most rural physicians are trained as generalists, therefore not trained to perform colonoscopies ([Evans et al., 2015](#)).

Mental health is another concern in rural settings as 19.1% of rural residents 18 years and older had any mental health issue and 4.9% experienced serious thoughts of suicide ([RHIH, 2020b](#)). The prevalence of

mental health is similar between rural and urban, yet there are limited services available to address this issue in rural communities. Accessibility of services, availability of services, and acceptability are all barriers for those residing in rural areas ([RHHH, 2020b](#)).

Rural C/PHNs need to consider the *Healthy People 2030* objectives priority areas as guides for improving the health status of clients in rural communities.

## Community Health Nursing in Rural Settings

Most rural nurses working in the community are thought to have little education in public health, as the associate degree in nursing is often accepted by health departments in rural areas (Harris et al., 2015). However, rural areas promote a broad scope of C/PHN practice, as these nurses deal with a wide variety of issues—immunizations, home health, school nursing, maternal–child health, emergency preparedness, as well as communicable disease/epidemiology. Rural health departments are often lacking in technological and communication systems, but there is an even greater need for reliable communication capability and training opportunities for rural C/PHNs who provide the majority of care in rural and frontier communities (Knudsen & Meit, n.d.).

Rural community health nurses most often grew up in rural areas or lived for a time in small communities. They frequently have extended family, are active members of their community, and are highly respected professionals.

The rural community health nurse plays many roles:

1. *Advocate*: Assists rural clients, families, and populations in obtaining the best possible care
2. *Coordinator/case manager*: Connects rural clients with needed health and social services, often assisting with information on transportation
3. *Health teacher*: Provides education to individuals, families, or groups on health promotion or other health-related topics (e.g., prepared childbirth, parenting, diabetes maintenance, home safety)
4. *Referral agent*: Makes appropriate connections between rural clients and urban service providers
5. *Mentor*: Guides new community health nurses, nursing students, and other nurses new to the rural community
6. *Change agent/researcher*: Suggests new approaches to solving patient care or community health problems based on research, professional literature, and community assessment
7. *Collaborator*: Seeks ways to work with other health and social service professionals to maximize outcomes for individual clients and the community at large
8. *Activist*: With a deep understanding of the community and its population, takes appropriate risks to improve the community's health

Rural C/PHNs have the opportunity to use autonomy in daily practice. Nurses must rapidly assume independent and interdependent decision-making roles because of the small workforce and large workload. For nurses who live and work in rural areas, resources are limited and demands are many. Rural C/PHNs learn to prioritize tasks quickly and work efficiently with others to get the job done. Referrals to other rural providers are facilitated because providers frequently know one another. Rural C/PHNs

may experience the challenge of physical isolation from personal and professional opportunities associated with urban areas. Rural nurses may also feel isolated in their clinical practices because of the scarcity of professional colleagues (Box 27-5).

## **BOX 27-5 STORIES FROM THE FIELD**

**Frontier Nursing: Then and Now** As described in [Chapter 2](#), Mary Breckinridge founded the Frontier Nursing Service in 1925, with nurse–midwives providing care to clients in their own homes. Nurses traveled by horseback and on foot into the sparsely populated hollows of Kentucky ([American Association for the History of Nursing, 2018](#)). Today, NPs working in nurse-managed clinics in rural Appalachian communities in Virginia were interviewed about their practices, in a classic study by [Caldwell \(2007\)](#), and spoke about their connections to the people and communities they serve. One said, “Here you get to know the whole family and that is rewarding...you know what is important to them...what their worries and concerns are....so you probably get closer to your patient in this area than you might outside here. It becomes an extended family, which is very rewarding” (p. 76).

Another NP described a man with severe COPD who visited her clinic. He was also a patient of another area provider, but when the NP examined the man, she noticed the gauze 4× 4 he had on the back of his neck and enquired about it. The man said he “cut himself shaving.” The NP pressed the man to see the wound and found that he had “cancer with the bone exposed,” describing it as “the most awful thing that I had

ever seen in my life. I could put my fist in there. And you could see his carotids pulsating.” She told the patient how serious this was and arranged for a plastic surgeon to see him right away. He had a total neck resection and recovered completely. She reflected, “What if I had accepted his story about the sore and it being all right? It was not what he was coming to see me for...I look at more than just the chief complaint” (p. 77).

1. *What factors are important to consider when caring for clients in a rural setting?*
2. *What situations have you seen in rural settings?*
3. *Knowing more about rural health, would you do anything differently in this scenario?*

The rural community health nurse often receives a salary that is lower than that of urban nurses in comparable positions (Harris et al., 2015). However, there are benefits to rural nursing. Housing costs are usually lower than in larger cities and long commutes to and from work on congested highways are often avoided, although rural driving can be hazardous. As a place to live and raise a family, rural communities offer a slower pace of life, open spaces, and friendly atmosphere. The smaller system of health care in a rural community can be advantageous to the C/PHN. It may be easier to understand the system and initiate planned change.

However, many rural areas find it difficult to recruit nurses and need to more effectively advertise their benefits. When RN to population ratios are high in both rural and urban areas, years of potential life lost and rates of poor health are significantly improved, as well as rates of teen births and mammography; however, this association was shown to improve even more as the level of rurality increased demonstrating the importance of adequate nurse staffing in all areas (Fields, Bigbee, & Bell, 2016).

# MIGRANT HEALTH

Have you ever thought about the people who harvest the fruits and vegetables that you eat? Have you ever thought about who they are, where they come from, where they live, or what their health is like? What would happen to the complex system of agricultural production and distribution if workers were not available to pick crops at peak harvest times? Whatever your political, social, or ethical views on this subject, migrant workers and their families often cross paths with C/PHNs, and we need to understand them in order to effectively provide care ([Box 27-6](#)).

## **BOX 27-6 What Do *You* Think?**

**Undocumented Migrant Workers** There are many critics of undocumented migrant workers. Some feel that their willingness to work for low wages keeps overall wages lower for everyone working in agriculture, while others feel that migrants are taking jobs away from Americans. The United Farmworkers, an agricultural worker union, introduced the *Take Our Jobs* program in 2010 to address these issues. Unemployed Americans were invited to work in the fields along with migrant farmworkers, but very few accepted this invitation; those that did attempt it had a difficult time keeping up with the grueling pace of work. Stephen Colbert, a television show host and comedian, picked beans and packed corn as part of the challenge, and filmed some of his workday experiences for his late-night show. He also gave testimony to

**Congress on the need for better wages, living conditions, and visa programs for these workers. What do you think about the issue? You can view this testimony first-hand in the following video (<https://www.youtube.com/watch?v=0TYyeNU8Wvc>). You can also view Charlie LeDuff taking this migrant challenge in the San Joaquin, California fields (<https://www.youtube.com/watch?v=J7TGWaHaUeU>).**

In addition, a government project was trialed in 1965, when the Bracero Agreement between the United States and Mexico, providing Mexican agricultural workers in the U.S. fields, expired. Farmers complained, stating that crops would rot in their fields. Therefore, project A-TEAM was created—Athletes in Temporary Employment as Agricultural Manpower. A nationwide call was placed to recruit high school boys, providing field labor as their summer job. Although initially 18,000 were registered, only 3,300 actually worked in the fields. Ironically, even though the initial intent was to recruit “jocks,” many of the recruits were not athletes but just boys looking for summer jobs. The boys were paid minimum wage—\$1.40 per hour at that time—plus a small stipend for filling crates with fruits or vegetables (i.e., 0.05 cents for every crate filled with 30 to 36 cantaloupe). Work was hard, days were long, temperatures were hot, and the boys were not allowed to return home until summer's end. Many of the boys did not last the entire stint. A university history professor, Lori Flores, was quoted as saying “The A-TEAM reveals a very important reality: It's not about work ethic for undocumented workers. It's about the fact that this labor is not meant to be done under such bad conditions and bad wages” (Arellano, 2018, p. 7). The A-TEAM was considered a giant failure and was never tried again!

**Migrant farmworkers** are an integral part of the farming community in the United States and across the world. In fact:

- The agricultural industry relies heavily on migrant workers to harvest the almost endless array of fresh produce that appears year-round in supermarkets across the United States as fresh, frozen, and canned fruits and vegetables.

- Opponents of immigration restrictions predict that imposing them would jeopardize the supply of labor available to farmers during critical plant and harvest seasons. They contend that more restrictive immigration policies could lead to reduced profits for some farms and threaten the sustainability of agricultural sectors that are heavily dependent on farm labor, especially fruit, tree nuts, vegetables, and horticulture ([USDA, 2020](#)).
- More than 3 million seasonal and migrant farmworkers provide labor for the \$28 billion vegetable and fruit crops of the United States ([National Center for Farmworker Health \[NCFH\], 2018a](#)).
- Many of these workers are unauthorized or illegal immigrants to the United States, often from Mexico. The vast majority entered this country in an unauthorized manner.

# AGRICULTURAL LABOR AND IMMIGRATION POLICIES CHANGING

Despite their importance to American agriculture, migrant workers often go unnoticed beyond the fringes of the camps and farms to which they travel in order to pursue their livelihood. The number of migrant agricultural workers there are in a particular region, state, or even in the nation is difficult to estimate due to high mobility, language and cultural differences, and varying levels of citizenship status (NCFH, 2018a). California, Texas, Washington, Florida, Oregon, and North Carolina currently have the highest number of migrant farmworkers (NCFH, 2018a). They come with the hope of bettering their impoverished lives. Some are legal residents, but most are undocumented aliens and live in fear of deportation. All endure backbreaking, menial labor for low wages and are often deprived of basic rights to safe working conditions, adequate sanitation/housing, health care, and a quality education for their children (see [Boxes 27-7](#) and [27-8](#)).

## **BOX 27-7 U.S. Migrant Worker Demographics**

### **Origin and Nationality**

- Most are foreign-born (73%), with about 69% from Mexico.
- Forty percent have been in the United States 20 or more years, while 35% for 10 to 19 years.
- Forty-seven percent of the crop workers are unauthorized, 31% are citizens, and 22% have work visas.

### **Age**

- The age of agricultural workers in the United States has been increasing since 2000.
- Seventeen percent are between the ages of 14 and 24, compared to 35% in 1999 to 2000.
- Twenty-seven percent are between 25 and 34 years.
- Twenty-four percent are between 35 and 44 years.
- Eighteen percent are between 45 and 54 years.

- Fourteen percent are 55 years or more, compared to 5% in 1999 to 2000.

## **Sex/Marital Status/Offspring**

- Seventy-two percent of agricultural workers are male, and 28% are female.
- Sixty-three percent are married, 29% are single, and 8% are divorced.
- Fifty-seven percent are parents, 29% have one to two children, and 14% have three or more children in the household.

## **Education**

- Thirty-six percent have completed grades 1 to 6.
- Twenty-one percent have completed grades 7 to 9.
- Twenty-eight percent have completed grades 10 to 12.
- Eleven percent have completed education beyond grade 12.

## **English Language**

- Twenty-seven percent cannot speak English “at all.”
- Forty-three percent speak English “a little” or “somewhat.”
- Thirty-one percent speak English “well.”

## **Migrant Status and Seasonality**

- Approximately 16% of farmworkers are considered migrant (traveling 75 miles to obtain farm jobs).
- Many travel to multiple farm sites within a year.
- About 84% are considered seasonal agricultural workers.
  - Most (41%) work in fruit and nut crops.
  - Others (22%) work in horticulture (22%) and vegetables (21%) (NCFH, 2018a).

## **Compensation**

- Only 8% of U.S. migrant farmworkers are salaried.
- The majority are paid low hourly wages (83%) or by the piece (9%).

Source: [National Center for Farmworker Health \(NCFH\) \(2018a\)](#).

## **BOX 27-8 STORIES FROM THE FIELD**

**A Case of Active Tuberculosis in a Rural Community As the C/PHN in a rural community, I received many types of referrals for families including maternal child, older adults, child abuse, or communicable disease cases. The small public health district office was located in a small agricultural town of approximately 20,000 people, with a large Spanish-speaking population. One day, I responded to a new, active tuberculosis (TB) case. A 20-year-old Hispanic male had been in the county hospital and was on respiratory isolation, I would need to examine his living conditions and his contacts.**

Gregorio explained that he and his brothers had traveled from his home country of Chiapas, Mexico, to the United States. There were 20 names in total that were close contacts and needed follow-up. They lived in a two-bedroom home, without furniture, and each man took a spot on the floor to sleep at night. One by one, each was interviewed for TB risk assessment and a TB skin test was placed. On return to the home in 2 days, skin tests were read, and those who had positive tests were referred to the community health center for chest x-rays.

Gregorio was hospitalized until he was no longer communicable. The county health department instituted daily directly observed therapy (DOT) and assisted with transportation to medical appointments.

- 1. What do you see as the role of the community health nurse in this situation?*
- 2. Discuss how communicable disease control and surveillance looks different in a rural setting.*

—Judy H. Pedro, MSN, RN, APHN-BC

The United States has passed legislation affecting agricultural workers. States across the nation have implemented policies to address growing numbers of unauthorized workers, whether they work on farms or elsewhere. In over 20 states, legislatures have passed laws that penalize employers who knowingly hire unauthorized workers. At least 100 municipalities around the nation have proposed or enacted ordinances that penalize businesses for hiring and landlords for renting to unauthorized workers ([USDA, 2018](#)).

The H-2A Temporary Agricultural Program provides a legal means to bring foreign-born workers to the United States to perform seasonal farm labor on a temporary basis; these consist of crop farmers and producers of livestock. Employers must demonstrate, and the U.S. Department of Labor must certify, that efforts to recruit U.S. workers were unsuccessful. Employers must also pay a state-specific minimum wage, provide housing, and pay for transportation. One of the most significant indicators of the scarcity of farm labor is the fact that H-2A employment applications and certifications have quadrupled in the past 12 years, increasing from just over 48,000 positions certified in 2005 to 200,000 in 2017 ([USDA, 2018](#)). With the H-2A visa, there are restrictions against farmworkers changing employers, and this could affect their work safety climate ([Arcury et al., 2015](#)).

## **Migrant Farmworkers: Profile of a Nomadic Population**

Maintaining a low public profile, migrant workers are often marginalized from mainstream society. They remain unseen, unheard, poorly understood, and excluded from many programs that provide health care assistance for low-income people.

- The migrant worker is a kind of disenfranchised person, for whom many do not want to take responsibility. Yet the needs of these workers are great. They are plagued with different, more complex, and more frequent health problems than the general population ([Migrant Clinicians Network, 2017a](#)).
- Common ailments include infectious diseases (e.g., TB, parasites), gastrointestinal disorders, dermatitis, pesticide exposure, emotional distress and depression, vision and eye problems, cancer, and chronic illnesses, such as asthma, bronchitis, diabetes, and hypertension.
- They are often afflicted by poverty, poor nutrition, substandard housing conditions, extended working hours, and grueling, often unsafe, working conditions.
- Their demographics, socioeconomic conditions, and lifestyle resemble those of a low-income country, despite the fact that they live and work in one of the most prosperous nations in the world.
- Although migrant families are in dire need of health resources, various economic, cultural, and language barriers prevent this aggregate from accessing available health services. Poverty, frequent mobility, low literacy, and language and cultural barriers impede farmworkers access to cost-effective health care and social services.
- Approximately 30% of all agricultural worker households had total family incomes below the U.S. government's poverty guidelines. The average wage earned by a migrant worker was \$10.19 per hour. Further, only 51% of agricultural workers reported being covered by workers' compensation insurance ([NCFH, 2018a](#)).

Migrant workers often live and work in areas where health care practitioners are in short supply. Among Latino immigrants, common barriers to utilizing the health care system include access to insurance, limitations in the type of health care utilized, discrimination in health care services, immigration fears, stigmas, lack of social and financial capital, communication problems, and long waiting periods for access to health care ([Migrant Clinicians Network, 2017a](#)). Additional barriers include limited transportation, prejudice because of immigrant status, mistreatment because they are “undocumented,” lack of time-efficient health care delivery

methods, increasing cost of health care, and needing services not being offered (NCFH, 2018a). Migrant workers may use traditional cultural remedies and folk healers, if available, but often also use low-cost, over-the-counter medications, and professional health care systems, blending both traditional and U.S. health care practices (McCullagh, Sanon, & Foley, 2015).

## *Historical Background*

Both historically and internationally, farmers have rarely been able to permanently employ the large workforces needed to harvest their crops.

- Throughout the 19th century, however, the small, family-owned farms typical in the United States got through the harvest by using schoolchildren, neighbors, and local day laborers. As time went by, this became more difficult to accomplish.
- During the 1920s, over half a million Mexicans migrated to the United States, many drawn to work in seasonal agriculture. With the Great Depression, many of the small, independently run farms went bankrupt, and citizens were concerned about limited employment opportunities.
- The United States has experienced farm labor shortages for the past century, becoming more severe during World War II. To meet the demand for farm laborers, the Bracero Program was created in 1942, which allowed over 4 million guest workers to come in from rural, poor areas in Mexico due to agricultural worker shortages in the United States.
- In 1964, the program was replaced by the H2 Temporary Guest Worker program, with H-2A being agricultural workers and H-2B being guest workers who perform nonagricultural work.
- In 2016, the U.S. Department of State certified 165,741 H-2A visas out of 172,654 that were requested (NCFH, 2018a).
- In 2016, the states with the highest numbers of H-2A workers were Florida, North Carolina, Georgia, and Washington (Figueroa, Moberg, & Hennen, 2017).
- Some studies have noted an increase in the agricultural worker population over the last decade, and the presence of agricultural workers has been shown to increase the overall economic output of the regions in which they work. In fact, research conducted about the agricultural economy of Michigan found that agricultural workers contributed over \$23.3 million dollars to the state's economy annually by enabling farmers to produce higher-value crops, after wages and housing were deducted. Stringent immigration laws passed in Arizona and Georgia demonstrated the devastating impact of farm labor shortages (NCFH, 2018a).

Living apart from society, the plight of migrant farmworkers was largely ignored until exposure on a 1960 television documentary—Edward R. Murrow's *Harvest of Shame*—created a national outcry. This led to the passage of the Migrant Health Act of 1962, which addressed the specific health needs of migrant workers for the first time in U.S. history. This act authorized delivery of primary and supplementary health services to migrant farmworkers (NCFH, 2018a). Federally funded migrant health clinics serve areas in the United States where significant number of migrant farmworkers gather. In 2010, 165 migrant clinics served more than 863,000 seasonal and migrant farmworkers and members of their families, a number far below the estimated 3+ million farmworkers thought to be in this country. Eligibility for services at the clinics includes being principally employed in agricultural labor for the prior 24 months (Farmworker Justice, 2020). Services may be provided seasonally, on a temporary basis, or year-round. Staffing usually includes doctors, nurses, NPs, PAs, outreach workers, social workers, and dental and pharmacy workers, along with health educators.

Transportation may also be a component in some areas. Primary and preventive health care services are provided to migrant workers and their families throughout more than 500 clinic sites. However, funding is often inadequate, and many clinics are not sufficiently staffed or operated to meet the health needs of migrant farmworkers and their dependents. Most migrant health centers receive funding from a variety of sources, including Medicaid in some instances. Additionally, although these clinics exist throughout the United States, large geographic regions are not served well or at all. Other services, such as *promotora programs* that employ Hispanic lay health workers or nursing voucher programs providing health care services at participating clinics and nurse referrals to specialists, are available in some areas. Encouraging recruitment of these health workers targeting Latino communities, especially underserved ones, could potentially increase Latinas' interest in serving as *promotoras*, improve the quality of *promotora* work, and more fully engage Latinos in community health programs to address their health issues (Molokwu, Penaranda, Flores, & Shokar, 2016; Schwingel et al., 2017).

## *Migrant Lifestyle*

To understand the health needs of migrant farmworkers and their families, it is important to realize their lifestyle. Migrant workers and their families endure a transient and uncertain life, with long hours, stressful working conditions, low wages, and poor health care. Substandard housing, unsafe working conditions, and language barriers make life even more difficult (USDHUD, 2016). In addition, about 25% of migrant farmworkers have been in the United States for under 1 year; therefore, American customs and

behaviors may be foreign to them ([Rao, Hancy, Velez, Freeman, & Davis, n.d.](#)).

- Migrant workers are exposed to environmental hazards such as pesticides, extreme temperatures, and chemicals.
- Up to 20,000 pesticide injuries are reported yearly of the 2 million agricultural workers in the United States.
- Those in agriculture and farming are at risk for musculoskeletal injury. In addition, limited or no PPE may be provided.
- Workplace demands such as pressure to work without breaks coupled with fear of job insecurity and deportation affects workplace stress ([Moyce & Schenker, 2018](#)).

Depending on the economy and the crop, a migrant farmworker's income varies widely. Migrant farmworkers' average annual income is \$11,000; for a family, it is approximately \$16,000. This makes farm work the second lowest paid job in the nation (after domestic labor). Even so, despite their poverty, most farmworkers are not eligible for social services. Less than 1% of all farmworkers use general assistance welfare, 2% use social security, and fewer than 15% are Medicaid recipients ([NCFH, 2018a](#)).

## *Migrant Hero*

César Chavez founded the National Farm Workers Association (NFWA; later changed to United Farm Workers [UFW]), the first union in agricultural labor history to successfully organize migrant farmworkers.

- As a child, he traveled with his family to harvest crops, but they rarely had enough food to eat and often lived in shacks.
- Work was frequently scarce, wages were low, and labor contractors cheated the family out of the money they earned.
- Moving to California during the Great Depression, the family became part of the migrant community.
- Chavez attended as many as 65 different schools and dropped out of school upon completing eighth grade, to help support his family by working full time in the fields ([Biography, 2019](#)).
- Chavez organized many successful strikes and boycotts, the most famous one being the boycott of California grapes as a protest against the indiscriminate use of spraying by growers in 1968. This boycott lasted for longer than 5 years, and on two occasions, he fasted as a protest against the use of agricultural pesticides. His efforts united people who, as individuals, had no significance in the power structure.
- His legacy is an example of how people can unite to build power together. He achieved great recognition, although he never had the financial trappings of success.

- Throughout his life, he ignored personal hardships to continue the struggle with union victories and losses. Chavez and his union won several victories for migrant farmworkers when many growers signed contracts with the union.
- As a labor leader, Chavez employed nonviolent means to bring attention to the plight of farmworkers. He led marches, organized boycotts, and went on several hunger strikes ([Biography, 2019](#)).

## Health Risks of Migrant Workers and Their Families

Poverty, transient lifestyle, low literacy, language barriers, and cultural barriers impede migrant workers' access to social services and cost-effective health care (MCN, 2017a). In addition, migrant workers who use health services must overcome other issues: limited means of transportation, lack of time-efficient health care delivery methods, and the medical referral system. In some areas, federally funded health centers are available to provide services to populations with limited access to health care. These include low-income populations, the uninsured, those with limited English proficiency, agricultural workers, individuals and families experiencing homelessness, and those living in public housing (NCFH, 2018a). In 2015, the Health and Resources Services Administration (HRSA) of the U.S. Department of Health and Human Services reported that the health center program provided health care to 910,172 agricultural workers and their families, with 92% covered by specific funds to provide services to this population. According to National Center for Farmworker Health (NCFH) (2018a) data, the most common diagnoses reported by these Health Centers for migrant workers included the following:

- Overweight/obesity
- Hypertension
- Diabetes mellitus
- Otitis media and eustachian tube disorders
- Depression and other mood disorders

Migrant workers who are lawfully in the United States (including H-2A workers) may receive coverage under the ACA. Legal farmworkers whose income is below 138% of the federal poverty line may receive health care through Medicaid. Workers unauthorized cannot receive health insurance (MCN, 2017a).

Undocumented migrant farmworkers are “10.7 and 3% less likely to use U.S. and foreign health care, respectively, compared to documented farmworkers” (Luo & Escalante, 2018, p. 923). Health insurance has been found to significantly increase hired migrant farmworkers' use of U.S. health care by 22.3%. Notably, compared to their documented working peers, undocumented migrant farmworkers are less likely to utilize private health clinics and are even less likely to rely on migrant health centers, even when these providers are their most viable sources of health services (Luo & Escalante, 2018). National statistics on migrant seasonal workers are sparse, with much of the data regional and only sporadically collected. Some of the statistics include the following:

- Migrant workers are a vulnerable and underserved population, with an average life expectancy of 49 years, compared to 77.2 years for most Americans. They have a greater disease burden than other populations and work in occupations with high hazard levels.
- TB rates tend to be 6 times higher for migrant workers and are at increased risk for contracting a viral, fungal, bacterial, and parasitic infections ([La Cooperativa, 2020](#)).
- Migrant children are often delayed for immunizations and have an increased incidence of TB; intestinal parasites and infections; nutritional deficiencies and malnutrition; skin, respiratory tract, and ear infections; dental problems; and pesticide and lead exposure ([SAF, 2011–2019](#)).
- Migrant workers have high rates of work-related conditions, such as musculoskeletal injuries, lacerations, falls, heat stress, eye injuries, hearing loss, and skin diseases, because of equipment use and exposure to pesticides and other chemicals, dust, exposure to hot and cold extremes, and sun exposure ([MCN, 2017a](#)).
- Migrant children are often exposed to heat and sun, musculoskeletal injuries, pesticides, and hazardous tools and machinery ([NCFH, 2018b](#)).
- The data indicate that HIV/AIDS is escalating among migrant farmworkers and that steps need to be taken to prevent the impact among the population and their families. Recommendations are provided for improving health outcomes among migrant workers, preventing HIV transmission, and providing continuous comprehensive care and support for HIV-infected migrant farmworkers ([CDC, 2020](#)).
- Poverty, migration patterns, lower educational level, and language barriers may make it harder for some Hispanics/Latinos to get HIV testing and care. Undocumented Hispanics/Latinos may be less likely to use HIV prevention services, get an HIV test, or get treatment for HIV because of concerns about being arrested and deported ([CDC, 2020](#)).
- Migrants disproportionately suffer from the effects of COVID19 due to economic hardships brought on by shutdowns and social distancing; contagion risk due to overcrowding, predisposed health issues, lack of access to health care, and uninsured status; and as targets for hate and discrimination ([Migrant Policy Institute, 2020](#)).

### *Occupational Hazard*

The hazards of agricultural employment, coupled with limited legal protection, jeopardize the health of the migrant farmworker. Migrant workers have higher rates of adverse job-related exposures and working conditions, which lead to poor health outcomes, injuries, and occupational fatalities. Health disparities of migrant workers are related to environmental and occupational exposures, as a result of language/cultural barriers, access to health care, documentation status, as well as the political climate of the host

country (Moyce & Schenker, 2018). In a Canadian study with migrant workers, participants reported that they did not speak up when they saw unsafe workplace practices and even did not report their injuries for fear of losing employment and fear of retaliation (Yanar, Kosny, & Smith, 2018). Falls, cuts, muscle strains and sprains, and repetitive motion injuries (e.g., carpal tunnel syndrome) commonly afflict migrant laborers. Migrant and seasonal farm work typically requires stooping, long hours working in wet clothes, working with sometimes contaminated soil and water, climbing, carrying heavy loads, and exposure to the sun and the elements. Failure to perform these activities on a rigid timetable dictated by seasons and weather can result in crop loss. This urgency compels farmworkers to labor in all weather conditions, including extreme heat or cold, rain, bright sun, and high humidity.

- Migrant workers are among the most vulnerable members of society. They are often engaged in what are known as “3-D jobs—dirty, dangerous, and demanding (sometimes degrading or demeaning)”—and these workers are often hidden from the public eye and from public policy.
- They work for less pay, for longer hours, and in worse conditions than do nonmigrants and are often subject to human rights violations, abuse, human trafficking, as well as violence.
- Migrant workers are more likely to take greater risks on the job, do work without adequate training or protective equipment, and do not complain about unsafe working conditions (Moyce & Schenker, 2018).

### *Pesticide Exposure*

Migrant farmworkers may be at higher risk of exposure to cancer-causing chemicals than the general population (Fig. 27-11). They are exposed to pesticides used routinely in the fields: picking produce that has been sprayed; walking behind farm equipment that is mobilizing dirt that has been treated; contact with pesticide spray from a neighboring field; bringing home pesticide residue on their clothes and shoes; or exposure to chemical residues in the soil, air, food, and well water (MCN, 2017a).

**FIGURE 27-11** A crop duster applies chemicals to a field of vegetation.

- A large body of evidence exists on the role of pesticide exposures in the increased incidence of human diseases such as cancers, Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis, asthma, bronchitis, infertility, birth defects, ADHD, autism, diabetes, and obesity ([Mostafalou & Abdollahi, 2017](#)).
- A study by [Butler-Dawson, Galvin, Thorne, & Rohlman \(2016\)](#) indicated that children in farming communities are at increased risk from pesticides due to a parent working in agricultural. Further, organophosphate exposure may be associated with deficits in learning on neurobehavioral performance, especially in tests of motor function. Even though this pesticide is being phased out in the United States, we still see elevated levels in agricultural households.
- While research shows pesticide-associated cancers are higher in farmworkers, data strongly suggest that cancer is even higher in farmworker children. This is due to “a number of predisposing events occurring prior to conception, in utero, and/or after birth” likely resulting in a greater incidence of pesticide-related cancer in farmworker children ([National Center for Farmworker Health, 2018b](#)).

Pesticide exposure levels in reproductive-age farmworkers consistently exceed levels in the general population. It is estimated that thousands of farmworkers suffer pesticide poisoning each year, but exact counts are not possible because of inadequate surveillance systems and reluctance of farmworkers to report injuries ([Farmworker Justice, 2020](#)). Surveillance systems are only in place in 11 states; the Sentinel Event Notification System or Occupational Risk (SENSOR) is a means of reporting pesticide-related injuries as well as other occupational illnesses and injuries ([CDC/National Institute for Occupational Safety & Health, 2017](#)). Some farmworkers,

primarily those without H-2A visas, were less likely to be provided pesticide safety equipment and often were not notified when pesticides were applied. Reporting of pesticide-induced morbidity and mortality is not required in every state. California has the oldest and most thorough pesticide surveillance system in the United States, beginning in 1971 that requires health care providers to contact their LHD whenever they suspect an illness or injury is related to pesticide exposure. The health department then alerts the county agricultural commissioner and also completes a Pesticide Illness Report ([California Department of Pesticide Exposure, 2020](#)).

But, even with reporting laws, many cases are never recognized because workers do not seek medical care. Pesticide burns and rashes often go untreated because of lack of education about the dangers of pesticides and lack of available services. Migrant workers are often unaware of the hazards of pesticides.

- [Arcury et al. \(2018\)](#) found that migrant farmworkers and nonfarmworkers had detections for pesticide and herbicide urinary metabolites.
- [Griffith et al. \(2018\)](#) compared children's pesticide exposures by expressing the child's pesticide metabolite concentration as a fraction of the adult's concentration living in the same household. Exposures in their community were consistently higher, often above the 95th percentile of the exposures reported by the National Health and Nutrition Examination Survey (NHANES).
- [Plascak et al. \(2018\)](#) determined that dimethyl OP house dust concentrations were 400% higher within homes where at least two residents were agriculture workers.
- Pesticide drift has been shown to result in elevated levels of active compounds in both indoor air and house dust in homes near agricultural application areas. Houses closer to agricultural herbicide applications had significantly elevated levels of herbicides in house dust than in homes that were further away ([Shelton & Hertz-Picciotto, 2015](#)).
- Orchard air-blast applications of pesticides, along with wind direction, can influence pesticide drift from crops into agricultural residences; potential exposures can be analyzed through screening tests ([U.S. Environmental Protection Agency, 2018](#)).

Even though it may be required of health care providers to report pesticide poisoning, it is often misdiagnosed because the symptoms can mimic those of viral infections or heat-related illness. Symptoms of pesticide exposure include sore throat, runny nose, headache, fatigue, red/swollen/watery eyes, drowsiness, itchy skin, abdominal pain, and nausea or vomiting. More severe symptoms may include sweating, salivation, blurred vision or pinpoint pupils, fever, severe thirst, muscle twitching, or

weakness and incontinence (especially with organophosphate or carbamate exposures). Finally, with the most severe exposures, seizures, respiratory depression, and unconsciousness or coma can occur. There are over 19,000 pesticide products registered with the EPA and more than one thousand active ingredients (U.S. Environmental Protection Agency, 2018). Only a few categories of pesticides account for more than half of the cases of acute illness; these include inorganic compounds, carbamates, pyrethroids, and organophosphates. Although the impact of acute pesticide poisoning is widely recognized, little is understood about the long-term effects of the repeated low-level exposures to which migrant farmworkers are constantly subjected. The Florida Department of Health lists the chronic effects of long-term pesticide exposure as birth defects, cancers, blood disorders, neurological problems, and reproductive issues. Extreme exposure can lead to loss of consciousness, coma, or death (NCFH, 2018a). Numerous studies have examined the link between exposure to pesticides and various neurologic problems and cancer—most often with organophosphate-based pesticides. Some evidence of an association between pesticide exposure and the incidence of diabetes has been found (Grice et al., 2017). Prenatal exposure to organophosphate pesticides has been significantly associated with slightly decreased intellectual development (Hertz-Picciotto & Sass, 2018). Today, it is more common for farmworkers to be exposed to “nonpersistent” pesticides that are metabolized in the body within days (NCFH, 2018a).

The Environmental Exposure History, I PREPARE in Chapter 9, is a helpful assessment tool for community health nurses working with migrant and seasonal workers to use to determine pesticide exposure. When a client presents with symptoms that may be suggestive of pesticide exposure, mnemonic prompts may help to clarify common symptoms (Box 27-9).

Pesticide exposure can be a single event, may occur multiple times, or can even be continuous. Health effects are thought to be a function of the frequency of exposure and the dose. Most migrant workers come into contact with pesticides through their work. However, exposure to pesticides does not affect only those working in the fields.

- Organophosphates decrease the levels of acetylcholinesterase, found in nerve endings, and can be absorbed through the skin, inhaled, or ingested. Most workers have metabolites present, and farm work and housing close to agricultural fields are common factors associated with exposure ([Chem-Tox.com, 2019](#)).
- Drifts from sprayed fields and residues on farmworker clothing, shoes, tools, and skin, as well as food brought from the fields, are all potential sources of exposure. Vehicles can also become contaminated, as can carpets and furniture. Contaminated clothing should be kept in separate hampers and laundered separately; workers need to be encouraged to leave boots and shoes outside their homes and to change clothing and shower before eating and playing with their children. Substandard housing is also a factor.

Agricultural fields are usually located in isolated areas on the outskirts of rural communities ([Fig. 27-12](#)). While in these isolated fields, migrant workers often are not provided with sanitation facilities or fresh drinking water. Farmworkers experience more heat fatalities than any other group of outdoor laborers. Migrant farmworkers are often paid by the piece instead of the hour, which incentivizes the workers to not stop for breaks. This is a ploy that employers use to get the workers to work faster and harder ([Moyce & Schenker, 2018](#)). Migrant farmworkers also face many cultural barriers that leave them “marginalized and unempowered” ([Kearney, Hu, Xu, Hall, &](#)

Balanay, 2016). These cultural barriers are often the reason that many employers do not offer sufficient safety education, shade, hydration, and cooldown rest to prevent heat-related illnesses. Employers must show the employees how important their safety and well-being is to them, while also take proactive measures to conduct risk assessments and health education to reduce unnecessary deaths and prevent heat-related injuries for agricultural workers (Kearney et al., 2016). In fact, it is the employer's responsibility to encourage workers to drink sufficiently to maintain hydration; to ensure water availability; to facilitate worker access to water, shade, and other resources; to provide regular rest breaks of appropriate duration for the work conditions; and to monitor workers for signs of illness (Kearney et al., 2016). California and Oregon have implemented such standards.

**FIGURE 27-12** Fields in Eastern Oregon. (Source: USDA, Agricultural Research Service.)

## *U.S. Laws Enacted to Protect the Migrant Farmworker*

Below are some of the laws that have been enacted to protect migrant farmworkers and their families. Even so, despite difficult working conditions, farmworkers in the United States are excluded from many federal-level labor protections ([Rodman et al., 2016](#)).

- The Migrant and Seasonal Agricultural Worker Protection Act (MSPA) (1992/revised in 2015): protects migrant and seasonal agricultural workers through the establishment of standards relating to wages, housing, transportation, disclosures, and record-keeping. This act also mandates that farm labor contractors register with the U.S. Department of Labor ([NCFH, 2018a](#)).
- Occupational Safety and Health Act (1970): specifies that agricultural employers with 11 or more employees who conduct hand labor operations in a field must provide drinking water at a suitable drinking temperature, toilet and handwashing facilities within a reasonable, accessible distance, and the employee must be notified by the employer of the location of such facilities ([NCFH, 2018a](#)).
- Agricultural Worker Protection Standard (1992/revised in 2015): Enforced by the Environmental Protection Agency (EPA), this standard is primarily focused on the safe handling of pesticides. It now prohibits children under the age of 18 from handling pesticides, requires that workers do not enter areas recently sprayed with pesticides, and improves protection for workers from retaliation if they make complaints about standard violations ([NCFH, 2018a](#)).
- Immigration and Nationality Act: The H-2A portion of this act offers protections for H-2A workers concerning: pay rate; written notification of a work contract with beginning and end dates; the three-fourths guarantee (employee must guarantee employment for at least 75% of the contract period); housing will be provided at no cost to the employee; and the employer will be responsible for transportation to and from work as well as to and from their country of origin ([NCFH, 2018a](#)).
- Title VII of The Civil Rights Act of 1964: This act initially involved the prohibition of employment discrimination based on race, sex, color, national origin, and religion. Multiple amendments of this act are especially significant for female migrant farmworkers. Title VII protects employees of both sexes against sexual harassment such as: Quid pro quo (offering a professional benefit in exchange for sexual acts); hostile environments (sexual comments, suggestive physical contact, or showing sexual materials); and retaliation (punishment from the employer for reporting or formalizing a complaint on sexual harassment) ([NCFH, 2018a](#)).

### *Substandard Housing and Poor Sanitation*

Quality of housing affects farmworker health ([Wiltz, 2016](#)). Formal demographic data on farmworker housing are often lacking. Migrant worker housing is often substandard or nonexistent.

- In 1989, the North Carolina Legislature passed the Migrant Housing Act of North Carolina, establishing minimum standards for agricultural worker housing. The Migrant Housing Act requires that any person owning or operating a housing unit for migrant workers and their dependents register with the North Carolina Department of Labor and have the housing inspected prior to the migrants moving in so that corrections needed can be made ([Langley et al., 2017](#)).
- Investigative reporting on migrant housing found that in seven states along the midwest and southern territories found mold, sewage, faulty electrical wiring, and pest infestation. To improve living conditions for workers some states have offered tax credit for investors who build farmworker housing ([Wiltz, 2016](#)). There is much room for sustained advocacy and action for migrant farmworker housing as access to adequate and safe employer-provided housing for migrant farmworkers is needed.
- Over the last decade, governmental agencies and nonprofit groups have become more interested in the improvement of agricultural worker housing conditions. The U.S. Department of Agriculture's Rural Housing Service, the U.S. Department of Labor, and the U.S. Department of Housing and Urban Development all provide housing services to agricultural workers and can be contacted with agricultural worker housing questions. Some of these programs include the Farm Labor Housing Loans and Grants Program, the National Farmworker Jobs Housing Assistance Program, and the Family Self-Sufficiency Program ([NCFH, 2018a](#)).
- In a classic article by [Cole and Crawford \(1991\)](#), a vivid example of one migrant camp in Alabama highlighted workers living in a converted chicken house. An upper portion of the wall had been removed for ventilation, creating easy access for insects and birds. A dirt floor, a single light bulb, and two portable toilets located a distance away were some of the other features. Two sinks in a common living area provided the only water for the almost 60 people who lived in the chicken house. Many did not have mattresses, and because the workers were harvesting potatoes, potato baskets often served as the only furniture.
- Such living situations still exist today. Living with 13 other workers in a three-bedroom home in Watsonville, California, a female farmworker remarked, “We have to put up with this because we can't afford anything else” ([Holden, n.d.](#), p. 40).

Migrant farmworkers move frequently, and often have great difficulty securing adequate housing. Farmers who hire workers on H-2A visas are required to provide free housing, but this accounts for only 2% to 5% of the workers. For farmworkers who don't live in state-licensed or inspected facilities, they may live in unregistered labor camps or rely on the private housing market ([Wiltz, 2016](#)).

Although data on migrant housing are scant, surveys have uncovered the following:

- Over 50% of all housing units surveyed were overcrowded (compared to only 3% of U.S. households), and 44% of mobile homes were substandard.
- Approximately 25% of the units surveyed had at least one broken appliance or fixture, and 11% had no working stove.
- Between 13% and 39% of housing is owned by employers, and for those lucky enough to find employer-owned housing, over half of those units were offered without charge.
- Agricultural employers most commonly own single-family homes (39%), apartments (14%), dorms/barracks (4%), motels (2%), and some even reported living conditions not meant for human habitation such as in cars, tents, and outdoors (2%).
- Over 25% of housing units were located adjacent to agricultural fields, and more than half of these had no working shower/tub.
- Families with children occupied 65% of moderately or severely substandard units ([HAC, n.d.](#)).

Substandard housing is not the only concern. Crowding is also a problem, as many farmworkers, unable to find sufficient numbers of rental units, share housing—sometimes paying per person costs. One of the few studies on migrant housing found that Minnesota seasonal vegetable workers' construction trailer barracks, housing 15 to 20 single migrant workers, rented for \$90 per month per person ([Migrant Housing, n.d.](#)). When housing cannot be found, workers and families may have to resort to paying rent to live in garages, barns, sheds, chicken coops, or they may be forced to stay in their cars.

### *Poor Nutrition, Overweight, and Obesity*

Migrant and seasonal farmworkers and their families have higher rates of obesity and are more likely to be obese and overweight ([Lim, Song, & Song, 2017](#)). Despite often working among fruit and vegetable crops, migrant families often have difficulty procuring food and maintaining a sufficient supply. Farmworkers constitute a vulnerable population with several characteristics that put them at risk for poor dietary quality: low income,

food insecurity, rural isolation, poor housing, and lack of access to food subsidy programs. In addition, parental feeding styles may underlie poor dietary quality for children in farmworker families, where dietary quality is poor. Because of the connections of diet quality to obesity and the negative health outcomes of obesity, interventions to improve dietary quality for migrant farmworker families are necessary (Quandt et al., 2016). Quandt et al. (2018) also found that less than one in five migrant families supplement meals with garden produce and food from food pantries, farmers markets, and hunting, and fishing. Approximately one half of lunches and 25% of dinners are purchased from vendors or other commercial sources, while 20% report issues with food security. Food-related practices of migrant farmworkers require change to improve the inclusion of fresh produce and other nutrient-dense foods. Common health problems of migrant children are similar to their parents and include general poor nutrition, anemia, vitamin A deficiency.

### *Risks to Social, Emotional, and Behavioral Health*

- Migrant children are often called upon by their families to stay home from school to care for younger children, attend to other household chores, or even to work alongside their parents in the fields. Many children of farmworkers report beginning as early as age 10 (MCN, 2017b).
- They may feel socially estranged, be constantly moving, have difficulty finding healthpromoting recreational activities, and have difficulty assimilating (MCN, 2017b). This causes stressors related to immigration status.
- Migratory patterns for farm worker's children make it difficult to complete credits and stay in school. The transient nature of farm working means children may leave the school year early or receive partial instruction for an academic year (Granados, 2018).

Migrant children are less likely to graduate from high school, because educational interruption and difficulty “catching up.” Globally, children between the ages of 7 and 14 who live in a rural setting are less likely to attend school but more likely to work. The average level of education completed was the eighth grade (NCFH, 2018b).

Research on children whose parents have been arrested, detained, and/or deported has led to parental depression and poor cognitive and behavioral outcomes for children (Migration Policy Institute, 2015). According to the AAP policy Detention of Immigrant Children, children seeking refuge in the United States endure emotional and physical stress and should not be separated from families but instead should be treated with dignity and

respect, according to the recently released. Separation from parents, siblings, and other relatives and caregivers could exacerbate the children's health problems and could also overwhelm the system and cause a crisis in care. The situation becomes even more complicated when one parent of legal children is born in the United States and is a legal citizen and the other is not. Mixed-status families are extremely vulnerable in terms of access to health care and increased chances of being impacted by family disruption through deportation removal (Vargas & Pirog, 2016).

Ramos, Carlo, Grant, Trinidad, & Correa (2016) study results indicated that stress and depression were positively associated with occupational injury. Further, occupational injury was a significant factor for depression. Participants who had been injured on the job were more than seven times more likely to be depressed. These results highlight the interconnection between the work environment and mental health.

### *Intimate Partner Violence*

Intimate partner violence (IPV) is a serious public health problem with substantial consequences for women's physical, sexual, and mental health. Migrant farmworking women are particularly at risk in an intimate relationship because of cultural beliefs and environmental factors, which include challenges with the migratory lifestyle, limited finances, as well as poor working and living conditions. In addition, the migrant women are often less aware of resources to advocate for themselves within the health care system, making interventions difficult (MCN, 2017a). While health care provider screening for IPV increases the rates of identification, many providers do not effectively screen (Wilson et al., 2015). Research on domestic violence among this vulnerable population is scant, but more than 1,000 battered farmworker women in a multicenter study were interviewed and researchers identified the typical profile as:

- Childbearing age (15 to 40)
- Hispanic
- Afraid of their partner
- Married or living with partner
- Drug or alcohol use by partner

The overall incidence was 24.5%. Fifty percent of abused women were pregnant at the time of the abuse (MCN, 2017c). What makes farmworker domestic violence so significant is the fact that these women often experience language barriers, do not have adequate access to health care, live isolated lives with little social support, and fear deportation if they report the abuse—all factors that lead them to endure their violent situation in silence. One example is a migrant woman, who shared a one-room dwelling with her

husband, infant, and five single men. Her husband became increasingly violent and unpredictable. He began to beat her and the baby, and she was unable to predict what would initiate a violent attack. She finally fled when one of the men living with them also began beating her. She attributed the aggressive behavior to the powerlessness felt by the men. The Violence Against Women Act of 1994 affords protection for undocumented battered women and children by allowing them to seek legal immigration status without the help of their abusers (MCN, 2017c). C/PHNs must be aware of these issues and what resources are available in the community (Box 27-10).

## **BOX 27-10 Levels Of Prevention Pyramid**

### **Domestic Violence in the Migrant Population**

**SITUATION:** Although the migrant lifestyle can be difficult for the entire family, women and children suffer most from family violence that the migrant way of life promotes. Research is scant; however, informal discussions occur among women and health care providers. Outreach workers sometimes possess lists of men who are abusive and their victims. Isolation and subjugation to a patriarchal system usually prohibit migrant women from seeking help if they are abused. Fear of consequences and difficulty expressing negative views about their husbands prevent women from speaking out (MCN, 2017c).

**GOAL:** Prevent intimate partner violence.

<b>Tertiary Prevention</b>		
<i>Rehabilitation</i>	<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>▪ Promote family rehabilitation, with or without abuser in the home.</li> <li>▪ Encourage ways to eliminate or reduce social and geographic isolation among vulnerable women.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Alleviate stressors of the migrant lifestyle, such as overcrowding and substandard living conditions.</li> <li>▪ Provide emotional support and educate on what constitutes abuse.</li> <li>▪ Promote self-esteem and encourage women can take control of their situation.</li> </ul>	<ul style="list-style-type: none"> <li>▪ Encourage women to contact health care providers as they migrate.</li> <li>▪ Encourage women to find appropriate lay community outreach workers for support.</li> <li>▪ Encourage migrant women to unite and create an environment that allows them to speak out while supporting one another against abuse.</li> </ul>

Secondary Prevention	
Early Diagnosis	Prompt Treatment
<ul style="list-style-type: none"> <li>Promptly identify abused women—through self-identification or by other family members or professionals—remove from the dangerous situation.*</li> <li>Keep communication lines open, be culturally sensitive, and examine for injuries.</li> </ul>	<ul style="list-style-type: none"> <li>Secure victim in a safe battered women's shelters.</li> <li>Assist victims to regain self-esteem.</li> </ul>
<p>*Secondary prevention is difficult because of limited financial resources, lack of transportation, no nearby friends or relatives for support, language barriers (e.g., non-English speaking), and limited safe shelters for battered women in rural areas.</p>	
Primary Prevention	
Health Promotion and Education	Health Protection
<ul style="list-style-type: none"> <li>Create awareness of the harsh living conditions that migrant families endure.</li> <li>Advocate for improved and safe living conditions on state and national levels.</li> <li>Provide adequate housing that eliminates.</li> </ul>	<ul style="list-style-type: none"> <li>Train bilingual and bicultural lay migrant women on the issues of spousal abuse and help them form support groups.</li> <li>Provide opportunities for women and men to improve self-esteem that will change attitudes toward each other.</li> </ul>

## *Infectious Diseases*

- TB is a common infectious disease among farmworkers.
- The number of agricultural worker patients diagnosed with TB at Migrant Health Centers in 2016 was 261, equating to a prevalence rate of 30.3 cases per 100,000 patients.
- Research conducted with migratory workers near the U.S.–Mexico border found that 55% of the 109 workers tested positive for a latent TB infection (NCFH, 2018a). Because of their migrant patterns, it is difficult to be accurately diagnosed and to complete treatment regimens; they endure poor access to health care and social isolation.
- Many factors may prevent them from successfully completing a treatment regimen, and language barriers, along with cultural differences, may preclude them from fully understanding the impact of their disease on themselves and others. For instance, a Mexican migrant worker may be diagnosed with TB in California and begin treatment there but may move to Washington state to pick cherries and run out of medication before completing treatment. Moving back to California for summer work, he may again start treatment but may travel home to Mexico during the winter, only to be reinfected by an older, untreated member of his extended family.
- Migrant children are at increased risk for respiratory and ear infections, intestinal parasites, skin infections, TB, and delayed development (MCN, 2017b). Lack of awareness that minor symptoms, such as diarrhea, fever, or ear aches, may indicate a more serious underlying issue can be problematic. An earache is minor, but it can lead to a major

problem, such as deafness, if left untreated. Delays in seeking medical attention, due to poverty and a lack of health insurance, can create long-standing health issues.

Migrant workers are at greater risk of HIV infection due to inconsistent condom use; heterosexual contact with an infected male; use of commercial sex workers due to the shortage of women in the rural communities; and use of lay injections, where untrained peers will inject a migrant with vitamins and antibiotics and reuse needles ([Rural Health Information Hub, 2018b](#)). They also note that there is now a higher prevalence of HIV found in rural areas of Mexico, as workers bring the infection back to their homes. HIV-positive status may be misunderstood and, because of stigmatization and fears of deportation, may be purposely hidden from health officials. Estimated HIV rates are reported to be between 0.47% and 13%, depending on geographic area and personal risk factors like drug abuse; however, accurate national prevalence rates are almost impossible to attain ([MCN, 2017a](#)). Other infectious diseases (e.g., hepatitis, enteric diseases, and parasites) may commonly afflict migrant workers, often because of inadequate sanitation and hygiene facilities.

Whatever your viewpoint on this issue, it is important to the public's health that basic health care services be available to vulnerable populations. Continued efforts must be made to conduct research assessing risks and hazards, especially those of pesticide exposure. Many government publications document the despair and isolation of migrant workers, yet very little has been done to address the living and working environments that contribute to diminished health. Although migrant workers are a mobile population and difficult to study, they represent an important, integral part of our economy; infectious disease among this population increases health risks for all ([NCFH, 2018a](#)).

## Unique Methods of Health Care Delivery and Primary Prevention

Because migrant health centers do not adequately meet the health needs of the entire migrant community, several innovative methods of health care delivery have been developed and implemented by community health nurses.

- Several programs are using promising models to intervene to address some of the social determinants of child health by utilizing existing programs and also linking community partners to better serve the community. An example is the partnership between Farmworker Justice and the Migrant Clinician's Network working together to monitor initiatives to improve children's health (MCN, 2017b). Migrant education programs, especially with Mexican American resource teachers as role models, have also been helpful.
- Mobile health vans staffed with bilingual community health nurses and lay workers can travel to migrant camps; this provides an effective strategy for outreach health screening and education. By going to migrant camps and delivering care during nonwork hours such as evenings and weekends, community health nurses increase health access and overcome barriers. Although migrant families receive only fragmented acute care, a nurses' outreach team can succeed in encouraging migrant farmworkers to prevent illness with immunizations, good nutrition, and healthy lifestyles. A viable alternative to traditional medical clinics, the mobile nursing clinic provides primary care to an underserved population through health promotion, disease prevention, and early treatment (Williams, 2017).
- Mobile dental vans can provide services to migrant worker's children, often with arrangements made through school nurses and dental care provided by dental schools or through partnerships. Barriers to good oral health include lack of insurance, high cost of services, language, immigration status, socioeconomic status, and fear/trust (Ponce-Gonzalez, Cheadle, Aisenberg, & Cantrell, 2019). Children of migrants are suffering from poor oral health; this disparity can be reduced by improving their parents' literacy in their primary language and educating parents regarding good oral health practices. An appropriate oral health policy remains crucial for marginalized populations (Reza et al., 2016). Migrant farmworkers were reported to have low levels of knowledge about oral cancer risk factors and signs/symptoms and to be less likely to seek preventive care (Dodd, Schenck, Chaney, & Padhya, 2016). Migrant preschoolers were found to have overall low-quality diets, with fewer than recommended levels of vegetables, fruits, and whole grains in one study (Quandt et al., 2016).

- Hispanic women have greater incidence and mortality rates of cervical cancer when compared with non-Hispanic Whites in the United States [Fleming et al. \(2018\)](#). Peer-led health instruction and coaching via Charles (talking circles) may improve cervical cancer screening and improve detection rates among farmworker communities.

Mobility impedes continuity of care, and the inadequate system of medical record keeping for the migrant population is frustrating and challenging. Data information systems are vital components for monitoring the health status of individual farmworkers as they migrate, as well as essential for generating research and follow-up care for long-range health planning. Data also help justify appropriation of monies to migrant health agencies. The [Health Center Resource Clearinghouse \(n.d.\)](#) is a 501c3 nonprofit organization that creates practical solutions intersecting poverty, migration, and health. They have instituted tracking systems and clinical tools for diabetes, CVD, cancer, and prenatal networks, to name a few. Another system, *TBNet* promotes the completion of TB treatment among migrant populations.

The medical histories of migrant children are often unknown to current providers. The [U.S. Department of Education \(n.d.\)](#) now offers the Migrant Student Information Exchange (MSIX) that permits states to transfer health and educational information on migrant students. The MSIX system was a part of the amended *No Child Left Behind Act* that was enacted by Congress to assist states in developing an effective method of tracking educational and health information as well as the number of migratory children in each state. However, the ability to track these children in the migratory lifestyle from one work location to another is often inconsistent. Early intervention for migrating children is not always feasible, but it can greatly improve outcomes.

MiVIA (“my way” in Spanish) is putting health records online and making them available to migrant workers and their health care providers. Workers get a photo identification card, and their records can be accessed only by the use of a personal password. They can access their medical files, medications, a medical reference guide (bilingual), and other resources, such as local clinics and doctors, public transportation, and housing online, no matter their location ([MiVIA, 2016](#)). The program began in California's wine country in 2002 but is spreading to more distant locations.

## Community Health Nursing in Migrant Settings

Beyond barriers to health care, such as lack of health services, language, and cultural impediments, inadequate transportation, financial strains, underinsurance, and questionable residency status, which are by themselves formidable obstacles, the migrant lifestyle is troubled with challenges. Because of the insecurity and instability inherent in a mobile lifestyle, long-term health goals are difficult to establish and long-term follow-up of any chronic illness is problematic. Nonetheless, C/PHNs provide much-needed services using community resources, innovative thinking, tenacity, and sensitivity.

Strategies for improving the health status and resource use of migrant workers and their families include the following:

- Improving existing services
- Advocating and networking
- Practicing cultural sensitivity
- Using lay personnel for community outreach
- Utilizing unique methods of health care delivery
- Employing information tracking systems

Community health nurses are the major providers of migrant health services and have a crucial role in the development and management of interventions. In response to the growing need for available, accessible, and affordable health care for farmworker families, nurses are called on not only to understand the migrant lifestyle but also to help migrant families overcome the barriers to health care ([Box 27-11](#)).

### BOX 27-11 PERSPECTIVES

**Nurse And Nursing Instructor Viewpoints On Migrant Health “I spoke with one of my students after clinical last week, and she told me about her work this semester with a 35-year-old single mother of two who had been discharged from the**

**hospital following a lupus flare-up. The student felt that her client was a devoted mother, but she let her 8-and 12-year-old children stay home from school to help with family farm tasks in order to make ends meet. After weekly visits with her client for almost 2 months, she told me—‘I was finally able to get her to trust me enough to help her trust others.’ She has reached out to her neighbors and asked for help and they are more than willing to lend a hand. Now, her children can return to school and go back to being children instead of day laborers! I told her that sometimes, it takes a strong person to reach out for help and that she is a strong woman!”**

*Kevin, nursing faculty member, faith-based college, western Massachusetts*  
“I was having a conversation with students about how to “break the ice” when making home visits to families who have never had home health services. One student mentioned that at the beginning of the semester, she was afraid that her shyness would be her downfall. But in the week that followed, it occurred to her that the best way to establish trust with anyone is to express an interest in answering questions they have before you pose your own. The student now makes it a habit to ask every patient the three things they would like her to know about them that will help her to personalize their care. During week 8 of the clinical semester, the student stated—This was a real “icebreaker” and my patients have been much more open to listening and learning from me once I listen and learn about them!”

*Betsy, community health nursing instructor in a northern California school of nursing* “First of all, a nurse should expect the unexpected. Because of the migratory way of life...clients do not always know where they will be next week or next month. Therefore, we must understand that they do not always have their medical records, immunization records, or income records. Hours are very irregular, depending on what time the workers get in from the fields and what time the shifts are. Because of the distances we travel, we work anywhere from 8 to 12 hours a day. The most rewarding part of the job is bringing health services to the underserved and uninsured. The people are so gracious and appreciative of whatever services we provide.”

*J. S., RN, Michigan*

“Since farmworkers come to our area for only 4 months of the year, it is rare that I care for a migrant woman through her entire pregnancy. I may diagnose her pregnancy, I may see her for three or four prenatal visits, or I may meet her only once before she goes into labor and delivers her baby. I struggle with the desire to make a difference in a short period of time and with the disappointment of not being able to follow through.”

*C. K., CNM, RN, Pennsylvania*

“I worked as a Head Start nurse for many years in an agricultural area of California. One of my assignments was a state/county migrant farm labor housing project. I was asked to make a home visit to check on a 4-year-old who hadn't come to preschool in a few days. When I arrived at the family's duplex, I found the sixth grader there, caring for all five of her younger siblings, including the 4-year-old and an 8-month-old baby. When I asked why she was home with all of the children, she guardedly informed me (after some coaxing) that her parents had been picked up in an immigration raid at the tree farm where they worked and had been taken back to Mexico. The children were now alone, with no family nearby. I worked with a nun at Catholic Social Services to provide care for the children until the parents returned to the United States so that the children, who were all U.S. citizens, would not be placed in foster care. The parents had not been allowed to contact their children before being placed on the bus to Mexico, but other workers, who were not undocumented, had seen them go and told the children about their plight. It was heartbreaking to see the fear in their eyes. I quickly went to work looking for resources for them.”

*Holly, Head Start nurse, California*

In the past, male migrant workers traveled primarily in organized crews; now, they may travel in family units with women and children. Added attention must be given to family members exposed to the hazards of the migrant lifestyle. Even as many migrant workers settle into communities, the cycle of poverty continues as other workers arrive from impoverished countries. With a paucity of health resources, the C/PHN is sometimes the only health provider who provides care for this population.

Providing care for migrant workers presents a challenge, requiring nurses to be innovative and to go beyond the boundaries of traditional health services (Box 27-12). Although many resources and programs exist to help migrant families, the needs are still overwhelming. By aligning with the goals of *Healthy People 2030* to improve the health of one of the most underserved populations, the community health nurse will also be improving the health of the nation as a whole.

## **BOX 27-12 C/PHN USE OF THE NURSING PROCESS**

### **Working With Migrant Families**

**Background Data and Assessment** Tom Reynolds is a community health nurse in central Montana. He has three migrant camps in his service area that are homes for primarily Mexican residents. The men primarily work in strenuous construction jobs—masonry, landscaping, and in agriculture (cherry orchards, dairy farm, and ranches). The women work as housekeeping staff in private homes, motels, and hotels in the area. In the evenings, he would stop by the camps to catch up with residents and assess any current health concerns. At the end of a 3-week period, Tom had met with the residents in each of the three camps. The feedback from these informal conversations assisted Tom in the formulation and implementation of a nursing plan of care targeting the health promotion needs of this unique population of residents.

### **Problem Statements**

1. Changes in the family health status secondary to language, transportation barriers, and health literacy barriers
2. Fear as it relates to deportation and separation from family members
3. Occupational and situational injury, illness, and stress because of extended work hours and poverty-level living conditions

**Plan and Implementation** Tom researched funding options for a demonstration project that was sponsored by the local health department. The

**director of the health department agreed to support the project for 6 months if Tom could find matching funds for the project from a local foundation, recruit the needed personnel, and the results were positive.**

Tom was able to recruit three other community health nurses, one of whom was bilingual and familiar with the cultural values and practices of the migrant workers. In addition, Tom reached out to the university's undergraduate nursing program and the community health instructor agreed to utilize the three camps as clinical sites for the upcoming semester. The nurses, students, and staff social worker from the health department coordinated weekly evening and weekend visits to each of the three camps. The teams completed a family assessment for each family: established health records, completed a community-based assessment for each of the three camps, administered immunizations, assisted with arranging transportation to and from medical appointments, and enrolled families in the Women, Infants, and Children Supplemental Food Program (WIC). In addition, the teams completed short teaching sessions on topics such as oral care, hand hygiene, family planning, and infant safety.

The students were inspired by Tom's energy and asked to utilize this experience to develop their Capstone Projects that centered on meeting an unmet need of the unique group of residents. The local farmworkers heard about all of the activities at the camp and they began to organize food and clothing drives to assist the residents in meeting the challenges of the warm Montana summers and snowy winters.

## **Evaluation**

The evaluation of the interventions was so positive that the program became a permanent service of the health department. In the months that followed, a nurse practitioner and volunteer dentist were added to the team to provide on-site care and evaluations. With optimal health and a decrease in issues related to health disparities, several families were able to leave the camps and establish permanent homes in the local community.

# URBAN HEALTH

**Urban health** is influenced by the interactions of citizens in three areas:

- Where they reside
- Where they work
- Where they gather for daily life events

According to the [World Health Organization \(WHO\) \(2020a\)](#) the following facts influence the social determinants of health in **urbanized area** settings:

- **Poverty:** Often, poor urban households may be hidden in urban areas of higher wealth. Many people are also likely to be pushed into poverty due to higher prices of essential commodities in urban areas.
- **Slums:** Approximately 33% of the developing world's urban population lives in slums, accounting for close to one quarter of the total global urban population. Slums are characterized by overcrowding, lack of access to safe water and sanitation, and safety concerns. Poor housing conditions, overcrowding, lack of access to safe water and sanitation, and a lack of secure tenure characterize slums. Lack of access to and use of safe, sustainable water and sanitation is globally one of the biggest contributors to ill-health and preventable mortality.
- **Poor air quality:** Data from >1,600 cities, 88% of the urban population are exposed to particulate matter levels in the air that exceed WHO Air Quality Guideline values.
- **Child labor:** Globally, 168 million children worldwide are child laborers. Child laborers comprise 11% of the child population as a whole. In urban settings, child domestic labor is a principal phenomenon.
- **Health concerns:** A range of acute and chronic health concerns and risk factors has emerged in urban settings, and these realities offset earlier gains. Noncommunicable diseases (NCDs) are pervasive to urban living.
- **Transportation:** Cities and towns within residential urban areas were designed for the convenience of private automobiles, which makes it extremely difficult today to provide efficient access to public services for older people, especially once they are no longer able to drive.
- **Substance use and abuse** (including alcohol, prescription, and illegal substances).

There is a direct relationship between the health of urban residents and the physical environment, the social influences within the environment, and access to services that support physical health and social well-being. Urban health considers those characteristics of the environment as they relate to the health of the population living within large cities. Characteristics that define urban areas such as size, density, and complexity come with advantages and disadvantages; large size in cities may mean that the public health system can efficiently reach large numbers of people for interventions but may also lead to incomplete coverage for services due to larger populations.

During recent decades, public health crises, such as the flooding from Texas to Arkansas due to excess rain (2019), the Flint, Michigan water crisis (2014) and wildfires in California (2018) powerfully demonstrate the convergence of race, place, and poverty in determining health outcomes. [Tung, Cagney, Peek, and Chin \(2017\)](#) described the Flint water crisis, as an urban nightmare marked by concentrated poverty, deteriorating housing conditions, infrastructure decay, and organizational failure in a city inhabited by predominately poor, black residents. See [Chapter 9](#) for more on this.

[Deaton \(2018\)](#) documented the link between poverty, human rights, and the inequities of the U.S. health system. According to Deaton, 40 million people (12.7%) of the population live in poverty within the United States and that number is growing exponentially because of the inequities in our nation's health system. The following are some of the most astounding findings from his analysis:

- U.S. infant mortality rates are one of the highest in the developed world (ranking 33 out of 36) ([America's Health Ranking, 2018](#)).
- The United States has the highest prevalence of obesity in the developed world.
- In access to clean water and safe sanitation, the United States ranked 36th in the world.
- The United States has the highest income inequality rate of all Western nations.
- Eight million more Whites are poor in America than are African Americans living in poverty. Thirty-one percent of poor children are White, 24% are Black, and 36% are Hispanic.
- Seven million Americans making more than 150% of the poverty line (\$31,000 for a family of three) dropped below the poverty line after paying medical costs between 2010 and 2014. Over half of them ended up below 50% of the poverty level.

How can the poorest of the poor Americans overcome the health disparities that surround their daily lives? The solution posed by Deaton and other health care advocates is to support the implementation of nationwide universal health coverage.

In 2000, the Johns Hopkins University founded the Urban Health Institute (JHI) as a means to bolster support among an inner-city population. The goals of the [Institute \(2018\)](#) include the following:

- *Facilitate collaborations* between JHI and the Baltimore community around research, community projects, program planning/implementation, and evaluation.
- *Improve the understandings* of JHI as they relate to the health needs and goals of the community and, concurrently, to improve the understandings of the community as to the work that JHI does that has the promise of improving the health and welfare of the community.
- *Strengthen the capacity* of the Baltimore community by bringing the knowledge and skills available through JHI to community-identified needs and issues.
- *Strengthen educational offerings* and opportunities within JHI as they relate to urban health and development.
- *Initiate long-term, cooperative interventions* that will improve the health and well-being of Baltimore and the East Baltimore community.

The [New York Academy of Medicine \(2020\)](#) has organized the Institute of Urban Health to the academy sponsors the *Journal of Urban Health*, a publication that focuses on population-based research with low-income and at-risk populations living in urban areas. But how did the health of these urban communities regress to such conditions that focused efforts are now required? The routes of these conditions trace their origins to the 1800s.

## History of Urban Health Care Issues

An examination of urban health care issues requires an in-depth analysis of the vulnerabilities of urban dwellers that has existed for centuries. The following list provides a historical summary of these unique issues:

- **Housing:** During the mid-1800s and early 1900s, U.S. population increased dramatically due to the influx of millions of immigrants from large European and Eastern European countries. Groups of individuals and families began to congregate in urban tenements and ghetto housing buildings. The 1893 World's Columbian Exposition in Chicago introduced the “city beautiful” concept of replacing crumbling urban cities and tenements with more classical buildings and parks/lakes to address the crime and social problems of the day ([Pain, 2016](#)).
- **Poverty:** Today, Haitian and Middle Eastern families inhabit some of the same neighborhoods that were inhabited by the Eastern European immigrants during the early 1900s. However, many of the same buildings continue to provide less than optimal shelter for this new group of immigrants. Although ghetto living provides a sense of belonging, for many, it is temporary because it engenders more negatives than positives. Children and grandchildren of the original immigrants seek different lives for themselves, away from the urban areas that are often riddled with crime, unsafe housing, and disease. Others, because of poverty, drugs, or fear of being homeless, remain in urban slum areas.
- **Access to health care:** Access to care remains inequitable due to cultural, economic, and health literacy barriers that were not adequately addressed by many health care organizations.

Two connected disciplines, **urban planning** and public health, have addressed housing and health care issues from the 19th century to the present. Urban planning worked to improve the welfare of individuals and communities by supporting the growth of healthy, effective, appealing, and accessible places. Urban planners often address the community's needs related to diversification of the transportation system, housing, reducing air pollution and greenhouse gases, street network design, and built environment site design; in some large cities, these tasks are handled by separate departments that do not often interface with environmental or public health ([Nieuwenhuijsen, 2016](#)).

- *The American Public Health Association* ([APHA, 2020](#)) describes the mission of public health to “promote and protect the health of people and the communities where they live, learn, work, and play.”

- Public health leaders promote wellness by encouraging healthy behaviors. Together, these disciplines addressed the needs of the identified vulnerable populations. Initially, during the late 19th and early 20th centuries, these two systems were linked in promoting health by facilitating physical activity through the creation of green space.
- They also designed cities to be less vulnerable to contagions. They joined together in preventing infectious diseases by ensuring healthful drinking water and sewage systems (Owens, 2016).
- The target of public health agencies shifted from investigating ways to improve the infrastructure to a focus on germ theories and immunizations, challenges that were easier for physicians to address than changing environments.

Objectives of specialists in urban planning and public health are to support sustainable urban development in developed nations are to mitigate climate change, minimize energy consumption, reduce pollution, protect natural areas, and provide a safe and healthy environment for the citizens, particularly those who comprise the most vulnerable populations. Leaders at the CDC are concerned with factors that affect people and their environments and support efforts that address the improvement of both physical and social environments as related to places to live, work, and play. The CDC's *Healthy Places* describes the components involved: interaction between environment and health, poorly planned growth leading to sprawl, and increased used of vehicles, and healthy community design that promotes health and well-being (2017).

The WHO provides education and information regarding strategies that will optimize the health of cities and their citizens (WHO, 2020b). WHO recognizes the opportunities that exist for urban residents regarding health, education, and safety while acknowledging the unique risks that face urban residents (WHO, 2020a). By 2050, 70% of the global population will live in cities (WHO, 2020a). Issues of overcrowding and lack of available sanitation facilities and clean water increase the risks of communicable diseases for urban residents who reside in urban slums and tenement housing projects. Additionally, there is an increased likelihood of substance use disorders, urban crime, violence, and mental illness due to global poverty issues and barriers posed by the limited health literacy of urban residents. WHO advocates for education and program initiatives that support the physical, emotional, and social health of all urban residents.

The *Healthy People 2030* document addresses societal determinants of health and the environments in which we live, work, and play. Notwithstanding the complexity of urban areas, particularly in large metropolitan cities, health promotion efforts and a focus on healthier environments are key components of this national health effort. Topical areas

of concentration include global health, adolescent and older health, and the social determinants of health. These foci allow governmental policy leaders to assess, implement, and evaluate health programs regarding information and resources to optimize health in urban communities.

## Emerging Issues in Access to Health Services

Access to health care in the United States is regarded as “unreliable” because many people do not receive the appropriate and timely care they need. The U.S. health care system, which was already overwhelmed, has faced an even greater influx of patients because health care reform was fully implemented in 2014; 20 million Americans have gained health insurance coverage yet millions still lack (U.S. Department of Health & Human Services [USDHHS], 2020b). Health care issues that should be monitored over the next decade include the following:

- Increasing and measuring insurance coverage and access to the entire care continuum (from clinical preventive services to oral health care to long-term and palliative care)
- Addressing disparities that affect access to health care (e.g., race, ethnicity, socioeconomic status, age, sex, disability status, sexual orientation, gender identity, and residential location)
- Assessing the capacity of the health care system to provide services for newly insured individuals
- Determining changes in health care workforce needs as new models for the delivery of primary care become more prevalent, such as the patient-centered medical home and team-based care
- Monitoring the increasing use of telehealth as an emerging method of delivering health care (USDHHS, 2020b, para. 10)

## Urban Populations and Health Disparities

The majority of the world's populace now lives in cities, which is a change from long-held rural dominance (Fig. 27-13). An analysis of the mortality rate differences between high-poverty urban and high-poverty rural areas suggest that place characteristics influence health and health outcomes above and beyond the impact of the social determinants of health for those populations. However, it is important to note that these populations are not static in their residence and the dynamic nature of urban living directly influences the health of populations over time.

**FIGURE 27-13** An example of urban housing: Colorful Victorian homes in San Francisco, California.

Along with urban living, other global challenges include health inequity, NCD, infectious disease, and the social determinants of health (Lee et al., 2018; Winchester et al., 2016). The greatest growth of large cities around the world is among less-wealthy nations, where urban slums are developing at a rapid rate, but leave many still impoverished and without piped water and sanitation (Ritchie & Roser, 2018). Depending upon the classification used, more than one third of the U.S. population lives in central cities.

In the United States, in 2018, 83.7% of the population is urban (273,368,693 people), which is expected to increase to 86.1% (305,356,412) by 2030 (Worldometers, 2017). According to the Pew Research Center (2020), in the United States, 14% of the population lives in rural areas (46 million), 31% are urban residents (98 million), and 55% live in the suburbs (175 million). Rural county populations have lagged in recent years, with one half having fewer residents now than in 2000 (Table 27-2).

TABLE	27-2	Urban	Versus	Rural	Trends
		<b>Urban Dwellers</b>		<b>Rural Dwellers</b>	
		<ul style="list-style-type: none"> <li>17% live in poverty/14% for suburbs</li> </ul>		<ul style="list-style-type: none"> <li>18% live in poverty</li> </ul>	
		<ul style="list-style-type: none"> <li>35% have a college degree</li> </ul>		<ul style="list-style-type: none"> <li>19% have a college degree</li> </ul>	
		<ul style="list-style-type: none"> <li>Smaller number of young adults</li> </ul>		<ul style="list-style-type: none"> <li>Increased number of adults aged 65 years or older</li> </ul>	

One example of how changes in population can adversely affect large cities can be found in Baltimore. Between 2017 and 2018, the city lost 7,436 or 1.2% of its population and marks the 4th year for a population decline. Domestic migration, where the population moves out of the city to other cities and counties than those that move into the county, accounts for the decline ([The Washington Post, 2019](#)). Population loss leads to a smaller tax base and a greater proportion of poor residents, yet the city had the same maintenance expenses for sewers, water lines, and streets.

- Historically, movement to the suburbs began with the housing boom and highway expansion occurring after WWII.
- People moved from large cities to more suburban areas, and shopping malls and schools followed.
- Cars became even more essential, because public transportation did not always extend into suburban areas thereby leading to long commute times and traffic congestion.

Although not all suburban areas have remained attractive and vital, an income gap persists between city and suburban residents. Poverty is two times greater in large central cities than in corresponding suburban areas (19.6% vs. 11.2%); the suburban poor, or those living below the poverty line, grew by 57% between 2000 and 2015. By 2012, 59 of the top 95 metropolitan areas in the United States found the majority of their region's poor located in the suburbs. In 2015, 16 million poor people lived in suburban areas ([Kneebone, 2017](#)). This is indicative of a “suburbanization of poverty” (p. 12). Poverty rates were highest in metropolitan areas in the Midwest and South, and almost half of all large cities had significant increases in poverty rates. Only about one third of suburban areas recorded poverty rate increases.

Today, the declining urban situation is not confined to a few large cities. To achieve the vision of creating “social, physical, and economic environments that promote full potential for health and well-being for all” as an overarching goal of *Healthy People 2030*, more must be done to promote health and prevent disease in urban areas (USDHHS, 2020a, para. 11). The primary reason for health disparities, as mentioned in [Chapter 23](#), is the disproportionate burden of certain health and social problems among different populations—in this instance, urban areas. Environmental exposure to air pollution contributes to illness and mortality including heart disease, cancer, and respiratory diseases. Consumer products (e.g., fast-food, alcohol, tobacco) are more readily available in urban and low-income areas and have been shown to be significant health risks that contribute to health disparities (Holleran, 2017).

Other environmental issues, such as extreme heat events where temperatures rise and lead to climate-related deaths, may amplify public health stressors and profoundly affect vulnerable populations. When examining urban form and its relationship to this weather phenomenon, exposures to dangerously high temperatures are a public health threat expected to increase with global climate change (CDC, n.d.).

- Heat waves can exacerbate the risks associated with heat exposure, and urban residents are more vulnerable to these threats due to the urban heat island effect. Urban planners are urged to consider construction limits in order to help with thermal regulation (Eagleview, 2016).
- Urban cities are often heat islands because of fewer green spaces and a larger proportion of asphalt. Extreme heat events not only lead to increased ED visits for heat-related illness, they can lead to increased hospitalizations for those with asthma and other chronic conditions, as well as death for elderly and other vulnerable populations (Matte et al., 2016; Soneja et al., 2016; Winqvist, Grundstein, Chang, Hess, & Sarnat, 2016).
- Cities provide interventions such as extreme heat warnings and cooling centers but not all residents avail themselves of these services.
- Canadian researchers (Bélanger et al., 2016) interviewed almost 3,500 people in 1,647 buildings in disadvantaged areas across nine of the largest cities to determine their perception of adverse health effects of urban heat. Those with negative health impacts relied more on adaptation methods (e.g., eating iced foods, visiting air-conditioned places, taking showers to cooldown, turning off appliances). As with rural areas, the built environment greatly impacts urban neighborhoods.

Urban health equity depends on political empowerment of the people to strongly represent their interests and needs in order to challenge unfair distribution of resources. Further, with most of the world living within the

built environment, this poses a major opportunity to improve urban health and equity (APHA, 2018). Poor social conditions and health inequalities have been recognized in urban areas around the world. Urban slums in low- and some middle-income countries provide social exclusion for many living in poverty and threaten development. For example:

- The Zika virus was, and continues to be, a disease of the urban poor. Slum-defining characteristics, such as poor water and sanitation, crowding, and poor structural quality of housing, offer ample opportunities for mosquitoes to breed and spread the Zika virus (Snyder et al., 2017).
- People in cities are also at risk for COVID19 infections based on risk factors such as household overcrowding, race, ethnicity, low income, and underlying health conditions such as diabetes and obesity (NYU Langone Health, 2020).
- Inadequate urban housing and neighborhood disorder are related to poor-quality sleep among Latino adults (Chambers, Pichardo, & Rosenbaum, 2016).
- Prenatal exposure to particulate matter (diesel fuel, perchloroethylene) has been shown to affect math scores when the children reach third grade; researchers suggest “individual pollutants may additively impact health” (Stingone, McVeigh, & Claudio, 2016, p. 144).
- Indoor environmental exposures are contributors to childhood asthma morbidity. Indoor area pollutants have been associated with asthma symptoms in children, and reduction of indoor allergens and pollutants has shown improvements in asthma symptoms (Matsui, Abramson & Sandel, 2016).
- Urban indoor environments in multifamily housing units pose challenges as pollutants may be seen in many of the units and residents have limited ability to make changes (EPA, 2018).

In addition to concerns about housing, hazardous waste landfill sites are often located in or near urban areas. Noise exposure, often associated with large inner cities, has been linked to cardiovascular death, hypertension, and ischemic heart disease (Munzel et al., 2018). In Flint, Michigan, following pollution of their water system, soil lead data show higher lead values in the metropolitan city center, and seasonal blood lead variations indicate that resuspension of lead dust may be to blame (Laidlaw et al., 2016). See [Chapter 9](#) for more on environmental health.

- Continued exposure to higher sound levels found in large cities can lead to noise-induced hearing loss as well as decreased levels of work performance, among other things (Recio, Linares, Banegas, & Diaz, 2016).

- Significantly lower psychomotor speed and reduced working memory were found in a sample of healthy adults when subjected to urban noise levels (Wright, Peters, Ettinger, Kuipers, & Kumari, 2016).
- Lead poisoning has been more often reported in older homes and apartments in large cities (Childers, 2017).
- A national study found that traffic-related air pollution (measured by nitrogen dioxide levels) was significantly associated with small for gestational age births and lower birth weights and may be a source of air pollution related to poor pregnancy outcomes in Canada (Fig. 27-14; Stieb et al., 2016).
- Another study examined the effects of long-term air pollution exposure on survival rates for acute myocardial infarctions (Chen et al., 2016). Researchers concluded 12.4% of deaths could have been prevented if the lowest measured concentration of ambient fine particulate matter in urban areas had been consistently achieved over the study period.
- The risk for major depressive disorder has also been shown to increase as exposure to particulate matter increased; this was true in the general population but was even more highly significant in people with chronic diseases (Kim et al., 2016).

**FIGURE 27-14** Air pollution is a common problem in metropolitan areas, as seen in this view of the Los Angeles skyline.

While global data have often suggested that urban residents have better health on average than their rural counterparts, this benefit is truly only greater for those at the high end of the income scale. This only magnifies the disparities in urban areas between rich and poor or the social gradient. A more current view is that those living in urban slums, often in megacities outside the United States, have health outcomes that are either similar to or worse than those of their rural neighbors (Kneebone, 2017).

Violence is often associated with large metropolitan cities. After many years of a decline, the national rates for violent crimes increased from 2014 to 2016 or 361.6 per 100,000 in 2014 to 386.3 per 100,000 in 2016. Crimes increased by 4% in cities >1 million, decreased by 4% in cities from 500,000 to 999,000, and increased by 5% in smaller cities <50,000 ([Congressional Research Service, 2018](#)).

- In 2015, victimizations of people from urban areas accounted for 40% of all rapes and sexual assaults, 48% of robberies, and 40% of aggravated assaults.
- In contrast, victimizations of those living in rural areas accounted for 5% of rapes and sexual assaults, 5% of robberies, and 14% of aggravated assaults.
- Over a four-decade period, [Parker and Stansfield \(2015\)](#) found that increased population diversity in U.S. cities contributed to declining homicide rates; racial differences were noted with growing Hispanic presence in Black areas leading to lower Black homicide rates, but no differences were found in White homicide rates.

Among youth, Latinos/Hispanics are disproportionately represented among youth gangs, and substance use and sales are gang-related activities. Individuals who are exposed to urban violence may develop PTSD, and a study examining health-related quality of life among those with PTSD who were exposed to urban violence found that they had higher levels of anxiety and depression, more childhood traumas, and more new trauma experiences ([Pupo, Serafim, & deMello, 2015](#)). Supportive family members were shown to be associated with decreased levels of involvement with violence during adolescence. While those living in low-resource urban areas may be unable to avoid witnessing violence, having one supportive parent was a predictor for significantly less violence involvement ([Culyba et al., 2016](#)).

Inner cities are often thought to be places with low-income residents living in large, poorly maintained government housing projects. Dilapidated housing in central cities exposes residents to cracks in walls and ceilings, peeling paint, broken windows, leaking pipes, and pests such as cockroaches and rats. There is often limited access to adequate rental properties, and rent is often higher in large cities, making it difficult for low-income residents to find adequate housing.

- Nationwide, about one third of households live in rentals, but 43% of rental properties are in central cities. Median rents in 90 cities were over 30% of the gross median income; no more than 30% of one's household income is considered to be affordable rent ([Pew Charitable Trusts, 2018](#)).

- In Chicago, the average rental percentage increased from 21% to 31%, and New Orleans reported 35%. Miami rent is now 43% of the typical household income, despite efforts to increase the number of apartment buildings.
- Apartment rental growth has seen an increase nationally of 1.6% with some areas such as Phoenix and Las Vegas seeing additional growth. Rental rates have increased by 1.3% nationally with rent hikes of over 30% in Colorado and California (Salviati, 2020). Low-income housing, when available, is often plagued with construction and maintenance problems and is characterized by crowding, poor quality, high population density, and attendant health problems. Over 1.3 million U.S. households are located in public housing. Over one third of rental housing was built before 1960, and owners of multifamily rental properties that have lost tenants and income may scrimp on maintenance that decreases property values even more (Pew Charitable Trusts, 2018).
- Urban poor are often forced to live in neighborhoods that do not facilitate outdoor activity or have markets that provide healthy foods, such as fresh fruits and vegetables.
- A walk through most urban corner markets reveals that they do not always offer low-fat dairy products or fresh produce but generally do their best business selling lottery tickets, liquor, sodas, and cigarettes.
- In New York City, it is estimated that only half of residents consume two or more servings of fruits and vegetables daily, and typical interventions aimed at increasing consumption are not likely to be effective in neighborhoods with low education levels (Li, Zhang, & Pagán, 2016).

In a Philadelphia study of patients with high hospital utilization ( $\geq 3$  inpatient admissions within 12 months;  $\geq 6$  chronic illnesses), 30% were found to be food insecure, and 25% were marginally food insecure (Phipps, Singletary, Cooblall, Hares, & Braitman, 2016). In the past 30 days, 40% were concerned that their food would run out, 17.5% said that they did not eat for a full day, and 10% reported being hungry and not eating some or all of the time. Food insecurity can have negative impacts on health, especially for those with chronic conditions. In a qualitative study of San Francisco area individuals with HIV/AIDS, participants discussed living on insufficient food supplies and being hungry, as well as having concerns about the potential poor health effects of eating a “cheap diet” (Whittle et al., 2015, p. 154). Some reported having to use socially and personally unacceptable means of getting food (e.g., trading sex for food, depending on friends/family/charities). High rents related to gentrification of their neighborhoods were cited as a cause of their food insecurity.

Sociologists Wilson and Kelling first proposed the *broken window theory* in 1982, noting that if a broken window goes unrepaired, soon more windows

are broken, and this sends a powerful message to residents that no one cares. A classic research study by [Keizer, Lindenberg, and Steg \(2008\)](#) tested this theory in six-field experiments where neighborhoods, characterized by broken windows, litter, unreturned shopping carts, and graffiti, were studied. They found that when residents see others violating social norms or rules (e.g., disorderly or petty criminal behavior), they are then more likely to also violate norms and rules and that this is a cause for the spread of disorder.

Population density, complexity, and racial/ethnic diversity are associated with urban areas. Central cities are often home to a large proportion of poor people and those from different racial and ethnic groups. In the 21st century, America has evolved into a metropolitan nation with more than 8 out of 10 Americans living in metropolitan areas of varying sizes. Between 2010 and 2018, the fastest growing U.S. cities included The Villages, Florida; Myrtle Beach, South Carolina; Austin, Texas; Midland, Texas; Greeley, Colorado; St. George, Utah; Cape Coral/Fort Myers, FL; and Redmond, Oregon. Conversely, the cities with the greatest rates of decline included Pine Bluffs, Arkansas; Johnstown, Pennsylvania; Charleston, West Virginia; Douglas, Arizona; and Beckley, West Virginia ([Stebbins, 2018](#)).

Urban poor have health problems characterized by accidental and violent injuries, as well as NCDs and chronic stress ([Maxmen, 2016](#)). As noted in [Chapter 23](#), poverty makes a significant difference in health status. Neighborhood disadvantage and disorder (drug activity, violent crime) have been related to the rapid transition from no drug involvement to problem drug use ([Reboussin et al., 2015](#)). Neighborhood poverty has been associated with HIV diagnosis in a New York City study ([Wiewel et al., 2016](#)). Working class urban residents no longer can find industrial jobs, and a concerted effort to improve conditions in urban America is needed in the form of urban policy development. Over the past 25 years, cities and their suburbs have become more alike, and the demographic and health profiles that were previously uniquely urban are now shared by “edge cities” and suburbs populated by poor and minority families. Political power has shifted to more affluent suburban areas, where the tax base and spending practices are greater, at the expense of these cities.

Urban health disparities present a challenge that can be addressed only by the joint effort of public health and urban planning bodies. Coalitions of public health professionals, planners, builders, architects, along with transportation engineers and government officials, are needed to promote healthy, sustainable communities ([Fig. 27-15](#)).

**FIGURE 27-15** This view of New York City shows Central Park, a *green area* interspersed among densely populated areas—an example of good urban planning.

- There is a move to make cities and their suburbs **sustainable communities**. These are seen as healthy places where both natural and historic resources are protected, employment is available, urban sprawl is contained, neighborhoods are safe, air pollution is minimized, lifelong learning is promoted, health care and transportation are easily accessible, and all citizens have the opportunity to improve their quality of life.
- A federal collaborative program, the [Partnership for Sustainable Communities \(2018\)](#), is a nonprofit organization that helps American cities become more socially, economically, and environmentally sustainable while focusing on land use planning, affordable housing, community development, energy use, and transportation.

As with all good plans, the sustainable development plan requires that the recipient of the planning be involved. Democratizing the practice of urban planning is vital to its success. Communities that have been victimized through ineffective planning must be included in the decision-making process. This process will require the inclusion of the practical experience that residents bring to the table, alongside expert input. The health of communities must be addressed from all levels of environmental impact (individual, community, and systems), and population health in the urban setting must be studied ([Gottlieb et al., 2016](#)). Data must be included from the various environments, such as homes, workplaces, schools, and community spaces. These approaches then bring such action in line with what is often referred to as *environmental justice* or the marriage of environmental health and civil rights ([Agyeman, Schlosberg, Craven, & Matthews, 2016](#)). A framework to ensure such justice requires that all individuals and communities have the right to work, play, and live in

environments that are safe and healthy. It also requires that polluters are punished and required to provide compensation for damages and/or renovation.

## Community Health Nursing in Urban Settings

Urban public health nursing can be very rewarding, and many nurses are drawn to urban areas where salaries are higher and opportunities for advancement or additional education greater. In urban areas, there are a larger number of nurses, more schools of nursing, and more intensive recruitment efforts than in rural areas, although inner-city areas, much like rural settings, can have problems filling C/PHN vacancies.

- RN workforce studies reveal a higher rate of nurses (935 vs. 853 per 100,000 populations) and a greater proportion of nurses with a BSN (65% vs. 48%) in urban areas when compared with rural areas ([HRSA, 2020](#)).
- The current health care education system tends to be urban-centric, with the exception of online education programs.
- Urban areas sometimes draw people away from rural areas.

C/PHN practice is population-focused care that requires unique knowledge, competencies, and skills. C/PHN roles have always extended beyond sick care, also encompassing advocacy, health education, community organization, collaboration with community agencies, as well as political and social reform. Primary prevention (health promotion) is a major focus. C/PHNs have a key role of working with populations to improve health and social conditions of vulnerable populations. These nurses practice in diverse settings such as community nursing centers, home health agencies, housing developments, local and state health departments, neighborhood centers, churches, schools, and worksites. C/PHNs can develop sustainable programs and build community capacity for health promotion in collaboration with community members. By utilizing a community-based participatory research (CBPR) model, C/PHNs can collaborate with community members, leaders, and stakeholders to identify resources and solutions to problems. Specific public health roles include advocates, collaborators, educators, partners, policy-makers, and researcher. An example is through the use of the “power of the pulpit.” The Black Church is seen as an influential political and social force in the Black community. Church leadership often supports a history of promoting encouraging and facilitating community-based screening and health care programs ([Bishop-McDaniel, 2017](#)). Community health nurses collaborate with their clients to develop their facility for long-term health promotion and improvement of their quality of life. Their ultimate goal is to empower clients to be self-sufficient.

There are many points at which the community health nurse can make a difference in people's lives. Nurses provide services in deteriorating urban areas, with those living in poverty in all settings and among all vulnerable

populations. Nurses first need to assess themselves for their attitudes and preconceptions. Although access to care can be improved for many low-income people in urban areas, many clients simply need an advocate. Our ability to envision solutions and join together with clients aids us in helping to create a healthier environment for all (Fullilove & Cantal-Dupart, 2016). The urban communities, and the poor or vulnerable people living in them, need strengthening and interventions that can be initiated by C/PHNs using the nursing process as a guide. See [Chapter 23](#).

### *Self-assessment*

Confronting poverty and caring for vulnerable people from diverse backgrounds, whether in rural or urban areas, necessitates reflective assessment of one's own assumptions and beliefs. Because poverty may be prevalent over a lifetime, nursing students may have personal or family experience of living in poverty. However, because the stigma is so great and faultfinding so pervasive in American society, acknowledging and reflecting on this experience may be painful. In contrast, because poverty is so hidden and frequently denied, some nursing students have lived apart from any knowledge of the human experience of poverty. They may have come to believe many of the negative stereotypes about poor people. Nursing students and practicing nurses need to ask such questions as “How have my judgments been shaped? How can I open myself to caring for those from whom most of society turns away?”

We learn from one another's stories ([Box 27-13](#)). First, learn from your classmates, friends, and neighbors who are courageous enough to tell you their own experiences of living in poverty. Ask them and listen intently. Then, let your clients teach you. One honor that nurses have is the opportunity to work with people from all walks of life. During your clinical experiences in community health, you are particularly likely to meet impoverished, vulnerable individuals and families living outside the mainstream. And you can join with them to empower them by helping to build skills and confidence and connecting them to resources.

### **BOX 27-13 PERSPECTIVES**

## **C/PHN Instructors' Viewpoints on Urban Health Nursing**

- Ann, a nursing faculty member at a small Roman Catholic college, had a one-to-one postclinical conference with a student and relays this conversation. The student had made many visits to an African American teen mother of two thriving children. The young mother lived in a dangerous housing project, and, although she locked him out of her second-floor apartment, her abusive boyfriend had been known to climb up the drainage pipe and over the porch roof. Sometimes, he forced open a window and beat her. The mother worked every day at a fast-food establishment; her grandmother took care of the children. After a couple of months of weekly visits, the student exclaimed, “When I read her chart, I saw her as an immoral girl— a slut—and I expected her to be a loser. Now, I can't believe what I've learned about how strong she is. She just keeps fighting for herself and for her kids to survive! She's a great mom and I told her so!”
- Another faculty member, Sharon, who taught community health nursing in a Midwestern school of nursing, was having an informal discussion with a student who related her experience of trying to get comfortable making home visits with low-income young women. She was making brave attempts at home visits to a pregnant woman, about her age, living in the deteriorating outskirts of a major city. She thought she had established rapport and was making headway developing trust with the client. One day, the client asked the student, with concern in her voice, if she had “broken off her engagement.” The flustered student then had difficulty explaining the absence of her engagement ring, which she had never mentioned, but the client had obviously noticed. During the previous week, she had suddenly realized she was wearing this special ring in marginal neighborhoods and thought it best to leave it at home. Of course, she thought that she had to fabricate another reason to tell the client but felt badly for being so judgmental when the client was identifying with the student and believed they had something in common.
- Lynn, a new public health nursing faculty member from a large state university in the West, was shocked and repulsed by the comment of one of her students during lecture one day. When discussing vulnerable populations in urban centers and rural areas, the point was made that poverty can be a generational phenomenon and that many of our clients may find it difficult to dig out of this circumstance. Social justice was discussed, along with the need for C/PHNs to become social activists in order to change political and socioeconomic factors that keep the status quo. One student, a Hispanic female from a

middle-class family, spoke up stating “they should all get jobs at McDonalds.” This spurred further discussion about population-focused versus individual-focused interventions and approaches and the need for all of us to be aware of our prejudices and stereotypical viewpoints.

### *Improving Access*

Even with ACA and government-sponsored health insurance and services, extensive barriers prevent many people from accessing services. The community health nurse serves as an advocate and bridge for families who need to gain access. Barriers to access associated with the clients themselves include reluctance to seek coverage because of feelings of powerlessness; being unaware that such services exist or are worthwhile; lacking resources such as a telephone or transportation; being illiterate; and preoccupation with meeting survival needs and competing life priorities instead of health needs. Barriers associated with applying for health insurance include a system that is unfriendly and complicated. The process may require a car, a phone, and appointments at inconvenient times. Also, service interruptions are not uncommon, as wages vary over time. The nurse can intervene as a coach and guide, interpreting the system to the client and the client to the system. Likewise, nurses can serve as change agents to improve the system whenever possible.

### *Strengthening Communities*

We are all connected. All of us as citizens have a stake in preventing the adverse hardships of poverty and ill health. All of society pays to support community members that do not contribute, to house those who are incarcerated, and to ignore the vulnerable. Many of us fear crime in our homes, schools, businesses, and communities. Society, as a whole, is impacted when adults are incapable of providing nurturing environments for their children. In addition, the alienation of many groups in society erodes our sense of community as a nation. Community health planning should seriously consider an organizing process that builds community and that focuses on developing neighborhood competence to solve problems and create solutions for itself (see the discussion of community development in [Chapter 15](#)).

# SUMMARY

- Rural clients are a unique aggregate, and community health nurses are key to ensuring the delivery of appropriate health services to this population. There are numerous definitions of the term *rural*. In this chapter, some characteristics of rural communities include the following:
  - Communities with fewer than 10,000 residents.
  - A county population density of fewer than 1,000 people per square mile.
  - Rural areas often have less diversity than urban cities but that is changing in many areas.
  - Rural clients generally have lower educational levels than urban clients, due in part to less access to higher education and lower-paying jobs.
  - Income levels and housing costs are frequently lower in rural areas than in larger cities.
  - Many at-risk populations live in these communities, where there are often fewer employment opportunities, a lack of adequate housing, and limited access to health and social services.
  - Rural elders may have more limited alternatives for housing if they can no longer live alone.
  - Mental health services are inadequate, even though the need may be great. Numerous risks are associated with agriculture.
- Between the 2000 and 2010 censuses, urban population growth was about twice that in rural areas. The elderly are a rapidly growing population in rural communities.
- Urban health issues have existed for hundreds of years in the United States, and they continue today. Many disenfranchised and minority groups call inner cities home. Air pollution, poverty, discrimination, substandard housing, crime, substance use disorder, and social inequities often characterize life in urban settings.
- The built environment is an important consideration in urban as well as rural settings and can contribute to greater health risks. Some large cities have had marked decreases in population and significant problems with unemployment, although more people around the world live in urban areas now than in rural areas.
- Migrant farmworkers are an integral part of the agricultural community in the United States and the world but are often barely visible in society. As members of the community with varied and significant health needs, these are complicated by social isolation, occupational hazards such as

pesticide exposure, poor working conditions, and working with dangerous farm equipment.

- Migrant workers and their families often endure substandard housing and poor sanitation, while living in high-risk environments. Migrant children are often educationally, socially, and physically disadvantaged. Migrant health care centers often do not adequately meet the health needs of the migrant community; therefore, innovative methods of health care delivery have been developed and implemented by community health nurses, including mobile health vans and information tracking systems.

# ACTIVE LEARNING EXERCISES

1. Search for two recent journal articles relating to access to health care or quality of care for rural, urban, or migrant population. After summarizing the content, identify barriers to access that are common to both and those that are different. What are the main themes relating to health and access to care?
2. Discuss the common characteristics of rural, migrant, and urban clients. How can the C/PHN be better prepared to meet their unique needs? What are some specific challenges facing the C/PHN working in a rural area? In an urban area? Or with the migrant farmworker population?
3. Describe some of the benefits of rural public health nursing. Describe some of the benefits of urban public health nursing.
4. Discuss health, living, and working concerns of migrant workers. How does a nomadic lifestyle affect the needs of migrant workers?
5. Using “Create, Champion, and Implement Policies, Plans, and Laws” (1 of the 10 essential public health services; see [Box 2-2](#) ), examine new or existing policies or laws and determine how they might affect today's migrant population.

**Settings for Community/Public  
Health Nursing**

# CHAPTER 28

## *Public Settings*

*“Public health nursing is the practice of promoting and protecting the health of populations using knowledge from nursing, social, and public health sciences.”*

—The Definition and Practice of Public Health Nursing: A Statement of the  
APHA Public Health Nursing Section, 2013

## **KEY TERMS**

Correctional nurses Indian Health Service (IHS) Individualized education plans (IEPs) Individualized health plans (IHPs) Local health departments (LHDs) School-based health centers (SBHCs) School nurse  
Section 504 plans Student study teams (SSTs) U.S. Public Health Service (USPHS) Commissioned Corps

## **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Explain the focus of the nursing process and how community/public health nurses (C/PHNs) and other nurses working in the publicly funded sector use the tool to provide care in their communities.
2. Describe how federal, state, and local public health infrastructures influence the population's health.
3. Evaluate the potential benefits of school-based health centers and possible parental or community objections.
4. Compare and contrast common roles and functions of C/PHNs, school nurses, and correctional nurses.

# INTRODUCTION

Many nursing students are not aware of the vast employment opportunities available outside the hospital in publicly funded settings. This chapter discusses several of these publicly funded health settings and the opportunities nurses can garner, particularly in services such as public health nursing, school nursing, and correctional nursing.

Although these nursing opportunities differ greatly from one another, they have several characteristics in common. Community nurses who work in a setting supported through public funds (e.g., taxpayer-funded):

1. Still use the nursing process, just with a population or group of people rather than an individual.
2. Emphasize *prevention* of disease or disability.
3. Work with a variety of people, usually vulnerable populations.
4. Focus on population-based care and must be able to network and collaborate with other agencies and disciplines (e.g., a nurse working in a correctional facility collaborating with mental health workers and correctional officers).
5. May advocate for individuals and the community and serve on regional task forces or advisory boards.
6. Must be autonomous, flexible, creative thinkers who are self-directed and able to prioritize and use the nursing process and evidence-based practices to make decisions and plan efficient care for their respective populations.

# PUBLIC HEALTH NURSING

A C/PHN is a nurse who works to promote and protect the health of an entire population ([American Nurses Association \[ANA\], 2013](#)). An estimated 231,000 to 341,000 workers compose the U.S. public health workforce ([University of Michigan Center of Excellence in Public Health Workforce Studies, 2018](#)). This workforce consists of epidemiologists, nurses, environmentalists, laboratory professionals, nutritionists, dental workers, social workers, and other health care providers.

Approximately 18% of all registered nurses (RNs) are employed in public or community health settings ([Beck & Boulton, 2016](#)). The trends of inadequate access to health care and rising costs of health care have contributed to more nurses working in these settings. Unfortunately, many are unaware of the employment opportunities available in the public sector. This section describes the roles and opportunities for RNs at the local, state, and federal levels of government, with particular focus on governmental agencies, as these facilities employ the majority of C/PHNs.

## **Education**

The [ANA \(2013\)](#) recommends that an entry-level C/PHN should have a bachelor's degree in nursing. This is important because baccalaureate programs provide additional training in public health and leadership. Some states, such as California, require nurses to take additional classes and obtain certification beyond a bachelor's degree if the Bachelor of Science in Nursing program does not offer specific content (e.g., child abuse, public health didactic, and practicum). C/PHNs working with specific populations or in administration should hold a master's degree.

## Key Functions of the C/PHN in the Public Setting

Public health nursing practice consists of many areas of expertise, including:

- Focusing on the health of populations
- Reflecting the needs and priorities of the community
- Establishing caring relationships with individuals, families, communities, and systems
- Being grounded in cultural sensitivity, compassion, social justice, and a belief in the worth of all people (e.g., vulnerable populations)
- Having a basic understanding of all aspects of health (e.g., physical, emotional, mental, social, spiritual, and environmental)
- Using strategies to promote health that are motivated by epidemiologic evidence
- Using individual, as well as collaborative, strategies to achieve results

In brief, the role of the C/PHN is to focus on the health of the public. C/PHNs combine their nursing and clinical knowledge of disease and the human response to it, along with public health skills, to accomplish their goals (ANA, 2015). They apply the nursing process, not only with individuals but also with populations. C/PHNs are a critical link between data tracking (e.g., epidemiology) and developing a clinical understanding of a disease or condition and use the data to prioritize their interventions to stop the spread of diseases, such as measles, and also to intercede with other concerns (e.g., childhood obesity). For example, C/PHNs may develop a campaign for children to wear bike helmets after an increase of fatal head injuries is noted in their area. A key emphasis of the C/PHN is prevention, and a key focus is educating and empowering the community.

The Council of Public Health Nursing Organizations (CPHNO) (<https://www.cphno.org>), formerly the Quad Council, developed the first Competencies for Public Health in 2010. The organization is composed of these organizations: Association of Community Health Nursing Educators (ACHNE), Association of Public Health Nurses (APHN), Rural Nurse Organization, American Nurses Association (ANA), Alliance of Nurses for Healthy Environment, American Public Health Association—Public Health Nursing Section (APHA). These competencies have been updated and are used as a tool in education and for agencies in orienting new C/PHNs (Quad Council Coalition, 2018). See [Box 28-1](#) for community settings for C/PHNs.

### **BOX 28-1 Community Settings for Public Health Nurses Community/Public**

## **health nurses (C/PHNs) can be found working in communities advocating for environmental, transportation, and safety policies in collaboration with community organizations.**

- C/PHNs may work in schools, public health clinics/departments, or local government agencies advocating for elimination of health disparities.
- C/PHNs are increasingly seen working on global health issues as the international borders are rapidly disappearing due to increased, rapid international travel and enhanced electronic communication technology ([American Public Health Association, 2013](#)).
- Visiting nursing is an opportunity for family health education and one-to-one educating for managing specific illness.
- Geriatric nursing is a growing specialty as the care for older adults in assisted living skilled care facilities or through home care is increasing with the aging baby boomer population.
- Correctional nursing provides an opportunity to impact community health by promoting healthy lifestyle practices and effective management of communicable diseases are implemented during incarceration prior to release.

C/PHNs may focus on a population that is a geographic community (e.g., a state or municipality) or a focus group (e.g., adolescents or older persons) spanning all socioeconomic levels. To accomplish this, C/PHNs often work with individuals or families at highest risk, and their motive is to improve, protect, and promote the health of the entire population. A distinctive goal of C/PHNs relative to the goals of other nursing disciplines is achieving the greatest good for the majority of people ([ANA, 2015](#)) (See [Chapter 23](#) for an in-depth discussion of social justice). This requires priority planning and a basic knowledge of the community. It can also create ethical dilemmas for C/PHNs when they have personal and passionate issues that they would like to pursue but which are not the top priority for the majority of community members.

For example, a child in a community may have been hit by a car while riding his bike without a helmet, while at the same time, in the same community, there may be 10 births to teen moms, 20 instances of drug overdose, and an outbreak of pertussis. The C/PHNs in that community must prioritize which issue to address first by deciding which issue impacts the

most people and what interventions will help the population thrive (ANA, 2015). Because each community is different, once all factors are taken into account, the priorities will vary among communities. Hence, *assessment* is a critical component of public health and a key tool for the nurses who work in the public sector (ANA, 2015; Turnock, 2016).

Another way Community/public health nursing differs from other areas in nursing is that C/PHNs must actively seek out and identify potential problems and situations (ANA, 2015). Nurses who work in a hospital setting address the issues that come to them. A nurse in the intensive care unit of a hospital works with an assigned patient load. C/PHNs, on the other hand, are out in the community identifying the problems, not waiting for problems to come to them. For example, C/PHNs may participate in visits to childcare centers to note any safety hazards and ensure that rules and regulations are being followed and that children are properly immunized. These visits are part of the priority of *assurance* (Turnock, 2016).

C/PHNs cannot perform all these activities alone. They need to collaborate with other partners and optimally use often limited resources. C/PHNs are in a unique situation because they work with their populations (i.e., clients) and with others to find the best solutions for a situation or problem. For instance, C/PHNs may notice an increase in the number of measles cases in their community. They may then work with families to identify where and how the children were exposed to the disease and with local health care providers to provide treatment and vaccinations for those at highest risk of exposure to and damage from measles. C/PHNs also work with school nurses and other school personnel to exclude from school attendance those children who are not adequately immunized against measles. This helps decrease the spread and potential harm because of measles. C/PHNs educate a variety of groups, such as parent–teacher associations and city or school officials, as to how measles spreads, what can be done to treat the disease, and the importance of herd immunity in protecting the public. Education thus empowers each group to be part of the solution. Finally, C/PHNs can work with public health officials to develop a policy for all new school entrants to receive a second booster of measles vaccine. *Policy development* is the third critical component of public health (Turnock, 2016).

# **PUBLIC HEALTH FUNDING AND GOVERNMENTAL STRUCTURES**

Well-functioning public health departments are critical entities in the effort to build a healthy nation. Accurate estimations of essential funding to support public health adequately are difficult to determine. Because C/PHNs can work at any and all levels of government, it is important to understand the organizational structure, communication, and funding streams between the federal, state, and local levels of government (see [Chapter 6](#) for more on the structure of the public health system).

## National Policy

The federal government oversees national policy and funding, provides expertise, and sets a national agenda (World Health Organization, 2019). Healthy People initiatives identify our nation's health improvement priorities by setting 10-year goals and targets. Since 1990, “Healthy People has established evidence-based national health objectives with clear targets that allow us to monitor progress, motivate action, and guide efforts to improve health across the country” (<https://health.gov/our-work/healthypeople/>). For example, see [Box 28-2](#) for content areas related to children and adolescents.

### **BOX 28-2 HEALTHY PEOPLE 2030**

#### **Content Areas for Children and Adolescents**

***Healthy People 2030* provides the direction and goals for all community/public health nurses (C/PHNs). *Healthy People 2030* is used to guide prioritizing activities for C/PHNs. Below are the Healthy People 2030 content areas that pertain to the health of children and adolescents.**

- Access to health
- Blood disorders
- Cancer
- Child and adolescent development
- Chronic kidney disease
- Chronic pain
- Drug and alcohol use
- Economic stability
- Education access and quality
- Emergency preparedness
- Environmental health
- Family planning
- Health care
- Health care access and quality
- Health communication
- Health insurance
- Health IT
- Health policy
- Hospital and emergency services

Housing and homes  
Injury prevention  
LGBT  
Neighborhood and built environment  
Nutrition and healthy eating  
Overweight and obesity  
Parents or caregivers  
People with disabilities  
Pregnancy and childbirth  
Preventative care  
Physical activity  
Respiratory disease  
Schools  
Sensory and communication disorders  
Sleep  
Sexually transmitted infections  
Social and community context  
Tobacco use  
Transportation  
Vaccination  
Violence prevention

## **State Agencies**

The U.S. Constitution bestows states with the responsibility to safeguard the health of their citizens ([Turnock, 2016](#)). Much of public health is overseen at the state level. However, the structure of where public health fits into the executive branch of state government varies. The governor appoints a commissioner, or leading health official, to oversee public health and serve as a member of the governor's cabinet.

The purpose of state agencies is to carry forth regulations and policies determined by the federal government (e.g., Medicaid, Medicare, and State Children's Health Insurance Programs). Many of these programs have specific federal requirements but also allow states the ability to personalize the programs to fit each state's individual needs.

## **Local Public Health**

**Local health departments (LHDs)** carry out state laws and policies (Turnock, 2016). They provide the most direct, immediate care to the population while providing the essential public health services at the local level (Moore, Berner, & Wall, 2020) and operate programs with funding from federal and state agencies. LHDs often work with state health departments to ensure that culturally appropriate and population-specific services are delivered to the community.

# NURSING ROLES IN LOCAL, STATE, AND FEDERAL PUBLIC HEALTH POSITIONS

Public health nurses are employed at federal, state, and local levels of government. Those working for LHDs are the eyes and ears of their communities (Fig. 28-1).

**FIGURE 28-1** C/PHNs are the eyes and ears of their community.

## Assess

An assessment of the situation is the key component to any nursing care. C/PHNs use the nursing process in a variety of ways when they are in the community and when they conduct home visits. Often, the C/PHNs work with other public health personnel when assessing and tracking data. By using data and conducting an assessment, C/PHNs are able to successfully target interventions for populations at risk ([Community Tool Box, 2020](#)). See [Chapters 12](#) and [15](#).

Environmental risks are important to the public's health and are often assessed by C/PHNs. A community positioned next to a factory that emits fumes will have different issues than a rural community 90 miles away from any industry. At the same time, a C/PHN may identify an outbreak of *Escherichia coli* in one town as a risk to a neighboring town. See [Chapter 9](#).

## Diagnose

Assessment is key to diagnosing a situation or problem (Box 28-3). For a C/PHN, diagnosis includes identifying priorities for the many concurrent issues which may be present.

### **BOX 28-3 STORIES FROM THE FIELD**

**Tuberculosis Exposure (Compare Your Local Response With That Outlined Here) As a community/public health nurse (C/PHN), you are alerted to a person who has an active TB case. He presents into the health department for a chest x-ray after he failed his tuberculin skin test. The person has recently arrived by plane from another state. He stayed for a few weeks with family members in a small house but now lives with friends in a small apartment. When talking to the patient, you note that he coughs often and does not cover his mouth.**

- 1. As a C/PHN, what steps would you take to determine exposure? How will you determine who was exposed and will need to be tested? What questions can you ask to help determine when and how the patient was exposed to TB?*
- 2. What type of education will you provide to him?*
- 3. How can you ensure that the patient is compliant with medication treatment?*
- 4. Imagine that you are the school nurse of the patient's 8-year-old daughter, who has also tested positive. What steps would you take?*
- 5. What would you do differently if you were a correctional nurse and the patient was an inmate?*
- 6. What are the ethical and legal issues related to TB?*

As nurses diagnose individual needs, they apply this information and watch for increased or decreased rates (e.g., of disease or injury) among the population. Nurses are in the perfect position to identify issues and trends early ([Community Tool Box, 2020](#)).

Constant assessment and diagnosis are tools by which C/PHNs identify critical situations and prioritize issues that must be addressed. Several documents have helped C/PHNs prioritize issues, such as *Healthy People 2030* a guide to identifying many of the nation's top priorities ([U.S. Department of Health and Human Services \[USDHHS\], 2020a](#)). Public health performance standards established by the [Centers for Disease Control and Prevention \(CDC, 2018a\)](#) and the [Institute of Medicine \(2015\)](#) have identified specific leading indicators for improving patient care and health research. See [Box 28-4](#).

## **BOX 28-4 HEALTHY PEOPLE 2030**

### **Public Health Priorities**

**Leading Health Indicators Framework** The *Healthy People* leading health indicators are selected to communicate high priority health issues and challenges. The focus is on social determinants of health that support quality of life, healthy behaviors, and healthy development across the life stages for all. The leading health indicators are selected and organized using the **Health Determinants and Health Outcomes by Life Stages** conceptual framework. This approach is intended to draw attention to both individual and societal determinants that affect the public's health and contribute to health disparities from infancy through old age, thereby highlighting strategic opportunities to promote health and improve quality of life for all Americans.

### **Healthy People 2030**

Every decade, the *Healthy People* initiative develops a new set of science-based, 10-year national objectives with the goal of improving the health of all Americans. The development of *Healthy People 2030* includes establishing a framework for the initiative—the vision, mission, foundational principles, plan of action, and overarching goals—and identifying new objectives.

The *Healthy People 2030* framework explains the central ideas and functions of the *Healthy People 2030* initiative. The purpose of the framework is to:

- Provide context and rationale for the initiative's approach
- Communicate the principles that underlie decisions about *Healthy People 2030*
- Situate the initiative in the 5-decade history of *Healthy People*

Leading health indicators will address the lifespan and focus on:

Upstream measures such as risk factors and behaviors Address issues of national importance

Address high-priority health issues that have an impact on community and public health nursing outcomes Be modifiable through evidence-based interventions and strategies Address social determinants of health, health disparities, and health inequity

Source: [Office of Disease Prevention and Health Promotion \(ODPHP\) \(2020\)](#); [U.S. Department of Health & Human Services \(USDHHS\) \(2020b\)](#).

## Plan and Implement

Once C/PHNs have diagnosed and prioritized the needs of their community, they develop and carry out plans to address those needs. Many interventions require collaborating and working with other agencies and professions. C/PHNs provide preventive health education and serve as advocates to influence those who can make essential policy and funding changes. The interventions are endless, but here are a few examples:

- A nurse conducts home visits to mothers at risk and concurrently conducts family assessments to determine the level of psychological issues and education needed by the family regarding specific needs.
- A community nurse working in risk management develops and teaches an education program about workplace safety and ergonomics and helps to develop policies regarding shift hours and heavy lifting.
- A school nurse serves as an advocate for a program that will help children with special health care needs attend a clinic closer to home.
- A C/PHN develops a campaign for social media sites (e.g., Twitter, Facebook), television, radio, and local newspapers regarding the need to receive a flu shot, including incentives that target older persons in the community, who are at additional risk for developing complications from this illness.
- A C/PHN organizes a health clinic at local shelters that provides foot care and screenings for blood pressure, diabetes, tuberculosis (TB), and cholesterol, as appropriate.
- A school nurse works with schools to educate teens regarding birth control and the impact of teen pregnancy. The nurse includes counseling regarding sexually transmitted diseases (STDs) and works with the community to ensure that a variety of teen-focused activities are available for this population.
- A C/PHN helps identify resources for families without insurance to ensure that well-child and adult screenings are performed regularly to reduce health care costs associated with illness.
- A C/PHN organizes a bicycle fair to educate the community regarding the need for bicycle helmets in hopes of decreasing head injuries, works to develop public policy related to child car seat/booster seat usage, and collaborates with local businesses to provide vouchers for discounts on child restraints for low-income parents.
- A nurse, who is an elected member of the state legislature, sponsors a bill to increase funding for school nurses.

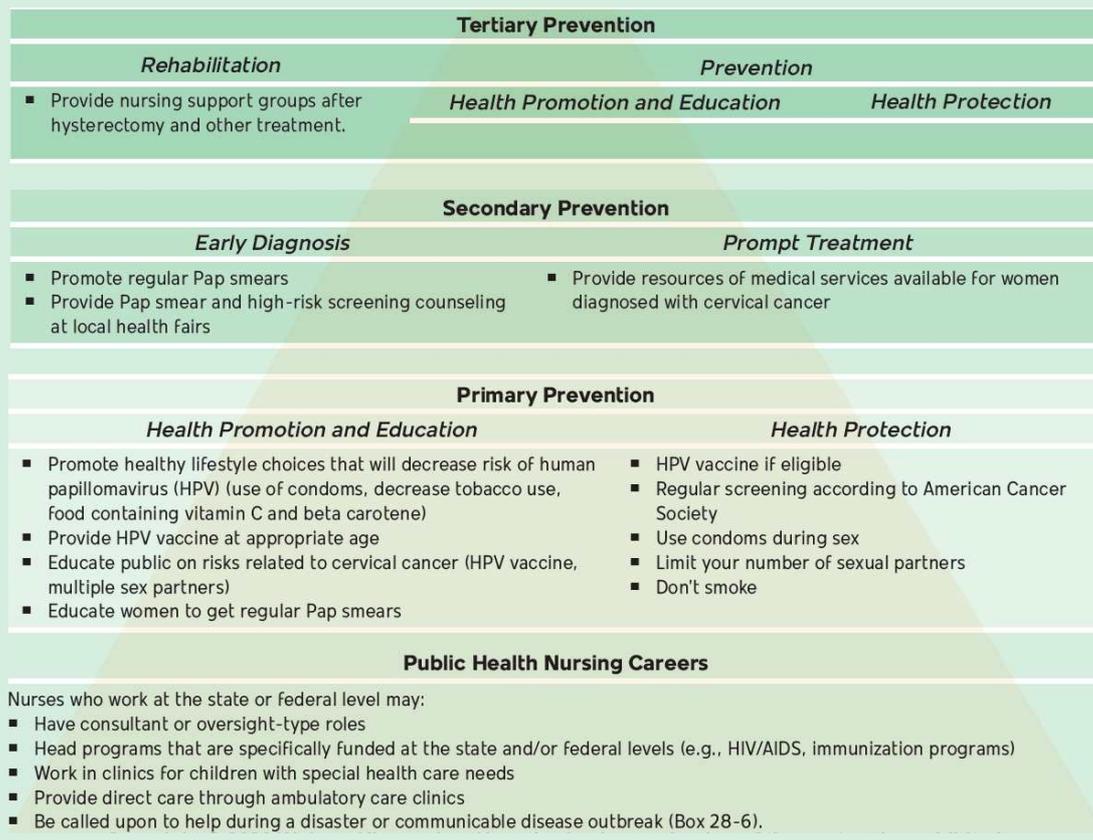

The following interventions are examples of evidence-based practice (see [Chapter 4](#)) in public health nursing:

- Media campaigns targeting specific populations to educate and promote healthy lifestyle behavior ([Atusingwize, Lewis, & Langley, 2015](#)).
- Improving work-based health literacy through educational programs to improve musculoskeletal pain ([Larsen et al., 2015](#)).
- Children with chronic conditions such as asthma are more likely to have anxiety, leading to increased morbidity, including missed days of school and caregiver work time. Asthma education programs along with behavioral building programs may influence mental health, leading to medication compliance and reduced anxiety ([McGovern, Arcoleo, & Melnyk, 2020](#)).
- Promoting the use of helmets in an attempt to reduce injuries among motorcyclists in a rural area by adopting a community-based participation approach ([Babazadeh, Kouzekanani, Ghasemzadeh, Matlabi, & Allahahverdipour, 2019](#)).

# Evaluate

The world in which C/PHNs work is always changing. It is crucial to constantly evaluate programs and interventions to determine whether interventions are effective and desired goals are reached (Box 28-5). The CPHNO supports research studies about the impact that C/PHNs have on improving population health and societal outcomes (Quad Council Coalition, 2018).

## BOX 28-5 Levels Of Prevention Pyramid Cervical Cancer in The Community Setting HEALTH ISSUE: Cervical cancer in the community setting

## BOX 28-6 PERSPECTIVES

**A C/PHN Instructor Viewpoint on Community Health Nursing** As an instructor of undergraduate nursing students, I want students to realize that public health nursing is a wonderful and rewarding employment opportunity. Many students often enter the nursing program not knowing much about public health nursing. They may only get minimal exposure to public health and thus do not often understand who or what is involved in public health nursing. In so doing, they miss out on a wonderful opportunity to work with a variety of people. It may be helping new moms, or working with children and adolescents, or the elderly. They may help give vaccinations or prepare for community disasters. They might teach about breast-feeding or conduct cancer-screening clinics. They are out working directly with the people, ensuring the public's health.

Community/public health nurses (C/PHNs) are able to use the science of nursing because they need to understand the pathophysiology, anatomy, human development, and disease transmission. They may not do as many hands-on procedures as hospital nurses, but they still must keep up-to-date in knowledge, as they are often teaching. In addition, they must be quick and receptive thinkers who can work independently and creatively. C/PHNs also are the essence of the “art” of nursing. They must understand and relate to people and grasp social systems and human behavior. They are the voice for the most vulnerable and the champion of all.

Although C/PHNs may not see an immediate reward for their actions, as a nurse who works in the hospital does, C/PHNs make a long and lasting impact not just to an individual but also for an entire society. They have the opportunity to really be a patient advocate. They do this by helping well people stay well and by preventing illness. They also help those who are sick obtain medical access. C/PHNs can also be involved in public policy change that can help an entire community. Public health nursing encompasses the entire art and science of nursing.

Erin M.

Among distinct opportunities at the federal level are those associated with the [Department of Veterans Affairs \(2020\)](#) and the [USDHHS \(2020c\)](#). See [Box 28-7](#).

## **BOX 28-7 Federal Agencies Employing U.S. Public Health Service Nurses**

- Administration for Children and Families (ACF)
- Centers for Disease Control and Prevention (CDC)
- Centers for Medicare and Medicaid Services (CMS)
- Health Resources and Services Administration (HRSA)
- Indian Health Service (IHS)
- National Institutes of Health (NIH)
- Substance Abuse and Mental Health Services Administration (SAMHSA)
- U.S. Department of Agriculture (USDA)
- U.S. Department of Commerce
- U.S. Department of Defense
- U.S. Department of Homeland Security
- U.S. Department of Justice
- U.S. Department of Veterans Affairs (VA)
- U.S. Food and Drug Administration (FDA)
- U.S. Marshals Service

C/PHNs in these agencies oversee and carry out the initiatives of *Healthy People 2030*, along with other program initiatives. Federally employed C/PHNs at the Health Resources and Services Administration may review state funding proposals for projects and ensure that guidelines are met. They are a resource for state health departments and LHDs and often are called upon as consultants. Nurses working at the National Institutes of Health (NIH) may assist in conducting research or work with legal and bioethics

staff in evaluating the impact of research on participants, monitoring patients for adverse reactions, or coordinate care for specific groups of patients (NIH, n.d.).

## **Indian Health Service**

C/PHNs working with the **Indian Health Service (IHS)** strive to ensure that comprehensive, culturally acceptable personal and public health services are available and accessible to the 573 federally recognized Tribes that consist of 2.56 million American Indians and Alaska Natives in 170 IHS and tribally managed service units (IHS, 2020). Employment with the IHS allows a C/PHN to live in a variety of rural and urban settings and to work specifically with Native Americans, a vulnerable population. This type of nursing, in remote areas with limited consistent electricity or telephone access, is very challenging but can also be extremely rewarding.

# Uniformed Public Health Nursing

Established in 1798, as part of an act to treat sick seamen in Marine hospitals, the **U.S. Public Health Service (USPHS) Commissioned Corps** is a group of more than 6,500 specially trained public health professionals committed to the mission of protecting, promoting, and advancing the health and safety of our nation (Fig. 28-2). As an essential component of the largest public health program in the world, these elite groups of officers are involved in:

**COMMISSIONED CORPS OF THE U.S. PUBLIC HEALTH SERVICE**

The Commissioned Corps of the U.S. Public Health Service is an elite team of over 6,500

**HIGHLY QUALIFIED HEALTH PROFESSIONALS**

**MISSION**  
Protect, Promote, and Advance the health and safety of the nation

**CORE VALUES**  
Leadership, Service, Integrity, Excellence

**UNIFORMED OFFICERS**  
Uniforms reflect the proud legacy and traditions of the Commissioned Corps linking today's officers to past, present, and future officers.

**SERVICE**  
With duty stations in over 20 federal departments or agencies, the Commissioned Corps provides officers the ability to pursue an exciting and fulfilling career. Officers deploy nationally in support of public health responses to man-made and natural disasters.

**MULTIPLE PROFESSIONS**

- Physicians
- Dentists
- Nurses
- Therapists
- Pharmacists
- Health Services
- Environmental Health
- Dietitians
- Engineers
- Veterinarians
- Scientists

**IMPROVING PUBLIC HEALTH**  
Driven by a passion for public service, these men and women fill essential public health, clinical, and leadership roles within the nation's Federal Government departments and agencies supporting care to underserved and vulnerable populations.

For more information visit [www.usphs.gov](http://www.usphs.gov) or call 1-800-279-1605.

Facebook.com/USPHS    Commissioned Corps of the U.S. Public Health Service    CommissionedCorpsUSPHS

**FIGURE 28-2** U.S. Public Health Service (USPHS) Commissioned Corps infographic. (From the Commissioned Corps of the USPHS. (2019). *USPHS Commissioned Corps infographic*. Retrieved from <https://usphs.gov/aboutus/>)

- Health care delivery to underserved and vulnerable populations, including immigrants entering the country
- Disease control and prevention, including communicable disease outbreaks
- Biomedical research
- Food and drug regulation
- Mental health and drug abuse services
- Response efforts for natural and man-made disasters, often as first responders, remaining involved until the situation is resolved

The U.S. Surgeon General oversees the Commissioned Corps and supports the officers stationed in more than 20 federal agencies or departments across the nation, filling essential public health leadership and clinical service roles within the nation's federal government agencies ([USDHHS, n.d.](#)).

The USPHS Chief Nurse Officer is integrally involved with global health care, ensuring that PHS nurses are improving health for the entire community by providing direct care, conducting research, or reviewing new medications. These nurses work in a variety of federal agencies and provide nursing care and health care leadership around the world. Commissioned Corps Officers are on the front line of the COVID-19 response, deploying 400 officers to aid in the response to the coronavirus health emergency ([US Food and Drug Administration, n.d.](#)). During the height of the Ebola virus global epidemic, the president of the United States called upon the USPHS Commissioned Corps to deploy to West Africa to provide care to the health care workers who had been exposed to or infected with the Ebola virus ([Pierson et al., 2017](#)). Four teams of approximately 70 officers composed of clinicians (physicians, nurses, and behavioral health specialists), pharmacists, infection control and laboratory officers, and administrative management personnel rotated to Liberia for 60 days at a time beginning in October 2014 ([Pierson et al., 2017](#)). Upon the departure of these specially trained teams of PHS officers in May 2015, Liberia was declared Ebola-free. Concurrently, smaller teams of PHS officers served to combat the Ebola outbreak in Guinea and Sierra Leone and remained on site educating the community on Ebola treatment and prevention. The president presented the USPHS Commissioned Corps with the Presidential Unit Citation, the highest award for a uniformed service, for their contributions in the fight against Ebola.

More recently Commission Corps officers were sent to Louisiana following catastrophic flooding and heavy rains in 2016 (Iskander et al., 2018). Officers provided round-the-clock medical and behavioral health care for special needs medical shelter residents. In addition, officers coordinated with other shelters and local providers to ensure care for patients with critical health care needs such as dialysis and placement in skilled care facilities (Iskander et al., 2018). For more information on Commissioned Corps deployment: <https://www.usphs.gov/>

For more information on the USPHS Commissioned Corps in general, visit their Web site at <https://dcp.psc.gov/ccmis/>

## School Nursing

School nursing is a specialized practice of professional nursing that advances the well-being, academic success, and lifelong achievement of students. School nurses are a link between the school, families, community, and health care stakeholders.

### *History of School Nursing*

In 1902, the practice of school nursing began when the New York Board of Education contracted with Lillian Wald's Henry Street Settlement to provide a C/PHN to work with the families and schools to facilitate the return of healthy children to school. The nurse, Lina Rogers, made home visits to follow up on children excluded from school for illness or poor health and was assisted by other Henry Street nurses in providing care, educating families about diseases and the need for hygiene, and working with other organizations to provide needed food, shoes, and clothing (Houlahan, 2018). The board hired 12 more school nurses, and over the next few years, other cities and states began hiring nurses to work in the schools. School nurses have historically advocated for hot lunches, breakfast programs, better social conditions, and the need for increased health education in schools and for families (Houlahan, 2018). See [Chapter 3](#).

School nurses are a professional nursing specialty that serves the school-age population through the age of 21 years, working with students' families and the school community in regular and special education schools, as well as other educational settings (e.g., preschools, court, and other community schools).

- The nationally recommended ratio of one school nurse for every 750 students was adopted to provide accommodations to both disabled and chronically ill students. Increasingly, school nurses are providing care to students with complex social, physical, and emotional needs (Endsley, 2017).
- The National Association of School Nurses (NASN) position statement on safe staffing recommends a 1:225 ratio for populations requiring daily professional nursing services, a 1:125 ratio for populations with complex health care needs, and a 1:1 ratio for students requiring daily professional nursing services (NASN, 2020b).

The role of the **school nurse** has expanded over the years, along with the increase in chronic conditions and challenges in accessing health care (Endsley, 2017). In addition, federal law requires school systems to provide care for children with disabilities. The [Individuals with Disabilities](#)

Education Act (IDEA, 1975), the Rehabilitation Act (1973), and Title II of the Americans with Disabilities Act (ADA) all mandate equal educational opportunities for all students, including children with complex medical conditions. It is now commonplace for children to attend school accompanied by feeding tubes, catheters, insulin pumps, glucose monitors, and ventilators. There is a growing population of adolescent and preadolescent children who are within 6 months of dying from chronic disease and are routinely attending school (NASN, 2018a). ANA and NASN (2017) defines the role of the school nurse as:

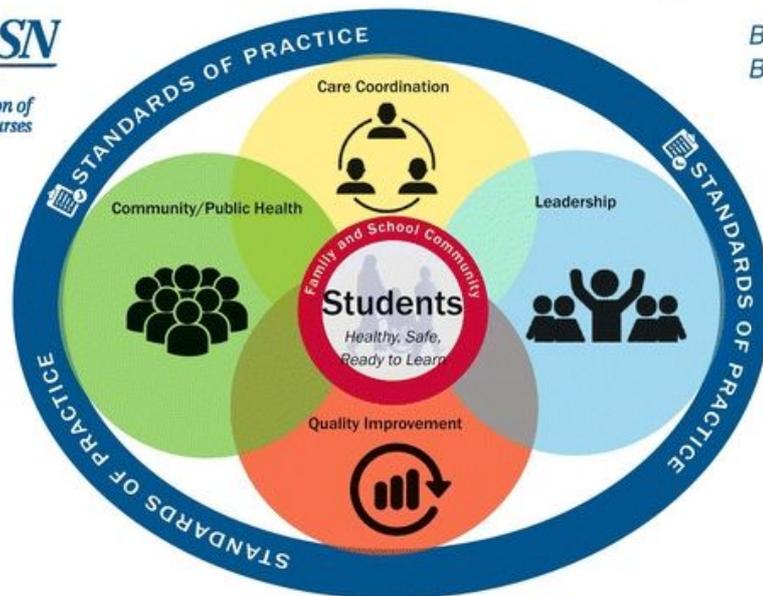

*School nurses, grounded in the ethical and evidence-based practice, are the leaders who bridge health care and education, provide care coordination, advocate for quality student centered care, and collaborate to design systems that allow individuals and communities to develop their full potential (p. 1).*

The school nurse role has dramatically changed, as has the student population, in this millennium. Children are affected by poverty, food insecurity, lack of access to medical care, language and cultural barriers, lower socioeconomic status, challenges to basic safety and security, chronic health issues, and discrimination. School nurses play a critical role in promoting the academic success of these and other children in school (Darnell, Hager, & Loprinzi, 2019). School nurses may be “the only contact a student has with a health care professional”; yet many schools across the United States have one nurse for large populations or no nurse, relying solely on office staff to care for complex medical conditions (Willgerodt, Brock, & Maughan, 2018, p. 232). Today's school nurse performs multiple roles, including care coordination, leadership, quality improvement, and community/public health (NASN, 2018c). See Figure 28-3.

## Framework for 21st Century School Nursing Practice™

BETTER HEALTH.  
BETTER LEARNING.™

NASN's *Framework for 21st Century School Nursing Practice™* (the *Framework*) provides structure and focus for the key principles and components of current day, evidence-based school nursing practice. It is aligned with the Whole School, Whole community, Whole Child model that calls for a collaborative approach to learning and health (ASCD & CDC, 2014). Central to the *Framework* is student-centered nursing care that occurs within the context of the students' family and school community. Surrounding the students, family, and school community are the non-hierarchical, overlapping key principles of *Care Coordination*, *Leadership*, *Quality Improvement*, and *Community/Public Health*. These principles are surrounded by the fifth principle, *Standards of Practice*, which is foundational for evidence-based, clinically competent, quality care. School nurses daily use the skills outlined in the practice components of each principle to help students be healthy, safe, and ready to learn.

Standards of Practice	Care Coordination	Leadership	Quality Improvement	Community/Public Health
<ul style="list-style-type: none"> <li>Clinical Competence</li> <li>Clinical Guidelines</li> <li>Code of Ethics</li> <li>Critical Thinking</li> <li>Evidence-based Practice</li> <li>NASN Position Statements</li> <li>Nurse Practice Acts</li> <li>Scope and Standards of Practice</li> </ul>	<ul style="list-style-type: none"> <li>Case Management</li> <li>Chronic Disease Management</li> <li>Collaborative Communication</li> <li>Direct Care</li> <li>Education</li> <li>Interdisciplinary Teams</li> <li>Motivational Interviewing/Counseling</li> <li>Nursing Delegation</li> <li>Student Care Plans</li> <li>Student-centered Care</li> <li>Student Self-empowerment</li> <li>Transition Planning</li> </ul>	<ul style="list-style-type: none"> <li>Advocacy</li> <li>Change Agents</li> <li>Education Reform</li> <li>Funding and Reimbursement</li> <li>Healthcare Reform</li> <li>Lifelong Learner</li> <li>Models of Practice</li> <li>Technology</li> <li>Policy Development and Implementation</li> <li>Professionalism</li> <li>Systems-level Leadership</li> </ul>	<ul style="list-style-type: none"> <li>Continuous Quality Improvement</li> <li>Documentation/Data Collection</li> <li>Evaluation</li> <li>Meaningful Health/Academic Outcomes</li> <li>Performance Appraisal</li> <li>Research</li> <li>Uniform Data Set</li> </ul>	<ul style="list-style-type: none"> <li>Access to Care</li> <li>Cultural Competency</li> <li>Disease Prevention</li> <li>Environmental Health</li> <li>Health Education</li> <li>Health Equity</li> <li>Healthy People 2020</li> <li>Health Promotion</li> <li>Outreach</li> <li>Population-based Care</li> <li>Risk Reduction</li> <li>Screenings/Referral/Follow-up</li> <li>Social Determinants of Health</li> <li>Surveillance</li> </ul>

ASCD & CDC. (2014). *Whole school whole community whole child: A collaborative approach to learning and health*. Retrieved from <http://www.ascd.org/ASCD/pdf/siteASCD/publications/wholechild/wscc-a-collaborative-approach.pdf>

**FIGURE 28-3** Framework for 21st century school nursing practice. (Reprinted with permission from the National Association for School Nurses. (2019). *Framework for 21st century school nursing practice*. Retrieved from <https://www.nasn.org/nasn/nasn-resources/professional-topics/framework>)

An integrative study looked at the relationship between school nurse interventions and the impact on health and education outcomes of school children. Using the NASN Framework for 21st Century School Nursing

Practice, Best, Oppewal, and Travers (2018) categorized school nurse interventions and health outcome measures through a systematic review and meta-analysis of the literature with studies falling under one of the Framework's four areas:

- 54% of the studies were in the area of care coordination, in which nurses provided case management, chronic disease management, collaborative communication with staff and parents, direct patient care, support groups, counseling, and student care plans.
- 18% of school nurse work was in the area of leadership and lifelong learning, in which nurses took classes to support their knowledge and care in areas such as asthma, child protective services, food allergies, and concussions.
- 25% of school nurses provided interventions in the area of health education, screenings, referrals, follow-up on medical issues, and surveillance.
- Less than 3% of the school nurse's time is spent in the area of quality improvement, including documentation and data collection.

School nurses, administrators, teachers, parents, and community stakeholders are all vital in coordinated school health programs and in developing health-promoting schools (Best et al., 2018). The NASN serves as a resource for school nurses across the United States. Their position papers and resources give guidance to nurses in the trenches who typically serve in autonomous positions and may be the only nurse for their district, traveling great distances between schools, especially in rural America. The NASN position papers provide direction for school nurses and include such categories as disaster preparedness, bullying and cyberbullying, chronic absenteeism, individual health care plans, school violence, sexual health education in schools, and telehealth. The full list of position papers can be found at <https://www.nasn.org/nasn/advocacy/professional-practice-documents/position-statements> (NASN, 2018b).

It is the position of NASN that school nurses play an essential role in keeping children healthy, safe, and ready to learn. The school nurse is a member of a unique discipline of professional nursing and is often the sole health care provider in an academic setting. Twenty-first century school nursing practice is student-centered, occurring within the context of the student's family and school community (NASN, 2016). “It is essential that all students have access to a full-time school nurse all day, every day” (American Academy of Pediatrics [AAP], 2016; NASN, 2018c, p. 3).

### *Key Roles of the School Nurse*

The school nurse's main role is to provide both individual and population health care and coordination for school-age children and adolescents. In providing services, school nurses use their knowledge of:

- Normal growth and development
- Social determinants of health
- Safety and health (including environmental health)
- The educational system
- The connection between health and learning

Other key roles of the school nurse are to ([AAP, 2016](#)):

- Promote health among students, families, and staff.
- Provide case management for children with chronic illnesses (e.g., diabetes, asthma, severe allergies).
- Provide immunization monitoring/access.
- Collaborate with parents, teachers, and psychologists in providing appropriate educational plans for students requiring special education services.
- Work with school staff to ensure a healthy and safe environment (e.g., nutrition, physical activity, playground safety).
- Collaborate with community agencies (e.g., public health departments, other health agencies, charitable groups, and service clubs), physicians, dentists, parent groups, and child protective services to meet students' and families' needs.
- Conduct screenings and work with school staff to promote their health and wellness.
- Work with school-based clinics to provide direct health care to children and their families.
- Assist in leading coordinated school health programs.

The [NASN \(2016\)](#) describes the broad role of the school nurse as a “specialized practice of professional nursing that advances the well-being, academic success, and lifelong achievement and health of students” (para. 8). The school nurse ([NASN, 2016](#)):

- Facilitates the normal development of students and promotes positive intervention outcomes
- Provides leadership in the areas of health promotion, safety, and a healthy school environment
- Provides high-quality health care and promotes early intervention for actual and potential student health problems
- Uses sound clinical judgment in the provision of case management for students

- Collaborates actively and professionally with others to promote student and family capacity for self-management and adaptation, as well as learning and self-advocacy

The partnership between school nurses and families is important for the child's health outcomes, and the use of problem-based communication strategies helps promote this collaboration (Roberts, Taylor, & Pyle, 2018).

### *Liaison With the Interdisciplinary School Health Team.*

School nursing services are part of a coordinated school health program that provides school health services, health education, and health promotion programs for faculty and staff (American School Health Association, n.d.). Although the school nurse plays a central role, collaboration with many other individuals is important. School nurses must be familiar with the education setting and work closely with teachers and aides, special education teachers and staff, principals, administrators, school office staff, health aides, psychologists, and speech therapists, as well as parents and families. The Whole School, Whole Community, Whole Child (WSCC) model focuses on the child, emphasizes a school-wide approach, and acknowledges learning, health, and the school as being a part and reflection of the local community (CDC, 2020). The Virtual Healthy School (<https://www.cdc.gov/healthyschools/vhs/#!/scene/1>) emphasizes the relationship between health and school, highlighting the WSCC model (CDC, 2018b). See Figure 28-4 for the WSCC model.

**WHOLE SCHOOL, WHOLE COMMUNITY, WHOLE CHILD**  
*A collaborative approach to learning and health*

---

**FIGURE 28-4** Whole School, Whole Community, Whole Child model. Reprinted from the Centers for Disease Control and Prevention. (2016). *Whole School, whole community, whole child*. Retrieved from <http://www.cdc.gov/healthyyouth/wsc/>

It includes 10 components:

- Health education
- Physical activity/education
- Nutrition services/environment
- Health services
- Counseling/social/psychological services

- Social/emotional climate
- Physical environment
- Employee wellness
- Family engagement
- Community involvement

## *Positive Working Relationship With School Team Members*

The school principal influences all phases of the school health program by promoting good school health through active support of the school's health services, participation in setting health-related policies, and tapping into community resources. The principal can reinforce positive efforts within the school, ranging from the health teaching in the classroom to the cleaning activities of the custodian. Because of the principal's influential position, it is absolutely essential for the nurse and principal to maintain a positive and cooperative working relationship.

Teachers, whether they are involved in regular instruction, physical education, or special education, play a major role in school health. Because they spend the most time with students, their observations, health teaching, and personal health habits have a profound effect on student health and the quality of school health services.

The school nurse and teachers must collaborate constantly, as the school nurse provides information and guidance to teachers regarding students in their classrooms with specific health conditions and concerns and teachers report on students' health concerns and behaviors. [Mink \(2019\)](#) found that teachers had higher levels of satisfaction when nurses were available on campus full time and appreciated nurses' help with students having chronic conditions, managing medical emergencies, and providing first aid when students were injured. They also found benefits when school nurses followed up on hearing and vision problems, making necessary referrals and getting services for students having problems.

**Student study teams (SSTs)**, where teachers, administrators, psychologists, school nurses ([Fig. 28-5](#)), and others meet to discuss students identified as having learning or health problems, were also noted as an important collaborative opportunity ([Merced Union High School District, n.d.](#)).

**FIGURE 28-5** The school nurse is part of a team providing a coordinated school health program.

Other health team members, such as health educators, health coordinators, psychologists, audiologists, speech therapists, occupational therapists, physical therapists, counselors, health care providers, dentists, dental hygienists, social workers, security and juvenile justice personnel, health aides, and volunteers, may also be involved, depending on size and financial resources of the school. All team members, including students, parents, bus drivers, and custodians, have a specialized role complementary to that of the school nurse.

**School-based health centers (SBHCs)** provide an access to health care services for youth confronted with barriers to social determinants of health and are often sponsored or funded by public health departments, community health centers, or hospitals. They often provide care for children, and sometimes their families, who otherwise do not have access to health care.

SBHCs provide “significant positive effects on youth health and academic outcomes including high school completion and grade point average, grade promotion, lower rates of hospitalizations, emergency room visits, substance use, and higher rates of contraception use.” (Bersamin et al., 2019, p. 11). SBHC are predominantly established in lower socioeconomic neighborhood and urban settings. Over the last 3 years, there has been a 20% increase or 2,315 new SBHC across the United States (Bersamin et al., 2019).

### *Responsibilities of the School Nurse*

School nurses address the social determinants of health such as environment, access to health insurance, housing, and income as most health issues are associated with social determinants of health (NASN, 2018c). They bridge

health and education preventing illness and promoting and maintaining the health of the school community. The school nurse serves not only individuals, families, and groups within the context of school health but also the school as an organization and its membership (students and staff) as aggregates. The school nurse identifies health-related barriers to learning, serves as a health advocate for children and families, and promotes health while preventing illness and disability (NASN, 2018c).

School nursing activities are varied and is composed of nursing care of children with special health needs, including nasogastric tube feedings, catheterization, insulin pumps, and suctioning; general and emergency first aid; vision, hearing, scoliosis, and TB screenings; height, weight, and blood pressure monitoring; oral health and dental education; immunization assessment and monitoring; medication administration; assessment of acute health problems; health examinations (athletic participation or school entry); and referrals (Best et al., 2018). School nurses also assess and are the frontline providers for identifying communicable diseases, such as outbreaks of influenza or meningitis. Medication administration is another common school nurse duty and includes giving a wide range of medications for acute and chronic issues, as well as delegation of medication tasks:

- 94.3% of school nurses reported giving ADHD medications
- 82.4% gave asthma-related medications
- 64% gave medication for either type 1 or 2 diabetes
- 45.2% gave psychiatric-related medication
- 31.5% of medications were for allergies, 19.6% of medications were for seizures
- 11.2% were for bowel or bladder management (Maughan, McCarthy, Hein, Perkhounkova, & Kelly, 2018).
- Administration of medication can be delegated 77.9% of the time to unlicensed assistive personnel (UAP), such as health aids or school clerks (Maughan et al., 2018).
- Administrators, teachers, and others may also give medications depending upon state laws.

In addition, school nurses perform first aid, help students with inhalers and nebulizer treatments, and some may do gastric tube feedings and ventilator/tracheostomy care. They are responsible for documenting their care, but this can be difficult because of time constraints, educational regulations, and lack of a functional standardized data set or method of collection. Other duties of a school nurse may include training school staff in cardiopulmonary resuscitation (CPR), universal precautions and first aid, as well as overseeing the health and wellness of school staff members. Each school nurse must assess and prioritize how to address the specific needs in each individual school and determine the order. As you can see, there are a

wide variety of activities involved in school nursing. This largely autonomous practice requires specific skills and training.

### *Education: Special Training and Skills of the School Nurse*

School nurses operate from one of two administrative bases: the school system or the public health department (NASN, 2016). In most localities, public or private school systems or districts hire school nurses, and they maintain a specialized, school-based practice. Private schools and universities also hire school nurses.

In this specialized role, the nurse can concentrate time and effort solely on the school health program and develop specialized skills in school health assessment and intervention. Today, with the emphasis on delivery of health care at community sites where clients spend most of their time (e.g., schools for children, the workplace for adults), the nurse whose specialty is school health care seems better prepared to meet the complex needs of the school-age population. In contrast, the school nurse who operates under the board of health's jurisdiction provides services to schools as one part of generalized public health nursing services to the community. The community health nurse working through the health department usually devotes only a portion of the workday to the school; she may have additional responsibilities, such as clinic nursing and home visits.

- Depending on the state of residence, a school nurse is usually an RN—frequently with additional education beyond the bachelor's degree in nursing, sometimes including a master's degree—that has primary responsibility for the health care of school-age children and school personnel in an educational setting.
- In some areas of the country, licensed practical nurses (LPNs) or licensed vocational nurses (LVNs) may be hired by school districts, but they must generally work under the supervision of an RN. *School nursing: Scope and standards of practice* (ANA & NASN, 2017) indicates that school nurses should, at minimum, possess a bachelor's degree.

As the needs of school-aged populations become increasingly complex, some states require even more specialized training for school nurses. In California, for instance, school nurses are expected to hold a school health services credential. This credential is obtained through a post-baccalaureate program that includes course work in audiology, guidance and counseling, exceptional children, school health principles and practice, a practicum in school nursing, child psychology, and health curriculum development, in

addition to other courses. A national certification is available as well ([NASN, 2018d](#)).

### *Functions of School Nursing Practice*

The three main functions of school nursing practice are health services, health education, and promotion of a healthy school environment. Health services include caring for individual students who have chronic conditions, acute situations, and comprehensive care coordination needs while at the same time thinking of the entire population and tracking trends ([Willgerodt et al., 2018](#)). For example, the school nurse observes an increase in the number of students diagnosed with asthma and investigates ways to help all students with asthma. One way of doing this may be to organize an *Open Airways* course ([American Lung Association, 2018](#)) to assist students in identifying triggers and managing their own care. The goal of this course would be to decrease student asthma attacks.

### *Health Services for Children With Chronic Conditions*

Chronic health conditions are commonly acquired, incurable and conditions lasting longer than 12 months with physical, emotional, functional, developmental, and behavioral conditions ([NASN, 2017a](#)). The number of children afflicted with chronic diseases is rising; it is estimated that 25% of children and adolescents in the United States are affected by a chronic condition ([Miller, Coffield, Leroy, & Wallin, 2016](#)).

Common chronic conditions include asthma, epilepsy, anaphylaxis, hypertension, diabetes, and oral health ([Leroy, Wallin, & Lee, 2017](#); [Miller et al., 2016](#)). A systematic review ([Leroy et al., 2017](#)) noted a significant reduction in absenteeism and positive trending in attendance with school-based care and/or education. Overall, there was improvement in medication adherence, improved symptoms, and health care use when plans of care in the school were put in place. Although, reducing absenteeism is a common function for school nurses, and chronic absences have often been linked with chronic conditions like asthma and diabetes ([Jacobsen, Meeder, & Voskuil, 2016](#)). School nurses will need to maintain knowledge and training in chronic issues ([NASN, 2017a](#)). Refer to content in [Chapter 20](#) and see [Box 28-8](#).

## **BOX 28-8 QSEN: Focus On Quality**

**Patient-Centered Care for Correctional Nurses Patient-Centered Care: Recognize the patient or designee as the source of control and full partner in providing compassionate and**

**coordinated care based on respect for patient preferences, values, and needs (Cronenwett et al., 2007, p. 123).**

(See [https://qsen.org/competencies/pre-licensure-ksas/#quality\\_improvement](https://qsen.org/competencies/pre-licensure-ksas/#quality_improvement) for the knowledge, skills, and attitudes associated with this QSEN competency.) Working in a correctional facility is unlike working in any other setting. Prior to being incarcerated, inmates may not have received health care. Custody is always with nurses when providing health care. This may cause problems with patient confidentiality. Nurses must remember not to self-disclose any part of their life outside of work. Instead, develop therapeutic relations by following through with statements made, ask questions, and practice active listening (Nursing @CSU Staff, 2019).

Common health issues with this population are many. Infectious disease includes HIV, STDs, hepatitis B and C, and tuberculosis. Mental illnesses are prevalent. When first arrested, inmates may experience drug or alcohol withdrawal (American Academy of Family Physicians, 2019). Chronic conditions such as hypertension, cancer, diabetes, asthma, and cirrhosis of the liver are seen in the population (USDOJ, 2016). Nurses need to be prepared to care for inmates experiencing a CVA, drug overdoses, or MI. Depression is the most common mental illness seen in this population. Other disorders include bipolar, anxiety, and PTSD (Reingle Gonzalez, & Connell, 2014).

1. *As a new correctional nurse, what concerns/fears might you have when providing patient-centered care to this population?*
2. *Do you think knowing the crime committed would affect the care you provide? Why or why not?*

Source: American Academy of Family Physicians (2019), Cronenwett *et al.* (2007), Nursing @CSU Staff (2019), Reingle Gonzalez & Connell (2014), U.S. Department of Justice (2016).

For students in special education programs, school nurses can coordinate **individualized education plans (IEPs)** with **individualized health plans (IHPs)** to develop health management goals for students. Medically fragile or technology-dependent students, who may require procedures such as suctioning or tube feeding, would have IHPs developed for *specialized physical health care procedures* (Orange County Department of Education, n.d.). Because these students are often hospitalized, interrupting their education, the school nurse needs to assist with transition planning. Collaboration with school psychologists and school and health team members is important to transition planning that is also needed as students move from elementary to middle school, from middle school to high school, and as they move out of public schools and on to other educational or job training settings (NASN, 2018e).

School nurses develop IHPs to ensure that students with special needs (e.g., chronic conditions) have these needs met. If these students attend the regular classroom and do not fall under the IDEA, the plans may be known as **Section 504 plans**, named after the section of the Rehabilitation Act and the accompanying statute, the ADA, that specifically allows for school accommodations with this population. Some examples might include severe peanut allergies that lead to anaphylaxis, serious asthma complications, diabetes, or heart disease.

Students are to be provided with a “free and appropriate public education,” and some students may be covered under both IEPs and Section 504 plans ([California Code of Regulations 5CCR 3030, n.d.](#)). See [Box 28-9](#) for a list of IEP-eligible disabilities.

## **BOX 28-9 Thirteen Disabilities Eligible for Individualized Education Plans**

- Autism
- Deaf-blindness
- Deafness
- Emotional disturbance
- Hearing impairment
- Intellectual disability
- Multiple disabilities
- Orthopedic impairment
- Other health impairment
- Specific learning disability
- Speech or language impairment
- Traumatic brain injury
- Visual impairment, including blindness

Source: [Galemone and Sheetz \(2015\)](#).

## **Asthma**

Asthma is often deemed the most common chronic disease of childhood. Students lose over 13 million missed school days a year from this chronic disease ([Everhart, Miller, Leinach, Koinis-Mitchell, 2018](#)). Student symptoms include shortness of breath, tightness of chest, wheezing, and lack of energy ([Everhart et al., 2018](#)). School environmental factors (e.g., mold, allergens, indoor air quality) also exacerbate asthma symptoms in children and youth.

Asthma management programs are useful in helping students manage symptoms and reduce asthma triggers. School nurses work with students, their families, and their doctors to develop an *asthma action plan* to control, prevent, or minimize untoward effects of acute asthma episodes. Peak flow meters can be used regularly to determine early signs of asthma problems. Monitoring asthma medications and teaching proper methods of inhaler use are also vital school nursing functions. It often falls to school nurses to ensure that proper protocols and training are in place. It is imperative that school nurses are well versed in the care and treatment of asthma.

In Colorado, a framework for asthma care curriculum was created to guide the continuing education of school nurses and health care team members in their state (Cicutto et al., 2017). A Healthy Homes program headed by C/PHNs in Baltimore, Maryland, focused upon home assessments for environmental health risks (lead, asthma triggers, carbon monoxide, pesticide use, environmental tobacco smoke) as well as source of heating in the home. They also included educational sessions to review home environmental health risks and a targeted hazard reduction intervention (U.S. Department of Housing and Urban Development, n.d.). Refer to content in Chapter 20.

## Diabetes

Diabetes is another common chronic illness in young people: approximately 208,000 or one in 433 children and adolescents have diabetes (National Diabetes Education Program, 2016). Of these, 87% are diagnosed with type 1 and 11% are diagnosed with type 2 diabetes (NASN, 2017b). It is estimated that there are 18,000 newly found youth under the age of 20 annually diagnosed with type 2 diabetes and over 5,000 newly diagnosed with type 1 diabetes (NASN, 2017b). Both types of diabetes are on the rise in adolescents, leading some scientists to frame it as a major public health crisis caused largely by obesity, sedentary lifestyle, and the predisposition of certain ethnic groups to diabetes (National Institute of Diabetes and Digestive and Kidney Diseases, 2017). Refer to content in Chapter 20.

Working with families and health care providers, school nurses assess and develop a care plan for students with diabetes. School nurses work closely with the family to maintain confidentiality and at the same time ensure that the school is a safe environment for the child:

- A multidisciplinary team approach is needed, with family, school, and physician collaboration.
- Training for teachers and fellow classmates is also important.
- Teachers are often called upon to assist students with their insulin or food management.

- Younger children with type 1 diabetes, especially those who use insulin pumps, may need careful monitoring—something that is not always possible for the school nurse, who may not be present where and when problems arise.
- A student experiencing a hypoglycemic reaction should never be left alone. It is important for school nurses to alert teachers and school personnel to the signs and symptoms (as well as the treatment) of hypoglycemia.
- A current position of NASN, NIH, and CDC is that a *diabetes medical management plan* should be in place to assist in the care of children with diabetes (NASN, 2017b; National Diabetes Education Program, 2016).
- Care coordination, training, and delegation are the roles of the school nurse (NASN, 2017b). However, many school nurses do not feel comfortable delegating tasks such as administration of insulin or glucagon.

Testing blood sugar and taking insulin at school can be frustrating and can cause children to feel different from their peers. Students may be required to administer medication or check blood sugar levels in health offices as well as follow protocol for needle dispensing. Diabetes must be managed 24 hours a day, seven day a week.

Type 2 diabetes cases have been rising, and school nurses can be instrumental in prevention measures and early identification. It is often found more frequently in Native American and Hispanic populations and less frequently among non-Hispanic Whites. Also, obesity is an independent risk factor, with close to a quarter of children and youth being obese. Visceral fat is associated with insulin resistance and impaired glucose tolerance, a pathology linked to type 2 diabetes. Culturally sensitive interventions that include increased physical activity and education on good nutrition, as well as behavior modification and ongoing methods of support (e.g., group meetings, phone/e-mail reminders) were shown to be effective in a systematic review (Brackney & Cutshall, 2015). School nurses should assess their school population and promote interventions that benefit at-risk students, as well as the general school population. Refer to content in [Chapter 20](#).

## Seizure Disorders

Seizure disorders are not uncommon in the school-age population. Epilepsy is a disorder of the brain in which neurons sometimes give abnormal signals. For the majority of those diagnosed, seizures can usually be controlled with medication (e.g., antiepileptic drugs specific to the pediatric population), surgical treatment, or a special (e.g., ketogenic) diet ([Epilepsy Foundation](#),

2017; [National Institute of Neurological Disorders and Stroke, 2018](#)). It is important for school nurses to develop care plans to address seizure concerns during school hours.

- Care plans include monitoring medication compliance and teaching school staff about first aid measures for seizure victims.
- Children and adolescents with seizure disorders may feel embarrassed or be the victims of teasing or bullying.
- They may exhibit signs of school avoidance. Nurses need to work with these children and to teach all students about the disease process and the need for empathy and understanding.
- Similar to issues related to insulin administration for diabetic students, children with seizure disorders may have an emergency medication ordered by their physician (e.g., Diastat, midazolam, lorazepam, clonazepam). Prescribing providers and school nurses should be aware of the laws regarding the administration of seizure rescue medications, particularly as they pertain to UAP ([Hartman, Devore, & Section on Neurology, Council on School Health, 2016](#)).
- The [Epilepsy Foundation \(n.d.\)](#) has advocated for its use in schools, and school nurses are often caught between the rights of students and their parents and their state's nursing practice act. Refer to content in [Chapter 20](#).

## **Food Allergies and Anaphylaxis**

Another leading chronic condition found in school settings is severe food allergies that can lead to anaphylactic shock.

- It is estimated that the 5.9 million school-aged children have food allergies ([Food allergy Research and Education \[FARE\], 2018](#)).
- Such severe allergies result in approximately 200,000 ED visits each year ([FARE, 2018](#)).
- Eight common foods account for 90% of severe food allergies. They are fish, shellfish, soy, milk, egg, wheat, peanuts, and tree nuts (e.g., cashews, walnuts).
- Many common foods and school supplies (e.g., play dough) can contain hidden allergens, and care must be taken to prevent exposure.
- School nurses coordinate and work with students and their families, along with school personnel, to raise awareness and enlist caution.
- School nurses also work with families, and health care providers, to ensure that epinephrine via an auto injector (EpiPen) are available for the child in case of emergencies. It is also used for bee sting and other allergies, in addition to food allergies.
- Although many factors are taken into consideration, most pediatric allergists believe students between 12 and 14 years should carry and be

able to self-administer their own EpiPen ([American Academy of Allergy, Asthma & Immunology, n.d.](#)).

- School nurses should coordinate with teachers and lunchroom personnel to ensure that proper protocol is followed for allergic reactions. School personnel should be made aware of the food allergy, understand an anaphylactic reaction, and be able to verbalize or demonstrate how to use the EpiPen or other needed medication ([CDC, 2018c](#)). School nurses need to ensure the Allergy and Anaphylaxis Emergency Plan is completed by the parent and physician to ensure proper treatment for a student with severe allergies while at school ([AAP, 2018a](#)). In addition, a 504 or IHP should be completed. Refer to content in [Chapter 20](#).

## **Behavioral Problems and Learning Disabilities**

Other chronic childhood health problems are those of emotional, behavioral, and intellectual development. These are not always easy to detect and measure, and they can be debilitating. Although these problems are not new, awareness and concern have increased as the rates of occurrence for other life-threatening childhood diseases have diminished.

- The National Institute of Mental Health (NIMH) reports that emotional and behavioral disorders affect 10% to 15% of children globally ([Kid's Mental Health Portal, 2018](#)).
- Problems such as oppositional defiant disorder, bipolar disorder, and early schizophrenia can affect the school-age population and is a concern to school nurses and staff ([Riley, Ahmed, & Locke, 2016](#)).
- The causes of emotional behavioral problems and learning disabilities appear to have genetic, environmental, and cultural influences.
- High-risk children often come from families with a high incidence of child abuse (physical and sexual) and neglect.
- The number of children affected by parental drug use has surpassed that of children with disabilities caused by lead poisoning, another major contributor to developmental problems in children.

Attention-deficit/hyperactivity disorder (ADHD) is a cluster of problems related to hyperactivity, impulsivity, and inattention. Approximately 6.4 million school-age children have been diagnosed with ADHD ([National Center for Learning Disabilities, 2017](#)). School nurses must be aware of the signs and symptoms and serve as an advocate for these children and their families. At each stage of development, those with ADHD are presented with distinct challenges. For example, children in elementary school may often have difficulty and conflict with peers, as well as problems organizing tasks. They may be more accident prone and may have more school-related problems, such as grade retention and suspension or expulsion. They often have problems with grooming and with handwriting, and they exhibit

difficulty sleeping. ADHD is sometimes found with associated disorders, such as communication or language disorders and learning disabilities. It is estimated that as many as one third of children with learning disabilities also have ADHD ([National Center for Learning Disabilities, 2017](#)). Counseling and behavior therapy are often used with these children with a 70% to 80% success rate demonstrated by improved behavior ([Substance Abuse Mental Health Services Agency, 2020](#)).

Behavioral and emotional problems of school-age children can stem from many causes. School nurses can be alert to early symptoms and refer families for counseling.

- Collaboration is needed between the child's family, the school, and the child's health care provider to diagnose ADHD and effectively plan appropriate interventions and educational accommodations.
- Numerous checklists and assessment tools are available, and school psychologists typically serve as a source for additional information and resources.
- School nurses can assist parents in recognizing the symptoms of ADHD and obtaining appropriate treatment and follow-up. A multimodal treatment approach may include stimulant medication, usually methylphenidate (Ritalin or Concerta), dextroamphetamine (Dexedrine), and amphetamine (Adderall).
- Family and individual counseling, parent support groups, and training in behavior management techniques, as well as family education about the condition, are also essential features of this method of treatment.
- Not all children and adolescents respond to medication, and medication dosage must be carefully monitored and titrated.
- School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens.

The main goal of medication for school-age children is academic improvement. If this does not occur, medication may need to be changed or discontinued. School nurses and community health nurses can work closely with school staff, parents, and physicians in determining the efficacy of treatment regimens ([Chan, Fogler, & Hammerness, 2016](#)).

## **Medication Administration**

Medication administration for a variety of conditions has historically been an important responsibility for school nurses ([NASN, 2017c](#)). In schools where a nurse is present every day, the nurse can personally oversee medication administration. Unfortunately, many nurses cover more than one school and so other school personnel (e.g., secretaries, health aides) may be tasked with

overseeing medication administration. The majority of states have laws allowing teachers or health aides to administer medication. In these situations, school nurses should provide training and audit records to ensure that proper guidelines are followed. In one study, over 800 schools were surveyed and medication administration errors occurred 15% of the time ([Maughan et al., 2018](#)):

- 58.4% occurred due to missed dose
- 19% for wrong time
- 18.3% for wrong dose
- 11.2% for wrong medication
- 10.6% for medication not documented
- 9.9% for wrong student
- 8.0% given without authorization

Another issue surrounding medication administration in the school setting is regarding delegation. Each state's individual nurse practice act provides rules on delegation of nursing tasks. School nurses must understand their own state's act and the legal implications regarding their decisions. School districts are responsible for including medication administration guidelines in their policies, and school nurses must comply with established guidelines ([NASN, 2017c](#)).

In a landmark case, the ANA filed a lawsuit on behalf of California school nurses to prevent insulin administration by unlicensed personnel. Their argument centered on the state's Nurse Practice Act and the need for licensed nurses to administer this medication (with dosage often checked by two nurses in hospital settings). However, the American Diabetes Association and others argued that not all schools have adequate school nurse coverage, and over one quarter of schools do not employ a licensed nurse. Two courts ruled on the side of the school nurses, but the California Supreme Court ultimately overturned those decisions, making it possible for unlicensed personnel to give medications, including insulin, with parental and medical permission ([American Diabetes Association, 2017](#)). The concept of “in loco parentis” instructs school staff to provide care for the student in the parent's place and with their consent ([Alliance of Schools for Cooperative Insurance Programs, 2017](#)).

### *Health Services to Prevent Illness and Injury*

School nurses emphasize prevention and focus many of their efforts on prevention of communicable disease (via immunizations) and of injuries.

## **Immunizations**

School immunization rates continue to be high due to vaccine mandates for school entry, yet areas where children remain unvaccinated affect herd immunity rates causing outbreaks of measles and pertussis (NASN, 2020a, 2020b). See [Chapter 8](#) for more on this.

Low immunization levels in many areas, in poor populations, public concern for vaccinations, and increased disease rates signal the need for constant surveillance, outreach programs, and educational efforts. School nurses are deeply involved in each of these preventive activities. Health departments and schools often work collaboratively to provide immunization services. Compulsory immunization laws for school entrance, which vary among states, have enabled public health personnel to carry out these preventive services. All states require children to be vaccinated against certain communicable diseases as a condition for school attendance (CDC, 2018d). Statewide immunization information systems can be beneficial for schools, school nurses, and children and their families. School nurses, like C/PHNs, may have access to not only viewing immunization records but also the ability to update them. This provides ready access for children and parents, as well as school nurses, to check immunization records, track those children whose immunizations are incomplete, and provide critical information during times of disease outbreaks.

School nurses often oversee and ensure that children are in compliance with school entrance laws regarding immunizations. They may call parents directly when they note that the student is out of compliance. They may also arrange to help the student get immunized by facilitating appointments or, in some school districts, by directly providing the immunizations.

The CDC provides information for National Immunization Awareness Month and provides a toolkit for school nurses and others to follow when developing successful immunization outreach programs in schools (CDC, 2018e). School nurses can be effective advocates in helping parents make decisions about vaccines (e.g., HPV for adolescents), especially when they have sufficient knowledge and recognize their role as an opinion leader (Rosen, Ashwood, & Richardson, 2016). See [Chapters 8](#) and [20](#) for more on parental resistance to vaccines, and current immunization schedules for school-age children and adolescents.

## Safety

School nurses are also involved in ensuring that school environments are safe places for students. School safety now incorporates more than just playground equipment. Safety includes the following:

- Safe neighborhood to walk to and from school
- Car safety whether passenger or driver
- Safety from gun violence

- Bullying
- Gangs violence
- Sexual violence
- Firearms, weapons, and mass shootings
- Playground injuries, sport injuries including risk for concussion
- Safety from natural disasters (CDC, 2017a)

Bullying behaviors affect 20% of students in their high school years; bullying includes both in-person and cyberbullying (NASN, 2018f). Cyberbullying occurs on social media sites and can have negative effects on student's health; despite increased attention to this problem students, including, LGBTQ students are at risk for physical, psychological, social, emotional, and academic problems (Byrne, Vessey, & Pfeifer, 2018).

Youth violence is a significant issue and is the third leading cause of death in the United States (CDC, 2016a). The rates and forms of violence vary with gang and violent crimes higher in large cities, LGBTQ and females having a higher prevalence of in-person and cyber bullying, and homicide and physical injuries greatest for racial/ethnic males (CDC, 2016a).

Emergency departments treat more than 800,000 children for concussions yearly; many concussions go undiagnosed (AAP, 2018b). New guidelines have been implemented by the American Pediatric Association using “age appropriate symptom scales to diagnose children and assess their recovery” (AAP, 2018b, para 8). The guidelines were created in response to health care providers asking for more evidence-based guidance, in addition, the guidelines can provide information for families, coaches, and schools (AAP, 2018b).

Another area of growing concern is student safety after natural disasters or emergency situations. Recent earthquakes and potential bioterrorism events may impact schools or not permit children to return home at the end of a school day. School nurses are ideal persons to assist in disaster/emergency relief. Students do spend much of their time in school, and local schools are often designated as shelters in times of disasters (NASN, 2016). School nurses can assist in the development of emergency plans, as well as provide care and comfort to children and their families in times of emergencies.

### *Health Education and Health Promotion*

Another main function of school nursing practice involves education and health promotion. This includes planned and incidental teaching of health concepts and health curriculum development. In some states, school nurses even teach the regular health classes. Education may be one-on-one to help a child obtain better control over asthma or to explain to a newly diagnosed diabetic student what is occurring in his body. As an educator, the school

nurse may also teach an entire class regarding a student's severe food allergy or the need for proper hand hygiene. The school nurse explains in simple terms what allergies are and helps students understand that allergies are not contagious, what to do in the case of an allergic reaction, and the importance of not sharing foods that may contain potential allergens (NASN, 2016). The application of research is important in school nursing. See [Box 28-10](#).

## **BOX 28-10 Evidence-Based Practice**

**School Nursing A study by Benjamin-Chung (2018) showed the impact of an elementary school influenza vaccination program to increase vaccination coverage, reduce school absenteeism, and interrupt influenza transmission in an elementary school in California. Outcomes of the study also identified influenza hospitalization numbers were reduced with an indirect effect on elderly hospitalization and nonelementary age groups. An elementary-school influenza program can profoundly impact absentee rates in school-aged children and have an indirect affect in older school-aged children and the community.**

Another example of evidence-based practice in school nursing involves testing for high-frequency hearing loss in adolescents (Sekhar et al., 2016). Not all states perform mandated hearing screening, and of those that do, not all test for high frequency hearing loss. This study compared sensitivity of current adolescent hearing screening test results with results from adolescents tested in a sound-treated booth. The researchers felt that if current hearing tests added multiple high frequencies this would improve sensitivity; the inclusion of a two-step screening of initial referrals could then be used to reduce false positives. Results of the study identified that traditional school-based testing methods had poor sensitivity for hearing loss in adolescents. Hearing screenings suggestions from the study include testing at 500, 1,000, 2,000, 4,000, and 6,000 Hz at 20 db HL with adolescents to identify high-frequency hearing loss.

*How could you use information from these studies to improve school nursing practice and the health of school-age children?*

Source: [Benjamin-Chung \(2018\)](#), [Sekhar et al. \(2016\)](#).

Because students trust school nurses, students often listen to them. Educational subjects are limitless but should always apply to the specific needs of the children in the school. The nurse must use creativity and autonomy to identify and prioritize needs. A school nurse may also teach about basic first aid, nutrition, physical exercise, sex education, and seat belt safety, or provide information about careers in the health care professions.

### *Screenings: Opportunities for Teaching*

Most local school districts provide some type of health screening services such as hearing and vision screenings, usually through the school nurse or local health care providers ([California School Based Health Alliance, 2020](#)). Although the goal of all screening is to promote early intervention, screening also provides the school nurse many opportunities to teach students and staff. Referral information resulting from screening results is usually given to parents, and school nurses may contact parents to encourage follow-through. Children who are not present for school screenings may not receive the benefits of these screenings (e.g., homeschooled and private school students). School nurses often help to coordinate screening resources and benefits, and they often carry out additional screenings for students who were absent when mass screenings were held.

## **Vision**

School nurses often oversee routine vision screenings at periodic intervals so that vision problems that can interfere with learning may be detected and treated early (e.g., nearsightedness, farsightedness, strabismus, and amblyopia) ([NASN, 2017d](#)). School nurses also are involved in follow-up and referral. They often send e-mails or letters to parents, make phone follow-ups, and provide referrals and resources to ensure that corrective eyewear is obtained.

The 2016 School Health Policies and Practices Study (SHPPS) noted that 82.7% of reporting school districts offered vision screening to kindergarten or first-grade students ([CDC, 2016b](#)). Local Lions Clubs may be involved in paying for area optometrists to assist with and/or direct screenings, as well as to provide follow-up care ([Lions Club, n.d.](#)).

## **Hearing**

Hearing screenings for kindergarten and first-grade students reported 79.5% of districts across the United States offered these services (CDC, 2016b). These mass screenings are done to detect any serious hearing deficits that may be related to recurrent ear infections or noise-induced hearing loss (NIHL), often resulting from loud music, video games, or excessive exposure to noise.

- About 2 to 3 of every 1,000 school-aged children, aged 6 to 19, have some type of detectable hearing loss in one or both ears (National Institute on Deafness and other Communication Disorders, 2016).
- Some have a type of *sensorineural hearing loss*—or one that involves the inner ear or the nerves leading from the inner ear. It is permanent and cannot be surgically or medically corrected (American Speech-Language-Hearing Association, n.d.).
- Similar to vision screening, school nurses screen and refer students with suspected hearing problems to medical specialists (e.g., audiologists, physicians).
- School nurses can use the opportunity afforded by vision and hearing screenings to provide education to students and their parents about preventing problems such as NIHL.

## Other Health Screenings

Height, weight, and sometimes blood pressure and cholesterol screenings may be done to monitor normal growth and development and allow for early intervention with populations who are especially susceptible to hypertension and heart disease. In some areas, scoliosis screening is also done, frequently during middle school years, to permit early detection and referral for medical intervention (e.g., bracing, surgery). Scoliosis may be congenital but is often idiopathic, and the efficacy of school screening programs has been questioned. There is much controversy surrounding scoliosis screenings in schools. One study found the lack of referrals, costs, or not having a school nurse to conduct the screenings as concerns. However, the study concluded that school screenings be conducted in the underserved populations that may lack yearly pediatrician visits (Kadhim et al., 2019). A systemic review of school screenings found screenings were successful in detecting problems in the early, treatable stages (Altaf, Drinkwater, Phan, & Cree, 2017).

In Texas, and some other areas of the country, *acanthosis nigricans* (hyperpigmentation from various causes, but sometimes a symptom of diabetes) screenings are being done to look for early markers of type 2 diabetes, especially in high-risk populations (Texas Department of Health Services, 2018).

Pediculosis (or head lice) in school-age children is a continual problem for school nurses. Between 6 and 12 million children aged 3 to 11 each year

are estimated to be infected with head lice, and school nurses are often called upon to do “head checks” for pediculosis. Pediculicides (e.g., permethrin, pyrethrins, dimethicone) are helpful in killing lice, and school nurses often provide families with education on prevention and eradication methods (Gunning, Kiraly, & Pippitt, 2019). In addition, a nonchemical based, heat-based treatment has provided families with an alternate option for lice treatment in many communities (Lice Clinics, 2019). See Chapter 20.

## **Oral and Dental Health: Teaching and Referral**

Dental caries affect more than half of school-age children and are the most common chronic disease for that age group. About 20% of 5-to 11-year-olds and 13% of 12-to 19-year-olds have at least one untreated decaying tooth (CDC, 2017b). The percentage of children and adolescents aged 5 to 19 years with untreated tooth decay is twice as high for those from low-income families (25%) compared with children from higher-income households (11%) (CDC, 2017b). School nurses can address dental health issues in a variety of ways.

- At a community level, they can educate the public about the benefits of dental fluoride treatments. They can advocate for fluoridation of drinking water, school-provided fluoride rinses or gels, and dental sealant programs. These are all cost-effective, proven methods of reducing dental caries in school-age children.
- At the classroom level, school nurses can provide dental education and provide toothbrushes, toothpaste, and floss to ensure that students are able to practice good dental hygiene habits.
- Local organizations and businesses often will donate such supplies. Many programs from the American Dental Association, the CDC, and other organizations provide resource materials.
- At an individual level, school nurses can assist in finding resources for those with no dental health insurance.
- Finally, school nurses can successfully educate parents, especially those who are immigrants or have different cultural beliefs, regarding the importance of oral and dental health (Hassmiller, 2016; Reza et al., 2016).

Dental screenings or clinics may be conducted to determine the incidence of dental caries, especially in elementary school children, and to encourage follow-up with local dentists for necessary restorations. At the time of the most recent national survey of schools, only 41.4% of districts reported performing some type of oral health screening (CDC, 2016b). See Chapter 20.

### *Promotion of a Healthful School Environment*

A third function of school nursing practice includes maintaining and promoting a healthful school environment. Promotion of healthful school living emphasizes planning a daily schedule for monitoring healthy classroom experiences, extracurricular activities, school breakfasts and lunches, emotional climate, discipline programs, and teaching methods. It also includes screening, observing, and assessing students to identify needs early and to report illegal drug use, bullying, suspected child abuse, and violations of environmental health standards (NASN, 2017e). Cyberbullying is another area where school nurses can provide education to students, parents, teachers, and school staff, as well as response to warning signs among school-age children and youth (Byrne et al., 2018). Health promotion also involves the nurse in supporting the physical, mental, and emotional health of school personnel by being an accessible resource to teachers and staff regarding their own health and safety.

## **Proper Nutrition and Exercise**

Many factors can affect the school environment—heating, cooling, lighting, safe playgrounds, and policies and practices to limit bullying and social aggression or other forms of school violence. The school cafeteria and physical education activities can promote health or contribute to obesity and sedentary lifestyles.

## **Obesity**

Obesity rates have steadily increased for all children since the 1980s; the rates have doubled for children between ages 2 to 5 and adolescents (ages 12 to 19). Rates have tripled for those between ages 6 and 11 years. Approximately 17% (or 12.7 million) of children and adolescents aged 2 to 19 years are obese (NASN, 2018g).

- American children get less than the recommended 60 minutes daily physical activity and over 90% of children have poor diets (NASN, 2018g).
- Only 58.9% of school districts across the United States assess student achievement of physical education standards (CDC, 2016b).
- Obesity often begins in childhood and becomes a risk factor for cardiovascular disease and diabetes later in life. With the increase in child obesity rates, the number of children diagnosed with type 2 diabetes continues to rise, especially among youth of minority race/ethnicity.
- As children become older, families have less impact on food choices, and peers begin to have more influence.
- Results of the 2017 YRBS indicate that very few high school students eat enough fruits and vegetables—of those surveyed only 13.9% of high

school students had consumed more than three servings of vegetables, and only 18% had consumed more than three servings of fruit or 100% fruit juice (CDC, 2018f).

School nurses should play an integral role in the prevention of overweight and obesity, as well as addressing the health needs of overweight and obese students (Box 28-11; NASN, 2018g). Many factors contribute to this health issue: diet, lack of physical activity, genetics, family and social factors, culture, socioeconomic status, and media marketing (NASN, 2018g).

## BOX 28-11 Levels Of Prevention Pyramid

### Obesity In A School Setting HEALTH ISSUE: Obesity in a school setting

Tertiary Prevention		
<i>Rehabilitation Move to</i>	<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>Work closely with the child, family, physician, and teacher to decrease body mass index (BMI)</li> </ul>	<ul style="list-style-type: none"> <li>Continue to promote healthy lifestyle choices and daily physical activity</li> </ul>	

Secondary Prevention	
<i>Early Diagnosis</i>	<i>Prompt Treatment</i>
<ul style="list-style-type: none"> <li>Conduct yearly screening of students' heights and weights to calculate BMI</li> <li>Complete health histories on at-risk children</li> </ul>	<ul style="list-style-type: none"> <li>Initiate referrals for health care provider follow-up in collaboration with parents of students at risk for obesity</li> </ul>

Primary Prevention	
<i>Health Promotion and Education</i>	<i>Health Protection</i>
<ul style="list-style-type: none"> <li>Limit passive activities and increase sports and physical activity</li> <li>Teach children how to make better food choices at fast food restaurants</li> <li>Educate children and teachers to promote good nutrition and a physically active lifestyle</li> <li>Promote a change of policy to take junk food out of vending machines</li> </ul>	

## Homelessness and Hunger

Poor nutrition and obesity are not uncommon among adolescents, whose diets often consist of snacks with limited nutritional value interspersed among unhealthful meals. Homelessness and hunger can also have serious consequences, one being an impact on the academic performance of children.

- Irritability, lack of energy, and difficulty concentrating are only some of the problems that arise from skipped meals or consistently inadequate nutrition.

- Infection and illness (e.g., ear infections, asthma, bronchitis, gastroenteritis) that lead to loss of school days can affect academic progress and interfere with the acquisition of basic skills, such as reading and mathematics.
- Dental caries are frequent.
- Poor nutrition is frequently associated with poverty and hunger, but social pressure to be thin can also spark purposeful malnutrition.
- Homelessness and food insecurity can lead to overreliance on fast food and convenience stores, and lack of stable housing triggers stress and anxiety, which can lead to ([Crawford et al., 2015](#)) obesity.

School nurses can help coordinate services for children that are homeless and advocate for better nutritional choices in the lunchroom and vending machines. This may include working for policy changes to limit soft drink sales in public schools. They can also teach all grade levels regarding proper nutrition, and they can educate students and parents alike about nutritious snacks in contrast to snacks with little food value, as well as provide information on community resources (e.g., food banks, health clinics, shelters). School nurses may also work with staff to provide nutrition and exercise programs, support groups, and collaborative efforts to assist families dealing with hunger and homelessness.

## Eating Disorders

Eating disorders are another area of concern. Issues with body image and control are at the heart of *anorexia nervosa* and *bulimia nervosa*, common problems for adolescent girls. These diseases have emotional causes that pose complex challenges to treatment. School nurses must be aware of the signs and symptoms of eating disorders and be proactive in identifying students at risk, working collaboratively with other members of the mental health treatment service team to advocate for the child. Scoliosis screenings are an optimal time to also observe for eating disorders, as examination of the spine allows for visualization of the body core. School nurses can work with students to develop a healthier self-concept and identify outside treatment resources ([National Eating Disorders Association, 2019](#)).

## Adolescent High-Risk Behaviors

Mortality and morbidity rates for adolescents are low overall and demonstrate considerable improvement since the early 1900s. High-risk behaviors that are directly related to morbidity and mortality in youth and young adults: behaviors that lead to unintentional injury and violence, tobacco use, alcohol and drug use, sexual behaviors that leads to pregnancies and sexually transmitted infections, unhealthy dietary behaviors, and lack of physical activity ([CDC, 2018g](#)). Many of the health problems faced by

adolescents are choices and high-risk activity; for example, sexual activity, substance abuse, injury, and violence are all high-risk behaviors in which adolescents can choose to participate or not. The effects of such choices may not be discovered for many years.

- Suicide is a leading cause of death of adolescents, according to the [Youth Risk Behavioral Survey \(2007–2017\)](#) 17.2% of students had seriously considered attempting suicide.
- Safety while driving or under the influence is other high-risk behaviors. Nationally, 62.8% of student's text while driving, 64.5% of youth drove when they had been using marijuana, 62.6% of students drove while under the influence of alcohol ([CDC, 2018f](#)).
- 4,300 youth ages 10 to 24 were victims of homicide, and homicide is the third leading cause of death for this age group ([CDC, 2016a](#)). 15.7% of youth carried a weapon (gun, knife, and club) 1 day in the past 30 days, while 3.8% of youth carried a weapon to school ([CDC, 2018f](#)). See [Chapter 20](#).

## **Sexual Activity: Teen Pregnancy and STDs**

Sexual activity is a sensitive issue. However, the 2017 YRBSS indicates that 39.5% of students surveyed reported they had had sexual intercourse, and 9.70% had had sexual intercourse with four or more partners in their lifetime ([CDC, 2018f](#)).

One in four sexually active adolescent females has an STI ([CDC, 2018h](#)). The overall rates of syphilis, gonorrhea, chlamydia, human papillomavirus (HPV), and herpes simplex virus are climbing.

Providing STD services and HIV/AIDS education can be a daunting task. Young people with STDs are often afraid or embarrassed to seek help. Those who have been exposed to the HIV virus may not know that they are infected. Although in some communities, the school-based clinic dispenses condoms, in other areas, school nurses may be restricted in what safer sex products they can provide. However, nurses *can* provide teens with education and with information about resources that are available outside of school property. School nurses can promote, at the local and state level, the HPV vaccine that guards against cervical cancer. They can promote abstinence or delaying sexual initiation, as well as fostering safer sex messages that promote the use of condoms. Sex education is effective at both delaying the onset of sexual activity and decreasing sexual activity in adolescents who are already sexually active. See [Chapter 20](#).

School nurses are sometimes restricted by state and/or district policies from addressing the issues of sex education and STI (including HIV) prevention. However, they can inform students and others in the community

about the existence of youth development and family planning programs, which are often stationed strategically in inner cities, near schools, or in school-based clinics. These agencies are empowered to provide birth control information and counseling to young people.

## Substance Abuse

Substance abuse among young people was almost unknown before 1950 and rare before 1960. Now, adolescent drug experimentation and use poses serious physical and psychological threats. During the 30 days before being surveyed, adolescent participants in the 2017 Youth Risk Behavior Survey reported that:

- 35.6% tried marijuana.
- 8.8% had smoked tobacco.
- 42.2% had used electronic vapor product. Vaping has increased significantly due to low perceived risk for youth with 12th graders reporting 11% use in 2017 and 21% use in 2018; 10th graders have also showed an increase with 8.2% use in 2017 and 16.1% use in 2018 ([National Institute of Drug Abuse, 2018](#)).
- 29.8% of students have had at least one alcoholic drink in the last 30 days ([CDC, 2018f](#)).

School nurses can assist in programs targeting all substance abuse. Successful programs focus on protective factors, instead of just high-risk behaviors. The programs focus more on the root causes, or why youth choose high-risk activities. See [Chapters 20](#) and [25](#).

School nurses can also provide resources for smoking cessation and substance abuse programs. In addition to school-based education, programs of peer leadership and parental education/involvement and community-wide task forces have been developed to lobby for local legislation and strengthen community–school ties. School nurses can be advocates at a community level by lobbying the city council for tougher ordinances controlling advertising content and zoning (especially near schools). School nurses often work in conjunction with law enforcement officials, school district administrators, and other community agencies to ensure compliance with local regulations and prevent or delay tobacco use. Other groups, such as 4-H clubs, religious congregations, the Catholic Youth Organization, and Boy Scouts, use peer counseling to influence young people to assume responsibility for healthy lifestyles, with the goal of developing decision-making skills that lead to healthy lifestyle choices in adolescence and through adulthood. The school nurse participates in and supports existing programs in addition to counseling and referring young people who need help.

## Mental Health Issues and Suicide

Depression, schizophrenia, and eating disorders may first appear during adolescence. It is estimated that 13% to 20% of children experience a mental disorder in a given year (NASN, 2018h). Many adolescents are reluctant to seek help for emotional problems or help may not be readily available to them.

- It is estimated that only 10% to 40% of those who need treatment actually receives it (NASN, 2018h).
- Common mental health disorders in adolescence include anxiety, depression, ADHD, eating disorders, bipolar disorder, and schizophrenia (NIMH, n.d.).
- Suicide is the third leading cause of death for young people between ages 15 and 24 years; it is the second leading cause of death in children between ages 5 and 14 years (American Academy of Child & Adolescent Psychiatry, 2017).
- School nurses must be aware of the signs and symptoms of mental illness and suicidal intentions. They can work with school psychologists, social workers, and other mental health workers to address the needs of the students and provide grief counseling to peers after a student commits suicide.
- Recent suicides by youth have been attributed to the students being bullied. School nurses also need to be aware of the increased issues related to bullying in the schools and in cyberspace. The YRBSS states that 19% of children had reported being bullied while at school, and 14.9% had experienced cyberbullying (NASN, 2018f).

Chapters 20 and 25 have more information on adolescent and behavioral health issues.

## Abuse and Maltreatment

In 2016, an estimated 676,000 children were victims of abuse and neglect. Of these children, one in four experienced some form of abuse or neglect in their lifetime with one in seven children being abused in the last year; approximately 1,750 children die as a result of child maltreatment (CDC, 2018i).

Child abuse prevention education programs can be found in many school districts as a primary preventive intervention. School nurses are required by law to report suspected or confirmed cases of abuse. In addition, school nurses can educate teachers and other school personnel regarding the signs and symptoms of abuse.

- Early identification of abuse and intervention is critical for the safety of the child. Approximately 18.4% of suspected child abuse reports came from education personnel (NASN, 2018i). It is important to be well versed in subtle signs and symptoms of maltreatment and develop strong collaborative relationships with social service professionals.
- Signs that a child might be maltreated include reports of abuse, a sudden change in behavior, lack of medical treatment follow-through, learning problems of unknown etiology, child responses that are consistently guarded or compliant, and an avoidance of home or certain individuals (NASN, 2018i).

For more information on health problems and issues concerning children and adolescents, see [Chapter 20](#).

### *School-Based Health Centers*

Because of the complex and intertwined emotional, physical, and educational needs of school-age children and adolescents, a more comprehensive interdisciplinary approach to services is needed than the piecemeal approaches attempted previously. School nurses are able to do much to influence school children's health. However, often they need to refer the children to a health care provider. Yet, more parents are working and less available to take care of their children's health care needs during the day. SBHCs provide ready access to health care for large numbers of children and adolescents during school hours, reducing absences from school due to health care appointments. SBHCs provide a variety of services in a user-friendly manner at a convenient location.

- In 2016 to 2017, there were a total of 2,584 SBHCs in the United States, Puerto Rico, and the District of Columbia, providing 6.3 million children with access to school-based health care ([School-Based Health Alliance, 2017](#)).
- These clinics are distributed in high schools, middle schools, and elementary schools and are generally established on school grounds. A large majority (81%) of the clinics serve grades 6th through 12th ([School-Based Health Alliance, 2017](#)).
- The health care providers consist of nurse practitioners (85%) and physician assistants (20%); 40% of the clinics have physicians ([School-Based Health Alliance, 2017](#)).
- Some clinics provide services only to schoolchildren, whereas others extend services to their families and to other neighborhood families with preschool-age children. Most centers are open full-time.
- Many SBHCs in middle schools and high schools offer abstinence counseling, pregnancy testing, sexually transmitted infection diagnosis

and testing, and pap tests ([School-Based Health Alliance, 2017](#)). SBHCs are staffed by interdisciplinary teams of helping professionals, paraprofessionals, and other staff and can include nurses, nurse practitioners, and social workers. Many hospitals, HMOs, and health departments are sponsors of these school clinics, because it is a cost-effective way to decrease visits to the emergency department and promote health, especially to underserved groups such as adolescents. They help meet the need for patient-centered medical homes, as outlined in the Affordable Care Act. Third-party billing, especially to access Medicaid funding, is increasingly more common among SBHCs, and private foundations have also been instrumental in providing financial and technical support. School nurses support the clinics by referring students who need additional attention. In some areas, school-linked health centers are utilized. These clinics are not on school property but may be nearby or easily accessible through mass transit. Mobile vans also provide access to health services for school-aged children, offering a wide range of services including medical, dental, and behavioral health; in addition, they can assist with health care enrollment ([La Clinica, 2019](#); [Metrohealth, 2019](#)).

Evaluation research has demonstrated that SBHCs are effective in increasing student access to health care. This is especially true for adolescents, who often are difficult to reach and do not willingly access health care. Onsite SBHC services are more appealing for adolescents, who have been shown to utilize substance abuse and mental health counseling services, as well as STD and family planning services ([School-Based Health Alliance, 2017](#)).

### *School Nursing Careers*

School nurses must be able to work autonomously. They need excellent communication skills and the ability to prioritize and collaborate with many others (professional and nonprofessional). The pay for school nurses depends on location and employer (health department or school district). School nurses save time for teachers and administrators, permitting them to focus on their job of educating students. School nurses positively influence management of student health concerns, student record accuracy, and student immunization rates. Many nursing schools are utilizing schools as clinical sites, with school nurses as preceptors, in an effort to bring more new nurses into this specialty area.

- There are many positive reasons to work as a school nurse: school nurses generally do not work on weekends, many have contracts that give them the summer off, and the daily work schedule and holidays

often coincide with those of the nurse's own school-age children, thus allowing a parent to be home with children during off-school hours.

- Finally, for most of those employed as school nurses, it is a wonderful and rewarding experience to work with children whose eagerness and innocence can often refresh the soul. It is an opportunity to protect and heal our future leaders, who may become the ones who will eventually protect and heal the world (Box 28-12).

## BOX 28-12 PERSPECTIVES

**A School Nurse Viewpoint on Community Health Nursing** A great aspect of being a school nurse is being able to work with many different people. I like being able to work with people who aren't necessarily sick but can benefit from my help. Additionally, school nurses must become familiar with resources and people in the community and surrounding areas. By making friends and connections in facilities, and the community, school nurses can involve local resources and individuals to improve the population. Resources aren't as readily available as they are for other types of nursing. Unlike working in a hospital, where results are apparent in just a few days, school nurses must work tirelessly for long periods of time to see the fruits of their labors.

Being a school nurse requires learning how to get funding for projects. School nurses often don't have a model to work from, because each situation may be unique. They must be innovative, resourceful, and dedicated in order to stick with a project long enough for it to be beneficial to the population.

School nursing is probably the epitome of what nursing was meant to be. It is focused on service and improving the health and well-being of the populace. The focus is on prevention; school nurses seem to get little recognition for their work—because they are saving lives before they are endangered, they are saving teeth before they fall out, and they are saving families before they are lost. I believe their work is pivotal to the improvement of society.

Neil P., school nurse

# CORRECTIONAL NURSING

**Correctional nurses** work within the criminal justice system—in correctional facilities, prisons, jails, detention centers, and substance abuse treatment programs—with clients spanning a range of ages from juvenile to elderly, both male and female (Fig. 28-6; ANA, 2013). Bureau of Justice Statistics dated December 31, 2016, reported an estimated 6,613,500 persons were supervised by U.S. adult correctional systems. The decrease in the incarcerated population was due to a decline in the prison population (down 21,200), while the jail population remained relatively stable (Kaeble & Cowhig, 2018).

**FIGURE 28-6** Correctional nurse taking an inmate's blood pressure.

About 1 in 38 adults (or 2.6% of persons age 18 or older in the United States) were under some form of correctional supervision at year-end 2016 (Bureau of Justice Statistics, 2018). An estimated 2% to 3% of RNs work in corrections (Correctional Nurse, 2019) as compared to the total national nursing workforce. This appears to be a low number considering there are various career options for working in a correctional setting (e.g., part time, contract service, academic affiliations, etc.) which may impact the total estimations.

## History of Nursing in the Correctional Setting

- In the past, the correctional system of prisons and jails has provided minimal, if any, health care to inmates. Historically, nurses involved with prisoner and mentally ill populations included Dorothea Dix, who visited prisons around the country in the 19th century and found prisoners in chains, without proper sanitation, living conditions, nutrition, or clothing (ANA, 2013).
- Prison was viewed as a punishment, and the inmates were seen as not deserving of care that was being paid for through public dollars (*Estelle v. Gamble*).
- The historic Supreme Court ruling *Estelle v. Gamble* stated that not providing medical services inflicted pain and denied inmates their Eighth Amendment rights (Box 28-13) and led to major reforms in the correctional health system. Medical providers were hired, and inmates' rights were established (Akiyama, Feffer, Von Oehsen, & Litwin, 2018; Dober, 2019).

### BOX 28-13 The Rights of Inmates

- Right to humane housing and treatment
- Right to not be a victim of sexual crimes
- Right not to be racially segregated
- Right to complain about conditions
- Rights provided by the American Disabilities Act
- Right to necessary medical care
- Right to necessary mental health care
- Right to a hearing

Source: Findlaw (2020).

Although the correctional health system is a relatively new specialty, it is under intense pressure from the courts to ensure that adequate and humane care is provided. Specific issues include the provision of ethically appropriate and timely patient care for inmates, the provision of adequate mental health treatment, prevention of prisoner-on-prisoner violence, maintenance of sanitary and safe conditions, and ending inmate neglect and abuse. Ensuring that inmates' health needs are met amidst the growing number of inmates and their increasing complex health concerns has imposed a huge financial burden on correctional systems.

Funding for correctional health care derives from public tax dollars and many are contesting that care and expense should be given to incarcerated

persons [National Commission on Correctional Health Care, 2017](#)). This is an ethical dilemma nurses working in correctional facilities must face every day. In an attempt to decrease costs and save money, several states utilize managed care organizations to provide some services for inmates and are increasingly relying on private prison health care providers and managed care organizations ([Pew, 2017](#)).

Correctional nurses must demonstrate nonjudgmental attitudes while at the same time ensuring self-protection from assault. Correctional nurses work in on-site medical units, clinics, or infirmaries housed in criminal justice facilities. These facilities can be local jails or state and federal prison. The care is focused on the individual, immediate, and ambulatory care, emergency needs, and management of chronic conditions, screenings and preventive services. Larger facilities offer ambulatory and inpatient mental health services, and subacute care units for short-term therapies (e.g., IV medications). In addition, the increased female incarceration rates highlight that women's health care concerns must be addressed. As prisoners age, long-term care and end-of-life care must also be provided ([Sanders & Stensland, 2018](#)); correctional systems are further challenged with these additional specialty care needs.

## **Education and Skills Needed**

The preferred educational level for correctional nurses is a bachelor's degree. The level of skill, judgment, and autonomy needed by nurses who work in corrections is supported and developed within baccalaureate education. National certification, through the National Commission on Correctional Health Care as a certified correctional health professional-RN (CCHP) ([National Commission on Correctional Health Care, 2020](#)) or the American Correctional Association (ACA) as a certified correctional nurse (CCN) ([American Correctional Association, n.d.](#)), is available. Some correctional systems employ licensed professional nurses (LPN) and medical assistant technicians (MATs).

## Functions of Correctional Nurses

Correctional nurses use public, community, and school health nursing skills, along with skills acquired from the ED, occupational health, mental health, orthopedics, and ambulatory care specialties. In general, primary care interventions are provided for the inmate population with a focus on health promotion and healthful lifestyles during incarceration.

- Nurses assess patients for basic health needs and treat injuries and minor acute medical conditions. As indicated, patients are scheduled for regular appointments to manage chronic conditions of hypertension, diabetes, pulmonary disorders, and mental health.
- The correctional nurses also track and screen for communicable diseases, providing essential related treatment as needed, provide health promotion education, and provide transitional or discharge education and preparation.
- The correctional nurses may encounter a critical medical emergency requiring stabilization before the inmate is transported to an outside treatment facility for complex medical care. Most correctional facilities do not have inpatient acute care medical units, while many have inpatient mental health units for varied behavioral health conditions.

Because correctional facilities operate 24 hours a day, every day of the year, it is vital that correctional nurses have cardiac life support certifications, emergency preparedness, and disaster planning training. To carry out its mission, the Federal Bureau of Prisons follows national preparedness goals; preparedness planning and an emergency operations plan are necessary (Johnson, 2018) (Table 28-1). A seminal study (Taylor & Crianza, 2011) provides vivid examples of natural disasters affecting a large jail system (over 10,000 inmates) and the need to plan for power, water, and telephone outages, as well as housing and moving prisoners under emergency conditions. Many correctional facilities include tabletop exercises in their annual training program, and ensure resources are available to provide adequate supplies to sustain health and wellness for a minimum of 72 hours post the impact of adverse weather. In many situations, nursing and other staff are often asked to remain on-site for extended periods of time and while making arrangements for their own families.

### **TABLE 28-1 Emergency Preparedness in Correctional Facilities**

Prevention	Plan for incidents by assessing threats and processes for response.
Protection	Provide for adequate support and equipment prior to the disaster
Mitigation	Practice and prepare through trainings, drills, and full-scale exercises
Response	Provide necessary response efforts to save lives, and protect property and the community.
Recovery	Assist in the recovery efforts after an incident; learn from the disaster and plan for future crisis.

Source: [Johnson \(2018\)](#).

FEMA Guidelines recommend identifying hazards early and then taking actions to mitigate those hazards before they become major problems ([FEMA, 2011](#)). Correctional and medical staff training, and routine facility inspections will enhance correctional disaster management outcomes ([Boxes 28-14, 28-15, 28-16](#)).

## BOX 28-14 PERSPECTIVES

**A Correctional Nursing Viewpoint on Community Health Nursing When I completed my graduate nursing program with an MSN and FNP, I planned to work on a mobile clinic/van travelling to several identified underserved communities providing chronic and preventive health care. Instead, I accepted the challenge of a uniformed service enchanted by the mission of providing**

**health care to underserved populations across the nation. Little did I know I would start my NP career working in a federal correctional facility. Honestly, I was a little nervous for the first 3 months as I adjusted to the security restrictions of the setting and the “inmate” population. One day I went to work and told myself “these are individuals coming to the clinic for health care service.” They are “patients.”**

From that time forward, I provided nonjudgmental, holistic nursing care to all the inmates I served for over 10 years. I developed a passion for this special, underserved population and became an advocate for preventive correctional health care and obtained correctional health care certification and a master's degree in criminal justice. What is most surprising about correctional nursing is that the inmates are very appreciative of the health care and preventive education provided. When told they are being empowered to manage their individual medical conditions, there is a motivation toward compliance. When measurable outcomes are presented during chronic care visits or follow-up appointments, the pattern of improvement and compliance is enhanced. It is a great feeling to see the outcomes of one's nursing interventions in this population especially during the chronic care appointments and/or during the release preparation process, when the inmate can explain healthy lifestyle practices learned and they plan to continue. What a validation of the impact of nursing practice!

CAPT Beverly Dandridge, USPHS Commissioned Corps

## **BOX 28-15 What Do *You* Think?**

**Potential Botulism Outbreak in Prison Inmates**  
**During sick call today, your correctional nurse colleague notices that four to five inmates from the same housing unit have similar complaints—blurred vision, feeling sick, and some difficulty**

## **breathing. It is flu season—could that be the cause?**

You know that homemade alcohol is not uncommon in prisons and that it can be easily made from fermented fruit or other food waste. Prisoners call it moonshine, pruno, hooch, brew, raisin jack, and other names. You remember reading about a recent CDC report regarding several outbreaks of botulism in California, Utah, and Arizona prisons. Prisoners there had used potato peels, and the closed containers used to produce alcohol permitted the toxin to grow during fermentation. With no heat used to kill it, the bacteria grew and affected everyone who drank the brew.

With botulism, it is most important to act quickly, as the toxin leads to nerve paralysis, and when it reaches the respiratory muscles, it can cause death. You talk with your colleague and decide to talk with the housing correctional officers and the patients for further information. I think it is better to be safe than sorry! What do you think?

Source: [Schoenly \(2016a\)](#).

## **BOX 28-16 Correctional System Challenges for Nursing**

- Understanding of the population
- Autonomous conditions
- No universal standard for experience/no certifications
- Strict facility protocols for safety and security
- Employee burnout
- Corrections fatigue

Source: [Nursing @CSU Staff \(2019\)](#).

## Future Trends

Because of advances in health care, longer prison terms, and more restrictive policies, inmates are older, sicker, and remain in prison longer than they did even 20 years ago. Historically, inmates have not taken good care of themselves, hence, a 50-year-old inmate may have the health of a typical 65 year old in the general public (Schoenly, 2014).

Correctional nurses can increase efforts to improve transitional health care programs, and serve as advocates, and lobby state and federal legislatures to allocate funding for the additional resources needed within the correctional health care systems (Hoke, 2015).

The female inmate population is also increasing. In addition to women's reproductive health issues, females tend to have higher rates of major mental illness, dental problems, insomnia, and chronic medical conditions (Mignon, 2016; Mollard & Hudson, 2016). Previous researcher has found that women in jail have a high risk of cervical cancer and increased rates of abnormal Papanicolaou (Pap) test results (Brousseau, Ahn, & Matteson, 2019).

Researchers have suggested that women in prison need trauma-informed, gender-responsive treatment because of past trauma histories (Mollard & Hudson, 2016). There has been a movement to provide trauma-informed care and gender-responsive programs (GRPs) to women in prison.

One study discovered one third of inmates being released from prison had at least one chronic condition; that number increased to 70% of those 55 years or older (Rosen et al., 2019). Correctional nurses can facilitate chronic disease management by coordinating chronic care education programs and empowering inmates to take better control their chronic conditions. Correctional nurses should also conduct thorough family health histories, as much as possible, as many health conditions tend to have a genetic component and discuss screenings to identify conditions with correctional health care providers to facilitate early intervention and decrease complications and potentially, disease progression.

Ethical and legal issues in correctional nursing often center on the patient (most often someone convicted of a crime, possibly involving violence). Caring for the patient is vital, but custody must also be maintained, and safety is essential. Correctional nurses have an opportunity, to help reduce the burden of disease for communities by providing tri-level preventive health care pre-, intra-, and post incarceration (La Cerra et al., 2017).

# CORRECTIONAL NURSING CAREERS

Correctional nurses must have good mental health and assessment skills, strong communication skills, and be strong advocates for nursing and their clients. These nurses work in an intense environment where their safety could be threatened, and they must deal with clients who may be noncompliant, combative, and manipulative. Correctional nurses are also increasingly becoming Certified Correctional Health Care Professionals ([Box 28-17; National Commission on Correctional Health Care, 2020](#)).

## BOX 28-17 PERSPECTIVES

**A Supervisor and a Director of Correctional Nursing Viewpoint on Hiring New Nurses Do you think you might like a job at a prison facility? A Director of Nursing and a Supervisor of Correctional Nursing provide some information on the interview process. Before hiring new correctional nurses, they ask candidates to review the [correctionalnurse.net](#) blog and the ([Schoenly, 2016b](#)) *Correctional Nurse Manifesto* ([Schoenly, 2014](#)). The nurses who are hired receive civilian training and are assigned a preceptor. The process is designed to educate the candidate about the realities and complexities of correctional nursing. As the director notes, “No one dreams of going into correctional nursing, but once you are in, you**

## **are hooked because you realize the difference you can make.”**

The interview process follows the guidelines set forth by the ANA *Correctional Nursing: Scope and Standards of Practice* (2013) and the textbook *Essentials of Correctional Nursing* (Schoenly & Knox, 2013), which provides crucial information such as the ethical, legal, and safety considerations of correctional nursing; common inmate-patient health care concerns and diseases; nursing care processes; and professional role and responsibilities. Also, unlike the nurses hired in the past, newer correctional nurses do provide health care education and health care clinics for chronic diseases on a regular basis. Because of the lack of an inpatient facility, 24-hour nursing care is not provided in some correctional facilities. When 24-hour nursing care is necessary, the inmates are transferred to a correctional facility where such coverage is available or to an acute care facility if more extensive care is required. In addition, the correctional officers are trained to follow procedure and call 911 during an emergency.

Challenges to correctional nursing include the philosophy in the prison setting that “safety comes first,” which could result in an inmate missing a sick call. Should this occur, however, their medical needs are taken care of as soon as it is safe and without compromise to their condition, according to both the supervisor and the director of nursing. An emergency that correctional nurses are occasionally faced with is suicide attempts—a situation that is always “scary” even if you have seen it happen before. This situation leads to a lock-down so that all resources can be focused on the suicidal inmate, who sometimes is found hanging and needs to be cut down and resuscitated.

The ability of correctional nurses to deliver medically appropriate care is hindered by the lack of access to preexisting medical records and history. Self-reporting is a far less reliable means for determining an inmate's risk factors and overall wellness. This is one reason that civil litigation by inmates, alleging medical negligence, is a weighty problem for all correctional agencies.

Nurses have an incredible opportunity to improve the health of the inmate population by returning their patients to the community healthier than when they arrived.

Source: [Schoenly \(2014, 2016b\)](#).

Stan, Supervisor of Correctional Nursing Denise, Director of Correctional Nursing

Correctional nurses usually receive extensive employee benefits and insurance packages as government employees. Correctional nurses have the ability to see recoveries from illnesses and injuries because they work with the same patients for a longer time than hospital-based nurses. Correctional nursing provides an opportunity to work with a vulnerable population and practice the true art and science of nursing. It can be a challenging and rewarding career. See Perspectives about the hiring process for new correctional nurses.

# SUMMARY

- C/PHNs manage a number of issues including communicable diseases, chronic diseases, injuries, maternal child health, immunizations, substance abuse, and disaster response.
- C/PHNs work with all ages, ethnicities, socioeconomic groups, and populations emphasizing health prevention and promotion.
- C/PHNs work in several branches of the uniformed services.
- School nurses work with school populations (elementary, middle, high schools, and college/university levels) including students, their families, and the school staff providing individual care and bridging the gap between medical providers and schools.
- School nurses provide direct nursing care, first aid, immunizations, environmental assessments, and specialized health care for children with special needs.
- Correctional nurses work with inmates in federal, state, or local facilities, including drug treatment and juvenile detention centers.
- Correctional nurses provide individual care in facility clinics and infirmaries while also identifying and developing programs to address major population health concerns of inmates, including mental illness, substance abuse, and communicable diseases.
- The inmate population is growing older, staying longer, and experiencing more from chronic disease. This, along with an increase in female inmates, brings additional challenges for correctional nurses.
- All nursing specialty areas provide valuable services which impact the health of our communities. Because of the high level of nursing knowledge, communication skills, autonomy, and leadership needed for professional nursing practice, the educational entry level should be a minimum baccalaureate degree.

# ACTIVE LEARNING EXERCISES

1. Interview a public health nurse asking the following questions:
  - a. Why did you choose public health nursing?
  - b. Within what area of public health nursing do you work?
  - c. Does an epidemiological background help with your work?
  - d. What is the most satisfying part of your job?
2. As a correctional nurse, you will care for people who are accused or sentenced for a variety of crimes. How might a correctional nurse utilize the 10 essential public health services to ensure high standards of health care when working with this vulnerable population?
3. Go to this Web site ([https://www.nhlbi.nih.gov/files/docs/public/lung/asthma\\_actplan.pdf](https://www.nhlbi.nih.gov/files/docs/public/lung/asthma_actplan.pdf)) and print out a copy of the *Asthma Action Plan*. Discuss this with the parent of a school-age child or adolescent who has asthma. Has a school nurse or public health nurse ever gone over a plan with them? Have they ever been shown how to use a peak flow meter or correctly use an asthma inhaler? What methods have they used to control asthma triggers?
4. Using “Utilize Legal and Regulatory Actions” (1 of the 10 essential public health services; see [Box 2-2](#)), consider the following question: Most schools require that children entering school show proof of being fully immunized for a variety of communicable diseases. With a partner, discuss what would happen if schools no longer had this requirement. How would you educate parents who refuse to immunize their child because of the unfounded fear that immunizations cause autism?
5. List five (5) potential areas of employment as a member of the U.S. Public Health Service. What types of services are rendered in each agency? What are benefits of this type of nursing career (uniformed service)?
6. Are prisons and jails appropriate facilities for meeting the needs of individuals with mental health and substance use diseases? Why or why not? If not, what other alternatives may be more effective?

# CHAPTER 29

## *Private Settings*

*“All Nurses need a plan B. Drastic changes in the health care environment are resulting in a reconfiguration of facilities and threatening job security for many nurses in this country. There is good news[:] there are fantastic opportunities for nurse owned and operated businesses to address these changes and challenges.”*

—National Nurses in Business Association, n.d., para. 3

## **KEY TERMS**

Case management

Comprehensive primary care center Entrepreneurial nurse Faith community nurse (FCN) Federally qualified health center (FQHC) Nurseled health centers/clinics (NLHCs) Occupational and environmental health nurses Occupational Safety and Health Administration (OSHA) Safety-net health care provider Sustainability

Total Worker Health (TWH) Transitional care

## **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Describe funding sources for nurseled health centers.
2. Articulate the importance of sustainability for nurseled health centers.
3. Describe the evolution of faith community nursing.
4. Describe and differentiate among the roles of the faith community nurse.
5. Explain the role of the occupational and environmental health nurse and other members of the occupational health team in protecting and promoting workers' health and safety.
6. Recognize at least three adverse working conditions that impact health status.
7. Discuss the opportunities for nurse entrepreneurship in community/public health practice.

# INTRODUCTION

[Chapter 28](#) discussed a wide variety of practice opportunities in the public sector. This chapter examines four unique private sector roles and practice environments available in the United States and in many other countries:

- Nurseled health centers offer the opportunity for more autonomous practice and present excellent learning venues for nursing students.
- Faith community nursing, begun in the mid-1980s, has gained increasing attention in many religious communities and continues the rich tradition of caring for those in need who may not have access to services.
- Occupational and environmental health is a specialty health practice that focuses on the health and well-being of the working population and therefore covers most of the country's working adults.
- Entrepreneurial roles for nurses offer new venues for meeting the health care needs in communities while providing challenging and autonomous practice.

Each of these areas of practice offers Community/public health nurses an avenue to address health disparities in their communities, increase years of healthy life, and provide holistic, client-centered care to meet the current and emerging health needs in their communities, as indicated in *Healthy People 2030* and Leading Health Indicators ([Boxes 29-1](#) and [29-2](#)).

## **BOX 29-1 HEALTHY PEOPLE 2030**

## Objectives Relevant to Nurses in Private Settings

AHS-08	Increase the proportion of adults who get recommended evidence-based preventative health care
EH-05	Reduce health and environment risks from hazardous sites
EH-06	Reduce the amount of toxic pollutants released into the environment
AHS-R01	Increase the ability of primary care and behavioral health professionals to provide more high-quality care to patients who need it

## Occupational Safety and Health Objectives

OSH-01	Reduce deaths from work-related injuries
OSH-02	Reduce work-related injuries resulting in missed workdays
OSH-03	Reduce work-related skin diseases
OSH-04	Reduce pneumoconiosis deaths
OSH-05	Reduce work-related assaults
OSH-06	Reduce new cases of work-related hearing loss
OSH-D01	Reduce the rate of high blood lead levels in adults exposed at work

Reprinted from U.S. Department of Health & Human Services (USDHHS). (2020). Healthy People 2030: Browse objectives.

Retrieved from <https://health.gov/healthypeople/objectives-and-data/browse-objectives>

## BOX 29-2 LEADING HEALTH INDICATORS 2030

## **Key Health Indicators Applicable to Nurses Working in Private Settings**

Access to Health Services

Medical insurance

Health Care System Quality

Health Care Access

Clinical Preventive Services

Reduce the number of adults with hypertension Children between the ages of 19 to 35 months receive the recommended doses of DTaP, polio, MMR, Hib, hepatitis B, varicella, and PCV vaccines Determinants of Health Equity

- Environmental Quality
- Environmental health
- General health, health-related quality of life, well-being

Injury

Maternal, infant, and child health

Mental health

Obesity

Oral health

Reproductive and sexual health

Social capital/civic engagement

Serious illness

Social determinants

Substance abuse

Tobacco

# NURSELED HEALTH CENTERS

**Nurseled health centers/clinics (NLHCs)**, or nursing centers (sometimes referred to as nurse-managed health centers), are organizations that give vulnerable and/or underserved clients access to professional nursing services (Fig. 29-1). NLHCs are found in convenient sites where people live, work, learn, and worship and are overseen by a nurse executive with an advanced degree. Traditionally, targets of service have been those who are least likely to be engaged in ongoing health care services for themselves and their family members. Currently, NLHCs serve population groups of all ages who are uninsured or underinsured.

**FIGURE 29-1** Bristol Health: an example of a nurseled health center. Bristol Health has both physicians and nurse practitioners who provide individual, couples, and family counseling and manage medications for mental health conditions. Bristol Health has physicians, nurse Practitioners, counselors, therapists, and psychological testing services. They provide services to children, adolescents, and adults. (Reprinted with permission from Bristol Health. (2019). *Services*. Retrieved from <https://bristolhealth.com/>)

Historically, the most frequently cited definition of a *nurse-managed health clinic* is the one developed in the mid-1980s by the American Nurses Association (ANA) Nursing Centers Task Force: “a nurse-practice arrangement, managed by advanced practice nurses, that provides primary care or wellness services to underserved or vulnerable populations and that is associated with a school, college, university or department of nursing,

federally qualified health center (FQHC), or independent nonprofit health or social services agency” ([Compilation of Patient Protection and Affordability Care, 2010](#), p. 542). The [Compilation of Patient Protection and Affordability Care](#) supports nurse-managed health centers to:

- Improve access to across-the-life span primary health care and wellness services.
- Provide services in medically underserved and vulnerable populations regardless of income or insurance status.
- Serve students as training sites in primary care.
- Establish and enhance electronic methods for effectively collecting patient and workforce data ([U.S. Department of Health and Human Services, n.d.](#)).

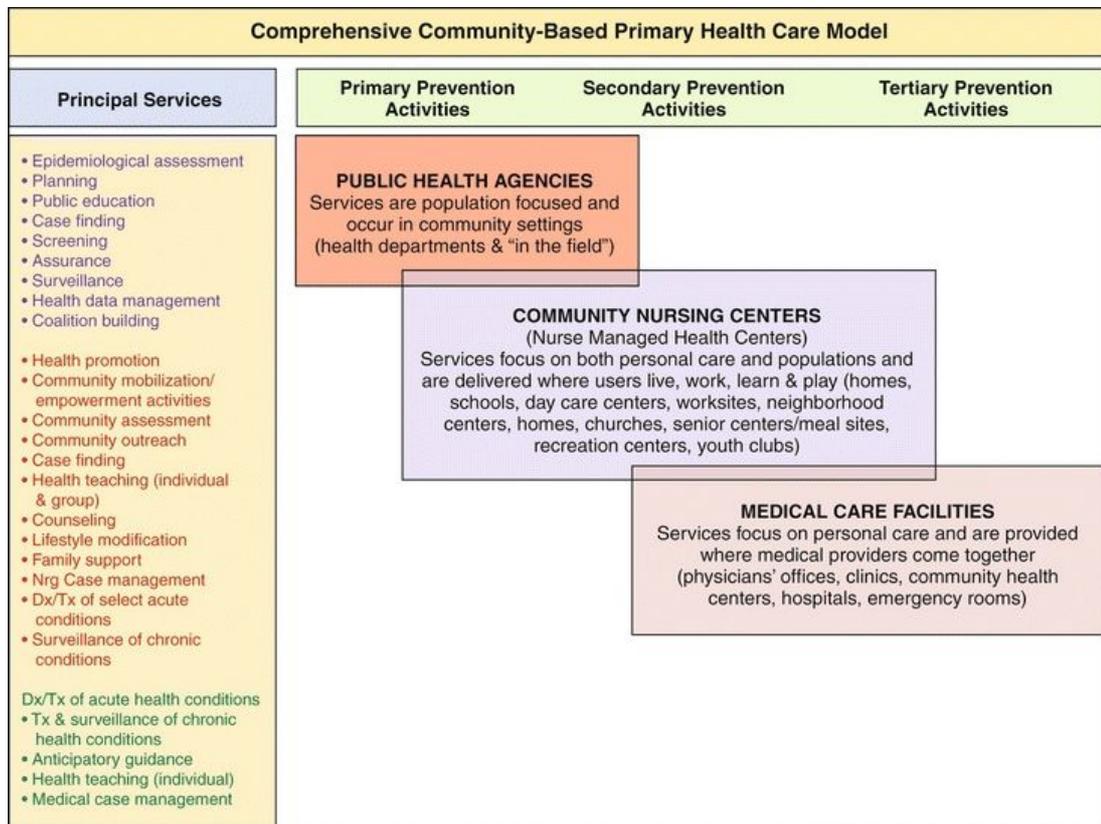

With an amendment to Title III of the Public Health Service Act (42 U.S.C. 241 et seq.), the [Nurse-Managed Health Clinic Investment Act of 2009](#) of the 111th Congress provides a more present-day definition of an NLHC.

A nurse practice arrangement, managed by advanced practice nurses, that provides primary care or wellness services to an underserved or vulnerable population and is associated with a school, college, university, or department of nursing; FQHC; or an independent nonprofit health or social services agency ([Nurse-Managed Health Clinic Investment Act, 2009](#), p. 2).

NLHCs represent a rising movement of health centers that have emerged as vital safety-net health care providers in America's health care delivery system ([Aveling, Martin, Herbert, & Armstrong, 2017](#); [Durovich & Roberts, 2018](#); Hansen-Turton, Sherman, & King, 2016). Although all NLHCs share the core elements of these definitions, they vary in their practice models. Services offered at NLHCs range from health promotion and wellness to conventional primary care ([Aveling et al., 2017](#); [Durovich & Roberts, 2018](#)).

- A **safety-net health care provider** is a provider who, by mandate or mission, organizes and delivers a significant level of health care and other health-related services to the uninsured, Medicaid recipients, and other vulnerable populations ([Agency for Healthcare Research and Quality, 2018](#); [Institute of Medicine, 2000](#); [U.S. Centers for Medicare and Medicaid Services \[CMS\], 2019](#)).
- NLHCs differ from other public health agencies and tertiary medical care facilities. Although some services overlap, the distinctiveness of NLHCs is found in the community orientation of the nurse-managed centers. This model is depicted by Lundeen's comprehensive community-based primary health care model ([Hong & Lundeen, 2009](#); [Lundeen, 2005](#)), in which NLHCs are referred to as community nursing

centers and are the central figure in this model of health care, which is used at the University of Milwaukee, Wisconsin (Fig. 29-2).

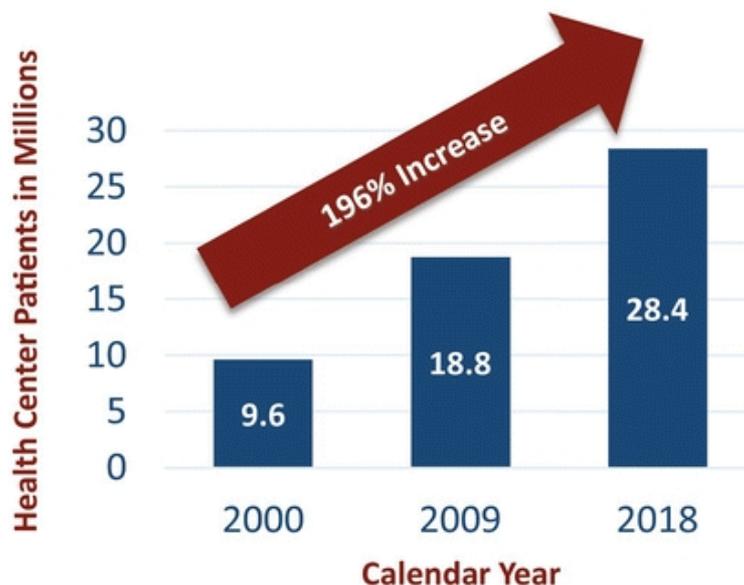

**FIGURE 29-2** Comprehensive community-based primary health care model. (Adapted with permission from Hong, W. S., & Lundeen, S. (2009). Using ACHIS to analyze nursing health promotion interventions for vulnerable populations in a community nursing center: A Pilot study. *Asian Nursing Research*, 3(3), 130–138; ©Sally P. Lundeen, RN, PhD, FAAN, UW-Milwaukee College of Nursing, 1993, 2005.)

## History of the NurseLed Model

Although today's NLHCs trace their roots to changes in national health care laws begun in the mid-1960s, the nursing model of holistic care that focuses on vulnerable populations and integrates primary care and public health dates back to the nineteenth century. Florence Nightingale's passion for at-risk populations, as well as her success related to health reform, provides a model for NLHCs today. Visionaries such as Lillian Wald, who founded the Henry Street Settlement, and Margaret Sanger, who initiated the first family planning clinic, are two examples of nurses providing holistic care to vulnerable populations (see [Chapter 3](#)). These nurse activists sought to resolve twentieth century problems caused by immigration, urbanization, and industrialization in the United States (Judd & Sitzman, 2014; Kurtzman et al., 2017).

- Since the late 1970s, in conjunction with the development of educational programs for nurse practitioners, faculties in schools of nursing have established NLHCs. Linkages have provided clinical sites for educating nurses at all levels and settings, as well as for faculty practice opportunities (Resick, Miller, & Leonardo, 2015).
- The Health Resource and Services Administration (HRSA) reports significant increases in the number of patients served in health centers in the past decade (Fig. 29-3). Overall, these health centers have been shown to improve health outcomes while reducing health care costs (HRSA, 2018; Sofer, 2018).

**FIGURE 29-3** Increase in numbers of patients served in health centers. (Reprinted from Health Resources and Services

Administration (HRSA). (2018). *HRSA health center program fact sheet*. Retrieved from <https://bphc.hrsa.gov/sites/default/files/bphc/about/healthcenterfact-sheet.pdf>)

## NLHC Models

There are several types of nursing centers; each has an individuality of its own that reflects the community in which it is located and the particular services it offers (Hansen-Turton, Sherman, & King, 2015):

- Academic-based nursing centers, which are located within schools of nursing, are a common organizational structure (Box 29-3).
- Hospital-based and freestanding community-based NLHCs offer a mixture of primary care, health promotion, wellness, and disease prevention services.

### BOX 29-3 Stories From The Field Three NurseLed Clinics

University of California Los Angeles (UCLA) began providing primary health care services to the homeless and indigent in 1983. It provides access to health care for children and families who have no place else to go—many suffering from the effects of an unstable home life or no home at all. Student nurses participate in the clinic and learn valuable lessons about the challenges of providing care for vulnerable populations. At the same time, the students gain first-hand experience working with resilient individuals who overcome significant hardships. Many students find their experiences in the clinics inspiring. In 2018, UCLA's Health Center at the Union Rescue Mission handled over 8,000 patient visits.

University of California Irvine (UCI) launched the first nurse-managed clinic at El Sol Charter School in Santa Ana. This clinic provides primary care to Orange County's underserved populations, primarily from the Latino community. This clinic is funded by a \$1.5 million federal grant and, like the University of California San Francisco (UCSF) clinic, serves the dual purpose of providing care while educating future nurses.

UCSF serves San Francisco's homeless and poor at the Glide Health Services Center in the Tenderloin district. This clinic takes a holistic approach, offering anything from acupuncture to behavioral health, diabetes, and more. The nurse-run clinic accommodates 13,000 visits each year, reaching people who historically felt marginalized by traditional medicine.

All three of these clinics are nurseled, working in partnership with underserved communities, while providing valuable experiential

learning opportunities for their student nurses.

*Find nurseled health centers in your area. What populations are served, and what services are provided?*

Source: [University of California San Francisco \(2019\)](#).

NLHCs meet requirements for the **federally qualified health center (FQHC)** designation as defined in Section 330 of the Public Health Service Act. FQHCs are safety-net providers whose main purpose is to enhance primary care services in underserved rural and urban communities ([U.S. Department of Health and Human Services, CMS, 2018](#)). Health care reform legislation has helped with this funding. This is an especially important designation, as it enables NLHCs to qualify for many funding sources vital to service provision that would not be available without this designation. The specific requirements are that they:

- Serve a medically underserved population.
- Have a nonprofit, tax-exempt, or public status.
- Designate a board of directors, a majority of whom must be consumers of the center's health services.
- Provide culturally competent, comprehensive primary care services to all age groups.
- Offer a sliding scale fee and provide services regardless of ability to pay.

The variety of nursing center models currently in use and their organizational structures demonstrate the diversity of contemporary NLHCs. [Box 29-4](#) describes the major types of centers, along with the various organizational structures that influence their delivery models.

## **BOX 29-4 Nurse-Managed Health Center Models**

### **Center Types**

- **Wellness Center:** provides public health as well as health promotion and disease prevention programs and focuses on primary and secondary prevention strategies
- **Special Care Centers:** provide programs that target specific health conditions such as HIV or diabetes
- **Comprehensive primary care center:** provides traditional primary care and public health programs

## Organizational Structures

- Academic Nursing Center: located within a School of Nursing
- Freestanding Center: independent center with its own governing board
- Subsidiary: part of a larger health care system, such as home health agencies, community centers, schools, and other venues
- Affiliated Center: legal partnership with a health care or human services organization

Adapted from [Hansen-Turton \*et al.\* \(2015\)](#); [Kinsey and Miller \(2016\)](#).

## Role of Students in NLHCs

Undergraduate and graduate students from many disciplines play a vital part in the activities of NLHCs. These disciplines include, but are not limited to, nursing, social work, mental health, dental and oral health, nutrition, speech–language–hearing sciences, and public health. When students engage in NLHC activities for their clinical experience, they become aware of the distinctiveness of nurse-managed centers from other health care delivery systems and the variety of models and organizational structures that exist and are active participants in vital nursing center activities. Most often, students are engaged in primary and secondary prevention strategies via health education, outreach, immunization, and screening programs. Roles that students fulfill are similar to the roles of their staff mentors (Box 29-5):

### **BOX 29-5 STORIES FROM THE FIELD**

**Wellness Screening Public health nurses from an academic wellness NLHC, along with undergraduate student nurses, are conducting blood pressure and glucose screenings at a church-sponsored health fair. This event is conducted on Sundays from 10 AM to 2 PM, before, during, and after church services. Approximately 50% of adults screened have hypertension and/or hyperglycemia. One participant, who was asymptomatic, had severe hypertension (220/154) and was immediately transported to the nearest hospital for evaluation.**

- 1. What are some feasible referrals that may have been made for those with abnormal screening results?*
- 2. What types of primary prevention strategies may benefit those attendees who had normal screening results?*
- 3. In what ways do student nurses benefit from participating at a health fair?*

- Advocate
- Case manager
- Change agent

- Educator
- Referral agent

Faculty roles in NLHC academic models involve clinical supervision and mentorship of undergraduate and graduate students assigned to the nursing center for their clinical experience ([American Association of Colleges of Nursing \[AACN\], 2016](#)).

## Community Service Learning in NLHCs

Additionally, schools of nursing and NLHCs are an excellent venue to conduct community service learning (CSL) projects with both undergraduate and graduate students. Using a “wall-less” concept of a nursing wellness center, undergraduate and graduate nursing students can participate in CSL activities in a variety of community settings. Outcomes for participating students include ([Marquette University, 2019](#), para. 3):

1. Appreciate people from diverse backgrounds.
2. Exhibit a commitment to social justice.
3. Demonstrate a commitment to be an involved citizen in his or her community.
4. Demonstrate an increased sense of vocation.

One exemplar of a CSL project conducted at urban and rural schools is the “Safety Town” initiative. This CSL project entails educating preschool and early elementary school-age children on indoor and outdoor safety for trauma prevention ([Miller & Mest, n.d.](#)). Qualitative feedback from nursing students reveals personal and professional growth regarding primary prevention in pediatric trauma in nontraditional clinical settings within the community.

## Funding for NLHCs

As NLHCs vary in their models, so too do they vary in their methods of cost reimbursement, including fee for service, sliding fees, contracts, grant support, third-party payments, and cost-based reimbursement (Hansen-Turton, et al., 2015). Most nursing centers' operational and salary budgets entail a combination of these funding sources.

- In **comprehensive primary care centers**, advanced practice nurses provide primary care services. Such services are usually reimbursable under Medicare, Medicaid, and managed care medical insurance plans (Health Care Provisions in Bipartisan Budget Act of 2018).
- In wellness centers, public health nurses and other interdisciplinary team members provide a range of primary and secondary prevention strategies (Box 29-6). These services are usually not reimbursed by insurance plans but are often covered by grants and contracts (Hansen-Turton, et al., 2015; Resick et al., 2015).

### BOX 29-6 STORIES FROM THE FIELD FAMILY-CENTERED CARE

Ms. Jones is a 22-year-old mother of three small children who recently moved to an urban area. She brings her oldest child, age 6, to a local comprehensive primary care nurse-managed health clinic for school immunizations. During the course of the history and physical examination, the nurse practitioner becomes aware that this mother also has two younger children, aged 2 and 3, at home. The family rents a small apartment in housing that was built in the mid-1950s. Ms. Jones mentions that her mother (the children's grandmother) also resides with them. The grandmother is the childcare provider, while Ms. Jones works as a local hair salon. The grandmother mother smokes 1.5 to 2 packages of cigarettes daily; Ms. Jones reports that she is a nonsmoker. Upon further questioning, the nurse practitioner learns that the 3-year-old child has a chronic cough and occasional wheezing. Ms. Jones also confides to the nurse practitioner that she recently missed two menstrual periods and is sexually active.

1. *What are some possible health care needs of Ms. Jones? Her mother?*
2. *What screenings should be performed on (a) Ms. Jones, (b) her mother, and (c) her children?*
3. *What other interdisciplinary team members should be involved in this family's health care?*

#### 4. *What are some possible referrals that would benefit this family?*

It is important to distinguish between grants and contracts as funding sources for NLHCs. Funding organizations usually release guidelines regarding what initiatives they will fund. Grant guidelines are frequently termed request for proposal (RFP).

- Grants can be a source of initial start-up funding as well as a support for ongoing activities (Torrise & Hansen-Turton, 2015).
  - A proposal submitted by the NLHC to the funding organization describes how the center would meet the goals and objectives set by the funding organization.
  - Outcomes, or the end results at a specific point in time, are increasingly becoming more important to funders.
  - NLHCs must include measures to collect outcome data and project what outcomes will occur in their submitted proposals.
- Contracts are another source of funding for NLHCs.
  - Contracts are awards for a legal procurement relationship between a funder and a recipient obligating the contractor to furnish a product or service defined in detail by the funder (Find RFP, 2019).
  - A contract has specific goals, objectives, and activities, as well as a time frame during which the activities are to be implemented and evaluated.
  - Contracts are awarded on a noncompetitive basis and often are renewable when goals and objectives are met.

Managing the various funding streams that feed the personnel and operations budgets of an NLHC is an arduous task. To ensure that budgetary dollars are spent in the manner specified by the funding organization, meticulous recordkeeping and itemization of spending is another undertaking that the nurse executive or an operations coordinator of an NLHC must carry out. It is imperative that key personnel from the NLHC maintain precise records and submit accurate quarterly, semiannual, or annual reports as specified in the grant or contract award (Zimmer & Knowlton, 2016).

## **Sustainability of Nurse-Managed Health Clinics**

**Sustainability**, or the ability to carry on services and health promotion activities, is one of the main challenges of NLHCs. NLHCs have much to offer toward resolving the national health care crisis facing vulnerable populations who are uninsured or underinsured. However, without the ability to maintain fiscal sustainability, NLHCs may fail to reach their full potential for positively influencing the future of health care (Hansen-Turton, et al., 2015). A seminal document by Cutler (2002, p. 23) proposes “critical sustainability questions” that can be used as a preliminary avenue of consideration for organizations such as NLHCs when completing a grant application for funding. The following are some strategies that can be implemented to promote sustainability of NLHCs (Cohn et al., 2017; Sofer, 2018):

- Demonstrate value for money, sometimes measured in terms of cost per client served.
- Track, monitor, and evaluate measurable outcomes that demonstrate the delivery of quality, cost-effective care.
- Hire and develop diverse and effective staff.
- Manage travel costs for serving remote populations through telehealth.
- Utilize technology.
- Develop a sustainability plan.
- Maintain strategic partnerships.

## The National NurseLed Care Consortium

The National NurseLed Care Consortium (NNCC, 2018a) strives to reduce health disparities and meet people's primary care and wellness needs through policy, consultation, programs, and applied research that advance nurseled health care (Box 29-7). They lead advocacy efforts for nurse-managed health care and support public health initiatives including the Nurse-Family Partnership (NNCC, 2018b). For more information, visit <https://www.nurseledcare.org/>.

### **BOX 29-7 National NurseLed Care Consortium**

**Mission To advance nurseled health care through policy, consultation, and programs to reduce health disparities and meet people's primary care and wellness needs.**

#### **Ways NNCC Supports NurseLed Care**

1. Offering a variety of educational opportunities to build practice, improve quality of care, and promote sustainability.
2. Advocate for policy that supports nurseled care in Washington, DC, and in state legislature.
3. Provide members with additional resources and discounts on educational opportunities and Annual Conference rates.
4. Build and manage public health programs, providing national models for nursing and public health.

Source: National NurseLed Care Consortium (2018a, 2018b).

The NNCC conducts a Best Practice Conference, which brings together nurses, staff members, funders, and political leaders to share best practices and participate in networking opportunities. Continuing education credits are available for attendance at scientific sessions.

## Nursing Research and NLHCs

NLHCs provide research opportunities for both primary prevention and wellness initiatives (AACN, 2016). Descriptive data have been collected about client demographics, types of service provided, funding methods, and sustainability efforts. The increasing presence of NLHCs had led to an increase in research primarily aimed at determining the quality and cost-effectiveness of care provided (Randall, Crawford, Currie, River, & Betihavas, 2017). NLHCs have been shown to have beneficial effects on patient satisfaction and health outcomes, as well as improved access to care (Sofer, 2018). Other studies include:

- [Randall \*et al.\* \(2017\)](#) conducted a systematic review of 15 studies that examined patient satisfaction, patient outcomes, objective clinical measures, access to care, and, to a limited extent, cost-effectiveness. Overall, results were favorable in all areas except for cost-effectiveness (evaluated in only two studies), for which results were mixed.
- [Baker and Fatoye \(2017\)](#) conducted another systematic review of 26 articles that provided data on the clinical and cost-effectiveness of nurseled care of patients with chronic obstructive pulmonary disease in a primary care setting. Initial results were favorable.

[Chan \*et al.\* \(2018, p. 61\)](#) examined outcomes for nurseled services in an ambulatory community care setting and found some evidence of “better outcomes in terms of health-related quality of life compared to physician-led care.” They also noted the lack of cost-effectiveness studies, an area needing further research to help guide future policy.

## Future Directions for NLHCs

In 2008, the IOM appointed a committee on the Robert Wood Johnson Foundation Initiative on the Future of Nursing. The purpose of this committee was to produce a report, making recommendations for the future of nursing. This committee developed four key messages regarding the future of nursing (IOM, 2011):

1. Nurses should practice to the full extent of their education and training.
2. Nurses should achieve higher levels of education and training through an improved education system that promotes seamless academic progression.
3. Nurses should be full partners with physicians and other health care professionals in redesigning health care in the United States.
4. Effective workforce planning and policy making require better data collection and information infrastructure.

The main areas of focus for health care reform are prevention and improving the quality of care (Patient Protection and Affordable Care Act [ACA], 2010).

- In NLHCs, advanced practice nurses lead interprofessional teams as critical safety-net providers in America's health care delivery system. Nurses in NLHCs are vital change agents as they partner with the community, interprofessional team members, and students to improve access to care and health outcomes (Randall et al., 2017).
- Community care centers, including NLHCs, have been shown to play a significant role in providing access to care for underserved populations on Medicare (Seo et al., 2019).
- Primary care is being transformed by registered nurses using their skills in coaching, case management, transitional care, chronic disease management, education, and health promotion to help meet the increasing demand for care (Josiah Macy Jr. Foundation, 2016).

Continued expansion of the NLHC model in the next decade and beyond will meet key recommendations from the IOM report on nursing's future and the goals of the ACA (AACN, 2017; Seo et al., 2019). See Box 29-8 for an example of an NLHC that meets the needs of the population served, provides continuity of care, and reduces the use of overcrowded and expensive emergency department services for routine health care.

## BOX 29-8 PERSPECTIVES

**Viewpoint of an Executive Director of a NurseLed Community Clinic In fall 2011, in our city of 120,000 in northeast Texas, many health care organizations here held the view that low-income or homeless population were “noncompliant” and did not care about their health. I had learned through volunteering that many barriers to their care existed. These included minimal payment amounts that were too high, service hours that were not convenient to the low-income population, and pre-enrollment criteria that many could not meet. To avoid this, the low-income and/or homeless populations tend to use the hospital EDs for care.**

I decided to set up a health clinic that didn't have unrealistic requirements. Individuals needing health services simply have to fill out an income self-declaration. The low-income and homeless populations are very mistrusting of community health and social services. They live day by day. They have to focus on the here and now: Where will my next meal come from? Where will I shower? Where will I launder my clothes? Where will I sleep?

Guided by the understanding that the low-income population has its own culture and very specific needs, the clinic was set up as a caring, compassionate, and supportive environment for this population. Patients of the clinic state that they feel “listened to,” even though the length of appointments is still only 20 minutes. Strategies contributing to quality care included:

- Offering clinic hours in the early morning hours, lunch time hours, and evening hours

- Providing behavioral care, counseling, and social services
- Treating patients' anxiety, depression, and other behavioral health conditions
- Building relationships with the patient and family
- Coordinating care and support services to strengthen coping and problem-solving skills

Outcomes of this approach included:

- Ability of patients to manage chronic illnesses
- Increased health-seeking behaviors at the Center rather than the ED
- Positive self-reporting that patients feel “listened to,” even though appointments are only 20 minutes long
- Improved ability of patients to seek follow-up care should their situation deteriorate

As a nurse, I find myself constantly advocating for patients and ensuring maximal health for our clients at a lower cost. It is a rewarding experience!

M. Alice Masciarelli, RN, DNP, FACHE, CPHQ Executive Director,  
Denton Community Health Clinic, Denton, TX

# FAITH COMMUNITY NURSING

A **faith community nurse (FCN)** focuses on the mental, physical, and spiritual health, using a holistic approach to prevention and treatment of illness within the context of a community of faith ([Deaconess Nurse Ministry, 2019](#)). Faith community nursing is one of the newest nursing specialties and one of the oldest means of health care delivery.

## Historical Background of Faith-Based Nursing

For hundreds of years, deaconesses, sisters, and lay members of religious communities have been involved in ministering to the sick. This tradition was revitalized through the efforts of Reverend Dr. Granger Westberg. As a hospital chaplain and Lutheran minister, Westberg observed a great need for preventive and holistic health services, especially among the underserved, and wrote several books. He launched several church-based holistic health clinics in the 1970s, each staffed by a physician, nurse, and chaplain, that provided health services to the underserved in the community for several years (Westberg Institute for Faith Community Nursing, 2019b). The clinics eventually closed, but the experience led Reverend Westberg to recognize the unique ability of nurses to bridge the disciplines of medicine and religion.

Westberg first coined the term *parish nurse* when he initiated a pilot project in 1984 in which nurses provided holistic, preventive health care for six Christian congregations in the Chicago area. Gradually, more and more churches sought to incorporate a parish nurse into their staff. The term faith community nursing is now commonly used in the United States. The Westberg Institute for Faith Community Nursing (2019b) provides educational programs and resources for nurses who seek to practice as parish nurses and for educators wishing to conduct training programs for parish nursing.

The Health Ministries Association (HMA), along with the ANA, was instrumental in writing the third edition of *Faith Community Nursing: Scope and Standards of Practice* (ANA & HMA, 2017). The term faith community nursing was defined as “a specialized practice of professional nursing that focuses on the intentional care of the spirit as well as the whole-person health and prevention or minimization of illness” (HMA, n.d., para. 1). Today, nurses who practice in a faith community may be referred to as FCNs, parish nurses, health ministry nurses, congregational nurses, or church nurses depending upon preference and the traditions of the faith community. No matter what title is used, a nurse who practices in a faith community should adhere to the standards of practice, which can be obtained through the ANA at <https://www.nursingworld.org/nurses-books/faithcommunity-nursing-scope-and-standards-of-practice-3rd-edition/>.

## What Do FCNs Do?

Activities and interventions FCNs implement are as diverse as their faith communities. Some examples include:

- Advocating for the needs of the dying
- Addressing health conditions that are stigmatized, such as HIV
- Supporting patients with mental health issues
- Providing guidance during life transitions such as marriage, divorce, birth, death, illnesses, *etc.*
- Promoting health education ( [Faith Community Nursing Health Ministries Northwest, 2019](#); [Nelson, 2018](#))

FCNs have been instrumental in meeting the educational and health promotion needs of underserved and older adult populations. A few examples of specific programs that have been successful in faith-based settings include:

- University of California, San Diego, offers a comprehensive faith-based wellness program that addresses health disparities in African-American, Latino, and Muslim communities ([UC San Diego, 2019](#)).
- The Bronx Health REACH Faith-Based Outreach Initiative provides programs addressing diabetes prevention and management, nutrition, fitness, and health disparities ([Institute for Family Health, 2019](#)).
- Abuelas en Acción (Grandmothers in Action) promotes physical activity, nutrition, and stress management in the Latino community ([University of Illinois at Urbana Champaign, 2016](#)).
- The “Fit Body and Soul” program strives to prevent diabetes among African American populations ([Sattin et al., 2016](#)).

## Roles of the FCN

The goal of the FCN is “protection, promotion and optimization of health and abilities; facilitation of healing, alleviation of suffering through the diagnosis and treatment of human responses and advocacy in the context of values, beliefs, and practices of the faith community, such as a church, congregation, parish, synagogue, temple, mosque, or faith-based community agency” (ANA/HMA, 2017, p. 2). Health promotion outcomes may be primary, directed at prevention of disease, illness, or injury; secondary, focused on early detection and appropriate intervention; or tertiary, concerned with promoting a sense of well-being when preventing or curing a condition may not occur. To achieve the goal of faith community nursing, seven diverse nursing roles are central to incorporate into practice (Schroepfer, 2016; Westberg Institute for Faith Community Nursing, 2019c; Zeibarth & Campbell, 2016). The roles of the FCN (Box 29-9) support the development, implementation, and evaluation of faith-based programs.

### **BOX 29-9 Assuring Congregational Health And Wholeness**

#### **Roles of the Faith Community Nurse**

1. Health educator
2. Health counselor
3. Advocate
4. Referral agent
5. Developer of support groups
6. Coordinator of volunteers
7. Integrator of faith and health

#### **Accountability**

1. ANA scope and standards of nursing practice
2. ANA scope and standards of faith community nursing
3. Congregational standards
4. Institutional standards
5. ANA social policy statement
6. ANA code of ethics for nurses with interpretive statements
7. State nurse practice act
8. Patients' rights

Source: Dandridge (2014); Schroepfer (2016); Westberg Institute for Faith Community Nursing (2019c).

## *Health Educator*

- A primary role of the FCN is as a health educator. Increasing awareness of health issues through health education is the foundation for health promotion and lifestyle changes. The FCN uses assessment skills to determine the health issues that may be present in the faith community and assesses the educational needs related to these issues.
- The FCN may provide individual and group education strategies such as providing health education materials, leading health education classes, or providing health screenings. The FCN may also develop educational displays or flyers or write educational articles for the faith community newsletter or Web site.

## *Health Counselor*

- In the health counselor role, the nurse seeks to understand the individual's perceptions, fears, and barriers that prevent the person from taking action.
- The FCN may use a five-step health counseling process described as the five A's (Cooper & Zimmerman, 2017; Smoking Cessation Advice, 2018):
  1. *Ask* about the person's perceptions related to a specific health concern.
  2. *Advise* the person about the health concern and the benefits of taking health-promoting actions.
  3. *Assess* the person's readiness to take action.
  4. *Assist* in planning ways to address the health concern.
  5. *Arrange* follow-up support.

## *Advocate*

- The third role of an FCN is that of an advocate, helping individuals obtain needed services or care whether in the hospital, a long-term care facility, or at home. In the advocate role, the FCN uses knowledge of the health care system and awareness of safe and effective care practices to facilitate appropriate, timely intervention (Mock, 2017).
- Advocacy is indicated when dealing with vulnerable populations, such as older adults, children, or the homeless, who may not have the ability to speak for themselves or may lack the knowledge or awareness of what constitutes safe, effective care. FCNs have actively advocated for those with mental health problems, finding treatment sources and providing referrals and support (Foster, Dawood, Pearson, Manteuffel, & Levy, 2019).

## *Referral Agent*

- The role of referral agent involves several related aspects. First, the nurse needs to develop knowledge of community resources and contacts. Knowledge of what is available, how the service is accessed, eligibility criteria, and limitations of the service is essential.
- Next, the nurse networks with and develops collaborative relationships with community leaders and agencies who provide the services. Through networking with community agencies, the FCN becomes aware of and is able to easily access a variety of community resources to support the client's physical, social, financial, emotional, or spiritual needs ([Association of Public Health Nurses, 2016](#)).

## *Developer of Support Groups*

- Receiving emotional support from persons who share similar experiences can provide strength, comfort, knowledge, and a sense of empowerment ([Frykedal, Rosander, Berlin, & Barimani, 2016](#)).
- The FCN develops groups tailored to the faith community needs such as coping with loss and grief, cancer, caregiver stress, chronic illness, single parenting, addiction recovery, health promotion, and more ([Callaghan, 2016](#); [Grebeldinger & Buckley, 2016](#)).

## *Coordinator of Volunteers*

- The health ministry mission of a faith community typically includes a variety of services and activities to provide holistic support of the physical, social, emotional, mental, and spiritual needs of its members. Such a diverse array of services cannot be provided by the FCN alone.
- In the role of coordinator of volunteers, the FCN recruits, trains, and coordinates other members of the faith community. Volunteers provide or assist with a variety of services such as ([Christian Community Health Fellowship, 2019](#)):
  - Home, hospital, or long-term care visitations
  - Respite care
  - Assisting with transportation needs of homebound individuals
  - Calling or sending cards to ill or injured members
  - Assisting with health screenings

## *Integrator of Faith and Health*

- A distinctly unique role of the FCN is as integrator of faith and health ([Fig. 29-4](#)). This role emphasizes the holistic relationship between the

physical, social, emotional, mental, and spiritual dimensions of the person.

- The FCN helps the person to improve health or enhance wellness by appreciating how the dimensions of the person are interconnected and by helping the person strengthen or support the weaker aspects, as needed.
- The FCN assesses community's strengths and health needs and incorporates an understanding of the connection between faith and health (Brewer et al., 2017; Tettey, Duran, Anderson, & Boutin-Foster, 2017).

**FIGURE 29-4** A faith community nurse provides comfort.

## Faith Community Nursing Practice

Models of faith community nursing practice are diverse and may be categorized according to volunteer versus salaried positions and institutional versus faith-based sponsorship. The type of practice model adopted depends on variables such as:

- The number of faith community members served
- The existing health ministry services in place
- The faith community's governance structure and financial resources
- Existing health care systems in the community at large

Early in the development of faith community nursing, FCNs were typically part-time volunteers who were members of the faith community they served. This voluntary, part-time status, coupled with the newness of faith community nursing practice, has resulted in limited research on faith community nursing. Nonetheless, studies that have been conducted have validated the effectiveness of FCNs and the programs they have implemented, such as the following:

- A faith-based lifestyle intervention was initiated to prevent diabetes among African Americans ([Sattin et al., 2016](#)).
- A cardiovascular health education program conducted by trained lay educators in 14 African American congregations found significant reductions in weight and blood pressure ([Tettey et al., 2017](#)).
- A 3-month program of coaching and blood pressure self-monitoring, led by 39 FCNs, resulted in decreased blood pressure and improved scores on a lifestyle satisfaction inventory ([Cooper & Zimmerman, 2017](#)).
- A gospel rescue mission established a wellness center at a homeless shelter for men and found improved access and treatment adherence ([Lashley, 2019](#)).
- A transition of care program led by an FCN reduced 30-day hospital readmission rates by 67% ([Strait, Fitzgerald, Zurmehly, & Overcash, 2019](#)).
- A breast cancer education program was shown to be effective in improving “general knowledge about breast cancer, higher breast cancer mortality among African American women, warning signs, risks and ways to mitigate risk, and the availability of low-cost or free mammograms” ([Brown & Cowart, 2018](#), para. 4).

There are growing trends in the types of FCN delivery models used today. These include ([Sabo et al., 2015](#)):

- Hire salaried full-or part-time staff positions serving one congregation.

- Hire salaried full-or part-time staff positions shared across multiple congregations.
- Maintain a separate health care facility.
- Form partnerships with organizations such as universities or hospitals that agree to provide nursing services to the faith community, possibly involving individual faculty and student groups.
- Invite student nurse participation in servicelearning projects that address public health issues in the church setting.

## Becoming an FCN

The FCN practices community nursing with a high degree of independence and autonomy. Often, the FCN deals with clients experiencing complex health care situations who may have limited resources and extensive health-related needs. The preferred minimum educational preparation for an FCN includes a bachelor's degree in nursing (ANA/HMA, 2017) and completion of additional education such as the 36-hour Foundations of Faith Community Nursing course offered through the International Parish Nurse Resource Center (The Center for Faith and Community Health Transformation, 2015; Westberg Institute for Faith Community Nursing, 2019a). This course addresses the roles of the FCN and provides information on establishing, promoting, and maintaining an FCN practice. Participants gain experience in resolving complex client situations using scenarios and case studies.

- Several steps are involved in creating an FCN position within a faith community. One of the first things to do is assess the community the nurse plans to serve, identifying the health needs of the faith community and the roles of the FCN that meet those needs through a needs-assessment survey.
- Once the nurse has assessed the needs of the faith community, the next step is to identify how an FCN could help to meet those needs. The FCN uses this information to seek the support of the faith community members and staff.

The Westberg Institute provides information and resources regarding establishing a program, along with the qualifications needed for the nurse. The center also provides an educational program called The Ministry of Church Health to guide the nurse in the many roles that the nurse will have in the community (Westberg Institute for Faith Community Nursing, 2019a).

Web sites for information on Faith Community Nursing include the following:

- International Parish/Faith Community Nursing: <https://westberginstitute.org/international-faith-communitynursing/>
- HMA: <https://hmassoc.org/>
- Nurses Christian Fellowship: <http://www.ncf-jcn.org/index.php>

# OCCUPATIONAL AND ENVIRONMENTAL HEALTH NURSING

Business and industry provide another group of settings for community health nursing practice. **Occupational and environmental health nurses** work with employers to cultivate creative and business-appropriate health and safety programs. Program development must consider the business's unique type of work, workforce demographics, and the work/community environments. The practice of occupational health nursing uses an interdisciplinary approach to advocate for the employee's right to have cost-effective, prevention-oriented health and safety programs (Fig. 29-5).

**FIGURE 29-5** An environmental health nurse works collaboratively with the community. (Photograph courtesy of the

Centers for Disease Control and Prevention. Retrieved from <https://phil.cdc.gov/Details.aspx?pid=22796>)

Organizations are expected to provide a safe and healthy work environment in addition to offering insurance for health care. Businesses often choose to hire occupational health nurses (OHNs) because occupational health programs help maximize employee efficiency and decrease costs by effectively reducing work-related injuries, disability claims, and absenteeism and improving employee health and safety.

- Present-day OHNs observe and assess workers' health status, considering the workers' job tasks and hazards. Using their specialized training, education, and experience, they use the nursing process to prevent occupational illness and injury.
- An equally important responsibility is to help organizations maintain compliance with federal, state, and local laws, regulations, and guidelines for workplace health and safety ([American Board for Occupational Health Nurses \[ABOHN\], n.d.](#)).

# History of the Occupational and Environmental Health Nurse

Community health nurses have a long history of involvement in occupational health. Early on, the profession primarily focused on providing infant and child health education to the employee families as well as the whole community. World War II showed a marked increase in employment of OHNs. In keeping with the changing times, the OHN's practice broadened to include comprehensive health and safety programs designed to prevent illness and injury for the US workforce. Historic examples include:

- Betty Moulder provided care for coal miners and families in Pennsylvania beginning in 1888 ([American Association of Occupational Health Nurses \[AAOHN\], 2019b](#)).
- In 1895, the Vermont Marble Company hired Ada Mayo Stewart, said to be the first *industrial nurse* in the United States. Stewart provided care for employees and their families, focusing on health promotion and disease prevention ([ABOHN, n.d.](#)).

Although occupational and environmental health nursing has been in existence since the late 1800s, the Occupational Safety and Health Act of 1970 led to the proliferation of occupational health nursing employment in the United States. This important legislation established the **Occupational Safety and Health Administration** ( [OSHA, 1970](#) ) in the Department of Labor, to ensure a safe working environment for workers in the United States. To ensure that business and industries meet OSHA standards, OHNs monitor the health status of individual workers, workforce populations, and community groups. Other prominent practice guidelines come from:

- US statutes, such as the Genetic Information Nondiscrimination Act
- Family Medical Leave Act
- [Americans with Disabilities Act \(2000\)](#)
- Health Insurance Portability and Accountability Act
- Department of Transportation and U.S. Environmental Protection Agency

OHNs can implement evidencebased interventions to prevent or mitigate negative health effects of the work environment by gathering health and hazard data, evaluating the effects of workplace exposures, and developing workplace prevention programs ([ABOHN, n.d.](#)).

# Settings for Occupational and Environmental Health Nursing

OHNs work in a variety of settings:

- The manufacturing sector has a strong tradition of employing OHNs, but utility companies, mines, retail store chains (e.g., grocery, department, home improvement), hospitals and medical centers, theme parks, banks, school systems, and government also employ OHNs (ABOHN, n.d.).
- Consulting for companies is a more independent type of employment for about 7% of OHNs, as noted in a seminal study by Harber, Alongi, and Su (2014). Or entrepreneurial nurses may set up an occupational health clinic in areas where many small businesses are located. See Box 29-10 for the perspective of a nurse entrepreneur.
- Nurse-managed clinics may use OHNs, a nurse practitioner or physician assistant, a physical therapist, a health educator, and a part-time occupational physician.
- A single-nurse unit is a common model of practice in many smaller companies. In a single-nurse unit, OHNs typically build strong networks of colleagues with whom they can discuss professional practice issues.
- Some companies use a medical model of practice, in that a physician determines clinic staffing and the department's approach to clinical practice.

## BOX 29-10 PERSPECTIVES

### A Nurse Entrepreneur's Viewpoint

As a newly graduated nurse practitioner, I was excited to step into the role in a small family practice clinic. I worked alongside a family physician who owned the clinic. We took pride in the product we delivered because we made decisions that directly impacted patient care.

A few years later, a corporation bought out that small family practice clinic. Upon the sale of the clinic, the administrative decisions were made by people not only unfamiliar with our patients but unfamiliar with family medicine. Nameless faces on the other end of phone trees addressed my

patients' concerns, as the corporation centralized the call centers under the direction of corporate management.

I became frustrated with the dictates of others and the negative impact it had on my patients. This frustration led to my desire to make a change. My first entrepreneurial experience came when an owner of a manufacturing plant approached me about creating and running an on-site clinic for his employees. Together, the company owner and I talked about our vision of the clinic. I created a model where I could run the clinic by myself, with one medical assistant. Care was free to employees, and insurance companies were not involved. The owner of the manufacturing plant paid the overhead. This was a model unlike any other on-site medical clinic in the area.

A few years after starting the on-site clinic, I saw the lack of access my patients had to mental health care in my state. There was a serious shortage of psychiatrists to manage psych meds, so I started a mental health clinic to provide better access to those in my community. I eventually transitioned out of my on-site employee clinic and expanded my mental health clinic to provide a broader array of services. I became a nurse practitioner to help others and make a difference in the world. In order to truly make a difference, I assessed the needs in my community and did what I could to fill the gaps.

Can you think of something that may frustrate you and see where you might provide a much-needed service, like this nurse entrepreneur?

—Kelly Wosnik, DNP, NP-C

Areas of focus in occupational health nursing could expand to include vulnerable populations, such as immigrant workers, and healthier communities, while continuing to include attending to chronic health conditions and promoting preventive approaches (McCauley & Peterman, 2017).

## **Roles and Career Opportunities of Occupational and Environmental Health Nurses**

There are a wide variety of settings that benefit from OHN programs. In addition to providing first aid for illness and injury that occurs in the workplace, occupational health practices are moving toward a model that provides not only basic occupational health services but also case management, telehealth, care coordination, and primary care (AAOHN, 2019b).

According to the Workforce Management Data Bank, the primary reasons employers establish an on-site clinic are to decrease health care costs, improve workers' quality of life, and improve the company's cost-effectiveness (National Association of Worksite Health Centers, 2019).

Comprehensive occupational worksite programs offer both health protection and health promotion services. After employees are injured or become ill at work, OHNs work to ensure a speedy and functional recovery, frequently helping employees work through the workers' compensation or insurance bureaucracy. Although some companies outsource case management for work-related injuries, many OHNs coordinate and manage cases to ensure the employee's optimum recovery while helping to control costs.

Occupational health nursing practice can be divided into three main categories: compliance, care, and health promotion. There is a wide range of career opportunities for the occupational and environmental health nurse to consider. Examples of the variety of roles and jobs in OHN practice beyond the typical clinical setting include international opportunities, case management, transitional care, and telemedicine.

OHNs practice around the world. There are positions with American companies that have foreign operations as well as with international companies. Depending on the global setting, OHN responsibilities and scope of services may differ from practice in the United States. However, the goals of mitigating factors that may affect a workplace population's health and working to protect and promote safe working conditions are the same. If going abroad sounds appealing, the AAOHN has published an international resource list that outlines the educational and training requirements for countries with an occupational health nursing specialty (Robinson, 2016).

Effective case management is one strategy for employers to not only quantify health care costs but also to demonstrate savings and ensure quality care delivery through coordination of services (Case Management Society of America, 2016; Workplace Health & Safety, 2015).

**Case management** is the process of assessment, planning, facilitation, care coordination, evaluation, and advocacy for services to meet an individual's and family's comprehensive health needs using resources to promote patient safety, quality of care, and cost-effective outcomes ([Case Management Society of America, 2017](#)).

Case management is a care-coordinated strategy that is patient-centered, continuous, and often used in transitional care situations. It is an approach that can be found across many specialties of nursing, from acute care to public health nursing. For example, an employee with asthma may be followed by an OHN for case management, as well as an employee who has been injured on the job. A C/PHN may follow a young mother and her healthy new infant, helping to remind the mother of vaccination clinics and educating on normal child development. If the child develops a chronic condition, such as sickle cell anemia, the C/PHN will help with arrangements for transportation, referrals, and finding resources. A patient may be followed from home to the hospital and back home again, with one nurse as the case manager. This represents the continuum of care. Case management may also be accomplished through a team effort of care collaboration, with physicians, nurses, occupational health specialists, and others involved in coordinating care.

A meta-analysis of studies evaluating the effect of case management on 4,000 patients with type 2 diabetes found statistically significant reductions in hemoglobin A<sub>1C</sub> and low-density lipoprotein levels, demonstrating the effectiveness of case management over a control group ([Zeng, Shuai, Yi, Wang, & Song, 2016](#)). Various methods of case management, from phone consultation to in-person visits, were included in the analysis.

Careful case management can ensure efficient, less fragmented, and more cost-effective use of the health care system, producing better patient outcomes while decreasing costs ([Joo & Huber, 2018](#)). It is especially helpful for fragile, vulnerable clients needing an advocate within the health care system.

**Transitional care** involves managing care from one level to another across the health care spectrum ([Naylor et al., 2018](#)). Transitional care strategies have been shown to reduce unnecessary use of health services and improve patient outcomes in chronically ill, injured, and older workers ([Social Programs that Work, 2017](#)). There are several models of transitional care ([Ortiz, 2019](#)):

- Colman's Care Transitions Intervention Model
- Naylor's Transitional Care Model
- Better Outcomes for Older Adults Through Safe Transitions
- The New York State Department of Health (NYSDH) Transitional Care Model

The NYSDH model is founded on five elements (Ortiz, 2019):

1. Determining the patient's strengths (e.g., emotional/cognitive, physical, medical, economic, abilities, support system)
2. Assessing the patient's functioning before admission to help determine potential resources needed on discharge
3. Informing decision-making through ongoing collaboration among the patient, family, and interdisciplinary transition team
4. Providing both verbal and written information on available options and the range of community services
5. Allowing the patient and family to select preferred providers when possible

One role of the OHN's practice is management of a program to help workers successfully return to work following work-related illness or injury and transition through the often-complex pathway to recovery. Collaboration between all members of the interdisciplinary transitional care team is essential to improve the proportion of employees who successfully return to work (Awang, Shahabudin, & Mansor, 2016).

Transitional care is also found in many nursing specialties and has been especially emphasized since 30-day readmission rates were tied to hospital Medicare payments (see Chapter 6). For example, one large-scale study of over 30,000 patient records found that case management by diabetes educators reduced the 30-day hospital readmission rate from 20.1% to 17.6% over an 18-month period (Drincic, Pfeffer, Luo, & Goldner, 2017).

OHNs can use telemedicine or telehealth (see Chapter 10) to teach, observe processes in distant locations, or provide consultations, to reduce or eliminate OSHA recordable incidents and loss of work time (American Telemedicine Association, 2019). The Chronic Care Act of 2017 expanded the use and reimbursement of telemedicine, addressing complaints by health care providers of their lack (Arndt, 2018).

- In 2018, the U.S. Department of Veteran Affairs (2018) launched an expanded telehealth program that enabled Veterans to access care from their homes, including mental health and suicide prevention programs.
- School nurses have explored the use of telehealth as a means of extending their availability and potential for meeting the health needs of all students, no matter how remote their locations (Reynolds & Maughan, 2015).
- A secondary analysis of a 2017 survey of registered nurses working in Vermont found that almost one fifth of the respondents reported working in telehealth/telephonic nursing. Although there is no real preparation for this skill in nursing school, there are concerns about providing “safe, effective, culturally relevant telehealth, and virtual care” and the need for policy development in this area (Rambur, Palumbo, & Nurkanovic, 2019, p. 64).

- Cost-effectiveness of telemedicine has been demonstrated. [Anderson \*et al.\* \(2018, p. 2031\)](#) found that electronic consultations (eConsults) with specialists in dermatology, gastroenterology, endocrinology, and orthopedics at a large, multisite safety-net health center had “average specialty-related episode-of-care costs” that were \$82 per month lower than patients having face-to-face appointments.
- Digital health interventions such as short message service, telephone support, mobile applications, video conferencing, telemonitoring with digitally transmitted physiological data, and wearable medical devices were evaluated for cost-effectiveness of cardiovascular disease management interventions in a systematic review of 14 studies published largely between 2015 and 2018 ([Jiang, Ming, & You, 2019](#)). Overall, the use of digital health interventions demonstrated higher quality-adjusted years of life (QALYs) while also saving costs in 43% of the studies reviewed. The remainder of the studies had QALY gains but higher costs, making them less cost-effective interventions.

## Health Promotion and Wellness

OHNs play a vital role in advocating for health promotion and wellness programs for the workforce they serve. OHNs are in an ideal position to provide guidance, counseling, education, and coaching for employees who want to improve their health. Faced with high health care costs, many employers are turning to worksite health programs to help employees adopt healthier lifestyles and lower their risk of developing costly chronic diseases while improving worker productivity ([AAOHN, 2019b](#)).

- The **Total Worker Health (TWH)** initiative is designed to provide holistic approaches to employee wellness. It integrates occupational safety and protection of health along with health promotion to prevent worker injury and illness and improve worker well-being and health ([National Institute for Occupational Safety and Health \[NIOSH\], 2018](#)).
- Because American workers spend a large part of their day at work, the workplace is now considered a social determinant of health; job-related factors include salary, the work environment, time spent at work, physical and psychological stress, employee–employer dynamics, and work–life balance (see [Chapters 1 and 11](#)).
- The AAOHN also crafted a position statement that calls for a multifaceted approach to address the rising opioid crisis as it affects the workplace, calling on OHNs to become actively engaged in workplace educational programs and other interventions, such as drug testing policies and procedures ([AAOHN, 2018](#)).

## The Occupational Health Team

OHNs work in a team environment with a variety of other professionals. Depending on the size of the company, the occupational health team may include the following:

- Safety specialist
- Industrial hygienist
- Ergonomist
- Industrial or organizational psychologist
- Toxicologist
- Physical or occupational therapist
- Physician
- Lawyer
- Employee assistance counselor

Human resources, management, security, and emergency response personnel are also part of the team. The employee is central to the team and is the reason for the team's existence. Team collaboration is essential to the success of the occupational and environmental health program, and the OHN has a key role in ensuring adequate and appropriate communication among the members of the team. Establishing working relationships is paramount to the success of a functional and effective team ([OSHA, 2018](#)). Strong interpersonal relationship skills are extremely valuable in a team environment.

Finally, the occupational health team is not complete without the workers themselves. Employees can help identify problems and needs while contributing to decision-making about health programs. Their cooperation in implementing and evaluating programs is essential for an effective health protection and promotion effort.

# Educational Preparation and EvidenceBased Practice

OHNs are the largest group of health professionals working in occupational health ([de Castro, Shapleigh, Bruck, & Salazar, 2015](#)). In many work settings, the occupational and environmental health nurse is the only health professional. Independent decision-making is critical. Nurses in occupational settings must also have strong communication skills, including listening, speaking, and writing. The broad knowledge base requirement necessitates a minimum of a bachelor's degree in nursing. During the last two decades, several nursing educational programs (primarily on the graduate level) have developed a specialty focus in occupational and environmental health.

Additionally, OHNs may become certified in this specialty field through ABOHN. Founded in 1972, ABOHN is an independent not-for-profit organization that sets professional standards and conducts occupational health nursing specialty certification. ABOHN is the sole certifying body for OHNs in the United States and has the stated purposes of ([ABOHN, 2018](#)):

1. Establishing standards and examinations for professional nurses in occupational health
2. Elevating and maintaining the quality of occupational health nursing service
3. Stimulating the development of improved educational standards and programs in the field of occupational health nursing
4. Encouraging OHNs to continue their professional education

In addition to formal training in occupational health, continuing education plays an important role in keeping abreast with evidencebased practice, as well as maintaining specialty certification. Opportunities range from formal in-person conferences to short, online courses addressing specific topics in occupational health ([AAOHN, 2019a](#)).

## The Effect of Work on Health

Workers in the United States generally spend more time at work than on any other activity except sleep. Thus, the work environment can have a significant impact on workers' health. A safe and supportive work environment can contribute to the well-being of employees (Fig. 29-6). However, the type of work that people engage in dictates the hazards they encounter. For instance, think about the work of hospital-based nurses. They encounter physical hazards, such as lifting patients in bed without mechanical lifting devices. There are biological hazards associated with blood and body fluids as well as infectious diseases. Some nurses are at risk for chemical exposures, such as those associated with operating room gases or chemotherapy. Radiation hazards may exist when working with patients undergoing radiation therapy.

**FIGURE 29-6** Example of workplace safety equipment. Firefighters in fireproof uniforms are well prepared to extinguish fires.

- Hazardous substances can get into a person's body through inhalation, ingestion, or absorption (percutaneously). Although personal protective equipment (PPE) is available to workers, some may not use PPE consistently, or the equipment may not be entirely effective. Workers exposed to chemicals may not wash their hands sufficiently before eating or smoking, thus providing an opportunity for chemicals to get into their system through ingestion or inhalation. Employers are responsible for training employees ([OSHA, n.d.](#)).
- Employees who work in awkward positions or who do repetitive tasks that use the same muscle groups are at risk for musculoskeletal disorders (MSDs). Carpel tunnel syndrome is often associated with

repetitive movements, such as typing at a computer keyboard (Hegmann *et al.* 2016).

- Workers who compound a workplace exposure with off-work activities that use the same muscle groups in similar actions will accelerate or aggravate a problem. For instance, an office manager may spend hours using electronic devices (cell phone, tablet, computer) in the evenings and on the weekend, so the muscles that are used every day never really get a chance to rest and recover.
- A research study examining the prevalence of MSDs among office workers found the highest number of MSDs noted in the lower back (almost 50%) and neck (49%) areas (Piranveyseh *et al.*, 2016).

Shift work, particularly rotating shift work, negatively impacts sleep and rest cycles. NIOSH offers a free online course that trains nurses and nurse managers on the risks associated with shift work and long working hours, including training on strategies to reduce such risks (NIOSH, 2018). Insufficient sleep is associated with obesity and diabetes (Gibson-Moore & Chambers, 2019). Low-paying jobs may drive workers to get a second or even a third job to make ends meet. Personal stressors or balancing work and family demands, plus employer expectations at work, can have an adverse effect on worker health (Box 29-11).

## **BOX 29-11 STORIES FROM THE FIELD**

**Creating a Safety Culture** A family-owned beverage distributing company with 150 employees is experiencing a higher than average injury rate. This prompted the onsite occupational health team consisting of an occupational health nurse, industrial hygienist, and safety manager to conduct a walkthrough. They identified hazards, such as frayed electrical extension cords, blocked egress (exit) doors, missing machine guarding, and air quality concerns.

1. *What actions should the occupational health nurse take?*

2. *What preventive measures could be put into place to inspire a more proactive safety culture?*

3. *What measures might motivate employees involved to prevent exposure to serious hazards?*

- A systematic review of research on workplace mental health interventions found moderate evidence for effectiveness of these programs and their outcomes. Programs that included both physical and mental health interventions and multicomponent interventions had greater evidence of support ([Wagner et al., 2016](#)).
- Education to reduce the stigma associated with mental illness has also been shown to be effective in improving worker knowledge and promoting more supportive behavior toward peers with mental health issues ([Hanisch et al., 2016](#)).

## Future Trends

Future practice considerations for occupational health professionals' center on promoting and maintaining the highest level of physical, social, and emotional health for all workers. Occupational health and environmental nurses play a key role in making positive strides toward this goal by embracing evidencebased research and best practices. Strategic visionaries from the nursing and occupational safety and health (OSH) fields stress the need for working collaboratively (ILO, 2017; 2019a). The Future of Nursing committee of the Institute of Medicine (now named the Health and Medicine Division of the National Academies of Sciences, Engineering, and Medicine) concluded that, “no single profession, working alone, can meet the complex needs of patients and communities” (Lynch, 2015, para. 2). Collaboration with all stakeholders in the health care sector, private industry, government agencies, trade unions, workers, employers, researchers, educators, consultants, administrators, managers, policy makers, technology developers, and human resource professionals is required to advance worker safety and health and create a culture of prevention.

In the progress report, the Future of Nursing committee gave specific recommendations in the areas of removing barriers to practice and care; transforming education; collaborating and leading; promoting diversity; and improving data. The update included progress made to date, remaining challenges, and recommendations towards reaching the goals of The Future of Nursing: Campaign for Action (Campaign for Action, 2019). As nurse specialists, OHNs must keep engaged and abreast of the direction of our nursing profession. The following updates convey highlights of the in-depth work done over the past 5 years. The full report is available for review at <https://campaignforaction.org/about/our-story/>.

Occupational and environmental health nurse practice will continue to evolve. To respond to these challenges, OHNs need to stay current and connected to the continuously growing body of OSH practices evidence. The International Labour Organization (ILO) is a United Nations agency that is tasked with bringing together “governments, employers and workers representatives of 187-member states, to set labor standards, develop policies and devise programs promoting decent work for all women and men” (ILO, 2019a, para. 1). ILO (2017) outlined five challenges:

1. The need for “OSH data that is reliable and comparable coupled with key indicators that will drive improved performance” (para. 9).
2. Giving priority to “those most vulnerable at work.” This requires that “the safety and health of migrant workers must be a global concern” (para. 10).

3. Upgrading OSH within global supply chains. Developing methodologies for “identifying OSH vulnerabilities in the agricultural supply chain and developing targeted interventions” to address them (para. 11).
4. Creating processes for the “global sharing of OSH data, knowledge and expertise and finding the means to sustain such networks” (para. 12).
5. The importance of proactively recognizing the “impact that future jobs and future ways of organizing work will have on the safety and health of workers” (para. 14).

There is still work to be done. The new global estimates on work-related illnesses and injuries represent ([ILO, 2019b](#)):

- Costs associated with the illnesses, injuries, and deaths amount to 3.94% of the global gross domestic product per year, or US \$2.99 trillion.
- 2.78 million workers continue to die each year from work-related injuries and illnesses.
- 2.4 of the 2.78 million deaths can be attributed to work-related diseases alone.

How the future of nursing is forged will have the greatest impact on this and the next generation of OHNs and the populations they serve and protect. It is critical to continue to develop skills and competencies, champion innovation, and collaborate with stakeholders to effect change in an evolving occupational and environmental health landscape. To accomplish this, “the nursing community, must build and strengthen coalitions with stakeholders both within and outside of nursing” ([Lynch, 2015](#), para. 2). The occupational and environmental health nurse will particularly need skills in effective communication, leadership, change management, research, business acumen, and assertiveness. These tools will be crucial for effectively interpreting the OHN's role and promoting future worker population needs.

# NURSE ENTREPRENEUR IN COMMUNITY/PUBLIC HEALTH NURSING

C/PHNs often work within an organization to address unmet needs in the community, with the ultimate goal of enhancing service delivery. These positions are often nonexistent until the nurse is able to identify a need and take the necessary steps to start a stand-alone service or to develop a role within an existing agency, often through grant writing. But a growing trend in nursing seeks a more independent practice through entrepreneurship. The National Nurses in Business Association (NNBA, 2018) was first started in 1985 as a grassroots effort for business-minded nurses to connect and share ideas. It has grown into a nursing organization that provides resources for nurses transitioning from traditional nursing positions to self-employment and business ownership. As you think about your own career in nursing, can you envision yourself running a health care business, seeking a small business loan to start a venture, or having the courage to explore other professional options? Independent practice is not for everyone, and nurses are often socialized to view their role as working within a larger organization, such as a health department, a community clinic, or, most often, a hospital. At some point in your career, you may find yourself working with a nurse entrepreneur or becoming one yourself.

- An **entrepreneurial nurse** is one who is willing to take on the risks of starting a new business within a health care or social context. Common examples of nurse entrepreneurs include legal consultants, forensic nurses, home health care agency owners, authors, and nurse consultants in a variety of areas.
- The NNBA (2018) offers membership and resources for those entrepreneurial nurses who are self-employed or small business owners.

For the community/public health nurse, these and many other options offer the independence to provide services in perhaps a new and innovative way. For health care to continue to respond to the changing environment, the innovators are often the ones who have the courage to test those new methods.

## Steps to Becoming a Nurse Entrepreneur

One of the first steps to becoming a nurse entrepreneur is to have an idea. It doesn't have to be a new idea or even a “big” idea, but it must address an unmet need within a community. Community/public health nurses are often the first to identify the challenges and needs within a community and to explore solutions. Very often, participation in professional organizations helps to identify health care issues that can be addressed by nurses. The common refrain “why doesn't someone just (invent, build, provide, etc.)?” can often be answered by a nurse. Nurses are problem-solvers, and using the nursing process, they assess the situation, identify the problem, determine a course of action, and evaluate the results. This nursing skill can be leveraged for entrepreneurship (e.g., to start a new business venture, to develop a nonprofit agency, or to create educational tools for use by other health care professionals or the general public).

Entrepreneurial nurses in the community often require skill with grant writing, agency and personnel management, collaboration both inter-and intraprofessionally, fiscal management, and agency promotion. Whatever the health care need, nurses can and do find the solutions. [Hahn and Cook \(2018\)](#) highlight the potential nurse practitioners with full practice authority have as entrepreneurs in their state. These nurse practitioners are finding new ways to practice outside the hospital while addressing gaps in direct patient care systems. They are able to serve vulnerable groups while leveraging reimbursement. Credentialing and payment from private insurance companies can be cumbersome. Legal consultation should be part of every nurse entrepreneur's business plan.

A business plan is essential to starting a business, growing a business, and obtaining financial support. At the very minimum, the business plan should include the description of the business; marketing strategies; competitive analysis, design, and development plan; operations and management plan; and financial factors ([Box 29-12](#)).

### **BOX 29-12 Small Business Start-Up Information**

1. Write a detailed business plans with goals, objectives, and financial costs. Include market research and competitive analysis for your business.
2. Set up the legal business structure. This might require legal consultation.
3. Register your business and obtain a Federal Employee Identification (FEI) number.

4. Obtain start up collateral. Create business or merchant bank account.
5. Determine whether business licensing is required for your business activities. What other government rules and licensing might need to be considered? Be aware of rules in all states you will interact with for business. Will you need business insurance?
6. Establish place of business including all contact and corresponding information.
7. Create a sales and marketing plan. Address marketing for your business including Web site and registered URL, advertising plan, and marketing products. Consider how you will “sell” your product. How will you establish a presence in your community or reach your target audience?
8. Establish accounting and payroll processes.
9. Create internal documents (this can include safety, education, and hiring process within your business).
10. Connect with local small business resources in your community.

Adapted from [U.S. Small Business Administration \(2018\)](#).

## Opportunities

As the health care needs of the population demand newer, better, and less expensive solutions, nurse entrepreneurs are well positioned to address those needs. Although there are many examples in your own communities of nurse entrepreneurship, the role of the community/public health nurse can serve as a strong base for meeting the health care challenges locally, nationally, and internationally. Some examples of nurse entrepreneurship include (NNBA, 2018):

- Nursing registry and staffing services agency
- Home care agency
- Specialty agencies (vascular, diabetes, dialysis)
- Nurse consultant for local and federal government, and organizations
- Legal, wellness, and coaching consultation
- Elder care managers
- Forensic nursing
- Nurse educators (seminar companies, national speakers, online courses, assisting with accreditation, writing, diabetes educator, podcasts, yoga, wellness, and training programs)
- Retail businesses (patient care products, wellness products, health foods, medical equipment and devices)
- Independent nurse contractor (private care and therapy)
- Nurse practitioner–owned clinic or wellness agency
- Esthetic care
- Adult day care
- Foot care services

One example of a nurse entrepreneur is Barbara Philips, a family nurse practitioner who opened a hypnotherapy practice in Missouri. After years of working in a pain management group in Washington that included use of hypnotherapy, Philips expanded her interest in this area, completing training and certification, and opened her own business in 2016. Her practice assists patients with such health issues as smoking, anxiety, and fibromyalgia. As practice authority can be different in every state, it is prudent to understand the laws affecting your nurse practitioner license and make every effort to practice to your full potential. In addition to Philips's hypnotherapy practice, she also consults on business start-up basics with other nurse entrepreneurs. She says many nurses want to have their own business but don't always consider the whole process. Her suggestions include:

- Know your potential customer.
- Do research and have a business plan.
- Investigate requirements such as regulations and credentialing.

- Have a financial plan.

Philips says that nurses do need to understand the money aspect and that having an expense and income report is a must (personal communication, Barbara Philips, APRN, GNP, FNP-BC, FAANP, NP, business owner).

The opportunities are limitless for nurse entrepreneurship; the only missing piece is the nurse willing to take that leap, come up with an idea, explore the options, create a business plan, garner funding, and make a difference. Community/public health nurses are uniquely qualified to address the ever-growing challenges in our communities. As opportunities in one area of nursing practice recede, other avenues open up. What is needed are nurses who enjoy a challenge and are willing to take risks to provide needed services and improve patient outcomes.

# SUMMARY

- Private sector practice opportunities for public health nurses include NLHCs, faith community nursing, occupational and environmental health, and entrepreneurial roles. Each of these areas of practice offers community health nurses an avenue to address health disparities in their communities, increase years of healthy life, and provide holistic, client-centered care.
- NLHCs represent a growing movement of health centers that have emerged as vital safety-net providers in America's contemporary health care delivery system and typically provide care to vulnerable or underserved populations.
- The Health Care Provisions in Bipartisan Budget Act of 2018 and the ACA of 2010 provide funding streams for NLHCs as an avenue to reach vulnerable populations and reduce the burden on traditional health models.
- Faith community nursing is a specialized area of practice that focuses on the care of the spirit as well as the whole-person health.
- The ANA and the HMA have published *Faith Community Nursing: Scope and Standards of Practice*, 3rd edition, which should be used to guide nursing practice in this area.
- FCNs act as health educators, health counselors, advocates, and referral agents. They also establish support groups, coordinate volunteers, and integrate concepts of faith and health.
- The [Occupational Safety and Health Act of \(1970\)](#) led to the proliferation of occupational health nursing employment in the United States and established OSHA, which developed standards for occupational health and monitors the health status of workers and community groups.
- OHNs play a vital role advocating health promotion and wellness programs for the workforce they serve, and OHN duties fall into three categories: compliance, care, and health promotion. OHNs are often involved in case management, transitional care, and telemedicine.
- Occupational and environmental health nurses work with employers to cultivate creative and business-appropriate health and safety programs, using an interdisciplinary approach to advocate for the employee's right to have cost-effective, prevention-oriented health and safety programs. OHNs can become certified in this specialty field through ABOHN.
- The TWH initiative is defined as a strategy that integrates occupational safety and protection of health along with health promotion to prevent

worker injury and illness and to improve worker well-being and health through a holistic approach.

- Case management is an approach used in many areas of nursing. It involves assessment, planning, facilitating, care coordination, evaluation, and advocacy for resources to meet client needs. Current research demonstrates cost-effectiveness and better patient outcomes.
- Transitional care is concerned with management of care across the health care system (e.g., hospital to home). Research has shown beneficial effects for patients and cost benefits to hospitals and health care agencies.
- Telemedicine is expanding and being used in a wide variety of settings. It can cut costs and shorten wait time for patients needing to see specialists. Several methods of digital health interventions were discussed (also see [Chapter 10](#)).
- There is a growing trend in nursing to seek a more independent practice in health care delivery through entrepreneurship. Common examples of nurse entrepreneurs include legal consultants, forensic nurses, home health care agency owners, authors, and nurse consultants in a variety of areas.
- The NNBA provides valuable resources and guidance on how to establish an independent practice (or health-related business).

# ACTIVE LEARNING EXERCISES

1. Using “Enable Equitable Access” (1 of the 10 essential public health services; see [Box 2-2](#) ) locate a NLHC or a federally qualified health center in your community. Interview a public health nurse or a nurse practitioner employed there. Ask the nurse to describe his or her role and duties. What types of patients are most often seen? What are typical problems or illnesses? If this clinic did not exist, where would those patients get care?
2. Contact a faith community nurse (FCN) in your area and arrange to interview or shadow the nurse. Explore the services offered by FCNs in your area. Identify the knowledge and skills needed to function effectively in the role. Discuss the process the nurse used to establish an FCN practice.
3. Search for current evidencebased practice research articles on case management, transitional care, and telemedicine in nursing practice. Where is most of this research being done (e.g., acute care, public health, ambulatory care, chronic illness care, palliative care)? How can these strategies be effectively employed in public health nursing, faith community nursing, and occupational health nursing and at nurseled clinics?
4. Research occupational hazards for nurses. You may find that hazards vary depending on specialty areas or geographic locations. Think of the kind of nursing that you see yourself doing after graduation. Identify the occupational risks associated and develop a list of strategies for mitigating those risks. Compare your findings with those of other class members.
5. Think about your clinical experiences in community/public health nursing. Are there unmet needs in the community that could be addressed through a nurseled business? What elements would you include in a business plan? Locate a nurse entrepreneur and discuss the challenges the nurse met in starting the business; how were those addressed?

# CHAPTER 30

## *Home Health and Hospice Care*

*“People from all walks of life agree that someone who is sick deserves, in principle, compassion and care.”*

—Paul Farmer, American anthropologist and physician

### **KEY TERMS**

Care coordination Centers for Medicare and Medicaid Services (CMS) Compassion fatigue Home health care Homebound Hospice Medicaid Medicare home health benefit Medicare hospice benefit Medicare prospective payment system Outcome and Assessment Information Set (OASIS) Palliative interventions Postacute care Value-based care Visiting Nurse Associations

### **LEARNING OBJECTIVES**

Upon mastery of this chapter, you should be able to:

1. Summarize the history and contemporary circumstances of home health and hospice care.
2. Describe reimbursement and payment models for home health care and hospice programs.
3. Explain family caregiver burdens of providing home and hospice care.
4. Describe essential characteristics of home health and hospice nursing practice.
5. Identify unique challenges of home and hospice nurses.
6. Contrast the goals of home health care and hospice.
7. Explain the gaps and future needs of home health care and hospice in the United States.

# INTRODUCTION

A home health nurse sits in an upscale condominium with a frail, older man tethered to his home oxygen unit and experiencing air hunger as he struggles to speak of the “good old days” when he was young, full of vigor, and taking on the world. During her next visit to a trailer park, she inspects an infected pressure sore that has become smaller and cleaner with each home visit, as the client's wife carefully follows through with wound care teaching. Next, she monitors the pulmonary and cardiac status of a patient newly discharged to his aging bungalow, detecting early signs of cardiac decompensation and treating him at home in close collaboration with his physician. At that same time, her hospice nurse colleague on arriving at the home of a woman near the end of life finds the patient in pain and vomiting and the family in chaos; by the time this colleague leaves, however, the family is calm and the patient comfortable.

These are the kinds of experiences that make up the daily lives of nurses who work with home care and hospice clients. Indeed, home health and hospice programs allow nurses to practice what some see as the very heart of compassionate and highly skilled nursing care. Home health care and hospice programs are expanding and are the work settings for more and more nurses. Almost 2% of registered nurses work in home health care settings ([United States Department of Labor, 2018](#)). This chapter considers the history and current status of home health care and hospice care, how these services are reimbursed, the unique burdens of caregivers in these settings, key aspects of nursing practice in these areas, and expected future trends. (Children and adults with disabilities also receive home health services. Specific care regarding these populations can be found in [Chapters 20](#) and [24](#), respectively.)

# HOME HEALTH CARE

The need for health care at home continues to accelerate as Americans live longer lives. An aging US population means an increasing number of people living with multiple chronic conditions, cognitive impairments such as dementia, and functional limitations that affect daily living. In addition, medical costs continue to escalate despite national insurance programs such as Medicare and Medicaid and expansion of private health insurance options as a result of the Patient Protection and Affordable Care Act (ACA).

- Early hospital discharges resulting from third-party payers' efforts toward cost containment have forced clients to return home quickly to recuperate from surgeries and severe illnesses. Likewise, a growing population survives and yet suffers from complex chronic and life-threatening illness that they struggle to manage at home.
- Advanced technologies such as telehealth monitoring, point-of-care devices, intravenous (IV) antibiotics, chemotherapy, total parenteral nutrition, dialysis, and mechanical ventilation are now routinely provided and maintained in the client's home.

As the population ages, and particularly now that the baby boomers are entering their elder years, home health nursing is challenged to respond. Professional home health care agencies seek to maximize the client's level of independence and to uphold the right to access high-quality health care and supportive services ([National Association for Home Care and Hospice \[NAHC\], 2018](#)). Those most in need of home care services are older adults and those with chronic illnesses. As the number of multiple chronic conditions rises, specifically for older beneficiaries, the need for health care in the home is critical.

Historically, home health care was delivered in the home as a house call ([Landers et al., 2016](#)). Today, C/PHNs provide home health care much like their early predecessors, where the focus of care is on maximum independence ([Landers et al., 2016](#)). The nurse's role in the home can be extensive. The nurse may be the coordinator of care, managing and providing a plan of care for the patient. The nurse monitors the progress of the patient, makes referrals as necessary, assesses for home safety, provides care such as dressing changes or blood pressure, coordinates communication with the health care team and family members, reviews the medication regime, and educates and advocates for the patient and family. Today's health care system requires nurses to employ a greater understanding of health care cost and

reimbursement, a population focus for improving health, and inclusion of quality and satisfaction in the care provided ([Landers et al., 2016](#)).

## History and Politics of Home Health

As the practice of home health care has evolved, so have the approaches to pay for it and contain its costs.

### *History of Home Health*

Home health, or home-based, care is as old as the nursing profession itself. For centuries, care of the sick and infirm in the home setting was the standard of practice. In the United States, the earliest known organized effort to care for the sick poor at home was made by the Ladies Benevolent Society in Charleston, South Carolina, in 1813 (Fitzgerald, 2016). Later in the 19th century, women were able to receive training to become nurses in the manner of Florence Nightingale, and wealthy women began to hire them as visiting nurses and to sponsor visiting nurse services. **Visiting Nurse Associations** were established in many American cities (Fulmer, 2017). In 1893, Lillian Wald began home visiting in New York City and is famed for professionalizing visiting nursing.

### *Evolution of the Laws and Models Governing Home Health Coverage*

The payment system for **home health care** has changed dramatically over the last 100 years, from the initiation of its coverage by health insurance to today's value-based models of care:

- 20th century insurance companies saw the benefit of home care as a less expensive alternative to hospitals. Private home health agencies evolved as a result of the demand to provide care for chronically ill clients in their homes.
- During the latter half of the 20th century, Medicare and health insurance companies began to cover home health care, allowing patients to rehabilitate in their homes.
- **Medicare home health benefit** was established to provide intermittent home visits in which nurses and therapists would provide services and instruct clients and families in self-care.

Initially, Medicare and other payers required the period of home health care to be brief and the provision of direct skilled care to be temporary. Home health care services were seen as extensions of medical care, with physicians certifying needed services for short-term treatment of sickness.

The number of Medicare-certified home care agencies grew rapidly until enactment of the [Balanced Budget Act of 1997](#) (Public Law 105-33), which

explicitly sought to reduce federal payments for home health care. Payment to providers was changed from reimbursement for each visit to the **Medicare prospective payment system**, which determined Medicare payment rates based on patient characteristics and need for services. Most private insurance agencies followed suit and adopted the standards of the Medicare prospective payment system.

- Standardized reimbursement rates forced Medicare-certified home health agency closures. Patients, requiring intensive skilled and personal services, needed to become independent in providing their health care needs at home. The focus of the home health nurse changed from provision of care to education and training, including evaluation of patient progress.
- The enactment of the ACA impacted the provision of home health care through programs and outcome-based quality care:
  - Supplemental payments for rural home care providers were reinstated for 2010–2015 to address the lower ratio of home care professionals in rural areas throughout the United States as compared with more urban areas.
  - The *Community First Choice Option* allowed states to offer home and community-based services to people with disabilities through Medicaid rather than institutional care in nursing homes.
  - The *Community Care Transitions Program* helped high-risk Medicare beneficiaries who were hospitalized avoid unnecessary readmissions by coordinating care and connecting patients to services in their communities.
- A 2012 ruling by the U.S. Supreme Court ([National Federation of Independent Business et al. vs. Sebelius, Secretary of Health and Human Services, et al., 2012](#)) allowed for states to opt out of the provision in the act to expand Medicaid services. **Medicaid** services are provided primarily to low-income populations. With a growing percentage of payments for home health coming from Medicaid, this is of concern to care providers and consumers of care. Home health care expenditures from Medicaid are expected to exceed Medicare payments in the coming years. The shift in payment source and the limitation that many states may impose on Medicaid coverage is unknown at this time. The **Centers for Medicare and Medicaid Services (CMS)** oversee expenditures and policy implementation.
- The *Improving Medicare PostAcute Care Transformation Act of 2014* required postacute care facilities to submit standardized data and changed the requirements for home care agency reimbursement. As a result, Medicare-certified agencies must provide outcome-based quality improvement measures for home care services. The Home Health Quality Reporting Program (HH QRP) uses outcome and process

measures and considers patient care, avoidable events, utilization, cost, and resources to mitigate costs and improve care (CMS, 2018a).

- It is mandatory for Medicare-certified home health agencies to participate in HH QRP, and their reporting must include data required by both **Outcome and Assessment Information Set (OASIS)** and Home Health Care Consumer Assessment of Healthcare Providers and Systems (CMS, 2018b).
- The Veterans Administration now pays for home and community-based services for extended care away from nursing homes (Miller et al., 2017).
- The CMS has also implemented the Home Health Value-Based Purchasing Model (Maddox, et al., 2018).

By 2050, the number of people needing home health care services will increase from 15 to 27 million (United States Department of Health and Human Services [USDHHS], 2018). Currently, 40% of Medicare reimbursement dollars are spent on home care services (MedPac, 2017). Today, over 12,000 home care agencies provide skilled, nonskilled, and therapeutic care services; 98% of these agencies are Medicare certified and 78% Medicaid certified. Home health referrals will continue to increase as an alternative to costly hospital stays as cost containment becomes a driving factor for care (Jones et al., 2017).

- Home health care agencies are increasingly relied on to provide postdischarge care as patients prefer to recover in their homes, shortened hospitalization stays become the mainstay, and insurers benefit from cheaper home care costs (David & Kim, 2018).
- Prior to the ACA, home health agencies had little incentive to reduce hospital readmission. With the current focus on cost containment and better patient outcomes, home care agencies are now held accountable for measurement outcomes as they vie for reimbursement dollars.

### *Value-Based Care and Cost Containment*

HH QRP ensures a **value-based care** reimbursement process for home health care, which has the potential to provide better care and improved patient outcomes at a reduced cost. With reduced readmission, a driving force in cost reduction, **postacute care** following hospitalization will need further scrutiny.

A systematic review by Ma, Shang, Miner, Lennox, and Squires (2018) determined that limited research has been done on patients in home health care who are at high risk for hospital readmission. Patients who were readmitted did not always have an identifiable reason documented, although heart failure and respiratory conditions were noted complications. Further

studies that identify the reasons for hospital readmission as well as risk factors associated with readmission are needed to mitigate the challenges associated with postacute home care.

Improving patient outcomes through better care transition processes will assist coordination efforts between agencies and providers. In addition, other models associated with cost reduction are being trialed. Home visit program models with practice-extended teams provide care coordination that is organized around patient and consumer engagement. These nurse-led teams show promise in reducing emergency department visits, Medicare expenditures, and hospitalizations through home visits and illness management for older patients and those with stroke, dementia, and late-stage illness (Ruiz et al., 2018).

## *Care Coordination*

The transition from acute care settings to home health requires coordination of services for seamless care. **Care coordination** is defined as “the organization of patient care activities between two or more participants (including the patient) involved in a patient's care to facilitate the appropriate delivery of health care services” (Agency for Healthcare Research and Quality, 2018, para. 1). Care coordination requires effective communication between agencies and health care providers to support the complex needs of patients.

Care coordination is centered on the patient and family, with attention to navigation through the health care system; care is proactive and planned. As health care shifts from acute to population-based care, the focus is not on episodic events but on postacute care, in which a plan of care and quality transition from the hospital to the community is imperative (Allen, Hutchinson, Brown, & Livingston, 2017). Care coordination models that educate and support families and patients, use registry-based information systems, and promote a team-based care delivery system have been shown to have good patient outcomes (Georgiadis & Corrigan, 2017; Noel, Kaluzynski, & Templeton, 2017; Smith & Treschuk, 2018). Currently, home health care is used to provide postacute care and, in many aspects, is considered a continuation of the acute care setting. However, today's community health nurses may find themselves providing increasingly complex care that requires advanced skills in case management, advocacy, and plan of care to support the comprehensive health care needs of patients and their families.

## Home Health Agencies

Home health agencies are organizations that provide various home health care services and equipment to patients in their homes, including skilled health care, custodial (unskilled) care, high-technology pharmacy services, and durable medical equipment (DME). These agencies may be nonprofit or for-profit, public or private, community- or hospital-based, and certified or noncertified.

- *Skilled home health care* is care provided by specialists with licenses, certifications, or specific qualifications, such as nurses, social workers, physical therapists, occupational therapists, and home health aides. Home care agencies who offer skilled care typically have internal and external standards that guide the practice of these skilled practitioners. One such external standard is the code of ethics developed by the [NAHC \(2020\)](#), which serves as a guideline for agencies in ensuring that patients and families are treated with a high standard of care and in an ethical manner. Professional home care agencies may receive referrals from hospitals or other facilities for postacute follow-up. These patients are considered **homebound** and have a plan of care signed by a physician.
- In contrast, *custodial care* involves unskilled or nonprofessional services, such as cleaning and assistance with daily living, and DME includes wheelchairs, commodes, beds, or oxygen. Agencies that provide such services are not held to the same standards as those that offer skilled care.
- *Nonprofit agencies* traditionally have a charitable mission and are exempt from paying taxes. They are financed with nontax funds such as donations, endowments, United Way contributions, and third-party provider payments.
- *For-profit agencies* are expected to turn a profit on the services they provide, either for the individual owners or for their stockholders.
- *Public agencies*, such as city and county agencies, are government agencies created and empowered through statutes enacted by legislation. These agencies include the nursing divisions of state or local health departments, which may or may not combine care of the sick with traditional public health nursing services, including health promotion, illness prevention, communicable disease investigation, environmental health services, and maternal–child care.
- *Private agencies* are those owned and operated not by government but rather by private individuals or large regional or national chains that are administered through corporate headquarters.

- *Community-based agencies* provide services outside of hospitals within a well-defined geographic location.
- *Hospital-based agencies* operate as separate departments within hospitals and may be nonprofit or for-profit. The referrals to such agencies usually come from the hospital staff. Similar agencies may be found as home health departments in rehabilitation and skilled nursing facilities.
- *Certified agencies* are those that have been certified by Medicare and/or Medicaid to provide and be reimbursed for skilled home health care services.
- *Noncertified agencies* remain outside the federal Medicare and/or Medicaid system that reimburses skilled nursing. Such agencies are usually private and derive their funding from direct payment by the client or from private insurers. They may be governed by individual owners or by corporations. For instance, some agencies offer private duty shifts, unskilled assistance in the home with homemaking or housekeeping, and live-in personal care.

## Clients and Their Families

The client in home health care is not only the individual patient but also the family and any significant others. The nurse must consider how the environmental, political, emotional, social, economic, cultural, and religious dimensions impact the client's illness and ability to meet the goals outlined in the plan of care. Not all patients in need of home care are able to pay for these services.

Home care recipients are predominantly older patients with acute and chronic health needs. The medical diagnoses coincide with the morbidity rates of the region. Many have chronic conditions that complicate any acute conditions they experience.

- In the United States, home care agencies serve over 5 million patients, with 82% of the patients over the age of 65 years. A majority of patients are women (70%) and non-Hispanic White; half of all clients cared for in home health have a diagnosis of diabetes ([USDHHS, 2018](#)).
- Individuals recovering from severe illness or living with debilitating chronic illness rely on family members or other sources of unpaid assistance. Forty-three million people provide informal caregiving for an adult family member or friend ([Family Caregiver Alliance, 2018](#)). Seventy percent of all caregivers are women, with an average age of 49.2 years. Family caregiving tasks range from personal care such as bathing and feeding to sophisticated skilled care, including managing tracheostomies or IV lines.

Nurses must assess the home environment and be responsive to family who may exhibit signs of **compassion fatigue**. These informal caregivers assume a considerable physical, psychological, and economic burden in the care of their loved one at home. As a result, caregivers often describe themselves as emotionally and physically drained and may need information about resources to assist them. Frail older caregivers are especially vulnerable to deterioration of their own health because of their caregiving burden. Likewise, the economic cost of providing home care places a significant burden on informal caregivers. Out-of-pocket expenditures include medications, transportation, home medical equipment, supplies, and respite services. These costs may be nonreimbursable and are often invisible, but they are very real to families struggling to provide care on a fixed income. Home health nurses must continually assess the strain on caregivers as they seek to develop a realistic plan of care.

## Home Health Care Personnel

Direct care workers (home care aides and personal care attendants) provide a majority of the functional assistance for the home care team and are expected to increase in number by 70% in the next 10 years (Fig. 30-1; Institute of Medicine [IOM], 2015). Wages in this sector of home care are low and have been stagnant for years. Turnover rates are between 60% and 75% and can affect continuity and the quality of care (IOM, 2015).

**FIGURE 30-1** Skilled care provided in the home setting.

Home care nurses, physical therapy staff, occupational therapists, social workers, and administrative personnel comprise the rest of the home health team. The business and office personnel of a home health agency are critical to the agency's ability to deliver services to clients.

# Reimbursement for Home Health Care: Medicare Criteria and Reimbursement

Corporate and governmental third-party payers, as well as individual clients and their families, pay for home health care services. Corporate payers include insurance companies, health maintenance organizations, preferred provider organizations, and case management programs. Government payers include Medicare, Medicaid, the military health system (TRICARE), and the Veterans Administration system. These governmental programs have specific conditions for coverage of services, which are often less flexible than those of corporate payers. For a general description of these reimbursement systems, see Chapter 6. The Medicare policies for home health programs set the precedent for all other reimbursement sources and are discussed below (Fig. 30-2).

## What services are available for America's home health care patients?

**FIGURE 30-2** Home health care services and benefits by payer. (Reprinted with permission from Alliance for Home Health Quality and Innovation. (2018). Home health care services and benefits by payer. Retrieved from <http://www.ahhqi.org/images/pdf/what-is-hhc-services-available.pdf>Figure)

Medicare is the largest single payer for home care services in the United States and has set the standard in establishing reimbursement criteria for other payers. Therefore, it is essential that home care nurses seek to understand the complex Medicare home health requirements and rules for determining eligibility for home care services. It is important to acknowledge that a person may be in dire need of care at home, yet not meet eligibility standards for home health care under Medicare. There are five criteria that must all be met to be eligible for reimbursement by Medicare (CMS, 2019; Boxes 30-1 and 30-2).

## **BOX 30-1 Medicare Home Health Eligibility Criteria**

1. The patient must be confined to the home or **homebound**.
2. The patient must need skilled services (from a nurse or therapist).
3. The patient must be under the care of a physician.
4. The patient must receive services under a home health plan of care (POC) that is established and periodically reviewed by a physician.
5. The patient must have had a face-to-face encounter that is related to the primary reason the patient requires home health services with a physician or an allowed NPP (this must be done 90 days prior to the home health start-of-care date or within 30 days of the start of the home health care).

## **BOX 30-2 PERSPECTIVES**

**A Nursing Instructor's Viewpoint on Medicare Guidelines It is vital to develop an expanded vision about the health care needs of frail elders and the kinds of services that are needed in the community. Sometimes, after nurses have been working in Medicare home health for a while, they may begin to identify more with the Medicare guidelines than with their patients. Too often, I**

**have heard experienced home health nurses say about a patient living with severe chronic illness, “She doesn't deserve services. She doesn't have skilled needs.”**

In contrast, I would hope knowledgeable nurses would say to families and decision makers, “She needs and deserves services, but the Medicare home health benefit will not pay for them. Our agency cannot continue to provide care because of the limits imposed on us. We'll do everything possible to find help for her, but resources are limited.” This kind of insight leads to patient advocacy, development of community networks, and becoming outspoken about needed changes in health policy. Visiting nurses witness the struggles of chronically ill people living at home; we must not abandon them.

Beth L., nursing instructor

The following steps are implemented while the patient is under Medicare-reimbursed home health care:

1. The Medicare prospective payment system pays an agency for a 60-day “episode of care.” All services and many medical supplies must be provided under the payment amount adjusted to geographic location and determined by the patient's clinical and functional status at the start of care, as well as the projected need for services over the anticipated 60-day period (CMS, 2018c).
2. When the patient is admitted, the patient is comprehensively assessed using an assessment tool called OASIS. OASIS is used to measure home health quality measures and is the basis for measuring patient outcomes and adherence to best practice for quality improvement.
3. The nurse also completes the Medicare plan of care at admission, and the physician must sign this. It is then used to assess agency compliance with Medicare and state requirements. All follow-up services must match the plan of care.
4. It is a Medicare requirement that patients receiving home health care must be recertified every 60 days. A determination of continued visits is then made based on the objective data obtained (CMS, 2018c). [Box 30-3](#) provides consumer information on quality home care agencies by zip code or city.

**BOX 30-3 Compare Home Health Care Providers** The [Medicare.gov](https://www.medicare.gov) Web site offers information for consumers about the quality of home health care agencies. It includes data on how frequently best practices are used in patient care and if patients improved in relation to certain aspects of care. It also includes patient feedback about recent home health agency experiences.

You and/or your clients can go to <https://www.medicare.gov/homehealthcompare/search.html> and enter your zip code (or city, state), and you can see a list of all agencies and the services provided by each (that meet certain criteria). You may select agencies for comparison, and general information is provided, along with the quality patient care information and results of patient surveys. For quality patient care, star ratings are used to denote summaries of 9 out of 29 quality measures, with 4 or 5 stars indicating better performance than other agencies. Star rankings of one or two indicate below-average performance. Most agencies nationwide fall within 3 or 3.5 stars. Survey results include percentages related to how often care was given in a professional manner, how well the team communicated with clients, if they discussed pain, medications, and home safety with clients, how the client rates their overall care from this agency, and would they recommend the agency to family/friends. Overall percentages can be graphed for comparison with state and national averages.

## Home Health Nursing Practice

The practice of home health nursing has roots in community/public health nursing (see [Chapters 2 and 3](#)). The nurse provides home health nursing care to acute, chronic, and terminally ill clients of all ages in their homes while integrating public health nursing principles that focus on the environmental, psychosocial, economic, cultural, and personal health factors affecting the client's health status and well-being. Home health is a unique field of nursing practice that requires a synthesis of public health nursing principles with the theory and practice of medical/surgical, geriatric, mental health, and other nursing specialties. According to the [American Nurses Association \(ANA\) \*Scope and Standards of Practice for Home Health Nursing\* \(2014\)](#), home health nursing goes beyond providing skilled nursing care in the home; it requires the ability of the nurse to coordinate a broad variety of services and professional caregivers to manage patients' complex health problems (the standards of practice are available on [thePoint](#) ).

### *Nursing Practice During the Home Visit*

A home visit by a home health nurse involves several steps: locating, promoting self-management, detecting, collaborating, mobilizing, strengthening, teaching, and solving problems.

### *Locating the Client and Getting through the Door*

The first step in making a home visit is finding where the person lives. Directions and household identification can be unclear. In rural areas, tracking down clients can involve vague instructions involving barns, bridges, trees, and other colorful local landmarks. When families are unstable, clients may not be staying in households designated on the nurse's paperwork. They may have moved in with relatives or friends or be back home alone despite major care needs ([Box 30-4](#)).

## **BOX 30-4 STORIES FROM THE FIELD**

**Beyond the Front Door I received a home visit referral from the VA clinic after the client missed two appointments. The client was a 77-year-old male veteran with a diagnosis of diabetes and right heel ulcer who needed IV**

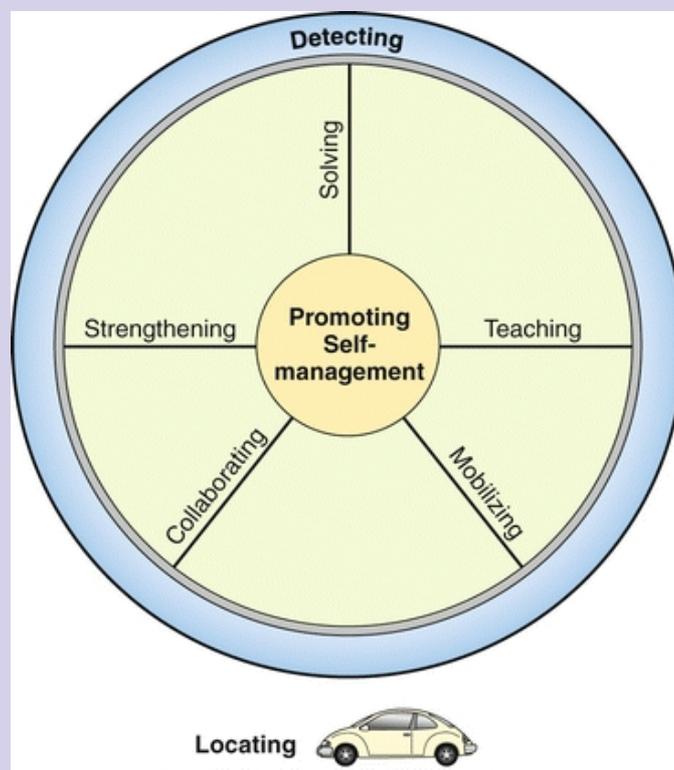

**antibiotics, and wound care twice a day. I had the address; I circled around the block a couple of times; the house was in a residential neighborhood in the middle of town, a block from an elementary school. The client did not have a phone. I parked close to the address and walked; only then did I see through the 5-foot weeds in front of the house. I approached the door, knocked, and called for Mr. P a couple of times. He finally answered. An unkempt, unbathed elderly man crawling on his knees (due to his inability to put weight on his right foot), with a toothless smile, let me in and sat in an old chair by the door. Introductions were made. The home was very dark and dusty; piles of books, magazines, and newspapers were stacked 3 and 4 feet high in between furniture leaving a small maze in which to walk through the house. The VA had sent 2 months of supplies, which were in dozens of boxes by the front door. The house was dark, but the kitchen windows provided some light. I noticed there were no appliances in the kitchen, only piles of books, a Styrofoam ice chest on the floor (inside was warm milk and green lunch meat), and open cans of food in the sink.**

Assessment reveals blood glucose of 355, 4-inch diameter stage 3 wound on the right heel, and pain level of 8 out of 10 (had not taken prescribed pain meds). Mr. P is very cooperative and talkative. He has lived alone in the house for over 40 years and never married. Family lives an hour away; he has not seen them in 10 or more years. No friends locally, many have passed on. Mr. P has no car; the closest VA

clinic is 90 miles away. He purchases food from the corner grocer but says he has been unable recently to walk to the store.

1. *What are your nursing priorities?*
2. *Reflect on Mr. P's lifestyle. What do you think would have happened to Mr. P. if the nurses did not find him?*
3. *Apply the nursing process to comprehensively identify and prioritize nursing diagnoses and propose interventions. Use [Figure 30-3](#) to guide your care planning.*

Anne Stokman, MSN, RN, CDE

**FIGURE 30-3** Home health nursing caregiving wheel.

Even when the wheels stop at the correct household, there is the challenge of getting through the closed door and making the connection. *Always remember that you are a guest in the home.* Respect and attentive listening are the foundation for establishment of trust between the client and nurse. Agendas must be laid aside initially as the nurse focuses on the concerns and realities of both the client and family. Assumptions and stereotypes are overturned in the process of discovering how clients live, what they believe, and who comprises their family and community. The nurse must take into account the spiritual, cultural, and developmental, as

well as environmental, realms of the client in order to be able to develop individualized plans of care to promote health.

The home health nurse is aware that the client is the driver of the plan of care. To have effective outcomes, the nurse must develop a therapeutic relationship in which the client identifies the desired outcomes. Autonomy should be respected, and the family should be empowered by actions recognizing that they are in charge of their lives. The nurse, the patient, and family must work together to establish mutually agreed-upon goals (see [Chapter 10](#)).

### *Hub of the Family Caregiving Wheel: Promoting Self-Management*

The practice competencies of home health nurses can be illustrated with the home health nursing caregiving wheel ([Fig. 30-3](#)). The hub, or most essential competency, of this wheel is promoting independent self-care and self-management. The challenge to the home health nurse is often assisting the severely chronically ill client be able to adapt in the community to be safe and functional. Coordination with other professionals must often be instituted to provide comprehensive quality care. This may include social workers, clergy, physical therapists, occupational therapists, as well as mental health professionals.

### *Rim of the Home Health Caregiving Wheel: Detecting*

Nurses in the home are challenged by an extraordinarily complex environment with much to investigate and continuing assessment process as the nurse seeks to understand the client's health in the context of home. The nurse keeps her ears and eyes “wide open.” Who lives in the home? How do they interact? Who are the caregivers, and how do they care? What is the relevance of culture and religion in the life of the household? How does the physical environment impact patient safety and security? Home visits reveal discoveries that can never be imagined in clinic or hospital settings. Take for example the client whose refrigerator no longer chills and whose impaired vision prevents awareness of the expanding family of roaches in the kitchen.

### *Spokes of the Home Health Caregiving Wheel: Collaborating, Mobilizing, Strengthening, Teaching, Solving Problems.*

Home health nursing competencies that radiate from the hub and contribute to promotion of self-care and family care include *collaborating* with multiple team members and *mobilizing resources* in the community that can sustain the client after discharge. The home health care nurse usually is the

coordinator of all other home health team members. Working with the social worker, the nurse proposes needed connections with community services. Likewise, *strengthening* involves development of self-management or family caregiving ability. The home health nurse is constantly *teaching* clients and/or family caregivers through concrete explanation, discussion, and modeling behavior. Concerns and relevant feelings must be validated, and the nurse leads the person to consider options for change. The solution develops through a mutual, participatory process. Ultimately, people are responsible for their own health decisions (see [Chapter 11](#)).

Finally, home health nursing competency requires flexibility and creativity in *solving* health care problems and the challenges of everyday living. All outcomes of care can be achieved only by adapting to the skills and resources available in the home. Although people of all socioeconomic backgrounds present with severe health problems requiring home health nursing, many families live on the margins. The home health nurse must often be creative in obtaining supplies and adjusting to conditions in the home. For example, how do patients and families with no running water wash their hands before providing care, such as dressing changes? This may lead the home health nurse to contact social agencies in order to provide services or teach the patient and family the use of alcohol-based gels to clean their hands. The home health nurse must be nonjudgmental but work with the patient and family to help them understand the need to keep areas clean.

### *Home Health Nursing Case Management*

The home health nurse is the case manager for each client and responsible for coordination of the other professionals and paraprofessionals involved in the client's care.

The home care nurse is frequently the primary contact with the client's physician, collaborating on the initial plan of care, reporting changes in the client's condition, and securing changes in the plan of care. The nurse may conduct case conferences among team members to share information, discuss problems, and plan actions to affect the best possible outcomes for the client. The nurse case manager also supervises the paraprofessionals, such as home health aides, who also serve the homebound client.

### *Selected Nursing Challenges in the Home*

Working in the home immerses the nurse in challenges unlike anything encountered in controlled institutional environments. Some of these include infection control, medication safety, fall risk, technology at home, and nurse safety (see [Chapter 22](#), Older Adults).

## *Infection Control*

Home health nurses frequently need to work with the family to prevent infection in clients who are debilitated and may be immunocompromised; in addition, many are now dwelling at home with invasive medical devices that make them especially vulnerable to infection. Likewise, nurses are challenged to consider how to protect the home health care team, family, and community from a client with contagious disease. In such cases, all people living in the home will need instruction. Some households have inadequate facilities to control disease transmission. There may be no access to running water, no heating unit to boil equipment, or inadequate facilities to dispose of contaminated equipment. These conditions necessitate the development of creative solutions to control infection.

To guide the nurse, home health agencies have adapted infection control policies and procedures based on the Centers for Disease Control and Prevention's (CDCs) Infection Control Precautions for health care settings with each agency setting up their own specific policy and procedure based upon the standard ([CDC, 2018a](#)).

## *Medication Safety*

The home health client taking multiple medications is at particular risk of multiple errors in self-administration, including incorrect medication, dose, time, interval, or route. Often, doses are missed or doubled. Clients may discontinue a drug or not complete the full course. Sometimes, the drug or drugs ordered are inappropriate considering the patient's condition at home.

The home presents risk of medication errors that are different from those found in hospital or nursing home. Every visiting nurse has stories of finding drawers and cupboards filled with multiple prescriptions from various physicians, some current and some outdated for many years. Polypharmacy becomes obvious in the home setting. Clients often have received prescriptions from multiple sources for similar drugs. Also, well-meaning friends often share their prescriptions with the attitude that it “helped them.” Even if the client is well organized and taking every drug prescribed, those prescriptions may have originated from several providers over time and may have contradictory side effects. Sometimes, medication errors at home include failure to clearly reconcile hospital or nursing home orders with home discharge orders. Although weekly medication organizers can helpfully put medications in order, they can also confuse new or impaired users. Distraction, visual impairment, forgetfulness, depression, and cognitive impairment are common causes of unintentional medication noncompliance. The home health nurse investigates how the medication is taken by reviewing and reconciling the current list of medications and having the patient explain and demonstrate the process he or she goes through.

Intervention requires clear and repeated instruction, updating the medication list, charting or diagramming the schedule for medication taking, and assuring that the client or caregiver knows how to use the medication box.

### *Risk of Falling*

Falls are a serious issue especially for the elderly. Estimates are that one in four adults 65 years and older will fall each year, and falls are the number one cause of injury and death from injuries in the United States (CDC, 2018b). Physiological risk factors include orthostatic hypotension and cardiac dysrhythmias, dizziness, neurologic and musculoskeletal effects on gait and balance, urinary urgency, impaired hearing or vision, alcohol or drug abuse, and medication effects impairing alertness, balance, urinary frequency, and blood pressure. Clients should be observed as they move through their home and carry out activities of daily living (Fig. 30-4). It is important to investigate factors that obstruct movement or threaten balance. The nurse in the home should inspect sidewalks, stairs, and surfaces outside the home; floor, rugs, electrical cords, stairs, lighting, and clutter inside the home; kitchen safety; and bathroom features including grab bars and a raised seat for the toilet and safety modifications for the bathtub. Common home modifications, such as eliminating throw rugs and loose mats and the use of nonslip bathmats, have a significant protective effect.

**FIGURE 30-4** Fall risk patients need safe home environments.

### *Technology at Home*

Advances in home health care technologies have the potential to improve care that is provided in the home setting and support community-based independence for the patient (National Institute of Aging [NIA], 2017). Active (real-time vital signs and remote reporting) and passive (action

through cameras and sensors) monitoring devices are now used to capture information and to make determinations regarding safety and health.

Low-level technologies such as stove sensors or door alarms can assist in keeping patients safe while also providing trended information for patterns and behaviors. Technology in the home can range from using a telephone to smart homes. Technology use has the potential to improve collaboration, care coordination, and communication with providers (NIA, 2017). Data gathered from technology devices can be compiled and used to evaluate patient outcomes and processes for better home care (Box 30-5).

## BOX 30-5 PERSPECTIVES

**A Home Care Nurse's Viewpoint on Home Care Technology During my early years in home care, we carried pagers, which resulted in delayed patient care coordination. Today, we have improved patient care transitions and outcomes with advances in home care technology.**

I recently visited a 98-year-old man discharged from the hospital with newly diagnosed heart failure. Prior to my visit, a home telehealth device was installed in his home. It was programmed to provide heart failure education daily for 1 year. The patient attaches a blood pressure cuff and O<sub>2</sub> oximeter and steps on a scale, and the device automatically records his blood pressure, pulse, O<sub>2</sub> saturation, and weight. A remote telehealth RN daily reviews his health data. Working from a standard order set, the RN had increased the patient's diuretic dose.

During the visit, the patient provided me health data from his telehealth log, and he had questions about his diuretic therapy. I accessed his clinic and hospital records through my laptop computer using a protected hotspot with my cell phone. I operated a mobile lab device to obtain laboratory results. The patient received immediate information about his diuretic regimen. Technology played an important role in preventing another hospitalization for this high-risk patient.

In addition, real-time information is now used in home health to update and change the plan of care. Nurses may use handheld devices to chart. Medical records may be available instantly on the nurse's laptop or tablet, and daily telemedicine monitoring of electrocardiogram, blood pressure, oxygen saturation, and other vital measures can be transmitted electronically to a home health agency or physician office. These assessments can be monitored, and the patient plan of care may be altered based on the analysis. See [Chapter 10](#) for more on technology in the community.

### *Nurse Safety*

Home health nurses face risks not only in driving to their client's homes but also because of environmental hazards: the nurses must be constantly aware of personal safety and surroundings. Client homes are uncontrolled environments, and nurses may face instances of family violence and illegal drug activity, or weapons may be present. The surrounding neighborhood also may pose risks of violence, car theft, vandalism, and robbery. Many home health organizations and their nurses work closely with local law enforcement agencies to identify the wisest process for visiting dangerous neighborhoods and isolated rural areas. Every home health care agency should have a carefully developed program to assure the safety of personnel traveling to homes and training on how to predict aggressive behaviors and diffuse threatening circumstances, along with methods of self-protection if threats escalate (see [Chapter 15](#) for more information on home visits).

## The Future of Care in the Home

Home health care has high value as it is patient preferred and low cost and has improved patient outcomes as compared to other postacute care settings (IOM, 2015). However, the current framework of home health care was not designed to support our aging demographic population.

- Key challenges for home health care include fragmented care coordination, delivery of optimal care with current Medicare restrictions, value over volume, and an infrastructure to support aging in the home (IOM, 2015).
- Rising medical costs support home health care as it is a cost-effective means of delivering care. System reforms that address value-based care, quality of care, cost reduction, and coordination of care are needed. Emerging models for payment and care delivery are starting to address these issues and to realize the full potential of home health for population care.

# HOSPICE CARE

Although science and technology have advanced in the world of health care, death is ultimately inevitable for all of us. The contemporary circumstances of death in America are often dehumanizing; most people die in hospitals and long-term care institutions, surrounded by strangers. Uncertainty and denial often prevail during the final stage of life because prognoses are uncertain, and many serious illnesses are now treated aggressively until the last breath. The battle against the “evil” of death seems to be the primary emphasis, with patient, family, and professionals wanting to believe that it is possible to win the final struggle. In the 21st century, fatal conditions have been turned into expensive chronic illnesses. Too often, discomfort is not relieved, and treatment causes further suffering. And as the period of disability extends and the body deteriorates, social isolation develops. In dramatic contrast to the dehumanization of death, the **hospice** movement has developed to humanize the end-of-life experience and provide palliative care. **Palliative interventions** relieve suffering without curing underlying disease. The hospice movement has emphasized four major changes in end-of-life care:

- Care should encompass body, mind, and spirit.
- Death should be discussed and not considered off-limits.
- Medical technology should be used only when absolutely necessary.
- Clients should be actively involved in discussions about treatment decisions.

[Table 30-1](#) contrasts home health with hospice. This section explores the evolution of hospice care in the United States, describes hospice agencies, and examines Medicare criteria for hospice reimbursement. It concludes with an exploration of the unique characteristics of hospice nursing practice.

**TABLE 30-1 Contrasts Between Home Health and Hospice**

Hospice	Home Health
Emphasis is on quality of life and comfort.	Emphasis is on treatment or therapy to restore independence.
Focus is on health of the whole family.	Focus is on health of the client.
Plan of care is guided by client choice.	Plan of care is determined by medical need and client choice.
The nurse is the case manager until death.	The nurse is the case manager until home health discharge.
The client chooses how to live last days.	Priority is given to correcting physiologic imbalances.
Intermittent visits increase in frequency as death becomes imminent.	Intermittent visits decrease in frequency as the client stabilizes.
Nurses are expert in symptom control.	Symptom control is the domain of the physician with some nurses having expertise.
Sedatives and opioids are expertly adjusted to eliminate suffering.	Sedatives and opioids are used hesitantly to reduce suffering.
End-of-life disease course is managed to avoid crises.	End-of-life problems tend to be seen as medical crises.
The goal is for symptoms at end of life to be managed at home if possible. Hospice care is also provided outside of home.	Care provided in client's home. The client must be homebound. The client is brought to a hospital for unmanaged symptoms.
Spiritual care is focus of whole team.	Spiritual needs are met by own clergy.
Survivors have bereavement support.	No bereavement support is provided.

## Evolution of Hospice Care

In medieval Europe, hospices were refuges for the sick and dying. The contemporary hospice movement originated in England, where a physician, Dame Cicely Saunders, founded St. Christopher's Hospice in 1967. Dr. Saunders was credentialed as a nurse, social worker, and physician, and she developed a unique program based both on compassion and skillful relief of physical discomfort through around-the-clock analgesics administered by mouth. It had been previously assumed that only injections, administered sparingly, could be used for terminal pain control. In 1974, the first hospice in the United States was established in Branford, Connecticut. Florence Wald, who was then Dean of the Yale School of Nursing, led this movement. Because even in the 1970s, there was concern about saving money by keeping less critical patients out of the hospital and shortening hospital stays, and hospices in the United States came to focus on providing care in the home. To that end, Congress established the permanent Medicare hospice benefit in 1986, with the intention of keeping people at home, yet receiving comprehensive services that are less expensive than hospitalization (National Hospice and Palliative Care Organization, 2015).

Hospice characteristics have changed over time. Initially, nearly all clients suffered from terminal cancer; presently, people with a variety of end-stage diseases are served. The criteria for being accepted into hospice care are that the patient has been diagnosed with a life-limiting disease and death is likely within 6 months or less. Hospice care is designed not only for the patient but also for support of family members. While cancer remains the top disease qualifying a patient for hospice services, cardiac, circulatory, and respiratory disorders and dementia are also predominant. Palliative care provided in hospice services is designed to ease pain and suffering and improve quality of life and can be offered in earlier stages of illness, along with continuing medical treatments. With prognoses difficult to predict and denial of death by the patient and family a continuing issue, some hospice referrals are now made very late in the disease process. The [National Hospice and Palliative Care Organization \(NHPCO\) \(2020\)](#) cites the fact that in 2016, 48% of all Medicare decedents or 1.43 million Medicare beneficiaries had received one or more days of hospice care (p. 3). The [NHPCO \(2020\)](#) also cites the average length of hospice services as 71 days with a median of 24 days of service (p. 4).

## Hospice Services and Reimbursement

As in home health care, Medicare has determined the way services are provided. The **Medicare hospice benefit** requires that a client who has a prognosis of 6 months or less must sign up for the comfort-focused hospice benefit and waive regular Medicare health services, except for conditions unrelated to their terminal illness. This mandates that the client acknowledges a terminal prognosis and chooses comfort care instead of life-extending care from a Medicare-approved hospice. When this choice is made, the hospice coordinates care in all settings, functioning both as clinical and financial case manager. The government pays a flat rate to the hospice for each day the patient receives care. There are four payment levels:

- Routine home care with intermittent visits
- Continuous home care when the patient's condition is acute and death is near
- Inpatient hospital care for symptom relief
- Respite care in a nursing home to relieve family members ([CMS, 2015](#))

Hospices coordinate home care and direct inpatient care if needed. The emphasis is on palliative care, with a focus on physical, psychosocial, and spiritual comfort. Palliative care is caring for the patient holistically with an emphasis on improving the quality of life through caring and decreasing the severity of the symptoms of the illness. A strong emphasis is placed on caring for the entire family.

The hospice team includes nurses, physicians, home health aides, physical and occupational therapists, social workers, volunteers, palliative medication and medical equipment specialists, and bereavement counselors. Staff members meet regularly to explore together the challenges of assuring comfort at the end of life. A nurse or physician is available on-call 24 hours a day/7 days a week ([CMS, 2015](#)).

Trained volunteers fill an important need in hospice care. They act as companions to the client when the family must be somewhere else or is away for short respite. They run errands for family members, shop, organize hot meals prepared by friends and neighbors, provide childcare, and perform other services as needed.

## Hospice and Palliative Care Nursing Practice

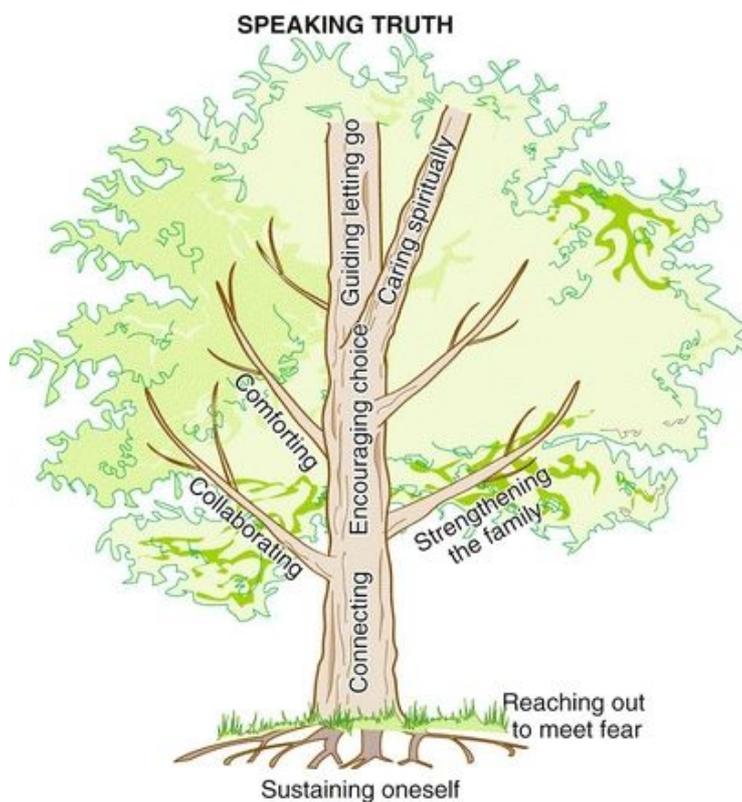

The nurse's role is central in the hospice interdisciplinary team. The hospice/palliative care nurse functions as case manager and visits the client more frequently than other members of the team. Nurses work in close collaboration with physicians in the development of a plan of care to assure management of symptoms. This plan of care changes rapidly as the end of life nears. In addition to home visits focusing on palliation and interdisciplinary planning, hospice nurses rotate through 24-hour call 7 days a week to assure continuous availability by telephone and visits for emergent problems reported by the client or family. Hospice nursing competencies and challenges are similar to those described for home health nurses, with the added expertise needed to relieve physical and emotional suffering of terminally ill clients and their families. Hospice and palliative care nurses become expert clinicians in symptom management as they anticipate and treat the physiological and psychological effects of the disease process on the patient. The [ANA and the Hospice and Palliative Nurses Association \(HPNA\) \(2014\)](#) have established standards of practice for hospice and palliative nursing. Certification of hospice and palliative nursing is available. An overview of palliative care nursing standards encompasses the same general standards as home health nursing standards, with specific competencies delineated (e.g., comfort care, suffering and symptom palliation, support of patient/family throughout illness course, reaffirmation of goals with families during regularly scheduled family meetings, care coordination with interdisciplinary team members).

Nursing practice in hospice settings is a continuation of acute care nursing. The emphasis is on holistic care not curative care. While the nurse has an expert role in pain management, he or she also plans a managerial role in controlling symptoms and adverse effects on the body from the disease process. The ultimate objective is to support the patient while on the journey to a peaceful dignified death ([Fig. 30-5](#)). Care is centered on patients and families, generally begins with life-threatening illness, and ends with family bereavement care.

**FIGURE 30-5** Providing comfort and emotional support to patients and their families is an essential role of hospice care.

Hospice caregiving can be illustrated as a tree, strongly rooted in the process of nurses deliberately practicing self-care for themselves (Fig. 30-6). This tree has been drawn to explain the expert competencies of hospice nurses who were interviewed to capture the essence of their practice, as described by [Zerwekh \(1995, 2006\)](#). Each of the hospice nursing practices visualized by the tree diagram is briefly summarized below.

**FIGURE 30-6** The hospice caregiving tree.

## *Roots of Hospice Nursing: Sustaining Oneself*

Effective hospice nurses understand that to care for others, they must care for themselves. Caring for clients at the end of life can be physically and emotionally draining. The hospice nurse works with clients and families to psychologically prepare for death of a loved one. The nurse often becomes emotionally attached to the dying client and needs to sustain their own emotional well-being to be an effective advocate for the client and family. *Sustaining oneself* requires deliberate effort to maintain one's own physical, emotional, and spiritual well-being. Knowing oneself, identifying sources of stress, and learning how to care for self are important and provide the roots for hospice caring. Expert hospice nurses keep themselves healthy by maintaining a balance between giving and receiving, letting go of predetermined agendas and idealistic hopes to achieve more than is humanly possible, being emotionally open and clear, and deliberately replenishing themselves to restore their energy. Hospice nurses described their emotional challenges as being simultaneously draining and enriching experiences leading to personal and professional growth and development ([Ingebretsen & Saghakken, 2016](#), p. 1).

## *The Trunk Reaching Upward: Connecting, Speaking Truth, and Encouraging Choice*

Rooted in self-care, hospice nurses practice *connecting*, which refers to the centrality of relationships in providing hospice care. The hospice nurse seeks to understand the emotional and spiritual distress common to the end of life, particularly the progressive experience of loss after loss. Guided by that understanding, hospice nurses emphasize attentive listening to understand each individual's unique story. This requires quieting your own thoughts to truly hear what is being expressed. Sometimes, listening involves simply being present in the moment, paying attention. Having heard the client's story, it is important for hospice nurses to speak honestly when other professionals and family feel obliged to keep being cheerful and positive. Hospice nurses openly seek to speak truthfully about many issues that can be painful to discuss. *Speaking truth* is visualized as encircling the entire top of the caregiving tree. Hospice nurses bring up difficult subjects, so that the client is freed to speak about his greatest fears and concerns. After truth has been discussed and the client has made a decision, the hospice nurse often advocates for client wishes against the resistance of various authorities. Remember that these are the final decisions in a dying person's life.

## *Collaborating*

Interdisciplinary teamwork is an essential branch on the tree. The hospice interdisciplinary team members share information and work interdependently. The hospice nurse coordinates the plan of care and day-to-day efforts to provide physical and psychosocial comfort. The hospice nurse supervises licensed and unlicensed personnel in carrying out comfort interventions. The physician is responsible for medical care and serves as liaison with the client's primary care physicians. Social workers, spiritual counselors, physical therapists, pharmacists, and volunteers are integral members of the hospice team as they provide environmental, developmental, and spiritual interventions to aid the patient with psychological peace. The hospice interdisciplinary team is constantly challenged to work creatively together to find solutions for complex end-of-life suffering with emotional, spiritual, and physical components.

### *Strengthening the Family*

The death of a family member causes great disruption for all involved. When family members are in a caregiving role in the home, they experience significant personal suffering. Caregivers are vulnerable to physical and emotional illness themselves. The process of taking care involves managing the illness as well as all practical assistance, seeking information and resources, and preparing for death itself. Family members often are caught up with family issues and struggles with the health care system. An extremely important role in hospice nursing involves supporting family members' abilities as caregivers. Teaching caregiving requires creative teaching methods and flexibility. The hospice nurse often acts as a liaison between the patient and family as well as among family members.

### *Comforting*

Hospice nurses develop extensive expertise in pain and symptom management. The fear of many hospice clients and families is that pain will not be controlled. Most pain can be controlled through careful monitoring and intervention. [Box 30-6](#) lists fundamental palliative principles, and [Box 30-7](#) identifies four important components of pain relief.

## **BOX 30-6 Fundamentals of Palliative Care**

- Make no assumptions about what is wrong.
- Believe the patient's report of symptoms.
- Relieve discomfort to the extent that the patient chooses and finds acceptable.

- Investigate the biologic, psychosocial, and spiritual dimensions of discomfort.
- Anticipate symptoms and relieve them before they occur again.
- Use nursing and complementary (integrative) interventions.
- Become an expert in the use of palliative medication.
- Continually evaluate the effectiveness of interventions.
- Choose the least complex and most manageable interventions that patients and families can manage themselves at home.
- Never give up. Persist in trying different palliative strategies. Remember the patient and caregiver are both involved in treatment.

## **BOX 30-7 Essential Components of Pain Relief**

1. Continually assess the extent of pain and the relief afforded by interventions.
2. Schedule analgesics around the clock to maintain continuous blood levels, and prevent the return of pain.
3. Use the least invasive route for analgesic administration, with oral as first choice.
4. Follow the [World Health Organization \(2016\)](#) three-step ladder:  
*Step 1 for mild pain:* Nonopioid (acetaminophen or NSAID) plus adjuvant such as corticosteroid, antidepressant, anxiolytic, or anticonvulsant  
*Step 2 for persisting pain:* Opioid and nonopioid and/or adjuvant  
*Step 3 for moderate to severe pain:* Strong opioid and nonopioid and/or adjuvant

Note: The WHO also offers guidelines for persisting pain in children:  
[www.who.int/medicines/areas.quality\\_safety\\_guide\\_perspainchild/en/](http://www.who.int/medicines/areas.quality_safety_guide_perspainchild/en/)  
 Source: [World Health Organization \(2016\)](#).

### *Spiritual Practice and Letting Go*

As death draws near, spiritual needs often intensify as the client searches for meaning and hope. Death is a developmental milestone as well as a spiritual and physical journey. The effect of the journey on the client is impacted by the environmental and cultural habits and customs the client has experienced through the lifetime. Spirituality is a broad concept that the individual client defines as to what has given his or her life meaning and purpose. Religion and spirituality are related in that religion is a system of beliefs and doctrines that aid the client in expressing what gives the client meaning and hope. In a multisite study of quality of life for advanced cancer patients being treated with palliative radiation, researchers found that those who used religious and spiritual coping reported improved quality of life on all outcome measures.

Spiritual distress has been long recognized by nurses as a factor that can rob the client of peace. Spiritual peace comes when the client realizes his or her life had meaning, purpose, and hope. Attainment of the spiritual peace calms the patient. Nurses may be called upon to intervene with their patient through prayer and active listening as they help the client to reframe life events and accept love and support from others. *Guiding letting go* is a truly unique nursing practice that involves helping the client to let go of former activities and hopes, including life itself. This involves listening to intense emotions and helping the person and family find resolution (Raingruber & Wolf, 2015). Sometimes, it involves participating in a vigil at the bedside of the dying person and encouraging loved ones to say their final words of farewell. It is this action that often is that one thing that gives the client peace (Box 30-8).

## BOX 30-8 PERSPECTIVES

**A Hospice Nurse's Viewpoint on Hospice/Palliative Care Nursing When I graduated from nursing school, I went directly into the intensive care unit. I loved it! I enjoyed the challenge of working intensely with one or two patients, as well as the supportive work environment with my close-knit group of colleagues.**

With marriage and children (my first pregnancy resulted in twins), the 12-hour shifts and full-time schedules were more difficult to balance with family life. At first, I dropped down to working one weekend a month. But, with our growing family, it seemed that I would not be able to remain in the ICU.

I talked to a friend and learned about our hospital's hospice agency; she enjoyed working there, and I thought I would give it a try. It was a perfect fit for me and for our four boys. People always think of hospice/palliative care as depressing, but I find it to be very fulfilling. I think about it as “joining with a family” at their most vulnerable time. The patients let you

in, sharing very personal things about their life with you, and they are grateful for your assistance at this time of transition. It can be a very spiritual experience, and I consider it a privilege to be able to share this time with my patients and their families.

The only difficult cases for me are the children; our agency doesn't have a large pediatric hospice, but it is beginning to expand. It is difficult for parents to lose a child, as one would expect. I remember coming home after a long night with a family whose young child lost his long battle with cancer and hosting my 2-year-old's birthday party with family and friends. I couldn't help but think about the contrast—my happy, healthy toddler and the loss of a young boy to cancer. But, I know that I made a difference for that family and child; I am honored to be a hospice/palliative care nurse.

Jessica, hospice RN

## Ethical Challenges in Hospice Nursing

The hospice nurse confronts striking ethical challenges at the end of life. As an advocate for the client, the hospice nurse must integrate his or her own knowledge of the pathophysiology of the disease process with the physiological needs of the dying client while accounting for the psychological and cultural needs of the client and family (Storch, 2015). As client advocates, we, as nurses, must be aware of the ethical challenges surrounding the dying experience. Wide-ranging issues include respect or disregard for client autonomy, relief or disregard for client suffering, and avoidance of killing at the very end of life (Fernandes, 2015). The hospice nurse needs to develop their own knowledge of nursing and medical ethics in order to question the ethical implications of interventions and to advocate for the client and family. An example is patient families will often insist that the patient be fed and given fluids. This may come from the aspect that in our culture food is thought to be comforting. Commonly, a patient close to death will not want to eat or drink; the body no longer needs those nutrients to sustain itself. This refusal on the part of the dying patient stresses the caregivers and the nurse may need to intervene to advocate for the patient's wishes. Ethical unrest in the client, family, as well as the nurse is best addressed through the institutional ethics board. This board consists of various disciplines specializing in health care, ethics, legal, and spiritual care. When the nurse is unsure of the ethical ramifications of decisions by the client or family, it is the nurse's obligation to bring the case before the board following the procedures of the institution. See Chapter 4 for more on ethics. See Box 30-9 for information on how nurses can recognize and manage compassion fatigue.

### **BOX 30-9 Evidence-Based Practice**

**Nurses and Compassion Fatigue Do you wonder how hospice nurses sustain compassionate practice as they work every day with suffering patients who always die? Expert hospice nurses embrace the suffering of the client and family and become susceptible to compassion fatigue. Compassion fatigue is often viewed as secondary stress. It is the stress felt by the caregiver from exposure to a traumatization.**

**Nurses often describe this as overload. Although signs of compassion fatigue are individualized, they often include exhaustion and a reduced ability to express empathy for the client. This may result in withdrawal by the nurse emotionally from the client and family, as well as the role of nurse.**

Staying psychologically as well as physically healthy as a hospice nurse requires a high level of self-awareness. Nurses must be aware of the signs and symptoms that they may have a tendency to exhibit. Symptoms are individualized based on how a particular nurse adapted to stress in the past and are often subject to developmental, spiritual, cultural, and environmental influences. Recognition of the symptoms allows the hospice nurse to institute stress-relieving activities early in the process. According to the [Compassion Fatigue Awareness Project \(2017\)](#), some symptoms that a nurse may experience include the following:

- Isolating oneself; poor self-care (appearance, hygiene)
- Repressed emotions; apathy; mentally/physically exhausted
- Always finding blame with others; many complaints about job/administration
- Substance abuse; compulsive behaviors (e.g., eating, spending, gambling)
- In debt; legal problems; recurrent flashbacks/nightmares; chronic health problems
- Problems concentrating; feeling preoccupied; denies problems

Compassion fatigue can affect an agency, if enough nurses suffer from the problem and nothing is done to assist them. It can cause problems between nurses and administrators, lead to high turnover and absenteeism, and lead to self-perpetuation. Organizations may exhibit these symptoms:

- Poor teamwork; high absentee rates; continually changing coworker relationships
- Challenging/breaking agency rules; aggression among staff members
- Poor task/assignment completion; unable to meet deadlines; lack of flexibility
- Negative feelings toward management; reluctance toward change

- Poor vision of future; not able to believe that improvements can be made

([Compassion Fatigue Awareness Project, 2017](#)) Compassion fatigue is not isolated to hospice nurses. All nurses are susceptible to the effects. This may lead to higher rates of turnover and an increase in the nursing shortage as nurses leave the profession.

Often, caregivers experiencing compassion fatigue are unable to identify it in themselves.

1. What ways can you identify compassion fatigue in others?
2. What recommendations can you make to reduce compassion fatigue for yourself?
3. How can you transform the organization to reduce compassion fatigue?

Source: [Compassion Fatigue Awareness Project \(2017\)](#); [Upton \(2018\)](#).

## **The Future of Hospice Care**

Given a rapidly expanding population of elders living longer with challenging chronic illnesses, home health and hospice care in the home will soon need to transform into a community-based long-term care system that doesn't discharge after an acute episode or admit only at the very end of life. In response to out-of-control medical inflation, federal and state governments have sought to hold down expenses in all areas, including restrictions on home health and hospice care. However, costs keep rising in step with technologic and pharmacologic innovation and marketing. Containing costs will eventually force a shift in services from expensive institutional and high-technology interventions to community-based home services.

The entire model for service provision in the home must change to a health care delivery system that continuously serves those living with disabling and terminal illness to maximize well-being at home, anticipate and prevent crises, and minimize emergent and inpatient interventions. Hospice care is focused on symptom management, not curative interventions. Care revolves around maintenance of quality of life, not necessarily quantity. Clients in hospice care, under Medicare regulations, receive care for symptom management. If care is needed for other health conditions not related to the terminal diagnosis, care is received under their original Medicare benefit. Hospice services should be based on client choice and the reality of a terminal diagnosis. The physician must sign a declaration stating that the terminal diagnosis, if it follows the normal course of the disease process, will cause death in a finite period of time (6 months or less). A sustainable, affordable approach to care in the home requires ongoing case management to coordinate and manage resources with incentives that control cost while assuring quality of life and comfort. The hospice nurse becomes a coordinator of an interprofessional team of health care, spiritual, and community resources. Team members often include volunteers, who, after training, become involved with respite care for the family. Determination of the team members is defined in collaboration with the client and family to allow them independence and minimize the disruption to their individual lifestyle. Although inpatient hospices do exist, the goal of the hospice nurse is to keep the client in their home environment for as long as possible. The purpose of palliative care is symptom control, thereby decreasing stress for the dying client.

Nurses, nurse practitioners, and home visiting physicians will need to have the diagnostic and therapeutic resources to monitor physiologic status and intervene in the home. Telehealth and home monitoring will be essential. The focus must change from doing everything possible to prolong

physiologic survival to promoting meaningful and comfortable lives. Nurses will have an active role in this process.

The [IOM \(2015\)](#) report *Dying in America: Improving Quality and Honoring Individual Preferences Near the End of Life* gives direction for needed changes that put the requirements of patients and families first. The report encourages policy changes and serves as a charge for all of us to advocate for improved social, spiritual, and psychological support and care for those of us nearing the end of our lives. As health care providers, we need to strive to provide compassionate, quality-centered, evidence-based care that is consistent with the wishes of our patients and their families ([Box 30-10](#)).

## **BOX 30-10 Population Focus**

**Hospice Care for Children Although it may be difficult for a family to accept hospice care for their terminally ill child, there is increasing evidence showing that a pediatric palliative care program reduces stress and worry for caregivers. Also, because medical care is received in a stress-free setting, the quality of life as well as length of life may be increased ([Gans et al., 2015](#)). Hospice plays an important role in supporting the child and family in the areas of medical, social, spiritual, and psychological support. The value of this service and underutilization justify research in this area. The National Hospice and Palliative Care Organization is committed to care of the child and family who can benefit from hospice care. They provide professional resources and education, as well as patient education information.**

Children with life-threatening illnesses are hospitalized more often and spend more days in the hospital than those whose diseases are not life threatening. This causes additional stress on the child as well as the

caregivers. Also, the child may be exposed to other diseases, which may affect the quality of their lives. There are many reasons hospice services are underutilized for children. Lack of education on the part of the health care team is a primary cause. Often the health care team is hesitant to recommend hospice until death is imminent on the hope that a curative treatment may be found. Families are often hesitant to commit to hospice as they remain in the denial phase of grieving. Hospice enables care for dying children by a multidisciplinary team supporting the child.

Most important to nursing practice is the limited access to ongoing education and the lack of consistent professional experiences with these children and their families. The National Hospice and Palliative Care Organization (NHPCO) offers palliative care resources for families and professionals at their website. Educating the health care team and family members regarding resources available through hospices services can increase the use, decrease acute care hospitalizations, and increase family satisfaction and coping.

1. *Do you think most nurses working in hospitals are aware of hospice and palliative care services for children?*
2. *What could you do to help communicate the availability and effectiveness of hospice services for children with life-threatening illnesses?*

Source: [Gans et al. \(2015\)](#).

# SUMMARY

- Nurses have an important role in working with clients who receive home care or hospice services. As the population continues to age, the need for nurses to work with older adults where they live, as they are discharged from acute care settings earlier and earlier, and, if they are terminally ill, during their final months and days, will only increase. Services are also needed for clients across the lifespan.
- Many types of home care agencies exist: voluntary, proprietary, hospital based, official, homemaker, and hospice. Both formal and informal caregivers provide service. Professional staff members, such as nurses, social workers, therapists, and certified nursing assistants, work in collaboration with family members and, in some situations, with friends and neighbors.
- Medicare covers hospice care without the restrictions experienced by skilled home care clients. Hospice and palliative care programs provide holistic care to clients during the last months of life. Many programs are home based, and they may be offered by a home health agency. In addition to in-home hospices, inpatient hospices exist; these can be located in a freestanding building, in an area of a SNF, or in a section of an acute care facility. The focus of hospice care is not historically aimed at cure, and it employs holistic caregiving practices that involve family members, professionals, and volunteers.
- The nurse provides direct physical nursing care both in home health care and with hospice clients. In addition, the nurse teaches clients, family members, and volunteers; supervises; collaborates with team members; and case manages. Nurse assessment of clients assists in determining plan of care and working toward client management of disease processes in a value-based health model.

# ACTIVE LEARNING EXERCISES

1. Search the Internet for home health and hospice agencies in your city or town. Select two agencies and compare services provided and the employment opportunities of each (one nonprofit and one for-profit). How do these job descriptions and the published pay ranges compare to hospitals in your area? What are the benefits of working in home health and hospice? Will the agency hire new graduates, or do they require prior acute care experience? What care is provided by these agencies? Where do you see gaps in services? What type of interventions does the agency utilize to prevent compassion fatigue among its staff?
2. Using “Communicate Effectively to Inform and Educate” (1 of the 10 essential public health services; see [Box 2-2](#) ), how would you assist the following client? Mr. H is a 72-year-old male who has just been sent home from the hospital following his second stroke and has right-sided weakness. He has a G-tube in place and requires a walker for ambulation. He lives alone but has family in the area. What are your priorities? Using the nursing process, determine a plan of action.
3. Review your personal health insurance policy or that of a family member. What coverage, if any, is provided for home health or hospice care? What restrictions are stated in the coverage—total reimbursement, source of care, or length of service? Do you think this will be adequate to meet your or your family member's needs when these services may be needed? What other options might be available to help defray the cost of this type of care?
4. Interview a home health, hospice, or palliative care nurse to find out the most rewarding part of their job. What things are problematic? Ask about a typical case and home visit. How does this compare to your experiences in your community health nursing clinical course? Do you feel that home health, hospice, or palliative nursing might be something you will consider in the future? What are some safety considerations taken by the home health nurse?
5. Informal caregivers assume additional duties and burdens when caring for a loved one. Find a systematic review or research study on caregiver burden and compare your findings with another classmate's findings. What are the most common issues, and how can the C/PHN address them?

# APPENDIX Quad Council Tier 1 Community/Public Health Nursing Competencies

## *Domain 1: Assessment and Analytic Skills*

Assessment/Analytic Skills focus on identifying and understanding data, turning data into information for action, assessing needs and assets to address community health needs, developing community health assessments, and using evidence for decision making.

- 1A1.** Assess the health status and health literacy of individuals and families, including determinants of health, using multiple sources of data.
- 1A2a.** Use an ecological perspective and epidemiological data to identify health risks for a population.
- 1A2b.** Identify individual and family assets, needs, values, beliefs, resources, and relevant environmental factors.
- 1A3.** Select variables that measure health and public health conditions.
- 1A4.** Use a data collection plan that incorporates valid and reliable methods and instruments for collection of qualitative and quantitative data to inform the service for individuals, families, and a community.
- 1A5.** Interpret valid and reliable data that impacts the health of individuals, families, and communities to make comparisons that are understandable to all who were involved in the assessment process.
- 1A6.** Compare appropriate data sources in a community.
- 1A7.** Contribute to comprehensive community health assessments through the application of quantitative and qualitative public health nursing data.

- 1A8.** Apply ethical, legal, and policy guidelines and principles in the collection, maintenance, use, and dissemination of data and information.
- 1A9.** Use varied approaches in the identification of community needs (i.e., focus groups, multi-sector collaboration, SWOT analysis).
- 1A10.** Use information technology effectively to collect, analyze, store, and retrieve data related to public health nursing services for individuals, families, and groups.
- 1A11.** Use evidence-based strategies or promising practices from across disciplines to promote health in communities and populations.
- 1A12.** Use available data and resources related to the determinants of health when planning services for individuals, families, and groups.

# **DOMAIN 2: POLICY DEVELOPMENT/PROGRAM PLANNING SKILLS**

Policy Development/Program Planning Skills focus on determining needed policies and programs, advocating for policies and programs; planning, implementing, and evaluating policies and programs, developing and implementing strategies for continuous quality improvement; and developing and implementing community health improvement plans and strategic plans.

- 2A1.** Identify local, state, national, and international policy issues relevant to the health of individuals, families, and groups.
- 2A2.** Describe the implications and potential impacts of public health programs and policies on individuals, families, and groups within a population.
- 2A3.** Identify outcomes of health policy relevant to public health nursing practice for individuals, families, and groups.
- 2A4a.** Provide information that will inform policy decisions.
- 2A4b.** Implement programs and services based on policy decisions.
- 2A5.** Use organizations' strategic plans and decision-making methods in the development of program goals and objectives for individuals, families, and groups.
- 2A6a.** Demonstrate knowledge of laws and regulation relevant to public health nursing services.
- 2A6b.** Plan public health nursing services consistent with laws and regulations.
- 2A7.** Function as a team member in developing organizational plans while assuring compliance with established policies and program implementation guidelines.
- 2A8.** Comply with organizational procedures and policies.

- 2A9.** Use program planning skills and CBPR (i.e., collaboration, reflection, capacity building) to implement strategies to engage marginalized/disadvantaged population groups in making decisions that affect their health and well-being.
- 2A10.** Apply methods and practices to access public health information for individuals, families, and groups.
- 2A11.** Participate in quality improvement teams by using quality indicators and core measures to identify and address opportunities for improvement in services for individuals, families, and groups.

# **DOMAIN 3: COMMUNICATION SKILLS**

Communication Skills focus on assessing and addressing population literacy; soliciting and using community input, communicating data and information; facilitating communications; and communicating the roles of government, health care, and others.

- 3A1.** Determine the health, literacy, and the health literacy of the population served to guide health promotion and disease prevention activities.
- 3A2.** Apply critical thinking and cultural awareness to all communication modes (i.e., verbal, nonverbal, written, and electronic) with individuals, the community, and stakeholders.
- 3A3.** Use input from individuals, families, and groups when planning and delivering health care programs and services.
- 3A4.** Use a variety of methods to disseminate public health information to individuals, families, and groups within a population.
- 3A5a.** Create a presentation of targeted health information.
- 3A5b.** Communicate information to multiple audiences including groups, peer professionals, and agency peers.
- 3A6.** Use communication models to communicate with individuals, families, and groups effectively and as a member of the interprofessional team(s) or interdisciplinary partnerships.
- 3A7.** Describe the role of public health nursing to internal and external audiences.
- 3A8.** Apply communication techniques and models when interacting with peers and other health care team members including conflict management.

# **DOMAIN 4: CULTURAL COMPETENCY SKILLS**

Cultural Competency Skills focus on understanding and responding to diverse needs, assessing organizational cultural diversity and competence, assessing effects of policies and programs on different populations, and taking actions to support a diverse public health workforce.

- 4A1.** Use determinants of health effectively when working with diverse individuals, families, and groups.
- 4A2.** Use data, evidence, and information technology to understand the impact of determinants of health on individuals, families, and groups.
- 4A3.** Deliver culturally responsive public health nursing services for individuals, families, and groups.
- 4A4.** Explain the benefits of a diverse public health workforce that supports a just and civil culture.
- 4A5.** Demonstrate the use of evidence-based cultural models in a work environment when providing services to individuals, families, and groups.

# **DOMAIN 5: COMMUNITY DIMENSIONS OF PRACTICE SKILLS**

Community Dimensions of Practice Skills focus on evaluating and developing linkages and relationships within the community, maintaining and advancing partnerships and community involvement, negotiating for the use of community assets, defending public health policies and programs, and evaluating and improving the effectiveness of community engagement.

- 5A1a.** Use assessments, develops plans, implements, and evaluates interventions for public health services for individuals, families and groups.
- 5A1b.** Assist individuals, families, and groups to identify and access necessary community resources or services through the referral and follow-up process.
- 5A2.** Use formal and informal relational networks among community organizations and systems conducive to improving the health of individuals, families, and groups within communities.
- 5A3a.** Select stakeholders needed to address public health issues impacting the health of individuals, families, and groups within the community.
- 5A3b.** Function effectively with key stakeholders in activities that facilitate community involvement and delivery of services to individuals, families, and groups.
- 5A4.** Build stakeholder capacity to advocate for the health issues of individuals, families, and groups.
- 5A5.** Use community assets and resources, including the government, private, and nonprofit sectors, to promote health and to deliver services to individuals, families, and groups.
- 5A6.** Use input from varied sources to structure public health programs and services for individuals, families, and groups.

- 5A7a.** Interview individuals, families, and groups to identify community resource preferences.
- 5A7b.** Build preferences into public health services.
- 5A7c.** Identify opportunities for individuals, families, and groups to link with advocacy organizations.
- 5A8.** Identify evidence of the effectiveness of community engagement strategies on individuals, families, and groups.

# DOMAIN 6: PUBLIC HEALTH SCIENCES SKILLS

Public Health Sciences Skills focus on understanding the foundation and prominent events of public health, applying public sciences to practice, critiquing and developing research, using evidence when developing policies and programs, and establishing academic partnerships.

- 6A1.** Use the determinants of health and evidence-based practices from public health and nursing science, when planning health promotion and disease prevention interventions for individuals, families, and groups.
- 6A2a.** Determine the relationship between access to clean, sustainable water, sanitation, food, air, and energy quality on individual, family, and population health.
- 6A2b.** Assess hazards and threats to individuals, families, and populations and reduce their risk of exposure and injury in natural and built environments (i.e., chemicals and products).
- 6A3.** Use evidence-based practice in population-level programs to contribute to meeting core public health functions and the 10 essential public health services.
- 6A4.** Participate in research activities impacting the health of populations.
- 6A5.** Use a wide variety of sources and methods to access public health information (i.e., GIS mapping, Community Health Assessment, local/state/and national sources).
- 6A6a.** Use research to inform the practice of public health nursing.
- 6A6b.** Identify gaps in research evidence that impact public health nursing practice.
- 6A7.** Demonstrate compliance with the requirements of patient confidentiality and human subject protection.
- 6A8.** Model public health science skills when working with individuals, families, and groups.

# **DOMAIN 7: FINANCIAL PLANNING, EVALUATION, AND MANAGEMENT SKILLS**

Financial Planning and Management Skills focus on engaging other government agencies that can address community health needs, leveraging public health and health care funding mechanisms, developing and defending budgets, motivating personnel, evaluating and improvement program and organization performance, and establishing and using performance management systems to improve organization performance.

- 7A1.** Explain the interrelationships among local, state, tribal, and federal public health and health care systems.
- 7A2.** Explain the public health nurse's role in emergency preparedness and disaster response during public health events (i.e., infectious disease outbreak, natural or manmade disasters).
- 7A3.** Implement operational procedures for public health programs and services.
- 7A4a.** Demonstrate knowledge of funding streams to support programs.
- 7A4b.** Select the data for inclusion in a programmatic budget.
- 7A5.** Interpret the impact of budget constraints on the delivery of public health nursing services to individuals, families, and groups.
- 7A6.** Explain implications of organizational budget priorities on individual, groups, and communities.
- 7A7.** Explain public health nursing services and programmatic needs to inform budget priorities.
- 7A8a.** Identify data to evaluate services for individuals, families, and groups.
- 7A8b.** Contribute to the evaluation plan for public health nursing services targeting individuals, families, and groups.

- 7A9.** Deliver public health nursing services to individuals, families, and groups based on reported evaluation results.
- 7A10.** Provide input into the fiscal and narrative components of proposals.
- 7A11.** Use public health informatics skills pertaining to public health nursing services of individuals, families, and groups.
- 7A12.** Provide input for contracts and other agreements for the provision of public health services.
- 7A13.** Organize public health nursing services and programs for individuals, families, and groups within budgetary guidelines.
- 7A14a.** Participate in the implementation of the organization's performance management system.
- 7A14b.** Use self-reflection to identify one's performance in the organization's performance management system.
- 7A14c.** List contributions to the organization's performance management system.

# DOMAIN 8: LEADERSHIP AND SYSTEMS THINKING SKILLS

Leadership and Systems Thinking Skills focus on incorporating ethical standards into the organization, creating opportunities for collaboration among public health, healthcare, and other organizations; mentoring personnel; adjusting practice to address changing needs and environment; ensuring continuous quality improvement; managing organizational change; and advocating for the role of governmental public health.

- 8A1.** Demonstrate ethical standards of practice in all aspects of public health and public health nursing as the basis of all interactions with individuals, communities, and organizations.
- 8A2.** Apply systems thinking to public health nursing practice with individuals, families, and groups.
- 8A3.** Participate in stakeholder meetings to identify a shared vision, values, and principles for community action.
- 8A4a.** Identify internal and external factors affecting public health nursing practice and opportunities for interprofessional collaboration.
- 8A4b.** Explain environmental hazards and emergency preparedness to protect individuals, families, and groups.
- 8A4c.** Respond to environmental hazards to protect individuals, families, and groups.
- 8A5.** Use individual, team, and organizational learning opportunities for personal and professional development as a public health nurse.
- 8A6.** Model personal commitment to lifelong learning, professional development, and advocacy.
- 8A7.** Identify organizational quality improvement initiatives that provide opportunities for improvement in public health nursing practice.
- 8A8.** Facilitate the development of interprofessional teams and workgroups.

- 8A9.** Interpret organization dynamics of collaborating agencies.
- 8A10a.** Provide feedback on the organization's mission and vision and the impact on individuals, families, and groups.
- 8A10b.** Influence others to provide feedback on the organization's mission and vision and the impact on individuals, families, and groups.
- 8A11.** Select advocacy strategies to address the needs of diverse and underserved population.
- 8A12.** Identify organizational policies and procedures that meet practice and public health accreditation requirements.
- 8A13.** Influence health as a shared value through community engagement and inclusion of individuals, families, and groups.
