When the physician or nurse practitioner is unable to determine capacity or there is disagreement regarding the patient's capacity, a competency hearing is conducted in court on the patient's behalf. As in involuntary commitment hearings, the court is asked to deny a US citizen the constitutional right to make decisions, which essentially takes away all rights and privileges provided as a US citizen. When a patient is determined to be incompetent, a guardian is appointed to make decisions regarding care the patient will or will not receive. No other person, including family members or providers, has the power to override the guardian's decisions. To do so, that person must return to court and explain why the guardian's decision should not be honored. Thus, under the Patient Self-Determination Act and state specific statutes, advance directives that include a DPAHC and orders whether to provide or not provide resuscitation must be clear and in compliance with law. Nursing care is individualized based on the patient's instructions and on the state in which the patient resides at the time a directive is implemented. The DPAHC's ability to make decisions for the patient ends at the time of death. Thus, it is important that patients and their families arrange their after-life care in advance when possible.

Living wills also include information about a patient's preferences regarding end-of-life care (Furrow et al., 2018; Touhy & Jett, 2018). Some include physician orders about sustaining life, such as use of enteral feedings. Others contain information on whether to initiate CPR on cessation of breathing. It is important to thoroughly read documents titled "living will." They are based on values of informed consent, patient autonomy over end-of-life decisions, truth telling, and control over the dying process. A patient must be capable to make decisions regarding his or her own health care treatment when creating a living will. Many

resources are available to help create a living will. For example, Five Wishes is an organization that helps patients write their directives when responding to five questions (<https://fivewishes.org/>). The questions help patients identify a DPAHC, the kind of medical treatment wanted or not wanted, comfort measures they wish to receive, how they want to be treated by those around them, and what they want those who love them to know. Providing this information and assisting patients in recording their wishes is rewarding for the patient, empowering to their loved ones, and humbling to the nurses who help them.

Patients make difficult decisions when writing a living will. Sometimes family and friends have difficulty in understanding and adhering to those decisions. The ethical doctrine of autonomy, which has been upheld in court, ensures the patient the right to refuse medical treatment. For example, courts upheld a patient's right to refuse medical treatment in the *Bouvia v Superior Court* case (1986). Courts have also upheld the right of a legally competent patient to refuse medical treatment for religious reasons. The US Supreme Court stated in the *Cruzan v Director of Missouri Department of Health* case (1990) that "we assume that the US Constitution would grant a constitutionally protected competent person the right to refuse lifesaving hydration and nutrition." In the Terri Schiavo case, (*Schindler & Schindler v Schiavo*, 2003) Schiavo's husband, who was her legal guardian, argued that his wife would not want to have her life artificially prolonged. Her parents disagreed and wanted her to continue to receive artificial nutrition and hydration. The court noted that it understood "why a parent who had raised and nurtured a child from conception would hold out hope that some level of cognitive function remained." However, after more than 10 years, the court upheld the guardianship court's initial decision to allow Ms. Schiavo's husband, as her guardian, to make medical decisions on her behalf in the absence of her wishes being known before her death.

In cases involving a patient's right to refuse or withdraw medical treatment, the courts balance the patient's interest with the interest of the state in protecting life, preserving medical ethics, preventing suicide, and protecting innocent third parties. Children are generally innocent third parties. Although the courts will not force adults to undergo treatment refused for religious reasons, they will grant an order allowing hospitals and health care providers to treat children of parents or groups who have denied consent for treatment of their minor children for religious reasons. This is based on the legal doctrine of *parens patriae* in which the state or

government makes decisions on behalf of those who are unable to make decisions for themselves.

In addition to patient refusals of treatment, nurses frequently encounter “do not resuscitate” (DNR) or “no code” DNR orders. The state of New York was the first to develop legislation based on the recommendations of the New York State Task Force on Life and the Law in 1986. These recommendations, which went into effect in 1988, allow competent adults to authorize a DNR order (Golden, 1988). Documentation that the health care provider has consulted with the patient and/or family is required before writing a DNR order in the patient’s medical record (Furrow et al., 2018; Touhy & Jett, 2018). Patient conditions change, and patients have the right to change their minds. The health care provider needs to review DNR orders with the patient periodically to assure that the order reflects current wishes.

When patients have living wills or advance directives remember that the “do not resuscitate” designation does not mean “do not care.” Although the patient has made the choice to refuse CPR and other acts (stated on DNR order) in the event of a cardiopulmonary arrest, you must provide patient care and meet the patient’s needs. Health care providers are required to make every effort to revive patients who arrest and do not have a DNR order. Some states offer DNR Comfort Care and DNR Comfort Care Arrest protocols. Protocols in these instances list specific actions that health care providers will take when providing CPR.

CPR is an emergency treatment provided without patient consent (see Chapter 41). Health care providers perform CPR when needed unless there is a DNR order in the patient’s chart. The statutes assume that all patients want to be resuscitated unless there is a written DNR order in the medical record. Legally, capable adult patients consent to a DNR order verbally or in writing after receiving the appropriate information by the health care provider. Be familiar with the DNR protocols of your state.

REFLECT NOW

You are caring for a patient who is terminally ill and has a "do not resuscitate" order, but the medical record does not have an entry regarding the physician's discussion with the patient prior to writing the order. How would you respond if the patient has a cardiac arrest? How would your response differ if the patient were 8 versus 80 years old?

Uniform Anatomical Gift Act

The Uniform Anatomical Gift Act (UAGA) (1987) was developed more than 50 years ago by the National Conference of Commissioners on Uniform Laws and was approved by the American Bar Association ([Sadler & Sadler, 2018](#)). The UAGA provides the foundation for the national organ donation system. Patient autonomy, individual autonomy, and public trust remain the ethical principles on which organ donation occurs. An individual who is at least 18 years of age can make an organ donation (defined as a "donation of all or part of a human body to take effect upon or after death"). Donors make the gift in writing. In many states adults sign the back of their driver's license, indicating consent to organ donation.

In most states Required Request laws mandate that, at the time of admission to a hospital, a qualified health care provider must ask each patient over age 18 whether he or she is an organ or tissue donor. If the answer is affirmative, the health care provider obtains a copy of the document. If the answer is negative, the health care provider discusses the option to make or refuse an organ donation and places such documentation in the patient's medical record. In most states there is a law requiring that at the time of death a qualified health care provider asks a patient's family members to consider organ or tissue donation ([National Organ Transplant Act, 1984](#)). Individuals are approached in the following order: (1) spouse, (2) adult son or daughter, (3) parent, (4) adult brother or sister, (5) grandparent, and (6) guardian. The health care provider who certifies death is not involved in the removal or transplantation of organs (see [Chapter 36](#)).

The [National Organ Transplant Act \(1984\)](#) prohibits the purchase or sale of organs ([Korobkin, 2017](#)). The act provides civil and criminal immunity to the hospital and health care provider who perform in accordance with the act. It also protects the donor's estate from liability for injury or damage that results from the use of the gift. Organ transplantation is extremely expensive. Patients in end-stage renal disease are eligible for Medicare coverage for a kidney transplant. Sometimes private insurance pays for other transplants. The United Network for Organ Sharing (UNOS) has a contract with the federal government and sets policies and guidelines for the procurement of organs. Recently UNOS changed policy regarding transplant eligibility. The patient with the most urgent need for a transplant will have first claim on any organ from a compatible donor within a 150-mile radius, then a 250-mile radius, and on up to a 500-mile radius ([Luthi, 2018](#)). This process will continue with the priority given to the sickest people. Older laws based on geographic proximity arguably reduced access to many critically ill people. Geography is still a factor, but patient need is now the priority ([Luthi, 2018](#)). Be familiar with the policies and procedures of your agency regarding organ donation.

The Omnibus Budget Reconciliation Act (1987)

The Omnibus Reconciliation Act (OBRA) of 1987 significantly altered the way in which health care is provided to older adults. It focused on patient rights, quality of life, quality of care, and the physical environment in which patients lived. One change focused on the use of restraints intended to change older adult behavior.

OBRA 1987 addressed the use of both physical and chemical restraint use (see [Chapter 14](#)). The legal definition of a restraint is any manual method, physical or mechanical device, or material or equipment that immobilizes or reduces the ability of a patient to move freely, with a chemical restraint including the use of medication to alter the behavior of a patient ([CMS, 2008](#)). The use of restraints has been associated with serious complications and even death. The [Centers for Medicare and Medicaid Services \(CMS\) \(2008\)](#), [ANA \(2012\)](#), and [TJC \(2018\)](#) set standards to reduce the use of all types of restraints in health care settings. All patients have a US constitutional right to be free from seclusion and physical or chemical restraints, except on rare occasions, to ensure the safety of patients, staff, and others in emergency situations.

Application of a physical restraint or administration of a chemical restraint must be the intervention of last resort and not the first

intervention of choice when a patient is nonadherent, aggressive, or combative. [Chapter 14](#) describes interventions for a restraint-free environment and the conditions that ultimately allow restraints to be ordered. You must know current evidence-based and legal procedures related to both the use of restraints and their discontinuation. It is critical to know who can legally order the use of restraints, the assessments required, and the length of time restraints can be used. You are required to continuously monitor patients who are restrained or secluded to assure they are safe. A physician, nurse practitioner, physician assistant, or RN who has been trained in CMS restraint and seclusion requirements is required to assess the patient face to face within 1 hour or less of applying the restraints ([CMS, 2018](#)).

Restraints can be used (1) only to ensure the physical safety of the patient or other patients, (2) when less restrictive interventions are unsuccessful, and (3) only on the written order of a health care provider ([CMS, 2018](#)). The regulations also describe documentation of restraint use and follow-up assessments. Litigation from improper restraint use may include allegations of unlawful imprisonment and/or harm associated with injury due to restraint use ([Pozgar, 2016](#)). Knowing when and how to use restraints correctly is key (see [Chapter 27](#)).

State Statutes Impacting Nursing Practice

State law directs how health care will be delivered and regulates and licenses health care agencies and health care professionals providing care to citizens. Thus, when harm occurs to patients, malpractice suits are filed primarily under state law, actions are taken against facilities to no longer operate, and charges are made against a nurse's license when it is determined that the nurse contributed to the harm. In *Gibbons v Ogden* (1824) the US Supreme Court established that regulation and licensure of local matters belong to the states under powers afforded to them under the US Constitution. Nursing licenses are issued and enforced by states.

Nurse Practice Act

Nurse Practice Acts are state laws intended to protect citizens, make nurses accountable, and ensure that care is consistent with best practice within the scope and standards of nursing. Creation of a state board of nursing, sometimes called the nursing commission, is part of a state Nurse Practice Act. Members of the boards and the boards' responsibilities are written in the statute and in the regulations that more clearly delineate their duties. State boards of nursing educate the public and nurses as the profession changes. For example, white papers to clarify administration of conscious sedation by a nurse have been shared with stakeholders when practice acts are revised or challenged. State boards regulate and disseminate information related to nursing practice.

A State Board of Nursing or Nursing Commission licenses all RNs in the state in which they practice. The requirements for licensure vary among states. States use the National Council Licensure Examinations (NCLEX®) for nursing examinations. Legally, a license to practice nursing is considered a privilege and not a right. Licensure permits people to offer special skills to the public, and it also provides legal guidelines for protection of the public.

The enhanced nurse licensure compact (eNLC) enables a nurse to practice in multiple states under one license; an individual license from each participating state is not required (NCSBN, n.d.). Having an eNLC license allows nurses to provide telehealth care when working in one state and the patient is in another state. It also facilitates care when nurses cross

state lines to provide care during emergencies. As practice acts change, more states are participating in the eNLC process ([NCSBN, n.d.](#)).

The State Board of Nursing investigates, suspends, and/or revokes a license if a nurse's conduct violates the Nurse Practice Act. For example, a nurse who wrongfully administers a medication that results in permanent harm to a patient may have a restriction placed on his or her license. If this occurs and the nurse has an eNLC license, other states may also investigate and take action in their jurisdictions, even though the act occurred in another state. Actions taken in other states may be less, worse, or the same as that taken in the originating state where the violation occurred. In part, this demonstrates the importance of having professional liability insurance.

While a license may be considered a privilege, it is also a means by which a person is employed. As such, when penalties are taken against a nurse's license, right to employment statutes may be triggered to protect the person's ability to work. Thus, actions taken to restrict, suspend, and/or revoke a nursing license may become daunting to the nurse who wishes to remain in practice.

The State Board of Nursing must provide notice and follow due process before revoking or suspending a license. Notice means that affirmative actions are taken to inform the nurse that a charge has been made and will be investigated by the Board. It also means that reasonable efforts will be made to inform the nurse of the date, time, and place where an action may be taken to restrict, suspend, or revoke the nurse's license. Due process means that the state is required to inform the nurse of the allegations and the investigation process, including who is being asked to provide information about the allegations. The name of the complainant is disclosed only under court order when anonymity is requested. Nurses should attend and respond to allegations during hearings regarding any allegations. They may and should request an attorney to represent and defend them in a hearing. Hearings for suspension or revocation of a license do not occur in court. Usually a panel of professionals conducts the hearing. Most states provide administrative and judicial review of these cases after nurses have exhausted all other forms of appeal. Actions and decisions by State Boards of Nursing are published and accessible by health care agencies and the public. When administrative appeals have been exhausted, nurses can bring their cases forward to the court for review of the actions taken by the Board in their respective states.

Professional licensure defense is expensive when nurses do not have insurance that covers the costs of keeping their licenses to practice nursing.

On average, \$12,000 or more is required to respond to a complaint and effectively defend a claim. Nurses often presume that either their personal or their employer's malpractice insurance will include costs of defending and retaining their nursing license. In most instances this is not true. Professional licensure defense insurance is a contract between a nurse and an insurance company. When a complaint is made to the State Board of Nursing, an action is initiated that could result in a restriction, suspension, or revocation of the nurse's license to practice. When a nurse specifically has professional licensure defense insurance, the nurse notifies the company. In response, the company will refer the nurse to an attorney, usually a nurse attorney, who will then represent the nurse when interacting with the state board. The insurance company will cover costs of representing the nurse when responding to allegations the state board is investigating.

Malpractice insurance is a contract between an insurance company and a nurse or employer. It is intended to cover costs incurred when a patient sues the employer and/or the nurse. Malpractice insurance provides for a defense of the nurse and the employer in a lawsuit. The insurance company pays for costs, attorney's fees, settlement, and other related fees generated in the representation of the nurse. It covers the costs to the patient; it does not cover the costs when a complaint is filed with the state licensing board. These are two different actions, and different laws apply. Therefore, it is suggested that nurses carry both professional licensure defense and malpractice insurance or one policy that specifically includes both actions. It is also often recommended that nurses have their own personal insurance policy. Relying on the employer's malpractice insurance is often inadequate.

Health care agencies have insurance intended to provide financial assistance when it is alleged that a patient was permanently harmed in one of their facilities. As an employee or agent of the agency, the actions of the nurse when caring for the patient are examined. It is important to remember in these cases that the lawyer is representing the employer and not the nurse. The insurance provided by the employing agency covers nurses only while they are working within the scope of their employment.

REFLECT NOW

Consider your role as a nursing student as it is defined in your state's Nurse Practice Act. What are you required to do when working in a hospital? In your state, is it different if you are working in a skilled nursing facility or nursing home? What about if you are in a retirement center? What can you do in one place that you cannot do in another?

Informed Consent and Health Care Acts

Health care acts within each state describe and define the minimum standards of care that will be provided within their geographic region. These acts and the regulations associated with them are interrelated with other laws governing the practice of nursing. For example, these acts include expectations regarding consent.

A patient's signed consent form is necessary for admission to a health care agency, invasive procedures such as intravenous central line insertion, surgery, some treatment programs such as chemotherapy, and participation in research studies (Furrow et al., 2018). State laws designate individuals who are legally able to give consent to medical treatment (Medical Patient Rights Act, 1994). Nurses need to know the law in their states and be familiar with the policies and procedures of their employing agency regarding consent (Box 23.2). Special consideration is used when a patient is deaf, illiterate, or speaks a foreign language. A professional interpreter must be present in person or remotely to explain the terms of consent. A family member or acquaintance who speaks a patient's language should not interpret health information. Make every effort to help the patient make an informed choice.

Box 23.2 Statutory Guidelines for Legal Consent for Medical Treatment

Those who may consent to treatment are governed by state law but generally include the following:

I. Adults

- A. Any competent individual 18 years of age or older for himself or herself
- B. Any parent for his or her unemancipated minor
- C. Any guardian for his or her ward
- D. Any adult for the treatment of his or her minor brother or sister (if an emergency and parents are not present)
- E. Any grandparent for a minor grandchild (in an emergency and if parents are not present)

II. Minors

- A. Ordinarily minors may not consent to medical treatment without a parent. However, emancipated minors may consent to medical treatment without a parent.
Emancipated minors include:
 - 1. Minors who are designated emancipated by a court order
 - 2. Minors who are married, divorced, or widowed
 - 3. Minors who are in active military service
- B. Unemancipated minors may consent to medical treatment if they have specific medical conditions
 - 1. Pregnancy and pregnancy-related conditions (Various states differ in characterizing a pregnant minor as either emancipated or unemancipated. Know your state rules in this matter.)
 - 2. A minor parent for his or her custodial child
 - 3. Sexually transmitted infection (STI) information and treatment
 - 4. Substance abuse treatment
 - 5. Outpatient and/or temporary sheltered mental health treatment
- C. The issue of emancipated or unemancipated minors does not relieve the health care provider's duty to attempt to obtain meaningful informed consent.

In addition, health care acts have been amended to include more specific direction to assure that patients receive information that the typical person would reasonably want to know when providing consent to medical care.

Informed consent is a patient's agreement to have a medical procedure after receiving full disclosure of risks, benefits, alternatives, and

consequences of refusal (Furrow et al., 2018; Pozgar, 2016). Informed consent requires a health care provider to disclose information in terms a patient can understand to make an informed choice (Cruzan, 1990; Furrow et al., 2018). Failure to obtain consent in situations other than emergencies can result in a claim of battery.

Informed consent is part of the health care provider–patient relationship. It must be obtained and witnessed when the patient is not under the influence of medication such as opioids. In most situations obtaining patients’ informed consent does not fall within the nurse’s responsibility. The person responsible for performing the procedure is responsible for obtaining the informed consent.

Key elements of informed consent include the following (Furrow et al., 2018):

1. The patient receives an explanation of the procedure or treatment.
2. The patient receives the names and qualifications of people performing and assisting in the procedure.
3. The patient receives a description of the serious harm, including death, that may occur as a result of the procedure and anticipated pain and/or discomfort.
4. The patient receives an explanation of alternative therapies to the proposed procedure/treatment and the risks of doing nothing.
5. The patient knows that he or she has the right to refuse the procedure/treatment without discontinuing other supportive care.
6. The patient knows that he or she may refuse the procedure/treatment even after the procedure has begun.

Nurses witness consent; they do not obtain consent for procedures performed by others (Furrow et al., 2018). The nurse’s signature as a witness to the consent means that the patient appeared to voluntarily give consent, he or she appeared capable to give consent, and that the patient signed the consent in the nurse’s presence. If you suspect that the patient does not understand or did not voluntarily and/or knowingly give consent, notify the health care provider and nursing supervisor. If necessary to assure valid consent, contact the medical director. If a patient refuses the treatment, ensure that documentation of the rejection is written, signed, and witnessed. Nursing students cannot and should not be responsible for or asked to witness consent forms because of the legal nature of the document.

Parents are usually the legal guardians of pediatric patients; they typically are the people who sign consent forms for treatment. Occasionally a parent or guardian refuses treatment for a child. For example, you are caring for a child whose parents do not want their child to receive the measles, mumps, rubella (MMR) vaccine. The court may intervene on the child's behalf. Courts generally consider the child's ultimate safety and well-being as the most important factors. Under these circumstances, the court may also order the child to be vaccinated under the doctrine of *parens patriae*, in the best interests of the child and those who may be exposed to the disease if the unvaccinated child is exposed to and develops measles.

In some instances, obtaining informed consent is difficult. For example, if a patient is unconscious, you must obtain consent from a person legally authorized to give it on the patient's behalf. Sometimes a patient has legally designated surrogate decision makers through special power of attorney documents or court guardianship procedures. In emergencies, if it is impossible to obtain consent from the patient or an authorized person, a health care provider may perform a procedure required to benefit the patient or save a life without liability for failure to obtain consent. In such cases the law assumes that the patient would wish to be treated.

Patients with mental illnesses or substance use disorders must also give consent. They have the right to refuse treatment until a court has determined legally that they are incompetent to decide for themselves. Informed consent is one aspect of health care statutes. Implications related to informed consent are influenced by many related statutes.

Good Samaritan Laws

Good Samaritan laws encourage health care professionals to assist in emergencies (Furrow et al., 2018). These laws limit liability and offer legal immunity if a nurse helps at the scene of an accident. For example, if you stop at the scene of an automobile accident and give appropriate emergency care such as applying pressure to stop hemorrhage, you are acting within accepted standards, even though proper equipment is unavailable. If the patient subsequently develops complications due your actions, you are immune from liability if you acted without gross negligence (Furrow et al., 2018; Good Samaritan Act, 1997). Although Good Samaritan laws provide immunity to a nurse who does what is reasonable to save a person's life, if you perform a procedure exceeding your scope of practice and for which you have no training, you are liable

for injury that may result from that act. You should only provide care that is consistent with your level of knowledge and experience. In addition, once you have committed to providing emergency care to a patient, you must stay with that patient until you can safely transfer his or her care to someone who can provide needed care, such as emergency medical technicians (EMTs) or emergency department staff. If you leave the patient without properly transferring or handing him or her off to a capable person, you may be liable for patient abandonment and responsible for any injury suffered after you leave him or her (Furrow et al., 2018; Pozgar, 2016).

Public Health Laws

Public health laws affect individuals, populations, and communities. They may be either federal or state statutes that are intended to improve the health of people. State legislatures enact statutes under health codes, which describe the requirements for reporting communicable diseases, school immunizations, and other conditions intended to promote health and reduce health risks in communities. The Centers for Disease Control and Prevention (CDC) (<http://www.CDC.gov>) and the Occupational Health and Safety Act (OHSA) (<http://www.osha.gov>) provide guidelines on a national level for safe and healthy communities and work environments. Public health laws protect populations, advocate for the rights of people, regulate health care and health care financing, and ensure professional accountability for care provided.

Nurses have the legal duty to provide care to protect public health (see [Chapter 3](#)). These laws include reporting suspected abuse and neglect of a child, older adult, or victim of domestic violence; reporting communicable diseases; ensuring that patients in the community have received required immunizations; and reporting other health-related issues to protect public health. In most states, all nurses are mandatory reporters of abuse or neglect of patients when they have reasonable suspicion to believe an individual is at risk of harm. In most states, **neglect** means a pattern of conduct by a person with a duty of care to provide services that maintain the physical and/or mental health of a child or vulnerable adult (Adigun & Hatcher, 2019). It may also be a one-time act that is a clear and present danger to another's health, welfare, or safety. Neglect does not usually require that a nurse intentionally acts to harm a patient; rather, the nurse knew or should have known that neglect would occur under the circumstances. Abuse means the willful act or inaction that inflicts injury,

confinement, intimidation, or punishment on a child or an adult. Of note in situations of neglect or abuse, the standard of proof to report is that a nurse has a reasonable suspicion that the person may be at risk of harm. Nurses must place the health and safety of the patient above that of the caregiver when making the decision to report. Health care professionals who do not report instances when they have suspicion of abuse or neglect may be liable for civil or criminal legal action. Some State Boards of Nursing now require mandatory continuing education on abuse and neglect for license renewal or before obtaining a new nursing license.

The Uniform Determination of Death Act

Many legal issues surround the event of death, including a basic definition of the actual point at which a person is legally dead. The definitions vary by state law. There are two standards for the determination of death. The cardiopulmonary standard requires irreversible cessation of circulatory and respiratory functions. The whole-brain standard requires irreversible cessation of all functions of the entire brain, including the brainstem. Most states have statutes like the proposed language in the [Uniform Determination of Death Act \(1980\)](#). It states that health care providers can use either the cardiopulmonary or the whole-brain definition to determine death. Be aware of legal definitions of death in your state because you need to document relevant information when the patient is in your care. Nurses have a specific legal obligation to treat the deceased person's remains with dignity (see [Chapter 36](#)). Wrongful handling of a deceased person's remains causes emotional harm to the surviving family.

Legal Implications and Issues Associated with Nursing Practice

Some patients or their families, especially those who experience poor health outcomes, believe that care provided by nurses failed to fall within the scope of nursing practice or failed to meet the standards of nursing practice. Sometimes in these cases, patients or their families file torts or lawsuits in the courts, alleging that the nurses knew, or should have known, that their behavior was less than what a reasonably prudent nurse would do under similar circumstances.

Torts

Torts are civil wrongful acts or omissions made against a person or property. They are classified as intentional, quasi-intentional, or unintentional.

Intentional torts are deliberate acts against a person or his or her property that may result in both civil and criminal actions. Assault is an intentional threat toward another person that places the person in reasonable fear of harmful, imminent, or unwelcome contact (Furrow et al., 2018). No actual contact is required for an assault to occur. For example, if a nurse threatens to give a patient an injection or to restrain a patient for an x-ray film procedure when the patient has refused consent, the nurse's action is considered an assault. Likewise, assault occurs when a patient threatens a nurse. **Battery** is any intentional offensive touching without consent or lawful justification (Furrow et al., 2018; Nuse, 2017). The contact can be harmful to the patient and cause an injury, or it merely can be offensive to the patient's personal dignity. In the example of a nurse threatening to give a patient an injection without the patient's consent, if the nurse gives the injection, it is battery. Battery also results if the health care provider performs a procedure that goes beyond the scope of a patient's consent. For example, if a patient gives consent for an appendectomy and the surgeon performs a tonsillectomy, battery has occurred. The key component is the patient's consent. False imprisonment occurs when a patient is restrained without a legal reason. False imprisonment happens when nurses restrain a patient in a confined area, preventing the ability to move freely in a bed, chair, room, or other area in which the patient wishes to be (Furrow et al., 2018; Yeung et al., 2019).

Quasi-Intentional Torts

Quasi-intentional torts are acts in which a person may not intend to cause harm to another but does. Typically, the person invades another's privacy or in some way defames his or her character. Quasi-intentional torts are alleged when a person should have known that harm to another person could occur.

Invasion of privacy is usually the release of a patient's health care information to an unauthorized person, such as a member of the press, the patient's employer, the patient's family, or online. HIPAA and the HITECH Act privacy standards have raised awareness of the need for health care professionals to provide confidentiality and privacy. The information that is in a patient's medical record is a confidential communication that may be shared only with health care providers to provide treatment. This includes electronic communication by e-mail, text, or other devices. All communications become part of the health care record and must be considered confidential. They may not be released without permission of the patient. Individuals who insist on receiving information without patient consent must immediately be referred to a supervisor. It is not within the nurse's scope of practice to determine when information should or should not be disclosed.

Defamation of character is the publication of false statements that result in damage to a person's reputation. **Slander** occurs when one speaks falsely about another. For example, if a nurse tells people erroneously that a patient has gonorrhea and the disclosure affects the patient's business, the nurse is liable for slander. **Libel** is the written defamation of character (e.g., charting false defamatory entries in a medical record) (Furrow et al., 2018; Philo et al., 2015).

Unintentional Torts

Unintentional torts arise when a person is harmed and the person inflicting the harm knew, or should have known, that his or her actions were less than the accepted scope and standard of practice.

Negligence is conduct that falls below the generally accepted standard of care of a reasonably prudent person (Furrow et al., 2018). Anyone, including people not in the medical field, can be liable for negligence. A nurse is negligent when he or she had a duty of care that is breached and a patient is physically harmed. A reasonably prudent nurse under similar circumstances would have provided care differently. The law establishes the standard of care to protect others against an unreasonably great risk of

harm (Furrow et al., 2018). Negligent acts, such as hanging the wrong intravenous solution for a patient, often result in disciplinary action by the State Board of Nursing and a lawsuit for negligence against the nurse and his or her employer. Most lawsuits allege negligence.

Malpractice is a type of negligence. A person being held liable for malpractice must be a professional. Certain criteria are necessary to establish nursing malpractice: (1) the nurse (defendant) owed a duty of care to the patient (plaintiff), (2) the nurse did not carry out or breached that duty, (3) the patient was injured due to the breach in duty, and (4) damages or remedies are allowed under state law to “make the person whole” in the eyes of the court. Even though nurses do not intend to injure patients, some patients file claims of malpractice if nurses give care that does not meet the appropriate standards. Most malpractice and professional licensure claims occur in hospital settings. Common causes of malpractice against nurses include failure to follow the standard of care (e.g., not implementing a pressure injury or fall prevention protocol), failure to communicate important information to another health care provider, failure to document appropriately, failure to assess and monitor a patient, and inappropriate delegation of nursing tasks.

More health care agencies are using medication administration technology, such as bar coding, to try to reduce medication administration errors. However, the capacity to override or work around intended safeguards has contributed to significant harm to patients. It is essential that you always follow the policies and procedures at your agency and never override safeguards intended to promote safe patient care. In Tennessee (2018), a nurse and medical center were found in violation of federal and state law after a “help-all” nurse erroneously retrieved and administered the wrong medication to a patient in radiology. The patient was left unsupervised, went into cardiac arrest, and later died. Subsequently, civil and criminal indictments have been filed.

Malpractice sometimes involves failing to check a patient’s identification correctly before administering blood and then giving the blood to the wrong patient. It also involves administering a medication to a patient even though the medical record contains documentation that the patient has an allergy to that medication. In general, courts define nursing malpractice as the failure to use a degree of skill or learning ordinarily used under the same or similar circumstances by members of the nursing profession (Furrow et al., 2018).

Another area of potential risk is associated with the use of electronic monitoring devices. No monitor is always reliable. Therefore, do not

depend on them completely. Continual assessment of a patient is necessary to help determine the accuracy of electronic monitoring. There are also electrical hazards to the nurse and the patient. Biomedical engineers check equipment to ensure that it is in proper working order and that a patient will not receive an electrical shock. Document when calibration of equipment occurs.

The best way for nurses to avoid malpractice is to follow evidence-based standards of care, deliver care competently, and communicate with other health care providers. You also avoid malpractice by developing a caring rapport with patients and thoroughly documenting assessments, interventions, and evaluation of care. Generate and act on your spirit of inquiry to provide the best care in conjunction with your patients' preferences and values. Know and follow the policies and procedures of the agency where you work. Be sensitive to your patients' risks and the common sources of patient injury such as pressure injuries, falls, and medication errors. Finally, communicate with your patients; explain all tests, medications, and treatments; document patient education you provide; and listen to your patients' concerns about treatments. You are accountable to report any significant changes in your patient's condition in a timely manner to the health care provider and to document these changes in the patient's electronic health record (see [Chapter 26](#)). Timely and truthful documentation is important to provide communication necessary among health care team members. Documentation must be accurate ([Furrow et al., 2018](#)). In the electronic health record (EHR), assure that assessments are complete and consistent with those completed previously. Ensure that you conduct your own assessment rather than copying the previous assessment in the patient's medical record to ensure accuracy of information. Investigate and do not override safeguards built into each program to alert you to concerns such as black box warnings when administering medications. Notify other team members in a timely manner when changes in condition are triggered within the record. If you are named in a malpractice suit, you need to know your rights and understand the legal process ([Box 23.3](#)). Work with your health care agency's legal team, and be sure to advocate for yourself.

Box 23.3 Anatomy of a Lawsuit

Pleadings Phase

Petition: Elements of the claim. The plaintiff outlines what the defendant nurse did wrong and, because of that alleged negligence, how the plaintiff was injured.

Answer: The nurse admits or denies each allegation in the petition.

The plaintiff must establish anything that the nurse does not admit.

Discovery: The process of discovering all the facts of the case involves using interrogatories, full access to the medical records in question, and the depositions. The patient and the health care staff are asked questions by counsel for the defense. They answer under oath, and their testimony is recorded and kept for reference.

Interrogatories: Written questions requiring answers under oath. Typically opposing counsel requests a list of possible witnesses, insurance experts, and which health care providers the plaintiff saw before and after the event.

Requests for productions: Opposing parties request relevant documents, pictures, or related materials such as medical records for treatment before and after the event.

Depositions: Questions are posed to opposing parties, witnesses, and experts under oath to obtain all relevant, nonprivileged information about the case. Experts establish the elements of the case and the applicable standard of care.

Medical records: The defendant obtains all the plaintiff's relevant medical records for treatment before and after the event. Everything written by the nurses and the health care provider in the medical record is open to examination by both the plaintiff and the defendants. This includes all e-mails, texts, and other social media communications.

Witnesses' deposition: Questions are posed to the witnesses under oath to obtain all relevant, nonprivileged information about the case.

Parties' depositions: The plaintiff and defendants (health care provider, nurse, and hospital personnel) are almost always deposed.

Other witnesses: Factual witnesses, both neutral and biased, are deposed to obtain information about their version of the case. They may include family members on the plaintiff's side and other medical personnel (e.g., nurses) on the defendant's side.

Experts: The plaintiff selects experts to establish the essential legal elements of the case against the defendant. The defendant selects

experts to establish the appropriateness of the nursing care. Nursing experts are asked to testify to the reasonableness or inappropriate actions of the health care staff once the patient's condition began to change. The expert is asked to compare the actions of the nursing staff to the standard of care.

Trial: The trial usually occurs 3 years after the filing of the petition. Most are settled before trial.

If a health care provider negligently alters or loses medical records relevant to a malpractice claim, the health care provider must explain why these events occurred. An agency must maintain nursing records according to specific statutes and accreditation regulations. Nursing notes contain substantial evidence needed to understand the care received by a patient. If records are lost, incomplete, or altered, there is a presumption that the care was negligent and therefore the cause of the patient's injuries. In addition, incomplete or illegible records make a health care provider less credible or believable. Determine changes in patient conditions documented by prior nursing staff, and document timely responses to those changes. In addition, it is essential to provide and document patient decision making; the patient is the primary decision maker, regardless of setting, when care is provided. EHRs can be retrieved in their existent form on any day. Thus, it is apparent when you have viewed or altered records documentation. In addition, EHRs can be retrieved and compared as they existed in real time from one moment to another. When making a late entry into an electronic record, it is essential that the amended note be entered as such; never delete and then reenter different language representative of the same date and time as had been previously erased. Regardless of intent, the record subsequently may be considered altered to protect the agency and hide information from the court regarding care received or not received by the patient.

Beginning- and End-of-Life Nursing Issues

Termination of Pregnancy

In 1973 in the case of *Roe v Wade*, the US Supreme Court ruled that there is a fundamental right to privacy, which includes a woman's decision to terminate a pregnancy. The court ruled that during the first trimester a woman could end her pregnancy without state regulation because the risk of natural mortality from abortion is less than with normal childbirth. During the second trimester the state has an interest in protecting maternal

health, and it enforces regulations regarding the person terminating the pregnancy and the agency where it is done. By the third trimester, when the fetus becomes viable, the interest of the state is to protect the fetus; therefore, it prohibits termination except when necessary to save the mother.

In *Webster v Reproductive Health Services (1989)*, the court substantially narrowed *Roe v Wade*. Some states require viability tests before conducting abortions. Other states require a minor's parental consent or a judicial decision that the minor is mature and can self-consent, while other states do not require parental consent. Recently, some states have passed "heartbeat" laws, which state a pregnancy may not be terminated after a heartbeat is heard. Thus it is critical to know the law in your state related to termination of pregnancy before working in this area of practice.

Death With Dignity or Physician-Assisted Suicide

Providing end-of-life care in today's world is challenging for health care professionals because people are living longer (see [Chapter 36](#)). The Oregon Death with Dignity Act (1994) was the first statute that legislatively defined "death with dignity," sometimes called *physician-assisted suicide*. The statute stated that a competent individual with a terminal disease could make an oral and written request for medication to end his or her life in a humane and dignified manner. A terminal disease is defined as an "incurable and irreversible disease that has been medically confirmed and will, within reasonable medical judgment, produce death within 6 months."

The [ANA \(2019a\)](#) believes that nurses' participation in assisted suicide violates the code of ethics for nurses. The American Association of Colleges of Nursing (AACN) has historically supported the International Council of Nurses' mandate to ensure an individual's peaceful end of life. The positions of these two national organizations are not considered contradictory and require nurses to approach a patient's end of life with openness to listening to a patient's expressions of fear and to attempt to control a patient's pain during his or her last months of life. You need to know your state's laws and ensure that your practice falls within the laws' requirements.

Nursing Workforce Issues

Nursing Students

Nursing students are liable if their actions exceed their scope of practice and cause harm to patients. Regardless of intent, students are expected to know what they can and cannot do when providing care to patients. If a student harms a patient as a direct result of a lack of action, the student, instructor, hospital or health care agency, and university or educational institution generally share the liability for the incorrect action. Nursing students should never be assigned to perform tasks for which they are unprepared, and instructors should supervise them carefully as they learn new skills. Although nursing students are not employees of the hospital, the agency has a responsibility to monitor their acts. They are expected to perform as professional nurses would in providing safe patient care. Faculty members are usually responsible for instructing and observing students, but in some situations staff nurses serving as preceptors share these responsibilities. Every nursing school should provide clear definitions of preceptor and faculty responsibility. It is equally important that nursing preceptors be aware of state laws applicable to nursing students, faculty, and the educational institution when supervising students.

Nursing students should perform only tasks that have been delegated to them and that are included in their titled job description when they are employed in health care settings (e.g., as nursing assistants, medication technicians). For example, if a student who also works as a medication technician has learned to administer intramuscular (IM) medications in a nursing class, the student cannot administer IM injections when working as a medication technician unless this is allowed under the state's Nurse Practice Act and the student's job description. If a staff nurse assigns a nursing student work without regard for the student's ability to safely conduct the task defined in the job description, the staff nurse is also liable. A student employed in the agency as a nurse's aide must refuse to perform tasks that he or she is not prepared to complete safely. The student employee must tell the supervisor so that the task can be assigned to an appropriate health care professional. Patient safety is essential. Nursing students must assure that their actions meet the scope of nursing required of them. Their actions must meet the standards of practice required for safe care of a patient whether they are at school, in the community, or employed at health care agency. While you may have learned about a nursing task, it does not mean that you can safely perform the task on a patient. Err on the side of caution. Do not exceed your scope of practice whether you are a nurse's aide, nursing assistant, medication assistant, nursing student medication technician, or any other title.

Staffing and Nurse-to-Patient Ratios

Adequate staffing is required to assure patient safety and satisfaction with care. Nurse-to-patient ratios are determined in different ways. Legal issues occur when there are not enough nurses to provide competent care or when nurses work excessive overtime. In the case of *Spires v Hospital Corporation of America* (2006), poor patient care due to insufficient RN staffing resulting in the death of a patient was alleged. This suit emphasized the potential seriousness of short staffing and the importance of nurses' asserting employee rights.

Many states require that safe staffing nursing committees in acute care settings determine safe staffing based on the needs of patients admitted to their facilities. While staffing committees have worked to determine appropriate staffing needs, employers have inappropriately asked some committees to make budgetary recommendations to pay for the staffing. In California, fixed nurse-patient ratios in acute care settings are mandated by law. The safe staffing ratio debate is occurring throughout the country and demands close attention by all nurses (ANA, 2019b).

The ANA and other professional nursing organizations have supported federal legislation titled the Safe Staffing for Nurse and Patient Safety Act of 2018 (ANA, 2019b). Ideally, hospitals receiving Medicare reimbursement will be required to have staffing committees, 55% of which will be direct-care nurses. Committees will develop and implement staffing plans for each unit. Patients will receive better care, and it is anticipated that a decrease will occur in adverse events, nurse turnover, and hospital readmissions. Under this act, nurses become an integral part of ensuring that patients receive care from nurses qualified to meet their needs in a safe environment.

Nursing Assignments

Nurses are sometimes required to work on a unit where they do not typically care for patients. In this practice, often called "floating," nurses temporarily work in another area because there are not enough nurses to care for the number of patients and the acuity of the patients' needs on that unit at that time. If you are asked to float, you must inform the supervisor if you do not have the required education or experience to care for the patients assigned to you. You should request and receive an orientation to the unit. Supervisors are responsible if they give a staff nurse an assignment that he or she cannot handle safely. Before accepting

employment, learn the policies of the agency regarding floating and understand what is expected ([ANA, 2018](#)).

Patient Abandonment

Patient abandonment occurs when a nurse refuses to provide care for a patient after having established a patient-nurse relationship. Before having established that relationship, a nurse may refuse an assignment when (1) the nurse lacks the knowledge or skill to provide competent care; (2) care exceeding the Nurse Practice Act is expected; (3) health of the nurse or the nurse's unborn child is directly threatened by the type of assignment; (4) orientation to the unit has not been completed and safety is at risk; (5) the nurse clearly states and documents a conscientious objection on the basis of moral, ethical, or religious grounds; or (6) the nurse's clinical judgment is impaired as a result of fatigue, resulting in a safety risk for the patient ([ANA, 2015a](#); [NSO, 2017](#)).

When refusing an assignment, it is important to give your immediate supervisor specific reasons for the refusal and to determine whether other alternatives, such as reassignment, are available. Document in your personal notes the specifics of the incident, to whom you reported it, and actions you took to ensure that patients were safe and that you did not abandon your patients.

Nurse Delegation

Nurse delegation is defined in Nurse Practice Acts; regulations vary from state to state. Generally, **nurse delegation** means that an RN educates, observes, and verifies that a non-nurse can do a specific task that is usually completed by a nurse (see [Chapter 21](#)). Several requirements assure patient safety when delegating care. The RN retains responsibility to supervise care received by the patient and to periodically reassess whether nurse delegation continues to be appropriate. RNs usually delegate to nursing assistants who work in specified settings. Delegated tasks may include administration of prescription medications or blood glucose monitoring. It is important to know delegation requirements, including patient consent, caregiver education and experience, and the role and responsibilities of the RN. Some State Boards of Nursing or commissions define responsibilities of the RN specifically and develop position statements and guidelines to help licensed nurses delegate safely to assistive personnel ([NCSBN, 2016](#); [NCSBN & ANA, 2019](#)).

Risk Management and Performance/Quality Improvement

Risk-management and performance improvement (PI) and quality improvement (QI) programs help to reduce a nurse's legal risk for malpractice and negligence because they help to identify potential hazards and eliminate them before harm occurs. The two processes are similar, but PI places more emphasis on human performance, whereas QI focuses on work processes. These programs also promote a "just culture" environment that encourages honest disclosure and systemwide resolution to prevent occurrence or reoccurrence of circumstances surrounding a concern. **Risk management** involves several components, including identifying possible risks, analyzing them, acting to reduce the risks, and evaluating the steps taken to reduce them (TJC, 2019). QI, PI, and risk-management procedures are essential; they require documentation of information to facilitate resolution of questions regarding care.

Nurses are risk managers. For example, surgeons rely on operating room nurses to compare the consent form with the indicated and prepped surgical site for accuracy. TJC's Universal Protocol helps prevent errors due to patients undergoing the wrong surgery or having surgery performed on the wrong site (TJC, 2020). The protocol requires mandatory time-outs before beginning any surgery. Nurses are responsible to implement this protocol whenever an invasive surgical procedure is to be performed, regardless of the location (hospital, ambulatory surgical center [ASC], or health care provider office). The three principles of the protocol are (1) preoperative verification that relevant documents and studies are available before the start of the procedure and that these documents are consistent with the patient's expectations; (2) marking the operative site with indelible ink to mark left and right distinction, multiple structures (e.g., fingers), and levels of the spine; and (3) a *time-out* just before starting the procedure for final verification of the correct patient, procedure, site, and any implants (see Chapter 50).

Patient safety and improved care are the goals of QI, PI, and risk management (TJC, 2019). Professional groups such as the Institute of Medicine focus on patient safety as major goals. *Never events* are preventable errors, which include falls, urinary tract infections from improper use of catheters, and pressure injuries (AHRQ, 2018). The federal government and health care insurance companies have developed policies to withhold reimbursement for never events (AHRQ, 2018) (see Chapter 27). All inpatient health care settings conduct routine monthly monitoring

of the incidence of never events, and health care staff are expected to maintain standards for prevention of these events. When trending shows an increase in never events, QI and PI activities are quickly implemented. Know your agency's policies and procedures to help develop a system and culture of patient safety.

One tool used in risk management is the **occurrence report** or incident report. Occurrence reporting provides a database to determine deviations from standards of care, to identify corrective measures needed to prevent recurrence, and to alert risk management to a potential claim (see Chapter 23). Examples of an occurrence include patient or visitor falls or injury; failure to follow health care provider orders; a significant complaint by patient, family, health care provider, or other hospital department; an error in technique or procedure; and a malfunctioning device or product. Agencies generally have specific guidelines to direct health care providers in how to complete occurrence reports. A report is confidential and separate from the health care record. However, it is discoverable by court order during a legal proceeding. Risk managers work with nurses to provide safe care and to determine how to prevent reoccurrence of circumstances when a patient is potentially or actually harmed.

Nurse Experts

A nursing expert testifies about the standards of nursing care as applied to the facts of a case (Box 23.4). An expert has education and experience related to the alleged complaint of the patient and accurately and concisely describes the pertinent scope and standards of practice required of a nurse under similar circumstances. For example, when a patient sustains an injury from a fall, a nurse with experience in risk management and fall prevention will be asked to consult as an expert on the case. The expert nurse must determine that no conflict of interest exists before accepting a case. For example, the expert nurse could not work for either party's employer. The expert will review all evidence before giving an opinion, including relevant laws and regulations, policies and procedures, patient records, other expert reports, and depositions. Depositions are interviews in which lawyers can ask questions of others who are under oath to provide honest and complete answers. These interviews are transcribed by a court reporter who is present during the sessions. For example, opposing counsel will depose the expert nurse. During the deposition, the nurse will respond to the questions that are asked. The court reporter will record the session in writing, on audiotape, and sometimes on videotape. Within a

couple of weeks, the deposition document will be given to all parties to make corrections. Once completed, the document is finalized and will be entered into the case record (Furrow et al., 2018). Nurse experts base their opinions on existing standards of practice established by Nurse Practice Acts, federal and state licensing laws, TJC standards, professional organizations, institutional policies and procedures, job descriptions, and current evidence-based literature. Nurses must meet the same standards as other nurses practicing in similar settings and under similar circumstances. Specialized nurses such as critical care nurses, wound care specialists, or surgical nurses have specially defined standards of care and skills. Ignorance of the law or of standards of care is not a defense against malpractice (Furrow et al., 2018). Nurses are required to know valid, reliable, and credible evidence that is applicable to their practice and the settings in which they work, including current standards of care and the policies and procedures of their employing agency (ANA, 2015a; TJC, 2019). Expert nurses offer opinions on whether others have met the standard of practice; they do not make legal decisions.

Box 23.4 Proof of Negligence

- The nurse owed a duty of care to the patient.
- The nurse did not carry out the duty or breached it (failed to use that degree of skill and learning ordinarily used under the same or similar circumstances by members of the profession).
- The patient was physically injured or harmed because the nurse breached the duty.
- The patient's injury resulted in compensable damages that can be qualified as medical bills, lost wages, and pain and suffering.

Common Sources of Negligence

Be aware of the common negligent acts that have resulted in lawsuits against hospitals and nurses.

- Failure to assess and/or monitor, including making a nursing diagnosis

- Failure to observe, assess, correctly diagnose, or treat in a timely manner
- Failure to use, calibrate, or replace equipment required to safely care for the patient
- Failure to document care and evaluation of care provided to the patient in a timely manner
- Failure to notify the health care provider of significant changes in a patient's status
- Failure to respond to or correctly implement new and existing orders
- Failure to follow the seven rights of medication administration
- Failure to convey discharge instructions to the patient, his or her family, or providers who are assuming responsibility for the patient
- Failure to ensure patient safety, especially patients who have a history of falling, are sedated or confused, are frail, are mentally impaired, get up in the night, or are uncooperative
- Failure to follow policies and procedures
- Failure to properly delegate and supervise

One of the first and most important cases to discuss a nurse's liability was *Darling v Charleston Community Memorial Hospital* (1965). It involved an 18-year-old man with a fractured leg. The emergency department physician applied a cast with insufficient padding. The man's toes became swollen and discolored, and he developed decreased sensation. He reported the decreased sensation to nursing staff many times. Although the nurses recognized the symptoms as signs of impaired circulation, they failed to tell their supervisor that the physician did not respond to their calls or the patient's needs. Gangrene developed, and the man's leg was amputated. Although the physician was held liable for incorrectly applying the cast, the nursing staff were also held liable for failing to adhere to the standards of care for monitoring and reporting the patient's symptoms. Even though the nurses attempted to contact the physician, the jury and subsequent judges held that when the physician failed to respond, the nurses should have acted on behalf of the patient's safety and obtained assistance from the charge nurse, nursing supervisor, and the chief medical officer to make sure that the patient received appropriate care. Almost every state uses this 1965 Illinois Supreme Court case as a legal precedent.

Building Competency in Quality Improvement

You are a member of your unit's task force focusing on quality improvement and reduction in sentinel events. The chairperson explains to the task force that quality improvement relates to data collection, evaluation, and improvement in patient outcomes. One of the nurses asks, "How can we reduce the number of occurrence reports being filed on the unit related to patient falls?" How would you respond?

Professional Involvement

As a professional nurse, it is important to remain aware of current issues in health care. Become involved in professional organizations and committees that define the standards of care for nursing practice. If current laws, rules and regulations, or policies under which nurses practice are not evidence based, advocate to ensure that the scope of nursing practice is defined accurately. Be willing to represent nursing and the patient's perspective in the community as well. The voice of nursing is powerful and effective when the organizing focus is the protection and welfare of the public entrusted to nurses' care.

Key Points

- Constitutional law refers to rights granted to citizens in the US Constitution and state constitutions. Civil laws are passed by Congress and state legislatures to protect the rights of individuals. Criminal laws are passed by Congress and state legislatures to protect society and provide punishment for crimes.
- Statutory law is civil or criminal. Civil laws protect the rights of individuals as in the case of a Nurse Practice Act, which defines the scope of nursing practice and the standards you must meet within individual states to ensure safe evidence-based and competent nursing practice.

- The scope of nursing practice defines nursing and reflects the values of the nursing profession. Standards of nursing care reflect the knowledge and skill ordinarily possessed and used by nurses.
- A nurse has a duty of care. When a nurse's performance is questioned, the standard of proof in nursing is typically what a reasonably prudent nurse would do under similar circumstances in the geographic area in which the alleged breach occurred.
- The Health Insurance Portability and Accountability Act, Health Information Technology Act, and Americans with Disabilities Act are examples of federal statutes that affect nursing practice.
- The Patient Self-Determination Act is a federal statute that requires health care institutions to provide information to patients regarding their rights to make informed decisions about their care, including the right to create an advanced directive. When a patient has an advanced directive that includes a "do not resuscitate" (DNR) order, you need to ensure that the patient and provider have discussed end-of-life choices and that the discussion is documented in the patient's medical record.
- Physical or chemical restraints are used only as a last resort to ensure the physical safety of the patient or other patients when less restrictive interventions are unsuccessful and require a written order from a health care provider.
- A nurse's witness to a patient's informed consent indicates that the patient appeared to voluntarily give consent, that he or she appeared capable to give consent, and that the patient signed the consent in the nurse's presence.
- Negligence occurs when a nurse had a duty of care that is breached, a patient is physically harmed, and damages are provided to "make the person whole"; a reasonably prudent

nurse under similar circumstances would have done care differently.

- Worsening pressure injuries, failure to contact the provider as conditions change, and medication errors often trigger complaints of negligence or malpractice against nurses.
- It is important to know your Nurse Practice Act, to implement and follow agency policies and procedures, to delegate care appropriately, and to participate in risk-management and quality improvement activities to reduce your legal risk when practicing nursing.

Reflective Learning

You are working in an outpatient clinic where you meet a 34-year-old married mother of two small children who is seeing the doctor for numbness and tingling in her right leg. Over the next 6 months, she has critically high glucose levels, she doesn't take her medication, and the provider is significantly concerned. She continues to have numbness and tingling that migrate from her left hip, leg, and foot. The physician orders scans of her leg and lower spine. Each scan is negative. She continues to have pain and numbness and tingling in her neck, back, and legs. During her most recent visit, the provider orders a scan of her thoracic spine and right knee. One week later, the patient e-mails the provider that while the knee scan was completed, no one has contacted her about the other scan. The nurse checks the record and responds, "My bad.... I missed it.... I'll order it now." The next day the patient unexpectedly appears at the clinic, where you observe her staggering at the desk and slurring her speech, asking to see you. You and the receptionist place her immediately into a wheelchair. After being assessed, she is admitted to the hospital, where she is diagnosed with a slow bleed into the spinal column. The patient has irreparable damage to the spine and will be quadriplegic the remainder of her life.

- What standards of practice apply in this scenario?
- Does this situation establish negligence? Specifically, what is the duty, the breach in duty, the permanent harm, and damages in

this case?

- What is the standard of proof that would be applied to this situation to determine whether the nurse is liable for the harm incurred by this patient? Make a case for either side.

Review Questions

1. A nurse is planning care for a patient going to surgery. Who is responsible for informing the patient about the surgery along with possible risks, complications, and benefits?
 1. Family member
 2. Surgeon
 3. Nurse
 4. Nurse manager
2. A woman has severe life-threatening injuries, is unresponsive, and is hemorrhaging following a car accident. The health care provider ordered two units of packed red blood cells to treat the woman's anemia. The woman's husband refuses to allow the nurse to give his wife the blood for religious reasons. What is the nurse's responsibility?
 1. Obtain a court order to give the blood.
 2. Convince the husband to allow the nurse to give the blood.
 3. Call security and have the husband removed from the hospital.
 4. Gather more information about the wife's preferences and determine whether the husband is her power of attorney for health care.
3. A nurse sends a text message to the oncoming nurse to report that a patient refuses to take medication as ordered. What should the oncoming nurse do? (Select all that apply).

1. Add this information to the board hanging at the patient's bedside.
 2. Tell the nurse who sent the text that the text is a HIPAA violation.
 3. Inform the nursing supervisor.
 4. Forward the text to the charge nurse.
 5. Thank the nurse for sending the information.
4. Which of the following actions, if performed by a registered nurse, could result in both criminal and administrative law sanctions against the nurse? (Select all that apply.)
1. Reviewing the electronic health record of a family member who is a patient in the same hospital on a different unit
 2. Refusing to provide health care information to a patient's child
 3. Reporting suspected abuse and neglect of children
 4. Applying physical restraints without a written order
 5. Completing an occurrence report on the unit
5. A nurse received bedside report at the change of shift with the night-shift nurse and the patient. The nursing student assigned to the patient asks to review the patient's medical record. The nurse lists patients' medical diagnoses on the message boards in the patients' rooms. Later in the day the nurse discusses the plan of care for a patient who is dying with the patient's family. Which of these actions describes a violation of the Health Insurance Portability and Accountability Act (HIPAA)?
1. Discussing patient conditions at the bedside at the change of shift
 2. Allowing the nursing student to review the assigned patient's chart before providing care during the clinical experience
 3. Posting medical information about the patient on a message board in the patient's room

4. Releasing patient information regarding terminal illness to family when the patient has given permission for information to be shared

6. A patient is in skeletal traction and has a plaster cast due to a fractured femur. The patient experiences decreased sensation and a cold feeling in the toes of the affected leg. The nurse observes that the patient's toes have become pale and cold but forgets to document this because one of the nurse's other patients experienced cardiac arrest at the same time. Two days later the patient in skeletal traction has an elevated temperature, and he is prepared for surgery to amputate the leg below the knee. Which of the following statements regarding a breach of duty apply to this situation? (Select all that apply.)
 1. Failure to document a change in assessment data
 2. Failure to provide discharge instructions
 3. Failure to provide patient education about cast care.
 4. Failure to use proper medical equipment ordered for patient monitoring
 5. Failure to notify a health care provider about a change in the patient's condition

7. A man who is homeless enters the emergency department seeking health care. The health care provider indicates that the patient needs to be transferred to the city hospital for care before assessing the patient. This action is most likely a violation of which of the following laws?
 1. Health Insurance Portability and Accountability Act (HIPAA)
 2. Americans with Disabilities Act (ADA)
 3. Patient Self-Determination Act (PSDA)
 4. Emergency Medical Treatment and Active Labor Act (EMTALA)

8. A home health nurse notices significant bruising on a 2-year-old patient's head, arms, abdomen, and legs. The patient's mother describes the patient's frequent falls. What is the best nursing action for the home health nurse to take?
1. Document her findings and treat the patient.
 2. Instruct the mother on safe handling of a 2-year-old child.
 3. Contact a child abuse hotline.
 4. Discuss this story with a colleague.
9. Which of the following statements indicate that the new nursing graduate understands ways to remain involved professionally? (Select all that apply.)
1. "I am thinking about joining the health committee at my church."
 2. "I need to read newspapers, watch news broadcasts, and search the Internet for information related to health."
 3. "I will join nursing committees at the hospital after I have completed orientation and better understand the issues affecting nursing."
 4. "Nurses do not have very much voice in legislation in Washington, DC, because of the nursing shortage."
 5. "I will go back to school as soon as I finish orientation."
10. You are floated to work on a nursing unit where you are given an assignment that is beyond your capability. Which is the best nursing action to take first?
1. Call the nursing supervisor to discuss the situation.
 2. Discuss the problem with a colleague.
 3. Leave the nursing unit and go home.
 4. Say nothing and begin your work.

Answers: 1. 2; 2. 4; 3. 2,3; 4. 1,4; 5. 3; 6. 1,5; 7. 4; 8. 3; 9. 1,2,3; 10. 1.

Communication

OBJECTIVES

- Identify ways to apply critical thinking to the communication process.
- Use the five levels of communication with patients.
- Describe features of the circular transactional communication process.
- Describe features of the verbal communication process
- Identify key aspects of nonverbal communication process.
- Incorporate features of a helping relationship when interacting with patients.
- Identify a nurse's communication approaches within the four phases of a nurse-patient helping relationship.
- Identify desired outcomes of nurse–health care team member relationships.
- Demonstrate professional communication while interacting with patients.
- Identify opportunities to improve communication with patients while giving care.
- Engage in effective communication techniques for older patients.
- Offer alternative communication devices when appropriate to promote communication with patients who have impaired communication.
- Implement nursing care measures for patients with special communication needs.

KEYTERMS

Therapeutic communication, p. 333

Communication and Nursing Practice

Communication is a lifelong learning process. Nurses make intimate journeys with patients and their families from the miracle of birth to the mystery of death. As a nurse you communicate with patients and families to develop meaningful relationships. Within those relationships you collect relevant assessment data, provide education and counseling and interact during nursing interventions. The use of therapeutic communication promotes personal growth and helps patients reach their health-related goals. Despite the complexity of technology and the multiple demands on nurses' time, it is the intimate moment of connection that makes all the difference in the quality of care and meaning for a patient and a nurse. Communication is essential when establishing nurse-patient relationships and delivering patient-centered care.

Patient safety also requires effective communication among members of the health care team as patients move from one caregiver to another or from one care setting to another. Good communication skills help to reduce the risk of errors. These skills promote improved patient outcomes and increased patient satisfaction (Sethi and Rani, 2017). Effective team communication and collaboration skills are essential to ensure patient safety and optimum patient care (Lazure et al., 2014). Competent communication maintains effective relationships within the entire sphere of professional practice and meets legal, ethical, and clinical standards of care. The qualities and behaviors of therapeutic communication described in this chapter characterize professionalism in caring relationships.

Communication and Interpersonal Relationships

Caring relationships formed by a nurse and those affected by the nurse's practice are at the core of nursing (see Chapter 7). All behavior communicates, and all communication influences behavior. Nurses demonstrate caring by being with, doing for, and enabling patient well-being (Lillykuty and Samson, 2018). The following nursing actions reflect caring:

- Becoming sensitive and supportive to self and others
- Being present and encouraging the expression of positive and negative feelings
- Developing healing relationships
- Instilling faith and hope
- Promoting interpersonal teaching and learning
- Providing for nursing care needs in a supportive way
- Respecting and allowing for spiritual expression

A nurse's ability to relate to others is important for interpersonal communication. This includes the ability to take initiative in establishing and maintaining communication, to be authentic (one's self), and to respond appropriately to the other person. Effective interpersonal communication also requires a sense of mutuality (i.e., a belief that the nurse-patient relationship is a partnership and that both are equal participants). Nurses honor the fact that people are very complex and ambiguous. Often more is communicated than first meets the eye, and patient responses are not always what you expect. Each patient is a unique individual, with specific communication needs. Nurses need to embrace a nonjudgmental, holistic view of people and understand the need for effective, supportive communication and human interaction. When patients and nurses work together, much can be accomplished. Patient- and family-centered communication, such as involving the patient in conversations about transitions in care, contributes to a culture of safety (Johnson, 2015). When these conversations occur at the bedside, providing for privacy is essential.

Therapeutic communication occurs within a healing relationship between a nurse and patient (Arnold and Boggs, 2016). Like any powerful therapeutic agent, a nurse's communication can result in both harm and good. Every nuance of posture, every small expression and gesture, every word chosen, every attitude held—all have the potential to hurt or heal, affecting others through the transmission of human energy. Knowing that intention and behavior directly influence health gives nurses the ethical responsibility to do no harm to those entrusted to their care. Respect the potential power of communication and do not misuse communication carelessly to hurt, manipulate, or coerce others. Skilled communication empowers others to express what they believe and make their own choices; these are essential aspects of the individualized healing process. Nurses have wonderful opportunities to bring about good things for themselves, their patients, and their colleagues through therapeutic communication.

Developing Communication Skills

Gaining expertise in communication requires both an understanding of the communication process and reflection about one's communication experiences as a nurse. Nurses who develop critical thinking skills make the best communicators. They form therapeutic relationships to gather relevant and comprehensive information about their patients. Then they draw on theoretical knowledge about communication and integrate this knowledge with knowledge previously learned through personal clinical experience. They interpret messages received from others to obtain new information, correct misinformation, promote patient understanding, and plan patient-centered care (Arnold and Boggs, 2016).

Critical thinking attitudes and ethical standards of care promote effective communication. When you consider a patient's problems, it is important to apply critical thinking and critical reasoning skills to improve communication in assessment and care of the patient (Arnold and Boggs, 2016). For example, curiosity motivates a nurse to communicate and learn more about a person. Patients are more likely to communicate with nurses who express an interest in them. Perseverance and creativity are also attitudes that motivate a nurse to communicate and identify innovative solutions. A self-confident attitude is important because a nurse who conveys confidence and comfort while communicating more readily establishes an interpersonal caring relationship. In addition, an independent attitude encourages a nurse to communicate with colleagues and share ideas about nursing interventions. Integrity allows nurses to recognize when their opinions conflict with others (e.g., patients, co-workers), review positions of those involved, and decide how to communicate to reach mutually beneficial decisions. It is also very important for a nurse to communicate responsibly and ask for help if uncertain or uncomfortable about an aspect of patient care. An attitude of humility is necessary to recognize when you need to better communicate and intervene with patients, especially related to their cultural needs (Isaacson, 2014).

It is challenging to understand human communication within interpersonal relationships. Each individual bases his or her perceptions about information received through the five senses of sight, hearing, taste, touch, and smell (Arnold and Boggs, 2016). An individual's culture and education also influence perception. Critical thinking helps nurses overcome **perceptual biases** or **stereotypes** that interfere with accurately perceiving and interpreting messages from others. People often incorrectly assume that they understand an individual's culture. They tend to distort or ignore information that goes against their expectations, preconceptions, or stereotypes (Isaacson, 2014). By thinking critically about personal communication habits, you learn to control these tendencies and become more effective in interpersonal relationships.

You become more competent in the nursing process as your communication skills develop. You learn to integrate communication skills throughout the nursing process as you collaborate with patients and health care team members to achieve goals (Box 24.1). Use communication skills to gather, analyze, and transmit information and accomplish the work of each step of the process. Each step of the nursing process depends on effective communication among nurse, patient, family, and others on the health care team. Although the nursing process is a reliable framework for patient care, it does not work well unless you master the art of effective interpersonal communication.

Box 24.1 **Communication Throughout the Nursing Process**

Assessment

- Verbal interviewing and history taking
- Visual and intuitive observation of nonverbal behavior
- Visual, tactile, and auditory data gathering during physical examination
- Written medical records, diagnostic tests, and literature review

Nursing Diagnosis

- Intrapersonal analysis of assessment findings
- Validation of health care needs and priorities via verbal discussion with patient
- Documentation of nursing diagnosis

Planning

- Interpersonal or small-group health care team planning sessions
- Interpersonal collaboration with patient and family to determine implementation methods
- Written documentation of expected outcomes
- Written or verbal referral to health care team members

Implementation

- Delegation and verbal discussion with health care team
- Verbal, visual, auditory, and tactile health teaching activities
- Provision of support via therapeutic communication techniques
- Contact with other health resources
- Written documentation of patient's progress in medical record

Evaluation

- Acquisition of verbal and nonverbal feedback

- Comparison of actual and expected outcomes
- Identification of factors affecting outcomes
- Modification and update of care plan
- Verbal and/or written explanation of care plan revisions to patient

Patients often experience high levels of anxiety when they are ill or receiving treatment. Nurses use self-awareness, motivation, empathy, and social skills to build therapeutic relationships with patients (Marquis and Huston, 2017). Patients' emotions can negatively influence their self-care behaviors. When you understand a patient's perceptions and motivations, you can help the patient make healthy behavior changes.

The nature of the communication process requires you to constantly decide what, when, where, why, and how to convey a message. A nurse's decision making is always contextual (i.e., the unique features of any situation influence the nature of the decisions made). For example, the explanation of the importance of following a prescribed diet to a patient with a newly diagnosed medical condition differs from the explanation to a patient who has repeatedly chosen not to follow diet restrictions. Effective communication techniques are easy to learn, but their application is difficult. Deciding which techniques best fit each unique nursing situation is challenging. Communicating with patients and families about illness such as cancer or advance care planning can be stressful. Nurses may experience grief and fatigue related to emotional exhaustion when discussing these topics, especially when they have developed a bond with patients or families. However, discussion of these important and sensitive topics is linked to an increased quality of life for patients and family members (Zajac et al., 2017).

Throughout this chapter, brief clinical examples will guide you in learning how to use effective communication techniques. Situations that challenge your decision-making skills and call for careful use of therapeutic techniques involve a variety of human behaviors, described in Box 24.2. Because the best way to acquire skill is through practice, it is useful for you to discuss and role-play these scenarios before experiencing them in the clinical setting. Effective communication and collaboration are imperative for success.

Box 24.2 Challenging Communication Situations

- People who are silent, withdrawn, and have difficulty expressing feelings or needs
- People who are sad and depressed

- People who require assistance with visual or speech disabilities (special needs)
- People who are angry or confrontational and cannot listen to explanations
- People who are uncooperative and resent being asked to help others
- People who are talkative or lonely and want someone to be with them all the time
- People who are demanding and expect others to meet their requests
- People who are frightened, anxious, and having difficulty coping
- People who are confused and disoriented
- People who speak and/or understand little English
- People who are flirtatious or sexually inappropriate

Levels of Communication

Nurses use different levels of communication in their professional role. A competent nurse uses a variety of techniques in each level.

Intrapersonal communication is a powerful form of communication that you use as a professional nurse. This level of communication is also called *self-talk*. People's thoughts and inner communications strongly influence perceptions, feelings, behavior, and self-esteem. Always be aware of the nature and content of your own thinking. Positive self-talk provides a mental rehearsal for difficult tasks or situations so that you can deal with them more effectively and with increased confidence ([Arnold and Boggs, 2016](#)). You use intrapersonal communication to develop self-awareness and a positive self-esteem to enhance appropriate self-expression. Positive self-talk can diminish cognitive distortions that lead to a decrease in self-esteem and impact your ability to work with patients. Transforming statements from "I'm scared to work with this type of patient" into "This is my opportunity to learn about this patient, and I can ask for help when it's needed" is an example of positive self-talk.

Interpersonal communication is one-on-one interaction between a nurse and another person that most often occurs face-to-face. It is the level most frequently used in nursing situations and lies at the heart of nursing practice. It takes place within a social context and includes all the symbols and cues used to give and receive meaning. Because meaning resides in people and not in words, messages received are sometimes different from intended messages. Nurses work with people who have different opinions, experiences, values, and belief systems; thus it is important to validate meaning or mutually negotiate it between participants. For example, use interaction to assess understanding and clarify misinterpretations when teaching a patient about a health concern. Meaningful interpersonal communication results in an

exchange of ideas, problem solving, expression of feelings, decision making, goal accomplishment, team building, and personal growth.

Small-group communication is the interaction that occurs when a small number of people meet. This type of communication is usually goal directed and requires an understanding of group dynamics. When nurses work on committees with nurses or other disciplines and participate in patient care conferences, they use a small-group communication process. Communication in these situations should be organized, concise, and complete. All participating disciplines are encouraged to contribute and provide feedback. Good communication skills help each participant better meet a patient's needs and promote a safer care environment.

Public communication is interaction with an audience. Nurses often speak with groups of consumers about health-related topics, present scholarly work to colleagues at conferences, or lead classroom discussions with peers or students. Public communication requires special adaptations in eye contact, gestures, voice inflection, and the use of media materials to communicate messages effectively. Effective public communication increases audience knowledge about health-related topics, health issues, and other issues important to the nursing profession.

Electronic communication is the use of technology to create ongoing relationships with patients and their health care team. Secure messaging provides an opportunity for frequent and timely communication with a patient's physician or nurse via a patient portal. An electronic portal enables patients to stay engaged and informed, though the empathetic nature of the therapeutic relationship with the health care team may be more challenging ([Brandt et al., 2018](#)).

Elements of the Communication Process

Communication is an ongoing and continuously changing process. You are changing, the people with whom you are communicating are changing, and your environment is also continually changing. [Fig. 24.1](#) shows an example of a **circular transactional communication process** model. The model shows the situational contextual inputs, channels of communication, interpersonal contextual concepts, and factors affecting the sender and receiver. Nursing situations have many unique aspects that influence the nature of communication and interpersonal relationships. As a professional you will use critical thinking to focus on each aspect of communication so that your interactions are purposeful and effective.

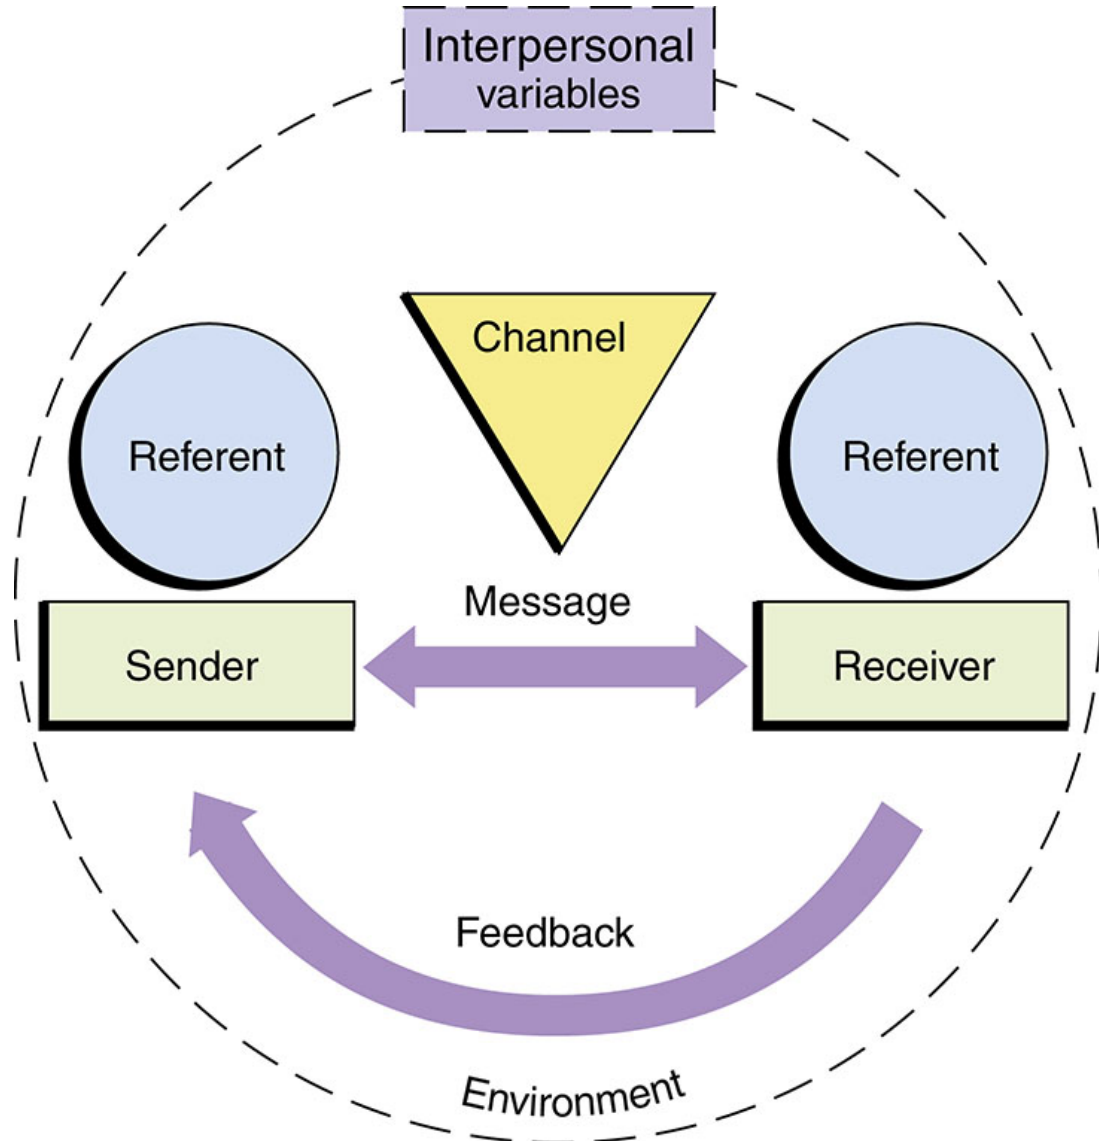

FIG. 24.1 Circular transactional model of communication.

Circular Transactional Model

The **circular transactional model** includes several elements: the referent, sender and receiver, message, channels, context or environment in which the communication process occurs, feedback, and interpersonal variables (see [Fig. 24.1](#)). In this model each person in the communication interaction is both a speaker and a listener and can be simultaneously sending and receiving messages. Both parties view the perceptions, attitudes, and potential reactions to a sent message. Communication becomes a continuous and interactive activity. Feedback from the receiver or environment enables the communicators to correct or validate the communication. This model also

describes the role relationship of the communicators as **complementary** and **symmetrical**. Complementary role relationships function with one person holding an elevated position over the other person. Symmetrical relationships are more equal. A complementary role occurs when a nurse provides education to a patient about a new medication. A group of patients discussing their plans after discharge is an example of a symmetrical role relationship ([Arnold and Boggs, 2016](#)).

Referent

The **referent** motivates one person to communicate with another. In a health care setting sights, sounds, sensations, perceptions, and ideas are examples of cues that initiate the communication process. Knowing a stimulus or referent that initiates communication allows you to develop and organize messages more efficiently. For example, a patient request for help prompted by his difficulty in breathing causes a different response than a patient request resulting from hunger.

Sender and Receiver

The **sender** is the person who encodes and delivers a message, and the **receiver** is the person who receives and decodes the message. The sender puts the message into verbal and nonverbal symbols that the receiver can understand ([Arnold and Boggs, 2016](#)). The sender's message acts as a referent for the receiver. Transactional communication involves the role of sender and receiver switching back and forth between nurse and patient. A decoding process includes the receiver interpreting the meaning of the word symbols. Active listening is important to accurately decode and understand a message. The more the sender and receiver have in common and the closer the relationship, the more likely they will accurately perceive one another's meaning and respond accordingly ([Arnold and Boggs, 2016](#)). Establishing rapport with a patient ensures more effective communication.

Message

The **message** is the content of the communication. It contains verbal and nonverbal expressions of thoughts and feelings. Effective messages are clear, direct, and in understandable language. Individuals with communication barriers may need assistance via clarification devices such as hearing aids, interpreters, or pictures to ensure that messages sent and received are understandable. Personal perceptions may also distort the receiver's interpretation of a message. As a nurse you send effective messages by expressing clearly, directly, and in a manner familiar to a patient. You determine the need for clarification by watching the patient listen for nonverbal

cues that suggest confusion or misunderstanding. Communication is difficult when participants have different levels of education literacy and experience. For example, statements such as “Your incision is well approximated without purulent drainage” means the same as “Your wound edges are close together, and there are no signs of infection,” but the latter is easier to understand. You can also send messages in writing, but make sure that patients are able to read.

Channels

Individuals use communication **channels** to send and receive messages through visual, auditory, and tactile senses. Facial expressions send visual messages; spoken words travel through auditory channels. Touch uses tactile channels. Individuals usually understand a message more clearly when the sender uses more channels to send it.

Feedback

Feedback is the message a sender receives from the receiver. It indicates whether the receiver understood the meaning of the sender’s message. Feedback occurs continuously between a sender and receiver. A sender seeks verbal and nonverbal feedback to evaluate the receiver’s response and effectiveness of a communicated message. The type of feedback a sender or receiver gives depends on factors such as their background, prior experiences, attitudes, cultural beliefs, and self-esteem. A sender and receiver need to be sensitive and open to one another’s messages, to clarify the messages, and to modify behavior accordingly for successful communication.

Interpersonal Variables

Interpersonal variables are factors within both the sender and receiver that influence communication. Perception provides a uniquely personal view of reality formed by an individual’s culture, expectations, and experiences. Each person senses, interprets, and understands events differently. A nurse says, “You haven’t been talking very much since your family left. Is there something on your mind?” One patient may perceive the nurse’s question as caring and concerned; another perceives the nurse as invading privacy and is less willing to talk. Cultural sensitivity enables you to explore the interpersonal variables such as educational and developmental level, sociocultural background, values and beliefs, emotions, gender, physical health status, and roles and relationships that affect how a patient communicates. Interpersonal variables associated with illness such as pain, anxiety, and medication effects also affect nurse-patient communication.

Environment

The **environment** is the setting for sender-receiver interaction. An effective communication setting provides participants with physical and emotional comfort and safety. Noise, temperature extremes, distractions, and lack of privacy or space create confusion, tension, and discomfort. Environmental distractions are common in health care settings and interfere with messages sent between people. You control the environment as much as possible to create favorable conditions for effective communication.

Forms of Communication

Messages are conveyed verbally and nonverbally, concretely and symbolically. As people communicate, they express themselves through words, movements, voice inflection, facial expressions, and use of space. These elements work in harmony to enhance a message or conflict with one another to contradict and confuse it.

Verbal Communication

Verbal communication uses spoken or written words. Verbal language is a code that conveys specific meaning through a combination of words. The most important aspects of verbal communication are presented in the following paragraphs.

Vocabulary

Communication is unsuccessful if senders and receivers cannot translate one another's words and phrases. When you care for a patient who speaks another language, a professional interpreter is necessary. Even those who speak the same language use subcultural variations of certain words (e.g., *dinner* means a noon meal to one person and the last meal of the day to another). Medical jargon (technical terminology used by health care providers) sounds like a foreign language to patients unfamiliar with the health care setting. Limiting use of medical jargon to conversations with other health care team members improves communication. Children have a more limited vocabulary than adults and often use special words to describe bodily functions or a favorite blanket or toy. Teenagers often use words in unique ways that are unfamiliar to adults.

Denotative and Connotative Meaning

Some words have several meanings. Individuals who use a common language share the denotative meaning: *baseball* has the same meaning for everyone who speaks English, but *code* denotes cardiac arrest primarily to health care providers. The connotative meaning is the shade or interpretation of the meaning of a word influenced by the thoughts, feelings, or ideas that people have about the word. For example, health care providers tell a family that a loved one is in serious condition and they believe that death is near; but to nurses *serious* simply describes the nature of the illness. You need to select words carefully, avoiding easily misinterpreted words, especially when explaining a patient's medical condition or therapy. Even a much-used phrase such as "I'm going to take your vital signs" may be unfamiliar to an adult or

frightening to a child. “I’m going to check your blood pressure, heart rate, and temperature” may be more appropriate.

Pacing

Conversation is more successful at an appropriate speed or pace. Speak moderately slowly and enunciate clearly. Talking rapidly, using awkward pauses, or speaking excessively slowly and deliberately conveys an unintended message. Long pauses and rapid shifts to another subject give the impression that you are hiding the truth. Think before speaking and develop an awareness of the rhythm of your speech to improve pacing.

Intonation

Tone of voice dramatically affects the meaning of a message. Depending on intonation, even a simple question or statement expresses enthusiasm, anger, concern, or indifference. Be aware of voice tone to avoid sending unintended messages. If a patient interprets your patronizing tone of voice as condescending, this will inhibit further communication. A patient’s tone of voice provides information about his or her emotional state or energy level.

Clarity and Brevity

Effective communication is simple, brief, and direct. For certain populations such as the elderly, fewer words result in less confusion. Speak slowly, enunciate clearly, and use brief examples to make explanations easier to understand. Repeating important parts of a message also clarifies communication. Phrases such as “you know” or “OK?” at the end of every sentence detract from clarity. Use sentences and words that express an idea simply and directly. “Where is your pain?” is much better than “I would like you to describe for me the location of your discomfort.”

Timing and Relevance

Timing is critical in communication. Even though a message is clear, poor timing prevents it from being effective. For example, you do not begin routine teaching when a patient is in severe pain or emotional distress. Often the best time for interaction is when a patient expresses an interest in communicating. If messages are relevant or important to the situation at hand, they are more effective. When a patient is facing emergency surgery, discussing the risks of smoking is less relevant than explaining presurgical procedures. Face-to-face time while performing assessments, administering medications, or performing procedures offers an excellent opportunity to talk with patients and provide support or education. Patients report improved satisfaction, understanding, and perception of safety with registered nurses (RNs) who provide a bedside

hand-off and communicate information about the plan of care (Ford et al., 2014).

Nonverbal Communication

Nonverbal communication includes the five senses and everything that does not involve the spoken or written word. Nonverbal aspects of communication such as voice tone, eye contact, and body positioning are often as important as verbal messages (Lorié, 2017). Thus nonverbal communication is unconsciously motivated and more accurately indicates a person's intended meaning than spoken words (Varcarolis, 2017). When there is incongruity between verbal and nonverbal communication, the receiver usually "hears" the nonverbal message as the true message.

All nonverbal communication is important, but interpreting it is often problematic. Sociocultural background is a major influence on the meaning of nonverbal behavior. In the United States, with its diverse cultural communities, nonverbal messages between people of different cultures are easily misinterpreted. Assessing and responding to nonverbal messages are important aspects of nursing care (Sethi and Rani, 2017).

Personal Appearance

Personal appearance includes physical characteristics, facial expression, and manner of dress and grooming. These factors are a powerful means of nonverbal communications to patients and the health care team. In the health care setting research shows patients prefer that nurses employed in an agency all wear a single uniform and that the "RN" or "LPN" tag be displayed prominently (West et al., 2016). Many health care agencies restrict how much jewelry you can wear and whether certain types of tattoos need to be covered. For hygienic reasons nurses should have long hair pulled back and off the shoulders and short clean fingernails. Remember, first impressions are largely based on appearance. Nurses learn to develop a general impression of patient health and emotional status through appearance, and patients develop a general impression of the nurse's professionalism and caring in the same way.

Posture and Gait

Posture and gait (manner or pattern of walking) can be forms of self-expression. The way people sit, stand, and move reflects attitudes, emotions, self-concept, and health status. For example, an erect posture and a quick, purposeful gait communicate a sense of well-being and confidence. Leaning forward conveys attention. A slumped posture and slow, shuffling gait indicate depression, illness, or fatigue.

Facial Expression

The face is the most expressive part of the body. Facial expressions convey emotions such as surprise, fear, anger, happiness, and sadness. Some people have an expressionless face, or flat affect, which reveals little about what they are thinking or feeling. An inappropriate affect is a facial expression that does not match the content of a verbal message (e.g., smiling when describing a sad situation). People are sometimes unaware of the messages their expressions convey. For example, a nurse frowns in concentration while doing a procedure, and the patient interprets this as anger or disapproval. Patients closely observe nurses. Consider the impact your facial expression could have on a person who asks, "Am I going to die?" The slightest change in the eyes, lips, or facial muscles reveals your feelings. Although it is hard to control all facial expressions, try to avoid showing shock, disgust, dismay, or other distressing reactions in a patient's presence.

Eye Contact

People signal readiness to communicate through eye contact. Maintaining eye contact during conversation shows respect and willingness to listen. Eye contact also allows people to closely observe one another. Lack of eye contact sometimes indicates anxiety, defensiveness, discomfort, or lack of confidence in communicating. However, people from some cultures consider eye contact intrusive, threatening, or harmful and minimize or avoid its use (see [Chapter 9](#)). Always consider a person's culture when interpreting the meaning of eye contact. Eye movements communicate feelings and emotions. Looking down on a person establishes authority, whereas interacting at the same eye level indicates equality in the relationship. Rising to the same eye level as an angry person helps establish autonomy.

Gestures

Gestures emphasize, punctuate, and clarify the spoken word. Gestures alone carry specific meanings, or they create messages with other communication cues. A finger pointed toward a person communicates several meanings, but when accompanied by a frown and stern voice, the gesture becomes an accusation or a threat. Pointing to an area of pain is sometimes more accurate than describing its location.

Sounds

Sounds such as sighs, moans, groans, or sobs also communicate feelings and thoughts. Combined with other nonverbal communication, sounds help to send clear messages. They have several interpretations. For example, moaning can convey pleasure or suffering, and crying can communicate happiness,

sadness, or anger. Validate nonverbal messages with patients to interpret them accurately. For example, “I notice you frowning as you move, are you having pain?”

Territoriality and Personal Space

Territoriality is the need to gain, maintain, and defend one’s right to space. Territory is important because it provides people with a sense of privacy, identity, security, and control. It is sometimes separated and made visible to others, as with a fence around a yard or a curtain around a bed in a hospital room. Personal space is invisible and individual and travels with a person. During interpersonal interaction people maintain varying distances between one another, depending on their culture, the nature of their relationship, and the situation. When personal space becomes threatened, people respond defensively and communicate less effectively. Situations dictate whether the interpersonal distance between nurse and patient is appropriate. [Box 24.3](#) provides examples of nursing actions within communication zones ([Varcariolis, 2017](#)). Nurses frequently move into patients’ territory and personal space because of the nature of caregiving. You need to convey confidence, gentleness, and respect for privacy, especially when your actions require intimate contact or involve a patient’s vulnerable zone.

Box 24.3 Zones of Personal Space

Zones Of Personal Space

Intimate Distance (0–18 inches)

- Holding a crying infant
- Performing physical assessment
- Bathing, grooming, dressing, feeding, and toileting a patient
- Changing a patient’s surgical dressing

Personal Distance (18 inches–40 inches)

- Sitting at a patient’s bedside
- Taking a patient’s nursing history
- Teaching an individual patient

Social Distance (4–12 feet)

- Giving directions to visitors in the hallway
- Asking whether families need assistance from the patient doorway
- Giving verbal report to a group of nurses

Public Distance (12 feet and more)

- Speaking at a community forum
- Lecturing to a class of students
- Testifying at a legislative hearing

Special Zones of Touch

Social Zone (Permission Not Needed)

Hands, arms, shoulders, back

Consent Zone (Permission Needed)

Mouth, wrists, feet

Vulnerable Zone (Special Care Needed)

Face, neck, front of body

Intimate Zone (Permission and Great Sensitivity Needed)

Genitalia, rectum

Metacommunication

Metacommunication is a broad term that refers to all factors that influence communication. Awareness of influencing factors helps people better understand what is communicated ([Arnold and Boggs, 2016](#)). For example, a nurse observes a young patient holding his body rigidly, and his voice is sharp

as he says, "Going to surgery is no big deal." The nurse replies, "You say having surgery doesn't bother you, but you look and sound tense. I'd like to hear more about how you're feeling." Awareness of the tone of the verbal response and the nonverbal behavior results in further exploration of the patient's feelings and concerns.

Professional Nursing Relationships

Your application of knowledge, understanding of human behavior and communication, and commitment to ethical behavior create professional relationships. Having a philosophy based on caring and respect for others helps you be more successful in establishing relationships of this nature.

Nurse-Patient Caring Relationships

Caring relationships are the foundation of clinical nursing practice. In such relationships you assume the role of a professional who cares about each patient and his or her unique health needs, human responses, and patterns of living. Therapeutic relationships promote a psychological climate that promotes positive change and growth, such as your patients ability to attain health-related goals (Arnold and Boggs, 2016). The goals of a therapeutic relationship focus on a patient achieving optimal personal growth related to personal identity, ability to form relationships, and ability to satisfy needs and achieve personal goals (Varcarolis, 2017). There is an explicit time frame, a goal-directed approach, and a high expectation that what you discuss together is kept confidential among only members of the health care team involved in the patient's care. You establish, direct, and take responsibility for the interaction, and a patient's needs take priority over your needs. Your nonjudgmental acceptance of a patient is an important characteristic of the relationship. Acceptance conveys a willingness to hear a message or acknowledge feelings. It does not mean that you always agree with the other person or approve of the patient's decisions or actions. A caring relationship between you and a patient does not just happen; you create it with skill and trust.

There is a natural progression of four goal-directed phases that characterize the nurse-patient relationship (Box 24.4). The relationship often begins before you meet a patient and continues until the caregiving relationship ends. Even a brief interaction uses an abbreviated version of preinteraction, orientation, working, and termination (Varcarolis, 2017). For example, a nursing student gathers patient information to prepare in advance for caregiving, meets the patient and establishes trust, accomplishes health-related goals through use of the nursing process, and says goodbye at the end of the day.

Box 24.4 Phases of the Helping Relationship

Preinteraction Phase

Before meeting a patient:

- Review available data, including the medical and nursing history.
- Talk to other caregivers who have information about the patient.
- Anticipate health concerns or issues that arise.
- Identify a location and setting that fosters comfortable, private interaction.
- Plan enough time for the initial interaction.

Orientation Phase

When you and a patient meet and get to know one another:

- Set the tone for the relationship by adopting a warm, empathetic, caring manner.
- Recognize that the initial relationship is often superficial, uncertain, and tentative.
- Expect the patient to test your competence and commitment.
- Closely observe the patient and expect to be closely observed by the patient.
- Begin to make inferences and form judgments about patient messages and behaviors.
- Assess the patient's health status.
- Prioritize the patient's problems and identify his or her goals.
- Clarify the patient's and your roles.
- Form contracts with the patient that specify who will do what.
- Let the patient know when to expect the relationship to be terminated.

Working Phase

When you and a patient work together to solve problems and accomplish goals:

- Encourage and help the patient express feelings about his or her health.
- Encourage and help the patient with self-exploration.
- Provide information needed to understand and change behavior.
- Encourage and help the patient set goals.
- Take action to meet the goals set with the patient.
- Use therapeutic communication skills to facilitate successful interactions.
- Use appropriate self-disclosure and confrontation.

Termination Phase

During the ending of the relationship:

- Remind the patient that termination is near.
- Evaluate goal achievement with the patient.
- Reminisce about the relationship with the patient.
- Separate from the patient by relinquishing responsibility for his or her care.
- Achieve a smooth transition for the patient to other caregivers as needed.

Socializing is an important initial component of interpersonal communication. It helps people get to know one another and relax. It is easy, superficial, and not deeply personal, whereas therapeutic interactions are often more intense, difficult, and uncomfortable. A nurse often uses social conversation to lay a foundation for a closer relationship: “Hi, Mr. Simpson, I hear it’s your birthday today. How old are you?” A friendly, informal, and warm communication style establishes trust, but you need to move beyond social conversation to talk about issues or concerns affecting the patient’s health. During social conversation, some patients ask personal questions such as those about your family or place of residence. Students often wonder whether it is appropriate to reveal such information. The skillful nurse uses judgment about what to share and provides minimal information or deflects such questions with gentle humor and refocuses conversation back to the patient.

In a therapeutic relationship, it may be helpful to encourage patients to share personal stories. Sharing stories is called *narrative interaction*. Through listening to stories, you begin to understand the context of others’ lives and learn what is meaningful for them from their perspective. For example, a nurse listens to a patient’s perception of what it means to refuse medication treatment for breast cancer and is then better able to articulate the patient’s wishes. Taking adequate time to listen to patients’ stories positively impacts the patient care experience (Sethi and Rani, 2017). This information is not usually revealed with a standard history form that elicits short answers.

As a nurse, you can also tell stories to enhance communication. Telling good stories frames important messages you wish to send and makes messages memorable for your patients. Purposeful storytelling brings across factual information along with a human interest perspective that draws on an individual’s emotions, such as a patient’s desire to get well or feel a sense of hope. Be mindful not to divulge confidential information while using a story to illustrate a point. Emotions play a significant role in helping adults learn the ability to grasp new ideas.

Motivational Interviewing

Motivational interviewing (MI) is a technique that encourages patients to share their thoughts, beliefs, fears, and concerns with the aim of changing their behavior. MI provides a way of working with patients who may not seem ready to make behavioral changes that are considered necessary by their health practitioners. You can use it to evoke change talk, which links to improved patient outcomes (Copeland et al., 2015). For example, an interviewer uses information about a patient's personal goals and values to promote the patient's adherence to a new medication or exercise plan. The interviewing is delivered in a nonjudgmental, guided communication approach. When using MI, a nurse tries to understand a patient's motivations and values using an empathic and active listening approach. The nurse identifies differences between a patient's current health goals and behaviors and his or her current health status. The patient is supported even though a phase of resistance and ambivalence often occurs. Communication then focuses on recognizing the patient's strengths and supporting those strengths to make positive changes. This can result in dramatic improvements in health outcomes and patient satisfaction (Stawnychy et al., 2014).

Nurse-Family Relationships

Many nursing situations, especially those in community and home care settings, require you to form caring relationships with entire families. The same principles that guide one-on-one helping relationships also apply when the patient is a family unit, although communication within families requires additional understanding of the complexities of family dynamics, needs, and relationships (see Chapter 10).

Nurse-Health Care Team Relationships

Your communication with other members of the health care team affects patient safety and the work environment. According to Hannawa (2018), patient health outcomes are optimized when health care team members communicate well. Problems occur when communication is ineffective. The acronym SACCIA is one way to assist nurses in communicating effectively. The acronym stands for Sufficiency, Accuracy, Clarity, Contextualization, and Interpersonal Adaptation.

When patients move from one nursing unit to another or from one provider to another, there is a risk for miscommunication. To address this risk, health care providers provide detailed hand-off reports at the end of shifts or when patients transfer off care units to ensure that patients have a safe and smooth transition in care (Bucknall, 2016). Standardized discharge or transfer

procedures and forms reduce the risk of errors during patient transitions. Timely follow-up after discharge or transfer is also appropriate.

Use of a common language such as the SBAR technique for communicating critical information improves the perception of communication and information about patients among health care providers (IHI, 2018; Stewart, 2017). This technique is a popular communication tool that standardizes communication. SBAR is the acronym for Situation, Background, Assessment, and Recommendation (IHI, 2018). Some organizations have added an Identify step (ISBAR) into the SBAR process. The Identify step is used when health care providers do not actively know one another. They start with an introduction, a description of their location, and their role in caring for the patient (IHI, 2018). The use of these easy-to-remember, orderly techniques relays relevant information in a structured and timely manner (Marquis and Huston, 2017). Evidence identifies nursing actions that increase the effectiveness of nurse-to-nurse interaction and interprofessional communication (Box 24.5).

Box 24.5 Evidence-Based Practice **Bedside Nurse to Nurse Handover Report**

PICOT Question: In the hospital setting, do nurses who use bedside nursing handover report improve patient satisfaction and patient care outcomes compared with nurses who do not use bedside nursing handover report?

Evidence Summary

It has been widely argued that many of the adverse events occurring during hospitalization may have been prevented with a complete and effective nurse-to-nurse handover report conducted by nurses with effective training (Slade et al., 2018). Nurse-to-nurse bedside handover report has been used as a tool to improve patient-centered care, enhance patient understanding of the care plan, and enhance the completeness of report, among other benefits (Bains et al., 2018). In a systematic review of the literature on bedside handover, Gregory et al. (2014) identified six potential areas of positive impact: enhanced team collaboration, effective dyadic relationships, individual patient benefit, satisfaction, accountability, and cost containment. In a more recent systematic review of bedside shift-to-shift handovers, Mardis et al. (2016) found that the nurse-to-nurse bedside handover methodology enhanced patient and nurse satisfaction, improved communication, and helped patients understand their condition. However, the evidence of improved safety outcomes was weak and was identified as an area for future controlled study.

Application to Nursing Practice

- Failure to completely and accurately communicate during nurse-to-nurse handovers is a course of miscommunication that can lead to patient care errors.
- Bedside nurse-to-nurse shift reporting is an important tool that may enhance patient-centered care, patient and nurse satisfaction, and patient understanding (Bains et al., 2018).
- Nurses who complete education on a standardized approach to bedside reporting are well prepared to use this important intervention (Slade et al., 2018).
- More study is needed to establish a clear link between bedside nurse-to-nurse shift reporting and patient care outcomes in many areas (Mardis et al., 2016).

Building Competency in Patient-Centered Care

You are assigned to work with Mr. Rodriguez, a patient with a recent fracture of the femur, who is having surgery later today. Mr. Rodriguez fractured his femur on the job as a landscaper. He is a legal immigrant whose family is from Mexico. Mr. Rodriguez speaks English but has limited literacy. The registered nurse (RN) providing a handover report to you gives the relevant objective data about the patient. As an aside, the RN complains about how demanding and difficult the patient has been and how she does not believe people like him belong here, and she berates his insistence on the inclusion of a family member in all conversations. You recognize that providing patient-centered care, including integration of many dimensions of care, as well as respect for diverse cultural, ethnic, and social backgrounds, may contribute to positive patient care outcomes. What possible values, preferences, and needs may the patient be experiencing? Describe communication strategies and approaches that you would use to facilitate effective patient-centered care. How should every nurse recognize and address personally held beliefs and attitudes about patients from diverse backgrounds?

Lateral Violence

Professional nursing care requires nurses to interact with members of the nursing team and interprofessional health care providers. Communication focuses on team building, facilitating group processes, collaborating, consulting, delegating, supervising, leading, and managing (see [Chapter 21](#)). Social, informational, and therapeutic interactions help team members build morale, accomplish goals, and strengthen working relationships. **Lateral**

violence or workplace bullying between colleagues sometimes occurs and includes behaviors such as withholding information, backbiting, making snide remarks or put-downs, and nonverbal expressions of disapproval such as raising eyebrows or making faces. Lateral violence adversely affects the work environment, leading to job dissatisfaction, a decreased sense of value, poor teamwork, poor retention of qualified nurses, and nurses leaving the profession. New nurses are especially prone to bullying behavior (Frederick, 2014). Lateral violence can be a precursor to compassion fatigue, when health care workers perceive a threat during interactions with colleagues and react emotionally rather than communicating intentionally in a professional manner.

Lateral violence interferes with effective health care team communication and jeopardizes patient safety (Marquis and Huston, 2017). Intimidation decreases the likelihood that a nurse will report a near-miss event, question an order, or act to improve the quality of patient care. There must be zero tolerance of lateral violence. Develop skills in conflict management and assertive communication to stop the spread of lateral violence in the workplace. Requesting a mentor can help a new nurse learn skills to address the perpetrators of bullying. The mentor can also be a personal support for the nurse and serve as a role model for the department (Frederick, 2014). The nurse experiencing lateral violence can also use additional techniques such as the following:

- Address the behavior when it occurs in a calm manner.
- Describe how the behavior affects your functioning.
- Ask for the abuse to stop.
- Notify the manager to get support for the situation.
- Plan for taking action in the future.
- Document the incidents in detail in your personal notes, not patient records.

Nurse-Community Relationships

Many nurses form relationships with community groups by participating in local organizations, volunteering for community service, or becoming politically active. As a nurse, learn to establish relationships with your community to be an effective change agent. Providing clear and accurate information to members of the public is the best way to prevent errors, reduce resistance, and promote change. Communication within the community occurs through channels such as neighborhood newsletters, health fairs, public bulletin boards, newspapers, radio, television, and electronic information sites. Use these forms of communication to share information and discuss issues important to community health (see Chapter 3).

Elements of Professional Communication

Professional appearance, demeanor, and behavior are important in establishing trustworthiness and competence. A professional is expected to be clean, neat, well groomed, conservatively dressed, and odor free. Visible tattoos and piercings may not be considered acceptable in some professional settings. Professional behavior reflects warmth, friendliness, confidence, and competence. Professionals speak in a clear, well-modulated voice; use good grammar; listen to others; help and support colleagues; and communicate effectively. Being on time, organized, well prepared, and equipped for the responsibilities of the nursing role also communicate professionalism.

Courtesy

Common courtesy is part of professional communication. To practice courtesy, say hello and goodbye to patients and knock on doors before entering. State your purpose, address people by name, and say “please” and “thank you” to team members. Introduce yourself and state your title. When a nurse is discourteous, others perceive him or her as rude or insensitive. It sets up barriers to forming helping relationships between nurse and patient and causes friction among team members.

Use of Names

Always introduce yourself. Failure to give your name and status (e.g., nursing student, RN, or licensed practical nurse) or to acknowledge a patient creates uncertainty about an interaction and conveys an impersonal lack of commitment or caring. Making eye contact and smiling are ways to recognize others. Addressing people by name conveys respect for human dignity and uniqueness. Because using last names is respectful in most cultures, nurses usually use a patient’s last name in an initial interaction and then use the first name if the patient requests it. Ask how your patients and co-workers prefer to be addressed and honor their personal preferences. Using first names is appropriate for infants, young children, patients who are confused or unconscious, and close team members. Avoid terms of endearment such as “honey,” “dear,” “grandma,” or “sweetheart.” Even the closest nurse-patient relationships rarely progress to identities beyond first names. Avoid referring to patients by diagnosis, room number, or another attribute, which is demeaning and sends the message that you do not care enough to know the person as an individual.

Trustworthiness

Trust is relying on someone without doubt or question. Being trustworthy means helping others without hesitation. To foster trust, communicate warmth and demonstrate consistency, reliability, honesty, competence, and respect. Sometimes it isn't easy for a patient to ask for help. Trusting another person involves risk and vulnerability, but it also fosters open, therapeutic communication and enhances the expression of feelings, thoughts, and needs. Without trust a nurse-patient relationship rarely progresses beyond social interaction and superficial care. Avoid dishonesty at all costs. Withholding key information, lying, or distorting the truth violates both legal and ethical standards of practice. Sharing personal information or gossiping about others sends the message that you cannot be trusted and damages interpersonal relationships.

Autonomy and Responsibility

Autonomy is being self-directed and independent in accomplishing goals and advocating for others. Professional nurses make choices and accept responsibility for the outcomes of their actions (Varcariolis, 2017). They take initiative in problem solving and communicate in a way that reflects the importance and purpose of a therapeutic conversation (Arnold and Boggs, 2016). Professional nurses also recognize their patients' autonomy.

Assertiveness

Assertiveness allows you to express feelings and ideas without judging or hurting others. Assertive behavior includes intermittent eye contact; nonverbal communication that reflects interest, honesty, and active listening; spontaneous verbal responses with a confident voice; and culturally sensitive use of touch and space. An assertive nurse communicates self-assurance; communicates feelings; takes responsibility for choices; and is respectful of others' feelings, ideas, and choices (Gultekin et al., 2018). Assertive behavior increases self-esteem and self-confidence, increases the ability to develop satisfying interpersonal relationships, and increases goal attainment. Assertive individuals make decisions and control their lives more effectively than nonassertive individuals. They deal with criticism and manipulation by others and learn to say no, set limits, and resist intentionally imposed guilt. Assertive responses contain "I" messages such as "I want," "I need," "I think," or "I feel" (Arnold and Boggs, 2016). Nurses may experience ethical issues that make it difficult to use their assertiveness skills for fear of retaliation (e.g., identifying an error made by another health care provider). In such a situation the individual needs to take steps to resolve this ethical dilemma (see Chapter 22).

AIDET® is a technique developed by the Studer Group to enable health care workers to provide accurate and timely communication to patients and

families while focusing on excellent patient service. It is a technique commonly used in hospitals today. The acronym stands for *Acknowledge, Introduce, Duration, Explain, and Thank you*. When using AIDET, you first acknowledge the person standing in front of you with a positive attitude and make the person feel comfortable. Introduce yourself and let the person know what his or her role is in the department and in the person's care. It is important to always wear a name badge when working in a health care setting. When possible, give a patient or family an idea of how long a procedure may take. This keeps the patient informed of any delays that may occur. It is also helpful to let a patient know how long it will take to get results if they are related to testing. When explaining procedures, describe what the patient will experience with the treatment, procedure, or test. Inform him or her of any safety precautions. When using AIDET, thank a patient for coming to your organization for care and let the patient know how much you enjoyed working with him or her ([Rubin, 2014](#)).

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. It guides care for patients who need special assistance with communication. Use therapeutic communication techniques as an intervention in any interpersonal nursing situations.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes

Patient-centered care requires careful assessment of a patient's values; preferences; and cultural, ethnic, and social backgrounds ([Harvey and Ahmann, 2014](#)). During assessment a nurse also explores any personal biases and experiences that might affect his or her ability to form a therapeutic relationship. If the nurse cannot resolve his or her bias related to a patient, care should be transferred to another individual. Internal and external factors also affect a patient's ability to communicate ([Box 24.6](#)). Assessing these factors keeps your focus on a patient and helps you make patient-centered decisions during the communication process. Seek to understand the patient's viewpoint as you provide patient-centered care.

Box 24.6 Assessment: Factors Influencing

Communication

Psychophysiological Context (Internal Factors Affecting Communication)

- Physiological status (e.g., pain, hunger, nausea, weakness, dyspnea)
- Emotional status (e.g., anxiety, anger, hopelessness, euphoria)
- Growth and development status (e.g., age, developmental tasks)
- Unmet needs (e.g., safety/security, love/belonging)
- Attitudes, values, and beliefs (e.g., meaning of illness experience)
- Perceptions and personality (e.g., optimist/pessimist, introvert/extrovert)

- Self-concept and self-esteem (e.g., positive or negative)

Relational Context (Nature of the Relationship Among Participants)

- Social, helping, or working relationship
- Level of trust among participants
- Level of caring expressed
- Level of self-disclosure among participants
- Shared history of participants
- Balance of power and control

Situational Context (Reason for Communication)

- Information exchange
- Goal achievement
- Problem resolution
- Expression of feelings

Environmental Context (Physical Surroundings in Which Communication Occurs)

- Privacy level
- Noise level
- Comfort and safety level
- Distraction level

Cultural Context (Sociocultural Elements That Affect an Interaction)

- Educational level of participants
- Language and self-expression patterns
- Customs and expectations

Physical and Emotional Factors

It is especially important to assess the psychophysiological factors that influence communication. Many altered health states and human responses limit communication. People with hearing or visual impairments often have difficulty receiving messages (see [Chapter 49](#)). Facial trauma, laryngeal cancer, or endotracheal intubation often prevents movement of air past vocal cords or mobility of the tongue, resulting in inability to articulate words. An extremely breathless person needs to use oxygen to breathe rather than speak. People with aphasia after a stroke or in late-stage Alzheimer's disease cannot understand or form words. Some mental illnesses such as psychoses or depression cause patients to jump from one topic to another, constantly verbalizing the same words or phrases or exhibiting a slowed speech pattern. People with high anxiety are sometimes unable to perceive environmental stimuli or hear explanations. Finally patients who are unresponsive or heavily sedated cannot send or respond to verbal messages.

Review of a patient's medical record provides relevant information about his or her ability to communicate. The medical history and physical examination document physical barriers to speech, neurological deficits, and pathophysiology affecting hearing or vision. Reviewing a patient's medication record is also important. For example, opiates, antidepressants, neuroleptics, hypnotics, or sedatives may cause a patient to slur words or use incomplete sentences. The nursing progress notes in the electronic health record (EHR) sometimes reveal other factors that contribute to communication difficulties, such as the absence of family members to provide more information about a patient who is confused.

Communicate directly with patients during assessment to determine their ability to attend to, interpret, and respond to stimuli. If patients have difficulty communicating, assess the effect of the problem. Patients who are unable to speak are at risk for injury unless nurses identify an alternate communication method. If barriers exist that make it difficult to communicate directly with patients, family or friends become important sources concerning the patients' communication patterns and abilities.

Developmental Factors

Aspects of a patient's growth and development also influence nurse-patient interaction. For example, an infant's self-expression is limited to crying, body movement, and facial expression, whereas older children express their needs more directly. Adapt communication techniques to the special needs of infants and children and their parents. Depending on a child's age, include the parents, child, or both as sources of information about the child's health. Giving a young child toys or other distractions allows parents to give you their full attention. Children are especially responsive to nonverbal messages. Sudden movements, loud noises, or threatening gestures are frightening.

Children often prefer to make the first move in interpersonal contacts and do not like adults who stare or look down at them. A child who has received little environmental stimulation possibly is behind in language development, thus making communication more challenging.

Age alone does not determine an adult's capacity for communication. Hearing loss and visual impairments are changes that may occur during aging that contribute to communication barriers (Dowd, 2015). Communicate with older adults on an adult level and avoid patronizing or speaking in a condescending manner. Simple measures facilitate communication with older individuals who have hearing loss (Box 24.7).

Box 24.7 Focus on Older Adults Tips for Improved Communication With Older Adults Who Have Hearing Loss

- Make sure the patient knows that you are talking.
- Face the patient, be sure that your face/mouth is visible to him or her, and do not chew gum or talk while chewing.
- Speak clearly but do not exaggerate lip movement or shout.
- Speak a little more slowly but not excessively slow.
- Check whether patient uses hearing aids, glasses, or other adaptive equipment.
- Choose a quiet, well-lit environment with minimal distractions.
- Allow time for the patient to respond. Do not assume that patient is being uncooperative if he or she does not reply or takes a long time to reply.
- Give the patient a chance to ask questions.
- Keep communication short and to the point. Ask one question at a time.

Data from Arnold E, Boggs KU: *Interpersonal relationships: professional communication skills for nurses*, ed 7, St Louis, 2016, Saunders; and Blevins S: Nurses as educators: teaching patients with hearing loss, *Medsurg Nurs* 24(2):128-129, 2015.

Sociocultural Factors

Culture influences thinking, feeling, behaving, and communicating. Be aware of the typical patterns of interaction that characterize various ethnic groups, but do not allow this information to bias your response. Know each patient individually (e.g., does he or she feel comfortable with eye contact or in sharing

information with others?). You will approach a patient very differently if he or she is open and willing to discuss private family matters versus others who are reluctant to reveal personal or family information to strangers.

People from other countries do not always speak or understand English. Those who speak English as a second language often have trouble with self-expression or language comprehension. To practice cultural sensitivity in communication, understand that people of different ethnic origins use different degrees of eye contact, personal space, gestures, loud voice, pace of speech, touch, silence, and meaning of language. Make a conscious effort not to interpret messages through your cultural perspective, but consider the communication within the context of the other individual's background. Avoid stereotyping, patronizing, and making fun of other cultures. Language and cultural barriers are not only frustrating but also dangerous, causing delay in care (Box 24.8).

Box 24.8 Cultural Aspects of Care **Cultural Diversity and Communication**

- Differences in language comprehension may impede understanding and negatively impact the quality and safety of nursing care.
- Even among native speakers, variability in word usage, vocabulary, and literacy may skew patient and nurse understanding.
- Differences in nonverbal communication styles may create misunderstanding or discomfort, including practices regarding personal space, privacy, eye contact, and touch.
- Among people of different cultures decision-making authority for patient care decisions may vary.
- Variability in religious and spiritual beliefs affects how individuals perceive the health care experience.
- Incorporating the patient's beliefs and practices into the health care situation contributes to a patient-centered care experience.

Implications for Patient-Centered Care

- Understand your own cultural values and biases.
- Assess the patient's primary language and level of fluency in English.
- Speak directly to the patient even if an interpreter is present.

- Nodding or statements such as “OK” do not necessarily mean that the patient understands.
- Provide written information in English and primary language.
- Learn about other cultures, especially those commonly encountered in your work area.
- Incorporate the patient’s communication methods or need into plan of care.

Communication with Non-English-Speaking Patients

Patients who speak little or no English present challenges for nurse-patient communication. Federal and state laws require that hospitals that receive federal funding, including Medicare, Medicaid, and SCHIP, are required to provide language access services for their patients. For hospitals unable to provide on-site interpreters, telephone interpretation services must be available (Marcus, 2014). Use of family members, friends, or bilingual staff members to interpret for patients is strongly discouraged. Sometimes communication with patients is needed in sudden crucial interactions. Use family members or friends cautiously when there is a delay in acquiring interpretive services. Use of family members, children, or auxiliary personnel poses legal liabilities. Language is not the only barrier. Cultural differences also lead to misunderstanding and have been identified as an important factor impacting patient satisfaction (Sethi and Rani, 2017).

Gender

Gender influences how we think, act, feel, and communicate. Men tend to use less verbal communication but are more likely to initiate communication and address issues more directly. They are also more likely to talk about issues. Women tend to disclose more personal information and use more active listening, answering with responses that encourage the other person to continue the conversation. It is important for you to recognize a patient’s gender communication pattern. Being insensitive blocks therapeutic nurse-patient relationships. Assess communication patterns of each individual and do not make assumptions based simply on gender, race, sexuality, or cultural differences.

REFLECT NOW

As you think back on a recent experience interacting with a patient or family member, describe the unique personal factors that you observed. How should you tailor your own communication to create an effective interaction?

• Nursing Diagnosis

Most individuals experience difficulty with some aspect of communication. Patients sometimes lack skills in attending, listening, responding, and self-expression as a result of illness, treatment effects, or cultural or language barriers. The primary nursing diagnostic label used to describe a patient with limited or no ability to communicate verbally is *Impaired Verbal Communication*. This occurs when an individual experiences difficulty receiving, processing, transmitting, and using symbols for a variety of reasons. Use this diagnosis if your patient is unable to articulate words or experiences inappropriate verbalization, difficulty in forming words, and difficulty in comprehending (ICNP, 2017). This diagnosis is useful for a wide variety of patients with special problems and needs related to communication, such as impaired perception, reception, and articulation. Although a patient's primary problem is *Impaired Verbal Communication*, the associated difficulty in self-expression or altered communication patterns may also contribute to other nursing diagnoses such as:

- *Communication Barrier*
- *Difficulty Coping*
- *Powerlessness*
- *Impaired Socialization*

Assessment findings in a patient with *Impaired Verbal Communication* focus on the causes of a communication disorder, which often include physiological, mechanical, anatomical, psychological, cultural, or developmental factors. Accuracy in identifying assessment findings is necessary so that you select interventions that effectively resolve the diagnostic problem. For example, you manage the diagnosis of *Impaired Verbal Communication related to cultural difference (Hispanic heritage)* very differently from the diagnosis of *Impaired Verbal Communication related to hearing loss*.

• Planning

Once you have identified the nature of a patient's communication issues, consider several factors when designing the care plan. Motivation is a factor in improving communication, and patients often require encouragement to try different approaches that involve significant change. It is especially important to involve the patient and family in decisions about the plan of care to determine whether suggested methods are acceptable. Consider ways to meet basic comfort and safety needs before introducing new communication methods and techniques. Allow adequate time for practice. Participants need to be patient with themselves and one another to achieve effective communication. When the focus is on practicing communication, arrange for a quiet, private place that is free of distractions such as television or visitors.

Goals and Outcomes

Once you identify a diagnosis, select a goal that is relevant and achievable for the patient, such as being able to express needs or achieving understanding of physical condition. Next select expected outcomes that are very specific and measurable. Outcomes identify ways to determine whether a broader goal is met. For example, outcomes for a patient possibly include the following:

- Patient initiates conversation about diagnosis or health care problem.
- Patient is able to attend to appropriate stimuli.
- Patient conveys clear and understandable messages with health care team.
- Patient expresses increased satisfaction with the communication process.

At times you care for patients whose difficulty in sending, receiving, and interpreting messages interferes with healthy interpersonal relationships. In this case impaired communication is a contributing factor to other nursing diagnoses such as *Impaired Socialization* or *Difficulty Coping*. Plan interventions to help these patients improve their communication skills. Expected outcomes for a patient in this situation possibly include demonstrating the ability to appropriately express needs, feelings, and concerns; communicating thoughts and feelings more clearly; engaging in appropriate social conversation with peers and staff; and increasing feelings of autonomy and assertiveness.

Setting Priorities

It is essential to always maintain an open line of communication so that a patient can express emergent needs or problems. This sometimes involves an intervention as simple as keeping the nurse call system in reach for a patient

restricted to bed or providing communication augmentative devices (e.g., message board or Braille computer). When you plan to have lengthy interactions with a patient, it is important to address physical care priorities first so that the discussion is not interrupted. Make the patient comfortable by ensuring that any symptoms are under control and elimination needs have been met.

Teamwork and Collaboration

To ensure an effective plan of care, you sometimes need to collaborate with other health care team members who have expertise in communication strategies. Speech language pathologists help patients with aphasia, professional interpreters are necessary for patients who speak a foreign language, and mental health nurse specialists help angry or highly anxious patients to communicate more effectively.

Implementation

In carrying out any plan of care, use communication techniques that are appropriate for a patient's individual needs. Before learning how to adapt communication methods to help patients with serious communication impairments, it is necessary to learn the communication techniques that serve as the foundation for professional communication. It is also important to understand communication techniques that create barriers to effective interaction.

Therapeutic Communication Techniques

Therapeutic communication techniques are specific responses that encourage the expression of feelings and ideas and convey acceptance and respect. These techniques apply in a variety of different situations. Although some of the techniques seem artificial at first, skill and comfort increase with practice. Tremendous satisfaction results from developing therapeutic relationships that achieve desired patient outcomes.

Active Listening

Active listening means being attentive to what a patient is saying both verbally and nonverbally. It facilitates patient communication. Inexperienced nurses sometimes feel the need to talk to prove that they know what they are doing or to decrease anxiety (Varcariolis, 2017). It is often difficult at first to be quiet and really listen. Active listening enhances trust because you communicate acceptance and respect for a patient. The SURETY Model is one model you can

use to facilitate attentive listening and therapeutic communication with your patients (Stickley, 2011).

- **S**— Sit at an angle facing the patient. Sitting at a slight angle to the patient creates a nonconfrontational seating arrangement that is conducive to communication. This posture conveys the message that you are there to listen and are interested in what the patient is saying.
- **U**— *Uncross* legs and arms. This position suggests that you are “open” to what the patient says. A “closed” position such as crossing arms conveys a defensive attitude, possibly provoking a similar response in the patient.
- **R**— *Relax*. It is important to communicate a sense of being relaxed and comfortable with the patient. Restlessness communicates a lack of interest and a feeling of discomfort to the patient.
- **E**— *Eye contact*— Establish and maintain intermittent eye contact to convey your involvement in and willingness to listen to what the patient is saying (Fig. 24.2). Absence of eye contact or shifting the eyes gives the message that you are not interested in what the patient is saying.

FIG. 24.2 Maintain eye contact when communicating with patients.

- **T—Touch.** Use touch that is respectful to communicate empathy and understanding to the patient. Ensure that your use of touch is therapeutic and acceptable to the patient.
- **Y—Your intuition.** Trust your intuition as you grow in confidence to individualize, adapt, and apply communication techniques in your interpersonal encounters with your patients.

Sharing Observations

Nurses make observations by commenting on how the other person looks, sounds, or acts. Stating observations often helps a patient communicate without the need for extensive questioning, focusing, or clarification. This technique can help start a conversation with a patient who is quiet or withdrawn. Do not state observations that will embarrass or anger a patient, such as telling someone, “You look a mess!” Even if you make such an observation with humor, the patient can become resentful.

Sharing observations differs from making assumptions, which means drawing unnecessary conclusions about the other person without validating them. Making assumptions puts a patient in the position of having to contradict you. Examples include interpreting a patient’s fatigue as depression or assuming that untouched food indicates lack of interest in meeting

nutritional goals. Making observations is a gentler and safer technique: “You look tired ...,” “You seem different today ...,” or “I see you haven’t eaten anything.”

Sharing Empathy

Empathy is the ability to understand and accept another person’s reality, accurately perceive feelings, and communicate this understanding to the other. This is a therapeutic communication technique that enables you to understand a patient’s situation, feelings, and concerns (Lorié, 2017). To express empathy, you reflect that you understand and feel the importance of the other person’s communication. Empathetic understanding requires you to be sensitive and imaginative, especially if you have not had similar experiences. Strive to be empathetic in every situation because it is a key to unlocking concern and communicating support for others. Statements reflecting empathy are highly effective because they tell a person that you heard both the emotional and the factual content of the communication. Empathetic statements are neutral and nonjudgmental and help establish trust in difficult situations. For example, a nurse says to an angry patient who has low mobility after a stroke, “It must be very frustrating to not be able to do what you want.”

Sharing Hope

Nurses recognize that hope is essential for healing and learn to communicate a “sense of possibility” to others. Appropriate encouragement and positive feedback are important in fostering hope and self-confidence and for helping people achieve their potential and reach their goals. You give hope by commenting on the positive aspects of the other person’s behavior, performance, or response. Sharing a vision of the future and reminding others of their resources and strengths also strengthen hope. Reassure patients that there are many kinds of hope and that meaning and personal growth can come from illness experiences. For example, a nurse says to a patient discouraged about a poor prognosis, “I believe that you’ll find a way to face your situation because I’ve seen your courage and creativity.”

Sharing Humor

Humor is an important but often underused resource in nursing interactions. It is a coping strategy that can reduce anxiety and promote positive feelings (Haydon et al., 2015). It is a perception and attitude in which a person can experience joy even when facing difficult times. It provides emotional support to patients and professional colleagues and humanizes the illness experience. It enhances teamwork and relieves tension. Bonds develop between people who laugh together (Mills et al., 2019). Patients use humor to release tension, cope

with fear related to pain and suffering, communicate a fear or need, or cope with an uncomfortable or embarrassing situation. The goals of using humor as a health care provider are to bring hope and joy to a situation and enhance a patient's well-being and the therapeutic relationship. It makes you seem warmer and more approachable (Haydon et al., 2015). Use humor during the orientation phase to establish a therapeutic relationship and during the working phase as you help a patient cope with a situation.

You will care for patients from different cultural backgrounds. Humor often has a cultural context. When you interact with patients, be sensitive and realize that they may misunderstand or misinterpret jokes and statements meant to be humorous. It is never appropriate, with any patient, to joke about sexual orientation, race, economic status, disability, or any cultural attribute.

Health care professionals sometimes use a kind of dark, negative humor after difficult or traumatic situations to deal with unbearable tension and stress. This coping humor has a high potential for misinterpretation as uncaring by people not involved in the situation. For example, nursing students are sometimes offended and wonder how staff are able to laugh and joke after unsuccessful resuscitation efforts. When nurses use coping humor within earshot of patients or their loved ones, great emotional distress results.

Sharing Feelings

Emotions are subjective feelings that result from one's thoughts and perceptions. Feelings are not right, wrong, good, or bad, although they are pleasant or unpleasant. If individuals do not express feelings, stress and illness may worsen. Help patients express emotions by making observations, acknowledging feelings, encouraging communication, giving permission to express "negative" feelings, and modeling healthy emotional self-expression. At times patients will direct their anger or frustration prompted by their illness toward you. Do not take such expressions personally. Acknowledging patients' feelings communicates that you listened to and understood the emotional aspects of their illness situation.

When you care for patients, be aware of your own emotions because feelings are difficult to hide. Students sometimes wonder whether it is helpful to share feelings with patients. Sharing emotion makes nurses seem more human and brings people closer. It is appropriate to share feelings of caring or even to cry with others if you are in control of the expression of these feelings and express them in a way that does not burden the patient or break confidentiality. Patients are perceptive and sense your emotions. It is usually inappropriate to discuss negative personal emotions such as anger or sadness with patients. A social support system of colleagues is helpful. Employee assistance programs, peer group meetings, and the use of interprofessional teams, such as social

work and pastoral care, provide other means for nurses to safely express feelings away from patients.

Using Touch

Because of modern fast-paced technical environments in health care, nurses face major challenges in bringing the sense of caring and human connection to their patients (see [Chapter 7](#)). Touch is one of the most potent and personal forms of communication. It expresses concern or caring to establish a feeling of connection and promote healing ([Varcarolis, 2017](#)). Touch conveys many messages, such as affection, emotional support, encouragement, tenderness, and personal attention. Comfort touch such as holding a hand is especially important for vulnerable patients who are experiencing severe illness with its accompanying physical and emotional losses ([Fig. 24.3](#)).

FIG. 24.3 The nurse uses touch to communicate.

Some students initially find giving intimate care to be stressful, especially when caring for patients of the opposite gender. They learn to cope with intimate contact by changing their perception of the situation. Since much of what nurses do involves touching, you need to learn to be sensitive to others' reactions to touch and use it wisely. It should be as gentle or as firm as needed and delivered in a comforting, nonthreatening manner. Sometimes you

withhold touch for highly suspicious or angry persons who respond negatively or even violently to you.

Nurses need to be aware of patients' nonverbal cues and ask permission before touching them to ensure that touch is an acceptable way to provide comfort. Some individuals may be sensitive to physical closeness and uncomfortable with touch. When this occurs, share the information with other nurses who will care for the patient. Nurses should be aware of a patient's concern and act accordingly. A nod, gesture, body position, or eye contact can also convey interest and acceptance of touch, which promotes a bonding moment with a patient (Varcarolis, 2017).

Using Silence

It takes time and experience to become comfortable with silence. Most people have a natural tendency to fill empty spaces with words, but sometimes these spaces really allow time for a nurse and patient to observe one another, sort out feelings, think about how to say things, and consider what has been communicated. Silence prompts some people to talk. It allows a patient to think and gain insight (Varcarolis, 2017). In general, allow a patient to break the silence, particularly when he or she has initiated it.

Silence is particularly useful when people are confronted with decisions that require much thought. For example, it helps a patient gain the necessary confidence to share the decision to refuse medical treatment. It also allows the nurse to pay attention to nonverbal messages, such as worried expressions or loss of eye contact. Remaining silent demonstrates patience and a willingness to wait for a response when the other person is unable to reply quickly. Silence is especially therapeutic during times of profound sadness or grief.

Providing Information

Providing relevant information tells other people what they need or want to know so that they are able to make decisions, experience less anxiety, and feel safe and secure. It is also an integral aspect of health teaching (see Chapter 25). It usually is not helpful to hide information from patients, particularly when they seek it. If a health care provider withholds information, the nurse clarifies the reason with him or her. Patients have a right to know about their health status and what is happening in their environment. Information of a distressing nature needs to be communicated with sensitivity, at a pace appropriate to a patient's ability to absorb it, and in general terms at first: "John, your heart sounds have changed from earlier today, and so has your blood pressure. I'll let your doctor know." A nurse provides information that enables others to understand what is happening and what to expect: "Mrs. Evans, John is getting an echocardiogram right now. This test uses painless

sound waves to create a moving picture of his heart structures and valves and should tell us what's causing his murmur."

Clarifying

To check whether you understand a message accurately, restate an unclear or ambiguous message to clarify the sender's meaning. In addition, ask the other person to rephrase it, explain further, or give an example of what the person means. Without clarification you may make invalid assumptions and miss valuable information. Despite efforts at paraphrasing, you still may not understand a patient's message. Let the patient know if this is the case: "I'm not sure I understand what you mean by 'sicker than usual.' What is different now?"

Focusing

Focusing involves centering a conversation on key elements or concepts of a message. If conversation is vague or rambling or patients begin to repeat themselves, focusing is a useful technique. Do not use focusing if it interrupts patients while they are discussing important issues. Rather use it to guide the direction of conversation to important areas: "We've talked a lot about your medications; now let's look more closely at the trouble you're having in taking them on time."

Paraphrasing

Paraphrasing is restating another's message more briefly using one's own words. Through paraphrasing you send feedback that lets a patient know that he or she is actively involved in the search for understanding. Accurate paraphrasing requires practice. If the meaning of a message is changed or distorted through paraphrasing, communication becomes ineffective. For example, a patient says, "I've been overweight all my life and never had any problems. I can't understand why I need to be on a diet." Paraphrasing this statement by saying "You don't care if you're overweight" is incorrect. It is more accurate to say, "You're not convinced that you need to make different food choices because you've stayed healthy."

Validation

This is a technique that nurses use to recognize and acknowledge a patient's thoughts, feelings, and needs. Patients and families know they are being heard and taken seriously when the caregiver addresses their issues ([Harvey and Ahmann, 2014](#)). For example, a nurse validates a patient's comments by asking, "Tell me if I understand your concerns regarding your surgery. You're worried that you will not be able to do some of the things you can do before your

surgery.” This type of statement enables a nurse to convey empathy and interest in the patient’s thoughts, feelings, and perceptions.

Asking Relevant Questions

Ask relevant questions to seek information needed for decision making. Ask only one question at a time, and fully explore one topic before moving to another area. During patient assessment you ask questions that follow a logical sequence and usually proceed from general to more specific. Open-ended questions allow patients to take the conversational lead and introduce pertinent information about a topic. For example, “What’s your biggest problem at the moment?” Use focused questions when more specific information is needed in an area: “How has your pain affected your life at home?” Allow patients to respond fully to open-ended questions before asking more focused questions. Closed-ended questions elicit a yes, no, or one-word response: “How many times a day are you taking pain medication?” Although they are helpful during assessment, they are generally less useful during therapeutic exchanges.

Sometimes asking too many questions is dehumanizing. Seeking factual information does not allow a nurse or patient to establish a meaningful relationship or deal with important emotional issues. It is a way for a nurse to ignore uncomfortable areas in favor of more comfortable, neutral topics. A useful exercise is to try to converse without asking the other person a single question. By using techniques such as giving general leads (“Tell me about it ...”), making observations, paraphrasing, focusing, and providing information, you discover important information that would have remained hidden if you had limited the communication process to questions alone.

Summarizing

Summarizing is a concise review of key aspects of an interaction. It brings a sense of satisfaction and closure to an individual conversation and is especially helpful during the termination phase of a nurse-patient relationship. By reviewing a conversation, participants focus on key issues and add relevant information as needed. Beginning a new interaction by summarizing a previous one helps patients recall topics discussed and shows that you analyzed their communication. Summarizing also clarifies expectations, as in this example of a nurse manager who has been working with an unsatisfied employee: “You’ve told me a lot of things about why you don’t like this job and how unhappy you’ve been. We’ve also come up with some possible ways to make things better, and you’ve agreed to try some of them and let me know if any help.”

Self-Disclosure

Self-disclosures are subjectively true personal experiences about the self that are intentionally revealed to another person. This is not therapy for a nurse; rather it shows a patient that the nurse understands his experiences and that they are not unique. You choose to share experiences or feelings that are like those of the patient and emphasize both the similarities and differences. This kind of self-disclosure is indicative of the closeness of the nurse-patient relationship and indicates respect for the patient. You offer self-disclosure as an expression of sincerity and honesty; it is an aspect of empathy (Lorié, 2017). Self-disclosures need to be relevant and appropriate and made to benefit the patient rather than yourself. Use them sparingly so that the patient is the focus of the interaction.

Confrontation

When you confront someone in a therapeutic way, you help the other person become more aware of inconsistencies in his or her feelings, attitudes, beliefs, and behaviors (Varcarolis, 2017). This technique improves patient self-awareness and helps him or her recognize growth and deal with important issues. Use confrontation only after you have established trust, and do it gently with sensitivity: “You say you’ve already decided what to do; yet you’re still talking a lot about your options.”

Nontherapeutic Communication Techniques

Certain communication techniques hinder or damage professional relationships. These specific techniques are referred to as *nontherapeutic* or *blocking* and often cause others to activate defenses to avoid being hurt or negatively affected. Nontherapeutic techniques discourage further expression of feelings and ideas and engender negative responses or behaviors in others.

Asking Personal Questions

“Why don’t you and John get married?” Asking personal questions that are not relevant to a situation simply to satisfy your curiosity is inappropriate professional communication. Such questions are nosy, invasive, and unnecessary. If patients wish to share private information, they will. To learn more about a patient’s interpersonal roles and relationships, ask questions such as: “How would you describe your relationship with John?”

Giving Personal Opinions

“If I were you, I’d put your mother in a nursing home.” When a nurse gives a personal opinion, it takes decision making away from the other person. It inhibits spontaneity, stalls problem solving, and creates doubt. Personal opinions differ from professional advice. At times people need suggestions and

help to make choices. Suggestions that you present are options; the other person makes the final decision. Remember that the problem and its solution belong to the other person and not to you. A much better response is: "Let's talk about which options are available for your mother's care." The nurse also should not make promises to a patient about situations that require collaboration. For example, "I can't recommend that you stop taking the medications because of your side effects, but I would be happy to inform your primary care provider and ask whether a change in medication is appropriate."

Changing the Subject

"Let's not talk about your problems with the insurance company. It's time for your walk." Changing the subject when another person is trying to communicate his or her story is rude and shows a lack of empathy. It blocks further communication, and the sender then withholds important messages or fails to openly express feelings. In some instances, changing the subject serves as a face-saving maneuver. If this happens, reassure the patient that you will return to his or her concerns: "After your walk let's talk some more about what's going on with your insurance company."

Automatic Responses

"Older adults are always confused." "Administration doesn't care about the staff." Stereotypes are generalized beliefs held about people. Making stereotyped remarks about others reflects poor nursing judgment and threatens nurse-patient or team relationships. A cliché is a stereotyped comment such as "You can't win them all" that tends to belittle the other person's feelings and minimize the importance of his or her message. These automatic phrases communicate that you are not taking concerns seriously or responding thoughtfully. Another kind of automatic response is parroting (i.e., repeating what the other person has said word for word). Parroting is easily overused and is not as effective as paraphrasing. A simple "oh?" gives you time to think if the other person says something that takes you by surprise.

A nurse who is task oriented automatically makes the task or procedure the entire focus of interaction with patients, missing opportunities to communicate with them as individuals and meet their needs. Task-oriented nurses are often perceived as cold, uncaring, and unapproachable. When students first perform technical skills, it is difficult to integrate therapeutic communication because of the need to focus on the procedure. In time you learn to integrate communication with high-visibility tasks and accomplish several goals simultaneously.

False Reassurance

“Don’t worry; everything will be all right.” When a patient is seriously ill or distressed, you may be tempted to offer hope to him or her with statements such as “You’ll be fine” or “There’s nothing to worry about.” When a patient is reaching for understanding, false reassurance discourages open communication. Offering reassurance not supported by facts does more harm than good. Although you are trying to be kind, it has the secondary effect of helping you avoid the other person’s distress, and it tends to block conversation and discourage further expression of feelings. To use a more facilitative response you can say, “It must be difficult not to know what the surgeon will find. What can I do to help?”

Sympathy

“I’m so sorry about your mastectomy; you probably feel devastated.” Sympathy is concern, sorrow, or pity felt for another person. A nurse often takes on a patient’s problems as if they were his or her own. Sympathy is a subjective look at another person’s world that prevents a clear perspective of the issues confronting that person. If a nurse overidentifies with a patient, objectivity is lost, and the nurse is unable to help the patient work through the situation (Varcarolis, 2017). Although sympathy is a compassionate response to another’s situation, it is not as therapeutic as empathy. A nurse’s own emotional issues sometimes prevent effective problem solving and impair good judgment. A more empathetic approach is: “The loss of a breast is a major change. Do you feel comfortable talking about how it will affect your life?”

Asking for Explanations

“Why are you so anxious?” Some nurses are tempted to ask patients why they believe, feel, or act in a certain way. Patients frequently interpret “why” questions as accusations or think nurses know the reasons and are simply testing them. Regardless of a patient’s perception of your motivation, asking “why” questions causes resentment, insecurity, and mistrust. If you need additional information, it is best to phrase a question to avoid using the word “why.” For example, “You seem upset. What’s on your mind?” is more likely to help an anxious patient communicate.

Approval or Disapproval

“You shouldn’t even think about assisted suicide; it’s not right.” Do not impose your own attitudes, values, beliefs, and moral standards on others while in the professional helping role. Other people have the right to be themselves and make their own decisions. Judgmental responses often contain terms such as *should*, *ought*, *good*, *bad*, *right*, or *wrong*. Agreeing or disagreeing sends the subtle message that you have the right to make value judgments about patient

decisions. Approving implies that the behavior being praised is the only acceptable one. Often a patient shares a decision with you not to seek approval but to provide a means to discuss feelings. Disapproval implies that the patient needs to meet your expectations or standards. Instead help patients explore their own beliefs and decisions. For example, the response of "I'm surprised you're considering assisted suicide; tell me more about it" gives the patient a chance to express ideas or feelings without fear of being judged.

Defensive Responses

"No one here would intentionally lie to you." Becoming defensive in the face of criticism implies that the other person has no right to an opinion. The sender's concerns are ignored when the nurse focuses on the need for self-defense, defense of the health care team, or defense of others. When patients express criticism, listen to what they have to say. Listening does not imply agreement. Listen nonjudgmentally to discover reasons for a patient's anger or dissatisfaction. By avoiding a defensive attitude, you are able to defuse anger and uncover deeper concerns. A better response would be: "You believe that people are dishonest with you. It must be hard to trust anyone."

Passive or Aggressive Responses

"Things are bad, and there's nothing I can do about it." "Things are falling apart, and it's all your fault." Passive responses serve to avoid conflict or sidestep issues. They reflect feelings of sadness, depression, anxiety, powerlessness, and hopelessness. Aggressive responses provoke confrontation at the other person's expense. They reflect feelings of anger, frustration, resentment, and stress. Nurses who lack assertive skills also use triangulation (i.e., complaining to a third party rather than confronting the problem or expressing concerns directly to the source). This lowers team morale and draws others into the conflict situation. Assertive communication is a far more professional approach for a nurse to take.

Arguing

"How can you say you didn't sleep a wink when I heard you snoring all night long?" Challenging or arguing against perceptions denies that they are real and valid. A skillful nurse gives information or presents reality in a way that avoids argument, with a statement such as "You feel as if you didn't get any rest at all last night, even though I thought you slept well since I heard you snoring."

REFLECT NOW

Learning to avoid nontherapeutic communication techniques is difficult, as they are often a part of everyday conversation. As you reflect on a recent conversation with a patient, which nontherapeutic communication techniques did you catch yourself using? What therapeutic response could you have used?

Adapting Communication Techniques for the Patient with Special Needs

As the population ages, more patients have difficulty in communicating. Hearing loss increases with age. Approximately 16% of the US population has hearing loss (CDC, 2018). Vision loss affects communication and presents a challenge for many individuals, particularly over the age of 65. Vision loss is among the top 10 disabilities in the United States and impacts activities of daily living, sometimes leading to depression and isolation (Kirtland et al., 2015).

Interacting with people who have conditions that impair communication requires special thought and sensitivity. For example, patients who have had a stroke or laryngectomy may require communication aids such as a writing or picture board or a special call system. Such patients benefit greatly when you adapt communication techniques to their unique circumstances, developmental level, or cognitive and sensory deficits. A nurse caring for a patient with *Impaired Verbal Communication related to cognitive impairment* can use several techniques such as pictures or demonstration to enable the patient to understand the caregiver. The nurse interacts with the patient and family caregiver, aiming to facilitate as much clarity of understanding as possible without causing undue frustration related to conveying a message that is too complex (Dooley et al., 2015).

A nurse directs actions toward meeting the goals and expected outcomes identified in the plan of care, addressing both the communication impairment and its contributing factors. Box 24.9 lists methods available to encourage, enhance, restore, or substitute for verbal communication. Be sure that a patient is physically able to use the chosen method and that it does not cause frustration by being too complicated or difficult. Patients and families who do not speak English need assistance with communication. You use interpretation services to facilitate communication, which improves patient safety and patient outcomes (Weldon et al., 2014).

Box 24.9 Communicating With Patients Who Have Special Needs

Patients Who Cannot Speak Clearly (Aphasia, Dysarthria, Muteness)

- Listen attentively, be patient, and do not interrupt.
- Ask simple questions that require “yes” or “no” answers.
- Allow time for understanding and response.
- Use visual cues (e.g., words, pictures, and objects) when possible.
- Allow only one person to speak at a time.
- Encourage patient to converse.
- Let patient know if you have not understood him or her.
- Collaborate with speech therapist as needed.
- Use communication aids: letter boards, flash cards, computer-generated speech program).

Patients Who Have a Cognitive Impairment

- Use simple sentences and avoid long explanations.
- Ask one question at a time.
- Allow time for patient to respond.
- Be an attentive listener.
- Include family and friends in conversations, especially in subjects known to patient.
- Use picture or gestures that mimic the action desired.

Patients Who Have a Hearing Impairment

- Check for hearing aids and glasses.
- Reduce environmental noise.
- Get patient’s attention before speaking.
- Face patient with mouth visible.
- Do not chew gum.
- Speak at normal volume—do not shout.

- Rephrase rather than repeat if misunderstood.
- Provide a sign-language interpreter if indicated.

Patients Who Are Visually Impaired

- Check for use of glasses or contact lenses.
- Identify yourself when you enter the room, and notify the patient when you leave the room.
- Speak in a normal tone of voice.
- Do not rely on gestures or nonverbal communication.
- Use indirect lighting, avoiding glare.
- Use at least 14-point print.

Patients Who Are Unresponsive

- Call patient by name during interactions.
- Communicate both verbally and by touch.
- Speak to patient as though he or she can hear.
- Explain all procedures and sensations.
- Provide orientation to person, place, and time.
- Avoid talking about patient to others in his or her presence.

Patients Who Do Not Speak English

- Speak to patient in normal tone of voice.
- Establish method for patient to ask for assistance (call light or bell).
- Provide a professional interpreter as needed.
- Avoid using family members, especially children, as interpreters.
- Use communication board, pictures, or cards.
- Translate words from native language into English list for patient to make basic requests.
- Have dictionary (e.g., English/Spanish) available if patient can read.

Because nursing care of the older adult ideally is delivered through an interprofessional model, the primary goal is to establish a reliable communication system that all health care team members can understand easily. Effective communication involves adapting to special needs resulting

from sensory, motor, or cognitive impairments. Encouraging older adults to share life stories and reminisce about the past has a therapeutic effect and increases their sense of well-being. Avoid sudden shifts from subject to subject. It is helpful to include a patient's family and friends and to become familiar with a patient's favorite topics for conversation.

Evaluation

Evaluate the effectiveness of your own communication by videotaping practice sessions with peers or by making process recordings—written records of your verbal and nonverbal interactions with patients. Process recording analysis reveals how to improve personal communication techniques to make them more effective. [Box 24.10](#) contains a sample communication analysis of such a record. Analysis of a process recording enables you to evaluate the following:

Box 24.10 Sample Communication Analysis

Nurse: Good morning, Mr. Simpson." (Smiles, approaches bed holding clipboard)

Acknowledged by name, social greeting to begin conversation

Patient: "What's good about it?" (Arms crossed over chest, frowning, direct stare)

Nonverbal signs of anger

Nurse: "You sound unhappy."

(Pulls up chair and sits at bedside)

Sharing observation, nonverbal communication of availability

Patient: "You'd be unhappy, too, if nobody would answer your questions. That girl wouldn't tell me my blood sugar." (Angry voice tone, challenging expression)

Further expression of feelings facilitated by nurse making accurate observation

Nurse: "This hospital has a fine staff, Mr. Simpson. I'm sure no one would intentionally keep information from you."

Feeling threatened and being defensive, a nontherapeutic technique

Nurse: "I'm going to test your glucose in a minute, and I'll tell you the results." (Does test) "Your blood sugar was 350."

Providing information, demonstrating trustworthiness

Patient: "I'm so afraid complications will set in since my blood sugar is high." (Stares out window)

Feels free to express deeper concerns, but they are hard to face

Nurse: "What kinds of things are you worried about?"

Open-ended question to seek information

Patient: "I could lose a leg, like my mother did, or go blind or have to live hooked up to a kidney machine for the rest of my life."

Nurse: "You've been thinking about all kinds of things that could go wrong, and it adds to your worry not to be told what your blood sugar is."

Summarizing to let patient "hear" what he has communicated

Patient: "I always think the worst." (Shakes head in exasperation)

Expressing insight into his "inner dialogue"

Nurse: "I'll pass along to the technician that it's OK to tell you your glucose levels. And later this afternoon I'd like us to talk more about some things you can do to help avoid these complications and set some goals for controlling your glucose."

Providing information, encouraging collaboration, and goal setting

- Determine whether you encouraged openness and allowed the patient to "tell his story," expressing both thoughts and feelings.
- Identify any missed verbal or nonverbal cues or conversational themes.
- Examine whether nursing responses facilitated or blocked the patient's efforts to communicate.
- Determine whether nursing responses were positive and supportive or superficial and judgmental.
- Examine the type and number of questions asked.
- Determine the type and number of therapeutic communication techniques used.
- Discover any missed opportunities to use humor, silence, or touch.

Through the Patient's Eyes

You and your patient determine the success of the plan of care by evaluating patient communication outcomes together. You determine which strategies or interventions were effective and which patient changes (behaviors or perceptions) resulted because of the interventions. Ask the patient whether you and other members of the interprofessional health care team met his or her expectations. For example, does the patient believe that nurses responded in a timely way when the call light was turned on? Does the patient feel able to express his needs clearly? Is the patient satisfied with the information that has been provided about his condition or hospitalization? Successful nursing care related to patients' communication needs results in clear and effective

communication between patients and all members of the health care team and can favorably impact patient satisfaction and the delivery of safe care.

Patient Outcomes

If expected outcomes for the patient's plan of care are not met or if progress is unsatisfactory, you determine which factors influenced the outcomes and modify the plan of care. If your evaluation data indicate that a patient perceives difficulty in communicating, you explore contributing factors so that they can be addressed. For example, if using a pen and paper is frustrating for a patient who is nonverbal and whose handwriting is shaky, you revise the care plan to include the use of a picture board instead. Possible questions you ask when a patient does not meet expected outcomes include:

- You seem to be having difficulty communicating right now. What do you think is contributing to this?
- You're telling me that you don't feel anxious right now, but your face appears tense. Help me better understand how you're feeling right now.
- You seem frustrated with the use of pencil and paper to communicate. Would you like to try a letter board or a picture board to see whether either of these is easier for you to use?

Evaluation of the communication process helps nurses gain confidence and competence in interpersonal skills. Becoming an effective communicator greatly increases your professional satisfaction and success. There is no skill more basic, no tool more powerful.

Key Points

- Effective use of critical thinking promotes good communication.
- Nurses use the five levels of communication in their interactions: intrapersonal, interpersonal, small group, public, and electronic.
- The circular transactional communication process demonstrates the ever-changing nature of communication, and includes the sender, the receiver, and referents.
- Verbal communication involves spoken or written words, and the vocabulary, pacing, tone, clarity, and brevity of the message.

- Nonverbal communication occurs through the five senses and includes everything except the written or spoken word.
- Nurse-patient caring relationships are the foundation of the nursing process.
- The four phases of a nurse-patient helping relationship are: preinteraction, orientation, working, and termination.
- Effective nurse–health care team relationships promote safe and effective care and contribute to satisfying professional working relationships.
- Use of both professional and therapeutic communication techniques contributes to achievement of patient outcomes. Practicing these techniques is essential in your development as a nurse.
- Nontherapeutic communication techniques damage professional and caring relationships; therefore pay attention to your own communication to remove these blocking techniques from your responses.
- Adapting your communication with older adults to meet their unique needs ensures an effective nurse-patient relationship.
- Patients with impaired communication benefit from the use of devices that overcome barriers to understanding and communicating.
- Patients with special communication needs such as an inability to speak, cognitive impairment, and hearing or vision loss require the nurse to employ specific techniques to facilitate mutual understanding.

Reflective Learning

- Compare and contrast the similarities and differences in factors that affect communication among two patients that you have cared for recently and describe how you altered your own communication style to create an effective nurse-patient communication.

- Describe a recent nurse-to-nurse handover that you observed or participated in. What were the elements of effective communication you observed? How might this interaction have been improved?
- Describe a recent patient care experience in which the patient demonstrated *Impaired Verbal Communication*. What were the impairments that you observed and how was nursing care adjusted to provide for mutual understanding and respect?

Review Questions

1. When working with an older adult who is hearing-impaired, the use of which techniques would improve communication? (Select all that apply.)
 1. Check for needed adaptive equipment.
 2. Exaggerate lip movements to help the patient lip-read.
 3. Give the patient time to respond to questions.
 4. Keep communication short and to the point.
 5. Communicate only through written information.
2. Nurses must communicate effectively with the health care team for which of the following reasons? (Select all that apply.)
 1. To improve the nurse's status with the health team members
 2. To reduce the risk of errors to the patient
 3. To provide an optimum level of patient care
 4. To improve patient outcomes
 5. To prevent issues that need to be reported to outside agencies
3. Motivational interviewing (MI) is a technique that applies understanding a patient's values and goals in helping the patient make behavioral changes. When using motivational interviewing, what outcomes does the nurse expect? (Select all that apply.)
 1. Gaining an understanding of the patient's motivations
 2. Directing the patient to avoid poor health choices

3. Recognizing the patient's strengths and supporting his or her efforts
 4. Providing assessment data that can be shared with families to promote change
 5. Identifying differences in patient's health goals and current behaviors
4. The nurse therapeutically responds to an adult patient who is anxious by: (Select all that apply.)
 1. Matching the rate of speech to be the same as that of the patient
 2. Providing good eye contact
 3. Demonstrating a calm presence
 4. Spending time attentively with the patient
 5. Assuring the patient that all will be well
 5. A nurse prepares to contact a patient's physician about a change in the patient's condition. Put the following statements in the correct order using SBAR (Situation, Background, Assessment, and Recommendation) communication.
 1. "She is a 53-year-old female who was admitted 2 days ago with pneumonia and was started on levofloxacin at 5 PM yesterday. She states she has a poor appetite; her weight has remained stable over the past 2 days."
 2. "The patient reported feeling very nauseated after her dose of levofloxacin an hour ago."
 3. "Is it possible to make a change in antibiotics, or could we give her a nutritional supplement before her medication?"
 4. "The patient started to complain of nausea yesterday evening and has vomited several times during the night."
 6. The patient states, "I don't have confidence in my doctor. She looks so young." The nurse therapeutically responds: (Select all that apply.)
 1. Tell me more about your concern.

2. You have nothing to worry about. Your doctor is perfectly competent.
 3. You are worried about your care?
 4. You can go online and see how others have rated your doctor. I do that.
 5. You should ask your doctor to tell you her background.
7. The nurse applying effective communication skills throughout the nursing process should: (Place the following interventions in the correct order.)
1. Validate health care needs through verbal discussion with the patient.
 2. Compare actual and expected patient care outcomes with the patient.
 3. Provide support through therapeutic communication techniques.
 4. Complete a nursing history using verbal communication techniques.
8. A nurse works with a patient using therapeutic communication and the phases of the therapeutic relationship. Place the nurse's statements in order according to these phases.
1. The nurse states, "Let's work on learning injection techniques."
 2. The nurse is mindful of his/her own biases and knowledge in working with the patient with B₁₂ deficiency.
 3. The nurse summarizes progress made during the nursing relationship.
 4. After providing introductions, the nurse defines the scope and purpose of the nurse-patient relationship.
9. Which strategies should a nurse use to facilitate a safe transition of care during a patient's transfer from the hospital to a skilled nursing facility? (Select all that apply.)
1. Collaboration between staff members from sending and receiving departments

2. Requiring that the patient visit the facility before a transfer is arranged
 3. Using a standardized transfer policy and transfer tool
 4. Arranging all patient transfers during the same time each day
 5. Relying on family members to share information with the new facility
10. The nurse uses silence as a therapeutic communication technique. What are the purposes of the nurse's silence? (Select all that apply.)
1. Allows the nurse time to focus and avoid saying the wrong thing
 2. Prompts the patient to talk when he or she is ready
 3. Allows the patient time to think and gain insight
 4. Allows time for the patient to drift off to sleep
 5. Determines whether the patient would prefer to talk with another staff member

Patient Education

OBJECTIVES

- Identify the three purposes of patient education.
- Identify when teaching and learning typically begin.
- Identify the role of the nurse in patient education.
- Identify the purpose of Speak Up initiatives set up by The Joint Commission.
- Describe appropriate communication principles when providing patient education.
- Describe the domains of learning.
- Identify basic learning principles.
- Describe how self-efficacy is important in terms of health promotion.
- Identify factors that influence an adult's readiness to learn.
- Compare and contrast the nursing and teaching process.
- Describe how to prioritize goals for patient education.
- Describe how to create an environment that promotes learning.
- Describe how to use the teach-back method during evaluation.

Teach-back, p. 361

Teaching, p. 343

Patient education is one of the most important nursing interventions in any health care setting. Shorter hospital stays, increased demands on nurses' time, an increased number of chronically ill patients, and the need to give acutely ill patients meaningful information quickly emphasize the importance of quality patient education. As nurses try to find the best way to educate patients, the public has become more assertive in seeking knowledge, understanding health, and finding resources available within the health care system. Through education, nurses empower their patients to prevent acute and chronic disease, decrease disability, and improve wellness (Miller & Stoeckel, 2019). Patient education is a key component in terms of enhancing a patient's quality of life, improving self-care, reducing hospital admissions, and improving medication adherence (Flanders, 2018).

Patients have the right to know and be informed about their health risks, diagnoses, prognoses, and available treatments to help them make intelligent, informed decisions about their health and lifestyle. Part of patient-centered care is to integrate educational approaches that acknowledge patients' understanding of their own health. The goals of a well-designed, comprehensive teaching plan include providing a good fit with each patient's unique learning needs, reducing health care costs, improving quality of care, and ultimately changing behaviors to improve patient outcomes. In due course this helps patients make informed decisions about their care and become healthier and more independent (Flanders, 2018).

Standards for Patient Education

Patient education has long been a standard for professional nursing practice. All state Nurse Practice Acts recognize that patient teaching falls within the scope of nursing practice (Bastable, 2017). In addition, various accrediting agencies set guidelines for providing patient education in health care institutions. For example, The Joint Commission (TJC, 2018a) sets standards for patient and family education. These standards require nurses and all health care providers to assess patients' learning needs and provide education on a variety of topics, including medications, nutrition, use of medical equipment, pain management, and the patient's plan of care. Implementing the standards successfully requires collaboration among health care professionals and enhances patient safety. Ensure that your educational efforts are patient centered by taking into consideration your patients' literacy level and own education and experience on the topic to be discussed. Do not assume that because your patient is educated that he or she has knowledge regarding this topic. For example, a nurse with 20 years' experience in obstetrics and gynecology may not be up-to-date regarding the latest treatment recommendations for colon cancer. Also consider patients' desire to actively participate in the educational process, as well as their psychosocial, spiritual, and cultural values. It is important to document patient education interventions and a patient's response to teaching in the medical record. These standards help to direct patient education and ensure the best outcomes.

Purposes of Patient Education

The primary goal of patient education is to help individuals, families, or communities achieve optimal levels of health (Miller & Stoeckel, 2019). Patient education through active patient participation and decision making is an essential component of providing safe, patient-centered care (QSEN, 2019). In addition, providing education about preventive health care helps reduce health care costs for individuals. Because most patients now know more about their health, they want to be actively involved in their health maintenance. Comprehensive patient education includes three important purposes, each involving a separate phase of health care: health promotion and illness prevention, health restoration, and coping.

Maintenance and Promotion of Health and Illness Prevention

As a nurse you are a visible, competent resource for patients who want to improve their physical and psychological well-being. In the school, home, clinic, or workplace you provide information and skills to help *patients* adopt healthier behaviors. For example, in childbearing classes you teach expectant parents about physical and psychological changes in a woman. After learning about normal childbearing, the mother who applies new knowledge is more likely to eat healthy foods, engage in physical exercise, and avoid substances that can harm the fetus. Success in patient education is not the ability of a patient to simply recall information that is provided to him or her but is the ability of the patient to incorporate knowledge into everyday life activities in a way that promotes health. Not only can nurses provide knowledge in terms of health maintenance or disease management, but nurses can also help patients come up with a plan to incorporate that knowledge into their own lives.

Restoration of Health

Patients recovering from and adapting to changes resulting from illness or injury often seek information about their conditions and need information and skills to help them regain or maintain their levels of health. However, some patients find it difficult to adapt to illness and become disinterested in learning. As the nurse you learn to identify patients' willingness to learn and motivate interest in learning (Bastable, 2017). The family often is a vital part of a patient's return to health if a patient chooses to involve

them. Family caregivers usually require as much education as the patient, including information on how to perform skills within the home. If you exclude a family from a teaching plan, conflicts can occur. However, do not assume that a family should be involved; assess the patient-family relationship before providing education for family caregivers.

Coping With Impaired Functions

Not all patients fully recover from illness or injury. In addition, patients with preexisting mental illness or those who have lower literacy skills have difficulty understanding patient education ([Bastable, 2017](#)). Many patients with impaired function have to learn to cope with permanent health alterations. New knowledge and skills are often necessary for patients to continue activities of daily living. For example, a patient loses the ability to speak after larynx surgery and has to learn new ways of communicating. Changes in function are physical and/or psychosocial. In the case of serious disability such as following a stroke or a spinal cord injury, the patient's family (as defined by the patient) needs to understand and accept many changes in his or her physical capabilities. The family's ability to provide support results in part from education, which begins as soon as you identify the patient's needs and the family displays a willingness to help. Teach family members to help the patient with health care management (e.g., giving medications through gastric tubes and doing passive range-of-motion exercises). Families of patients with alterations such as alcohol use disorder, intellectual disability, or substance abuse disorder learn to adapt to the emotional effects of these chronic conditions and provide psychosocial support to facilitate the patient's health. Comparing a realistic desired level of health with the actual state of health enables you to identify deficits and needs and then plan effective teaching programs.

Teaching and Learning

It is impossible to separate teaching from learning. **Teaching** is the concept of imparting knowledge through a series of directed activities. It consists of a conscious, deliberate set of actions that help individuals gain new knowledge, change attitudes, adopt new behaviors, or perform new skills (Billings and Halstead, 2016). An educator needs to be knowledgeable about the subject matter and patient teaching principles in order to provide individuals with guidance, appropriately set the learning pace, and creatively introduce concepts to successfully achieve the objectives of new knowledge, behaviors, or changed attitudes.

Learning is defined as a “conscious or unconscious permanent change in behavior as a result of a lifelong, dynamic process by which individuals acquire new knowledge, skills, and/or attitudes that can be measured and can occur at any time or in any place through exposure to environmental stimuli” (Bastable, 2017). It is a process of both understanding and applying newly acquired concepts. For example, an adult exhibits learning when he demonstrates how to set up his weekly pillbox correctly. He shows transfer of learning when he demonstrates how to set up his wife’s pillbox. Teaching and learning begin when a person identifies a need for knowing or acquiring an ability to do something. Teaching is most effective when it responds to a learner’s needs. An educator assesses these needs by asking questions and determining a learner’s interests. Interpersonal communication is essential for successful teaching (see Chapter 24).

Role of the Nurse in Teaching and Learning

Nurses are legally responsible for providing education to all patients, regardless of gender, culture, age, literacy level, religion, or any other defining characteristics (Bastable, 2017). In The Patient Care Partnership, the American Hospital Association (2018) indicates that patients have the right to make informed decisions about their care. The information required to make informed decisions must be accurate, complete, and relevant to patients’ needs, language, and literacy. Medicare (medicare.gov, n.d.) also has standards for residents’ rights in nursing homes, including the right to be informed about one’s medical condition, medications, and to see one’s own doctor.

The Joint Commission’s Speak Up program helps patients understand their rights when receiving medical care (TJC, 2018b). The assumption is

that patients who ask questions and are aware of their rights have a greater chance of getting the care they need when they need it. The program offers the following Speak Up tips to help patients become more involved in their treatment:

- **Speak up** if you have questions or concerns. If you still do not understand, ask again. It is your body, and you have a right to know.
- **Pay attention** to the care you get. Always make sure that you are getting the right treatments and medicines by the right health care professionals. Do not assume anything.
- **Educate yourself** about your illness. Learn about the medical tests that are prescribed and your treatment plan.
- **Ask a trusted family member or friend** to be your advocate (adviser or supporter).
- **Know which medicines you take and why you take them.** Medication errors are the most common health care mistakes.
- **Use a hospital, clinic, surgery center, or other type of health care organization** that you have researched or checked carefully.
- **Participate in all decisions about your treatment.** You are the center of the health care team.

In addition, patients are advised that they have a right to be informed about the care they will receive, obtain information about care in their preferred language, know the names of their caregivers, receive treatment for pain, receive an up-to-date list of current medications, and expect that they will be heard and treated with respect.

Teach information that patients and their families need. You frequently clarify information provided by health care providers, such as how a patient can limit lifting heavy objects upon returning home or how to restrict activities as prescribed by the health care provider. You are the primary source of information to help patients adjust to health problems (Bastable, 2017). It is also important to understand patients' preferences for what they wish to learn. For example, a patient requests information about a new medication, or family members question the reason for their mother's pain. Identifying the need for teaching is easy when patients request information. However, a patient's need for teaching (such as how to avoid complications from an illness) is often less obvious to the patient. To be an effective educator, the nurse has to do more than just pass on facts. Carefully determine what patients need to know, their preferences,

and existing knowledge and then find the time to educate them when they are ready to learn. When you value and provide education, patients are better prepared to assume health care responsibilities. Nursing research about patient education supports the positive impact of patient education on patient outcomes (Box 25.1).

Box 25.1 Evidence-Based Practice **The Effectiveness of the Teach-Back Method to Reduce Hospital Readmissions**

PICOT Question: In adult patients who are discharged from the hospital, does utilizing the teach-back method compared with standard review of teaching content result in fewer hospital readmissions?

Evidence Summary

As of 2016, there were approximately 39 million inpatient hospital discharges in the United States each year, and almost 1 in 5 patients covered by Medicare are readmitted within 30 days, which has been an increasing trend (Axon et al., 2016). There is a nationwide focus on how to improve care transitions from the hospital to home or treatment center, such as a nursing home or rehabilitation center. The Centers for Medicare and Medicaid (CMS) has sponsored more than 100 projects to explore the best practice in terms of care transitions. Research has shown that effective education that includes ensuring the patient understands the discharge plan may decrease the likelihood of readmission by 30% (Almkuist, 2017). The teach-back method has been linked to a more effective discharge process, which helps ensure safer transitions from the hospital (Peter et al., 2015). The importance of understanding discharge instructions is imperative as patients need to know how to take medications and when to make follow-up appointments once leaving the hospital. When patients understand discharge information, current evidence supports that patient readmissions or visits the emergency department after discharge are reduced. Some research has focused on specific patient diagnoses, such as heart failure, while other studies have looked at generalized patient populations. For example, heart failure affects 5.7 million people and 1 in 4 patients discharged with heart failure are readmitted within 30 days (Almkuist, 2017). Almkuist (2017) conducted a systematic review of patients with heart failure and found that using the teach-back method during discharge can reduce readmission rates and also improve self-care

abilities and increase the patient and family's knowledge about a specific disease. Peter et al. (2015) found that when a nurse used the teach-back method for patients with heart failure, it improved the patients' understanding of their disease, improved adherence to patient education, and caused a decline in readmission rates. While examining the impact of the teach-back method in general patient populations in terms of reducing readmission, Axon (2016) found decreases in readmission rates for several patient populations, including acute myocardial infarction, heart failure, and chronic obstructive pulmonary disease.

Application to Nursing Practice

- Implement the teach-back method when teaching about complex chronic illnesses, such as heart failure (Almkuist, 2017).
- The use of teach-back is an effective tool to use during hospitalization to help prepare patients for self-care after discharge (Almkuist, 2017).
- The teach-back method increases patients' and caregivers' understanding of and adherence to postdischarge instructions, which helps decrease readmissions (Peter et al., 2015).
- Not utilizing the teach-back method can lead to gaps in understanding between health care providers, patients, and family caregivers.

Teaching as Communication

The teaching process closely parallels the communication process (see [Chapter 24](#)). Effective teaching depends in part on effective interpersonal communication. An educator applies each element of the communication process while providing information to learners. Thus the educator and learner become involved together in a teaching process that increases the learner's knowledge and skills.

The steps of the teaching process are similar to those of the communication process. You use patient requests for information or perceive a need for information because of a patient's health restrictions or the recent diagnosis of an illness. Then you identify specific **learning objectives** to describe the behaviors the learner will exhibit as a result of successful instruction ([Bastable, 2017](#)).

The nurse is the sender who conveys a message to the patient. Many intrapersonal variables influence your style and approach. Attitudes, values, emotions, cultural perspective, and knowledge influence the way

information is delivered. Past experiences with teaching are also helpful for choosing the best way to present necessary content.

The receiver in the teaching-learning process is the learner. A number of intrapersonal variables affect the motivation and ability to learn. Patients are ready to learn when they express a desire to do so and are more likely to receive your message when they understand the content. Attitudes, anxiety, physical symptoms, literacy level, and values influence the ability to understand a message. The ability to learn depends on factors such as emotional and physical health, education, cultural perspective, patients' values about their health, the stage of development, and previous knowledge.

Effective communication involves feedback. An effective educator provides a mechanism for evaluating the success of a teaching plan and then provides positive reinforcement ([Bastable, 2017](#)). This type of response reinforces health behavior and promotes continued self-management. You need to provide feedback both during and at the completion of each instructional encounter. Feedback needs to affirm the level of success of the learner in achieving objectives (i.e., the learner successfully verbalizes information or provides a return demonstration of skills learned). Feedback you receive from the learner is also important because it indicates the effectiveness of instruction and whether you need to modify your approach.

Domains of Learning

Learning occurs in three domains: cognitive (understanding), affective (attitudes), and psychomotor (motor skills) (Bastable, 2017). The most effective learning takes place when all three of these domains are utilized (Miller & Stoeckel, 2019). You often work with patients who need to learn in each domain. For example, patients who have undergone surgery for colon cancer and who have an ostomy to manage need to learn how the ostomy is affected by diet, medications, and activity (cognitive domain). In addition, a patient begins to learn coping skills to accept the change in body image created by the ostomy (affective domain). The patient with an ostomy needs to learn how to change an ostomy pouch and provide skin care (psychomotor domain). The characteristics of learning within each domain influence your teaching and evaluation methods. Understanding each learning domain prepares you to select proper teaching techniques and apply the basic principles of learning (Box 25.2).

Box 25.2 Appropriate Teaching Methods Based on Domains of Learning

Cognitive

- Discussion (one-on-one or group)
 - Involves nurse and one patient or a nurse with several patients
 - Promotes active participation and focuses on topics of interest to patient
 - Allows peer support
 - Enhances application and analysis of new information
- Lecture
 - Is more formal method of instruction because it is educator controlled
 - Helps learner acquire new knowledge and gain comprehension
- Question-and-answer session
 - Addresses patient's specific concerns
 - Helps patient apply knowledge

- Role play, discovery
 - Allows patient to actively apply knowledge in controlled situation
 - Promotes synthesis of information and problem solving
- Independent project (computer-assisted instruction), field experience
 - Allows patient to assume responsibility for completing learning activities at own pace
 - Promotes analysis, synthesis, and evaluation of new information and skills

Affective

- Role play
 - Allows expression of values, feelings, and attitudes
- Discussion (group)
 - Allows patient to receive support from others in group
 - Helps patient learn from others' experiences
 - Promotes responding, valuing, and organization
- Discussion (one-on-one)
 - Allows discussion of personal, sensitive topics of interest or concern

Psychomotor

- Demonstration
 - Provides presentation of procedures or skills by nurse
 - Permits patient to incorporate modeling of nurse's behavior
 - Allows nurse to control questioning during demonstration
- Practice
 - Gives patient opportunity to perform skills using equipment in a controlled setting
 - Provides repetition
- Return demonstration
 - Permits patient to perform skill as nurse observes
 - Provides excellent source of feedback and reinforcement

- Assists in determining patient's ability to correctly perform a skill or technique
- Independent projects, games
 - Requires teaching method that promotes adaptation and origination of psychomotor learning
 - Permits learner to use new skills

Cognitive Learning

Cognitive learning occurs when an individual gains information to further develop his or her intellectual abilities, mental capacities, understanding, and thinking processes (Bastable, 2017). Bloom's revised taxonomy of six cognitive behaviors is a hierarchy, which increases in complexity (Anderson and Krathwohl, 2001; Krathwohl, 2002) (Fig. 25.1). Each simpler category was originally a prerequisite to mastery of the next more complex one. For example, knowledge or remembering has to be mastered before someone can master the higher level of understanding or comprehension. Each of the cognitive behaviors is divided into subcategories. For example, remembering (formerly *Knowledge*) includes factual, conceptual, procedural, and metacognitive knowledge (Krathwohl, 2002). The revised taxonomy includes these domains:

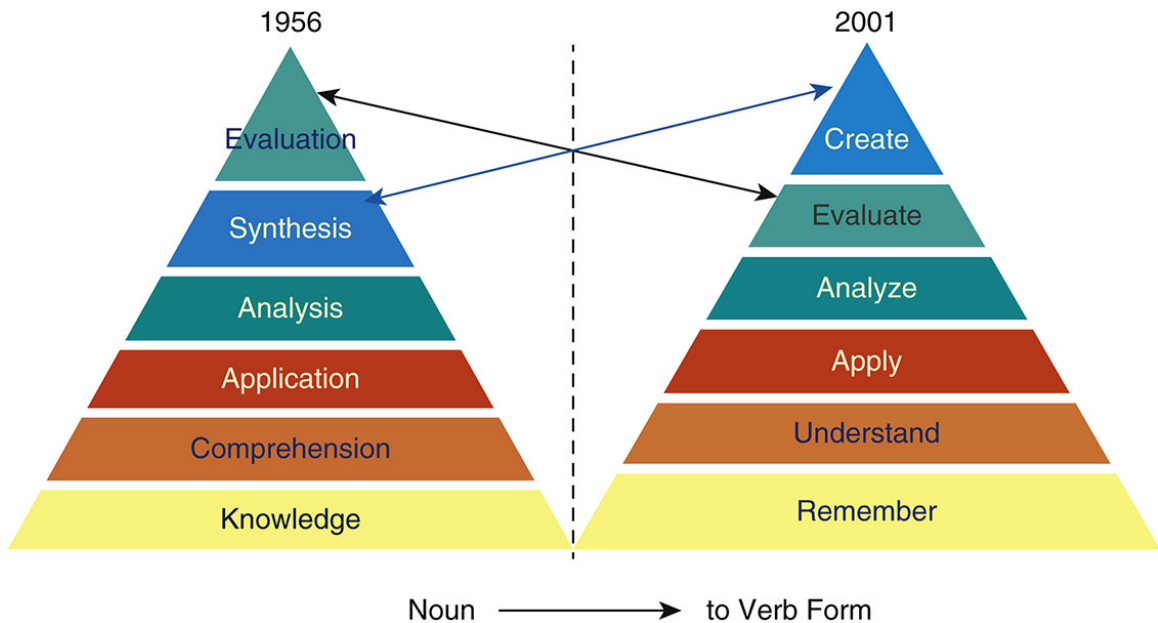

FIG. 25.1 Bloom's taxonomy: Bloom vs. Anderson/Krathwohl.
 From Wilson LO: Anderson and Krathwohl — Bloom's taxonomy revised,
 The Second Principle, available at: <https://thesecondprinciple.com/teaching-essentials/beyond-bloom-cognitive-taxonomy-revised/>.

- Remember (formerly *Knowledge*): Recognizing or recalling knowledge from memory
- Understand (formerly *Comprehension*): Constructing meaning from different types of messages or activities, such as interpreting, exemplifying, classifying, summarizing, inferring, comparing, or explaining
- Apply: Carrying out or using a procedure through executing or implementing
- Analyze: Breaking materials or concepts into parts, then determining how the parts relate to one another or how they interrelate, or how the parts relate to an overall structure or purpose
- Evaluate: Making judgments based on criteria and standards through checking and critiquing
- Create (formerly *Synthesis*): Putting elements together to form a coherent or functional whole; reorganizing elements into a new pattern or structure through generating, planning, or producing

Affective Learning

Affective learning deals with the expression of feelings and emotions and the development of values, attitudes, and beliefs (Billings and Halstead, 2016). Values clarification (see Chapter 22) is an example of affective learning. The affective domains of learning were developed by Krathwohl and Bloom (Krathwohl et al., 1956) The simplest behavior in affective learning is receiving, and the most complex is characterizing. Affective learning includes the following (Wilson, 2019):

- Receiving: Learner is passive but is aware of stimuli and willing to receive information.
- Responding: Requires active participation. This refers to a learner's active attention to stimuli, verbal and nonverbal responses, and motivation to learn.
- Valuing: Attaching worth and value to the acquired knowledge as demonstrated by the learner's behavior through acceptance, preference, or commitment.
- Organizing: Developing a value system. Learner internalizes values and beliefs involving (1) the conceptualization of values and (2) the organization of a value system.
- Characterizing: Highest level of internalization. Acting and responding with a consistent value system; requires introspection and self-examination of one's own values in relation to an ethical issue or particular experience

Psychomotor Learning

Psychomotor learning involves the development of manual or physical skills, such as learning how to walk or how to type on a computer (Billings and Halstead, 2016; Wilson, 2019). The simplest behavior in the hierarchy is fundamental (depending on the hierarchical model), whereas the most complex is origination. Psychomotor learning includes the following:

- Fundamental: Skills, movements, or behaviors related to walking, running, jumping, pushing, pulling, and manipulating. They are often components for more complex actions.
- Perception: Skills related to kinesthetic (bodily movements), visual, auditory, tactile (touch), or coordination abilities as they are related to the ability to take in information from the environment and react

- Guided response: Early stages of learning a particular skill under the guidance of an instructor that involves imitation and practice of a demonstrated act
- Mechanism: Higher level of behavior in which a person gains confidence and proficiency in performing a skill that is more complex or involves several more steps than a guided response
- Complex overt response: Smoothly and accurately performing a motor skill that requires complex movement patterns
- Adaptation: Motor skills are well developed and movements can be modified when unexpected problems occur
- Origination: Using existing psychomotor skills to create new movement patterns and perform them as needed in response to a particular situation or problem

Basic Learning Principles

To teach effectively and efficiently you must first be aware of the principles that influence how a person learns ([Bastable, 2017](#)).

Achievement of the desired learning outcomes (objectives) depends on a number of principles, including an individual's motivation, readiness and ability to learn, and the environment where learning will take place. The ability to learn depends on physical and cognitive attributes, developmental level, physical wellness, and intellectual thought processes. All of these principles influence your teaching approach.

A person's learning style may affect his or her preferences for learning. People process information in a number of ways: through seeing, touch and hearing, reflecting and acting, reasoning logically and intuitively, and analyzing and visualizing. Effective teaching plans incorporate a combination of activities that target a variety of learning styles ([Savage et al., 2017](#); [Miller and Stoeckel, 2019](#)). When you tailor your teaching approach to meet your patient's needs and learning style, you will optimize the learning experience at the individual level.

Motivation to Learn

Motivation is an internal state (e.g., an idea, emotion, or a physical need) that helps arouse, direct, and sustain human behavior ([Miller and Stoeckel, 2019](#)). A patient's motivation to learn is influenced by his or her belief of the need to know something. Patients who need knowledge for survival have a stronger motivation to learn than patients who need it for promoting health ([Bastable, 2017](#)). Unfortunately not all people are interested in maintaining health. Many do not adopt new health behaviors or change unhealthy behaviors unless they perceive a disease as a threat, overcome barriers to changing health practices, and see the benefits of adopting a healthy behavior. For example, some patients with lung disease continue to smoke. No therapy has an effect unless a person believes that health is important and that the therapy will improve health.

Motivational interviewing is a counseling and educational technique that is focused on patient goals and is goal directed and patient centered ([Stewart and Fox, 2011](#)). It is based on the principle that the motivation for change must come from the patient rather than the health care provider. As health care providers we may think we know what a patient "needs to learn." However, if the information we choose to deliver does not meet a patient's own personal goals or values, teaching efforts may be ineffective.

Motivational interviewing (MI) is often particularly successful with patients who are not motivated to change (Miller and Rollnick, 2002). Solid evidence exists for the efficacy of MI to address lifestyle behaviors such as diet, exercise, and smoking cessation, as well as the psychosocial needs of patients living with cancer (Spencer and Wheeler, 2016). MI has also been shown to be effective in primary care settings with improvement in patient management of body weight, alcohol and tobacco use, sedentary behavior, and self-monitoring (Lundahl et al., 2013). The objective of MI is not to solve a patient's problem or even to develop a plan; the goal is to help patients resolve their ambivalence about adopting new self-care behaviors, develop some momentum, and believe that behavioral change is possible (Stewart and Fox, 2011). MI interview questions are also useful in the assessment process for determining patients' learning needs.

Use of Theory to Enhance Motivation and Learning

Health education often involves changing attitudes and values that are not easy to change simply through transfer of information. Therefore it is important for you to use theory-based interventions when developing patient education plans. Learning theories focus on how individuals learn. Such theories are typically based on learning research. The use of theory facilitates the teaching-learning process by creating the desired climate for learning and guiding the selection of instructional strategies. Because patient education is complex, there are different theories and models available to guide patient education (Table 25.1). Using a theory that matches a patient's needs and personal learning preferences allows the patient to become an active participant, leading to effective instruction.

TABLE 25.1**Learning Theories**

Learning Theory	Definition	Application
Cognitive Dissonance	Individuals desire consistency and will make necessary changes and adaptations to gain that consistency (Festinger, 1957; Gruber, 2003). Cognitive dissonance is experienced in situations in which a patient is challenged by an inconsistency requiring a life change.	A patient with a recent myocardial infarction (MI) faces stressors associated with potential and actual health risks and changes needed as result of diagnosis. There are lifelong implications. The patient needs to change beliefs, attitudes, and values to regain consistency in life during recovery.
Health Belief Model	A patient will perceive a certain susceptibility and severity of their disease. Modifying factors include knowledge, as well as demographics and social and psychological variables. Likelihood of action is based on the perceived barriers and benefits of the situation (Hochbaum, 1958).	How a patient who has an MI copes with illness will depend on all modifying factors. If the patient does not feel threatened, believes that he or she will not benefit from interventions, or is not confident that he or she will be effective in the management of the condition, the patient may not be as receptive to teaching.
Transtheoretical Model of Change	Model is used to define how individuals initiate change in their lives, progress through those changes, and process and maintain behaviors. There are five stages in the model: precontemplation, contemplation, preparation, action, and maintenance (Prochaska, et al., 1998).	If the patient has experienced serious damage to the heart and requires cardiac rehabilitation, there are lifestyle changes to consider, such as diet, exercise, and medication management. With each stage of the model the patient makes decisions weighing the pros and cons and probable outcomes. Positive outcomes must outweigh negative aspects of change.
Self-Efficacy	Model focuses on the patient's belief in his or her own abilities to make and maintain changes and positive outcomes in the patient's life (Bandura, 1977). Self-efficacy is based on self-confidence and is a good indicator for motivation to make behavioral changes.	If a patient who has an MI is discharged home, he or she must provide some level of self-care. Break down any skill into manageable steps with encouragement and support from others. The patient moves from self-doubt and anxiety to comfort and confidence in his or her abilities.
Health Promotion	Model is based on the premise that characteristics and experiences of an individual affect actions specific to behaviors and in turn affect outcomes specific to behavior (Pender, 1975). The model applies general information from social learning theory to build on the nursing perspective of the holistic patient.	The behaviors of a patient who has an MI are driven by prior health promotion behaviors, as well as personal factors (biological, psychological, and sociocultural). Patients must be active participants in initiating and maintaining health promotion.

Adapted from Syx RL: The practice of patient education: the theoretical perspective, *Orthop Nurs* 27(1):50-54, 2008.

Among the various theories, social learning theory is one of the most useful approaches to patient education. It considers the personal characteristics of the learner, behavioral patterns, and the environment and guides the educator in developing effective teaching interventions that motivate and enhance learning (Bastable, 2017). According to social learning theory, a person's state of mind and intrinsic motivational factors (i.e., sense of accomplishment, pride, or confidence) reinforce behaviors and influence learning (Miller and Stoeckel, 2019). This type of internal reward system allows a person to attain desired outcomes and avoid undesired outcomes, resulting in improved motivation. **Self-efficacy**, a concept included in social learning theory, refers to a person's perceived ability to successfully complete a task. When people believe that they can achieve a particular behavior, they are more likely to perform the behavior consistently and correctly. Motivational interviewing techniques incorporate self-efficacy principles.

Self-efficacy beliefs come from four sources: verbal persuasion, vicarious experience, enactive mastery experience, and psychological and affective states (Bandura, 1997; Miller and Stoeckel, 2019). For example, a nurse who is teaching a child recently diagnosed with asthma how to correctly use an inhaler expresses personal belief in the child's ability to use the inhaler (verbal persuasion). Then the nurse demonstrates how to use the inhaler (vicarious experience). Once the demonstration is complete, the child uses the inhaler (enactive mastery experience). As the child's wheezing and anxiety decrease after the correct use of the inhaler, he or she experiences positive feedback, further enhancing his or her confidence to use it (physiological and affective states). Interventions such as these enhance perceived self-efficacy, which in turn improves the achievement of desired outcomes.

Self-efficacy is a concept included in many health promotion theories because it often is a strong predictor of healthy behaviors and because many interventions improve self-efficacy, resulting in improved lifestyle choices (Bandura, 1997). For example, Kate Lorig (2015), as the director of the Stanford Patient Education Research Center, developed a Chronic Disease Self-Management Program based on self-efficacy theory. The program uses skill mastery, modeling, reinterpretation, and social persuasion to enhance a person's self-efficacy. Dr. Lorig's programs have been especially effective for patients with diabetes, chronic lung problems and those in cardiac rehabilitation (see Chapter 8). When nurses implement interventions to enhance self-efficacy, their patients frequently experience positive outcomes. For example, researchers associated

increased self-efficacy scores and increased achievement of health goals when patients had follow-up education through telephone encounters over a period of 6 months (Zhou et al., 2018). In another study, researchers found that a self-care education program was effective at reducing all unplanned readmission for patients with heart failure (Boyde et al., 2018).

Cultural Factors

Knowing your patients' cultural preferences (see Chapter 9) and health beliefs (Chapter 6) helps you develop patient-centered interventions that will motivate your patients to learn. Carefully assess a patient's cultural needs and preferences for instructional methods to enhance learning and adherence. Using a model such as ACCESS helps you to focus on cultural factors that influence patient education outcomes. The six ACCESS model components are (Purnell, 2014):

1. **Assessment** of a patient's lifestyle, health beliefs, cultural traditions, and health practices.
2. **Communication** with an awareness of the many variations in verbal and nonverbal responses.
3. **Cultural** negotiation and compromise that encourages awareness of characteristics of a patient's culture and one's own biases.
4. **Establishment** of respect for a patient's cultural beliefs and values; creating a caring rapport.
5. **Sensitivity** to how patients from diverse backgrounds perceive their care needs and the patterns of communication they use.
6. **Safety** that enables patients to feel culturally secure and avoids disempowerment of their cultural identity.

Active Participation

Learning occurs when a patient is motivated to be actively involved in an educational session (Edelman and Kudzma, 2017). A patient's involvement in learning implies an eagerness to acquire knowledge or skills. It also improves the opportunity for the patient to make decisions during teaching sessions. For example, when teaching car-seat safety during a parenting class, hold a teaching session in the parking lot where the participants park their cars. Encourage active participation by providing the learners with several different car seats for them to place in their cars. At the completion of this session, the parents are able to determine which type of car seat fits best in their cars and which is the easiest to use. This

provides participants with the information needed to purchase the appropriate car seat.

Readiness to Learn

Readiness to learn is based on a patient’s willingness to engage in learning (Miller and Stoeckel, 2019). Many factors affect readiness to learn. A loss of health is usually very difficult for patients to accept. Grief is a complex process that patients experience during illness (see Chapter 36). The process of grieving gives individuals time to adapt psychologically to the emotional and physical implications of their illnesses. Readiness to learn is affected by each stage of grieving (Table 25.2). Patients cannot learn when they are unwilling or unable to accept their illness. However, properly timed teaching during the grieving process facilitates adjustment to illness or disability.

TABLE 25.2

Relationship Between Psychosocial Adaptation to Illness, Grief, and Learning

Stage	Patient’s Behavior	Learning Implications for Nurse and Family Caregiver	Rationale
Denial or disbelief	Patient avoids discussion of illness (“I’m fine; nothing is wrong with me”), withdraws from others, and disregards physical restrictions. Patient suppresses and distorts information that has not been presented clearly.	Provide support, empathy, and careful explanations of all procedures while they are being done. Remain available and accessible for discussion. Explain situation to family or significant other if appropriate. Teach in present tense (e.g., explain current therapy).	Patient is not prepared to deal with problem. Any attempt to convince or tell patient about illness results in further anger or withdrawal. Provide only information patient pursues or absolutely requires.
Anger	Patient blames and directs anger toward nurse or others.	Do not argue with patient. Listen to concerns. Use good eye contact. Teach in present tense. Reassure family and significant others that patient’s anger is normal.	Patient needs opportunity to express feelings and anger; he or she is still not prepared to face the future.
Bargaining	Patient offers to live better life in exchange for promise of better health. (“If God lets me live, I promise to quit smoking.”)	Continue to introduce only reality. Teach only in present tense.	Patient is still unwilling to accept limitations.
Resolution	Patient begins to express emotions openly, realizes that illness has created changes, and begins to ask questions.	Encourage expression of feelings. Find out what patient wants to learn. Begin to share information needed for future and set aside formal times for discussion.	Patient begins to perceive need for assistance and is ready to be responsible for learning.
Acceptance	Patient recognizes reality of condition, actively pursues information, and strives for independence.	Focus teaching on future skills and knowledge required. Continue to teach about present occurrences. Involve family/significant other in teaching information for discharge.	Patient is more easily motivated to learn. Acceptance of illness reflects willingness to deal with its implications.

A patient’s health status also affects readiness to learn. Patients move along a continuum of health. As a patient moves along this continuum, the readiness to learn changes as well (Miller and Stoeckel, 2019). For example,

a patient who is acutely ill is concerned with survival and will likely be most interested in a treatment plan before learning about long-term implications of illness. A patient who has had a stroke will be most ready to learn about self-care skills when receiving rehabilitation care.

An **attentional set** is the mental state that allows a learner to focus on and comprehend a learning activity. Before learning anything, patients must be able to pay attention to or concentrate on the information to be learned. Physical discomfort, anxiety, confusion, and environmental distractions influence the ability to concentrate. Therefore determine a patient's level of comfort before beginning a teaching plan, and ensure that the patient is able to focus on the information. As anxiety increases, a patient's ability to pay attention often decreases. A mild level of anxiety can be conducive to learning. However, a high level of anxiety prevents learning from occurring. At times when a patient is unable to attend, a family caregiver often becomes the recipient of education. Simple facts, rather than detailed teaching strategies, are most important during these times. For example, a patient in pain is receptive to learning about how to use a patient-controlled analgesia pump but not how to use crutches.

Ability to Learn

A patient's developmental level and cognitive and physical capabilities influence the ability to learn. In addition the learning environment is a significant factor affecting learning ability.

Developmental Capability

Cognitive development influences a patient's ability to learn. You can be a competent educator, but if you do not consider a patient's intellectual abilities, teaching is unsuccessful. Learning, like developmental growth, is an evolving process. Assess a patient's level of knowledge and intellectual skills (e.g., simple problem solving, decision making, applying a concept such as infection control in the home) before beginning a teaching plan. Learning occurs more readily when new information complements existing knowledge. For example, measuring liquid or solid food portions requires the ability to perform mathematical calculations. When caring for a patient in the home setting, first determine whether the patient understands what a portion consists of and then observe the patient prepare the liquid or solid food. Reading a medication label or discharge instructions requires reading and comprehension skills. Assessing a

patient's health literacy level will help determine the patient's existing ability.

Learning in Children

The capability for learning and the type of behaviors that children are able to learn depend on the child's maturation ([Chapter 12](#)). Without proper physiological, motor, language, and social development, many types of learning cannot take place. In addition, every child learns in different ways. However, learning occurs in children of all ages. Intellectual growth moves from the concrete to the abstract as the child matures. Therefore information presented to children needs to be understandable, and the expected outcomes must be realistic based on the child's developmental stage ([Box 25.3](#)). Remember that a child's developmental stage may not correspond to the child's chronological age. Use teaching methods that are evidence-based. Some evidence-based teaching strategies include creating clear lesson goals, using questions to check understanding, summarizing learning in a graphic way (with charts or concept maps), providing feedback, and being flexible in terms of how long it takes to learn ([Killian, 2013](#)). Use teaching aids that are developmentally appropriate ([Fig. 25.2](#)). Learning occurs when behavior changes as a result of experience or growth ([Miller and Stoeckel, 2019](#)).

Box 25.3 Teaching Methods Based on Patient's Developmental Capacity

Infant

- Keep routines (e.g., feeding, bathing) consistent.
- Hold infant firmly while smiling and speaking softly to convey sense of trust.
- Have infant touch different textures (e.g., soft fabric, hard plastic).

Toddler

- Use play to teach procedure or activity (e.g., handling examination equipment, applying bandage to doll).

- Offer picture books that describe story of children in hospital or clinic.
- Use simple words such as “cut” instead of “laceration” to promote understanding.

Preschooler

- Use role play, imitation, and play to make learning fun.
- Encourage questions and offer explanations. Use simple explanations and demonstrations.
- Encourage children to learn together through pictures and short stories about how to perform hygiene.

School-Age Child

- Teach psychomotor skills needed to maintain health. (Complicated skills such as learning to use a syringe take considerable practice.)
- Offer opportunities to discuss health problems and answer questions.

Adolescent

- Help adolescent learn about feelings and need for self-expression.
- Use teaching as collaborative activity.
- Allow adolescent to make decisions about health and health promotion (safety, sex education, substance abuse).
- Use problem solving to help adolescent make choices.

Young or Middle Adult

- Encourage participation in teaching plan by setting mutual goals.
- Encourage independent learning.
- Offer information so adult understands effects of health problem.

Older Adult

- Teach when patient is alert and rested.
- Involve adult in discussion or activity.
- Focus on wellness and person's strength.
- Use approaches that enhance patient's reception of stimuli when he or she has a sensory impairment (see Chapter 49).
- Keep teaching sessions short.

FIG. 25.2 Young child learning about healthy foods with plastic food models.

Adult Learning

Teaching adults differs from teaching children. Adults are able to reflect on their current situation critically but sometimes need help to see their problems and change their perspectives. Because adults become independent and self-directed as they mature, they are often able to identify their own learning needs (Billings and Halstead, 2016). Learning needs come from problems or tasks that result from real-life situations. Although adults tend to be self-directed learners, they often become dependent in new learning situations. The amount of information you provide and the amount of time you spend with an adult patient vary depending on the patient's personal situation and readiness to learn. An adult's readiness to learn is often associated with his or her developmental stage and other events that are occurring in his or her life. Help patients resolve any needs they perceive as important so that learning can occur.

Adults have a wide variety of personal life experiences. Adult learners do best when asked to both use their previous experiences and apply new knowledge to solve a real-life problem (Billings and Halstead, 2016). Adult learners are more successful when they view the information as personally relevant and important to their daily lives (Billings and Halstead, 2016). For example, if you instruct a patient to limit certain activities after surgery, learn what activities a person normally performs that may conflict with the restrictions. Find ways that will help the patient adhere to the restrictions. Assessing what an adult patient currently knows or does, teaching what the patient wants to know, and setting mutual goals improve the outcomes of patient education (Bastable, 2017).

Health Literacy and Learning Disabilities

Research shows that not only is health literacy a strong predictor of a person's health status but that it is a stronger predictor compared with several other factors, including age, income, employment status, educational level, and race (Parnell, 2015). The World Health Organization (WHO, 2018) defines **health literacy** as the cognitive and social skills that determine the ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health. Health literacy pertains not only to a patient's ability to read and comprehend health-related information but also to having the skills to problem solve, articulate, and make appropriate health care decisions (Parnell, 2015). People most likely to be at risk for low health literacy include older adults, minority populations, immigrant populations, people of low income,

people without a high school education, and people with chronic mental and/or physical health conditions ([US Department of Education, 2015](#)). According to the [Centers for Disease Control and Prevention \(2016\)](#) 9 of 10 adults struggle to understand and use health information if it is unfamiliar, complex, or uses jargon.

The [US Department of Health and Human Services \(USDHHS, n.d.b\)](#) reports that only 12 percent of adults have proficient health literacy, meaning nearly 9 of 10 adults may lack the skills needed to manage their health and prevent disease. To compound the problem, research has shown that health materials are often written at complex levels that exceed not only the general public's reading level but also the reading level of average high school graduates ([Parnell, 2015](#)). This discrepancy results in unsafe health care. Health literacy is one of the most important predictors of health outcomes. Low health literacy can lead to more emergency department visits, along with more hospital admissions and readmissions ([Miller and Stoeckel, 2019](#)). To ensure patient safety, all health care providers need to ensure that information is presented clearly and in a culturally sensitive manner ([TJC, 2018a](#)). Many people need printed health information at a fifth-grade level or lower and people often read at a level or two lower than their highest level of education ([Miller and Stoeckel, 2019](#)).

Physical Capability

Readiness to learn often depends on a patient's level of physical development and overall physical health. Many factors impair the ability to learn, including preexisting physical or mental illness, fatigue, body temperature, electrolyte imbalance, oxygenation status, and blood glucose level. To learn psychomotor skills a patient must possess a certain level of strength, coordination, and sensory acuity. For example, it is useless to teach a patient to transfer from a bed to a wheelchair if he or she has insufficient upper body strength. An older patient with poor eyesight or the inability to grasp objects tightly cannot learn to apply an elastic bandage. Therefore do not overestimate the patient's physical development or status. The following physical characteristics are necessary to learn psychomotor skills:

- Size (patient's height and weight should match the task to be performed or the equipment being used)
- Strength (ability of the patient to follow a strenuous exercise program)

- Coordination (dexterity needed for complicated motor skills such as using utensils or changing a bandage)
- Sensory acuity (visual, auditory, tactile, gustatory, and olfactory; sensory resources needed to receive and respond to messages taught)

Determining a patient's ability to perform psychomotor skills is best assessed by a physical therapist or occupational therapist. Also, consider how a patient adapts any physical limitations to performing skills at home.

Any condition or symptom (e.g., pain, nausea, or fatigue) that depletes a patient's energy also impairs the ability to learn. For example, a patient who spends a morning having rigorous diagnostic studies is unlikely to be able to learn later in the day because of fatigue. Postpone teaching when an illness becomes aggravated by complications such as a high fever or respiratory difficulty. As you work with a patient, assess energy level by noting the patient's willingness to communicate, the amount of activity initiated, and responses to questions. Temporarily stop teaching if the patient needs rest. You achieve better outcomes when patients are physically able to actively participate in learning.

Learning Environment

Factors in the physical environment where teaching takes place make learning either a pleasant or a difficult experience (Bastable, 2017). The ideal setting helps a patient focus on the learning task. The number of people included in the teaching session; the need for privacy; the room temperature; and the lighting, noise, ventilation, and furniture in the room are important factors when choosing a setting. The ideal environment for learning is well lit and has good ventilation, appropriate furniture, and a comfortable temperature. A darkened room interferes with a patient's ability to watch your actions, especially when demonstrating a skill or using visual aids such as posters or pamphlets. A room that is cold, hot, or stuffy makes a patient too uncomfortable to focus on the information being presented.

It is also important to choose a quiet setting. A quiet setting offers privacy; infrequent interruptions are best. Provide privacy even in a busy hospital by closing cubicle curtains or taking the patient to a quiet spot. Family caregivers often need to share in discussions in the home setting. However, patients who are reluctant to discuss the nature of the illness

when others are in the room benefit from receiving education in a room separate from household activities, such as a bedroom.

Teaching a group of patients requires a room that allows everyone to be seated comfortably and within hearing distance of the educator. Make sure that the size of the room does not overwhelm the group. Arranging the group to allow participants to observe one another further enhances learning. More effective communication occurs as learners observe others' verbal and nonverbal interactions.

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care. There are distinct similarities between the nursing process and the teaching process. During the assessment phase of the nursing process, you determine a patient's health care needs (see Unit 3). Like the nursing process, the teaching process requires assessment—in this case analyzing a patient's learning needs, motivation, and ability to learn. Your findings regarding the type of information, skill, or behavioral change that a patient needs to learn will lead to a nursing diagnostic statement. An example is *Lack of Knowledge* regarding a newly diagnosed condition related to insufficient information. A diagnosis such as *Anxiety* will often identify factors interfering with learning. Instead of outcomes, you develop specific learning objectives for a teaching plan. The nursing and teaching processes differ in that the nursing process requires assessment of all sources of data to determine a patient's total health care needs. The teaching process focuses on a patient's learning needs and willingness and capability to learn.

Implementation involves the use of appropriate patient-centered and evidence-based teaching strategies. Incorporate learning principles to ensure that your patient acquires the necessary knowledge and skills. Finally, the teaching process requires an evaluation of learning, including patient feedback based on learning objectives. [Table 25.3](#) compares the teaching and nursing processes.

TABLE 25.3**Comparison of the Nursing and Teaching Processes**

Basic Steps	Nursing Process	Teaching Process
Assessment	Collect data about patient's physical, psychological, social, cultural, developmental, and spiritual needs from patient, family, diagnostic tests, medical record, nursing history, and literature.	Gather data about patient's learning needs, motivation, ability to learn, health literacy, and teaching resources from patient, family, learning environment, medical record, nursing history, and literature.
Nursing diagnosis	Identify appropriate nursing diagnoses on basis of assessment findings.	Identify patient's learning needs on basis of three domains of learning. Nursing diagnoses may identify learning need or conditions that interfere with learning.
Planning	Develop an individualized care plan. Set diagnosis priorities on basis of patient's immediate needs, expected outcomes, and patient-centered goals. Collaborate with patient on care plan.	Establish learning objectives stated in behavioral terms. Identify priorities regarding learning needs. Collaborate with patient about teaching plan. Identify type of teaching method(s) to use.
Implementation	Perform nursing care therapies. Include patient as active participant in care. Involve family/significant other in care as appropriate.	Implement teaching methods. Actively involve patient in learning activities. Include family caregiver as appropriate.
Evaluation	Identify success in meeting desired outcomes and goals of nursing care. Alter interventions as indicated when goals are not met.	Determine outcomes of teaching-learning process. Measure patient's achievement of learning objectives. Reinforce information as needed.

Assessment

Through the Patient's Eyes

When providing patient education, it is important to partner with the patient to ensure safe, compassionate, and coordinated care (QSEN, 2019). This means that during the assessment you determine a patient's expectations for any teaching encounter. What does the patient expect to learn? What type of information does the patient perceive will be needed to maintain self-care at home or in a transitional care setting? During the assessment process thoroughly assess a patient and critically analyze your findings to ensure that you make patient-centered clinical decisions required for appropriate patient education. Assess the patient's preferences, values, and expressed needs in order to see the health care situation through his or her eyes (QSEN, 2019). In this way you gain a better appreciation of your patient's knowledge, expectations, and preferences for learning. Teaching will be more effective.

Learning Needs

Learning needs are defined as “gaps in knowledge that exist between a desired level of performance and the actual level of performance” (Miller & Stoeckel, 2019). Box 25.4 summarizes examples of specific assessment questions to use in determining a patient’s unique learning needs.

Box 25.4 Nursing Assessment Questions

Motivation to Learn

- If you had one habit that you wanted to change to improve your health, what would that be?
- What goal for your health would you like to set that you are willing to achieve?
- Listen reflectively—let patients express their thoughts and then, instead of telling them what they need to learn, capture the essence of what they have said, with the purpose of eliciting conversation and helping them arrive at an idea for change.

Previous Learning and Identification of Learning Needs and Preferences

- What do you want to know about _____?
- What do you know about your illness and your treatment plan?
- Which experiences have you had in the past that are similar to those you are experiencing now?
- Together we can choose the best way for you to learn about your disease. How can I best help you?
- When you learn new information, do you prefer to have it given to you in pictures or written down in words?
- When you give someone directions to your house, do you tell the person how to get there, write out the instructions, or draw a map?

Self-Management

- How does (or will) your illness affect your current lifestyle?

- Which barriers currently exist that prevent you from managing your illness the way you would like to manage it?
- What role do you believe your health care providers should take in helping you manage your illness or maintain health?
- How involved do you want a family member to be in the management of your illness? Who is that family member?

Cultural and Spiritual Influences

- Which cultural or spiritual beliefs do you have about your illness and its treatment?

For Family Caregivers

- When are you available to help, and how do you plan to help your loved one?
- Your spouse needs some help. How do you feel about learning how to assist him or her?
- Tell me how you feel about performing the care activities that your family member requires.

Sometimes nurses use formal educational assessment tools to determine their patients' perceived learning needs. Other times they identify their patients' expectations during routine assessments. Patients often identify their own learning needs on the basis of the implications of living with their illness. To meet these learning needs, assess what patients view as important information to know. When a patient has a need to know something, he or she is likely to be receptive to information presented. For example, new parents need to know how to care for their baby. Therefore they are often very receptive to information about infant care (e.g., how to feed the infant and make sure that he or she gets enough sleep).

Determine information that is critical for patients to learn. Learning needs change, depending on a patient's current health status. Because health status is dynamic, assessment is an ongoing activity. Assess the following:

- Information or skills needed by a patient to perform self-care and to understand the implications of a health problem: Health care team members anticipate learning needs related to specific health problems. For example, you teach a young man who has just entered high school how to prevent sexually transmitted infections (STIs).
- Patient experiences (e.g., new or recurring problem, past hospitalization) that influence the willingness and need to learn.
- Information that family caregivers require to support the patient's needs: The amount of information needed depends on the extent of a family member's role in helping the patient.

Motivation to Learn

Ask questions to identify and define a patient's motivation. These questions determine whether a patient is prepared and willing to learn. Assess the following factors:

- Behavior (e.g., attention span, tendency to ask questions, memory, and ability to concentrate during the teaching session)
- Health beliefs and sociocultural background: Norms, values, experiences, and traditions all influence a patient's beliefs and values about health and various therapies, communication patterns, and perceptions of time (see [Chapter 9](#)).
- Perception of the severity and susceptibility of a health problem and the benefits and barriers to treatment
- Identification of patient goals for learning, which must originate from the patient and not be imposed from outside by health care providers ([Stewart and Fox, 2011](#))
- Perceived ability to perform needed health behaviors
- Desire to learn
- Attitudes about health care providers (e.g., role of patient and nurse in making decisions)
- Learning style preference: As the nurse, any educational effort will be more effective if the chosen method of instruction aligns with your patient's preferred learning style ([Billings and Halstead, 2016](#)). Education may require more than one instructor as each instructor may excel at different types of teaching (verbal versus role-playing). Patients who are visual-spatial learners enjoy learning through pictures, visual charts, or any exercise that allows

them to visualize concepts. The verbal/linguistic learner demonstrates strength in the language arts and therefore prefers learning by listening or reading information. Kinesthetic learners process knowledge by moving and participating in hands-on activities. Role-play and return demonstrations are popular activities for the kinesthetic learner. Patients who learn through logical-mathematical reasoning think in terms of cause and effect and respond best when required to predict logical outcomes. If a patient is unable to identify a preferred learning style, delivering a combination of strategies will be more effective than just focusing on one type of learning style.

Readiness and Ability to Learn

Determine a patient's physical and cognitive ability to learn. Health care providers often underestimate patients' cognitive and physical deficits. Assess the following factors:

- Physical strength, endurance, movement, dexterity, and coordination: Determine the extent to which a patient can perform skills by having him or her practice with equipment that will be used in self-care at home ([Chapter 30](#)).
- Sensory deficits (see [Chapter 49](#)) that affect a patient's ability to understand or follow instruction
- Patient's reading level: This is often difficult to assess because patients who are functionally illiterate are often able to conceal it by using distractors such as not having the time to read or not being able to see the print. Two ways to assess a patient's reading level and level of understanding are to ask the patient to read instructions from an educational handout and then explain their meaning or to complete a health literacy screening tool (see the discussion of health literacy below).
- Patient's developmental level, which influences the selection of teaching approaches (see [Box 25.3](#)). Consider age-appropriate abilities.
- Patient's cognitive function, including memory, knowledge, association, and judgment
- Pain, fatigue, depression, anxiety, or other physical or psychological symptoms that interfere with the ability to maintain attention and participate: In acute care and rehab settings a

patient's physical condition can easily prevent a patient from learning.

Teaching Environment

The environment for a teaching session needs to be conducive to learning. Assess the following environmental factors:

- Distractions or persistent noise: A quiet area is essential for focusing on the topic and effective learning.
- Comfort of the room, including ventilation, temperature, lighting, furniture, and size
- Room facilities and available equipment

Resources for Learning

A patient often requires the support of family members or significant others. Determine who is the patient's primary family caregiver. If this support is necessary, assess the readiness and ability of family caregivers to learn the information necessary for the care of the patient. Also review resources within the home environment. Assess the following:

- Patient's willingness to have family caregivers involved in the teaching plan and provide health care: Information about a patient's health care is confidential unless the patient chooses to share it. Sometimes it is difficult for a patient to accept the help of family caregivers, especially when bodily functions are involved.
- Family caregiver's perceptions and understanding of a patient's illness and its implications: Conflict occurs in a teaching plan if the family caregiver's perceptions do not match those of the patient.
- Family caregiver's willingness and ability to participate in care: If a patient chooses to share information about his or her health status with family members, they need to be responsible, willing, and physically and cognitively able to assist in care activities such as bathing or administering medications. Not all family members meet these requirements.
- Resources, including financial or material, such as having the ability to obtain health care equipment
- Teaching tools, including brochures, audiovisual materials, or posters: Materials should be current, written clearly and logically,

and match the patient's reading level.

Health Literacy

Because health literacy influences how you deliver teaching strategies, it is critical for you to assess a patient's health literacy before providing instruction. Assessing health literacy is challenging, especially in busy clinical settings where often there is little time to conduct a thorough health literacy assessment. However, all health care providers need to identify problems and provide appropriate education to people who have special health literacy needs (TJC, 2018a).

To assess health literacy, ask patients to perform simple literacy skills. For example, can a patient read a medication label back to you correctly? After you give a simple 1-minute explanation of a diet or exercise program, can the patient explain it back to you? Can a patient correctly describe in his or her own words the information in a written handout? A variety of screening tools are available to test literacy. The Wide Range Achievement Test (WRAT 3) is a word-recognition screening test that evaluates reading, spelling, and arithmetic skills for patients from 5 to 74 years of age. The Rapid Estimate of Adult Literacy in Medicine (REALM) uses pronunciation of health care terms to determine a patient's ability to read medical vocabulary. The Cloze test, used to assess comprehension of health education materials, asks patients to fill in the blanks that are in a written paragraph.

In addition to literacy level, assess patients for learning disabilities. For example, many self-care behaviors require an understanding of mathematics, including computation and fractions. If a learning disability impairs a patient's ability to effectively use mathematics skills, teaching is challenging, especially when trying to teach him or her about complex medication dosages and frequencies. Although not considered a learning disability, attention-deficit hyperactivity disorder (ADHD) also affects a patient's ability to learn. Patients with ADHD frequently experience inattention, hyperactivity, and impulsivity, which makes it difficult for them to stay focused during educational sessions, making learning challenging (Learning Disabilities Association of America, 2018).

Patients who have low health literacy or learning disabilities may be ashamed of not being able to understand you and often try to mask their inability to comprehend information. Therefore make sure that you are sensitive and maintain a therapeutic relationship with your patients while assessing their ability to learn. Appreciating the unique qualities of your patients helps to ensure safe and effective patient care (QSEN, 2019).

REFLECT NOW

You are creating a teaching plan for your local community regarding road safety. The plan will be presented at a weekly community safety class for older adults and for a group of sixth graders at a local school. How do you differentiate your teaching plan for adults versus children?

Nursing Diagnosis

After assessing information related to the patient's motivation, readiness, and ability to learn, interpret data and cluster assessment findings to form diagnoses that reflect his or her specific learning needs or factors affecting the ability to learn (Box 25.5). This ensures that teaching will be goal directed and individualized. If a patient has several learning needs, the nursing diagnoses guide priority setting. When the nursing diagnosis is *Lack of Knowledge*, the diagnostic statement describes the specific type of learning need and its cause (e.g., *Lack of Knowledge* regarding a surgical procedure). Providing a related factor (e.g., related to lack of recall and exposure to information) for a problem-oriented or negative diagnosis offers further specificity in how to design teaching strategies. Patients often require education to support resolution of their various health problems. Examples of nursing diagnoses that indicate a need for education include the following:

Box 25.5 Nursing Diagnostic Process **Lack of Knowledge (Psychomotor) Regarding Use of Crutches Related to Lack of Experience**

Assessment activities	Assessment findings
Have patient describe how to walk with crutches.	Patient states that he or she has not received information about use of crutches. Patient asks questions about how to use crutches.
Have patient demonstrate three-point crutch walking on level surfaces and up stairs.	Patient uses crutches inappropriately. Patient cannot go up or down stairs on crutches.

- *Decisional Conflict*
- *Lack of Knowledge (Affective, Cognitive, Psychomotor)*
- *Impaired Health Maintenance*
- *Impaired Ability to Manage Dietary/Exercise Regime*
- *Self Care Deficit*

When you can manage or eliminate health care problems through education, the related factor of a diagnostic statement is *Lack of Knowledge*. For example, an older adult woman is having difficulty managing a medication regimen that involves a number of newly prescribed medications that she has to take at different times of the day. The nursing diagnosis is *Impaired Health Maintenance regarding scheduling of medications related to lack of knowledge*. In this case educating the patient about her medications and the correct dosage schedules improves her ability to schedule and take them as directed. When you identify conditions that cause barriers to effective learning (e.g., nursing diagnosis of *Acute Pain* or *Activity Intolerance*), teaching is inappropriate. In these cases delay teaching until the nursing diagnosis is resolved or the health problem is controlled.

• Planning

After determining the nursing diagnoses that identify a patient's learning needs, develop a teaching plan, determine goals and expected outcomes, and involve the patient in selecting learning experiences (see the [Nursing Care Plan](#)). Expected outcomes of an education plan are learning objectives. They guide the choice of teaching strategies and approaches with a patient. Patient participation ensures a more relevant, meaningful plan.

Goals and Outcomes

Goals of patient education identify what a patient needs to achieve to gain a better understanding of a health care topic and to better manage his or her illness (e.g., “achieves ostomy self-care”). Outcomes describe the specific behaviors that a patient must achieve to meet each goal, such as “empties colostomy bag” and “describes diet options to reduce diarrhea.” When developing outcomes, conditions or time frames need to be realistic and meet the patient’s needs (e.g., “will identify the side effects of aspirin by discharge”). Consider conditions under which the patient or family will typically perform the behavior (e.g., “will walk from bedroom to bathroom using crutches”). Include the patient when establishing learning goals and outcomes, and serve as a resource in setting the minimum criteria for success.

In some health care settings nurses develop teaching plans in the electronic health record. The teaching plan includes standard topics for

Nursing Care Plan

Anxiety Related to Lack of Knowledge About Impending Surgery

Assessment

Connie, a nurse who practices in a surgeon’s office, is preparing Mr. Holland for a colon resection that is scheduled in 1 week. Mr. Holland is 75 years old, alert and oriented. He is married and lives with his wife of 45 years. He was recently diagnosed with colorectal cancer and has not had surgery in the past. He displays a number of behaviors that Connie wishes to further assess to determine their impact on his ability to learn.

Assessment Activities	Assessment Findings ^a
Ask Mr. Holland to describe his planned surgery.	Mr. Holland responds, " I can't remember what the doctor told me when I saw him last week, but I know it is for my cancer."
Observe the patient's verbal and nonverbal behavior.	Patient has poor eye contact , restless in chair. States, " I am a bit worried about all of this. "
Ask the patient if his wife can be included in discussion. Ask Mrs. Holland, "Tell me if you feel your husband is ready for surgery?"	Patient consents to wife's participation. Wife explains, "He has not been sleeping well since knowing he had to have surgery. He has looked at a booklet the doctor gave him, but he has already forgotten what to do before he comes to the hospital. I am not sure he know how serious this is. "
Assess Mr. Holland's previous coping strategies.	Mr. Holland states, "The last time I felt stressed was when a good friend died. I found it helped to talk about it."

^a Assessment Findings are shown in bold type.

Nursing Diagnosis

Anxiety related to lack of knowledge about impending surgery

Planning

Goals	Expected Outcomes (NOC) ^b
	Anxiety Self-Control
Patient will attend to teaching session.	Patient will ask relevant questions specific to surgery. Patient will perform relaxation exercises during instructional session.

^b Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Learning Readiness Enhancement	
Provide planned time for patient and wife to ask questions and clarify what is expected. Show your interest, and ask patient to describe his feelings and fear about surgery.	Establishes a trusting relationship. Aids in gaining understanding of patient's perspective of stressful situation so that clarification can be provided (Butcher et al., 2018)
Use a calm, reassuring approach to explain purpose of surgery. Be factual and clarify any patient misconceptions. Use plain language and follow EDUCATE model (see Table 25.4).	EDUCATE model is an evidence-based model to improve outcomes from verbal instruction (Marcus, 2014).
Learning Facilitation	
Use visual charts of colectomy and website that explains preoperative and postoperative activities, including exercises and ambulation while teaching patient and wife.	Preoperative educational interventions can help reduce preoperative anxiety, particularly when information is given by a nurse expert (Alanazi, 2014).
Instruct patient on relaxation exercise using controlled breathing during times of perceived stress.	Offers coping mechanism to reduce sympathetic stimulation accompanying stress.

^c Intervention classification labels from Butcher HK, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Observe patient's behaviors during teaching sessions.	Patient asks relevant questions about activity restriction after surgery. States, "I'm still really worried about my surgery though. I just don't know if I'm going to need a colostomy or not."	Patient asks relevant questions specific to surgery. Still has concerns about outcome of surgery.
Observe patient performing deep breathing and relaxation.	Patient describes and demonstrates deep breathing technique.	Patient demonstrates deep breathing.

instruction, resources (e.g., equipment, teaching booklets, and referrals to special educational programs), recommendations for involving family, and objectives of the teaching plan. Some plans are very detailed, whereas others are in outline form. Use the plan to provide continuity of instruction. The more specific the plan, the easier it is to follow.

The setting influences the complexity of any teaching plan. In an acute care setting plans are concise and focused on the primary learning needs of the patient because there is limited time for teaching. Home care and outpatient clinic teaching plans are usually more comprehensive in scope because you often have more time to instruct patients and patients are often less anxious in outpatient settings.

Setting Priorities

Include the patient when determining priorities for patient education. Base priorities on a patient's nursing diagnoses or collaborative problems and the goals and outcomes established for him or her. Priorities also depend on what a patient perceives to be most important, his or her anxiety or physical comfort level, and the amount of time available to teach. You set a patient's learning needs in order of priority. For example, a patient recently diagnosed with coronary artery disease has *Lack of Knowledge regarding newly diagnosed illness*. The patient benefits most by first learning about the correct way to take nitroglycerin and how long to wait before calling for help when chest pain occurs. Once you assist in meeting patient needs related to basic survival, you can discuss other topics such as exercise and nutritional changes.

Timing

When is the right time to teach? Before a patient enters a hospital? When a patient first enters a clinic? At discharge? At home? Each is appropriate because patients continue to have learning needs for as long as they stay in a health care system. Plan teaching activities for a time when a patient is most attentive, receptive, and alert and organize the patient's activities to provide time for rest and teaching-learning interactions.

In acute care, timing instruction is sometimes difficult because the emphasis is on a patient's timely discharge from a hospital. For example, it takes several hours after surgery for a patient to be alert and comfortable enough to learn. By the time a patient feels ready to learn, discharge is already scheduled. Limited time is available for short teaching sessions and opportunity for patient feedback. Therefore, to improve patient outcomes, anticipate patients' educational needs before they enter the hospital, and involve family if possible.

Although prolonged teaching sessions reduce concentration and learner attentiveness, make sure that teaching sessions are not too brief. A patient needs time to comprehend the information and give feedback. It is easier

for patients to tolerate and retain interest in the material during frequent sessions lasting 10 to 15 minutes. However, factors such as shorter hospital stays and lack of insurance reimbursement for outpatient education sessions often necessitate longer teaching sessions. Follow-up care in the form of referrals to home health or rehab can help provide continuity of instruction after a patient goes home.

The frequency of teaching sessions depends on a learner's abilities and the complexity of the material. For example, a child newly diagnosed with diabetes requires more visits to an outpatient center than the older adult who has had diabetes for 15 years and lives at home. Make sure that intervals between teaching sessions are not so long that the patient forgets information. Home care nurses frequently reinforce learning during home visits after patients are discharged from the hospital.

Organizing Teaching Material

An effective educator carefully considers the order of information to present. When a nurse has an ongoing relationship with a patient, as in the case of home health or case management, an outline of content helps organize information into a logical sequence. Material needs to progress from simple to complex because a person must learn the simple facts and concepts before learning how to make associations or complex interpretations of ideas. Staff nurses in acute care settings often focus on the simpler, more essential concepts, whereas home health nurses can better address complex issues. For example, a nurse plans to teach a wife how to feed her husband, who has a gastric tube. The nurse will first teach the wife how to measure the tube feeding and manipulate the equipment. Once the wife has accomplished this, instruction on how to administer the feeding will occur.

Begin instruction with essential content because patients are more likely to remember information that you teach early in a teaching session. For example, immediately after surgical removal of a malignant breast tumor, a patient has many learning needs. To ensure that all essential material is covered, start with content considered to be high priority, such as how to monitor an incision site for signs of infection. Deal with the emotional aspects of a cancer diagnosis and complete the teaching session with informative but less critical content, such as how often follow-up appointments will occur. Repetition reinforces learning. A concise summary of key content helps the learner remember the most important information ([Bastable, 2017](#)). Using instructional materials that contain the same summaries is very helpful.

Teamwork and Collaboration

During planning choose appropriate teaching methods that match the topics to be presented. Encourage the patient to offer suggestions about timing and methods and make referrals to other health care professionals (e.g., dietitians and physical, speech, or occupational therapists) when appropriate. As a nurse you are the member of the health care team primarily responsible for ensuring that all patient educational needs are met. However, sometimes patient needs are highly complex. In these cases identify appropriate health system educational resources available in the patient's community during planning. Examples of resources for patient education include diabetes education clinics, cardiac rehabilitation programs, prenatal classes, and support groups. When patients receive education and support from these types of resources, the nurse obtains a referral order (if necessary), encourages patients to attend educational sessions, and reinforces information taught. Resources that specialize in a particular health need (e.g., wound care or ostomy specialists) are integral to successful patient education.

REFLECT NOW

Your patient is a 44-year-old single man who was recently hospitalized due to an embolic stroke with residual left-sided weakness. He is left-handed and does not currently have any fine motor skills on the left side. He was found to have untreated hypertension and high cholesterol, so he was started on clopidogrel for secondary stroke prevention along with lisinopril for hypertension and atorvastatin for high cholesterol. What disciplines would you include when providing his discharge education?

Implementation

The implementation of patient education depends on the accuracy of the nursing diagnoses identified for the patient's learning needs. On the basis of the nursing diagnoses, you develop a teaching plan (see [Nursing Care](#)

[Plan](#)). Carefully evaluate the learning objectives and determine which teaching and learning principles most effectively and efficiently help the patient meet expected goals and outcomes. Implementation involves believing that each interaction with a patient is an opportunity to teach. Use evidence-based interventions to create an effective learning environment.

Maintaining Learning Attention and Participation

Active participation is key to learning. People learn better when more than one of the senses is stimulated. Audiovisual aids, group discussion, and role-playing are good teaching strategies. By actively experiencing a learning event, a person is more likely to retain knowledge. An educator's actions also increase learner attention and interest. When conducting a discussion with a learner, an educator stays active by changing the tone and intensity of his or her voice, making eye contact, and using gestures that accentuate key points of discussion. An effective educator engages learners, includes active learning strategies, and talks and moves among a group rather than remaining stationary behind a lectern or table. A learner remains interested in an educator who is actively enthusiastic about the subject under discussion.

If a patient is anxious or inattentive, implement strategies such as relaxation and deep breathing to decrease the patient's anxiety (see [Chapter 37](#)). Have the patient practice these skills before instruction to improve his or her comprehension and understanding of the information given ([Bastable, 2017](#)). Also remember to manage any symptoms, such as pain or nausea, before beginning a teaching session so that a patient can better relax during instruction.

Building on Existing Knowledge

A patient learns best on the basis of preexisting cognitive abilities and knowledge. Thus an educator is more effective when he or she presents information that builds on a learner's existing knowledge. For example, a patient who has lived with multiple sclerosis for several years is beginning a new medication that is given subcutaneously. Before teaching the patient how to prepare the medication and give the injection, the nurse asks about the patient's previous experience with injections. On assessment the nurse learns that the patient's father had diabetes and that the patient administered the insulin injections. The nurse thus individualizes the teaching plan by building on the patient's previous knowledge and

experience with insulin injections and focuses on the unique approach the patient will use for self-injection.

Teaching Approaches

A nurse's teaching approach is different from teaching methods. Some situations require an educator to be directive. Others require a nondirective approach. An effective educator concentrates on the task and uses teaching approaches appropriate to the learner's needs. A learner's needs and motives frequently change over time. Thus the effective educator is always aware of the need to modify teaching approaches.

Telling

Use the telling approach when there is limited time for teaching information (e.g., preparing a patient for an emergent diagnostic procedure). If a patient is highly anxious but it is vital for information to be given, telling is effective. When using telling, the nurse outlines the task that a patient will perform and gives simple, explicit instructions. There is no opportunity for feedback with this method.

Participating

In the participating approach a nurse and patient set objectives and become involved in the learning process together. The patient helps decide content, and the nurse guides and counsels the patient with pertinent information. In this method there is opportunity for discussion, feedback, mutual goal setting, and revision of the teaching plan. For example, a parent caring for a child with leukemia must learn how to care for the child at home and recognize problems that need to be reported immediately. The parent and nurse collaborate on developing an appropriate teaching plan for how to recognize and manage complications, maintain a healthy diet for the child, and maximize the child's ability to remain active. After each teaching session is completed, the parent and nurse review the objectives together, determine whether the objectives were met, and plan what will be covered in the next session.

Entrusting

The entrusting approach provides a patient the opportunity to manage self-care. The aim of the instructional approach is to provide the knowledge and skills that enable a patient to accept responsibilities and perform tasks correctly and consistently. The nurse observes the patient's

progress and remains available to assist without introducing more new information. For example, a patient has been managing type 2 diabetes well for 10 years with oral medications, diet, and exercise. However, 1 year ago his diabetes changed, and it was difficult to control his hemoglobin A1c level (which reflects glucose control). As a result, the oral medications were discontinued, and insulin was added to his self-management plan. After initial instruction on dose management and injections, the nurse now monitors the patient's A1c level, offers reinforcement, and asks the patient if any new learning needs have developed. The nurse trusts the patient has become self-sufficient with managing insulin doses and injections.

Reinforcing

Reinforcement requires the use of a stimulus to increase the probability of a desired response. A learner who receives reinforcement before or after a desired learning behavior is more likely to repeat that behavior.

Reinforcers are positive or negative. Positive reinforcement such as a smile or verbal praise promotes desired behaviors. Although negative reinforcement such as frowning or criticizing can decrease an undesired response, it may also discourage participation and cause the learner to withdraw (Bastable, 2017). The effects of negative reinforcement are less predictable and often undesirable.

Reinforcers can come in the form of social acknowledgments (e.g., nods, smiles, words of encouragement), pleasurable activities (e.g., walks or play time), and tangible rewards (e.g., toys or food). Choosing an appropriate reinforcer to alter behavior requires careful observation of an individual's response to specific stimuli. When a nurse works with a patient, most reinforcers are social; however, material reinforcers may work well with young children. In adults reinforcement is more effective when the nurse has established a therapeutic relationship with the patient. Whatever the form, it is important that reinforcement closely follows the desired behavior. Timing is essential so that a clear correlation between the desired behavior and reward is established (Bastable, 2017).

Incorporating Teaching With Nursing Care

Many nurses find that they are able to teach more effectively while delivering nursing care. This becomes easier as you gain confidence in your clinical skills. For example, while hanging blood, you explain to the patient why the blood is necessary and the symptoms of a transfusion reaction that need to be reported immediately. Another example is to

explain the side effects of a medication while administering it. An informal, unstructured style relies on the positive therapeutic relationship between nurse and patient, which fosters spontaneity in the teaching-learning process. Teaching during routine care is efficient and cost-effective (Fig. 25.3).

FIG. 25.3 Teaching postoperative care while walking with the patient uses time efficiently.

Instructional Methods

Choose instructional methods that match a patient's learning needs, the time available for teaching, the setting, the resources available, and your comfort level with teaching. Skilled educators are flexible in altering teaching methods according to a learner's responses. An experienced educator uses a variety of techniques and teaching aids. Specific teaching strategies should include open-ended questioning and problem-solving

exercises. Do not expect to be an expert educator when first entering nursing practice. Learning to become an effective educator takes time and practice.

When first starting to teach patients, it helps to remember that patients perceive you as an expert. However, this does not mean that they expect you to have all of the answers. It simply means that they expect that you will keep them appropriately informed. Effective nurses keep the teaching plan simple and focused on patients' needs.

Verbal One-on-One Discussion

The most common method of instruction is a one-on-one verbal discussion. This approach involves sharing information directly with a patient. Verbal education of patients and family members requires an interdisciplinary approach that takes into account learning styles, literacy, and culture to apply clear communication and instructional methods (Marcus, 2014). This approach typically is done in an informal manner, allowing a patient to ask questions and share concerns. Speaking with an "expert" nurse or health care provider is a preferred educational modality for many patients (Kit Delgado et al., 2010). However, education is ineffective if verbal instruction is not done well. Instructional information must be accurate, timely, complete, and unambiguous when presented. Research has shown that verbal communication is often partly understood, misunderstood, or misinterpreted (Marcus, 2014). Also, nurses today often do not have the time to fully listen to patients and engage in quality verbal instruction. The Brigham and Women's Faulkner Hospital (BWFH) Patient/Family Education Committee reviewed research on verbal instruction and developed the EDUCATE Model (Table 25.4) (Marcus, 2014). It is a process-based model that leads a nurse educator through five stages of verbal education to reach teaching and education goals. The EDUCATE model is simple but enables all health care providers to better guide verbal education and ensure that education is more patient- and family-centered.

TABLE 25.4

Educate Model

E	D	U	C	A	TE
Enhance Comprehension and Retention	Deliver Patient-Centered Education	Understand the Learner	Communicate Clearly and Effectively	Address Health Literacy and Cultural Competence	Teaching and Education Goals
Use a question list so that patients can ask questions and providers can answer them (Posma et al., 2009).	Talk to—NOT AT—people (Behar-Horenstein et al., 2005).	Find out what the patient already knows before providing information; ask, “What do you already know about high blood pressure?” (Kripalani and Weiss, 2006).	New communication skills require practice to use them effectively, and structured skill development exercises may be helpful for providers (Kripalani and Weiss, 2006).	Ask patients, “Do you need help understanding health information?” (TJC, 2010).	Adequate preparation for teaching and learning
Repeat the most important information (Margolis, 2004; Ronco et al., 2012; Takemura et al., 2011).	Practice empathetic skills, especially when the view of the patient is different from that of the provider (Cant and Aroni, 2008; Posma et al., 2009; Skorpen and Malterud, 1997).	Be aware of nonverbal messages when delivering verbal communication, including gestures, body language, and dress (Cant and Aroni, 2008).	Present the most important information first (Margolis, 2004). Emphasize one to three key points (Kripalani & Weiss, 2006). Focus on one issue at a time (Avitzur, 2011). Present the information in logical blocks (Remshardt, 2011). Use concrete instructions (Margolis, 2004).	Supplement and reinforce verbal education with simple written and visual materials (Behar-Horenstein et al., 2005; Margolis, 2004); however, the materials should be used for reinforcement and not to replace verbal instruction or direct interaction.	Effective teaching methods
Ask patients to repeat information in their own words (Engel et al., 2009).	Ask patients about their life experiences and build upon them when teaching (Montin et al., 2010). Use metaphors comparing the patient’s care to his or her life situation (Behar-Horenstein et al., 2005).	Determine the patient’s barriers to health literacy (Paasche-Orlow, 2011). Use interviews and observation to assess a patient’s ability to learn (Behar-Horenstein et al., 2005).	Use easy-to-understand language (Kripalani and Weiss, 2006; Margolis, 2004; Posma et al., 2009).	Use an interpreter if a patient requires one due to language or disability (Dreger, 2001; Lieu et al., 2007). Avoid using technical terminology or medical jargon (The Joint Commission, 2010).	Overcoming barriers to learning
Provide information in several different ways to make sure the patient understands (Skorpen & Malterud, 1997). Digital recordings of patient consultations can be effective for patient recall of verbal education (Friedman, et al., 2011).	Pay attention to the patient’s worries and fears and try to dispel them (Posma et al., 2009).	Include family members in your education when appropriate. On many occasions (e.g., for pain management) family members also need to be educated (Behar-Horenstein et al., 2005).	Patients must be given an opportunity to ask questions before discharge. Give them time to speak (Behar-Horenstein et al., 2005).	Consider using a scripted tool to make patient education clearer and more understandable (Piazza et al., 2012).	Teaching as an interactive process
Use the teach-back method (Anonymous, 2008; Kripalani and Weiss, 2006; The Joint Commission, 2010).	Ask patients to state their goals of medical care to begin a discussion (Paasche-Orlow, 2011).	Realize that patients may not be aware that they do not understand what is being communicated to them (Engel et al., 2009).	Consider using audio recordings of patient consultations to improve patient recall of important information (Friedman et al., 2011).	Do not just ask the patient, “Do you understand?” Regardless of their ability to understand, many patients may still answer, “Yes” (The Joint Commission, 2010).	Assessment of learning

Note: The last column of the EDUCATE model stands for T and E, Teaching and Education goals; it outlines principles of the model as they relate to the model’s individual components.

From Marcus C: Strategies for improving the quality of verbal patient and family education: a review of the literature and creation of the EDUCATE

model, *Health Psychol Behav Med.* 2(1): 482–495, 2014.

Group Instruction

You may choose to teach patients in groups because of the advantages associated with group teaching. Groups are an economical way to teach a number of patients at one time. Patients are able to interact with one another and learn from the experiences of others. Learning in a group of six or less is most effective and avoids distracting behaviors (Bastable, 2017). Group-based instruction benefits include deeper understanding, longer retention, increased social support, and more active participation (Bastable, 2017). Group instruction often involves both lecture and discussion. Lectures are highly structured and efficient in helping groups of patients learn standard content about a subject. A lecture does not ensure that learners are actively thinking about the material presented; thus discussion and practice sessions are essential. After a lecture, learners need the opportunity to share ideas and seek clarification. Group discussions allow patients and families to learn from one another as they review common experiences. A productive group discussion helps participants solve problems and arrive at solutions toward improving each member's health. To be an effective group leader, you guide participation. Acknowledging a look of interest, asking questions, and summarizing key points foster group involvement. However, not all patients benefit from group discussions; sometimes the physical or emotional level of wellness makes participation difficult or impossible.

Preparatory Instruction

Patients frequently face unfamiliar tests or procedures that create significant anxiety about the procedure and outcome. Providing information about procedures often decreases anxiety because this gives patients a better idea of what to expect during their procedures, enhancing their sense of control. The known is less threatening than the unknown. Follow these guidelines for giving preparatory explanations:

- Describe physical sensations during a procedure. For example, when drawing a blood specimen, explain that the patient will feel a sticking sensation as the needle punctures the skin.
- Describe the cause of the sensation, preventing misinterpretation of the experience. For example, explain that a needlestick burns

- because the alcohol used to clean the skin enters the puncture site.
- Prepare patients only for aspects of the experience that others have commonly noticed. For example, explain that it is normal for a tight tourniquet to cause a person's hand to tingle and feel numb.
 - Be sure the patients know when the results will be available and who will give them the results of their tests and/or procedures.

A cognitive regulation technique called "reappraisal" can be effective in reducing anticipatory anxiety. This cognitive change strategy involves changing the meaning of a stimulus in a way that alters its emotional impact (Sheppes and Gross, 2011). For example, rather than saying to a patient during the insertion of an intravenous catheter, "You are going to feel a stick," say instead, "The catheter I am about to place in your arm will be our way of giving you the fluids and medications you need." Reappraisal typically includes reconsideration or reframing of an emotional event in less emotional terms (Yoshimura et al., 2014).

Demonstrations

Use demonstrations when teaching psychomotor skills such as preparing a syringe, bathing an infant, crutch walking, or taking a pulse. Demonstrations are most effective when learners first observe the educator and during a **return demonstration** have the chance to practice the skill. Combine a demonstration with discussion to clarify concepts and feelings. An effective demonstration requires advanced planning:

1. Be sure that the learner can see each step of the demonstration easily. Position the learner to provide a clear view of the skill being performed.
2. Assemble and organize the equipment. Make sure that all equipment works.
3. Perform each step slowly and accurately in sequence while analyzing the knowledge and skills involved, and allow the patient to handle the equipment.
4. Review the rationale and steps of the procedure.
5. Encourage the patient to ask questions so that he or she understands each step.
6. Judge proper speed and timing of the demonstration on the basis of the patient's cognitive abilities and anxiety level.

7. To demonstrate mastery of the skill, have the patient perform a return demonstration under the same conditions that will be experienced at home or in the place where the skill is to be performed. For example, when a patient needs to learn to walk with crutches, simulate the home environment. If the patient's home has stairs, the patient would practice going up and down a staircase in the hospital.

Analogies

Learning occurs when an educator translates complex language or ideas into words or concepts that a patient understands. **Analogies** supplement verbal instruction with familiar images that make complex information more real and understandable. For example, when explaining arterial blood pressure, use an analogy of the flow of water through a hose. Follow these general principles when using analogies:

- Be familiar with the concept.
- Know the patient's background, experience, and culture so that you can make an analogy relevant.
- Keep the analogy simple and clear.

Role-Playing

In role-playing people are asked to play themselves or someone else. Patients learn required skills and feel more confident in being able to perform them independently. The technique involves rehearsing a desired behavior. For example, a nurse who is teaching a parent how to respond to a child's behavior pretends to be a child who is having a temper tantrum. The parent responds to the nurse who is pretending to be the child. Afterward the nurse evaluates the parent's response and determines whether an alternative approach would have been more appropriate.

Simulation

Simulation is a useful technique for teaching problem solving, application, and independent thinking. During individual or group discussion you pose a pertinent problem or situation for patients to solve. For example, patients with heart disease plan a meal that is low in cholesterol and fat. The patients in the group decide which foods are appropriate. You ask the

group members to present their diet, providing an opportunity to identify mistakes and reinforce correct information.

Illiteracy and Other Disabilities

Patients with low health literacy, illiteracy, and learning disabilities have an impaired ability to analyze instructions or synthesize information. Many of these patients have not acquired or are unable to acquire the problem-solving skills of drawing conclusions and inferences from experience, and they do not ask questions to obtain or clarify information that has been presented. Using strategies to promote health literacy creates a more patient-centered approach to health education and can have a significant impact on patient outcomes (Edelman and Kudzma, 2017) (Box 25.6). You can promote health literacy by creating a safe, shame-free environment, using clear and purposeful communication techniques, using visual aids to reinforce spoken material, and by taking special care to evaluate patient understanding of the content. Follow the EDUCATE model (see Table 25.4).

Box 25.6 Patient Teaching Teaching a Patient With Literacy or Learning Disability Problems

Objective

- Patient will perform desired behaviors accurately.

Teaching Strategies

- Establish trust with patient before beginning the teaching-learning session.
- Face patient when speaking. Sit at his or her level to maintain eye contact.
- Speak slowly and encourage questions.
- Use simple terminology. If necessary, explain medical terms using basic one- or two-syllable words.
- Keep teaching sessions short and to the point and minimize distractions. Include the most important information at the beginning

of the session.

- Teach in increments and organize information into sections.
- Provide teaching materials written in plain language that reflect the reading level of the patient, with attention given to short words and sentences, large type, and simple format (generally, information written on a fifth-grade reading level is recommended for adult learners).
- Relate practical information to personal experiences or real-life situations.
- Use visual aids when appropriate and simple analogies or stories to personalize messages.
- Model appropriate behavior and use role-playing to help patient learn how to ask questions and ask for help effectively.
- Frequently ask patient for feedback to determine whether he or she comprehends information.
- Ask for return demonstrations, use the teach-back method, and clarify instructions when needed.
- Keep motivation high and recognize progress with positive reinforcement.
- Reinforce the most important information at the end of the session.
- Schedule teaching sessions at frequent intervals.

Evaluation

Use the principles of teach back to evaluate patient/family caregiver learning:

- I want to make sure I explained this information clearly. Please tell me why it is important for you to manage your illness.
- We discussed how it will be important for you to prepare a diet at home with the right type of foods. Let me see you prepare a sample menu for a breakfast, lunch, and dinner.

Data from Bastable S: *Nurse as educator: principles of teaching and learning for nursing practice*, ed 5, Burlington, VT, 2017, Jones & Bartlett.

Sometimes patients have sensory deficits that affect how you present information (see [Chapter 49](#)). For example, patients who are deaf may

require a sign language interpreter. Not all people who are deaf read lips. Therefore it is very important to provide clear written materials that match the patients' reading level. Visual impairments also affect the teaching strategy you use. Many people who are blind have acute listening skills. Avoid shouting, and announce your presence to patients with visual impairments before approaching them. If the patient has partial vision, use colors and a print font size (14-point font or greater) that the patient is able to see. Be sure to use proper lighting. Other helpful interventions include audio recording teaching sessions and providing structured, well-organized instructions (Bastable, 2017).

Building Competency in Patient-Centered Care

You are assessing a 62-year-old patient named Betty at an outpatient neurology clinic; Betty was recently discharged from the hospital following an ischemic stroke. Betty was recently started on several new medications for secondary stroke prevention, including medications for high cholesterol and high blood pressure and thrombolytic therapy. While reviewing her medications, you find that she has difficulty understanding printed teaching sheets. Betty discloses to you, "I had to drop out of school when I was 13 years old to take care of my younger siblings. I really haven't been to the doctor since my old doctor retired and I didn't like his replacement, and that was over 10 years ago." When asked where she keeps her medication, Betty shows you a grocery bag that has prescription bottles inside, and it includes both current and expired prescriptions. Which assessment questions and teaching strategies, approaches, and tools do you need to enhance Betty's learning and ability to take her medications as prescribed?

Cultural Diversity

Accept a patient's cultural background and belief system and be prepared to offer culturally sensitive approaches in a patient's native language (see [Chapter 9](#) and [Box 25.7](#)). Be careful not to generalize or stereotype patients solely on the basis of their culture. Collaborate with other nurses and educators to develop appropriate teaching approaches, and ask people from their cultural group to help by sharing their values and beliefs. Ethnic nurses are excellent resources who are able to provide input

through their experiences to improve the care provided to members of their own community.

Box 25.7 Cultural Aspects of Care Patient Education

Patient-centered education needs to be culturally sensitive for learning to occur. Sociocultural norms, values, and traditions often determine the importance of different health education topics and the preference of one learning approach over another. Educational efforts are especially challenging when patients and educators do not speak the same language or when written materials are not culturally sensitive and are written above patients' reading abilities.

Implications for Patient-Centered Care

- Develop a cultural awareness to establish and maintain respectful relationships with culturally diverse patients to encourage trust and communication (Bastable, 2017) (see Chapter 9).
- Implement the National CLAS Standards (<https://www.thinkculturalhealth.hhs.gov/clas>), a set of 15 action steps intended to advance health equity, improve quality, and help eliminate health care disparities (USDHHS, n.d.a).
- When you and the patient do not speak the same language, use trained and certified health care interpreters to provide health care information.
- Sociocultural factors influence a patient's perception of health and illness and how patients seek health care information (Bastable, 2017).
- Nurses need to have access to a variety of culturally diverse health care resources and should select teaching strategies that are relevant to the individual patient.

In addition, be aware of intergenerational conflicts of values. This occurs when immigrant parents uphold their traditional values and their children, who are exposed to American values in social encounters, develop beliefs similar to those of their American peers. Consider this conflict in values when providing information to families or groups who have members from different generations. To enhance patient education in culturally diverse populations, know when and how to provide education

while respecting cultural values. Modify teaching to accommodate for cultural differences. Research has shown that health outcomes are improved when education is given in the context of each person's specific cultural beliefs and practices ([Bastable, 2017](#)).

Using Teaching Tools

Many teaching tools are available for patient education. Selection of the right tool depends on the instructional method, a patient's learning needs, and the ability to learn ([Table 25.5](#)). For example, a printed pamphlet is not the best tool to use for a patient with poor reading comprehension, but an audio recording is a good choice for a patient with visual impairment. Health care agencies often provide clinicians with access to a variety of teaching resources. Be knowledgeable about what is available in your agency to better serve your patients. Also, if patients show interest in seeking information about their health from the Internet, inform them of the most reliable sources. For example, the American Cancer Society, American Lung Association, American Heart Association, and Centers for Disease Control and Prevention offer excellent information for laypeople.

TABLE 25.5**Teaching Tools for Instruction**

Description	Learning Implications
Written Materials	
Printed and Online Materials	
Written teaching tools available as pamphlets, booklets, brochures	Material needs to be easy to read. Information needs to be accurate and current. Method is ideal for understanding complex concepts and relationships.
Programmed Instruction	
Written sequential presentation of learning steps requiring that learners answer questions and educators tell them whether they are right or wrong	Instruction is primarily verbal, but the educator sometimes uses pictures or diagrams. Method requires active learning, giving immediate feedback, correcting wrong answers, and reinforcing right answers. Learner works at own pace.
Computer Instruction	
Use of programmed instruction format in which computers store response patterns for learners and select further lessons on basis of these patterns (programs can be individualized)	Method requires reading comprehension, psychomotor skills, and familiarity with computer.
Nonprint Materials	
Diagrams	
Illustrations show interrelationships by means of lines and symbols	Method demonstrates key ideas, summarizes, and clarifies key concept.
Graphs (Bar, Circle, or Line)	
Visual presentations of numerical data	Graphs help learner grasp information quickly about single concept.
Charts	
Highly condensed visual summary of ideas and facts that highlights series of ideas, steps, or events	Charts demonstrate relationship of several ideas or concepts. Method helps learners know what to do.
Pictures	
Photographs or drawings used to teach concepts in which the third dimension of shape and space is not important	Photographs are more desirable than diagrams because they more accurately portray the details of the real item.
Physical Objects	
Use of actual equipment, objects, or models to teach concepts or skills	Models are useful when real objects are too small, large, or complicated or are unavailable. Allows learners to manipulate objects that they will use later in skill.
Other Audiovisual Materials	
Slides, audiotapes, television, and videotapes used with printed material or discussion	Materials are useful for patients with reading comprehension problems and visual deficits.

Special Needs of Children and Older Adults

Children, adults, and older adults learn differently. You adapt teaching strategies to each learner. Children pass through several developmental stages (see Unit 2). In each developmental stage children acquire new cognitive and psychomotor abilities that respond to different types of teaching methods. Incorporate parental input in planning health education for children.

Older adults experience numerous physical and psychological changes as they age (see [Chapter 14](#)). These changes not only increase their educational needs but also create barriers to learning unless adjustments are made in nursing interventions. Sensory changes such as visual and hearing changes require adaptation of teaching methods to enhance functioning. Older adults learn and remember effectively if you pace the learning properly and if the material is relevant to the learner's needs and abilities. Although many older adults have slower cognitive function and reduced short-term memory, you facilitate learning in several ways to support behaviors that maximize the individual's capacity for self-care ([Box 25.8](#)).

Box 25.8 Focus on Older Adults **Providing Patient Education**

Facilitate learning by using the following teaching strategies when providing patient education to older adults:

- Promote concentration and learner readiness by scheduling teaching sessions when the patient is comfortable and well rested. Provide medication for pain relief when necessary. Ensure that the patient is not drowsy from medication during the education session.
- Create a casual and relaxed learning environment.
- Establish personalized, realistic short-term learning goals.
- Provide sufficient lighting with low glare.
- If using visual aids or written materials to supplement instruction, assess the patient's reading ability and make sure that information is printed in a large-size font and in a color that contrasts with the background (e.g., black 14-point print on matte white paper). Avoid blues and greens because these colors can become more difficult to distinguish with age.
- To accommodate for hearing loss, present information slowly and in a clear, low tone of voice. Eliminate any extraneous noises and directly face the learner when speaking. Do not place your hand near your mouth while a hearing-impaired patient is trying to hear (or lip-read) instructions. Mustaches can make lipreading difficult for a hearing-impaired patient.

- Encourage the use of prosthesis (i.e., glasses, hearing aid), and ensure proper fit and working condition.
- Allow sufficient time to process and comprehend new information.
- Build on existing knowledge and present content in a way that relates to relevant past life experiences.
- Make information meaningful by using concrete examples that apply to current situations.
- Present only the most significant information to avoid overwhelming the learner. Use repetition to reinforce content.
- When giving instructions or teaching a new skill, give concise, step-by-step directions. Assess understanding of each step before moving ahead.
- Provide regular positive reinforcement.
- Keep teaching sessions short and allow for frequent breaks. Schedule follow-up sessions as needed to ensure learning.
- Conclude with a brief summary and allow sufficient time for questions and feedback.

Data from Touhy TA, Jett KF: *Ebersole and Hess' toward healthy aging*, ed 9, St Louis, 2015, Mosby; Edelman C, Kudzma EC: *Health promotion throughout the life span*, ed 9, St Louis, 2017, Mosby.

Establish short-term goals when teaching older patients. Include family members who assume care for the patient. However, be sensitive to a patient's desire for assistance because offering unwanted support often results in negative outcomes and perceptions of nagging and interference. Not all relationships between older adults and other family members are therapeutic.

• Evaluation

Through the Patient's Eyes

An important part of evaluation is to determine whether the patient's expectations, identified during assessment, were met. You engage patients to determine if they perceive having learned what they expected. Be sure their expectations have been fully met. Does the patient have the sense that he or she can maintain self-care based on the information received? It is important to evaluate through the patient's eyes, considering the types of

situations and environments that patients return to after receiving care. Evaluation helps the educator determine adequacy of teaching. If expectations have not been met, you revise the plan of care and offer additional instruction or reinforcement.

Patient Outcomes

Evaluation of any instructional approach involves measuring whether learning objectives were met. You gather data to measure whether the patient has the new knowledge, behaviors, or skills that education aimed to provide. You observe a patient's performance of any expected behavior or skill. You also ask evaluative questions, phrased carefully, then guide the patient to identify or describe information so that you can determine whether the established goals and learning objectives were met. For example, you might say, "Tell me specifically the times of day you are to take this new medication" or "We discussed the safety risks in your home; tell me what you plan to do to remove them." Consider these questions as you evaluate a patient's education plan.

- Were the patient's goals or outcomes realistic and observable?
- Is the patient able to perform the behavior or skill in the natural setting (e.g., home)?
- How well is the patient able to answer questions about the topic?
- Does the patient continue to have problems understanding the information or performing a skill? If so, how can you change the interventions to enhance knowledge or skill performance?

Evaluate a patient's learning in a timely manner so that you can make adjustments or changes as needed.

The nurse is legally responsible for providing accurate, timely patient information that promotes continuity of care; therefore, it is essential to document the outcomes of teaching. Documentation of patient teaching also supports quality improvement efforts, meets TJC standards, and promotes third-party reimbursement. Teaching flow sheets and written plans of care (e.g., CareMaps) are excellent records that document the plan, implementation, and evaluation of learning.

Teach-Back

It is imperative to assess whether a patient understands information during an educational session. One way to evaluate patient understanding

is with the teach-back method. **Teach-back** is a closed-loop communication technique that assesses patient retention of the information given during a teaching session. To perform teach-back, ask the patient to explain material that was discussed, such as the role of diet and exercise in managing blood glucose levels, or to demonstrate a skill, such as self-monitoring blood glucose. The response allows you to determine the degree to which the patient remembers and understands what was taught or demonstrated. Use nonjudgmental language so that patients do not feel tested (Flanders, 2018). For example, say, "I want to be certain that I taught this well. Can you please describe some symptoms of a stroke?" Examples of teach-back prompts and questions include:

1. "Tell me in your own words how you will take this medication at home."
2. "Please demonstrate how to use this blood glucose monitor."
3. "What are some of the side effects that you should watch for?"
4. "When will you call the office regarding your blood pressure?"
5. "Please show me how to request a refill of this medication online."

If the patient has difficulty recalling the material or demonstrating a skill, modify and repeat the content and reassess his or her retention. Also, take ownership of the teaching experience by responding, "I must not have explained stroke symptoms very well. Let me try again." Patient understanding is confirmed when the patient can accurately restate the information in his or her own words (Bastable, 2017).

Key Points

- The three purposes of patient education are health promotion and illness prevention, health restoration, and coping.
- Teaching and learning generally begin when a person identifies a need for knowing or acquiring an ability to do something.
- Nurses have a legal responsibility to provide education to all patients.
- The Joint Commission's Speak Up initiatives help patients understand their rights when receiving medical care.

- An effective educator provides a mechanism for evaluating the success of a teaching plan and then provides positive reinforcement.
- The three domains of learning including cognitive, affective, and psychomotor.
- The ability to learn depends on physical and cognitive attributes, developmental level, physical wellness, and intellectual thought processes. A person's learning style affects his or her preferences for learning.
- Self-efficacy is a concept included in many health promotion theories because it often is a strong predictor of healthy behaviors.
- An adult's readiness to learn is often associated with his or her developmental stage and other events occurring in his or her life.
- Both the nursing and teaching processes require assessment and evaluation. The nursing and teaching processes differ in that the nursing process requires assessment of all sources of data to determine a patient's total health care needs.
- A nurse bases educational priorities on a patient's immediate needs, nursing diagnoses, and the goals and outcomes established for the patient. Priorities also depend on what a patient perceives to be most important.
- The ideal environment for learning is well lit and has good ventilation, appropriate furniture, and a comfortable temperature.
- At the end of the session, the nurse uses the teach-back technique to evaluate learning by asking the patient to explain the material that was discussed.

Reflective Learning

- Reflect on a patient you cared for recently. How did you determine if the patient understood the care you provided during that experience?
- Consider that you have a young adult patient who has to take an antibiotic three times a day. How would your teaching approach be different if the patient were an older adult and had difficulty seeing and hearing?
- Go to a website that provides patient information about an illness (e.g., heart disease, diabetes). Is the information easy to understand? How could the information be presented in a way that would enhance its readability?

Review Questions

1. A patient asks a nurse to provide instruction on how to perform a breast self-exam. Which domains are required to learn this skill? (Select all that apply.)
 1. Affective domain
 2. Sensory domain
 3. Cognitive domain
 4. Attentional domain
 5. Psychomotor domain
2. A patient suddenly experiences a severe headache with numbness and decreased movement in the left arm. The emergency room physician suspects a stroke and is going to have the patient undergo an emergent angiogram to remove the clot. Which teaching approach is most appropriate?
 1. Selling approach
 2. Telling approach

- 3. Entrusting approach
- 4. Participating approach

3. A nurse is caring for a young patient who has been told he has multiple sclerosis. The nurse has planned time to conduct a teaching session that will focus on the disease and principles of management. The nurse chooses to use the EDUCATE model to proceed with instruction. Which of the following are components of the model? (Select all that apply.)

- 1. State goals of the session for the patient.
- 2. Repeat the most important information.
- 3. Practice empathetic skills.
- 4. Be aware of nonverbal messages.
- 5. Use a standard question list for the chosen topic.

4. A nurse is teaching an older adult patient about ways to detect a melanoma. Which of the following are age-appropriate teaching techniques for this patient? (Select all that apply.)

- 1. Speak in a low tone.
- 2. Begin and end the session with the most important information regarding melanoma.
- 3. Provide a pamphlet about melanoma with large font in blues and greens.
- 4. Provide specific information in frequent, small amounts for older adult patients.
- 5. Speak quickly so that you do not take up much of the patient's time.

5. A 55-year-old adult male has been in the hospital over a week following surgical complications. The patient has had limited activity but is now finally ordered to begin a mobility program. The patient just returned from several diagnostic tests and tells the nurse he is feeling quite fatigued. The nurse prepares to instruct the patient on the mobility program protocol. Which of

the following learning principles will likely be affected by this patient's condition?

1. Motivation to learn
 2. Developmental stage
 3. Stage of grief
 4. Readiness to learn
6. A patient recovering from open heart surgery is taught how to cough and deep breathe using a pillow to support or splint the chest incision. Following the teaching session, which of the following is the best way for the nurse to evaluate whether learning has taken place?
1. Verbalization of steps to use in splinting
 2. Selecting from a series of flash cards the images showing the correct technique
 3. Return demonstration
 4. Cloze test
7. A patient's cultural background affects the motivation for learning. Using the ACCESS model, match the nursing approach with the correct model component.

ACCESS model component	Nursing approach
1. Assessment	A. Help patients feel culturally secure and able to maintain their cultural identity.
2. Communication	B. Remain aware of verbal and nonverbal responses.
3. Cultural	C. Be aware of how patients from diverse backgrounds perceive their care needs.
4. Establishment	D. Become aware of your patient's culture and your own cultural biases.
5. Sensitivity	E. Learn about the patient's health beliefs and practices.
6. Safety	F. Show respect by creating a caring rapport.

8. A 63-year-old woman is a family caregiver for her 88-year-old mother who has dementia. The caregiver asked the home health nurse how to manage her mother when she becomes confused and violent. The best instructional method a nurse can use for this situation is:
1. Demonstration

2. Preparatory instruction
 3. Role-playing
 4. Group instruction with other family caregivers
9. A nurse is preparing to teach a patient who has sleep apnea how to use a CPAP machine at night. Which action is most appropriate for the nurse to perform first?
1. Allow patient to manipulate machine and look at parts.
 2. Provide a teach-back session.
 3. Set mutual goals for the education session.
 4. Discuss the purpose of the machine and how it works.
10. Which of the following scenarios demonstrate that learning has taken place? (Select all that apply.)
1. A patient listens to a nurse's review of the warning signs of a stroke.
 2. A patient describes how to set up a pill organizer for newly ordered medicines.
 3. A patient attends a spinal cord injury support group.
 4. A patient demonstrates how to take his blood pressure at home.
 5. A patient reviews written information about resources for cancer survivors.

Informatics and Documentation

OBJECTIVES

- Identify the purposes of a health care record.
- Discuss the relationship between documentation and financial reimbursement for health care.
- Discuss legal guidelines for documentation.
- Identify ways to maintain confidentiality of health care record data.
- Describe guidelines for quality documentation.
- Identify appropriate and inappropriate use of abbreviation(s) in health care documentation.
- Describe different methods used in record keeping.
- Identify elements to include when documenting a patient's discharge plan.
- Describe elements to include in documentation of telephone conversations with providers.
- Discuss the relationship between informatics and quality health care.
- Discuss the specific competencies in informatics for new graduate nurses entering the workforce.

Documentation is a key communication strategy that produces a written account of pertinent patient data, clinical decisions and interventions, and patient responses in a health record. Documentation in a patient's **health record** is a vital aspect of nursing practice. Health care documentation consists of all information entered into a health record, which may be electronic, paper, or a combination of both formats. Nursing documentation systems should reflect current standards of nursing practice and minimize the risk of errors. Documentation systems need to be flexible enough to allow members of the health care team to efficiently document and retrieve clinical data, track patient outcomes, and facilitate

continuity of care. Information in a patient's record provides a detailed account of the level of quality of care delivered. The quality of care, the standards of regulatory agencies and nursing practice, the reimbursement structure in the health care system, and legal guidelines make documentation and reporting an extremely important nursing responsibility.

The information you enter into a patient's individual medical record communicates within the patient's integrated health record the type and frequency of patient care delivered and provides accountability for the care you implemented. This information is then available for all members of the health care team in all settings to review.

It is necessary to document all the nursing care you provide for each patient, including assessment data, nursing problems or diagnoses, interventions, and evaluation of patient responses, in the health record. Your data enable providers and outside reviewers of the medical record to track a patient's clinical course. In 2008, the Centers for Medicare and Medicaid (CMS) implemented a policy under which hospitals are no longer reimbursed for the treatment of 11 specific hospital-acquired conditions (HAC) or preventable adverse events, commonly known as "never events" ([Cantrell, 2017](#)). Four of these preventable adverse events are considered "nurse-sensitive": stage III and IV pressure injuries, falls with injury, catheter-associated urinary tract infections (CAUTIs), and central line–catheter-associated bloodstream infections (CLABSIs) ([Bae & Yoder, 2015](#)). Identifying the progress of a patient and how events develop is crucial to clinical care and ultimately hospital reimbursement. It is also crucial that your documentation accurately reflects the status of the patient and responses to interventions, especially upon admission, transfer, or discharge.

Purposes of the Health Care Record

The health care record is a valuable source of data for all members of the health care team. Data entered into the health care record serve many purposes, including facilitating interprofessional communication among health care providers, providing a legal record of care provided, justification for financial billing and reimbursement of care. Data are also used to audit, monitor, and evaluate care provided to support the process needed for quality and performance improvement ([Wager, et al., 2017](#)). In addition the health care record is a resource for education and research. There are privacy and ethical considerations to address when accessing health care information and when health records serve as resources for nursing and health care education and for research data ([Hwang, 2017](#)).

Interprofessional Communication Within the Health Record

The health care record provides a way for members of the interprofessional health care team to communicate about multiple aspects of patient care, including patient needs and response to care and therapies; clinical decision making; and the content and outcomes of consultations, patient education, and discharge planning. Information communicated in the health care record allows health care providers to know a patient thoroughly, facilitating safe, effective, timely, and patient-centered clinical decision making. The health care record is the most current and accurate, continuous source of information about a patient's health care status, allowing the plan of care to be clear to anyone who accesses the record. To enhance communication and promote safe patient care, you document assessment findings and patient information as soon as possible after you provide care (e.g., immediately after providing a nursing intervention or completing a patient assessment). The quality of patient care depends on your ability to communicate with other members of the health care team (see [Chapter 24](#)). When a plan is not communicated to all members of the health care team, care becomes fragmented, tasks are repeated, and delays or omissions in care often occur. The health record is an important means of communication because it is a confidential, permanent, legal documentation of information relevant to a patient's health care. The record is an ongoing current and accurate account of a patient's health care status and is available to all members of the health care team.

The record is one resource that prepares the health care provider to know a patient thoroughly so that timely and appropriate care decisions can be made. All health records contain the following information:

- Patient identification and demographic data
- Existence of "living will" or "durable power of attorney for health care" documents
- Informed consent for treatment and procedures
- Admission data
- Nursing diagnoses or problems and the nursing or interprofessional care plan
- Record of nursing care treatment and evaluation
- Medical history
- Medical diagnoses

- Therapeutic orders, including code status (i.e., provider order for “do not resuscitate”)
- Medical and interprofessional progress notes (including treatments administered)
- Physical assessment findings
- Diagnostic study results
- Patient education
- Summary of operative procedures
- Discharge summary and plan

Legal Documentation

Accurate documentation is one of the best defenses for legal claims associated with nursing care. Documentation is an important professional responsibility. To limit liability, your documentation needs to follow organizational standards, which include a clear description of individualized and goal-directed nursing care you provide based on your nursing assessment. Always document patient care in a timely manner following agency standards. Documenting all aspects of the nursing process is a critical nursing responsibility that limits nursing liability by providing evidence that you maintained or exceeded practice standards while taking care of patients (Lewis et al., 2017; Wager et al., 2017).

Mistakes in documentation that can result in malpractice include the following examples: (1) failing to record pertinent health or drug information, (2) failing to record nursing actions, (3) failing to record medication administration, (4) failing to record drug reactions or changes in patients' conditions, (5) incomplete or illegible records, and (6) failing to document discontinued medications. Table 26.1 provides guidelines for avoiding these mistakes and gives some examples of basic criteria for legally sound documentation in a health record.

TABLE 26.1**Legal Guidelines for Documentation**

Guidelines for Electronic and Written Documentation	Rationale	Correct Action
Do not document retaliatory or critical comments about a patient or care provided by another health care professional. Do not enter personal opinions.	Statements can be used as evidence for nonprofessional behavior or poor quality of care.	Enter only objective and factual observations of a patient's behavior or the actions of another health care professional. Quote all patient statements.
Correct all errors promptly.	Errors in recording can lead to errors in treatment or may imply an attempt to mislead or hide evidence.	Avoid rushing to complete documentation; be sure that information is accurate and complete.
Record all facts.	Record must be accurate, factual, and objective.	Be certain that each entry is thorough. A person reading your documentation needs to be able to determine that a patient received adequate care.
Document discussions with providers that you initiate to seek clarification regarding an order that is questioned.	If you carry out an order that is written incorrectly, you are just as liable for prosecution as the health care provider.	Do not record "physician made error." Instead document that "Dr. Smith was called to clarify order for analgesic." Include the date and time of the phone call, with whom you spoke, and the outcome.
Document only for yourself.	You are accountable for information that you enter into a patient's record.	Never enter documentation for someone else (exception: if caregiver has left unit for the day and calls with information that needs to be documented; include date and time of entry and reference specific date and time to which you are referring and name of source of information in entry; include that information was provided via telephone).
Avoid using generalized, empty phrases such as "status unchanged" or "had good day."	This type of documentation is subjective and does not reflect patient assessment.	Use complete, concise descriptions of assessments and care provided so that documentation is objective and factual.

Guidelines for Electronic and Written Documentation	Rationale	Correct Action
Begin each entry with date and time and end with your signature and credentials.	Ensures that the correct sequence of events is recorded; signature documents who is accountable for care delivered.	Do not wait until the end of shift to record important changes that occurred several hours earlier; sign each entry according to agency policy (e.g., M. Marcus, RN).
Protect the security of your password for computer documentation.	Maintains security and confidentiality of patient health records.	Once logged into a computer, do not leave computer screen unattended. Log out when you leave the computer. Make sure that a computer screen is not accessible for public viewing.
Guidelines Specific to Written Documentation	Rationale	Correct Action
Do not erase or scratch out errors made while recording.	Charting becomes illegible: it appears as if you were attempting to hide information or deface a written record.	Draw single line through error, write word "error" above it, and sign your name or initials and date it. Then record note correctly.
Do not leave blank spaces or lines in a written nurses' progress note.	Allows another person to add incorrect information in open space.	Chart consecutively, line by line; if space is left, draw a line horizontally through it and place your signature and credentials at the end.
Record all written entries legibly using black ink. Do not use pencils, felt-tip pens, or erasable ink.	Illegible entries are easily misinterpreted, causing errors and lawsuits; ink from felt-tip pen can smudge or run when wet and may destroy documentation; erasures are not permitted in clinical documentation; black ink is more legible when records are photocopied or scanned.	Write clearly and include appropriate abbreviations using black ink.

Reimbursement

Documentation of patient care by all members of the health care team allows one to determine the severity of a patient's illness, the intensity of services received, and the quality of care provided during an episode of care. Insurance companies use this information to determine payment or reimbursement for health care services. **Diagnosis-related groups (DRGs)** are classifications based on a hospitalized patient's primary and secondary medical diagnoses that are used as the basis for establishing Medicare reimbursement for patient care. Hospitals are reimbursed a predetermined

dollar amount by Medicare for each DRG. Private insurance carriers and auditors from federal agencies review records to determine the reimbursement that a patient or a health care agency receives ([Bauder et al., 2017](#)). Accurate documentation of nursing services provided, as well as the supplies and equipment used in a patient's care, clarifies the type of treatment a patient received and supports accurate and timely reimbursement to a health care agency and/or patient.

Auditing and Monitoring

Quality patient care depends on the ability of all members of the interprofessional team to communicate effectively and in a timely manner. As a member of that team, you are held accountable for the accuracy of the documentation you enter into the patient's record. Regulations from agencies such as The Joint Commission (TJC) and the Centers for Medicare and Medicaid Services (CMS) require health care institutions to monitor and evaluate the quality and appropriateness of patient care ([TJC, 2018](#); [US Centers for Medicare & Medicaid Services, 2019](#)). Audits of health records offer information on recurrent health care problems, specific patient incidents, and whether health care providers follow standards of care. Health care record audits help to identify areas for improvement and staff development. For example, a quality improvement (QI) nurse may monitor a unit's records to determine whether nurses consistently and accurately documented implementation of fall precautions or evaluation of pain management interventions. Any deficiencies identified are shared with all members of the nursing staff so that changes in policy or practice can occur.

Education

Health care records are a rich source of information about a patient's health care. Reading the record of a patient for whom you are assigned to care is an effective way to learn the nature of a patient's condition and response to treatment. Over time, as you care for patients with similar diagnoses or problems, the information gained from those patients' records allows you to identify patterns and trends and to build your clinical knowledge. As you identify patterns associated with specific diseases and conditions, you are able to anticipate the type of care your patients require and how patients respond to treatment ([Fig. 26.1](#)).

FIG. 26.1 Nursing students and nursing faculty at computer screens.

Research

De-identification is a process used to prevent a person's identity from being connected with information. For example, when a data form is used to collect information from a health record a patient's name or Social Security number is not entered; instead a random number is used for labeling and categorizing the form. De-identified data obtained from health records can be used for statistical analysis (e.g., frequency of clinical disorders, complications, use of specific medical and nursing therapies, clinical outcomes achieved during care for specific illnesses, and patient mortality). Analysis of the data contributes to evidence-based nursing practice and quality health care (Polit & Beck, 2018). After obtaining appropriate approval from an Institutional Review Board (IRB) of a health care agency or hospital, a nurse researcher reviews patients' records in a research study to collect information on a particular health problem. For example, if a nurse researcher suspects that early ambulation decreases the complication rate in postoperative patients, the researcher could review

the records of select surgical patients to compare the rates of postoperative complications following early versus late ambulation.

The Shift To Electronic Documentation

Historically, health care professionals documented on paper health care records. Paper records were episode oriented, with a separate record created for each patient visit to a health care agency. Because a health care provider could not easily review a previous record, key information such as patient allergies, current medications, and complications from treatment were lost from one episode of care (e.g., hospitalization or clinic visit) to the next, jeopardizing a patient's safety (Hebda et al., 2019).

To facilitate communication among health care providers and improve patient safety, the American Recovery and Reinvestment Act (ARRA) of 2009 set a goal that all health care records would be kept electronically as of 2014 (Hebda et al., 2019). Since 2011, the Health Information Technology for Economic and Clinical Health Act (HITECH), enacted under Title XIII of ARRA, has been a major driver in the adoption and use of electronic health records (EHRs) across the United States. HITECH established provisions to promote the **meaningful use** of health information technology (HIT) to improve the quality and value of health care (Compliance Group: HIPAA Done Right, 2019). Meaningful use requires that use of an **electronic health record system (EHRs)** results in improved quality, safety, and efficiency of health care; increases health care consumers' active involvement in their care; increases coordination of health care delivery; advances public health; and safeguards the privacy and security of personal health records (Stimson & Bodruff, 2017). The goal of the ARRA was to have all health care records maintained electronically by 2014. Although the goal has not been fully met, the [Office of the National Coordinator for Health Information Technology \(2018\)](#) reports the following as of 2017:

- Ninety-six percent of all nonfederal acute care hospitals possessed certified health IT.
- Small rural and critical access hospitals had the lowest rates at 93%.
- Ninety-nine percent of large hospitals (more than 300 beds) had certified health IT, while 97 percent of medium-sized hospitals (more than 100 beds) had certified health IT.

Although the terms *EHR* and *EMR* have been used interchangeably in practice, there are differences between them. The term **electronic health record (EHR)** has become the favored term for an individual's lifetime computerized record; it means both the displayed or printed record. The addition of an "S" at the end of the acronym (EHRS) indicates the supporting software system. The term **electronic medical record (EMR)** refers to a patient's record within an integrated health care information system for an individual visit to a health care provider's office or for an individual admission to an acute care setting that allows for seamless documentation of the progression of care. To meet agreed-on standards, EHRs are expected to have the following attributes or components ([Hebda et al., 2019](#)):

- Provide a longitudinal or lifetime patient record by linking all patient data from previous health care encounters.
- Contain a problem list that indicates current clinical problems for each health care encounter, the number of occurrences associated with all past and current problems, and the current status of each problem.
- Use accepted standardized measures to evaluate and record health status and functional levels.
- Provide a method for documenting the clinical reasoning or rationale for diagnoses and conclusions that allows clinical decision making to be tracked by all providers who access the record.
- Support confidentiality, privacy, and audit trails.
- Provide continuous access to authorized users at any time, and allow multiple health care providers access to customized views of patient data at the same time.
- Support links to local or remote information resources such as databases using the Internet or intranet resources based within an organization.
- Support the use of decision analysis tools.
- Support direct entry of patient data by providers.
- Include mechanisms for measuring the cost and quality of care.
- Support existing and evolving clinical needs by being flexible and expandable.

A unique feature of an EHR is its ability to integrate all patient information into one record, regardless of the number of times a patient

enters a health care system. An EHR also includes results of diagnostic studies that may include diagnostic images (e.g., x-ray or ultrasound images) and decision support software programs. Because an unlimited number of patient records potentially can be stored within an EHR system, health care providers can access clinical data to identify quality issues, link interventions with positive outcomes, and make evidence-based decisions (Rajkovića et al., 2018) The key advantages of an EHR for nursing include a means for nurses to compare current clinical data about a patient with data from previous health care encounters, maintain ongoing symptom management, and provide an ongoing record of health education provided to a patient and the patient's response to that information (Ostrovsky, et al., 2016; Ozkaynak, et al., 2017).

Maintaining Privacy, Confidentiality, and Security of the Health Care Record

Nurses are legally and ethically obligated to keep information about patients confidential. Only members of the health care team who are directly involved in a patient's care have legitimate access to a patient's health record. You discuss a patient's diagnosis, treatment, assessment, and any personal conversations only with members of the health care team who are specifically involved in the patient's care. Do not share information with other patients or with health care team members who are not caring for the patient. Patients have the right to request copies of their medical record and read the information. Each institution has policies that describe how medical records are shared with patients or other people who request them. In most situations, patients are required to give written permission for release of their medical information.

The Health Insurance Portability and Accountability Act (HIPAA) of 1996 was the first federal legislation to provide protection for patient records; it governs all areas of patient information and management of that information. To eliminate barriers that potentially delay access to care, HIPAA requires providers to notify patients of privacy policies and to obtain written acknowledgment from patients indicating they received this information. Under HIPAA, the Privacy Rule requires that disclosure or requests regarding health information are limited to the specific information required for a particular purpose (Hebda et al., 2019). For example, if you need a patient's home telephone number to reschedule an appointment, access to the health record is limited solely to telephone information. Of equal importance under HIPAA is the Security Rule,

which specifies administrative, physical, and technical safeguards for 18 specific elements of **protected health information (PHI)** in electronic form (HIPAA [Journal, 2019](#)).

Nurses are permitted to use health records for data gathering, research, or continuing education as long as records are used as specified and permission is granted from an Institutional Review Board (for research) or appropriate administrative department. When you are a student learning in a clinical setting, maintaining patient confidentiality and adherence to HIPAA are required as part of professional practice. You can review patient health records only for information needed to provide safe and effective patient care. For example, when you are assigned to care for a patient, you need to review the patient's health record and the interprofessional plan of care. You *do not* share this information with classmates (except for clinical conferences) and *do not* access the health records of other patients on the unit. Access to an EHR is traceable through user log-in information. It is unethical to view health records of other patients, and breaches of confidentiality will lead to disciplinary action by employers and potentially dismissal from work or nursing school. To protect patient confidentiality, you must ensure that any electronic or written materials you use in your student clinical practice *do not* include patient identifiers (e.g., name, room number, date of birth, demographic information). *Never* print material from an EHR for personal use; any information printed must be for professional use only and should not include identifiable information.

Privacy, Confidentiality, and Security Mechanisms

There are legal implications associated with the use of electronic documentation. It is possible for anyone to access a computer within a health care agency and gain information about almost any patient. Under HIPAA, ensuring appropriate access to and confidentiality of personal health information (PHI) is the responsibility of all persons working in health care. Personal health information is individually identifiable information relating to an individual's past, present, or future health status that is created, collected, transmitted, or maintained by a HIPAA-covered entity in relation to the provision of health care, payment for health care services, or use in health care operations (HIPAA [Journal, 2019](#)). Protection of information and computer systems is one of your top priorities.

Most computer information system security mechanisms use a combination of logical and physical restrictions to protect information. For example, an automatic sign-off is a safety mechanism that logs a user off a computer system after a specified period of inactivity ([Hebda et al., 2019](#)). Other security measures include firewalls and the installation of antivirus and spyware-detection software. A **firewall** is a combination of hardware and software that protects private network resources (e.g., the information system of the hospital) from outside hackers, network damage, and theft or misuse of information.

Physical security measures include placing computers or file servers in restricted areas or using privacy filters for computer screens that are visible to visitors or other people who should not have access to the information displayed. This form of security has limited benefit, especially if an organization uses mobile wireless devices such as notebooks, tablets, personal computers (PCs), and smartphones. These devices are easily misplaced or lost, and at risk for falling into the wrong hands.

Access or log-in codes along with passwords are frequently used for authenticating authorized access to electronic records. A **password** is a collection of alphanumeric characters and symbols that a user types into a computer sign-on screen before accessing a program after the entry and acceptance of an access code or user name. Strong passwords use combinations of letters, numbers, and symbols that are difficult to guess. When using a health care agency computer system, it is essential that you do not share your computer password with anyone under any circumstances. A good system requires frequent changes in personal passwords to prevent unauthorized persons from tampering with records. A password does not appear on the computer screen when it is typed, and it should not be known to anyone but the user and information system administrators ([Hebda et al., 2019](#)). Most health care personnel are given access only to patients in their work area. Some staff (e.g., administrators or risk managers) have authority to access all patient records. To protect patient privacy, health care agencies track who accesses patient records and when they access them. Failure to adhere to HIPAA can result in civil and criminal penalties for health care agencies and providers. Depending on the nature of a violation, civil penalties can result in minimal fines of \$100 per violation and maximum fines of \$50,000 per violation with an annual maximum of \$1.5 million ([American Medical Association, 2017](#)). Thus employers have policies for disciplinary action.

Handling and Disposing of Information

Maintaining the confidentiality of health records is a fundamental responsibility of all members of the health care team. It is essential to safeguard any information that is printed from the record or extracted for report purposes. For example, you print a copy of a nursing activities work list to use in planning your shift while providing patient care. You refer to information on the list and write notes to record into the computer and share later during hand-off report. Information on the list is PHI; you must not leave it out for view by unauthorized persons. Destroy (e.g., shred or place in a locked receptacle designated for collection of material that is to be shredded) anything that is printed when the information is no longer needed. Nursing students should not print information from the health record to take away from the clinical agency to complete written assignments for clinical. Instead, patient information needed for clinical assignments should be transcribed to academic forms or notebooks directly from viewing the health record on the computer screen or the physical chart. All patient data must be de-identified when transcribed onto forms or used for academic papers for clinical courses in nursing school. Any information that is transcribed and must be removed from the clinical setting and any documents that must be printed out must be kept secure and destroyed through shredding or disposal in a locked receptacle as soon as possible.

REFLECT NOW

To adhere to HIPAA guidelines, in addition to the name of the agency and the patient's room number and date of birth, which patient care data that can be found in the EHR are considered "demographic" information and should not be included in the paperwork you complete for clinical assignments?

Historically, information printed from a patient record and/or faxed to other health care providers has been the primary source for accidental, unauthorized disclosure of PHI. All papers containing PHI must be

destroyed after use or after being faxed. Nurses also work in settings where they may be responsible for erasing files from a computer hard drive that contains calendars, schedules for surgery or diagnostic procedures, or other daily records that contain PHI ([Hebda et al., 2019](#)). You are responsible to know and follow disposal policies for these types of records in the agency where you work.

Health care facilities and departments should have policies for the use of fax machines that specify the kinds of information that can be faxed, who can receive faxed information, where information can be sent, and the process used to verify that information was sent to and received by the appropriate person or persons. Information sent by fax should not exceed what was requested or required for immediate clinical needs. Following are some steps that can be taken to enhance fax security ([Touchstone Compliance, 2017](#)):

- Always use a cover letter.
- To prevent numbers from being misdialed, use saved speed-dial numbers for frequently used fax recipients. Check those numbers regularly.
- For any new recipient, verify the number with a test fax before sending PHI.
- Follow policies for what to do if a fax is sent to the wrong number.
- Set up fax machines to never save copies of faxes sent or received.
- Make sure that faxes containing PHI are promptly delivered to the intended recipient.
- Follow agency policies for storing, copying, and disposing of faxes containing PHI.
- Use a fax machine designated exclusively for PHI, and keep it separate from other fax machines.

Standards and Guidelines for Quality Nursing Documentation

Whether the transfer of patient information occurs through verbal reports or electronic or written documents, you need to follow basic guidelines and standards for nursing documentation. Every health care organization has standards that govern the type of information nurses document and for which they are held accountable. Agency standards or policies often dictate the frequency of documentation, such as how often you record a nursing assessment or a patient's level of pain. You are responsible for knowing the standards of care for every nursing procedure and the standards for providing complete and accurate documentation. Information in patient health records can be used as evidence in a court of law to demonstrate whether nursing standards of practice were, or were not, met.

In addition, your documentation needs to conform to the standards of the National Committee for Quality Assurance (NCQA) and accrediting bodies such as TJC to maintain institutional **accreditation** and to minimize liability. Health care organizations usually incorporate accreditation standards into policies and revise documentation systems and forms to suit these standards. Current documentation standards require that all patients admitted to a health care agency be assessed for physical, psychosocial, environmental, self-care, spiritual, cultural, knowledge level, and discharge planning needs. Your documentation needs to demonstrate application of the nursing process, describe clinical decision making, and include evidence of patient and family teaching and discharge planning (TJC, 2018). In addition to HIPAA standards, health care documentation is affected by standards from state and federal regulatory agencies, the Department of Justice, and CMS.

Guidelines for Quality Documentation

Quality nursing documentation enhances efficient, individualized patient care and has five important characteristics: factual, accurate, current, organized, and complete. It is easier to maintain these characteristics in your documentation if you continually seek to express ideas clearly and succinctly by doing the following:

- Stick to the facts.

- Write in short sentences.
- Use simple, short words.
- Avoid the use of jargon or abbreviations.

Factual

A factual record contains clear descriptive, objective information about what a nurse observes, hears, palpates, and smells. Avoid vague terms such as *appears*, *seems*, or *apparently*. These words suggest you are stating an opinion; they do not accurately communicate facts and do not inform other caregivers about the details regarding the behaviors exhibited by a patient. Objective data are obtained through direct observation and measurement and include description of a patient's behaviors, for example, *"BP 90/50, heart rate 115 and regular, patient diaphoretic and holding both hands over abdominal dressing."* The only subjective data included in the record are statements made by a patient. When recording subjective data, document a patient's exact words within quotation marks whenever possible. Include objective data to support subjective data so that your documentation is as descriptive as possible. For example, instead of documenting *"the patient seems anxious,"* provide objective signs of anxiety and document the patient's statement about the feelings experienced: *"patient's heart rate 110 beats/min, respiratory rate is slightly labored at 22 breaths/min, and patient states, 'I feel very nervous.'"*

Accurate

Using exact measurements establishes accuracy and helps you determine whether a patient's condition has changed in a positive or negative way. For example, a description such as *"Intake, 360 mL of water"* is more accurate than *"Patient drank an adequate amount of fluid."* Documenting that an abdominal incision is *"Approximated, 5 cm in length without redness, drainage, or edema"* is more descriptive than *"Large abdominal incision healing well."* Documentation of concise data is clear and easy to understand. Avoid using unnecessary words and irrelevant detail. For example, the fact that the patient is watching television is necessary only when this activity is significant to the patient's status and plan of care. Examples of criteria for documentation or reporting specific situations can be found in [Table 26.2](#).

TABLE 26.2**Examples of Criteria for Documentation and Reporting**

Topic	Criteria To Report or Record
Subjective assessment data	Patient's description of episode in quotation marks (e.g., <i>"I feel like an elephant is sitting on my chest, and I can't catch my breath."</i>) Describe in patient's own words the onset, location, description of condition (severity, duration, frequency, precipitating, aggravating, and relieving factors) (e.g., <i>"The pain in my left knee started last week after I knelt on the ground. Every time I bend my knee, I have a shooting pain on the inside of the knee."</i>).
Objective assessment data (e.g., rash, tenderness, breath sounds, or descriptions of patient behavior [e.g., anxiety, confusion, hostility])	Onset, location, description of condition (e.g., 11:00: 2-cm raised pale, red area noted on back of left hand). Precipitating factors, behaviors exhibited (e.g., Physician informed patient of diagnosis, patient pacing in room, avoiding eye contact with nurse), patient statements (e.g., repeatedly stating, <i>"I have to go home now."</i>)
Nursing interventions, treatments, and evaluation (e.g., enema, bath, dressing change)	Time administered, equipment used, patient's response (subjective and objective response) compared with previous treatment (e.g., denied incisional pain during abdominal dressing change, ambulated 300 feet in hallway without assistance)
Medication administration	At time of administration when using a computerized bar-code medication administration program (or immediately after administration), document: time medication given, medication name, dose, route, preliminary assessment (e.g., pain level, vital signs), patient response, or effect of medication (e.g., 1500: Reports <i>"throbbing headache all over my head."</i> Rates pain at 6 (scale 0 to 10). Tylenol 650 mg given PO. 1530: Patient reports pain level 2 (scale 0 to 10) and states, <i>"the throbbing has stopped."</i>
Patient and/or family teaching	Information presented; method of instruction (e.g., discussion, demonstration, videotape, booklet); and patient response, including questions and evidence of understanding such as teach-back, return demonstration, or change in behavior
Discharge planning	Measurable patient goals or expected outcomes, progress toward goals, need for referrals.

Appropriate Use of Abbreviations in Health Care Documentation

Use abbreviations carefully to avoid misinterpretation and promote patient safety. TJC (2018) developed a list of "do not use" abbreviations in 2004 that is still used by all health care providers today to promote patient safety (Table 26.3). In addition, TJC requires that health care institutions develop a list of standard abbreviations, symbols, and acronyms to be used by all members of the health care team when documenting or

communicating patient care and treatment. To minimize errors, spell out abbreviations in their entirety when they become confusing.

TABLE 26.3

The Joint Commission’s Official “Do Not Use” List of Abbreviations

Do Not Use	Potential Problem	Use Instead
U, u (unit)	Mistaken for “0” (zero), the number “4” (four) or “cc”	Write “unit.”
IU (International Unit)	Mistaken for “IV” (intravenous) or the number “10” (ten)	Write “International Unit.”
Q.D., QD, q.d., qd (daily) Q.O.D., QOD, q.o.d., qod (every other day)	Mistaken for each other Period after the Q mistaken for “I” and the “O” mistaken for “I”	Write “daily.” Write “every other day.”
Trailing zero (X.0 mg) ^a Lack of leading zero (.X mg)	Decimal point is missed	Write X mg. Write 0.X mg.
MS MSO ₄ and MgSO ₄	Can mean morphine sulfate or magnesium sulfate Confused for one another	Write “morphine sulfate.” Write “magnesium sulfate.”

^a Exception: A “trailing zero” may be used only where required to demonstrate the level of precision of the value being reported, such as for laboratory results, imaging studies that report size of lesions, or catheter/tube sizes. It may not be used in medication orders or other medication-related documentation.

From https://www.jointcommission.org/facts_about_do_not_use_list/. Accessed June 10, 2019.

Correct spelling demonstrates a level of competency and attention to detail. Many terms are easily misinterpreted (e.g., *dysphagia* or *dysphasia*). Some spelling errors can result in serious treatment errors (e.g., the names of medications such as lamotrigine and lamivudine or hydromorphone and hydrocodone are similar). Transcribe medication information carefully to ensure a patient receives the correct medication.

All health care record entries should be dated and timed, and the author of each entry must be clearly identified (TJC, 2018). Each entry in a patient’s record must end with the caregiver’s full name or initials and credentials/title/role such as “Jane Cook, RN.” If initials are used in a signature, the full name and credentials/title/role of the individual needs to be documented at least once in the health care record to allow others to readily identify that individual. As a nursing student, enter your full name and nursing student abbreviation, such as “David Jones, NS” or “David

Jones, SN.” The abbreviation for *nursing student* varies between *NS* for *nursing student* or *SN* for *student nurse*. Include information about your educational institution at the end of your signature when required by agency policy.

Current

Timely entries are essential in a patient’s ongoing care, as delays in documentation can lead to unsafe patient care. Many health care agencies keep records or computers near a patient’s bedside to facilitate immediate documentation of information. Document the following activities or findings at the time of occurrence:

- Vital signs
- Pain assessment
- Administration of medications and treatments
- Preparation for diagnostic tests or surgery, including preoperative checklist
- Change in patient’s status, treatment provided, and who was notified (e.g., health care provider, manager, patient’s family)
- Admission, transfer, discharge, or death of a patient
- Patient’s response to treatment or intervention

Most health care agencies use military time, a 24-hour system that avoids misinterpretation of AM and PM times (Fig. 26.2). Instead of two 12-hour cycles in standard time, the military clock is one 24-hour time cycle. The military clock ends with midnight at 2400 and begins at 1 minute after midnight as 0001. For example, 10:22 AM is 1022 military time, and 10:22 PM is 2222 military time.

FIG. 26.2 Comparison of 24 hours of military time with the hourly positions for civilian time on the clockface.

Organized

Documentation is more effective when notes are concise, clear and to the point, and presented in a logical order. To document notes about complex situations in an organized fashion, first think about the situation, and then make decisions about what information and words you need to include before beginning to enter data in the health care record. Application of your critical thinking skills and the nursing process will help you document clearly and comprehensively in a logical order. For example, an organized entry would describe a patient's pain, your assessment and interventions, and the patient's response to treatment.

Complete

Be sure the information within a recorded entry or a report is complete, containing appropriate and essential information. Follow established criteria and standards for thorough communication within the health care record or when reporting certain health problems or nursing activities.

Methods of Documentation

There are several documentation methods for recording patient assessment data and progress notes. Regardless of whether documentation is entered electronically or on paper, each health care agency selects a documentation system that reflects the philosophy of nursing at that agency. The same system is used throughout a specific agency and sometimes is used throughout a health care system as well.

Documentation of Patient Assessment Data

Within the EHR, nurses routinely document patient physiologic data and routine care using **flow sheets** (graphic records) that are organized by body system and navigated through use of the computer mouse with a series of tabs or rows (Fig. 26.3). These forms allow you to quickly and easily enter assessment data about a patient, such as vital signs, admission and or daily weights, and percentage of meals eaten. They also facilitate the documentation of routine, repetitive care, such as hygiene measures, ambulation, and safety and restraint checks. These documents provide current patient information accessible to all members of the health care team and help team members quickly see patient trends over time.

Respiratory Assessment

No assessment required at this time

Respiratory Pattern
Mark All That Apply:

- Even
- Effortless
- Uneven
- Labored
- Deep

Respiratory Effort
Mark All That Apply:

- Dyspnea/shortness of breath
- Shortness of breath on exertion
- Increased chest expansion
- Orthopnea
- Use of accessory muscles

Lung Auscultation

Left Lateral

Describe any routine data in greater detail when a change in a patient's functional ability or status occurs. For example, if your patient's blood

pressure, pulse, and respirations are elevated above expected values after a walk down the hall, you would first complete and record a focused assessment in the flow sheet, and then document additional, detailed information about the patient's status and response to the walk in the appropriate place in the health care record using narrative free text within the flow sheet, or in a narrative progress note.

Progress Notes

Health care team members monitor and record the progress made toward resolving a patient's problems in progress notes. Health care providers write narrative progress notes in one of several formats or structured notes within the EHR. Notes may take the form of traditional narrative documentation or make use of precise formats such as (1) focus charting, incorporating data, action, and response (DAR); (2) SOAP notes, identifying interprofessional problems; or (3) notes with a specific nursing focus, identifying nursing problems or diagnoses (PIE). See [Box 26.1](#) for examples of nursing documentation using these formats. **Narrative documentation** is the format traditionally used by nurses and health care providers to record patient assessment, clinical decisions, and care provided; it consists of a storylike format to document information. In an electronic nursing information system, this is accomplished through the use of free text entry or menu selections ([Hebda et al., 2019](#)). An example of a comprehensive narrative note written by a nurse looks like this:

Box 26.1 Examples of Nursing Documentation in Different Formats

Narrative Note

- **Patient states**, "My leg is so swollen. I'm worried about this blood clot." Is asking question about medications and how DVT will be treated. Alert and oriented; responds appropriately to instruction. Discussed importance of bed rest and the reason for treatment with heparin infusion. Explained need for daily blood tests to check anticoagulation levels. Provided brochure on anticoagulation therapy for DVT. Used teach-back method to validate patient understanding; he is able to describe that the heparin infusion will be stopped when

his PT/INR is therapeutic on warfarin and he can expect to take warfarin for about 6 months after discharge until clot is resolved.

PIE

- A PIE note has a specific nursing focus.
- **P: Nursing problem or diagnosis**—*Lack of Knowledge* related to inexperience with disease condition
- **I: Interventions that will be used to address the problem**—Provided brochure on anticoagulation therapy for DVT. Explained rationale for bed rest and daily blood tests to check anticoagulation levels. Explained that heparin infusion will be stopped when PT/INR is at therapeutic level and that he can expect to take warfarin for about 6 months until clot resolves.
- **E: Nursing evaluation:** Patient states, “I’m worried about the blood clot, but I understand how it is being treated.” Able to teach back and verbalize that the heparin infusion will be stopped when PT/INR tests are “normal.” Also states that he expects to take warfarin for about 6 months until clot in leg dissolves.

Focus Charting

- Uses a DAR format to report problems. DAR notes address patient concerns such as a sign or symptom, condition, nursing diagnosis, behavior, significant event or change in condition.
- **D: Data** (subjective and objective)—Patient states, “My leg is so swollen. I’m worried about this blood clot. Do you know how they are going to treat it?”
- **A: Action or nursing intervention**—Provided brochure on anticoagulation therapy for DVT. Explained rationale for bed rest and daily blood tests to check anticoagulation levels. Explained that heparin infusion will be stopped when PT/INR is at therapeutic level.
- **R: Response of the patient**—Able to teach back and verbalized that heparin infusion will be stopped when PT/INR reaches “normal level” and that he can expect to take warfarin for 6 months after discharge until clot is fully resolved.

SOAP Note—Used By All Health Care Disciplines

- **S: Subjective**—Patient states, “My leg is so swollen. I’m worried about this blood clot. Do you know how they are going to treat it?”
- **O: Objective**—Patient asking question about medications and how DVT will be treated. Alert and oriented; responds appropriately to instruction.
- **A: Assessment**—Patient lacks knowledge regarding anticoagulation therapy, seeking information about therapy.
- **P: Plan:** Discussed importance of bed rest and the reason for treatment with heparin infusion. Provided brochure on anticoagulation therapy for DVT. Explained rationale for bed rest and daily blood tests to check anticoagulation levels. Explained that heparin infusion will be stopped when PT/INR is at therapeutic level and that he can expect to take warfarin for about 6 months until clot resolves.

1915: Adhering to bed rest as ordered. Left lower extremity is swollen; calf circumference is 30 inches. Areas of redness that are warm and tender to touch are noted over anterior (3 cm by 4 cm) and medial areas (3 cm by 3 cm) of left leg. Left lower leg elevated on one pillow. Heparin infusing at 3600 units/hour via 20-gauge peripheral IV in left lower forearm. Site without redness, swelling, or drainage. Verbalizes sharp throbbing leg pain rated at 8 on a 0-to-10 scale. Pedal pulses 3+ bilaterally. Capillary refill in toes of both feet is less than 3 seconds. Oxycodone/acetaminophen 2 tablets (PO) given for pain as ordered. Chris Banks, RN.

2000: States, “The pain medication really helped.” Rates pain in left lower leg at 4 on a 0-to-10 scale. Comfort level goal is 4/10. Chris Banks, RN.

While the nursing patient assessment flow sheet section of the EHR allows users to enter descriptive details through the use of short, narrative comments, these sections of the EHR are primarily designed to allow the use of multiple checkboxes or drop-down lists. Research has shown that some nurses believe flow sheet data may not adequately convey the details of significant events that result in a change in patient condition (Brown, 2016; Topaz et al., 2016). When entering a narrative progress note in the EHR, be clear and accurate when describing subjective and objective patient assessment findings, as well as any interventions taken to resolve patient problems and maintain patient safety. Health care providers

review nursing documentation for details about changes in a patient's condition, and use of narrative documentation within the EHR may provide more detail than charting by exception when trying to document complex situations. EHRs that enable all health care providers to easily retrieve important patient information from narrative notes, as well as flow sheet data, may augment clinician communication and interprofessional understanding for patient care ([Bardach et al., 2017](#)).

REFLECT NOW

What patient situations have you observed in the clinical setting that might be more appropriately documented through use of a narrative note versus use of flow sheet documentation within the EHR? Think of a recent patient situation you observed that you believe should be documented in narrative fashion. Practice writing a narrative note about that situation, and ask your clinical faculty to review and comment on your work.

Charting By Exception

The philosophy behind **charting by exception (CBE)** is that all standards for normal assessment findings or for routine care activities are met unless otherwise documented. Exception-based documentation systems incorporate standards of care and use clearly, predefined statements for the nursing documentation of "normal" body system findings. These normal findings called "within defined limits" (WDL) or "within normal limits" (WNL) consist of written criteria for a "normal" assessment for each body system. Documentation within a computerized system allows nurses to select a WDL statement or to choose other statements from a drop-down menu that allow description of any unexpected assessment findings or assessment findings that deviate from the WDL definition ([Elliott et al., 2018](#)). Well-designed flow sheets are a key part of a good exception-based documentation system within the EHR. But this form of documentation also calls for use of narrative notes concerning any significant indicator of the patient's condition or change in status, any

subsequent interventions, and the patient's response ([Nurses Service Organization, 2018](#)). When an exception occurs, if a nurse's note offers few explanations, little description of key findings, or no mention of periodic patient checks, a patient's lawyer could claim negligence on the part of the nurse ([Nurses Service Organization, 2018](#)).

The SBAR or ISBAR format is a commonly used framework for a narrative note when exceptions occur. Both are also popular formats for verbal reporting (see [Chapter 24](#)). When changes in a patient's condition develop, a narrative progress note must include a thorough and precise description of the effects of the changes on the patient and the actions taken to address those changes.

Common Record-Keeping Forms Within The Electronic Health Record

Nurses use a variety of electronic or paper forms for the type of information routinely documented within the EHR. The categories or data fields within a form are usually derived from institutional standards of practice or guidelines established by accrediting agencies.

Admission Nursing History Form

A nurse completes a nursing history form when a patient is admitted to a nursing unit. The fields in the form guide you through a comprehensive assessment to identify relevant nursing diagnoses or problems (see [Chapters 16](#) and [30](#)). Completion of this form provides baseline data that you use for comparison when a patient's condition changes.

Patient Care Summary

Many computerized documentation systems generate a patient care summary document that you review (and sometimes print) for each patient at the beginning and/or end of each shift to use as a worksheet for organizing care and in giving hand-off report ([Fig. 26.4](#)). The document automatically updates and provides the most current information that was entered into the EHR and usually includes the following information:

- Basic demographic data (e.g., age, religion)
- Health care provider's name
- Primary medical diagnosis
- Medical and surgical history
- Current orders from the health care provider (e.g., dressing changes, ambulation, glucose monitoring)
- Nursing care plan
- Nursing orders (e.g., education needed, symptom relief measures, counseling)
- Scheduled tests and procedures
- Safety precautions used in a patient's care
- Factors that affect patient independence with activities of daily living
- Nearest relative/guardian or person designated as a patient's health care power of attorney to contact in an emergency
- Emergency code status (e.g., indication of do-not-resuscitate order)

- Allergies

Care Plans

Many computerized documentation systems include **standardized care plans** or **clinical practice guidelines (CPGs)** to facilitate the creation and documentation of a nursing and or interprofessional plan of care (see [Chapter 18](#)). Each standardized plan facilitates safe and consistent care for an identified problem by describing or listing institutional standards and evidence-based guidelines that are easily accessed and included within a patient's EHR ([Khokhar et al., 2017](#)). After completing a nursing assessment, you identify and select the standardized plans that are appropriate for the patient and are to be included in the individualized plan of care. Most computer documentation systems allow these care plans to be modified by creating individualized interventions, goals, and outcomes for each patient.

Standardized care plans are useful when conducting QI audits. They also improve continuity of care among professional nurses. When they are used, the nurse still remains responsible for providing individualized care to each patient. Standardized care plans cannot replace a nurse's professional judgment and decision making. You update care plans on a regular basis to ensure that the documents are appropriate and evidence-based.

Discharge Summary Forms

Nurses help ensure cost-effective care and appropriate reimbursement by preparing patients for a safe, effective, and timely discharge from a health care institution. Developing a comprehensive plan for a safe discharge relies on interprofessional discharge planning. This process includes identification of key clinical outcomes and appropriate timelines for reaching them, the appropriate level of care for discharge, and all necessary resources.

Ideally discharge planning begins at admission, which requires partnering with the patient and family to identify goals for recovery and identifying potential discharge needs. Nursing and other health care professionals then begin to plan with the patient for discharge to the appropriate level of care. Consideration is given to the support services (i.e., home care, physical therapy) required and whether any health care equipment is needed in the home setting. Involvement of the patient and

family in the discharge planning process ensures that they have the necessary information and resources to return home or move to the next level of care. Discharge documentation includes medications, diet, community resources, follow-up care, and the name of a person to contact for questions or in case of an emergency. All of this information is included in a discharge summary document that is printed out and given to the patient on discharge. The information remains in the EHR as a record of the discharge teaching that was provided (Box 26.2).

Box 26.2 Guidelines for Information to Include on a Discharge Summary

- Use clear, concise descriptions in the patient's own language.
- Provide step-by-step instructions for how to perform any procedure that the patient or family will be doing independently (e.g., emptying a urinary catheter drainage bag or self-administration of an injectable medication).
- Identify precautions to follow when performing self-care or administering medications.
- List signs and symptoms of complications that a patient needs to report to a health care provider.
- List names and phone numbers of health care providers and community resources that the patient can contact.
- Identify any unresolved problems, including plans for follow-up and continuous treatment.
- List actual time of discharge, mode of transportation, and who accompanied the patient.

Documenting Communication With Providers and Unique Events

Telephone Calls Made to a Provider

Document every phone call you make to a health care provider. Your documentation needs to include when the call was made, the number called, who made the call, who was called, to whom information was given, what information was given, and what information was received. For example: *“08/25/2018 (2130): Called Dr. Banks’ office at 123-456-7890. Spoke with L. Matthews, RN, who will inform Dr. Banks that Mr. Andrews’ potassium level drawn at 2000 was 5.9 mEq/dL. Informed that Dr. Banks will call back after he is finished seeing his current patient. R. Jenner, RN.”*

Telephone and Verbal Orders

Telephone orders (TOs) occur when a health care provider gives therapeutic orders over the phone to an RN. Verbal orders (VOs) occur when a health care provider gives therapeutic orders to an RN face-to-face while they are standing in proximity to each other. The potential for verbal orders to be misunderstood, misheard, or transcribed incorrectly makes them error prone, particularly given different care provider accents, dialects, and drug name pronunciations (Institute for Safe Medication Practices [ISMP], 2017) Use of VOs is discouraged except in urgent or emergent situations. TOs and VOs should be used only when absolutely necessary and not for the sake of convenience for the health care provider. In some situations, it is wise to have a second person listen on the telephone line as a TO is given by a health care provider; some agency policies require this. Check your agency’s policy. [Box 26.3](#) provides guidelines that promote accurate documentation of TOs or VOs.

Box 26.3 Guidelines for Telephone and Verbal Orders

- Clearly identify the patient’s name, room number, and diagnosis.
- Use clarification questions to avoid misunderstandings.

- Document “TO” (telephone order) or “VO” (verbal order), including date and time, name of patient, the complete order; the name and credentials of the health care provider giving the order(s); and your name and credentials as the nurse taking the order.
- Read back all orders prescribed to the health care provider who gave them and document “TORB” (telephone order read back) when signing your name and credentials.
- Follow agency policies; some institutions require telephone (and verbal) orders to be reviewed and signed by two nurses.

A nurse receiving a TO or VO enters the complete order into the computer using the computer provider order entry (CPOE) software or writes it out on a physician’s order sheet for entry into the computer as soon as possible. The Joint Commission requires the receiver of a VO or TO record it and read (not repeat) it back to the prescriber. This helps assure that one has not only heard an order correctly but also transcribed it accurately (ISMP, 2017). For example, document a TO as follows: “09/30/2016 (1015), Change IV fluid to Lactated Ringers with potassium 20 mEq/L to run at 125 mL/hr. TO: Dr. Knight/K. Day, RN, telephone order read back (TORB).” The health care provider later verifies the TO or VO legally by co-signing it within a time frame (e.g., 24 hours) set by agency policy.

Incident or Occurrence Reports

An incident or occurrence is any event that is not consistent with the routine, expected care of a patient or the standard procedures in place on a health care unit or within an agency (Chapter 23). Examples include patient falls, needlestick injuries, medication administration errors, accidental omission of ordered therapies, a visitor losing consciousness, and any circumstances that lead to injury or pose a risk for patient injury such as a “near miss.” There are several definitions for “near miss”; however, there is consensus that this term should be used to indicate incidents in which a patient is exposed to a hazardous situation with the potential to cause harm but in which, for a variety of reasons (luck or early detection), no harm did occur (Agency for Healthcare Research and Quality, 2019).

An **incident report (occurrence report)** is completed whenever an incident occurs. Analysis of incident reports helps to identify system and/or individual human issues in which educational or in-service programs or changes in policies and procedures are needed to reduce the

risk of future occurrences. Incident reports are an important part of the QI program of a unit or agency; however, they are not part of the health care record. Incident reports contain confidential information; distribution of the report is limited to the individuals responsible for reviewing the forms.

Follow agency policy when completing an incident report, and file the report with your agency's risk-management department. When an incident occurs, document an objective description of what happened, what you observed, and the follow-up actions taken, including notification of the patient's health care provider in the patient's health care record. Remember to evaluate and document the patient's response to the incident in the health care record as well. Do not label this as an "incident," "near miss," or "sentinel event" in the health care record, and do not make any reference to these types of documents. A notation about an incident, near miss, or sentinel event report in a patient's health care record makes it easier for a lawyer to argue that the reference makes the incident report part of the health care record and therefore admissible for attorney review.

Acuity Rating Systems

Nurses use **acuity rating systems** to determine the hours of care and number of staff required for a given group of patients every shift or every 24 hours. A patient's acuity level, usually determined by the assessment data an RN enters into a computer program, is based on the type and number of nursing interventions (e.g., IV therapy, wound care, or ambulation assistance) required by that patient over a 24-hour period. Although acuity ratings are not part of a patient's health care record, nursing documentation within the health care record provides evidence that supports the assessment of an acuity rating for an individual patient.

The acuity level is a classification that compares one or more patients with another group of patients. An acuity system classifies patients from 1 (independent in all but one or two aspects of care; almost ready for discharge) to 5 (totally dependent in all aspects of care; requiring intensive care). Using this system, a patient returning from surgery requiring frequent monitoring and extensive care has an acuity level of 3, compared with another patient awaiting discharge after a successful recovery from surgery who has an acuity level of 1. Accurate acuity ratings justify the number and qualifications of staff needed to safely care for patients. The patient-to-staff ratios established for a unit depend on a composite gathering of 24-hour acuity data for all patients receiving care (Sir et al., 2015).

Documentation in the Long-Term Health Care Setting

Long-term health care settings include skilled nursing facilities (SNFs), in which patients receive 24-hour-a-day care, including housing, meals, specialized (skilled) nursing care, treatment services, and long-term care facilities, in which patients with chronic conditions receive 24-hour-a-day care, including housing, meals, personal care, and basic nursing care. Requirements for documentation in these facilities are governed by individual state regulations, TJC, and CMS. CMS mandates use of the Resident Assessment Instrument (RAI), which includes the Minimum Data Set (MDS) and the Care Area Assessment (CAA) to document data in long-term care facilities. MDS assessment forms are completed on admission and then periodically within specific guidelines and time frames for all residents in certified nursing homes ([Ahn et al., 2015](#)). MDS data also determine the reimbursement level under the prospective payment system for Medicare Part A residents in an SNF ([Chapter 2](#)).

Communication among nurses; social workers; dietitians; and recreational, speech, physical, and occupational therapists is essential. Documentation in the long-term care setting supports an interprofessional approach to the assessment and planning process for all patients. Adherence to state and federal requirements as well as reimbursement for care provided in a long-term care facility is dependent on accurate completion of the required documentation to justify the care provided ([Hebda et al., 2019](#)).

Documentation in the Home Health Care Setting

Documentation in the home care setting is different from other areas of nursing. The use of laptop and tablet computers makes it possible for home health care records to be available in multiple locations (i.e., the patient's home and the home care agency). This system improves accessibility to information and facilitates interprofessional collaboration. Medicare has specific guidelines to establish eligibility for home care reimbursement. Information used for reimbursement is gathered from documentation of care provided in the home care setting. Documentation is the quality control and the justification for reimbursement from Medicare, Medicaid, or private insurance companies. Information in the home care health care record includes patient assessment, referral and intake forms, the interprofessional plan of care, a list of medications, and reports to third-party payers. Nurses document all their services for payment (e.g., direct skilled care, patient teaching, skilled observation, and evaluation visits) (TJC, 2018).

Nurses use two different data sets to document clinical assessments and care provided in the home care setting. Assessment using the Outcome and Assessment Information Set (OASIS) is required for all patients age 18 years and older (with the exception of patients receiving prenatal or postnatal care) who are receiving skilled care through a home health agency that is reimbursed by Medicare or Medicaid (Shang et al., 2015). OASIS includes a comprehensive admission assessment and allows for the calculation of clinical, functional, and service scores that provide justification for reimbursement of services (Research Data Assistance Center, 2016). The Omaha System is a research-based, comprehensive, standardized taxonomy or classification designed to enhance practice, documentation, and information management. It consists of three components (Problem Classification Scheme, Intervention Scheme, and Problem Rating Scale for Outcomes) and provides a useful model for comprehensive evaluation of the quality of nursing care provided in the home care setting (Hebda et al., 2019; Martin & Monsen, 2018).

Case Management and use of Critical Pathways

The **case management** model incorporates an interprofessional approach to delivery and documentation of patient care (see [Chapter 2](#)). **Critical pathways** (also known as clinical pathways, practice guidelines, or CareMap tools) are interprofessional care plans that identify patient problems, key interventions, and expected outcomes within an established time frame ([AHC Media, 2015](#)). Critical pathway documents facilitate integration of care because all members of the health care team use the same document to monitor a patient's progress during each shift or, in the case of home care, every visit. Evidence-based critical pathways can improve patient outcomes. For example, use of critical pathways has been shown to improve adherence to evidence-based guidelines for administration of antibiotics for community-acquired pneumonia ([Almatar et al., 2016](#)).

Unexpected outcomes, unmet goals, and interventions not specified within a critical pathway are called **variances**. A variance occurs when the activities on the critical pathway are not completed as predicted or a patient does not meet the expected outcomes. Variances sometimes result from a change in a patient's health or because of other health complications not associated with the primary reason for which a patient requires care. Once you identify a variance, you modify the patient's care to meet the needs associated with the variance. A positive variance occurs when a patient makes progress faster than expected (e.g., an indwelling urethral catheter is discontinued a day earlier than anticipated according to the critical pathway). An example of a negative variance is when a patient develops pulmonary complications after surgery, requiring oxygen therapy and monitoring with pulse oximetry. Variances to expected outcomes are documented with a progress note ([Box 26.4](#)). Documentation allows trends to be identified and analyzed, which can provide data to develop an effective action plan for responding to identified patient problems. Over time health care teams sometimes revise critical pathways if similar variances reoccur.

Box 26.4 Example of Variance Documentation

An RN working in the case management role is using a critical pathway for “Routine Postoperative Care” for a 56-year-old man who had abdominal surgery yesterday. One of the expected outcomes for postoperative day 1 on the critical pathway document is “Afebrile with lungs clear bilaterally.” This patient has an elevated temperature, his breath sounds are decreased bilaterally in the bases of both lobes of the lungs, and he is slightly confused.

The following is an example of how the RN case manager documents this variance on the pathway:

“Breath sounds diminished bilaterally at the bases. T-100.4; P-92; R-28/min; pulse oximetry 84% on room air. Daughter states he is “confused” and did not recognize her when she arrived a few minutes ago. Oxygen 2 L nasal cannula started per standing orders. Oxygen saturation improved to 92% after 5 minutes. Dr. Lopez notified of change in status. Daughter remains at bedside.”

Informatics and Information Management in Health Care

Health information technology (HIT) is the use of information systems and other information technology to record, monitor, and deliver patient care, and to perform managerial and organizational functions in health care (Hebda et al., 2019). The focus of HIT is the patient and the process of care, and the goal of using HIT is to enhance the quality and efficiency of care provided.

Health Care Information System

A **health care information system (HIS)** consists of “computer hardware and software dedicated to the collection, storage, processing, retrieval, and communication of patient care information in a healthcare organization” (Hebda et al., 2019). An HIS consists of two major types of information systems: a clinical information system and an administrative information system. Together the two systems operate to make the entry and communication of data and information more efficient. Individual health care agencies sometimes use one or several clinical information systems and administrative information systems. Administrative information systems include databases such as payroll, financial, and quality improvement systems (Hebda et al., 2019).

Clinical Information System

A **clinical information system (CIS)** (also known as a patient care information system) is a large, computerized database management system that is used to access patient data needed to plan, implement, and evaluate care (Hebda et al., 2019). A CIS can include monitoring systems; order entry systems; and laboratory, radiology, and pharmacy systems. A monitoring system can include devices that automatically monitor and record biometric measurements (e.g., vital signs and oxygen saturation) in acute care, critical care, and specialty care areas. Some of these devices can be programmed to electronically send measurements directly to a nursing documentation system, decreasing nursing workload.

One example of an order-entry system is a computer program that allows nurses to order supplies and services from another department, such as sterile supplies from the central supply department. This

eliminates the use of written order forms and expedites the delivery of needed supplies to a nursing unit. Another example is a **computerized provider order entry (CPOE)** system that allows health care providers to directly enter standardized, legible, and complete orders for patient care into a medical record from any computer in the HIS. Advanced CPOE systems have built-in clinical decision support tools and alerts to help a health care provider select the most appropriate medication or diagnostic test and automatically check for drug interactions, medication allergies, and other potential problems ([HealthIT.gov, 2018](#)). The direct entry of orders by providers eliminates safety issues related to illegible handwriting and transcription errors. In addition, a CPOE system potentially speeds the implementation of ordered diagnostic tests and treatments, which contributes to quality care and better patient outcomes. A CPOE system improves reimbursements since some orders require preapprovals from insurance plans. CPOE, when integrated with an electronic practice management system, can flag orders that require preapproval, helping a health care institution reduce denied insurance claims ([HealthIT.gov, 2018](#)). Use of a CPOE system has been shown to improve productivity and cost-effectiveness in the communication and implementation of health care provider orders. More important, most CPOE systems have significant potential to reduce medication errors associated with illegibility and inappropriate drug use and dosing ([Hebda et al., 2019](#)).

Nursing Clinical Information Systems

A well-designed **nursing clinical information system (NCIS)** incorporates the principles of nursing informatics to support the work that nurses do by facilitating documentation of nursing process activities and offering resources for managing nursing care delivery ([Box 26.5](#)). It is important for nurses to be able to access computer programs easily, review patients' medical histories and health care provider orders, and then go to the patients' bedsides to conduct comprehensive assessments. Once you complete an assessment, you enter data into the computer terminal at the patient's bedside and develop a plan of care from the information gathered. This allows you to quickly share the plan of care with your patient and other health care providers. You will periodically return to the computer to check on laboratory test results and document the care you deliver. The computer screens and optional pop-up windows make it easy to locate information, enter and compare data, and make changes.

Box 26.5 Evidence-Based Practice

PICOT Question: For nurses working in acute care settings, what is the effect of using the electronic health record for documentation on time spent at the bedside providing patient care?

Evidence Summary

Nurses have long perceived that the time needed to complete documentation of patient care has negatively impacted the quality and time available for provision of direct patient care (Michel et al., 2017). However, technologies such as electronic health record systems have increasingly become integrated in the support of nursing practice, including direct patient care, health care administration, and health care education and research. There are few current studies demonstrating effective ways to integrate use of today's health information technology with the concept of caring. In a study by Schenk and colleagues (2016) clinical RNs were surveyed about ease of use, usefulness, and attitude before and after implementation of an EHR. While participants commented on both their frustration and optimism about EHRs, on average, one year after adoption, nurses believed that the EHR did not improve patient care, that the learning curve was steep, and they had lower confidence in using the EHR than anticipated. However, a second study surveyed nurses from eight medical-surgical units working 12-hour shifts, across four hospitals in two states, 6 months after implementation of an EHR (Gomes et al, 2016). Data demonstrated that after implementation nurses spent more time in patient rooms engaged in purposeful interaction with patients and that time required for nursing documentation decreased by 4%, which may have been related to increased skill in using the EHR for documentation.

In a systematic review conducted by Baumann and colleagues (2018), the proportion of staff time spent on documentation was higher in the presence of an EHR system compared with settings without EHR implementation for physicians, nurses, and interns, and this difference was statistically significant for nurses. Study results indicated that pre-EHR, interns had the largest proportion of total workload spent on documentation tasks, followed by physicians, and that nurses had the lowest workload time spent completing documentation. After implementation of an EHR, physicians had the largest proportion of total workload spent on documentation tasks, followed by interns and then nurses. However, there is some evidence that over a longer period of time

with full implementation of an EHR, documentation time may ultimately decrease, accompanied by improved work and information flow, significant decreases in multitasking, and improved patient safety (Baumann et al., 2018).

Application to Nursing Practice

- More studies are needed to clearly demonstrate the percentage of time needed for nurses to satisfactorily document the care they provide. Institutions should monitor clinical nurses' perceptions of EHR functions.
- Using technology, including electronic documentation systems for patient intake and assessment, can help enhance quality and safety in nursing. However, establishing a therapeutic nurse-patient relationship is essential to quality care.

NCISs have two designs. The nursing process design is the most traditional. It organizes documentation within well-established formats such as admission and postoperative assessment problem lists, care plans, intervention lists or notes, and discharge planning instructions. The nursing process design facilitates the following:

- Generation of a nursing work list that outlines routine scheduled care activities for a patient
- Documentation of routine aspects of patient care such as hygiene, positioning, fluid intake and output, wound care measures, and blood glucose measurements
- Progress note entries: narrative notes, charting by exception, and/or flow sheets
- Documentation of medication administration (see [Chapter 31](#))

More advanced systems incorporate standardized nursing languages such as the International Classification of Nursing Practice (ICNP), the North American Nursing Diagnosis Association–International (NANDA-I) nursing diagnoses, the Nursing Interventions Classification (NIC), and the Nursing Outcomes Classification (NOC) into the software ([Hebda et al., 2019](#)).

The other model for an NCIS is the protocol or critical pathway design ([Hebda et al., 2019](#)). This design facilitates interprofessional management of information because all health care providers use evidenced-based

protocols or critical pathways to document the care they provide. The information system allows a user to select one or more appropriate protocols for a patient. An advanced system merges multiple protocols, using a master protocol or path to direct patient care activities. Standard health care provider order sets are included in the protocols and automatically processed. The system also integrates appropriate information into the medication delivery process to enhance patient safety. In addition, the system identifies variances of the anticipated outcomes on the protocols as documentation is entered. This provides all caregivers the ability to analyze variances and offer an accurate clinical picture of a patient's progress.

Advantages of a Nursing Clinical Information System

Anecdotal reports and descriptive studies suggest that NCISs offer important advantages to nurses in practice. According to [Hebda et al. \(2019\)](#), some specific advantages include:

- Better access to information.
- Enhanced quality of documentation through prompts.
- Reduced errors of omission.
- Reduced hospital costs.
- Increased nurse job satisfaction.
- Adherence to requirements of accrediting agencies (e.g., TJC).
- Development of a common clinical database.
- Enhanced ability to track records.

Many NCISs include content-importing technologies that allow the use of templates, macros, automated data points, and the ability to copy forward either parts of or entire nursing shift assessments that enable nurses to quickly document their assessment or the care they provided. These features have benefits and risks associated with their use. When allergy and current medication lists are automatically imported into nursing admission documentation from a previous hospital encounter, you need to meticulously review this information for accuracy and update it as needed to avoid documentation errors and patient safety concerns. When nursing shift assessment data is copied forward from a previous shift or day, it must be updated so that it accurately reflects a patient's current clinical status ([National Institute of Standards and Technology - US Department of Commerce, 2017](#)).

Clinical Decision Support Systems

A **clinical decision support system (CDSS)** is a computerized program that aids and supports clinical decision making. The knowledge base within a CDSS contains rules and logic statements that link information required for clinical decisions to generate tailored recommendations for individual patients; the recommendations are presented to health care providers as alerts, warnings, or other information for consideration (Hebda et al., 2019). For example, an effective CDSS notifies health care providers of patient allergies before entering a medication order using CPOE to increase patient safety during the medication-ordering process.

CDSSs also improve nursing care. When patient assessment data are combined with patient care guidelines, nurses are better able to implement evidence-based nursing care. These programs are called a *nursing CDSS (NCDSS)* when used to support nursing decisions.

An example of an NCDSS is a program that requires entry of data regarding a patient's risk factors for falls and provides evidence-based alternatives for fall prevention interventions. The interventions are displayed through the decision support system based on a patient's fall risk score and are selected for the plan of care, thus supporting clinical decision making (Ahamed et al., 2016). Use of nursing-specific CDSSs has not been implemented as often as CDSSs in other disciplines. However, CDSSs are in development for acute care nursing settings (Ahamed et al., 2016; Rudolph et al., 2016).

Nursing Informatics

You need to be knowledgeable in the science and application of nursing informatics. **Nursing informatics** is the specialty that integrates nursing science, computer science, and information science to manage and communicate data, information, knowledge, and wisdom in nursing and informatics practice (American Nursing Informatics Association, 2019). Nursing informatics is recognized as a specialty area of nursing practice at the graduate level. Nurses who specialize in informatics have advanced knowledge in information management and demonstrate proficiency with informatics to support all areas of nursing practice, including QI, research, project management, and system design (American Nursing Informatics Association, 2019). Through the application of nursing informatics, technology is put to practical use to enhance bedside care and education. It offers an efficient and effective nursing information system that facilitates

the integration of data, information, and knowledge to support patients, nurses, and other providers in patient care decision making.

Informatics Competencies for Nursing Graduates Entering the Workforce

Nursing competence in **health care informatics** is a priority as health care providers and agencies across the United States shift to the use of electronic documentation. You need informatics competencies to deliver safe and efficient care and to facilitate the implementation of evidence-based practice. Professional organizations such as the American Association of Colleges of Nursing, the National League for Nursing, and the Quality and Safety Education for Nurses (QSEN) Institute recommend that all nurses acquire a minimal level of awareness and competence in informatics and the use of information technology (Hebda et al., 2019). The American Association of Colleges of Nursing (2008) established a framework that outlines curricular goals and informatics competencies for baccalaureate, master's, and doctoral programs of nursing that remains current today.

QSEN defined the scope of RN competencies for informatics as “the use of information and technology to communicate, manage knowledge, mitigate error, and support decision making” and outlined specific knowledge, skills, and attitudes that nursing students need to learn to use informatics technology to provide patient care in an effective and safe manner (QSEN Institute, 2018). Competence in informatics is not the same as computer competency. To become competent in informatics, you must use evolving methods of discovering, retrieving, and using information in practice (Hebda et al., 2019). Patients' records contain multiple types of data, and you need to know how to record, interpret, and report data and use critical thinking to apply your knowledge when providing patient care. You must also recognize when information is needed and have the skills to find, evaluate, and use that information effectively. QSEN competencies in informatics for prelicensure nursing students are outlined in [Box 26.6](#).

Box 26.6 QSEN Competencies for Informatics

QSEN Competency in Informatics: Use information and technology to communicate, manage knowledge, mitigate error, and support decision

making.

Knowledge:

Explain why information and technology skills are essential for safe patient care.

Skills:

Seek education about how information is managed in care settings before providing care.

Apply technology and information management tools to support safe processes of care.

Attitudes:

Appreciate the necessity for all health professionals to seek lifelong, continuous learning of information technology skills.

Knowledge:

Identify essential information that must be available in a common database to support patient care.

Contrast benefits and limitations of different communication technologies and their impact on safety and quality.

Skills:

Navigate the electronic health record.

Document and plan patient care in an electronic health record.

Employ communication technologies to coordinate care for patients.

Attitudes:

Value technologies that support clinical decision making, error prevention, and care coordination.

Protect confidentiality of protected health information in electronic health records.

Knowledge:

Describe examples of how technology and information management are related to the quality and safety of patient care. Recognize the time, effort, and skill required for computers, databases, and other technologies to become reliable and effective tools for patient care.

Skills:

Respond appropriately to clinical decision-making supports and alerts.

Use information management tools to monitor outcomes of care processes.

Use high-quality electronic sources of health care information.

Attitudes:

Value nurses' involvement in design, selection, implementation, and evaluation of information technologies to support patient care.

From QSEN Institute: *QSEN*

competencies. <http://qsen.org/competencies/pre-licensure-ksas/#informatics>. Accessed June 10, 2019.

As a nurse you need to know how to use clinical databases within your institution and apply the information so that you can deliver high-quality, appropriate patient care. You will collect data, including numbers, characters, or facts, according to a perceived need for analysis and possible action. You gain knowledge from gathering and using information from several sources. For example, you review several consecutive assessments of a wound documented within the EHR. Reviewing changes in the descriptions of the wound's edges, color of drainage, and measurements over several days allows you to evaluate and identify a pattern that indicates that the wound is not healing. Based on evidence available in the scientific literature, you apply knowledge of wound care principles and

intervene to develop new nursing interventions to manage the patient's wound and promote healing.

Building Competency in Informatics

A patient diagnosed with a deep vein thrombosis in the left lower leg was admitted 3 days ago and has been receiving a continuous heparin infusion of 1300 units/hr via the peripheral IV located in the left lower forearm. You are the RN caring for this patient from 1500 to 2300 today, and you learn during hand-off report that the patient's most recent partial thromboplastin time (PTT) is 70 seconds, indicating that the current dose of heparin infusing at 1300 units/hr is therapeutic (Pagana et al., 2019). The goal for this patient is to establish therapeutic anticoagulation levels using warfarin (an oral anticoagulant) so that the heparin infusion can be discontinued. The patient will be discharged with a prescription for warfarin, which will be taken daily for 6 months until the DVT has resolved. The patient received the first dose of warfarin 10 mg PO yesterday evening.

The patient's next dose of warfarin 10 mg PO is due at 1800. You log on to the computer located in the patient's room at that time and open the medication administration record in the patient's EHR. As you scan the package of warfarin using the bar code medication administration function, a warning statement, "Review most recent PT/INR results before administration," pops up on the computer screen. You switch screens in the EHR to review the patient's laboratory results and note that the patient's most recent prothrombin time (PT) is 21 seconds, and the international normalized ration (INR) is 2.3, indicating that the dose of warfarin that the patient received yesterday was too high and that the patient has a critically increased risk for bleeding (Pagana et al., 2019). The abnormal results are displayed in red font in the EHR, and a notation reading "Critical Value" is displayed next to each of the results displayed in red. What does the warning statement that popped up on the computer screen represent? What is the most appropriate action for you to take in this situation?

Key Points

- The health care record provides a legal and financial record of care, aids in clinical education and research, and guides professional and organizational performance improvement.
- Nursing documentation supports reimbursement to health care agencies through accurate accounting of the use of services and equipment and medications administered.
- Effective nursing documentation limits liability through objective description of what happened to a patient and clearly indicates that individualized, goal-directed nursing care was provided based on nursing assessment.
- Nurses must understand and be able to implement administrative, physical, and technical safeguards for protected health information (PHI) found in all forms of the health care record.
- Quality documentation is accurate, detailed, timely, and incorporates precise measurements, correct spelling, and proper use of abbreviations.
- Patient safety is enhanced when health care professionals eliminate the use of dangerous abbreviations, acronyms, symbols, and dose designations from their documentation.
- Documentation in the electronic health record requires nurses to be skilled in the use of flow sheets and narrative formats for recording patient information.
- Documentation of a safe plan for discharge includes information given on medications, diet, community resources, follow-up care, and contact information for whom to call with questions or in case of an emergency.
- When information relevant to care is communicated by telephone, verification of information through use of a read-back process should be documented in the health care record.

- Health care informatics facilitates the integration of data, information, knowledge, and wisdom to support patients, nurses, and other providers in decision making in all roles and settings.
- Nursing students must develop the knowledge, skills, and attitudes that will enable them to facilitate safe patient care and maintain patient confidentiality when using electronic documentation systems.

Reflective Learning

- Describe the actions you will take to protect the privacy of patient information if you need to print information from an EHR during clinical to complete your clinical paperwork after returning to campus.
- Using a recent clinical experience, describe how a clinical decision support system could support evidence-based practice allowing you to make decisions that would result in safe and effective nursing actions.
- Imagine there is an increased incidence of pressure injuries among the patients on the unit where you have clinical. Describe what data you could collect from the agency's nursing information system to determine why these patients are at greater risk for skin breakdown and what factors related to the nursing care provided on the unit are influencing the prevalence of hospital-acquired pressure injuries. Discuss why this information is important to collect.

Review Questions

1. The nurse contacts a provider about a change in a patient's condition and receives several new orders for the patient over

the phone. When documenting telephone orders in the electronic health record, most hospitals require a nurse to do which of the following?

1. Print out a copy of all telephone orders entered into the electronic health record in order to keep them in personal records for legal purposes.
 2. "Read back" all telephone orders to the provider over the phone to verify all orders were heard, understood, and transcribed correctly before entering the orders in the electronic health record.
 3. Record telephone orders in the electronic health record, but wait to implement the order(s) until they are electronically signed by the health care provider who gave them.
 4. Implement telephone order(s) immediately, but insist that the health care provider come to the patient care unit to personally enter the order(s) into the electronic health record within the next 24 hours.
2. The nurse is working in an agency that has recently implemented an electronic health record. Which of the following are acceptable practices for maintaining the security and confidentiality of electronic health record information? (Select all that apply.)
1. Using a strong password and changing your password frequently according to agency policy
 2. Allowing a temporary staff member to use your computer user name and password to access the electronic record
 3. Ensuring that work lists (and any other data that must be printed from the electronic health record) are protected throughout the shift and disposed of in a locked receptacle designated for documents that are to be shredded when no longer needed

4. Ensuring that the patient information that is displayed on the computer monitor that you are using is not visible to visitors and other health care providers who are not involved in that patient's care
 5. Remaining logged in to a computer to save time if you only need to step away to administer a medication
3. When documenting an assessment of a patient's cardiac system in an electronic health record, the nurse uses the computer mouse to select the "WNL" statement to document the following findings: *"Heart sounds S1 & S2 auscultated. Heart rate between 80–100 beats per minute, and regular. Denies chest pain."* This is an example of using which of the following documentation formats?
1. Focus charting incorporating "Data, Action & Response" (DAR)
 2. Problem-intervention-evaluation (PIE)
 3. Charting-by-exception (CBE)
 4. Narrative documentation
4. The nurse works at an agency where military time is used for documentation, and needs to document that a patient was transported to the operating room for an emergency procedure at 8 in the evening. Point to the area on the clockface below that indicates 8 in the evening in military time:

5. The nurse who works at the local hospital is transferring a patient to an acute rehabilitation center in another town. To complete the transfer, information from the patient's electronic health record must be printed and faxed to the acute rehabilitation center. Which of the following actions is most appropriate for the nurse to take to maintain privacy and confidentiality of the patient's information when faxing this information? (Select all that apply.)
1. Confirm that the fax number for the acute rehabilitation center is correct before sending the fax.
 2. Use the encryption feature on the fax machine to encode the information and make it impossible for staff at the acute

rehabilitation center to read the information unless they have the encryption key.

3. Fax the patient's information without a cover sheet so that the person receiving the information at the acute rehabilitation center can identify it more quickly.
4. After sending the fax, place the information that was printed out in a standard trash can after ripping it into several pieces.
5. After sending the fax, place the information that was printed out in a secure canister marked for shredding.
6. The nurse is administering a dose of metoprolol to a patient, and is completing the steps of bar code medication administration within the EHR. As the bar code information on the medication is scanned, an alert that states "Do not administer dose if apical heart rate (HR) is <60 beats/minute or systolic blood pressure (SBP) is <90 mm Hg" appears on the computer screen. The alert that appeared on the computer screen is an example of what type of system?
 1. Electronic health record (EHR)
 2. Charting by exception
 3. Clinical decision support system (CDSS)
 4. Computerized physician order entry (CPOE)
7. The nurse is writing a narrative progress note. Identify each of the following statements as subjective data (S) or objective data (O):
 1. April 24, 2019 (0900)
 2. Repositioned patient on left side.
 3. Medicated with hydrocodone-acetaminophen 5/325 mg, 2 tablets PO.
 4. "The pain in my incision increases every time I try to turn on my right side."
 5. S. Eastman, RN

6. Surgical incision right lower quadrant, 3 inches in length, well approximated, sutures intact, no drainage
7. Rates pain 7/10 at location of surgical incision.
8. The nurse is discussing the advantages of using computerized provider order entry (CPOE) with a nursing colleague. Which statement best describes the major advantage of a CPOE system within an electronic health record?
 1. CPOE reduces the time necessary for health care providers to write orders.
 2. CPOE reduces the time needed for nurses to communicate with health care providers.
 3. Nurses do not need to acknowledge orders entered by CPOE in an electronic health record.
 4. CPOE improves patient safety by reducing transcription errors.
9. The nurse is reviewing health care provider orders that were handwritten on paper when all computers were down during a system upgrade. Which of the following orders contain an inappropriate abbreviation included on The Joint Commission's "Do Not Use" list and should be clarified with the health care provider?
 1. Change open midline abdominal incision daily using wet-to-moist normal saline and gauze.
 2. Lorazepam 0.5 mg PO every 4 hours prn anxiety
 3. Morphine sulfate 1 mg IVP every 2 hours prn severe pain
 4. Insulin aspart 8u SQ every morning before breakfast
10. The nurse is changing the dressing over the midline incision of a patient who had surgery. Assessment of the incision reveals changes from what was documented by the previous nurse. After documenting the current wound assessment, the nurse contacts the surgeon (Dr. Oakman) by telephone to discuss

changes in the incision that are of concern. Which of the following illustrates the most appropriate way for the nurse to document this conversation?

1. Health care provider notified about change in assessment of abdominal incision. T. Wright, RN
2. 09-3-18: Notified Dr. Oakman by phone that there is a new area of redness around the patient's incision. T. Wright, RN
3. 1015: Contacted Dr. Oakman and notified about changes in abdominal incision. T. Wright, RN
4. 09-3-18 (1015): Dr. Oakman contacted by phone. Notified about new area of bright red erythema extending approximately 1 inch around circumference of midline abdominal incision and oral temperature of 101.5 F. No orders received. T. Wright, RN

UNIT 5

Foundations for Nursing Practice

OUTLINE

27. Patient Safety and Quality

28. Infection Prevention and Control

29. Vital Signs

30. Health Assessment and Physical Examination

31. Medication Administration

32. Complementary Therapies and Integrative Health

Patient Safety and Quality

OBJECTIVES

- Discuss the key factors in patient-centered care that can improve patient safety.
- Discuss the vulnerable populations most at risk for threats to safety.
- Discuss common physical hazards and methods for preventing them.
- Discuss how an individual's developmental age creates safety risks.
- Explain the mobility alterations that pose risks for falling.
- Describe ways to prevent procedure-related accidents.
- Describe assessment activities that identify the physical, psychosocial, and cognitive status of a patient as it pertains to his or her safety.
- Discuss how to select environmental interventions for fall prevention for the home environment.
- Identify evidence-based alternatives to restraints for patients who are alert, oriented, and low risk.
- Identify factors to assess before placing patients in physical restraints.
- Identify the factors to assess when a patient is in restraints.

Seizure precautions, p. 407

Status epilepticus, p. 407

Workplace violence, p. 393

Safety, often defined as freedom from psychological and physical injury, is a basic human need. Health care provided in a safe manner and in a safe community environment is essential for a patient's survival and well-being. A safe environment reduces the risk for illness and injury and helps to contain the cost of health care by preventing extended lengths of treatment and/or hospitalization, improving or maintaining a patient's functional status, and increasing a patient's sense of well-being. Nurses are responsible for incorporating critical thinking skills to promote patient safety. This involves using the nursing process—assessing patients' risks for injury in their home or health care environment, assessing for hazards that threaten safety, accurately diagnosing problems, and then planning and intervening appropriately to maintain a safe environment.

As members of the health care team, nurses are professionally responsible for engaging in activities that support a patient-centered safety culture. Patient-centered care promotes safety and requires you to recognize your patients or their designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient preferences, values, and needs (QSEN, 2018). Partnership is the key factor. The National Academy of Medicine's scientific panel defined patient and family engaged care (PFEC) as care planned, delivered, managed, and continuously improved in active partnership with patients and their families to ensure integration of their health and health care goals, preferences, and values (Frampton et al., 2017). It is difficult to achieve positive patient outcomes without nurses actively involving patients and families in safety promotion.

Health care organizations use a variety of processes and approaches to improve the quality of care delivered to patients. Much of the force behind the focus on safety comes from regulatory and accrediting agencies such as the Centers for Medicare and Medicaid Services (CMS) and The Joint Commission (TJC). [The Joint Commission's 2020 National Patient Safety Goals \(Box 27.1\)](#) are standards for all health care institutions and are specifically directed at reducing the risk of medical errors (TJC, 2020).

Box 27.1 The Joint Commission 2020 Hospital National Patient Safety Goals

- Identify patients correctly.
- Improve staff communication.

- Use medicines safely.
- Use alarms safely.
- Prevent infection.
- Identify patient safety risks.
- Prevent mistakes in surgery.

Copyright © The Joint Commission, 2020. Reprinted with permission.

A culture of safety within a health care institution is important for minimizing adverse events even as nurses perform complex and hazardous work. The Agency for Healthcare Research and Quality ([AHRQ, 2018a](#)) describes key features of a “culture of safety”:

- Acknowledgment of the high-risk nature of an organization’s activities and the determination to achieve consistently safe operations
- A blame-free environment where individuals are able to report errors or near misses without fear of reprimand or punishment
- Encouragement of collaboration across levels of employees and disciplines to seek solutions to patient safety problems
- Organizational commitment of resources to address safety concerns

Recently the Joint Commission issued a safety alert, emphasizing the importance of identifying and reporting unsafe conditions before they cause harm, trusting that other health care staff and leadership will act on the report, and taking personal responsibility for one’s actions to create a safety culture within a health care organization ([TJC, 2018d](#)). Organizations that support a culture of safety continually focus on performance improvement efforts, empowering employees to actively participate in the safety activities of the organization, risk-management findings, and safety reports to design safer work environments (see [Chapter 23](#)) ([Boysen, 2013](#)).

Scientific Knowledge Base

Environmental Safety

A patient's environment includes physical and psychosocial factors that influence or affect the life and survival of that patient. This broad definition of environment crosses the continuum of care for settings in which the nurse and patient interact, such as the hospital, long-term care facility, clinic, community center, school, and home. A safe environment protects the staff as well, allowing them to function optimally. Vulnerable populations are especially at risk for alterations in safety because of reduced access to health care, fewer resources, and increased morbidity. Those vulnerable groups most affected include infants, children, older adults, individuals with a chronic disease or a physical or mental disability, individuals who have difficulty communicating, and individuals who have a low-income or are homeless (Joszt, 2018; CDC, 2018a). A safe environment meets basic needs, reduces physical hazards as well as the transmission of pathogens, and controls pollution.

Basic Human Needs

Physiological needs, including the need for sufficient oxygen, nutrition, and optimum temperature, influence a person's safety. According to Maslow's hierarchy of needs, these basic needs must be met before physical and psychological safety and security can be addressed (see Chapter 6).

Oxygen

Supplemental oxygen is sometimes needed to meet a person's oxygenation needs. Patients who require supplemental oxygen in health care settings are at risk because oxygen is highly flammable. Fire can occur when a patient on oxygen therapy chooses to smoke or is exposed to a heat source. Strict codes regulate the use and storage of medical oxygen in health care agencies. This is not the case in home environments. Be sure to administer oxygen safely and provide patients and family caregivers the information needed to manage oxygen correctly in the home (see Chapter 41). Oxygen can build up in a home and on a patient's clothing and hair. If a person smokes in an environment that has supplemental oxygen, such as a house, even a small spark can cause a fire that will spread very quickly, resulting in extensive burns and even death. Thus it is essential that no one smokes in a home equipped with supplemental oxygen.

Know factors in a patient's environment that decrease the amount of available oxygen. An improperly functioning heating system is a hazard in the home. A furnace, fireplace, or stove that is not properly vented introduces carbon monoxide (CO) into the environment. Carbon monoxide affects

oxygenation by binding strongly with hemoglobin, preventing the formation of oxyhemoglobin and reducing the supply of oxygen delivered to tissues. Low concentrations of oxygen cause nausea, dizziness, headache and fatigue. Unintentional, non–fire-related (UNFR) carbon monoxide poisoning is one of the most common causes of poisoning in the United States. The (CDC 2018b) reports that every year approximately 50,000 people in the United States visit the emergency department due to accidental CO poisoning.

Nutrition

Meeting nutritional needs of patients requires knowledge about healthy food and food safety. Chapter 45 details the principles of balanced nutrition. Health care agencies are required to meet State Board of Health regulations for the storage, preparation, and provision of food to patients. In the home some patients do not know how to properly refrigerate, store, and prepare food. The (CDC 2018c) estimates that 48 million people get sick from a foodborne illness, 128,000 are hospitalized, and 3000 die each year. When you care for patients returning home or if you work in home health, educate them about food safety principles. Also, patients require an adequate, clean water supply for drinking and to wash fresh produce and dishes. If a patient does not prepare or store foods properly, it increases the risk for infections and food poisoning from norovirus or bacteria such as *Escherichia coli*, *Salmonella*, or *Listeria*.

Temperature

Temperature extremes that frequently occur during the winter and summer pose safety risks for vulnerable populations. Exposure to severe cold for prolonged periods causes frostbite and accidental hypothermia. Older adults, the young, patients with cardiovascular conditions, patients who have ingested drugs or alcohol in excess, and people who are homeless are at high risk for hypothermia. In contrast, exposure to extreme heat changes the electrolyte balance of the body and raises the core body temperature, potentially resulting in heatstroke or heat exhaustion. Chronically ill patients, older adults, and infants are at greatest risk for injury from extreme heat.

Physical Hazards

Physical hazards in the home and work environment threaten a person's safety and often result in physical or psychological injury or death. In 2016 unintentional injuries became the third leading cause of death (Kochanek et al., 2017). Motor vehicle accidents, poisonings, and falls were the leading causes of unintentional injuries. Additional environmental hazards include fire and disasters. In the work setting, repetitive motion injuries, vehicle accidents, falling objects and falls are common causes of injuries. A nurse's role is to

educate patients about the common safety hazards in the home and at work, teaching them how to prevent injury and emphasizing the hazards to which patients are the most vulnerable.

Motor Vehicle Accidents

Vehicle design and equipment such as seat belts, airbags, laminated windshields, and accident prevention systems have improved vehicular safety. State laws relating to licensing of young drivers, safety belt use, child restraint use, and motorcycle helmets exist for driver protection. It is important that children ride in child safety seats and booster seats appropriate for their age and weight and type of car. The American Academy of Pediatrics ([AAP, 2018a](#)) recommends the following:

- Infants and toddlers should ride in a rear-facing car safety seat ([Fig. 27.1](#)) as long as possible, until they reach the highest weight or height allowed by their seat (see manufacturer's directions). Most convertible seats have limits that will allow children to ride rear-facing for 2 years or more.

Using the correct car seat or booster seat can be a lifesaver: make sure your child is always buckled in an age- and size-appropriate car seat or booster seat.

Keep children ages 12 and under in the back seat. Never place a rear-facing car seat in front of an active air bag.

*Recommended age ranges for each seat type vary to account for differences in child growth and height/weight limits of car seats and booster seats. Use the car seat or booster seat owner's manual to check installation and the seat height/weight limits, and proper seat use.

Child safety seat recommendations: American Academy of Pediatrics.
 Graphic design: adapted from National Highway Traffic Safety Administration.

FIG. 27.1 Car seat and booster seat guidelines.

From <https://www.cdc.gov/injury/features/child-passenger-safety/>. Accessed January 9, 2020.

- Once they are facing forward, children should use a forward-facing car safety seat with a harness for as long as possible, until they reach the height and weight limits for their seats. Many seats can accommodate children up to 65 lb or more.
- When children exceed these limits, they should use a belt-positioning booster seat until the vehicle's lap and shoulder seat belt fits properly. This is often when they have reached at least 4 feet, 9 inches in height and are 9 to 12 years of age.
- When children are old enough and large enough to use the vehicle seat belt alone, they should always use lap and shoulder seat belts for optimal protection.
- All children 12 years of age and younger should be restrained in the rear seats of vehicles for optimal protection.

According to the (CDC 2018d), the risk of motor vehicle accidents is higher among 16- to 19-year-old drivers than any other age-group, with motor vehicle crashes being the leading cause of death for this age-group. Teens often

underestimate dangerous situations or are unable to recognize hazardous situations (e.g., texting or talking on a phone while driving). In addition, they tend to speed and allow shorter headways, ride with intoxicated drivers, drive at night, and drive after using alcohol or drugs. Teens also have the lowest rate of seat belt use.

Elderly drivers are keeping their licenses longer and driving more miles than in the past. Driving is an important way in which older adults remain independent. But there are often risks, the longer an older adult drives. Age-related decline in vision and cognitive functioning (ability to reason and remember) and physical changes affect driving abilities of some older adults (CDC, 2017a). Ways to promote safety among older adult drivers include:

- Exercising regularly to increase strength and flexibility.
- Asking the doctor or pharmacist to review medications—both prescription and over-the counter—to reduce side effects and interactions.
- Having eyes checked by an eye doctor at least once a year and wearing glasses and corrective lenses as required.
- Driving during daylight and in good weather.
- Finding the safest route, with well-lit streets, intersections with left-turn arrows, and easy parking.

Poison

A **poison** is any substance that impairs health or results in death when ingested, inhaled, injected, or absorbed into the body. Poisons often impair the function of every major organ system. Almost any substance is poisonous if too much is taken. Sources of poison in a person's home may include medicines, solid or liquid cleaning substances, gases, and vapors. Toddlers, preschoolers, and young school-age children are at greatest risk because of their curiosity, often ingesting household cleaning solutions, medications, or personal hygiene products in the home. Medications are commonly packaged in containers that hold multiple doses. As a result a child who is able to open a medicine container has access to multiple tablets or capsules. Emergency treatment is necessary when a person ingests a poisonous substance or comes into contact with a chemical that is absorbed through the skin. Every day, over 300 children in the United States ages 0 to 19 are treated in an emergency department as a result of being poisoned (CDC, 2016a). A poison control center is the best resource for patients and parents needing information about the treatment of an accidental poisoning. The nationwide poison control hotline center phone number is 1-800-222-1222.

Although lead has not been used in house paint or plumbing materials since the US Consumer Product Safety Commission banned it in 1978, some older

homes still contain high lead levels. Soil and water systems are sometimes contaminated. Lead is emitted into the environment from industrial sources and contaminated sites, such as former lead smelters (EPA, 2018). Poisoning occurs from swallowing or inhaling lead. Fetuses, infants, and children are more vulnerable to lead poisoning than adults because their bodies absorb lead more easily, and small children are more sensitive to the damaging effects of lead. Exposure to excessive levels of lead affects a child's growth or causes learning and behavioral problems and brain and kidney damage.

Falls

A fall is an event that results in a person coming to rest inadvertently on the ground or floor or other lower level (WHO, 2018). Falls have been a major health problem, ranking as the second leading cause of accidental or unintentional injury deaths worldwide (WHO, 2018). Falls contribute to disability, lost work time, and in the case of many older adults, long-term care and institutionalization. Fall prevention has been a major quality health care initiative for community-dwelling older adults, as well as those in health care settings.

Falls are multifactorial; numerous factors increase the risk of falls. Older adults have the highest risk of death or serious injury following a fall (WHO, 2018). Other risk factors include (WHO, 2018; National Institute on Aging 2017):

- Occupations at elevated heights or other hazardous working conditions.
- Alcohol or substance use.
- Socioeconomic factors, including poverty, overcrowded housing, sole parenthood, or young maternal age.
- Underlying medical conditions, such as neurological, cardiac (orthostatic hypotension), or other disabling conditions.
- Polypharmacy and side effects of medications.
- Physical inactivity and loss of balance, particularly among older adults.
- Poor mobility (impaired balance, gait, coordination), cognition, and vision, particularly among those living in an institution, such as a nursing home or chronic care facility.
- Unsafe environments (e.g., broken stairs, icy sidewalks, inadequate lighting, throw rugs, exposed electrical cords, barriers along walking paths, and improper equipment for ambulation).
- Foot problems that cause pain and unsafe footwear, such as backless shoes or high heels.

Hospitals throughout the country carefully monitor the incidence of falls and fall-related injuries as part of their ongoing performance improvement work. Some of the agencies that provide education, monitoring guidelines, and fall prevention resources include:

- The Joint Commission—<https://www.jointcommission.org/>.
- The Institute for Healthcare Improvement—www.ihl.org.
- The US Department of Veterans Affairs Center for Patient Safety—https://www.patientsafety.va.gov/index.asp?_ga=2.255699786.35041262.1543845065-460341664.1543845065.
- US Department of Health and Human Services—www.HHS.gov.

Falls often lead to serious injuries such as fractures or internal bleeding. Patients most at risk for injury are those with osteoporosis or with bleeding tendencies resulting from disease or medical treatments. Fear of falling is a concern of community-dwelling older adults, and many avoid activities because of their fear.

Fire

A total of 358,500 structure fires were reported in the United States in 2011 to 2015, resulting in 2510 deaths, 12,300 injuries, and \$6.7 billion in direct damage (NFPA, 2017a). The leading cause of fire-related death is careless smoking, especially when people smoke in bed at home. Cooking equipment was the leading cause of home structure fires and home fire injuries and the second leading cause of home fire deaths. Heating equipment (e.g., space heaters) was the second most common cause of home fires and fire injuries and the third leading cause of fire deaths (NFPA, 2017a). The improper use of cooking equipment and appliances, particularly stoves, is a major cause of in-home fires and fire injuries. Nurses play a role in educating the public about fire prevention measures.

Fires occur in health care facilities each year, with most occurring in nursing homes, followed by mental health facilities, hospitals, and hospices. Because patients in health care facilities are sick, disabled, or elderly, health care staff must know how to protect patients and respond to fires appropriately. Health care agencies have routine fire drills to measure staff responsiveness and understanding of fire safety protocols (NFPA, 2017b).

Disasters

Natural disasters such as floods, tsunamis, hurricanes, tornadoes, and wildfires are a major cause of death and injury. These types of disasters may result in death and can leave many people homeless. Every year millions of Americans

are affected by natural disasters and their terrifying consequences. Bioterrorism is another cause of disaster and refers to biological agents (microbes or toxins) used as weapons to further personal or political agendas. A bioterrorist attack could be caused by virtually any pathogenic microorganism. The agents of greatest concern are anthrax (a bacterium) and smallpox (a virus). Both can be lethal. Anthrax is not communicable from direct contact but is transmitted in spores that become aerosolized. Smallpox is readily transmitted from person-to-person contact. Symptoms caused by these pathogens vary depending upon how the person was exposed but generally occur within 7 days of the exposure. Hospitals that are accredited by The Joint Commission must demonstrate they have proper plans and response mechanisms in place if a disaster occurs. The hospitals conduct annual disaster-preparedness exercises and must monitor the following six critical factors ([Response Systems, n.d.](#)):

- Communications—internal and external to community care partners, state/federal agencies
- Supplies—adequate levels and appropriateness to hazard vulnerabilities
- Security—enabling normal hospital operations and protection of staff and property
- Staff—roles and responsibilities within a standard hospital incident command structure
- Utilities—enabling self-sufficiency for as long as possible, with a goal of 96 hours
- Clinical activity—maintaining care, supporting vulnerable populations, and alternate standards of care

Transmission of Pathogens

Pathogens and parasites pose an ongoing threat to an individual's safety (see [Chapter 28](#)). Both patients and health care providers are at risk for exposure to pathogens. A **pathogen** is any microorganism capable of producing an illness. The most common means of transmission of pathogens is by the hands. For example, if an individual infected with hepatitis A does not wash his or her hands thoroughly after having a bowel movement, the risk for transmitting the disease to others during food preparation is increased. Nurses must educate patients about their unique risks for developing infection, such as immunosuppression from medications, chronic disease, or older age.

When a patient acquires an infection in a health care setting, it is called a nosocomial infection or health care-acquired infection (HAI). An HAI is one not present in the patient at the time of admission to the health care agency but that develops during the course of the stay. Health care facilities have standards for infection prevention in a variety of clinical situations, such as

prevention of surgical site infections or catheter-associated urinary tract infections. One of the most effective methods for limiting the transmission of pathogens in health care is the medically aseptic practice of hand hygiene (see [Chapter 28](#)). It is important that nurses adhere to the practice of hand hygiene, follow standard and transmission-based isolation precautions, and educate patients, families, and caregivers about the importance of incorporating hand hygiene in all aspects of their lives.

Immunizations

Childhood vaccination has proven to be one of the most effective public health strategies to control and prevent disease ([Ventola, 2016](#)). **Immunization** reduces, and in some cases prevents, the transmission of disease from person to person. Recently, however, parents have shown concerns about immunizing their children. For example, some parents have had concerns that autism might be linked to the vaccines children receive, but studies have shown that there is no link between receiving vaccines and developing autism ([CDC, 2016b](#)). Another parental concern has been whether the timing of the 2-month and 4-month vaccinations is associated with sudden infant death syndrome, which commonly occurs in that same time frame. Studies have found that vaccines do not cause and are not linked to SIDS ([CDC, 2016b](#)). Currently, early childhood vaccination rates continue to improve among commercially insured children in the United States, with 77% of children born in 2013 completing their CDC-recommended seven-vaccine series by 2016, up from 69% for children born in 2010 ([Blue Cross Blue Shield, 2018](#)). Adherence to childhood vaccinations is a problem for vulnerable populations. In 2014, black children were less likely to be fully vaccinated than white or Hispanic children, and children in families with incomes below the poverty level were less likely than those in families with incomes at or above the poverty level to receive the combined-series vaccination ([Child Trends Data Bank, 2015](#)). Missed well-child visits are a primary driver of undervaccinated children ([Blue Cross Blue Shield, 2018](#)). Nurses play a role in informing parents about the importance of adhering to vaccination schedules for their children.

Adults require regular vaccinations depending on their age, job, lifestyle, travel, or health conditions ([CDC, 2018e](#)). For example, older adults are at risk for infectious disease if not regularly immunized for the flu and pneumonia. People in this age-group should also consult with their health care providers about receiving the vaccine for shingles as it is recommended for healthy adults 50 years and older ([CDC, 2018e](#)). Health care workers who are at risk for being exposed to blood or other body fluids should receive the three-dose series of vaccinations for hepatitis B.

REFLECT NOW

Think about the members of your family and identify any physical hazards that each member is likely to experience.

Nursing Knowledge Base

Factors Influencing Patient Safety

In addition to being knowledgeable about the home and health care environment and the inherent safety risks, nurses need to know a patient's developmental level; mobility, sensory, and cognitive status; lifestyle choices; and knowledge of common safety precautions. Nurses apply scientific evidence in managing developmental risks and the unique safety risks that are found in health care settings.

Developmental Stages and Risks

A patient's developmental stage can create threats to safety because of lifestyle, cognitive and mobility status, sensory impairments, and safety awareness. With this information safety-prevention programs are tailored to address the needs, preferences, and life circumstances of particular age-groups. Unfortunately, all age-groups are subject to physical and mental abuse. Child abuse, domestic violence, and elder abuse are serious threats to safety (see [Chapters 11 to 14](#)).

Infant, Toddler, and Preschooler

Injuries are the leading cause of death in children over age 1. The nature of the injury sustained is closely related to normal growth and development. For example, because of improved motor skills, coordination, and balance, preschoolers are less prone to falls than toddlers ([Hockenberry et al., 2019](#)). Infants and toddlers explore the environment and, because of their increased level of oral activity, put objects in their mouths. This increases their risk for poisoning or aspiration and choking on foreign material such as small toys. Parents do not always recognize the danger in seemingly harmless items, such as remote control devices and keyless remote door openers for vehicles. Button batteries if swallowed can cause serious injury or death ([National Safety Council, 2019](#)).

A safe sleep environment for an infant involves the placement of the infant on his back on a firm mattress in a safety-approved crib

that is free of pillows, toys, and blankets, as these are suffocation hazards. Instruct parents about the hazards of sleeping with an infant in bed, on the sofa, or on the floor ([National Institutes of Health, 2014](#)).

Fortunately, preschoolers are generally less reckless and are aware of potential dangers such as hot objects or sharp instruments ([Hockenberry et al., 2019](#)). Limited physical coordination in preschoolers contributes to falls from riding bicycles and using playground equipment. Other injuries include burns and drowning. Most drowning or near-drowning incidents happen when a child falls into a pool or is left alone in the bathtub ([National Safety Council, 2019](#)). Accidents involving children are largely preventable. But accident prevention requires health education for parents and the removal of dangers whenever possible.

School-Age Child

School-age children enter a period of less intense emotions, secure in their dependency on parents and family and with self-confidence tempered by a more realistic perspective. They have energy to explore the environment beyond the home and to gradually increase the scope of interpersonal interaction ([Hockenberry et al., 2019](#)). When a child enters school, the environment expands to include the school, transportation to and from school, school friends, and after-school activities. School-age children are learning how to perform more complicated motor activities and often are uncoordinated. They are also expanding their cognitive and psychosocial skills. A child at this age needs to learn to cope with the rules and expectations of schools and peers. School-age children involved in team and contact sports may not consistently follow the rules for playing safely and may fail to use protective safety equipment, such as helmets and other protective gear. School-agers are exposed to more environments in which they need protection, they have less supervision, and they take more responsibility as they participate in a more adult world ([Hockenberry et al., 2019](#)).

The incidence of school violence, including fighting/assaults (with or without weapons by two or more individuals); bullying; physical, sexual, and psychological abuse; and violence against oneself

(intentional nonsuicidal self-injury) has increased. The CDC's Youth Risk Behavior Survey found that nearly 24% of students had been in a physical fight on school property one or more times during the 12 months before the survey (CDC, 2018f). Violence in any form disrupts a child's ability to learn and may have a negative effect on health throughout life (National Association of School Nurses, 2018). School nurses are able to recognize the multiple factors that may increase or decrease a youth's risk of becoming a perpetrator or victim of school violence and may be able to identify students at risk (Box 27.2).

Box 27.2 Risk Factors for Violence

Adolescent

As children enter adolescence, they develop greater independence and a sense of identity. Adolescents begin to separate emotionally from their families, and peer groups begin to have a stronger influence. Adolescents typically have wide variations that swing from childlike to mature behavior. They test their boundaries by trying risky behaviors. Experimentation with the use of tobacco, alcohol, and other substances is common. By the 12th grade, approximately 63% of students have used alcohol, 45% have used electronic vapor cigarettes, 32% have smoked tobacco, 39% have tried cannabis, and 6% have tried illicit drugs (Kann et al., 2016).

Trends such as the current opioid epidemic have alerted school communities to the dangers of prescription painkillers, as overdoses among young adults in the United States have quadrupled in the past decade ([National Institute on Drug Abuse \[NIDA\], 2016](#)). Without appropriate health literacy skills, misinformed parents and students can overlook or downplay the risks of substance use ([NIDA, 2016](#)). Environmental clues of substance abuse include the presence of drug-oriented magazines, beer and liquor bottles, or drug paraphernalia and the wearing of long-sleeved shirts in hot weather. Psychosocial clues include failing grades, change in dress, absenteeism from school, isolation, and changes in interpersonal relationships. Substance abuse increases the risks for accidents such as drowning and motor vehicle accidents. The Insurance Institute for Highway Safety ([IIHS, 2016](#)) reports that males ages 20 to 24 and adults ages 85 and older had the highest rates of crash deaths.

Adolescents are also at risk for suicide because of feelings of decreased self-worth and hopelessness. Risk factors include ([Kaslow, 2018](#)):

- A recent or serious loss, such as the death of a family member, a friend, or a pet.
- A psychiatric disorder, particularly a mood disorder, such as depression, or a trauma- and stress-related disorder.
- Prior suicide attempts.
- Alcohol and other substance abuse disorders, as well as getting into a lot of trouble, having disciplinary problems, or engaging in high-risk behaviors
- Struggling with sexual orientation in an environment that is not respectful of or accepting of that orientation.
- A family history of suicide, as well as a history of domestic violence, child abuse, or neglect.
- Lack of social support. A child who doesn't feel support from significant adults in her life, as well as her friends, can become isolated.
- Bullying. It is known that being a victim of bullying is a risk factor, but there's also some evidence that kids who are bullies may be at increased risk for suicidal behavior.

- Access to lethal means, such as firearms and pills.

Adult

The threats to an adult's safety are frequently related to lifestyle habits. For example, a person who uses alcohol excessively is at greater risk for motor vehicle accidents or sustaining an injury at home. People who smoke long-term have a greater risk of cardiovascular or pulmonary disease because of the inhalation of smoke and the effect of nicotine on the circulatory system. Likewise, the adult experiencing a high level of stress is more likely to have an accident or illness such as headaches, gastrointestinal (GI) disorders, and infections.

Older Adult

The physiological changes associated with aging, the effects of multiple medications, psychological and cognitive factors, and the effects of acute or chronic disease increase an older adult's risk for falls and other types of accidents (e.g., burn injuries, vehicular crashes). More than one out of four adults 65 years of age and older falls each year, but fewer than half tell their health care providers ([CDC, 2017b](#)). Falls are the major cause of injury leading to disability and death among adults 65 years of age and older. Once a patient falls, the risk of falling a second time is increased ([CDC, 2017b](#)).

There are multiple reasons for cognitive changes in older adults. Some cognitive changes are part of the natural aspect of aging. For example, an older adult may walk into a room and forget the purpose of going to the room or begin to leave the home and find the car keys are misplaced. However, there are also reasons for abnormal cognitive changes that need to be assessed in the older adult. For example, the changes may be associated with treatment for a disease process (such as chemotherapy for cancer). [Lange et al. \(2018\)](#) studied patients who were 65 years or older with newly diagnosed early-stage breast cancer (EBC). The researchers noted five significant patterns of cognitive decline and impairment after the patients had completed their treatments.

Dementia is a clinical syndrome caused by neurodegeneration and characterized by progressive deterioration in cognitive ability and capacity for independent living. A systematic review of the literature estimated that 35.6 million people lived with dementia worldwide in 2010, with numbers expected to almost double every 20 years, to 65.7 million in 2030 and 115.4 million in 2050 ([Prince et al., 2013](#)).

Dementia limits the ability to process information cognitively that normally allows people to perform tasks and prevent injury. Older adults who develop dementia often suffer from wandering.

Wandering is the meandering, aimless, or repetitive locomotion that exposes a person to harm and is often in conflict with boundaries (such as doors), limits, or obstacles ([Herdman and Kamitsuru, 2018](#)).

Wandering is dangerous. Individuals can walk away from home or off care units or enter restricted or closed areas without the knowledge of caregivers. Interrupting a wandering patient can increase his or her distress. Family caregivers, as well as professional caregivers, must apply safety principles to reduce patients' tendencies to wander and to provide safe living environments.

Mind-wandering is common among all older adults. It involves engaging in task-irrelevant thoughts that can have negative functional consequences, such as falls, and impaired task performance. In a study by [Nagamatsu and colleagues \(2013\)](#), falls were associated with an increased frequency of mind-wandering, involving an inability to actively control attention to align with current behavioral goals while simultaneously inhibiting task-unrelated thoughts. The tendency to mind-wander poses an obstacle for individuals to safely navigate their environments. Research is needed to explore whether mind-wandering is related to changes in gait.

Individual Risk Factors

Other risk factors posing threats to safety include lifestyle, impaired mobility, sensory or communication impairment, limited economic resources, and the lack of safety awareness. Know patients' risks when you plan nursing care.

Lifestyle

Some lifestyle choices increase safety risks. People who drive or operate machinery while under the influence of chemical substances (drugs or alcohol), who work at dangerous jobs, or are risk takers are at greater risk of injury. In addition, people experiencing stress, anxiety, fatigue, or alcohol or drug withdrawal or those taking prescribed medications are sometimes more accident prone. Because of these factors, some people are too preoccupied to notice the source of potential accidents, such as cluttered stairs or a stop sign.

Impaired Mobility

A patient with impaired mobility has many kinds of safety risks. Muscle weakness, paralysis, abnormal gait, and poor coordination or balance are major factors in placing patients at risk for falls. Immobilization predisposes patients to physical deconditioning and emotional hazards, which in turn further restrict mobility and independence. People who are physically challenged are at greater risk for injury when entering motor vehicles and buildings that are not handicap accessible.

Sensory or Communication Impairment

Cognitive impairments associated with delirium, dementia, and depression alter concentration and attention span and cause impaired memory and orientation changes. Patients with these alterations become easily confused about their surroundings and are more likely to have falls and burns. This is a common problem when such patients temporarily or permanently move to a health care setting. Patients with visual, hearing, tactile, or communication impairment, such as aphasia or a language barrier, are not always able to perceive a potential danger or express their need for assistance (see [Chapter 49](#)). Patients with reduced health literacy are unable to understand the information needed to make the decisions required for providing safe home environments.

Economic Resources

People with lower incomes (including the homeless) are more likely to have behavioral health issues, such as depression or substance use

problems, that place them at risk for injury. They also do not have access to the health care resources (such as medications and treatments) that those with higher incomes have (see [Chapter 9](#)). Those who are homeless are less likely to report having a regular source of health care and are more likely to have forgone needed care ([McInnes et al., 2013](#)). Those who are homeless may also not have a safe place to stay. When a patient who has a lower income enters a health care agency, ensure you assess all the patient's safety risks.

Lack of Safety Awareness

Some patients are unaware of or inexperienced in following safety precautions in the home, such as keeping medicine or poisons away from children or reading the expiration dates on food products. You cannot assume a patient's knowledge about a safety topic. A nursing assessment that includes a home inspection will help to identify a patient's level of knowledge about home safety. Use this information to guide patient education and when creating an individualized nursing care plan.

Risks in Health Care Agencies

The prevention of medical errors continues to be one of the most pressing health care challenges in the nation. Medical errors occur when planned actions are not completed as intended or wrong plans of care are used. They occur in all health care settings. Be aware of the organizational and regulatory patient safety measures that have been established in the health care setting where you work. The AHRQ lists 20 tips for patients to become partners and help prevent medical errors ([AHRQ, 2018b](#)). The patient fact sheet can be viewed at the AHRQ website, <https://www.ahrq.gov/patients-consumers/care-planning/errors/20tips/index.html>.

TJC and the Centers for Medicare and Medicaid Services (CMS) emphasize error prevention and patient safety. Their "Speak Up" campaign encourages patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team ([TJC, 2018a](#)). For example, patients are

encouraged to ask health care workers whether they have washed their hands before providing care. The National Patient Safety Goals of [The Joint Commission \(2019\)](#) highlight specific improvements in patient safety and ongoing problematic areas in health care. These evidence-based recommendations require health care agencies to focus their attention on a series of specific actions.

Another national organization, the National Quality Forum (NQF), leads the national collaboration among health care agencies and the public to improve health and health care quality through measurement ([NQF, 2018a](#)). The NQF brings key public- and private-sector leaders together to establish national priorities and goals to achieve health care that is safe, effective, patient-centered, timely, efficient, and equitable. In addition the organization creates NQF-endorsed standards used to measure and report on the quality and efficiency of health care in the United States. Many of the NQF measurement standards for patient safety (e.g., patient falls with injury, incidence of pressure injuries, and central line bloodstream infection [CLBSI]) are standards for judging the quality of care of health care organizations. Among the safety measures, the NQF endorsed a select list of serious reportable events (SREs) that include a range of clinical settings where patients receive care, including office-based practices, ambulatory surgery centers, and skilled nursing facilities ([Box 27.3](#)) ([NQF, 2018b](#)). The 29 events are a major focus of health care providers for patient safety initiatives.

Box 27.3 National Quality Forum Serious Reportable Events in Health Care

1. Surgical or Invasive Procedure Events

- A. Surgery or other invasive procedure performed on the wrong site (updated)
- B. Surgery or other invasive procedure performed on the wrong patient

- C. Wrong surgical or other invasive procedure performed on a patient (updated)
- D. Unintended retention of a foreign object in a patient after surgery or other invasive procedure (updated)
- E. Intraoperative or immediately postoperative/postprocedure death in an ASA Class 1 patient (updated)

2. Product or Device Events

- A. Patient death or serious injury associated with the use of contaminated drugs, devices, or biologics provided by the health care setting (updated)
- B. Patient death or serious injury associated with the use or function of a device in patient care, in which the device is used or functions other as intended (updated)
- C. Patient death or serious injury associated with intravascular air embolism that occurs while being cared for in a health care setting (updated)

3. Patient Protection Events

- A. Discharge or release of a patient/resident of any age who is unable to make decisions to other than an authorized person (updated)
- B. Patient death or serious injury associated with patient elopement (disappearance) (updated)
- C. Patient suicide, attempted suicide, or self-harm that results in serious injury, while being cared for in a health care setting (updated)

4. Care Management Events

- A. Patient death or serious injury associated with a medication error (e.g., errors involving the wrong drug, wrong dose,

- wrong patient, wrong time, wrong rate, wrong preparation, or wrong route of administration) (updated)
- B. Patient death or serious injury associated with unsafe administration of blood products (updated)
- C. Maternal death or serious injury associated with labor or delivery in a low-risk pregnancy while being cared for in a health care setting (updated)
- D. Death or serious injury of a neonate associated with labor or delivery in a low-risk pregnancy (new)
- E. Patient death or serious injury associated with a fall while being cared for in a health care setting (updated)
- F. Any Stage 3, Stage 4, and unstageable pressure ulcers acquired after admission/presentation to a health care setting (updated)
- G. Artificial insemination with the wrong donor sperm or wrong egg (updated)
- H. Patient death or serious injury resulting from the irretrievable loss of an irreplaceable biological specimen (new)
- I. Patient death or serious injury resulting from failure to follow up or communicate laboratory, pathology, or radiology test results (new)

5. Environmental Events

- A. Patient or staff death or serious injury associated with an electric shock in the course of a patient care process in a health care setting (updated)
- B. Any incident in which systems designated for oxygen or other gas to be delivered to a patient contain no gas, the wrong gas, or are contaminated by toxic substances (updated)
- C. Patient or staff death or serious injury associated with a burn incurred from any source in the course of a patient care process in a health care setting (updated)
- D. Patient death or serious injury associated with the use of physical restraints or bedrails while being cared for in a health care setting (updated)

6. Radiologic Events

- A. Death or serious injury of a patient or staff associated with the introduction of a metallic object into the MRI area (new)

7. Potential Criminal Events

- A. Any instance of care ordered by or provided by someone impersonating a physician, nurse, pharmacist, or other licensed health care provider (updated)
- B. Abduction of a patient/resident of any age (updated)
- C. Sexual abuse/assault on a patient or staff member within or on the grounds of a health care setting (updated)
- D. Death or serious injury of a patient or staff member resulting from a physical assault (i.e., battery) that occurs within or on the grounds of a health care setting (updated)

Copyright © 2018 National Quality Forum.

The CMS selects some SREs as their *Never Events* ([Box 27.4](#)). Many of the hospital-acquired conditions (e.g., fall or stage III pressure injury) are nurse-sensitive indicators, meaning that a nurse directly affects their development. These indicators are the focus of performance improvement efforts by nursing departments across the country. The NQF released 34 Safe Practices for Better Healthcare (last updated in 2010) are effective in reducing the occurrence of adverse health care events across a variety of environments ([NQF, 2018c](#)). Scientific evidence supports the effectiveness of these practices in reducing the occurrence of adverse health care events.

Box 27.4 The 2014 Centers for Medicare and Medicaid Services Hospital-Acquired Conditions

(Present-on-Admission Indicator)

For discharges occurring on or after October 1, 2008, hospitals will not receive additional payment for cases in which one of the selected conditions was not present on admission:

- Foreign object retained after surgery
- Air embolism
- Blood incompatibility
- Pressure injury Stages 3 or 4
- Falls and trauma (fracture, dislocation, intracranial injury, crushing injury, burn, electric shock)
- Catheter-associated urinary tract infections
- Vascular catheter-associated infections
- Manifestations of poor glycemic control (diabetic ketoacidosis, nonketotic hyperosmolar coma, hypoglycemic coma, secondary diabetes with ketoacidosis, secondary diabetes with hyperosmolarity)
- Surgical site infections following:
 - Mediastinitis following coronary artery bypass graft
 - Certain orthopedic procedures (spine, neck, shoulder, elbow)
 - Bariatric surgery for obesity (laparoscopic gastric bypass, gastroenterostomy, laparoscopic gastric restrictive surgery)
 - Cardiac implantable medical device
 - Deep-vein thrombosis (DVT)/pulmonary embolism (PE) following certain orthopedic procedures (total knee replacement, hip replacement)
 - Iatrogenic pneumothorax with venous catheterization

From Centers for Medicare and Medicaid Services (CMS): *Hospital-acquired conditions (present on admission indicator)*, 2018, http://www.cms.gov/HospitalAcqCond/06_Hospital-Acquired_Conditions.asp. Accessed December 2018.

Health care agencies often conduct a failure mode and effect analysis (FMEA) to identify problems with health care processes and products before they occur. When an actual or potential adverse event occurs, the nurse or health care provider involved completes an incident or occurrence report. An incident report is a confidential document that completely describes any patient accident occurring on the premises of a health care agency (see [Chapter 23](#)). Reporting allows an organization to identify trends or patterns throughout the agency and areas to improve. Focusing on the root cause of an event instead of the individual involved promotes a culture of safety that helps in specifically identifying what contributed to an error. The evidence shows that the use of evidence-based practices can have a favorable impact on patient safety. The strongest evidence exists for interventions that are effective in preventing delirium, adverse drug events, infections, and falls ([Zegers et al., 2016](#)).

Chemical Exposure

Both patients and health care workers face serious environmental health risks within health care agencies. An example of a risk to health care workers is exposure to various forms of chemicals. Chemicals found in some medications (e.g., chemotherapy), anesthetic gases, cleaning solutions, and disinfectants are potentially toxic if ingested, absorbed into the skin, or inhaled. A health care provider or family caregiver who becomes exposed to a chemotherapeutic agent, especially one in liquid form, has an increased risk for leukemia, other cancers, and adverse reproductive outcomes and chromosomal damage ([CDC, 2018g](#)). When exposure to a chemical occurs, material safety data sheets (MSDSs) provide detailed information about the chemical, the precautions for safe handling and use, health hazards related to exposure, first aid guidelines, and steps for containment and removal in case of release or spillage. MSDSs are required resources available in any health care agency ([OSHA, n.d.a](#)). Nurses need to know the location of the MSDSs and how to follow safety guidelines within their agencies.

Falls

Falls result in minor-to-severe injuries such as bruises, hip fractures, or head trauma that result in reduced mobility and independence and increase the risk for premature death. Falls often occur in health care settings. As is the case in home and community environments, falls are multifactorial in health care settings. Approximately 30% to 35% of patients who fall sustain injuries ([[The Joint Commission Center for Transforming Healthcare TJCCTH, 2018](#)]). Common factors within the hospital environment that contribute to falls include sleep deprivation, a new environment, a change in medications, or deterioration in physical strength brought on by change in a disease process. A fall contributes to a patient's functional decline and increased health care use. A fall can cause lasting pain and suffering and may limit physical, psychological, and social function, placing burdens on patients, families, and society. Each injury resulting from a fall, on average, adds 6.3 days to a hospital stay and costs about \$14,056 ([TJCCTH, 2018](#)). When a patient death or serious injury is associated with a fall while the patient is being cared for in a health care setting, it is called a *Never Event*. The Centers for Medicare and Medicaid will not pay for additional costs associated with *Never Events*. When a fall occurs within a health care setting, The Joint Commission (TJC) mandates the organization perform a thorough **root cause analysis** after the event in an effort to find approaches to prevent similar events in the future ([AHRQ, 2018c](#)). Health care agencies have initiatives in place to reduce falls, including use of special fall risk assessment tools, evidence-based fall prevention protocols, fall alert room signs, and special identification bands ([Box 27.5](#)).

Box 27.5 Evidence-Based Practice Fall Prevention

PICOT Question: Does a multifactorial fall-intervention program compared with single interventions reduce the incidence of falls among hospitalized adult patients?

Evidence Summary

Research shows that fall prevention is successful with an interprofessional approach; however, using only one intervention is not successful (TJC, 2016). A systematic review revealed that using multiple interventions along with exercise is most successful at preventing falls (Zegers, 2016). Hospitals use multiple evidence-based fall prevention interventions aimed at each patient's fall risk factors to reduce falls and falls with injuries. Interventions include fall risk assessments, purposeful interprofessional hourly rounding, bed exit alarms and sensor technology, environmental and equipment modifications (e.g., bedside commode, low beds), improved medication management (evaluating polypharmacy), assistance with transfer and activities of daily living (e.g., showering and toileting), and post-fall evaluations (Hempel et al., 2013; Potter et al., 2017; Stanford Health Care, 2017; CDC, 2017b). The TJCCTH targeted solutions online tool allows organizations to use a systematic approach to fall prevention. The use of the tool has reduced the rate of patient falls by 35% and the rate of patients injured in a fall by 62% (TJCCTH, 2018). Use of the tool involves selection of multiple interventions.

Application to Nursing Practice

- All clinical and nonclinical staff within a health care agency need to attend a mandatory in-service program describing the purpose and goals of the fall management program (ECRI, 2017).
- Implement a fall prevention bundle that includes multiple interventions (fall risk armband, skidproof socks, gait belt use) (TJCCTH, 2018).
- Purposeful rounding as part of a staff-led quality improvement intervention can decrease fall rates by up to 50% with hospitalized patients (Morgan et al., 2017). Purposeful or hourly rounding is a work process that structures time with patients by using an actual standard or mental checklist of procedures meant to promote optimal outcomes in a clean, comfortable, safe environment (McLeod and Tetzlaff, 2015).

- Interventions shown to be effective in preventing falls in the acute care setting include fall risk cards, short-term administration of vitamin D supplementation, one-on-one patient-centered education focusing on the individual patient's risk factors and preventive strategies, and targeted risk factor reduction intervention that includes screening for fall risk factors (Avanacean et al., 2017).

Patient-Inherent Accidents

Patient-inherent accidents are accidents (other than falls) in which a patient is the primary reason for the accident. Examples include self-inflicted cuts, injuries, and burns; ingestion or injection of foreign substances; self-mutilation or setting fires; and pinching fingers in drawers or doors. A diagnosis of a seizure disorder places a patient at risk for a patient-inherent accident. Place patients with seizure disorders on seizure precautions to reduce risk of injury.

Procedure-Related Accidents

Procedure-related accidents are caused by health care providers and include medication and fluid administration errors, improper application of external devices, and accidents related to improper performance of procedures such as dressing changes or urinary catheter insertion. Always follow the policies and procedures of a health care agency and the standards of nursing practice to prevent these accidents. For example, proper preparation and administration of medications, use of patient and medication bar coding, and “smart” intravenous (IV) pumps reduce medication errors (see [Chapters 31](#) and [42](#)). All staff need to be aware that distractions and interruptions contribute to procedure-related accidents and need to be limited, especially during high-risk procedures such as medication administration. Another common procedure that places patients at risk for injury is transferring to a bed or chair. Correct use of safe patient handling techniques and equipment reduces the risk of injuries when moving and lifting patients (see [Chapter 38](#)).

Equipment-Related Accidents

Equipment-related accidents result from an electrical hazard or malfunction, disrepair, or misuse of equipment. To avoid rapid infusion of IV fluids, all general-use and patient-controlled analgesic pumps need to have free-flow protection devices. To avoid accidents, do not operate medical equipment without adequate instruction. If you discover a faulty piece of equipment, replace it with properly working equipment, place a tag on the faulty one, take it out of service, and promptly report any malfunctions. Assess potential electrical hazards to reduce the risk of electrical fires, electrocution, or injury from faulty equipment. Clinical engineering staff in health care settings regularly make safety checks of equipment. Agencies must report all suspected medical device-related deaths to the US Food and Drug Administration ([FDA, 2018a](#)) and the product manufacturer.

Workplace Safety

Violence is a familiar occurrence in health care settings. The sources of violence include patients, visitors, intruders, and co-workers. The National Institute for Occupational Safety and Health ([NIOSH, 2018](#)) defines **workplace violence** as the act or threat of violence, ranging from verbal abuse to physical assault, directed toward persons at work or on duty. The impact of workplace violence ranges from psychological issues (e.g., posttraumatic stress disorder [PTSD], compassion fatigue) to physical injury or death. When subjected to workplace violence, health care staff experience anger, frustration, fear, stress and irritability.

From 2002 to 2013, incidents of serious workplace violence (incidents requiring victims to take days off to recuperate) were four times more common in health care than in private industry ([OSHA, n.d.b](#)). However, workplace violence occurs on a continuum. Bullying, verbal threats, and name calling are common. In health care settings patients are most commonly the source of violence resulting from hitting, kicking, beating, and shoving ([OSHA, n.d.b](#)). Risk factors for workplace violence caused by patients include working with patients who have a history of violence, overcrowded waiting areas, poor lighting in hallways, working in isolation from co-workers, inadequate security staff, work setting located in high-

crime neighborhood, having a mobile workplace, transporting or lifting patients, and presence of firearms (OSHA, n.d.b). Many incidents of violence are not reported, but violence can be prevented with proper safety policies and environmental adaptations.

Answers to QSEN Activities can be found on the Evolve website.

QSEN Building Competency in Safety

A nurse is caring for a patient who is receiving chemotherapy. The patient becomes confused and pulls out her IV line, and the chemotherapy drug leaks into the bed linens and all over the floor. What risks are posed for this patient? What risks are posed for the nurse? How should the nurse manage the situation?

Critical Thinking

Successful critical thinking requires a synthesis of knowledge, experience, critical thinking attitudes, reflective reasoning, and adherence to professional standards. Clinical judgments that are based on critical thinking require nurses to anticipate necessary information, analyze the data, and make decisions regarding patient care. During an assessment (Fig. 27.2) all critical thinking elements and information about a specific patient should be considered to make appropriate nursing diagnoses.

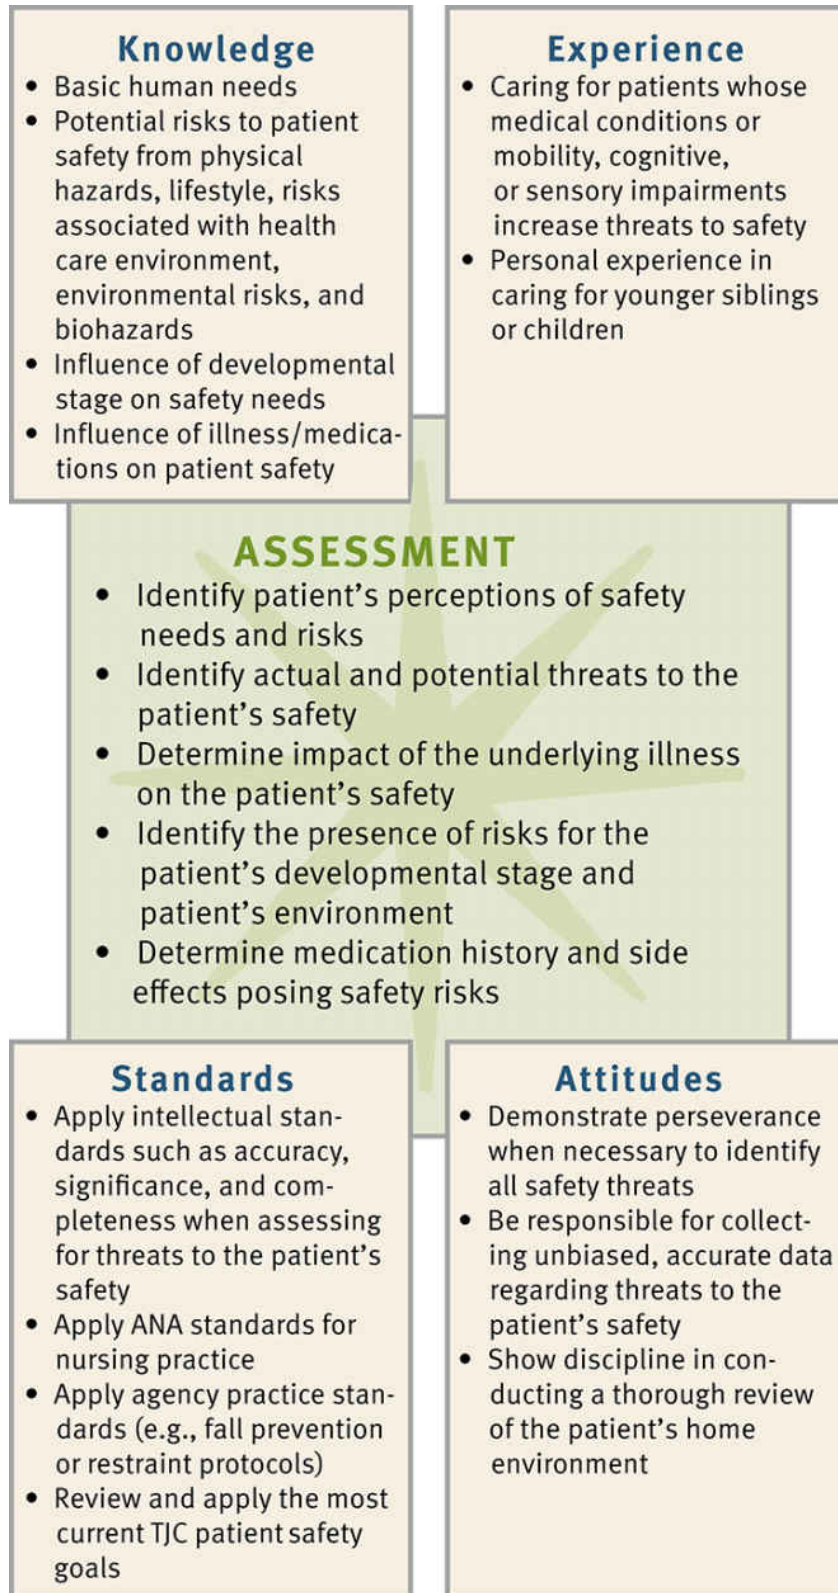

FIG. 27.2 Critical thinking model for safety assessment. ANA, American Nurses Association; TJC, The Joint Commission.

In the case of safety, nurses integrate knowledge from nursing and other scientific disciplines, previous experiences in caring for patients who were at risk for or had an injury, critical thinking attitudes such as responsibility and discipline, and any standards of practice that are applicable. The American Nurses Association (ANA) standards for nursing practice address the nurse's responsibility in maintaining patient safety. (TJC 2018b) also provides standards for safety. Critical thinking allows nurses to anticipate the needs of their patients and make conclusions about available data. For example, while assessing a patient's home environment, you consider typical locations within the home where dangers commonly exist. If a patient has a visual impairment, you apply previous experiences in caring for patients with visual changes to anticipate how to thoroughly assess his or her needs.

REFLECT NOW

Reflect on your last clinical experience. What risks to patient safety did you observe? Describe interventions taken to reduce risks to patient safety.

❖ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

❖ Assessment

During the assessment process thoroughly assess each patient and his or her environment and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe patient care.

Through the Patient's Eyes

Patients generally expect to be safe in health care settings and in their homes. However, sometimes a patient's view of what is safe is different from that of the nurse and the standards associated with safety in the health care environment. For this reason your nursing assessment needs to be patient centered; this includes (1) the patient's own perceptions of his or her risk factors, (2) the patient's concerns about being in a health care setting, (3) the patient's knowledge of how to adapt to safety risks, and (4) information about a patient's previous experience with accidents ([Box 27.6](#)). Consult with family caregivers when appropriate.

Box 27.6 Nursing Assessment Questions

Activity and Exercise

- Do you use any assistive devices, such as a wheelchair, walker, or cane, to help you move or get around? Did someone show you how to use them safely? (Have patient demonstrate use.)
- Describe for me any difficulties you have with bathing, dressing, or toileting.
- Describe for me the type of exercise or physical activity you do regularly. How often do you exercise?
- Explain how you prepare meals at home (e.g., use stove and appliances safely).

- Do you do your own laundry? How do you do this, and where are these appliances located?
- Do you drive a car or motorcycle? When do you normally drive? How far?
- How often do you wear a seat belt when in the car or a helmet when on your bike?

Medication History

- Which medications (prescription, over-the-counter, herbal) do you take?
- Has your doctor or pharmacist reviewed your medicines with you in the last year?
- Describe for me any side effects that you have after taking your medications.

History of Falls

- Have you ever fallen or tripped over anything in your home? Have you had any near misses?
- Tell me what you think caused you to fall. Which activity were you performing before the fall?
- Have you ever suffered an injury from a fall? What was it and how did it happen?
- Did you have any symptoms right before you fell? What were they?

Home Maintenance and Safety

- Who does your simple home maintenance or minor home repairs?
- Who shovels your snow? Mows your lawn?
- Do you feel safe in your home? Describe anything in your environment that makes you feel unsafe.
- If you have an emergency at home, whom can you call for help?
- How do you feel about modifying your home to make it safer? Do you need help finding resources to help you do this?

Patients recognize when errors occur or when they feel at risk. Research involving over 19,000 patients from 11 countries has shown that patient self-report of poor coordination of care is common: 10.9% reported that test results or medical records were not available, 19.6% perceived to have received conflicting information by care providers, and 10.5% reported that tests were ordered although they had been performed before (Schwappach, 2014). Patients and their families are your partner; involve them in any safety assessment.

Nursing History and Examination

A nursing history (see Chapter 30) includes data about a patient's medical history and fall risk factors to determine whether any underlying conditions pose threats to safety. A physical examination focuses on bodily functions that can affect a patient's mobility and ability to interact safely in his or her environment. For example, an assessment with a safety focus should include a patient's cognitive status, gait, lower-body muscle strength and coordination, balance, and visual status. Measure balance and gait by having the patient walk in his or her room; do not rely on patient self-report. Include a review of a patient's perception of health and his or her developmental status as you analyze physical and cognitive assessment information. For example, if a patient is an adolescent, does he or she show risk factors for suicide or drug and alcohol abuse? Also review the patient's medication history and any planned procedures that pose risks. For example, the use of diuretics increases frequency of voiding and results in the patient having to use toilet facilities more often. Frequent toileting is a risk factor for falls, especially when patients get out of bed quickly without assistance.

Health Care Environment

When caring for patients within a health care setting, determine whether any hazards exist in the immediate care environment:

- Does the placement of equipment (e.g., drainage bags, IV pumps) or furniture pose barriers when the patient tries to ambulate?
- Does positioning of the patient's bed allow him or her to reach items on a bedside table or stand easily? Does the patient need help with ambulation?
- Is there a gait belt or an assist device available for when the patient ambulates?

- Are health care workers and family visitors following hand hygiene guidelines?
- Are there multiple tubes or IV lines?
- Is the nurse call system within reach?

Contact the clinical engineering staff if there are questions as to whether equipment is functioning properly and in good condition.

Risk for Falls

Assessing a patient's risk factors for falling is essential to determine specific needs and develop targeted interventions to prevent falls. Many fall risk–assessment instruments are available; use the tool chosen by your health care agency. Most tools include risk categories on age, fall history, elimination habits, high-risk medications, mobility, and cognition. At a minimum the assessment needs to be completed on admission, following a change in a patient's condition, after a fall, and when transferred. If it is determined that a patient is at risk for falling, ongoing assessments are required. When a patient has a previous history of falling, ask about the nature of the fall and what the patient thinks precipitated it. Focus the assessment on that information to determine whether a condition or risk persists. In many cases family members are important resources in assessing a patient's fall risk. Families often can report on the patient's level of confusion and ability to ambulate or safely toilet. Based on the results of a fall risk assessment, you will implement multiple evidence-based interventions for fall prevention. It is very important that you inform the patient and family members about the fall risks that you identify from the assessment. Often younger patients are not aware of how medications and treatments cause dizziness, orthostatic hypotension, or changes in balance. When patients are unaware of their risks, they are less likely to ask for assistance. If family members are informed, they will often call for help (when they are visiting patients) to be sure that patients have appropriate assistance.

Risk for Medical Errors

Be alert to factors within your own work environment that create conditions in which medical errors are more likely to occur. Distractions during medication preparation or nursing procedures in the form of phone calls, alarms, or staff needing assistance are common. Studies show that overwork and fatigue, particularly when working consecutive 12 hour-

shifts, cause a significant decrease in alertness and concentration, leading to errors (Geiger-Brown et al., 2012). It is important for you to be aware of risk factors in the workplace and to include checks and balances when working under stress. For example, to reduce the chance for a medical error, it is essential that a patient's identification be checked by using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy before beginning any procedure or administering a medication (see [Chapter 31](#)).

Disasters

Hospitals must be prepared to respond to and care for a sudden influx of patients at the time of a community disaster. Although the occurrence of bioterrorism attacks has been limited to the anthrax deaths following September 11, 2001, the threat is very real. Be prepared to make accurate and timely assessments in any type of setting. Initially, a bioterrorist attack is likely to resemble a natural outbreak. Acutely ill patients representing the earliest cases after a covert attack seek care in emergency departments. Patients less ill at the onset of an illness possibly seek care in primary care settings. Rapid detection of a bioterrorism attack occurs through syndrome surveillance and reporting of suspected cases. The early signs of a bioterrorism-related illness often include nonspecific symptoms (e.g., nausea, vomiting, diarrhea, skin rash, fever, confusion) that may persist for several days before the onset of more severe disease. Patients with prodromal illnesses seek outpatient care and are assigned nonspecific diagnoses such as "viral syndrome." Data on patients fitting various syndromic criteria are then transferred to a health department and tested.

Patient's Home Environment

When caring for a patient in the home, a home hazard assessment is necessary. A thorough hazard assessment includes all the rooms in a home and the outdoor entrance areas. Each room assessment covers topics such as adequacy of lighting (inside and outdoors), condition of flooring and walking surfaces, presence of safety devices (e.g., alarms, side rails on steps, safety bars in bath tubs), and placement of furniture or other items that can create barriers. Know where medications and cleaning supplies are located. Walking through the home with the patient and discussing how he or she normally conducts daily activities and whether the environment poses problems is important. Additional assessment includes the presence of locks on doors and windows. Getting a sense of a patient's

routines helps you recognize less obvious hazards. It is also important to learn the patient's willingness to make changes in his or her environment. Decisions on changing the environment require the patient's full participation.

Assessment for risk of food-borne illness includes assessing a patient's knowledge of food preparation and storage practices. For example, does a patient know to check expiration dates of prepared food and milk products? Does he or she keep foods in the refrigerator that are fresh and not spoiled? Does the patient clean fresh fruits and vegetables correctly before eating them? Assess for clinical signs of infection by conducting an examination of GI and central nervous system function, observing for a fever, and analyzing the results of cultures of feces and emesis. Further assessment includes inspecting the food and water sources and assessing the patient's and family members' handwashing practices.

Assessment of the environmental comfort of a patient's home includes a review of when the patient normally has heating and cooling systems serviced. Does the patient have a functional furnace or space heater? Does the home have air conditioning or fans? Inform patients who use space heaters of the risk for fires. Are smoke detectors and carbon monoxide detectors up-to-date and functional, and are fire extinguishers present and placed strategically throughout the home and checked routinely?

When patients live in older homes, encourage them to have inspections for lead in paint, dust, or soil. Because lead also comes from the solder or plumbing fixtures in a home, patients need to have water from each faucet tested. Local health offices will help homeowners locate a trained lead inspector who takes samples from various locations and has them analyzed at a laboratory for lead content.

It is important that your nursing assessment and interventions help individuals focus on avoiding losses and reducing their risk for injury associated with disasters. The Federal Emergency Management Agency (<http://www.fema.gov/>) and the American Red Cross (<http://www.redcross.org/>) provide nationwide education to help community members prepare for disasters of all types.

REFLECT NOW

Go to the CDC website (https://www.cdc.gov/HomeandRecreationalSafety/pubs/English/booklet_Eng_desktopa.pdf) and conduct a home risk assessment on your own home or the home of someone you know who is 65 years of age or older. Once completed, think about how to minimize safety risks.

• Nursing Diagnosis

Gather data from your nursing assessment and analyze clusters of assessment findings, including risk factors, to identify relevant nursing diagnoses (Box 27.7). In addition to the accurate clustering of assessment data, an important part of formulating nursing diagnoses is identifying the relevant causative or related factor (when a diagnosis is *negative* or problem focused) or risk factors (when a diagnosis is a risk diagnosis). You choose interventions that treat or modify the related factor *or risk* for the diagnosis to be resolved. For example, the nursing diagnosis of *Risk for Fall* might be associated with altered mobility or a visual alteration as risk factors. Altered mobility will lead you to select such nursing interventions as range-of-motion (ROM) exercises; more frequent supervised ambulation; or teaching the proper use of safety devices such as side rails, canes, or crutches. Also consult with a patient's health care provider about a physical therapy referral. If visual impairment is the risk factor, select different interventions, such as keeping the living area well lit; orienting the patient to the surroundings; or keeping eye glasses clean, handy, and well protected. When you do not identify the correct risk factors for the diagnosis *Risk for Fall*, the use of inappropriate interventions or omission of proper interventions may increase a patient's risk for falling. Examples of additional nursing diagnoses for patients with safety risk include the following:

Box 27.7 Nursing Diagnostic Process Risk for Fall

Assessment Activities	Assessment Findings
Observe patient's posture, range of motion, gait, strength, balance, and body alignment.	Decrease in left lower-extremity strength; demonstrates unsteady gait, impaired balance when standing
Assess patient's visual acuity—ability to read, identify distant objects.	Reports difficulty seeing at night Vision blurred, unable to identify near objects without glasses
Complete a home hazard appraisal.	Poorly lighted home Excessive amount of furniture in living room Rugs not secure throughout home No grab bars in bath

- *Risk for Injury*
- *Impaired Cognition: Confusion*
- *Lack of Knowledge*
- *Risk for Poisoning*
- *Risk for Trauma*

• Planning

Patients with actual or potential risks to safety require a nursing care plan with interventions that prevent and minimize threats to their safety. Design your interventions to help a patient feel safe to move about and interact freely within the environment. The plan of care addresses all aspects of patient needs and uses resources of the health care team and the community when appropriate. Critically synthesize information from multiple sources (Fig. 27.3). Critical thinking ensures that a patient's plan of care integrates all that you learned about the patient and the key critical thinking elements. For example, you reflect on knowledge regarding the services that other health professions (e.g., occupational therapy, case management) provide to help patients return to their home environments safely. Also reflect on previous experiences when patients benefited from safety interventions. Such experience helps you adapt approaches with each new patient. Applying critical thinking attitudes such as creativity helps you to collaborate with a patient in planning interventions that are relevant and most useful, particularly when making changes in the home environment.

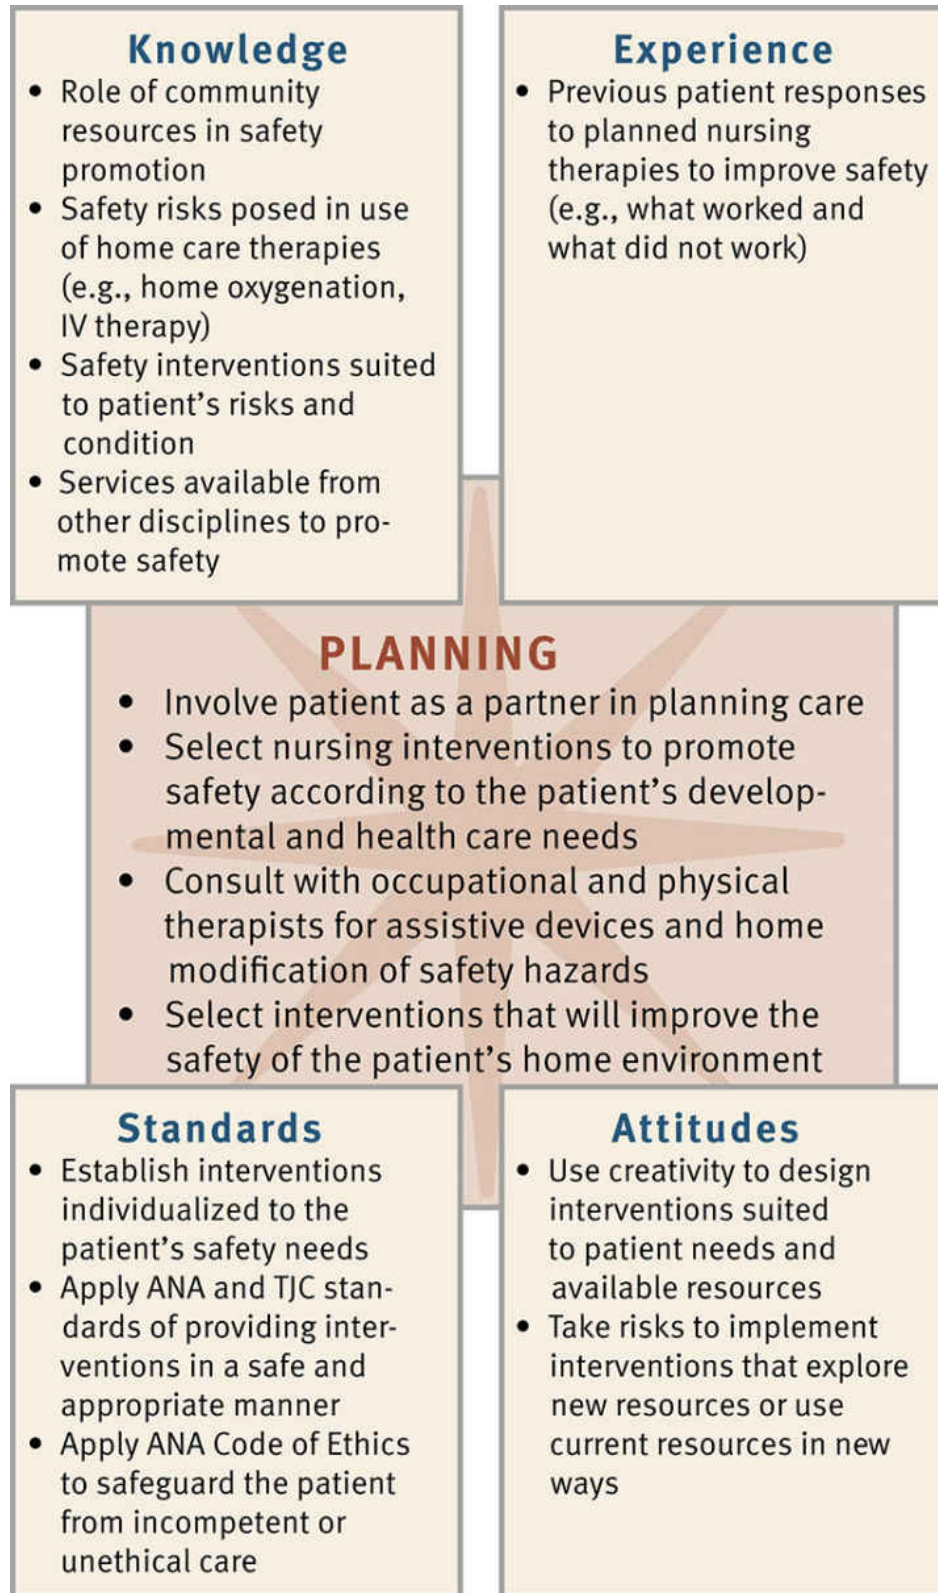

FIG. 27.3 Critical thinking model for safety planning.
 ANA, American Nurses Association; IV, intravenous; TJC, The Joint Commission.

Goals and Outcomes

You collaborate with a patient, family, and other members of the health care team when setting goals and expected outcomes during the planning process (see the [Nursing Care Plan](#)). The patient who actively participates in reducing threats to safety becomes more alert to potential hazards and is more likely to adhere to the plan. Make sure that goals and outcomes for each nursing diagnosis are measurable and realistic, with consideration of the resources available to the patient. For example, in the case of the nursing diagnosis of *Impaired Walking related to left-sided paralysis*, the goal is the patient “will remain free of injury throughout hospitalization.” Examples of expected outcomes include:

- Patient uses tripod cane correctly within 24 hours.
- Patient describes approach to rise up from bed correctly with assistance by end of the teaching session today.

Setting Priorities

Prioritize a patient’s nursing diagnoses and interventions to provide safe and efficient care. For example, the concept map ([Fig. 27.4](#)) has several nursing diagnoses that apply to promoting a patient’s safety. The patient’s mobility problem is an obvious priority because of its influence on risk for fall. Plan individualized interventions based on the severity of risk factors and the patient’s developmental stage, level of health, lifestyle, and cultural needs ([Box 27.8](#)). Planning involves an understanding of the patient’s need to maintain independence within physical and cognitive capabilities. Build a consensus with the patient and family (when appropriate) as to the type of interventions to deliver ([QSEN, 2018](#)). Collaborate to establish ways of maintaining the patient’s active involvement within the home and health care environment. Education of the patient and family is also an important intervention to plan for reducing safety risks over the long term.

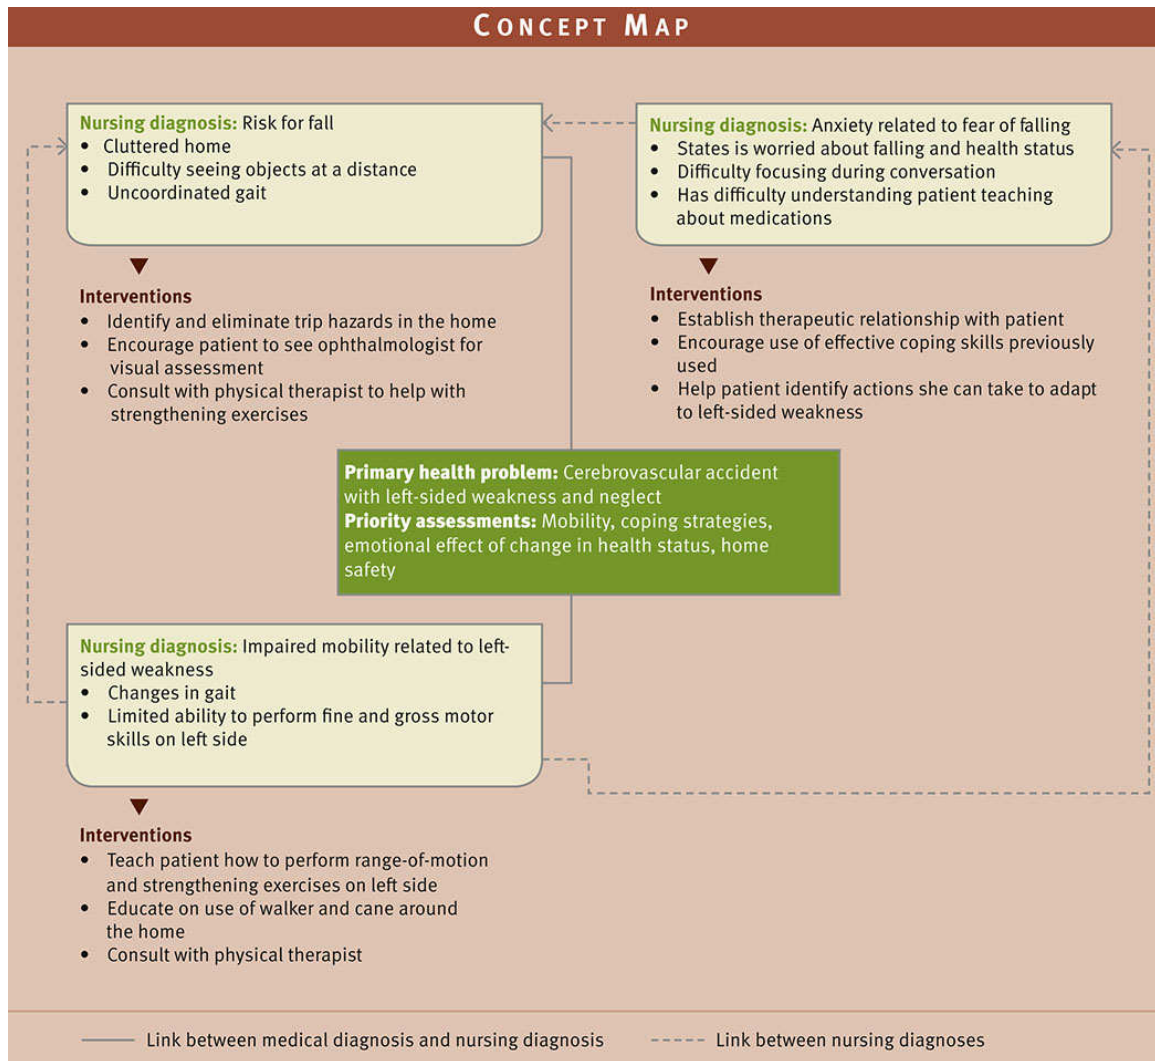

FIG. 27.4 Concept map for Ms. Cohen.
 ADLs, Activities of daily living; CVA, cerebrovascular accident.

Box 27.8 Cultural Aspects of CareA Patient-Centered Care Approach

Hospitalization places patients at risk for injury in an unfamiliar and confusing environment. The experience is usually at least minimally frightening. Normal life cues such as a bed without side rails and the direction one usually takes to the bathroom are absent. Thought processes and coping mechanisms are affected by illness and its accompanying emotions. Thus patients are more vulnerable to injury. This vulnerability is often intensified for patients of diverse backgrounds. It is a nurse's

responsibility to diligently protect all patients, regardless of their socioeconomic status and cultural background. Most untoward events are related to failures of communication. Patients who have low health literacy create challenges for nurses during assessments and efforts at implementing safe care measures. Screen all patients for health literacy. Ensure that you use an approach that recognizes a patient's cultural background so that you ask appropriate questions to reveal health behaviors and risks. Be aware of cultural beliefs about physical restraints when caring for patients who need them. A physical restraint is a way of purposely limiting or obstructing the freedom of a person's bodily movement and can be seen as a significant threat by anyone who comes from a culture of violence. Patient safety is enhanced when you consider the whole person and value seeing each care situation through "the patient's eyes" and not just through your own perspective. Some specific patient-centered safety guidelines about the use of restraints follow.

Implications for Patient-Centered Care

- When restraints are needed, assess their meaning to the patient and the family. Some cultures may find restraints to be disrespectful. Similarly, some survivors of war or persecution or those suffering from posttraumatic stress disorder may view restraints as imprisonment or punishment.
- Collaborate with family members in accommodating a patient's cultural perspectives about restraints. Removing the restraints when family members are present shows respect and caring for the patient.
- Define the protocol of the nursing unit on the use of restraints. Identify potential areas for negotiation with the patient's/family's preferences for using restraints, including having family members stay with the patient.

REFLECT NOW

Consider a patient you cared for recently. How did you prioritize meeting the patient's safety needs?

Teamwork and Collaboration

Collaboration with the patient, family, and other health care professions, such as social work and occupational and physical therapy, becomes an important part of a patient's plan of care. For example, a patient in a hospital needs to go to a rehabilitation center to gain strength and endurance before being discharged home. An occupational therapist is helpful in the home setting for making recommendations for installation of stairway railings, slip-resistant surfacing in the bathroom, and provision of lighting (Stark et al., 2017). Communication with all participants in the plan of care is essential. You

Nursing Care Plan

Risk for Fall

Assessment

Mr. Key, a home health nurse, is visiting Ms. Cohen, an 85-year-old woman living at home. The patient is recovering from a stroke affecting her left side. Ms. Cohen lives alone but receives regular help from her daughter and son, who both live within 10 miles of the patient.

Assessment Activities	Assessment Findings ^a
Ask how the stroke has affected her mobility.	She responds, " I bump into things, and I'm afraid I'm going to fall. "
Conduct a home hazard assessment.	Kitchen table is cluttered with unopened mail, plastic bags, and papers. Cabinets in kitchen are cluttered and full of breakable items that could fall out. Throw rugs are on floors ; bathroom lighting is poor (40-watt bulbs); bathtub lacks safety strips or grab bars; home is cluttered with furniture and small objects.
Observe gait and posture.	She has kyphosis and a hesitant, uncoordinated gait ; frequently holds walls for support.
Ask patient her age.	Patient is 85 years old.
Assess visual acuity with corrective lenses.	She has trouble reading and seeing familiar objects at a distance while wearing current glasses. The patient confirms that her vision has been getting worse over the last year; things are not "clear and crisp," almost like there is a layer of "cotton candy" blurring her vision.

^a **Assessment Findings** are shown in bold type.

Nursing Diagnosis:

Risk for fall

Planning

Goals	Expected Outcomes (NOC) ^b
Knowledge: Personal Safety	
Patient and family will understand patient's fall risks and develop a plan to reduce risks within 1 month.	Patient and daughter will identify personal and environmental risks for falls in 1 week. Patient and daughter will select prevention methods to avoid falls in home at conclusion of teaching session next week.
Fall Prevention Behavior	
Patient will be free of injury at 1 month.	Patient will safely ambulate throughout the home within 1 week.

^b Outcome classification labels from Moorhead S et al: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	Rationale
Fall Prevention	
Review findings from home hazard assessment with patient and her daughter, and collaborate with an occupational therapist on proposed changes.	Home hazard assessment highlights extrinsic factors that lead to falls and that can be changed. Home modifications, when delivered by occupational therapists, can reduce falls among high-risk community-dwelling older adults (Stark et al., 2017)
Establish a list of patient's priorities to modify the home.	Implementing home modifications based on home assessment decreases falls. Successful home modifications, such as bathroom safety devices, are tailored to the participant's needs and expressed wishes (Stark et al., 2017).
Discuss with patient and daughter the normal changes of aging, effects of recent stroke, associated risks for injury, and how to reduce risks.	Education regarding hazards reduces fear of falling (Olsen and Bergland, 2014).
Encourage daughter to schedule vision testing for new prescription within 2 to 4 weeks.	Studies have found correlations between the aging of visual functions and falls in elderly people (Saftari and Kwon, 2018).
Refer to physical therapist to assess need for strengthening and endurance training and use of assistive devices for kyphosis, left-sided weakness, and gait.	A multicomponent exercise intervention composed of strength, endurance, and balance training has been shown to be the best strategy to improve rate of falls, gait ability, balance, and strength performance in physically frail older adults (Cadore et al., 2013).

^c Intervention classification labels from Butcher HK, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Ask patient and daughter to identify fall risks and the plan for changes in home.	Patient identified the piles of magazines and mail cluttered in family room and throw rugs on floors as safety hazards. Daughter identified bathroom hazards, including bathroom lighting and lack of grab bars. Have plan to install grab bars in bathroom.	Patient and family have gained knowledge of modifiable hazards in the home. Need to reinforce value of installing safety strips in bath tub.
Reassess if patient has experienced a fall in the last month.	Patient has not experienced a fall	Fall prevention achieved.

communicate risk factors and the plan of care with the patient, family, and other health care providers, including other disciplines and nurses on other shifts. Permanent dry-erase boards in the patient's room with patient information such as activity and level of assistance communicate information to all health care providers. A standard approach to communication such as ISBAR or SBAR ([Introduction], Situation, Background, Assessment, Recommendation, Request, or Readback) helps you obtain and organize information about patients when problems develop (see [Chapter 24](#)).

Building Competency in Patient-Centered Care.

A 78-year-old patient comes to the outpatient medicine clinic for a follow-up visit after being hospitalized for pneumonia. The patient's 45-year-old daughter accompanies him. The patient asks to have the daughter in the examination room. The patient answers questions readily, is oriented, and shows appropriate nonverbal expressions during conversation. What assessment factors does the clinic nurse include in determining whether the patient is at risk for fall in the home?

Patients need to be able to identify, select, and know how to use resources within their communities (e.g., neighborhood block homes, local police departments, and neighbors willing to check on their well-being) that enhance safety. Make sure that the patient and family understand the need for these resources and how to contact these resources, and determine whether they are willing to make changes that promote their safety.

Implementation

[QSEN \(2018\)](#) outlines recommended skills to ensure nurse competency in patient safety. Among these skills are those involving safe nursing practice during direct care:

- Demonstrate effective use of technology and standardized practices that support safety and quality.
- Demonstrate effective use of strategies to reduce risk of harm to self or others.
- Use appropriate strategies (e.g., forcing functions, checklists) to reduce reliance on memory.
- Communicate observations or concerns related to hazards and errors to patients, families, and the health care team.

Direct your nursing interventions toward maintaining a patient's safety in all types of settings. You implement health promotion and illness prevention measures in the community setting, whereas prevention is a priority in the acute care setting.

Health Promotion

Health promotion requires a person to be in a safe environment and practice a lifestyle that minimizes risk of injury. There are both passive and active strategies aimed at health promotion. Passive strategies include public health measures (e.g., public education about neighborhood safety, closing schools during inclement weather, issuing travel restrictions and screening travelers) and governmental legislative interventions (e.g., sanitation and clean water laws) (see [Chapter 3](#)). Active strategies are those in which an individual is actively involved through changes in lifestyle (e.g., engaging in better nutritional health or exercise programs, wearing seat belts) and participation in wellness programs.

Nurses promote individual and community health by supporting legislation, acting as positive role models, and working in community-based settings. Because environmental and community values have the greatest influence on health promotion, community and home health nurses can assess and recommend safety measures in the home, school, neighborhood, and workplace.

Developmental Interventions

Infant, Toddler, and Preschooler

Growing, curious children need adults to protect them from injury. Educate parents or guardians about reducing risks of disease and injuries to children, and teach ways to promote safety in the home ([Table 27.1](#)). One area that is crucial is the encouragement of parents to follow immunization guidelines for their children. The ([American Academy of Pediatrics 2018b](#)) recommends these steps for vaccine-hesitant parents:

TABLE 27.1

Interventions to Promote Safety for Children and Adolescents

Intervention	Rationale
Infants and Toddlers	
Keep soft objects, toys, crib bumpers, and loose bedding out of a baby's sleep area to reduce the risk of sudden infant death syndrome (SIDS). Make sure nothing covers the baby's head.	Possibility exists for these items to cause risk of suffocation, strangulation, or entrapment.
Use a firm sleep surface, such as a mattress in a safety-approved crib covered by a fitted sheet.	Reduces suffocation.
Prepare a baby's sleep area next to where parents sleep. A baby should not sleep in an adult bed, on a couch, or on a chair alone or with a parent or anyone else.	
Infants should be immunized and have regular health checkups.	Evidence suggests that immunization reduces the risk of SIDS and other preventable diseases. Access the American Academy of Pediatrics current immunization schedule at https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/immunizations/Pages/Immunization-Schedule.aspx .
Do not attach pacifiers to string or ribbon and place around a child's neck.	String or ribbon around the neck increases risk for choking.
Follow all instructions for preparing and storing formula.	Proper formula preparation and storage prevent contamination. Following product directions ensures proper concentration of formula. Undiluted formula causes fluid and electrolyte disturbances; much-diluted formula does not provide sufficient nutrients.
Use large, soft toys without small parts such as buttons.	Small parts become dislodged, and choking and aspiration can occur.
Do not leave the mesh sides of playpens lowered; spaces between crib slats need to be less than 23/8 inches (6 cm) apart.	Possibility exists for a child's head to become wedged in the lowered mesh side or between crib slats, and asphyxiation may occur.
Never leave crib sides down or babies unattended on changing tables or in infant seats, swings, strollers, or high chairs.	Infants and toddlers roll or move and fall from changing tables or out of accessories such as infant seats or swings.
Discontinue using accessories such as infant seats and swings when the child becomes too active or physically too big and/or according to the manufacturer's directions.	When physically active or too big, the child can fall out of or tip over these accessories and suffer an injury.
Never leave a child alone in the bathroom, tub, or near any water source (e.g., pool).	Supervision reduces risk for accidental drowning.
Baby-proof the home; remove small or sharp objects and toxic or poisonous substances, including plants; install safety locks on floor-level cabinets.	Babies explore their world with their hands and mouth. Choking and poisoning can occur.
Remove plastic bags from the cleaners or grocery store from the home.	Removal reduces risk for suffocation from plastic bags.
Cover electrical outlets.	Covers reduce opportunity for crawling babies to insert objects into outlets and experience an electrical shock.
Install keyless locks (e.g., deadbolts) on doors above a child's reach, even when they are standing on a chair.	Deadbolts prevent a toddler from leaving the house and wandering off. Keyless locks allow for rapid exit in case of fire.
Follow the American Academy of Pediatrics guidelines for rear-facing car safety seats.	Protects infants and toddlers from injury during motor vehicle accidents.
Caregivers need to learn cardiopulmonary resuscitation (CPR) and the Heimlich maneuver.	Caregivers need to be prepared to intervene in acute emergencies such as choking.
Preschoolers	
Teach children to swim at an early age, but always provide supervision near water.	Learning to swim is a useful skill that can someday save a child's life. However, all children need constant supervision.
Teach children how to cross streets and walk in parking lots. Instruct them to never run out after a ball or toy.	Pedestrian accidents involving young children are common.
Teach children not to talk to, go with, or accept any item from a stranger.	Avoiding strangers reduces the risk of injury and stranger abduction.
Teach children basic physical safety rules such as proper use of safety scissors, never running with an object in their mouth or hand, and never attempting to use the stove or oven unassisted.	Risk of injury is lower if children know basic safety procedures.
Teach children not to eat items found in the street or grass.	Avoiding these items reduces risk for possible poisoning.
Remove doors from unused refrigerators and freezers. Instruct children not to play or hide in a car trunk or unused appliances.	If a child cannot freely exit from appliances and car trunks, asphyxiation can occur.
School-Age Children	
Teach children proper bicycle and skate board safety, including use of helmet and rules of the road.	Reduces injuries from falling off a bike or skateboard or being hit by a car.

Intervention	Rationale
Teach children proper techniques for specific sports and the need to wear proper safety gear (e.g., helmets, eyewear, mouth guards).	Using proper techniques, correct equipment, and protective gear prevents injuries.
Teach children not to connect electrical equipment while	If an electrical mishap were to occur, no one would be available to help

Teach children not to operate electrical equipment while unsupervised.	If an electrical mishap were to occur, no one would be available to help.
Do not allow children access to firearms or other weapons. Keep all firearms in locked cabinets.	Children are often fascinated by firearms and often try to play with them.
Adolescents	
Encourage enrollment in driver education classes.	Many injuries in this age-group are related to motor vehicle accidents.
Provide information about the effects of smoking and using alcohol and drugs.	Adolescents are highly prone to risk-taking behaviors and are subject to peer pressures.
Refer adolescents to community- and school-sponsored activities.	The adolescent needs to socialize with peers, yet needs some supervision.
Encourage mentoring relationships between adults and adolescents.	Adolescents are in need of role models after whom they can pattern their behavior.
Teach them safe use of the Internet.	Avoids overuse and possible exposure to inappropriate websites.

Modified from Hockenberry M, Wilson D: *Wong's nursing care of infants and children*, ed 11, St Louis, 2019, Elsevier.

- Listen to parents' concerns and acknowledge them in a nonconfrontational manner. This will increase their willingness to listen to a pediatrician's views.
- Promote partnerships with parents in decision making. Make sure the parent understands the information about vaccines. Clarify and reaffirm parents' correct beliefs about immunization and modify misconceptions.
- Discuss the benefits of vaccines and the possibility of adverse events. Be open about what is known about immunizations and what is not known.
- Stress the number of lives saved by immunization, as a positive approach.

Nurses working in prenatal and postpartum settings routinely incorporate safety into the care plans of childbearing families. Community health nurses assess the home and show parents how to promote safety.

School-Age Child

School-age children increasingly explore their environment (see [Chapter 12](#)). They have friends outside their immediate neighborhood, and they become more active in school, church, and community activities. The school-age child needs specific teaching regarding safety in school and at play. See [Table 27.1](#) for nursing interventions to help guide parents in providing for the safety of school-age children.

Adolescent

Risks to the safety of adolescents involve many factors outside the home because much of their time is spent away from home and with their peer group (see [Chapter 12](#)). Adults who serve as positive role models for adolescents provide examples of how to behave, set expectations, and provide education to minimize risks to the adolescent's safety. Because of peer pressure this age group is at risk for alcohol and drug use. In addition, this age-group has a high incidence of suicide. Be aware of the risks posed at this time and be prepared to teach adolescents and their parents the measures needed to prevent accidents and injury. You can also help parents be aware of ways to minimize risk of adolescent suicide, including the promotion of good problem-solving abilities (e.g., conflict with peers); support for strong connections to their families, friends, and people in the community; restricted access to highly lethal means of suicide; and demonstration of cultural and religious beliefs that discourage suicide and that support self-preservation ([Kaslow, 2018](#)).

Adult

Risks to young and middle-age adults frequently result from lifestyle factors such as childrearing, high stress levels, inadequate nutrition, use of firearms, excessive alcohol intake, and substance abuse (see [Chapter 13](#)). In this fast-paced society there also appears to be more expression of anger, which can quickly precipitate accidents related to "road rage." Help adults understand their safety risks and guide them in making lifestyle modifications by referring them to resources such as classes to help quit smoking or for stress management, including employee-assistance programs. Also encourage adults to exercise regularly, maintain a healthy diet, practice relaxation techniques, and get adequate sleep (see [Chapter 43](#)).

Older Adult

Nursing interventions for older adults reduce patients' risk for falls and other accidents and compensate for the physiological changes of aging ([Box 27.9](#)). The [American Geriatric Society \(2015\)](#) developed an algorithm for fall prevention ([Fig. 27.5](#)). Use this resource to reduce risks in the home. Provide information about neighborhood resources to help an older adult maintain an independent lifestyle. Older adults frequently relocate to new neighborhoods and need to become acquainted with new resources, such as modes of transportation, church schedules, and food resources (e.g., Meals on Wheels).

Box 27.9 Focus on Older Adults Physiological

Changes of Aging and Their Effect on Patient Safety

As people age, physiological changes occur. They experience visual and hearing alterations, slowed reaction time, and decreased range of motion, flexibility, and strength. In addition, reflexes are slowed, and the ability to respond to multiple stimuli is reduced. Memory can become impaired, and nocturia and incontinence are more frequent in older adults. The family plays a significant role in the care of older adults. There are nearly 44 million family caregivers in the United States, nearly 20% of the US adult population (National Alliance for Caregiving, 2019). Educate family members on how to best support the older adult.

The high prevalence of chronic conditions in older adults results in the use of a high number of prescription and over-the-counter medications. Coupled with age-related changes in pharmacokinetics, there is a greater risk of serious adverse effects. Medications typically prescribed for older adults include anticholinergics, diuretics, anxiolytic and hypnotic agents, antidepressants, antihypertensives, vasodilators, analgesics, and laxatives, all of which pose risks or interact to increase the risk for falls.

Implications for Practice

- Encourage family caregivers to allow older adult to remain as independent as possible.
- Offer family caregivers resources from the CDC on the STEADI fall prevention program (CDC, 2017c). Available at <https://www.cdc.gov/steady/patient.html>.
- Encourage annual vision and hearing examinations and frequent cleaning of glasses and hearing aids as a means of preventing falls and burns.
- Teach patients safety tips for avoiding automobile accidents. Sometimes driving needs to be restricted to daylight hours or temporarily or permanently suspended.
- Encourage supervised strengthening and balance exercise classes for older adults.
- Install safety features in the home such as grab bars and smoke alarms.

- Be sure that adults know how to use assistive devices (e.g., walkers and canes) correctly. Consult with a physical therapy staff member.
- Consult with an occupational therapist to help patients make adaptations needed to feed, bathe, eat, and toilet independently.
- Institute a regular toileting schedule for the patient. A recommended frequency is every 2 or 3 hours. Give diuretics in the morning. Provide assistance, along with adequate lighting, to patients who need to go to the bathroom at night.
- Encourage patients to use medication organizers, which can be purchased at any drugstore at a very reasonable cost. Fill these dispensers once a week with the proper medications to be taken at a specific time during the day.
- Review the patient's drug profile to ensure that these drugs are used cautiously, and assess the patient regularly for any adverse effects that increase fall risk.

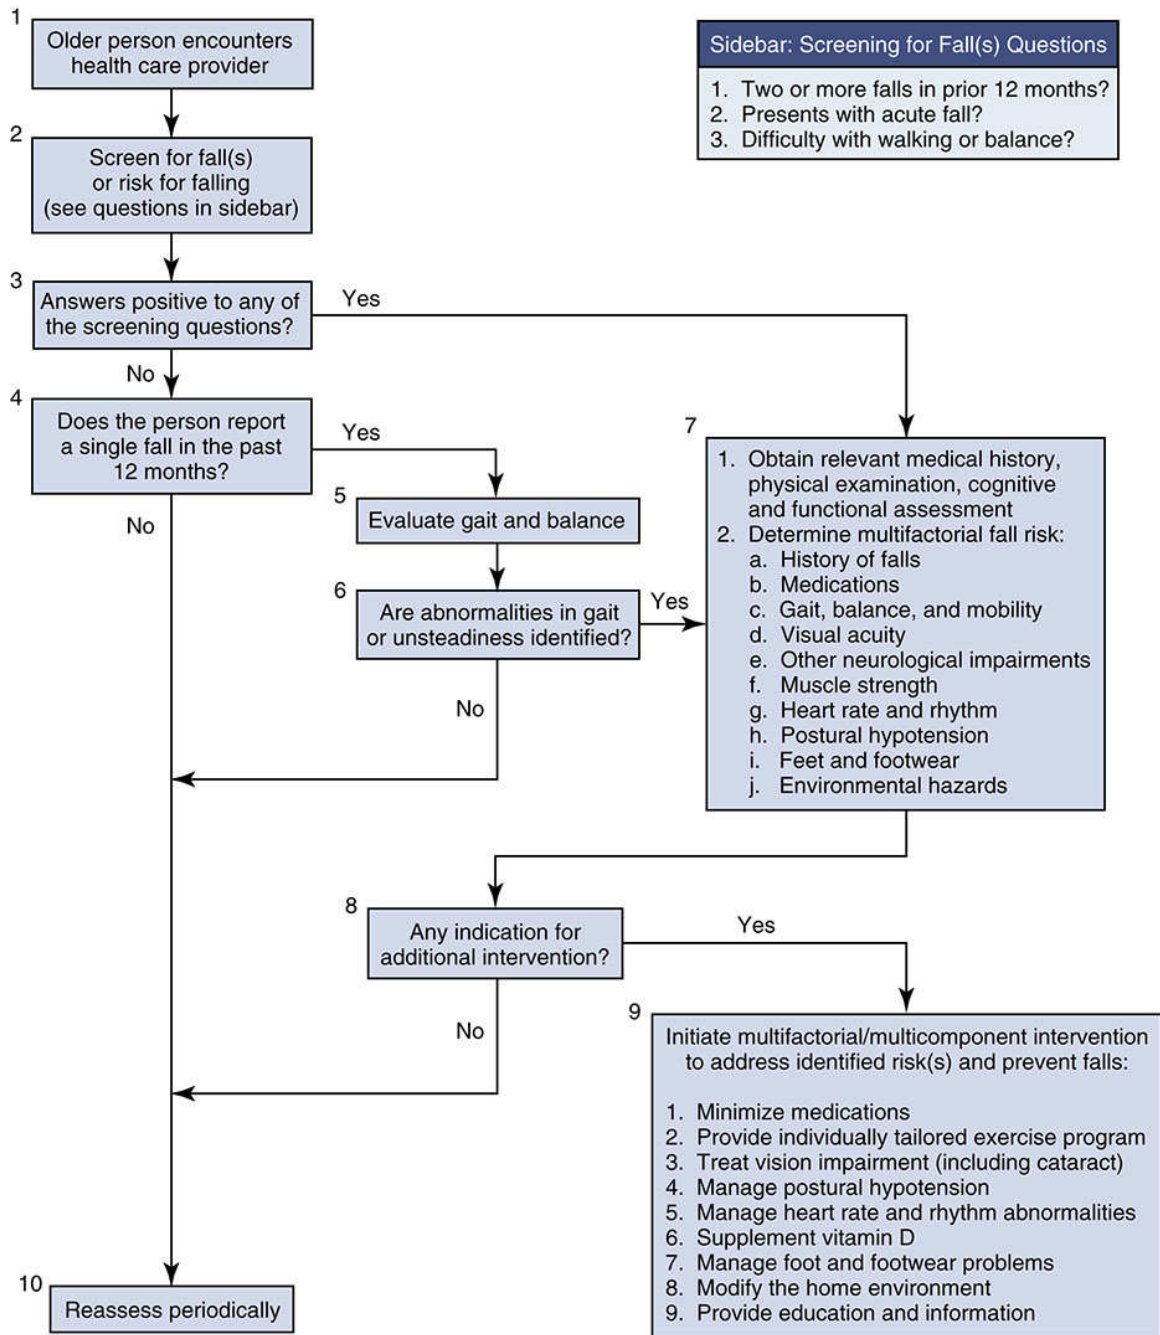

FIG. 27.5 American Geriatrics Society Clinical Practice Guideline Fall Prevention Algorithm 2010.

From American Geriatrics Society/British Geriatrics Society. (2010). *AGS/BGS Clinical Practice Guideline: Prevention of falls in older persons algorithm*. New York: American Geriatrics Society.)

Educate older adults about safe driving tips (e.g., driving shorter distances, using side and rearview mirrors carefully, and looking behind them toward their “blind spot” before changing lanes). If hearing is a problem, encourage the patient to keep a window rolled down while

driving or to reduce the volume of the radio. Counseling is often necessary to help older patients decide when to stop driving. At that time help locate resources in the community that provide transportation.

Burns and scalds are also more apt to occur with older people because they sometimes forget and leave hot water running or become confused when turning the dials on a stove or other heating appliance. Nursing measures for preventing burns minimize the risk from impaired vision. Hot-water faucets and dials are color coded to make it easier for an adult to know which is hot and which is cold. Reducing the temperature of the hot water heater is also very beneficial.

Many older adults love to walk. Reduce pedestrian accidents for older adults and all other age-groups by persuading people to wear reflectors on garments when walking at night; to stand on the sidewalk and not in the street when waiting to cross a street; to always cross at corners and not in the middle of the block (particularly if the street is a major one); to cross with the traffic light and not against it; and to look left, right, and left again before entering the street or crosswalk. Also encourage people to assess their walking route for hazards such as unequal or damaged walkways, unrestrained dogs, and excessive toys; all of these increase the risk for falls.

Environmental Interventions

Nursing interventions directed at eliminating environmental threats include those associated with a person's basic needs and general preventive measures.

Basic Needs

When administering oxygen, take appropriate precautions to prevent fire. In home settings, post "No Smoking" and "Oxygen in Use" signs. Do not use oxygen around electrical equipment or flammable products. Store oxygen tanks upright in carts or stands to prevent tipping or falling over. [Chapter 41](#) outlines guidelines for proper oxygen administration. In the home setting a home medical provider and home health nurse educate patients who require oxygen in the home about safe oxygen use.

Fire safety in the home requires education of patients and families about the importance of purchasing modern space heaters that include safety features, placing smoke detectors and carbon monoxide detectors strategically throughout the home, and keeping multipurpose fire extinguishers in close proximity to the kitchen and workshop areas. Recommend that patients have annual inspections of heating systems,

chimneys, and fuel-burning appliances in the home. Carbon monoxide detectors are not expensive but are not a replacement for proper use and maintenance of fuel-burning appliances. Space heaters are a fire risk. Instruct patients on proper use in the home ([Electrical Safety Foundation International, 2015](#)):

- Be sure a space heater has a label showing that it is listed by a recognized testing laboratory.
- Before using any space heater, read the manufacturer's instructions carefully.
- Inspect heaters for cracked or broken plugs or loose connections before each use. If frayed, worn, or damaged, do not use the heater.
- Never leave a space heater unattended. Turn it off when you're leaving a room or going to sleep, and don't let pets or children play too close to a space heater.
- Space heaters are only meant to provide supplemental heat and should never be used to warm bedding, cook food, dry clothing or thaw pipes.
- Install smoke alarms on every floor of your home and outside all sleeping areas.
- Proper placement of space heaters is critical. Heaters must be kept at least 3 feet away from anything that can burn, including papers, clothing, and rugs.
- Plug space heaters directly into a wall outlet. Do not use an extension cord or power strip, which could overheat and result in a fire.

Food safety requires a patient and family to understand the principles of food preparation and storage. Patients should follow four basic safety tips ([CDC, 2018c](#)).

- First, wash hands and food preparation and cooking surfaces often. This includes cooking utensils and cutting boards thoroughly.
- Second, do not cross contaminate food while preparing or while stored in a refrigerator. Keep raw meat, poultry, seafood, and their juices away from other foods. Use separate cutting boards. Rinse fruits and vegetables thoroughly.
- Third, always cook food to the proper temperature. Refrigerate leftovers promptly.

- Fourth, be sure a patient living at home has a functioning refrigerator with a freezer compartment to keep perishable foods fresh. Keep a refrigerator below 40° F, and know when to throw leftovers or opened containers of food away.

Fall Safety in the Home

Modifications in the home environment easily reduce the risk of falls. Collaborate with patient and family caregiver to make changes based on their home fall risk assessment and the patient's risk factors. For example, remove all obstacles (e.g., furniture, piles of magazines or boxes) from halls and other heavily traveled areas. Be sure that end tables are secure and have stable, straight legs. Place nonessential items in drawers to eliminate clutter. Patients who have problems stumbling or tripping should never have small area rugs in the home. If small area rugs are used, secure them with a nonslip pad or skid-resistant adhesive strips. Make sure that carpeting on the stairs is secured with carpet tacks. If patients have a history of falling and live alone, recommend that they wear an electronic safety alert device. When activated by the wearer, this device alerts a monitoring site to call emergency services for assistance.

Observe patients using assistive devices (e.g., canes, walkers) in the home to ensure the devices are held and used correctly. Inform patients about how to keep these devices in safe working order.

General Preventive Measures

Neighborhood safety is important. Often patients are not aware of basic safety tips. Proper lighting and locks on windows and doors help reduce the risk of injury from crime. The local police department and community organizations often have safety classes available for residents to learn how to take precautions to minimize the chance of becoming involved in a crime. For example, some useful tips include always parking the car near a bright light or busy public area, carrying a whistle attached to the car keys, keeping car doors locked while driving, and always paying attention while driving to notice if anyone starts to follow the car.

Accidental home fires typically result from smoking in bed, placing cigarettes in trash cans, grease fires, improper use of candles or space heaters, or electrical fires resulting from faulty wiring or appliances. Teach patients and families how to reduce the risk of electrical injury in the home (Box 27.10) and how to use a home fire extinguisher (Box 27.11). To reduce the risk of fires in the home, counsel patients to quit smoking or to smoke outside the home. Have them inspect the condition of cooking equipment

and appliances, particularly irons and stoves. Have patients with visual deficits install dials with large numbers or symbols on temperature controls. Make sure that smoke detectors are in strategic positions throughout the home so that the alarm will alert the occupants in a home in case of fire. All patients, even young children, need to know the phrase “stop, drop, and roll,” which describes what to do when a person’s clothing or skin is burning.

Box 27.10 Patient Teaching **Prevention of Electrical Hazards**

Objective

- Patient will recognize and eliminate electrical hazards in the home.

Teaching Strategies

- Discuss importance of checking for grounding of electrical appliances and other equipment.
- Provide examples of common hazards: frayed cords, damaged equipment, and overloaded outlets.
- Discuss guidelines to prevent electrical shocks:
 - Use extension cords only when necessary and use electrical tape to secure the cord to the floor, preferably against baseboards.
 - Do not run wires under carpeting.
 - Grasp the plug, not the cord, when unplugging items.
 - Keep electrical items away from water.
 - Do not operate unfamiliar equipment.
 - Disconnect items before cleaning.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- I want to be sure I explained fire hazards clearly. What electrical hazards exist in your home right now, and what steps can you take to eliminate them?
- What can you do to prevent getting an electrical shock?

Box 27.11 Patient Teaching **Correct Use of a Fire Extinguisher in the Home**

Objective

- Patient will use a fire extinguisher in the home correctly.

Teaching Strategies

- Discuss how to choose a correct location for an extinguisher: Place on each level of the home, near an exit, in clear view, away from stoves and heating appliances, and above the reach of small children.
- Keep a fire extinguisher in the kitchen, near the furnace, and in the garage.
- Make sure that patients read instructions after purchasing the extinguisher and that they know how often to review the instructions.
- Describe considerations to make before using a fire extinguisher. Attempt to fight the fire only when all occupants have left the home, the fire department has been called, the fire is confined to a small area, there is an exit route readily available, the extinguisher is the right type for the fire, and the patient knows how to use it.
- Instruct the patient to memorize the mnemonic *PASS*:
 - *P*ull the pin to unlock handle,
 - *A*im low at the base of the fire,
 - *S*queeze the handles,
 - *S*weep the unit from side to side (see Fig. 27.9).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- When would it be appropriate to use a fire extinguisher at home?
- Explain for me what the mnemonic *PASS* means.

Help parents reduce the risk of accidental poisoning by teaching them to keep hazardous substances such as medications, cleaning fluids, and batteries out of the reach of children. Drug and other substance poisonings in adolescents and adults are commonly related to suicide attempts or drug experimentation. Teach parents that calling a poison control center for information before attempting home remedies will save their child's life. Guidelines for accepted interventions for accidental poisonings are available to teach a parent or guardian (Box 27.12). Older adults are also at risk for poisoning because diminished eyesight may cause an accidental ingestion of a toxic substance. In addition, the impaired memory of some older adults results in an accidental overdose of prescription medications. In health care settings it is important for you to know how to respond when exposure to a poisonous substance occurs. In addition, adhere to guidelines for intervening in accidental poisoning.

Box 27.12 Intervening in Accidental Poisoning *CPR, Cardiopulmonary resuscitation.*

1. If the person is conscious and alert, go online at <https://www.poison.org/> or call the national toll-free poison control center number (1-800-222-1222) before trying any intervention. **Post this number in a visible area in the home.** Poison control centers have information needed to treat poisoned patients or offer referral to treat. *The administration of ipecac syrup or induction of vomiting is no longer recommended for routine home treatment of poisoning.*
2. Assess for signs or symptoms of ingestion of harmful substance, such as nausea, vomiting, foaming at the mouth, drooling, difficulty breathing, sweating, and lethargy.
3. Stop exposure to the poison. Have the person empty his or her mouth of pills, plant parts, or other material.
4. If poisoning is caused by skin or eye contact, irrigate the skin or eye with copious amounts of cool tap water for 15 to 20 minutes. In the case of an inhalation exposure, safely remove the victim from the potentially dangerous environment.

5. Identify the type and amount of substance ingested to help determine the correct type and amount of antidote needed.
6. If the victim has collapsed or stopped breathing, call 911. Initiate CPR if indicated until emergency personnel arrive. Ambulance personnel can provide emergency measures if needed. In addition, a parent or guardian is sometimes too upset to drive safely.
7. Position the victim with head turned to the side to reduce risk for aspiration.
8. Never induce vomiting if the victim has ingested the following poisonous substances: lye, household cleaners, hair care products, grease or petroleum products, furniture polish, paint thinner, or kerosene.

Modified from Hockenberry MJ, Wilson D: *Wong's essentials of pediatric nursing*, ed 11, St Louis, 2019, Elsevier; American Academy of Pediatrics, Committee on Injury, Violence and Poison Prevention: Gastrointestinal decontamination of the poisoned patient, *Pediatr Emerg Care* 24(3):176, 2008.

Be sure that a patient's home medications are kept in their original containers and labeled in large print. Recommend the use of medication organizers that are filled once a week by the patient and/or family caregiver. Have patients keep poisonous substances out of the bathroom and discard old or unused medications appropriately.

To prevent the transmission of pathogens, nurses teach aseptic practices. Medical asepsis, which includes hand hygiene and environmental cleanliness, reduces the transfer of organisms (see [Chapter 28](#)). Patients and family members need to learn how to perform thorough hand hygiene (handwashing or use of a hand rub) and when to use it (i.e., before and after caring for a family member, before food preparation, before preparing a medication for a family member, after using the bathroom, and after contacting any bodily fluids). Patients also need to know how to dispose of infectious material such as wound dressings and used needles in the home setting. Heavy plastic containers such as hard, colored plastic liquid detergent bottles are excellent for needle disposal. [The US Food and Drug Administration \(2018b\)](#) recommends a two-step process:

- Place all needles and other sharps (e.g., lancets) in a sharps container immediately after use.

- Dispose of used sharps disposal containers according to community guidelines, including drop box or supervised collection sites, household hazardous waste collection sites, mail-back programs, or residential special waste pickup services.

Acute and Restorative Care

Within hospital and long-term care settings nurses take various measures to maintain patient safety, including fall prevention strategies, prevention of injuries from use of restraints and side rails, and precautions to prevent fires and exposure to poisoning and electrical hazards. Special precautions are also necessary to prevent injury in patients susceptible to having seizures. Radiation injuries are also a specific safety concern in hospitals.

Nurses are responsible for making a patient's bedside safe. Explain and demonstrate to patients how to use the call light or nurse call system device, and always place the device close to the patient. Respond quickly to call lights and bed/chair alarms. Keep the environment free from clutter around the bedside.

Fall Prevention

Patient falls continue to be a top adverse event in hospitals, often resulting in injury and even death ([Joint Commission International, 2017b](#)). Falls are also a serious concern in skilled nursing and long-term care settings. Fall reduction programs are a routine part of any hospital and long-term care setting. Implementing such a program begins with the nurse and patient partnering in recognizing the patient's fall risks. A fall reduction program includes a fall risk assessment of every patient, conducted routinely (see hospital policy) until a patient's discharge. Many hospitals have implemented hourly/purposeful rounding to reduce falls (see [Box 27.5](#)). In addition, most organizations apply yellow color-coded wristbands to patients' wrists to communicate to all health care providers that a patient is a fall risk. The American Hospital Association recommended that hospitals standardize wristband colors: red for patient allergies, yellow for fall risk, and purple for do-not-resuscitate preferences ([AHA, 2008](#)). Most hospitals have adopted this practice. However, wristbands can be difficult to discern at a distance, in low light, or when obscured, and can go unnoticed during a crisis ([Wood and Bagian, 2011](#)); therefore, additional measures are needed.

Patient-centered care is an important component of any fall reduction plan, with nurses making patients and families their partners in taking

preventive action. A fall reduction plan should include individualized nursing interventions (see [Skill 27.1](#)). For example, if a patient has postural hypotension, the nurse will place the bed in the low position and have the patient dangle his or her feet on the side of bed for 3 to 5 minutes before ambulation. A patient with a history of urinary urgency or incontinence should be provided a bedside commode instead of being expected to walk to the bathroom unassisted. Gait belts and additional safety equipment should be used as needed when moving, transferring, and ambulating patients (see [Chapter 38](#)).

When patients use assistive aids such as canes, crutches, or walkers, it is important to routinely check the condition of rubber tips and the integrity of the aid. Additionally, it is important to ensure that patients use their devices correctly. Remove excess furniture and equipment and instruct patients to wear rubber-soled shoes or slippers for walking or transferring. Safety bars near toilets ([Fig. 27.6](#)), locks on beds and wheelchairs ([Fig. 27.7](#)), and a nurse call system are additional safety features found in health care settings.

FIG. 27.6 Safety bars around toilets and showers.

FIG. 27.7 Wheelchair with safety locks and anti-tip bars.

Another area of fall risk includes wheelchair-related falls involving older adults or patients with disabilities. Patients are at risk for falls during transfer tasks and reaching while seated in a wheelchair. An example of a wheelchair characteristic that increases risk for falls is having smaller and harder front wheels that cause a chair to tip when striking uneven terrain (such as an uneven floor surface moving into an elevator). Tripping over the front foot or leg rest and leaning over the back of a wheelchair to engage or disengage the wheel lock are common causes of injury.

Restraints

Patients who are confused or agitated or who repeatedly try to remove medical devices (e.g., IV lines, urinary catheters, or wound dressings) may temporarily require physical restraints to keep them safe. In the nursing home environment, research shows restraints being used when there are increases in the degree of care dependency as well as mobility limitations (Hofmann et al., 2015). A physical **restraint** is any manual method, physical or mechanical device, material, or equipment that immobilizes or reduces the ability of a patient to move arms, legs, body, or head freely. A restraint does not include devices such as orthopedically prescribed devices, protective helmets, or methods that involve physically holding a patient to conduct an examination or test, protecting a patient from falling out of bed or permitting a patient to participate in activities without risk of physical harm (TJC, 2018b). Chemical restraints are medications such as anxiolytics and sedatives used to manage a patient's behavior and are not a standard treatment for a patient's condition. Restraints are not a solution to a patient problem, rather a temporary means to provide safety. You must use all alternatives before placing patients in restraints. Federal and state laws prohibit Medicare- and Medicaid-certified nursing homes from using restraints unless they are medically needed. Only in emergencies can restraints be applied without a resident's or family member's informed consent.

Patients who are confused or disoriented, who repeatedly wander or fall, or who try to remove medical devices may require the temporary use of restraints to keep them safe. *However, the use of alternatives to restraints is preferred, and if a restraint is required, use the least restrictive type (e.g., soft mitt versus a limb restraint).* Individualize your choice of a restraint alternative based on each patient's situation (Box 27.13). An interprofessional approach that includes individualized assessments and development of structured treatment plans reduces restraint use. The optimal goal for all patients is a restraint-free environment.

Box 27.13 Alternatives to Restraints

- Orient patients and family members to the environment; explain all procedures.
- Provide companionship and supervision; use trained sitters; adjust staffing and involve family.

- Offer diversional activities: music, puzzles, activity aprons, folding towels. Use ideas of the patient and/or family.
- Assign confused or disoriented patients to rooms near nurses' stations, and observe frequently.
- Use de-escalation, time-out, and other verbal intervention techniques when managing aggressive behaviors.
- Provide visual and auditory stimuli (e.g., family pictures, a clock, music).
- Remove cues that promote leaving the room (e.g., close doors to block view of stairs; do not allow inpatient to wear street clothes).
- Promote relaxation techniques and normal sleep patterns.
- Institute exercise and ambulation schedules as allowed by patient's condition.
- Attend frequently to patient's needs for toileting, food and liquid, and pain management.
- Camouflage intravenous lines with clothing, stockinette, or Kling gauze dressing.
- Evaluate all medication effects and ensure timely and effective pain management.
- Discontinue bothersome treatments (e.g., nasogastric tubes or Foley catheters) as soon as possible.
- Use protective devices such as hip pads, helmet, skidproof slippers, and nonskid strips near bed.

The use of restraints is associated with serious complications resulting from immobilization, such as pressure injuries, pneumonia, constipation, and incontinence. Loss of self-esteem, humiliation, and agitation are also serious problems. In some cases, death has resulted because of restricted breathing and circulation. A study from Australia revealed that neck compression and entrapment by a restraint was the mechanism of harm in all reported cases, resulting in patient asphyxia ([Bellenger et al., 2017](#)). Because of these risks, legislation and regulatory standards have reduced the use of restraints. The Joint Commission and Centers for Medicare and Medicaid enforce standards for safe use of restraint devices. Many health care agencies have eliminated the use of the once-common jacket (vest) restraint ([Ealey and Cameron, 2016](#)). One standard involves staff training. All direct care staff must receive training in a health care setting's restraint and seclusion policies and procedures, and all staff who may be involved

in the use of restraints must be trained in safe use of mechanical restraint devices (CMS, 2007).

For patients who continue to try to ambulate without assistance, use low beds and electronic bed/chair alarms (see Skill 27.1). An alarm device warns nursing staff that a patient is attempting to leave a bed or chair unassisted. There are a variety of devices, including one with a knee band that sounds an alarm when the patient reaches a near-vertical position. An infrared type of alarm is affixed to a headboard or bedframe, allowing a patient to move freely with a bed. If a patient tries to leave the bed, the infrared beam detects motion and sends out an alarm. Alarm devices help avoid physical restraints and, when responded to promptly, can prevent patient falls and subsequent injuries.

When restraints are required to protect a patient (or nursing staff from being assaulted), involve the patient and family in the decision to use them. Help them adapt to this change by explaining the purpose of the restraint, expected care while the patient is in restraints, and that the restraint is temporary and protective. For legal purposes know agency-specific policy and procedures for appropriate use and monitoring of restraints. The use of a restraint must be clinically justified and part of a patient's prescribed medical treatment and plan of care. A health care provider's order based on a face-to-face assessment of a patient is required (TJC, 2018b). The order must be current (within 24 hours), stating the type and location of the restraint, and specify the duration and circumstances (e.g., preventing removal of medical device) under which it will be used. For restraints applied for violent or self-destructive behavior, a health care provider must assess the patient within 60 minutes. The orders need to be renewed within a specific time frame according to agency policy. In hospitals each original restraint order and renewal is limited to 4 hours for adults (18 years of age and older), 2 hours for children 9 through 17 years of age, and 1 hour for children younger than 9 years of age (CMS, 2016; TJC, 2018b). Orders may be renewed to the time limits for a maximum of 24 consecutive hours. Restraints are not to be ordered prn.

Nurses are responsible for making ongoing assessments of patients who are restrained. After a restraint is applied, monitor a patient closely (i.e., every 15 minutes for a violent patient and every 2 hours for a nonviolent patient). Monitoring should include vital signs, skin integrity underneath the restraint, nutrition, hydration, circulation to an extremity, range of motion, hygiene, elimination needs, cognitive functioning, psychological status, and need for restraint. Remove restraints periodically per agency

policy. Assess patients who are violent continuously via audio or video monitors.

Skill 27.2 includes guidelines for the proper use and application of restraints. Their use must meet one of the following objectives:

- Reduce the risk of patient injury from falls.
- Prevent interruption of therapy such as traction, IV infusions, nasogastric (NG) tube feeding, or Foley catheterization.
- Prevent patients who are confused or combative from removing life-support equipment.
- Reduce the risk of injury to others by the patient.

Collaborate with other members of the health care team to design fall prevention approaches and a restraint-free environment for patients. The goal is to discontinue the use of restraints as soon as possible.

Side Rails

When used correctly, side rails help to increase a patient's mobility and/or stability when repositioning or moving in bed or moving from bed to chair. Although side rails are the most commonly used physical restraint, they increase the risk of falls when patients attempt to get out of bed or crawl over a rail. Side rails also can lead to patients becoming caught, trapped, entangled, or strangled, especially in the frail, elderly, or confused (FDA, 2017). Therefore an assessment of a patient's mobility and responsiveness to instructions helps determine whether using a side rail is safe. The same bedrail may have the effect of restraining one individual but not another, depending on the patient's condition.

A patient needs to have a route to exit a bed safely and to maneuver freely within the bed; in this case side rails are not considered a restraint. For example, raising only the two side rails at the top of a bed so that the lower part of the bed is open gives a patient room to exit the bed safely. Side rails used to prevent a patient such as one who is sedated from falling out of bed are not considered a restraint. Always know agency policy about the use of side rails. Be sure a bed is in the lowest position possible when side rails are raised. Check the condition of rails; bars between the bedrails need to be closely spaced to prevent entrapment. A potential exists for trapping a person's head and body in gaps and openings between the bedframe and mattress.

The use of side rails alone for a patient who is disoriented usually causes more confusion and further injury. Frequently a patient who is confused or determined to get out of bed because of pain or toileting needs tries to climb over a side rail or out at the foot of the bed. Either attempt often results in a fall. To reduce a patient's confusion, focus your interventions first on the cause, such as a response to a new medication, dehydration, or pain. Frequently nurses mistake a patient's attempt to explore his or her environment or to self-toilet as confusion. Additional safety measures include the use of a low bed with a nonskid mat placed alongside the bed on the floor. A low bed reduces the distance between the bed and floor, facilitating a roll rather than a fall from the bed.

Fires

Although smoking is not allowed in hospital and long-term care settings, smoking-related fires continue to pose a significant risk because of unauthorized smoking in beds or bathrooms. Institutional fires also may result from an electrical or anesthetic-related fire. The best intervention is to prevent fires. Nursing measures include complying with the smoking policies of an agency and keeping combustible material away from heat sources. [Box 27.14](#) highlights fire intervention guidelines in health care agencies. Health care agencies are required to have practice fire drills annually.

Box 27.14 Fire Intervention Guidelines

- Always keep the phone number for reporting fires visible on the telephone.
- Know the fire drill and evacuation plan of the agency.
- Know the locations of all fire alarms, exits, extinguishers, and oxygen shut-offs in your work area.
- Use the mnemonic *RACE* to set priorities in case of fire:
 - R*—Rescue and remove all patients in immediate danger.
 - A*—Activate the alarm. Always do this before attempting to extinguish even a minor fire.
 - C*—Confine the fire by closing doors and windows and turning off oxygen and electrical equipment.
 - E*—Extinguish the fire with an appropriate extinguisher.

If a fire occurs in a health care agency, protect patients from immediate injury, report the exact location of the fire, contain it, and extinguish it if possible. [Fig. 27.8](#) demonstrates the process of using an extinguisher. Some agencies have fire doors that are held open by magnets and close automatically when a fire alarm sounds. It is important to keep equipment from blocking these doors. All personnel evacuate patients when appropriate. Patients who are close to a fire, regardless of its size, are at risk of injury and need to be moved to another area. If a patient is on life support, maintain his or her respiratory status manually with a bag-valve-mask device (e.g., Ambu-bag) (see [Chapter 41](#)) until he or she is moved away from the fire. Direct all ambulatory patients to walk by themselves to a safe area. In some cases, they can help move patients in wheelchairs. Move patients who cannot get out of bed from the scene of a fire by a stretcher, their bed, or a wheelchair. Try to avoid carrying patients. If you overextend your physical limits for lifting, injuring yourself results in further injury to the patient. If fire department personnel are on the scene, they help evacuate the patients.

FIG. 27.8 Correct use of a fire extinguisher. **A**, Pull pin. **B**, Aim at base of fire. **C**, Squeeze handles and Sweep from side to side to coat area evenly.

Electrical Hazards

Much of the equipment used in health care settings is electrical and must be well maintained. The clinical engineering departments of hospitals inspect biomedical equipment such as hospital beds, infusion pumps, or ventilators regularly. You know that a piece of equipment is safe to use when you see a safety inspection sticker with an expiration date. Decrease the risk for electrical injury and fire by using properly grounded and functional electrical equipment. The ground prong of an electrical outlet carries any stray electrical current back to the ground. Remove equipment that is not in proper working order or that sparks when plugged in for service, and notify the appropriate hospital staff.

Seizures

Patients who have experienced some form of neurological injury or metabolic disturbance are at risk for a seizure. A **seizure** is hyperexcitation and disorderly discharge of neurons in the brain, leading to a sudden, violent, involuntary series of muscle contractions that is episodic, causing loss of consciousness, falling, tonic (rigidity of muscles), and clonic (jerking of muscles). At the time of a seizure patients are at risk for musculoskeletal or head injury as a result of a fall or striking a body part against a hard object. Patients with a history of seizures should be placed on seizure precautions so that if a seizure occurs, the risk of injury can be minimized.

Know the signs and symptoms of seizures. A generalized tonic-clonic, or grand mal, seizure lasts approximately 2 minutes (no longer than 5) and is characterized by a cry and loss of consciousness with falling, tonic, clonic, and incontinence. Before a convulsive episode a few patients report an aura, which serves as a warning or sense that a seizure is about to occur. An **aura** is often a bright light or a smell or taste. During a seizure the patient often experiences shallow breathing, cyanosis, and loss of bladder and bowel control. A postictal phase follows the seizure, during which the patient has amnesia or confusion and falls into a deep sleep. A person in the community needs immediate medical attention if he or she has repeated seizures, if a seizure lasts 5 minutes or longer, if one seizure occurs right after another without the person regaining consciousness between seizures, if seizures occur closer together than usual for that person, if breathing is difficult or the person appears to be choking, if the seizure occurs in water, or if an injury is suspected ([Epilepsy Foundation, 2018](#)). Instruct family members in the steps to take when a patient

experiences a seizure. Assess a patient's home for environmental hazards considering a seizure condition.

Prolonged or repeated seizures indicate **status epilepticus**, a medical emergency that requires intensive monitoring and treatment. It is important that you observe the patient carefully before, during, and after the seizure so that you can document the episode accurately. **Seizure precautions** encompass nursing interventions to protect a patient from traumatic injury, to position for adequate ventilation and drainage of oral secretions, and to provide privacy and support following a seizure (Box 27.15).

Box 27.15 Tips for Protecting Patients During a Seizure

1. When a seizure begins, note the time, stay with the patient, and call for help. Track duration of seizure. Notify health care provider immediately.
2. Position patient safely. If standing or sitting, ease the patient safely to the floor and protect head by cradling in your lap or placing a pad under head.
3. Do not lift patient from floor to bed while seizure is in progress. Clear surrounding area of furniture and anything else that is hard or sharp.
4. If patient is in bed, remove pillows and raise side rails.
5. If possible, turn patient onto one side, head tilted slightly forward.
6. Do not restrain patient; hold limbs loosely if they are flailing. Loosen clothing. Remove eyeglasses.
7. Never force apart a patient's clenched teeth. Do not place any objects into patient's mouth such as fingers, medicine, tongue depressor, or airway when teeth are clenched. **Insert a bite-block or oral airway in advance only if you recognize the possibility of a tonic-clonic seizure.**
8. Stay with patient, observing sequence and timing of seizure activity.
9. As patient regains consciousness, reorient and reassure. Assist patient to position of comfort in bed with side rails up (one rail down for easy exit) and bed in lowest position.
10. Conduct a head-to-toe evaluation, including an inspection of oral cavity for breaks in mucous membranes from bites or broken teeth;

look for bruising of skin or injury to bones and joints.

Disasters

As a nurse be prepared to respond and care for a sudden influx of patients during a disaster. [The Joint Commission \(2018b\)](#) requires hospitals to have an emergency-management plan that addresses the identification of possible emergency situations and their probable impact, maintenance of an adequate amount of supplies, and a formal response plan that includes actions to be taken by staff and steps to restore essential services and resume normal operations following the emergency. Infection control practices are critical in the event of a biological attack. You must manage all patients with suspected or confirmed bioterrorism-related illnesses with standard precautions (see [Chapter 28](#)). Additional precautions including airborne or contact isolation are needed for diseases such as smallpox and pneumonic plague. Most infections associated with biological agents are not transmissible from patient to patient. However, limit the transport and movement of patients only to movement that is essential for treatment. An important aspect of care for patients who have a bioterrorism-related illness is postexposure management.

Preventing Workplace Violence

Being able to work in a safe environment is central to job satisfaction. As a nurse, be aware of your risks of being exposed to violence in the setting where you work. Nurses do not always know what acts constitute violence. A study involving nurses in emergency departments found that nurses often underreport violence, and as a direct result resources are not recognized or provided ([Stene et al., 2015](#)). It is important to recognize the patients who are most likely to enact violence. [Jackson and colleagues \(2014\)](#) reported from an observational study, conducted in an acute care setting, six key behaviors that predict patient violence: (1) increased volume of speech, (2) irritability, (3) prolonged or intense glaring, (4) mumbling, (5) abusive language toward caregivers (e.g., name calling/swearing), and (6) pacing around waiting area or bed. In a study that reviewed hospital incident reports involving patient violence, health care staff reported these causal factors for violence ([Arnetz et al., 2015](#)):

- Patient behavior—cognitive impairment and demanding to leave.
- Patient care issues—use of needles, pain/discomfort, and physical transfers.

- Situational events—restraints (holding or use of physical/chemical restraint), transitions in care, intervening (attempts to stop a patient from acting), and redirecting (helping a patient back into bed/back to hospital room).

Assessment tools are available for nurses to predict patients who are likely to act violently (see agency procedure). If you face a violent situation, use the following tips for reducing violence (CPI, n.d.):

1. Be nonjudgmental and empathic of the patient's feelings.
 - Whatever the patient's problem is, it can be highly important to him or her.
2. Respect personal space.
 - Stand 1.5 to 3 feet away from a patient who is escalating. This helps reduce a patient's anxiety and can help you prevent acting-out behavior.
 - If you must enter personal space to provide care, first explain what you are doing and why.
3. Use nonthreatening nonverbal communication.
 - As a patient loses control, he or she does not listen to what you have to say. Instead the patient reacts to your nonverbal communication (see [Chapter 24](#)).
 - Keep your voice tone, facial expressions, and movements neutral.
4. Do not overreact.
 - Stay calm, rational, and professional. Use positive thoughts, such as "I can manage this."
5. Focus on feelings.
 - Some people cannot identify how they really feel in a situation. Watch and listen carefully for the patient's real message.
6. Redirect or refocus any challenging questions, such as "Why does it always take so long for the doctor to see me?" or "Who's going to make me go to that test?"
 - Restate your request or directive; do not ignore the patient.
 - Bring the discussion back to how you can work together.
7. Set limits.
 - If patients become belligerent, defensive, or disruptive, give them *clear, simple, enforceable limits*.

- Speak clearly, and offer a positive choice first.
8. Choose wisely what you insist on.
 - Be thoughtful in deciding *which rules are negotiable and which are not*. For example, if a patient is unwilling to walk at a given time, can you let the patient choose a better time?
 - When patients have options and flexibility, you may avoid an altercation.
 9. Allow silence for reflection.
 - Silence gives a person a chance to think about what is happening and how to proceed.
 10. Allow time for the patient to make a decision.
 - Give patients a few moments *to think through what you have said*. A person's stress increases when they feel rushed.

If you find that you work in a setting where violence is common, be sure to take care of yourself. Dealing with patients who are potentially violent is stressful and sometimes dangerous. Find positive ways to care for yourself away from work using stress-management approaches (see [Chapter 37](#)).

REFLECT NOW

Consider the following situation. You are caring for a 10-year-old child who has recently been diagnosed with acute lymphocytic leukemia. The child has started receiving treatment and is experiencing many side effects. The child's father is extremely angry about his child's diagnosis and perceives that family and friends are not providing appropriate support. You walk into the patient's room to administer a medication and the father begins to yell at you because he believes you are not providing appropriate care to his son. How would you respond to the father at this time? Role play your response with a peer.

• Evaluation

Through the Patient's Eyes

Patient-centered care involves a thorough evaluation of a patient's perspective related to safety and whether his or her expectations have been met. Ask the patient questions, such as "Are you satisfied with the changes you have chosen to make for your home? Do you feel safer because of the changes? Are you still afraid of falling? In what way could we make you feel safer?" Involve the family in your evaluation, especially if they live with the patient and provide assistance in the home.

Patient Outcomes

Evaluation involves monitoring the actual care delivered by the health care team based on the expected outcomes (Fig. 27.9). For each nursing diagnosis measure whether the outcomes of care have been met. If your patient meets the goals, the diagnosis is resolved, and your nursing interventions were effective and appropriate. If not, determine whether new safety risks to the patient have developed or whether previous risks remain. For example, if the patient has a recurrent fall, reassess the conditions surrounding that fall and determine whether contributing

factors can be removed or managed. The patient and family need to participate to find permanent ways to reduce risks to safety. When patient outcomes are not met, ask the following questions:

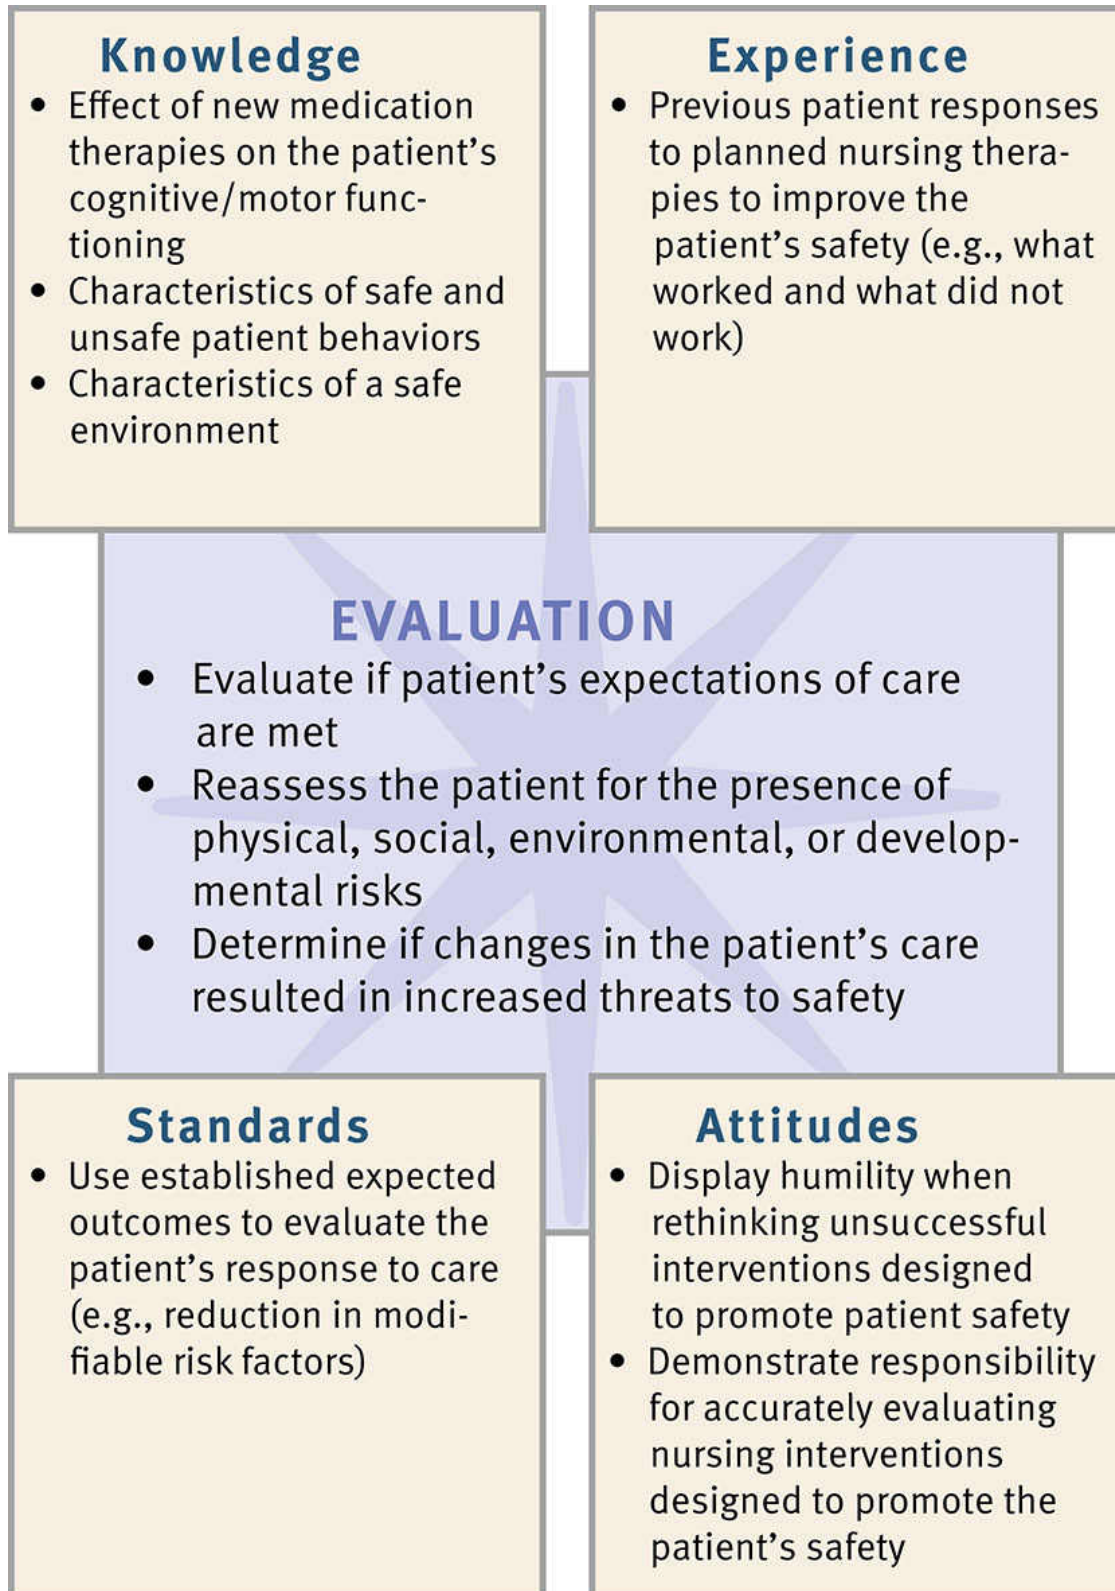

FIG. 27.9 Critical thinking model for safety evaluation.

- What factors led to your fall/injury?
- Help me understand what makes you feel unsafe in your environment.
- What questions do you have about your safety?
- Do you need help locating community resources to help make your home safer?
- What changes have you recently experienced that you believe contribute to your risk for falling or lack of safety?

Continually reassess a patient's and family's need for additional support services, such as home care, physical therapy, counseling, and further teaching. A safe environment is essential to promoting, maintaining, and restoring health. Overall your expected outcomes include a safe physical environment and a patient whose expectations have been met, who is knowledgeable about safety factors and precautions, and who is free of injury.

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about the interventions to use in patient care delivery. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care:

- Anticipate a patient's fall risks based on your assessment and knowledge of physiological and behavioral factors when choosing fall prevention strategies.
- Involve patients and families in the selection of fall prevention strategies to improve adherence.
- Always try restraint alternatives before using a restraint. Involve family in your approach.
- Implement fall prevention protocols and provide patient and family education about fall prevention.

Skill 27.1. Fall Prevention in Health Care Settings • Delegation and Collaboration

The skill of assessing and communicating a patient's risks for falling cannot be delegated to assistive personnel (AP). Skills used to prevent falls can be delegated. The nurse directs the AP by:

- Explaining a patient's specific fall risks and associated prevention measures needed to minimize risks.
- Explaining environmental safety precautions to use.
- Explaining specific patient behaviors (e.g., disorientation, wandering) that are precursors to falls and that should be reported to the RN immediately.

Equipment

- Standardized and valid fall risk assessment tool (TJC, 2018b)
- Hospital bed with side rails; *option*—low bed
- Wedge cushion
- Nurse call system
- Gait belt for assisting with ambulation
- Wheelchair and seat belt (as needed)
- Optional safety devices: bed alarm pad, nonslip floor mat, head protective gear, hip protector

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Review medical record and determine whether patient has a recent history of a fall or risks for injury (ABCs) (HH, n.d.): Age over 85 Bone disorders (e.g., metastasis, osteoporosis) Coagulation disorders (e.g., leukemia, thrombocytopenia, anticoagulant use) Surgery (specifically, thoracic or abdominal surgery or lower limb amputation)	Conditions increase likelihood of serious injury from a fall such as fracture or internal hemorrhage.
3. Assess patient and family health literacy.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
4. Perform hand hygiene. Assess for fall risks using a validated fall risk assessment tool. Compute fall risk score. Conduct a comprehensive individualized patient assessment and consider patient's unique fall risks (TJC, 2018b) Perform a fall risk assessment in general acute care settings on admission, on transfer from one unit to another or with a significant change in a patient's condition, or after a fall (AHRQ, 2013).	Reduces transmission of microorganisms. A variety of intrinsic physiological factors predispose patients to falls. Tools based on the risk factors of a population (e.g., elderly, oncology, or neurological patient) are more likely to be sensitive to predicting falls.
5. Perform the Banner Mobility Assessment Tool (BMAT) (Boynton et al., 2014) or the "timed get up and go (TUG)" test (CDC, n.d.) if patient is able to ambulate. At a minimum, observe patient walk in room (with or without help).	The BMAT assesses 4 functional tasks to identify the level of mobility a patient can achieve, revealing whether assistance is needed (Boynton et al., 2014). The TUG test measures the progress of balance, sit to stand, and walking.
CLINICAL DECISION: Do not ask patient to provide a self-report of balance, gait, or ability to ambulate. Ask patient to walk a short distance using Timed Get Up and Go (Podsiadlo and Richardson, 1991), or complete the BMAT (Boynton, 2014) assessment, and observe each factor.	
6. Assess patient's pain severity (use rating scale ranging 0 to 10).	Fear of falls and a history of falls are substantially more common among older adults with bothersome pain than in those without pain (Patel et al., 2014).
7. Ask patient or family caregiver whether patient has a history of recent falls or other injuries within the home. Assess previous falls using the acronym SPLATT (Touhy and Jett, 2018). Symptoms at time of fall Previous fall Location of fall Activity at time of fall Time of fall Trauma after fall	Symptoms are helpful in identifying cause for fall. Onset, location, and activity offer details on how to prevent future falls.
8. Review patient's medications (including over-the-counter [OTC] medications and herbal products) for drugs that create risk for falls. Also assess for polypharmacy (unnecessary use of multiple [five or more] and/or redundant medications in management of the same condition and drugs inappropriate for condition).	Effects of certain medications, such as those that depress the central nervous system (e.g., benzodiazepines, antipsychotics, antidepressants, opioids and barbiturates, antihistamines, and anticonvulsants), antihypertensives, diuretics, and laxatives, increase risk for falls (Severo et al., 2014). Over a 2-year period polypharmacy was significantly associated with a 21% increased rate of falls in a study involving adults over 60 years (Dhalwani et al., 2017).
9. Assess patient's fear of falling: consider if patient is female, older age, lower level of education, chronic illness (more than three chronic illnesses), poor subjective health, functional impairment, a history of falling, and depression.	Factors found to be associated with a severe fear of falling (Park et al., 2017)
10. Assess condition of equipment (e.g., legs on bedside commode, end tips on a walker).	Equipment in poor repair increases risk for fall.
11. Use patient-centered approach to determine what patient already knows about risks for falling. Show patient and family caregiver results of fall risk assessment and explain significance of risk factors. Explain how a plan for fall prevention will be developed.	Knowledge of fall risks influences one's ability to take necessary precautions in reducing falling. Matching interventions with factors that patient perceives as relevant may increase success in preventing falls.

Table Continued

Step	Rationale
12. If patient is a fall risk, apply color-coded wristband (see illustration). Some agencies institute fall risk signs on doors, while others may use color-coded socks or gowns.	Color-coded yellow bands, socks, and gowns are easily recognizable.
13. If patient is in a wheelchair, assess his or her level of comfort, fatigue, boredom, mental status, or level of engagement with others.	These factors can cause patient to make an attempt to exit wheelchair without help.
PLANNING	
1. Prepare equipment, being sure all is functional.	A well-equipped room with functioning equipment promotes safety.
2. Provide patient privacy and drape as appropriate for comfort.	Maintaining privacy promotes patient dignity and respect.
3. Position the patient in a comfortable position, depending on mobility restrictions.	Appropriate positioning allows for increased participation in care activities.
4. Explain safety measures taken as they pertain to patient's specific fall risks.	Clear, concise information with explanations for purpose, benefits, and expectations results in increased patient participation.
IMPLEMENTATION	
1. Conduct hourly purposeful rounds on all patients to determine status of pain, need to toilet, comfort of position, and need to relocate personal items for easy reach; provide pain relief intervention.	Effective purposeful rounding can promote patient safety, encourage team communication, and improve staff ability to provide efficient patient care (McLeod and Tetzlaff, 2015).
2. Implement early mobility protocols within health care agency (see Chapter 38). Follow protocols to ensure that patient increases level of mobility progressively. Consider use of accelerometers, small devices that can be worn by a patient and that quantify biomechanical body movement and number of steps per shift (Growdon et al., 2017).	A patient's functional decline (loss of the ability to perform self-care activities or activities of daily living) may result from deconditioning, which is associated with inactivity (Gorman et al., 2014). Deconditioning is a risk for hospitalized patients who spend most of their time in bed, even when they are able to walk.
3. Adjust bed to low position with wheels locked (AHRQ, 2013). Option: Place nonslip padded floor mats at exit side of bed.	Height of bed allows ambulatory patient to get in and out of bed easily and safely. Mats provide nonslippery surface for preventing falls and injuries.
4. Encourage use of properly fitted skidproof footwear (AHRQ, 2013).	Prevents falls from slipping on floor.
5. Orient patient to surroundings, nurse call system, and routines to expect in plan of care (AHRQ, 2013).	Orientation to room and plan of care provides familiarity with environment and activities to anticipate.
a. Provide patient's hearing aid and glasses. Be sure that each is functioning/clean (AHRQ, 2013). If patient states he or she is having visual or hearing problems, refer to appropriate health care provider.	Enables patient to remain alert to conditions in environment.
b. Place nurse call system in an accessible location within patient's reach (see illustration). Explain and demonstrate how to use system at bedside and in bathroom. Have patient perform return demonstration.	Knowledge of location and use of nurse call system is essential for patient to be able to call for help quickly. Reaching for an object when in bed can lead to an accidental fall.
c. Explain to patient/family member when and why to use nurse call system (e.g., report pain, assistance needed to get out of bed or go to bathroom). Provide clear instructions regarding mobility restrictions.	Increases likelihood that patient/family caregiver will call for help and allows nurse to respond to patient's needs in a timely way.
6. Safe use of side rails:	
a. Explain to patient and family caregiver reason for patient to use side rails: moving and turning self in bed.	Promotes a feeling of comfort and security. Aids in turning and repositioning and provides easy access to bed controls (FDA, 2017).
b. Check agency policy regarding use of side rails. (1) Dependent, less mobile patients: In two-side rail bed, keep both rails up. (Note: Rails on newer hospital beds allow for room at foot of bed for patient to safely exit bed.) In four-side rail bed, leave two upper rails up.	Side rails are restraint devices if they restrict a patient's freedom of movement and therefore do not promote the individual's independent functioning (TJC, 2017a).
STEP 12 A "fall risk" = risk of falling.	STEP 12b Nurse demonstrates use of nurse call system to patient.

Table Continued

Step	Rationale
(2) Patient able to get out of bed independently: In four-side rail bed, leave two upper side rails up. In two-side rail bed, keep only one rail up.	Allows for safe exit from bed.
c. Use a proper-size mattress or mattress with raised foam edges (FDA, 2017).	Prevent patients from being trapped between the mattress and rail.
d. Reduce the gaps between the mattress and side rails (FDA, 2017)	Prevent patient entrapment.
7. Make patient's environment safe:	
a. Remove excess equipment, supplies, and furniture from rooms and halls.	Reduces likelihood of falling or tripping over objects.
b. Keep floors free of clutter and obstacles (e.g., intravenous [IV] pole, electrical cords), particularly path to bathroom (AHRQ, 2013).	Reduces likelihood of falling or tripping over objects.
c. Coil and secure excess electrical, telephone, and any other cords or tubing.	Reduces risk of entanglement.
d. Clean all spills on floors promptly (AHRQ, 2013). Post sign indicating wet floor. Remove sign when floor is dry (usually done by housekeeping).	Reduces risk of falling on slippery, wet surfaces.
e. Ensure adequate glare-free lighting; use a night-light at night.	Glare may be a problem for older adults because of vision changes.
f. Have assistive devices (e.g., cane, walker, bedside commode) on exit side of bed. Have chair back of a bedside commode placed against wall of room if possible.	Provides added support when transferring out of bed. Stabilizes commode.
g. Arrange personal items (e.g., water pitcher, telephone, reading materials, dentures) within patient's easy reach and in logical way (AHRQ, 2013).	Facilitates independence and self-care; prevents falls related to reaching for hard-to-reach items.
h. Secure locks on beds, stretchers, and wheelchairs (AHRQ, 2013).	Prevents accidental movement of devices during patient transfer.
8. Provide nonpharmacological comfort measures (Chapter 44); offer ordered analgesics for patients experiencing pain, preferably around-the-clock.	Pain can cause patients to exit bed and increases risk for falls (Patel et al., 2014). Be cautious as opioids further increase fall risk.
9. Interventions for patients at moderate-to-high risk for falling (based on fall risk assessment):	
a. Prioritize nurse call system responses to patients at high risk; use a team approach with all staff knowing responsibility to respond.	Ensures rapid response by care provider when patient calls for help; decreases chance of patient trying to get out of bed on own.
b. Establish elimination schedule; use bedside commode when appropriate.	Proactive toileting keeps patients from being unattended with sudden urge to use toilet.
CLINICAL DECISION: Toileting is a common event leading to a patient's fall (Berry and Kiel, 2016).	
c. Stay with patient during toileting (standing outside bathroom door). Increase availability and use of raised toilet seats (VA Healthcare, 2015).	Patients often try to get up to stand and walk back to their beds from the bathroom without help. Raised seats make it easier to sit on or stand up from toilet.
d. Place patient in a geri-chair or wheelchair with wedge cushion. Use wheelchair only for transport, not for sitting an extended time.	Maintains alignment and comfort and makes it difficult to exit chair.
e. Consider use of a low bed that has lower height than standard hospital bed. Option: Apply nonskid floor mats (VA Healthcare, 2015).	Low beds may reduce fall-related injuries by making it difficult for patients with lower extremity weakness or pain in lower joints to exert effort needed to stand. Mats prevent slipping when walking and standing.
f. Activate a bed alarm or camera monitoring system for patient (VA Healthcare, 2015).	Alarm activates when patient rises off sensor. Alarm sounds alert to staff. Camera can detect falls.
CLINICAL DECISION: Use judgment in choosing use of a bed alarm. Bed alarms alert nursing staff so that if a patient exits a bed, a quick response may prevent a fall. If a patient exits a bed quickly and falls, the alarm alerts staff to respond so that further injury does not occur while patient lies on floor. However, bed and chair alarms can restrict patient activity. Reports have shown that patients perceive an alarm as restraining (Growdon et al., 2017). Determine whether use of bed or chair alarm is limiting frequency of patient getting up and remaining active.	
g. Confer with physical therapy about gait training, strength and balance training, and regular weight-bearing activities.	Exercise can reduce falls, fall-related fractures, and several risk factors for falls in individuals with low bone density and older adults. Strength and balance training reduces the rate of falls with injuries in older adults (Uusi-Rasi et al., 2015).
h. Use sitters or restraints only when alternatives are exhausted.	A sitter is a nonprofessional staff member or volunteer who stays in a patient room to closely observe patients who are at risk for falling. Restraints should be used only as a final option (see Skill 27.2).

Table Continued

Step	Rationale
(1) Consider having patient wear head protective gear (e.g., patient with cancer or patients at risk for bleeding) or hip protectors (patients at risk for fracture) (VA Healthcare, 2015).	Contains impact-resistant material within the hat that surrounds the head and protects against head injury. Hip protectors have padding to reduce fall impact.
10. When ambulating patient, have patient wear a gait belt or walking sling, and walk along his or her side (see Chapter 38).	Safe patient-handling techniques allow for safe patient ambulation and prevention of injury to you and patient.
11. Safe use of wheelchair:	
a. Be sure that wheelchair is correct fit for patient: patient thighs are level while sitting, feet flat on floor; back of chair comes up to midshoulder, elbows rest on armrests without leaning over or tucking arms in, and two fingerwidths of space between patient and side of chair.	Correctly fitted chair promotes comfort, making it less likely for patient to try to exit it.
b. Transfer patient to wheelchair using safe handling techniques (see Chapter 38). Use a wedge cushion in chair (see illustration).	Cushion prevents patient from slipping out of chair.
c. Back wheelchair into and out of elevator or door, leading with large rear wheels first (see illustration).	Prevents smaller front wheels from catching in crack between elevator and floor, causing chair to tip.
d. Manage patient's pain and do not allow him or her to sit in wheelchair an extended amount of time; provide alternative sitting option.	Reduces restlessness and discomfort that can lead to wheelchair exit.
12. Schedule oral medication administration for at least 2 hours before "bedtime" (TJC, 2016).	Reduces risk created by medications that can cause patients to have to use bathroom during night.
13. Remove unnecessary supplies at bedside from patient room. Perform hand hygiene.	Reduces clutter. Reduces transmission of microorganisms.
EVALUATION	
1. Ask patient/family caregiver to identify patient's fall risks.	Demonstrates learning.
2. Ask patient/family caregiver to describe fall prevention interventions to implement.	Demonstrates learning.
3. Evaluate patient's ability to use assistive devices such as walker or bedside commode at different times during the day.	Adjustments in devices may become necessary. Evaluating at different times can help identify strengths and weaknesses.
4. Evaluate for changes in motor, sensory, and cognitive status, and review if any falls or injuries have occurred.	May require different interventions to be added. Fall outcomes determine success of plan.
5. Evaluate patient's level of pain using a pain rating scale.	Determines whether patient's pain is under adequate control.
6. Continue hourly purposeful rounding.	Reduces patient anxiety, lessens need for patient to exit bed independently
7. Use Teach-Back: "I want to be sure I explained clearly to you why you are at risk to fall. Tell me some of those reasons." Revise your instruction now or develop plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Step 11b Wheelchair with footplates raised and wedge cushion in place.	Step 11e Nurse backing wheelchair into elevator.

Table Continued

Step	Rationale
Unexpected Outcomes and Related Interventions	
1. Patient/family caregiver unable to identify fall risks or fall prevention strategies. <ul style="list-style-type: none"> Reinforce identified risks, and review safety measures with patient and family caregiver. Consider using other instructional options. 	
2. Patient found after falling. <ul style="list-style-type: none"> Call for assistance. Assess patient for injury, and stay with him or her until help arrives. Notify primary health care provider and family caregiver. Complete an agency occurrence or incident event report (see agency policy). Conduct a huddle/debrief as soon as possible after the fall. Involve staff at all levels and the patient if possible. Discuss whether appropriate interventions were in place, considerations as to why fall occurred, staffing at time of fall, which environment of care factors were in place, and how care plan will change (VA Healthcare, 2015; TJC, 2016). 	
Recording and Reporting	
<ul style="list-style-type: none"> Record in the plan of care specific fall prevention interventions. Use white boards in patient rooms to communicate patient fall risks to all staff (TJC, 2016). Document what patient is able to explain or not explain about fall risks and interventions taken. Complete a facility safety event or incident report noting objective details of a fall (time, location, patient's condition, treatment, treatment response). Do not place the report in patient's medical record. Use a hand-off communication tool that includes specific patient risks for falls and falls with injury between caregivers. Discuss patient specific interventions taken. (VA Healthcare, 2015; TJC, 2016). Report immediately to the health care provider if patient sustains a fall or an injury. 	

Skill 27.2. Applying Physical Restraints

Delegation and Collaboration

The skill of assessing a patient's behavior, orientation to the environment, need for restraints, and appropriate use of restraints cannot be delegated. The application and routine checking of a restraint can be delegated to assistive personnel (AP). CMS (2016) requires training of all direct care staff who apply restraints. The nurse instructs the AP about:

- Appropriate restraint to use and correct placement of restraint.
- When and how to change patient's position and provide range-of-motion exercises, hydration, toileting, skin care, and time for socialization.
- When to report signs and symptoms of patient not tolerating restraint and what to do.

Equipment

- Proper-sized restraint
- Padding (if needed)

Step	Rationale
ASSESSMENT	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Review medical record to assess for underlying cause(s) of agitation and cognitive impairment leading to patient-initiated medical device removal (Bradas et al., 2012).	
a. Assess for life-threatening physiological impairments, e.g., respiratory, neurological, fever and sepsis, hypoglycemia or hyperglycemia, alcohol or substance withdrawal, or fluid and electrolyte imbalance.	Physiological alterations might lead to accidental patient-initiated medical device removal (Bradas et al., 2012). Identification of conditions might lead to more appropriate medical or pharmacological treatment, eliminating need for restraints.
b. If there is abrupt change in perception, attention, or level of consciousness, perform hand hygiene and assess for these same life-threatening conditions.	Reduces transmission of microorganisms. Factors that affect patient cognition can develop quickly.
c. Notify health care provider of change in mental status and compromised physiological status.	
3. Assess patient's or family caregiver's health literacy level and then determine knowledge about use of restraints and experience.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
4. Obtain baseline or premorbid cognitive function from family caregivers.	Excellent sources of information for patient's behavioral patterns and history.
5. Establish whether patient has history of dementia or depression (Bradas et al., 2012).	Patients who are cognitively impaired are at risk for exiting bed without asking for assistance.
6. Review medications that can cause risk for falling (e.g., antiemetics, opioid analgesics, anticholinergic agents acting on the bladder, and benzodiazepines/hypnotics) (Bradas et al., 2012; Browne et al., 2014).	Medications can alter cognition, cause postural hypotension, and create other risks.
7. Review current laboratory values (e.g., electrolytes, blood glucose, blood culture, urinalysis).	May reveal a fluid and electrolyte imbalance or other problems, such as a blood glucose imbalance or an infection, all of which can cause sudden confusion in the elderly (National Health Service [NHS], 2015).
Table Continued	

Step	Rationale
8. Assess patient's current behavior (e.g., confusion, disorientation, agitation, restlessness, combativeness, inability to follow directions, or repeated removal of therapeutic devices). Does patient create a risk to other patients?	If patient's behavior continues despite treatment or restraint alternatives, use of least restrictive restraint might be indicated.
CLINICAL DECISION: In the case of alcohol withdrawal, the use of restraints can increase agitation and worsen neuropsychiatric disturbances (Rainier, 2014).	
9. If restraint alternatives failed earlier, confer with health care provider. Review agency policies and state laws regarding restraints. Obtain current health care provider's order for restraint, including purpose, type, location, and time or duration of restraint. Determine whether signed consent for use of restraint is necessary (long-term care). For patients who are nonviolent/non-self-destructive, orders are renewed per hospital policy.	A restraint order that is being used for violent or self-destructive behavior has a definite time limit (e.g., every 4 hours for adults, every 2 hours for children); these orders may be renewed according to the prescribed time limits for a maximum of 24 consecutive hours (TJC, 2017b). A health care provider's order for least restrictive type of restraint is required. (TJC, 2018b).
CLINICAL DECISION: A licensed independent health care provider responsible for the care of the patient evaluates the patient in person within 1 hour of the initiation of restraint used for the management of violent or self-destructive behavior that jeopardizes the physical safety of the patient, staff, or others. A registered nurse or a physician assistant may conduct the in-person evaluation if he or she is trained in accordance with the requirements and consults with the above health care provider after the evaluation as determined by hospital policy (TJC, 2018b).	
10. Review manufacturer instructions for restraint application. Determine most appropriate size restraint. Be familiar with all devices.	Incorrect sizing and application of restraint device can result in patient injury or death.
Planning	
1. Prepare restraint, being sure it is intact.	Ensures restraint is in condition for correct use.
2. Provide patient privacy, and drape as appropriate for comfort.	Promotes patient comfort.
3. Explain purpose of restraint, how it will be applied, length of time to be used, and procedure for ongoing assessment.	Promotes patient cooperation and helps to minimize any anxiety.
Implementation	
1. Perform hand hygiene. Adjust bed to proper height and lower side rail on side of patient contact. Be sure that patient is comfortable and in proper body alignment.	Reduces transmission of microorganisms. Allows you to reposition patient during restraint application without injuring self or patient. Proper alignment prevents contracture formation when restraints are in place.
2. Inspect area where restraint is to be placed. Note whether there is any nearby tubing or device. Assess condition of skin, sensation, adequacy of circulation, and range of joint motion.	Restraints sometimes compress and interfere with functioning of devices or tubes. Assessment provides baseline to monitor patient's response to restraint.
3. Pad skin and bony prominences (as necessary) that will be under restraint.	Reduces friction and pressure from restraint to skin and underlying tissue.
4. Apply proper-sized restraint. Note: Refer to manufacturer directions.	
a. Mitten restraint: Thumbless mitten device restrains patient's hands. Place hand in mitten, being sure that Velcro strap is around wrist and not forearm (see illustration).	Prevents patient from dislodging or removing medical device, removing dressings, or scratching but allows greater movement than wrist restraint. It is considered a restraint alternative if untethered and patient is physically and cognitively able to remove it.
b. Elbow restraint (freedom splint): Restraint consists of rigidly padded fabric that wraps around arm and is closed with Velcro. The upper end has a clamp that hooks to sleeve of patient's gown or shirt (see illustration). Insert arm so that elbow joint rests against padded area, keeping joint extended.	The restraint makes it difficult to remove or disrupt a medical device near the face or neck. It does not impede removing abdominal or urinary medical devices.
<p>Step 4a Mitten restraint. From Sorrentino SA, Rivera-LIN Mosby's textbook for nursing assistants ed 10, St Louis, 2021, Elsevier.</p>	<p>Step 4b Freedom elbow restraint Copyright © Mosby's Clinical Skills: Essentials Collection</p>

Table Continued

Step	Rationale
<p>c. Belt or body restraint: Have patient in sitting position in bed. Apply belt over clothes, gown, or pajamas. Be sure to place restraint at waist, not chest or abdomen. Slot in belt may be positioned in front for limited movement or rear for increased movement. Remove wrinkles or creases in clothing. Bring ties through slots in belt. Help patient lie down in bed. Have patient roll to side and avoid applying belt too tightly. Ensure that straps secured to bedframe are snug so that belt does not slide to sides of bed. <i>Option:</i> Apply restraint net if intent is to limit patient turning.</p>	<p>Restrains center of gravity and prevents patient from rolling off stretcher, sitting up while on stretcher, or from falling out of bed. Tight application interferes with ventilation if belt moves up over abdomen or chest.</p>
<p>d. Soft extremity (ankle or wrist) restraint: Restraint made of soft quilted material or sheepskin with foam padding. Wrap limb restraint around wrist or ankle with soft part toward skin and secure snugly (not tightly) in place by Velcro strap. Insert two fingers under secured restraint (see illustration).</p>	<p>Restraint designed to immobilize one or all extremities. Maintain immobilization of extremity to protect patient from fall or accidental removal of therapeutic device (e.g., IV tube, Foley catheter). Tight application interferes with circulation and potentially causes neurovascular injury.</p>
<p>CLINICAL DECISION: Patient with wrist and ankle restraints is at risk for aspiration if positioned supine. Place patient in lateral position or with head of bed elevated rather than supine.</p>	
<p>5. Attach restraint straps to part of bedframe that moves when raising or lowering head of bed. Be sure that straps are secure. <i>Do not attach to side rails.</i> Attach restraint to chair frame for patient in chair or wheelchair, being sure that buckle is out of patient's reach.</p>	<p>Properly positioned strap does not tighten and restrict circulation when bed is raised or lowered.</p>
<p>6. Secure restraints on bedframe with quick-release buckle (see illustration). <i>Do not tie strap in a knot.</i> Be sure that buckle is out of patient's reach.</p>	<p>Allows for quick release in emergency.</p>
<p>7. Double-check and insert two fingers under secured restraint one more time. Assess proper placement of restraint, including skin integrity, pulses, skin temperature and color, and sensation of restrained body part. Place bed in lowest position after restraint(s) applied.</p>	<p>Provides baseline to later evaluate if injury develops from restraint. Provides safest environment in which to leave a patient who is restrained.</p>
<p>8. Perform hand hygiene. Remove restraint at least every 2 hours (TJC, 2018b) or more frequently as determined by agency policy. Reposition patient, provide comfort and toileting measures, and evaluate patient condition each time. If patient is agitated, violent or noncompliant, remove one restraint at a time and/or have staff assistance while removing restraints.</p> <p style="text-align: center;"><small>Step 4d Soft extremity restraint. Check restraint for constriction by inserting two fingers under restraint.</small></p>	<p>Provides opportunity to attend to patient's basic needs and determine need for continuation of restraints.</p> <p style="text-align: center;"><small>Step 8 Quick-release buckle makes it easier to disconnect and evacuate patients in an emergency.</small></p>

Table Continued

Step	Rationale
CLINICAL DECISION: Do not leave a patient who is violent or aggressive unattended while restraints are off. Monitoring of violent/self-destructive patients placed in restraints is continuous (by way of video or audio) versus every 2 hours for nonviolent patients.	
9. Be sure nurse call system is within patient's reach.	Allows patient, family, or caregiver to get help quickly.
10. Leave bed or chair with wheels locked. Keep bed in lowest position.	Prevents bed or chair from moving if patient tries to get out. If patient falls with bed in lowest position, this reduces chance of injury.
11. Remove and dispose of any supplies. Perform hand hygiene.	Reduces transmission of microorganisms.
Evaluation	
1. After restraint application, evaluate patient's response to restraints: a. For patients who are nonviolent, conduct evaluation for signs of injury (e.g., circulation, ROM, vital signs, skin condition), behavior and psychological status, and readiness for discontinuation (frequency based on agency policy) (TJC, 2018b). b. For patients who are violent/self-destructive, conduct same evaluation every 15 minutes. Perform visual checks if patient is too agitated to approach (TJC, 2018b).	Frequent evaluation prevents injury to patient and ensures removal of restraint at earliest possible time. Frequency of monitoring guides staff in determining appropriate intervals for evaluation based on patient's needs and condition, type of restraint used, risk associated with use of chosen intervention, and other relevant factors.
2. Evaluate patient's need for toileting, nutrition and fluids, hygiene, and elimination, and release restraint at least every 2 hours.	Prevents injury to patient and attends to basic needs.
3. Evaluate patient for any complications of immobility.	Early detection of skin irritation, restricted breathing, or reduction in mobility prevents serious adverse events.
4. Renewal of restraints: a. Patients who are not violent may have renewal of restraints based on hospital policy. However, the restraint must be discontinued at the earliest possible time, regardless of the scheduled expiration of the order. b. Patients who are violent/self-destructive may have restraints renewed within the following limits: • 4 hours for adults 18 years of age or older • 2 hours for children and adolescents 9 to 17 years of age • 1 hour for children under 9 years of age These orders may be renewed according to the time limits for a maximum of 24 consecutive hours.	Ensures that restraint application continues to be medically appropriate.
5. Observe IV catheters, urinary catheters, and drainage tubes to determine that they are positioned correctly and that therapy remains uninterrupted.	Reinsertion is uncomfortable and increases risk for infection or interrupts therapy.
6. Use Teach-Back: "We've talked about the reason we're using restraints on your father. Tell me that reason. I want to be sure you understand." Revise your instruction now or develop a plan for revised family caregiver teaching if family caregiver is not able to teach back correctly.	Determines family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
1. Patient experiences impaired skin integrity. <ul style="list-style-type: none"> Evaluate need for continued use of restraint and whether alternatives can be used. If restraint is still needed, be sure that it is applied correctly, and provide adequate padding. Check skin under restraint for abrasions, and remove restraints more often. Provide appropriate skin care and change wet or soiled restraints. 2. Patient becomes more confused or agitated. <ul style="list-style-type: none"> Try to determine cause of behavior and eliminate if possible; consult with health care provider. Determine need for more or less sensory stimulation and make stimulation meaningful. Reorient as needed and try restraint-free options. 3. Patient has neurovascular injury (e.g., cyanosis, pallor, and coldness of skin or complaints of tingling, pain, or numbness). <ul style="list-style-type: none"> Remove restraint immediately, stay with patient, and have health care provider notified. Protect extremity from further injury. 	
Table Continued	

Step	Rationale
Recording and Reporting	
<ul style="list-style-type: none"> • Record restraint alternatives tried, patient's behavior, level of orientation, and patient or family member's statement of understanding of the purpose of restraint and consent for application (if required by the agency). • Record placement and purpose for restraint, type and location of restraint, time applied, time restraint ended, and all routine assessments made in nurses' notes and flow sheet. • Record patient's behavior after restraint application. Record times patient was assessed, attempts to use alternatives to restraint and patient's response, times restraint was released (temporarily and permanently), and patient's response when restraint was removed. • Document evaluation of patient learning. • Report any injury resulting from a restraint to RN in charge and health care provider immediately. • During handoff, report location of restraint, last time assessment was conducted, and findings. 	
Home Care Considerations	
<ul style="list-style-type: none"> • A physical restraint is a device that requires a health care provider's order. Do not send a patient home with intent of restraining unless device is necessary to protect patient from injury. If patient's family wishes to use restraint at home, a health care provider's order is required, and you need to give clear instructions regarding proper application, care needed while in restraints, and complications for which to look. Carefully assess the family for competency and understanding of intent for using restraint. 	

Key Points

- Patient-centered care involves a patient as a full partner in providing coordinated care based on respect for a patient's preferences, values, and needs, with partnership as the essential factor.
- Patient-centered care is planned, delivered, managed, and continuously improved in active partnership with patients and their families to promote safety.
- Vulnerable populations such as infants, children, older adults, individuals with chronic disease or a physical or mental disability, individuals who have difficulty communicating, and individuals with a low income or who are homeless are at risk for threats in safety because of reduced access to health care, fewer resources, and increased morbidity.
- Motor vehicle accidents, poisonings, and falls are the leading causes of unintentional injuries and can be prevented by following recommended precautions such as child safety seat use, safe driving practices for older adults, and reducing exposure to poisonous substances in the home.
- School-age children are expanding their cognitive and psychosocial skills and need to learn to cope with the rules and expectations of schools and peers, such as rules for playing safely and using protective safety equipment.
- Adolescents begin to separate emotionally from their families, and the peer group begins to have a stronger

influence, increasing the risk for experimentation with alcohol, tobacco, and drugs.

- Muscle weakness, paralysis, abnormal gait, and poor coordination or balance are major factors in placing patients at risk for falls.
- Distractions and interruptions contribute to accidents and need to be limited, especially during high-risk procedures such as medication administration.
- Correct use of safe patient-handling techniques and equipment reduces the risk of injuries when moving and lifting patients.
- The assessment of a patient's medical history, current physical condition (e.g., alertness, gait, lower-body muscle strength, and vision), medication history, developmental status, and safety risk factors determines whether any underlying conditions exist that pose threats to a patient's safety.
- When caring for a patient in the home, a home hazard assessment and a review of a patient's home routines help you recognize less obvious hazards and the type of environmental changes needed.
- It is important to learn the patient's willingness to make changes in his or her environment since decisions on ways to change the environment require the patient's full participation.
- Restraint alternatives for patients at low risk include adjusting beds to low position with wheels locked, providing properly fitted skidproof footwear, providing clear walking paths, and orienting patients to surroundings

with easy access to assistive devices and the nurse call system.

- Before applying restraints, review the medical record for underlying cause(s) of agitation and cognitive impairment, assess whether the patient has a history of dementia or depression, and review medications and current laboratory values.
- When a patient is in a physical restraint, assess the placement of the restraint, and note skin integrity, pulses, skin temperature and color, and sensation of the restrained body part.

Reflective Learning

- Consider the patients you interacted with today and describe their age-specific safety risks.
- Thinking back over your past week of interacting with patients, identify factors that created a culture of safety as well as opportunities you saw for creating or improving a culture of safety.
- Consider the patients you interacted with today and their safety risks. What types of interventions would you include in your nursing care plan to help prevent and minimize the intrinsic and extrinsic threats to their safety?

Review Questions

1. Which of the following are safe practices to follow in the safe preparation and storage of food? (Select all that apply.)

1. Always use a single cutting board to prepare foods for cooking.
 2. Refrigerate leftovers as soon as possible.
 3. Always buy vegetables in packages marked "prewashed."
 4. Cook meats to the proper temperature.
 5. Wash hands thoroughly before food preparation.
2. A nurse enters the hospital room of a patient who had a total knee replacement the day before. Which of the following pose potential safety risks? (Select all that apply.)
1. A current safety inspection sticker is on the IV fluids pump.
 2. A walker is positioned near the patient's bedside.
 3. The hospital bed is in the high position.
 4. There is no gait belt at the bedside.
 5. The overbed table with the patient's glasses is positioned against the wall opposite the end of the bed.
3. A nurse working on a medicine unit in the hospital hears the fire alarm go off. As the nurse walks down the hallway, there is smoke coming from the family waiting area. Which of the following steps should the nurse take? (Select all that apply.)
1. Immediately phone in to the hospital alert system the exact location of the fire.
 2. Direct the nurse technician to place empty stretchers behind the fire doors.
 3. Go to each patient room, and direct ambulatory patients to walk themselves to a safe area.

4. Work with the nurse technician to help move patients requiring wheelchairs from their rooms.
 5. Close the room doors of patients who cannot get out of bed, and keep them in their rooms.
4. Match the threats to safety on the right to the category of risk factors on the left.

<p>A. Individual Risks</p> <p>B. Developmental Risks</p>	<ol style="list-style-type: none"> 1. An older adult has limited finances. 2. A young toddler likes to explore objects by placing them in his mouth. 3. A 55-year-old patient has a residual gait change due to a stroke. 4. A school-age child chooses to play ice hockey. 5. A patient newly diagnosed with diabetes has low health literacy.
--	--

5. A nurse working on a surgery floor is assigned four patients. The nurse assesses each patient, noting behaviors and physical signs and symptoms. Which of the following patients is more likely to be violent toward the nurse?
1. The first patient maintains eye contact with the nurse, is calm during the nurse's assessment, and asks questions frequently.
 2. The second patient is very drowsy, loses attention span when the nurse asks questions, and mumbles when speaking.
 3. The third patient moves nervously in bed, swears and grimaces when trying to cough, and speaks in a low volume.
 4. The fourth patient speaks in a loud voice and becomes irritable when the nurse arrives to help walk the patient.
6. A nurse working the night shift is assigned a patient who has a history of having fallen in the hospital during a previous admission. The nurse wants to review the

admission assessment completed by the nurse on the day shift. Which of the following sections in the assessment are most likely to provide information about the patient's current fall risks? (Select all that apply.)

1. Allergy history
 2. Medication history
 3. Patient age
 4. Patient's occupation
 5. Physical exam of neuromuscular function
7. Match the intervention for promoting child safety on the left with the correct developmental stage on the right.

<ol style="list-style-type: none">1. Teach children proper bicycle and skate board safety.2. Teach children how to cross streets and walk in parking lot.3. Teach children proper techniques for specific sports.4. Teach children not to operate electric toothbrushes while unsupervised.5. Teach children not to talk to or go with a stranger.6. Teach children not to eat items found in the grass.	<ol style="list-style-type: none">A. School-age childB. Preschooler
---	--

8. The nurse finds a 68-year-old woman wandering in the hallway and exhibiting confusion. The patient says she is looking for the bathroom. Which interventions are appropriate for this patient? (Select all that apply.)
1. Ask the health care provider to order a restraint.
 2. Recommend insertion of a urinary catheter.
 3. Provide scheduled toileting rounds every 2 to 3 hours.
 4. Institute a routine exercise program for the patient.
 5. Keep the bed in high position with side rails down.
 6. Keep the pathway from the bed to the bathroom clear.
9. Place the following steps for applying a wrist restraint in the correct order:

1. Pad the skin overlying the wrist.
 2. Insert two fingers under the secured restraint to be sure that it is not too tight.
 3. Be sure that the patient is comfortable and in correct anatomical alignment.
 4. Secure restraint straps to bedframe with quick-release buckle.
 5. Wrap limb restraint around wrist or ankle with soft part toward skin and secure snugly.
10. Match the fall prevention intervention on the left with the scientific rationale on the right.

<ol style="list-style-type: none"> 1. Prioritize nurse call system responses to patients at high risk. 2. Place patient in a wheelchair with wedge cushion. 3. Establish elimination schedule with bedside commode. 4. Use a low bed for patient. 5. Provide a hip protector. 6. Place nonskid floor mat on floor next to bed. 	<ol style="list-style-type: none"> A. Maintains comfort and makes exit difficult B. Makes it difficult for patients with lower extremity weakness to stand C. Reduces slipping when walking D. Reduces fall impact E. Ensures rapid response for help F. Reduces chance of patient trying to get out of bed on own

Infection Prevention and Control

OBJECTIVES

- Explain the relationship between the infection chain and transmission of infection.
- Give an example of preventing infection for each element of the infection chain.
- Describe the signs/symptoms of a localized infection and those of a systemic infection.
- Identify the normal defenses of the body against infection.
- Discuss the events in the inflammatory response.
- Explain conditions that promote the transmission of health care–associated infection.
- Identify patients most at risk for infection.
- Explain the difference between medical and surgical asepsis.
- Explain the rationale for Standard Precautions.
- Perform proper procedures for hand hygiene.
- Explain procedures for each isolation category.
- Explain how infection control measures differ in the home versus the hospital.
- Properly apply a disposable mask and sterile gloves.
- Understand the definition of occupational exposure.
- Explain the postexposure process.

Virulence, p. 423

The incidence of infectious diseases such as AIDS, influenza, pneumonia, measles, and sexually transmitted infections are a significant public health problem in the United States and around the world ([Centers for Disease Control and Prevention \[CDC\], 2017d](#)). In 2016 there were 15.5 million visits to physician offices, with infectious and parasitic diseases as the primary diagnosis ([CDC, 2017d](#)). Multiple factors affect the spread of infectious diseases, such as humans' susceptibility, drug resistance, human tendency to avoid vaccination, and drug immunosuppression. The effects of infectious disease are constantly evolving; an infection that is considered a national or global threat one year could be eliminated the next (Contagion Live, 2019). For example, the opioid crisis has increased the number of people diagnosed with infective endocarditis as a result of IV injections, subsequently requiring cardiac valve replacements ([CDC, 2017d](#)). As a nurse it is critical to understand how infections develop, your patients' risk for infection, and how to institute preventive measures.

The incidence of patients who develop infections as the direct result of contact with health care personnel is an increasing health problem. Based on a large sample of US acute care hospitals, a CDC survey found that, on any given day, about 1 in 25 patients who are hospitalized has at least one health care–associated infection (HAI) ([CDC, 2018a](#)). Current trends, public awareness, and rising costs of health care have increased the importance of infection prevention and control. [The Joint Commission \(TJC\) \(2020\)](#) views HAIs as a patient safety issue. Nurses are essential to infection prevention and control when creating a safe health care environment for patients, families, and health care staff. Patients in all health care settings are at risk for acquiring infections because of lower resistance to **pathogens**; increased exposure to pathogens, some of which may be resistant to most antibiotics; and **invasive** procedures. Health care workers are at risk for exposure to pathogens as a result of contact with patient blood, body fluids, and contaminated equipment and surfaces. By practicing basic infection prevention and control techniques, you avoid spreading pathogens to patients and sustaining an exposure when providing direct care.

Patients and their families need to be able to recognize sources of infection and understand measures used to protect themselves. Patient teaching must include basic information about infection, the various modes of transmission, and appropriate methods of prevention such as hand hygiene and covering the mouth during a cough.

Health care workers protect themselves from contact with infectious material, sharps injury, and/or exposure to communicable diseases by applying knowledge of the infectious process and using appropriate personal protective equipment (PPE). Increases in multidrug-resistant organisms (MDROs), health care–acquired infections (HAIs), and concern about diseases such as hepatitis B virus (HBV) and hepatitis C virus (HCV), human immunodeficiency virus (HIV) infection, and tuberculosis (TB) require a greater emphasis on infection prevention and control techniques ([CDC, 2007](#), [2013a](#), 2017).

Scientific Knowledge Base

Nature of Infection

It is important to know the difference between an infection and a colonization. An **infection** results when a pathogen invades tissues and begins growing within a host. **Colonization** is the presence and growth of microorganisms within a host but without tissue invasion or damage (Tweeten, 2018). Disease or infection results only if the pathogens multiply and alter normal tissue function. Some **infectious** diseases such as viral meningitis and pneumonia have a low risk or no risk for transmission. Although these illnesses can be serious for patients, they do not pose a risk to others, including caregivers.

If an infectious disease can be transmitted directly from one person to another, it is termed a **communicable disease** (Tweeten, 2018). If the pathogens multiply and cause clinical signs and symptoms, the infection is symptomatic. If clinical signs and symptoms are not present, the illness is termed asymptomatic. HCV is an example of a communicable disease that can be asymptomatic. It is most efficiently transmitted through the direct passage of blood into the skin from a percutaneous exposure, even if the source patient is asymptomatic (CDC, 2018b).

Chain of Infection

The presence of a pathogen does not mean that an infection will occur. Infection occurs in a cycle that depends on the presence of all of the following elements:

- An infectious agent or pathogen
- A reservoir or source for pathogen growth
- A port of exit from the reservoir
- A mode of transmission
- A port of entry to a host
- A susceptible host

Infection can develop if this chain remains uninterrupted (Fig. 28.1). Preventing infections involves breaking the chain of infection.

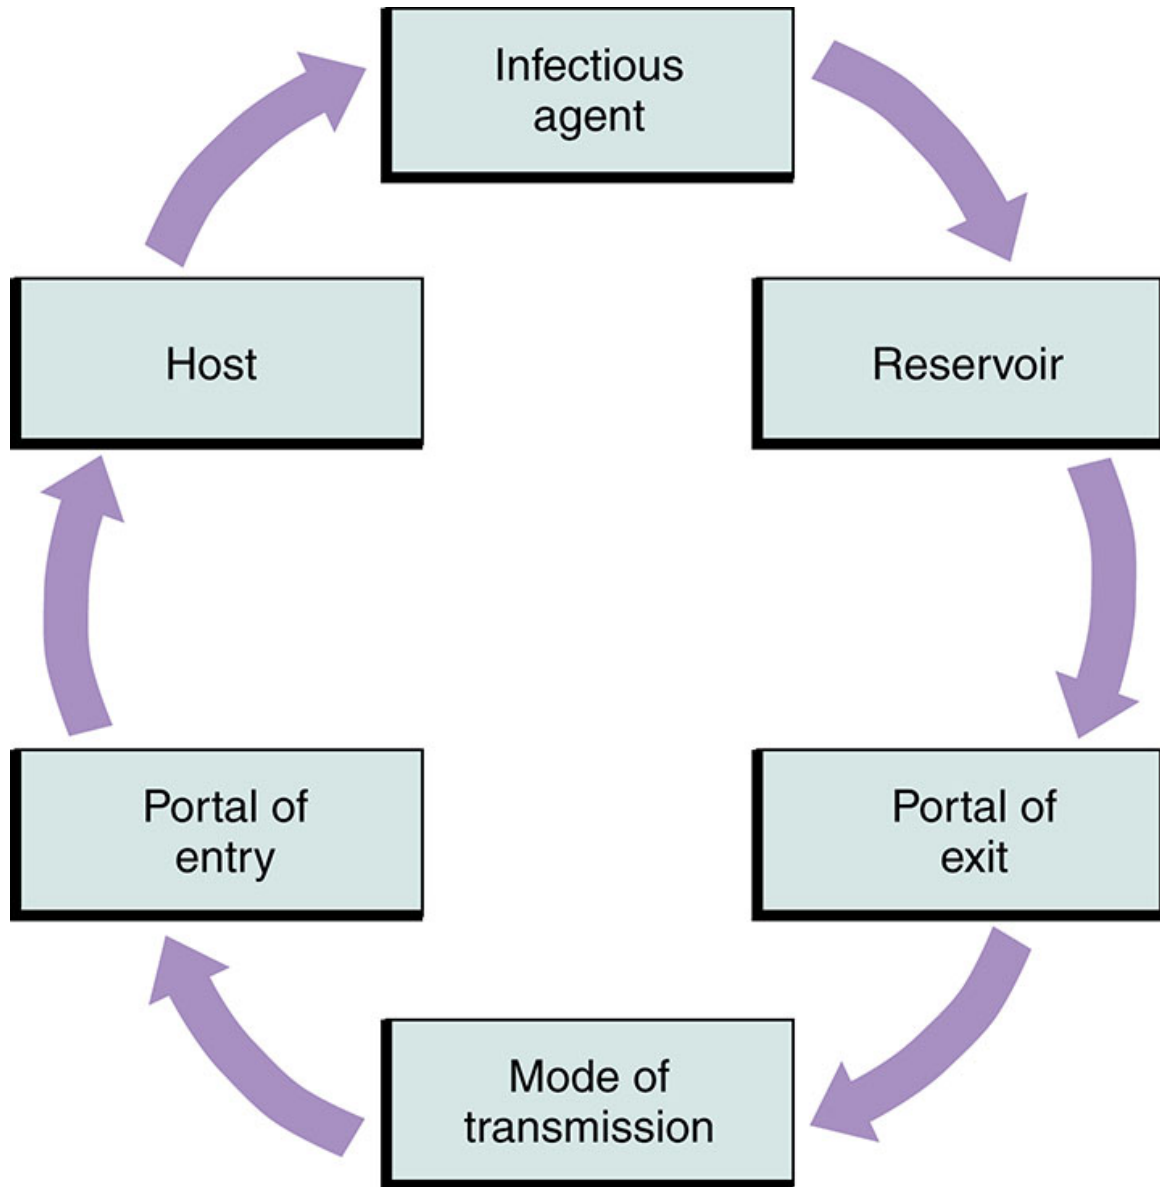

FIG. 28.1 Chain of infection.

Infectious Agent

Microorganisms include bacteria, viruses, fungi, and protozoa (Table 28.1). Microorganisms on the skin are either resident or transient flora. Resident organisms (normal flora) are permanent residents of the skin and within the body, where they survive and multiply without causing illness (CDC, 2008; World Health Organization [WHO], 2009). The potential for microorganisms or parasites to cause disease depends on the number of microorganisms present; their **virulence**, or ability to produce disease; their ability to enter and survive in a host; and the susceptibility of the

host. Resident skin microorganisms are not virulent. However, they can cause serious infection when surgery or other invasive procedures allow them to enter deep tissues or when a patient is severely **immunocompromised** (has an impaired immune system).

TABLE 28.1

Infections and Common Causative Organisms

Infection Site	Common Organisms
Bronchitis	<i>S. pneumoniae</i> , <i>H. influenzae</i> , respiratory viruses
Device-related	Coagulase-negative staphylococci, <i>Corynebacterium</i> sp.
Empyema	<i>S. aureus</i> , streptococci, anaerobes
Endocarditis	<i>S. viridans</i> , <i>S. aureus</i> , enterococci
Gastroenteritis	<i>Salmonella</i> sp., <i>Shigella</i> sp., <i>Campylobacter</i> sp.,
Meningitis	<i>E. coli</i> O157:H7, viruses
Pelvic inflammatory disease	<i>H. influenzae</i> , <i>N. meningitidis</i> , <i>S. pneumoniae</i>
Peritonitis	<i>C. trachomatis</i> , <i>N. gonorrhoeae</i> , <i>Bacteroides</i> sp., Enterobacteriaceae
Pneumonia (community)	<i>S. pyogenes</i> , respiratory viruses
Pneumonia (health care-associated)	<i>S. pneumoniae</i> , <i>H. influenzae</i> , <i>M. pneumoniae</i> , <i>C. pneumoniae</i> , <i>M. tuberculosis</i>
Osteomyelitis	<i>Pseudomonas</i> sp., <i>S. aureus</i> , Enterobacteriaceae
Septic arthritis	<i>S. aureus</i>
Septicemia	<i>S. aureus</i> , <i>N. gonorrhoeae</i>
Skin	<i>S. pneumoniae</i> , <i>H. influenzae</i> , <i>S. pyogenes</i> , <i>S. aureus</i>
Urinary tract	<i>S. aureus</i> , <i>S. pyogenes</i> , <i>Candida</i> sp., dermatophytes

Modified from Brown M: Microbiology basics. In Grota P, editor: *APIC text of infection control and epidemiology*, Washington, DC, 2018, Association for Professionals in Infection Control and Epidemiology.

Transient microorganisms attach to the skin when a person has contact with another person or object during normal activities. For example, when you touch a contaminated gauze dressing or cleanse a patient following a diarrheal episode, transient bacteria adhere to your skin. These organisms may be readily transmitted unless removed using hand hygiene ([Ellingson et al., 2014](#)). If hands are visibly soiled with proteinaceous material or care is being provided to a patient with *Clostridium difficile* (*C. difficile*), washing with soap and water is the preferred practice ([Dubberke et al., 2014](#)). If hands are not visibly soiled, use of an alcohol-based hand product or

handwashing with soap and water is acceptable for disinfecting hands of health care workers. Hand hygiene is the most effective way to break the chain of infection (CDC, 2008; WHO, 2009).

Reservoir

A **reservoir** is a place where microorganisms survive, multiply, and await transfer to a susceptible host. Common reservoirs are humans and animals (hosts), insects, food, water, and organic matter on inanimate surfaces (fomites). Frequent reservoirs for HAIs include health care workers, especially their hands; patients; equipment; and the environment. Human reservoirs are divided into two types: those with acute or symptomatic disease and those who show no signs of disease but are carriers of it. Humans can transmit microorganisms in either case. Animals, food, water, insects, and inanimate objects can also be reservoirs for infectious organisms. To thrive organisms require a proper environment, including appropriate food, oxygen, water, temperature, pH, and light.

Food

Microorganisms require nourishment. Some such as *Clostridium perfringens*, the microbe that causes gas gangrene, thrive on organic matter. Others such as *Escherichia coli* consume undigested foodstuff in the bowel. Carbon dioxide and inorganic material such as soil provide nourishment for other organisms.

Oxygen

Aerobic bacteria require oxygen for survival and for multiplication sufficient to cause disease. Aerobic organisms cause more infections in humans than anaerobic organisms. An example of an aerobic organism is *Staphylococcus aureus*. **Anaerobic** bacteria thrive where little or no free oxygen is available. Anaerobes typically cause infections deep within the pleural cavity, in a joint, or in a deep sinus tract. An example of an anaerobic organism is *Bacteroides fragilis*, an organism that is part of the normal flora of the human colon but that can cause infection if displaced into the bloodstream or surrounding tissue following surgery or injury.

Water

Most organisms require water or moisture for survival. For example, a frequent place for microorganisms is the moist drainage from a surgical wound. Some bacteria assume a form, called a *spore*, that is resistant to

drying and can live on inanimate surfaces for long periods. A common spore-forming bacterium is *C. difficile*, an organism that causes antibiotic-induced diarrhea.

Temperature

Microorganisms can live only in certain temperature ranges. Each species of bacteria has a specific temperature at which it grows best. The ideal temperature for most human pathogens is 20° to 43°C (68° to 109°F). For example, *Legionella pneumophila* grows best in water at 25° to 42°C (77° to 108°F). Cold temperatures tend to prevent growth and reproduction of bacteria (**bacteriostasis**). A temperature or chemical that destroys bacteria is **bactericidal**.

pH

The acidity of an environment determines the viability of microorganisms. Most microorganisms prefer an environment within a pH range of 5.0 to 7.0. Bacteria thrive in urine with an alkaline pH.

Light

Microorganisms thrive in dark environments such as those under dressings and within body cavities.

Portal of Exit

After microorganisms find a site to grow and multiply, they need to find a portal of exit if they are to enter another host and cause disease. Portals of exit include sites such as blood, skin and mucous membranes, respiratory tract, genitourinary (GU) tract, gastrointestinal (GI) tract, and transplacental (mother to fetus). Some viruses such as Ebola virus are transmitted through direct contact with the blood or body fluids of a person who is sick with Ebola. However, droplets (e.g., splashes or sprays) of respiratory or other secretions from a person who is sick with Ebola could also be infectious. Therefore, certain precautions (called Standard, Contact, and Droplet Precautions) are recommended for use in health care settings to prevent the transmission of the virus from patients who are sick with Ebola to health care personnel and other patients or family members ([CDC, 2015a](#)).

Skin and Mucous Membranes

The skin is considered a portal of exit because any break in the integrity of the skin and mucous membranes allows pathogens to exit the body. This may be exhibited by the presence of purulent drainage.

Respiratory Tract

Pathogens that infect the respiratory tract, such as the influenza virus, are released from the body when an infected person sneezes or coughs.

Urinary Tract

Normally urine is sterile. However, when a patient has a urinary tract infection (UTI), microorganisms exit during urination.

Gastrointestinal Tract

The mouth is one of the most bacterially contaminated sites of the human body, but most of the organisms are normal floras. A common flora in the stomach is *Helicobacter pylori*, the organism that can cause peptic ulcers. The *Lactobacillus* and *Enterococcus* are bacteria found in the duodenum.

Organisms that are normal floras in one person can be pathogens in another. For example, organisms exit when a person expectorates saliva. In addition, gastrointestinal portals of exit include emesis, bowel elimination, drainage of bile via surgical wounds, or drainage tubes.

Reproductive Tract

The female reproductive tract contains normal microbial flora that are developmentally and age related. *Lactobacilli* are typically the dominant organism in adult females, but other organisms present in the vagina include staphylococci, *Coryneform* bacteria, *Candida*, and *Streptococcus*.

Organisms such as *Neisseria gonorrhoea* and HIV exit through a man's urethral meatus or a woman's vaginal canal during sexual contact.

Blood

The blood is normally a sterile body fluid; however, in the case of communicable diseases such as HBV, HCV, or HIV, it becomes a reservoir for pathogens. Organisms exit from wounds, venipuncture sites, hematemesis, and bloody stool.

Modes of Transmission

Each disease has a specific mode of transmission. Often, you are able to do little about the infectious agent or the susceptible host, but by practicing infection prevention and control techniques such as hand hygiene, you interrupt the mode of transmission (Box 28.1). The same microorganism is sometimes transmitted by more than one route. For example, varicella zoster (chickenpox) is spread by the airborne route in droplet nuclei or by direct contact.

Box 28.1 Modes of Transmission

Contact

Direct

- Person-to-person (fecal, oral) physical contact between source and susceptible host.
- A health care provider's hands become contaminated by touching germs present on a patient, medical equipment, or high-touch surfaces, and the health care worker then carries the germs on his or her hands and spreads to a susceptible person.

Indirect

- Personal contact of susceptible host with contaminated inanimate object (e.g., needles or sharp objects, soiled linen, dressings, environment)

Droplet

- An infected person coughs or sneezes, creating droplets that carry germs short distances (within approximately 6 feet). These germs can land on a susceptible person's eyes, nose, or mouth and can cause infection (e.g., pertussis or meningitis).

Airborne

- Organisms are carried in droplet nuclei or residue or evaporated droplets suspended in air during coughing or sneezing. Germs are aerosolized by medical equipment or by dust from a construction zone (e.g., nontuberculous mycobacteria or *Aspergillus*).

Vehicles

- Contaminated items. For example, sharps injuries can lead to infections (e.g., HIV, HBV, HCV) when bloodborne pathogens enter a person through a skin puncture by a used needle or sharp instrument.
- Water
- Drugs, solutions
- Blood
- Food (improperly handled, stored, or cooked; fresh or thawed meats)

Vector

- External mechanical transfer (flies)
- Internal transmission such as parasitic conditions between **vector** and host such as:
 - Mosquito
 - Louse
 - Flea
 - Tick

Modified from Tweeten S: General principles of epidemiology. In Grota P, editor: *APIC text of infection control and epidemiology*, Washington, DC, 2018, Association for Professionals in Infection Control and Epidemiology; Centers for Disease Control and Prevention (CDC): How infections spread, 2016, <https://www.cdc.gov/infectioncontrol/spread/index.html>.

The major route of transmission for pathogens identified in the health care setting is the unwashed hands of the health care worker (Ellingson et al., 2014; WHO, 2009). Equipment used within the environment (e.g., a stethoscope, blood pressure cuff, or bedside commode) often becomes a source for the transmission of pathogens.

Portal of Entry

Organisms enter the body through the same routes they use for exiting. For example, during venipuncture when a needle pierces a patient's skin, organisms enter the body if proper skin preparation is not performed first. Factors such as a depressed immune system that reduce body defenses enhance the chances of pathogens entering the body.

Susceptible Host

Susceptibility to an infectious agent depends on an individual's degree of resistance to pathogens. Although everyone is constantly in contact with large numbers of microorganisms, an infection does not develop until an individual becomes susceptible to the strength and numbers of the microorganisms. A person's natural defenses against infection and certain risk factors (e.g., age, nutritional status, presence of chronic disease, trauma, and smoking) affect susceptibility (resistance) (Tweeten, 2018). Organisms such as *S. aureus* with resistance to key antibiotics are becoming more common in all health care settings but especially acute care. The increased resistance is associated with the frequent and sometimes inappropriate use of antibiotics over the years in all settings (i.e., acute care, ambulatory care, clinics, and long-term care) (Arnold, 2018).

The Infectious Process

By understanding the chain of infection, you have knowledge that is vital in preventing infections. When a patient acquires an infection, observe for signs and symptoms of infection and take appropriate action to prevent its spread. Infections follow a progressive course (Box 28.2).

Box 28.2 Course of Infection by Stage

Incubation Period

Interval between entrance of pathogen into body and appearance of first symptoms (e.g., chickenpox, 14 to 16 days after exposure; common cold, 1 to 2 days; influenza, 1 to 4 days; measles, 10 to 12 days; mumps, 16 to 18 days; Ebola 2 to 21 days (CDC, 2015a).

Prodromal Stage

Interval from onset of nonspecific signs and symptoms (malaise, low-grade fever, fatigue) to more specific symptoms. (During this time microorganisms grow and multiply, and patient may be capable of spreading disease to others.) For example, herpes simplex begins with itching and tingling at the site before the lesion appears.

Illness Stage

Interval when patient manifests signs and symptoms specific to type of infection. For example, strep throat is manifested by sore throat, pain, and swelling; mumps is manifested by high fever and parotid gland swelling.

Convalescence

Interval when acute symptoms of infection disappear. (Length of recovery depends on severity of infection and patient's host resistance; recovery may take several days to months.)

If an infection is **localized** (e.g., a wound infection), a patient usually experiences localized symptoms such as pain, tenderness, warmth, and redness at the wound site. An infection that affects the entire body instead of just a single organ or part is **systemic** and can become fatal if undetected and untreated.

The course of an infection influences the level of nursing care provided. The nurse is responsible for implementing infection control practices, properly administering antibiotics, monitoring the response to drug therapy (see [Chapter 31](#)), using proper hand hygiene, following Standard Precautions, and using Isolation Precautions when necessary. Supportive therapy includes providing adequate nutrition and rest to bolster defenses of the body against the infectious process. The course of care for the patient often has additional effects on body systems affected by the infection.

Defenses Against Infection

The body has natural defenses that protect against infection. Normal floras, body system defenses, and inflammation are all nonspecific defenses that protect against microorganisms regardless of prior exposure. If any of these body defenses fail, an infection usually occurs and leads to a serious health problem.

Normal Floras

The body normally contains microorganisms that reside on the surface and deep layers of skin, in the saliva and oral mucosa, and in the GI and GU tracts. A person normally excretes trillions of microbes daily through the intestines. Normal floras do not usually cause disease when residing in their usual area of the body but instead participate in maintaining health.

Normal floras of the large intestine exist in large numbers without causing illness. They also secrete antibacterial substances within the walls of the intestine. The normal floras of the skin exert a protective, bactericidal action that kills organisms landing on the skin. The mouth and pharynx are also protected by floras that impair growth of invading microbes. Normal floras maintain a sensitive balance with other microorganisms to prevent infection. Any factor that disrupts this balance places a person at increased risk for acquiring a disease. For example, the use of **broad-spectrum antibiotics** for the treatment of infection can lead to **suprainfection**. A suprainfection develops when broad-spectrum antibiotics eliminate a wide range of normal flora organisms, not just those causing infection. When normal bacterial floras are eliminated, body defenses are reduced, which allows disease-producing microorganisms to multiply, causing illness ([Arnold, 2018](#)).

Body System Defenses

A number of body organ systems have unique defenses against infection ([Table 28.2](#)). The skin, respiratory tract, and GI tract are easily accessible to microorganisms. Pathogenic organisms can adhere to the surface skin, be inhaled into the lungs, or be ingested with food. Each organ system has defense mechanisms physiologically suited to its specific structure and function. For example, the lungs cannot completely control the entrance of microorganisms. However, the airways are lined with moist mucous membranes and cilia, or hairlike projections, that rhythmically beat to move mucus or cellular debris up to the pharynx to be expelled through swallowing.

TABLE 28.2**Natural Defense Mechanisms Against Infection**

Defense Mechanisms	Action	Factors That May Alter Defense Mechanisms
Skin		
Intact multilayered surface (first line of defense against infection)	Provides barrier to microorganisms and antibacterial activity	Cuts, abrasions, puncture wounds, areas of maceration
Shedding of outer layer of skin cells	Removes organisms that adhere to outer layers of skin	Failure to bathe regularly, improper handwashing technique
Sebum	Contains fatty acid that kills some bacteria	Excessive bathing
Mouth		
Intact multilayered mucosa	Provides mechanical barrier to microorganisms	Lacerations, trauma, extracted teeth
Saliva	Washes away particles containing microorganisms Contains microbial inhibitors (e.g., lysozyme)	Poor oral hygiene, dehydration
Eye		
Tearing and blinking	Provides mechanisms to reduce entry (blinking) or help wash away (tearing) particles containing pathogens, thus reducing dose of organisms	Injury, exposure—splash/splatter of blood or other potentially infectious material into eye
Respiratory Tract		
Cilia lining upper airway, coated by mucus	Traps inhaled microbes and sweeps them outward in mucus to be expectorated or swallowed	Smoking, high concentration of oxygen and carbon dioxide, decreased humidity, cold air
Macrophages	Engulf and destroy microorganisms that reach alveoli of lung	Smoking
Urinary Tract		
Flushing action of urine flow	Washes away microorganisms on lining of bladder and urethra	Obstruction to normal flow by urinary catheter placement, obstruction from growth or tumor, delayed micturition
Intact multilayered epithelium	Provides barrier to microorganisms	Introduction of urinary catheter, continual movement of catheter in urethra can facilitate migration of organisms to bladder
Gastrointestinal Tract		
Acidity of gastric secretions	A gastric fluid pH of 1 to 2 is deleterious to many microbial pathogens	Administration of antacids Inhibition of acid secretion by various drugs
Rapid peristalsis in small intestine	Prevents retention of bacterial contents	Delayed motility resulting from impaction of fecal contents in large bowel or mechanical obstruction by masses
Vagina		
At puberty normal flora causing vaginal secretions to achieve low pH	Inhibit growth of many microorganisms	Antibiotics and oral contraceptives disrupting normal flora

Inflammation

The cellular response of the body to injury, infection, or irritation is termed *inflammation*. Inflammation is a protective vascular reaction that delivers fluid, blood products, and nutrients to an area of injury. The process neutralizes and eliminates pathogens or dead (necrotic) tissues and establishes a means of repairing body cells and tissues. Signs of localized inflammation include swelling, redness, heat, pain or tenderness, and loss of function in the affected body part. When inflammation becomes systemic, other signs and symptoms develop, including fever, increased

white blood cells (WBCs), malaise, anorexia, nausea, vomiting, lymph node enlargement, or organ failure.

Physical agents, chemical agents, or microorganisms trigger the inflammatory response. Mechanical trauma, temperature extremes, and radiation are examples of physical agents. Chemical agents include external and internal irritants such as harsh poisons or gastric acid. Sometimes microorganisms also trigger this response.

After tissues are injured, a series of well-coordinated events occurs. The inflammatory response includes vascular and cellular responses, formation of inflammatory exudates (fluid and cells that are discharged from cells or blood vessels [e.g., pus or serum]), and tissue repair.

Vascular and Cellular Responses

Acute inflammation is an immediate response to cellular injury. Rapid vasodilation occurs, allowing more blood to be delivered near the location of the injury. The increase in local blood flow causes the redness and localized warmth at the site of inflammation.

Injury causes tissue damage and possibly necrosis. As a result, the body releases chemical mediators that increase the permeability of small blood vessels, and fluid, protein, and cells enter interstitial spaces. The accumulation of fluid appears as localized swelling (edema). Another sign of inflammation is pain, which is caused by the swelling of inflamed tissues that increases pressure on nerve endings. As a result of the physiological inflammatory response, the involved body part may have a temporary loss of function. For example, a localized infection of the hand causes the fingers to become swollen, painful, and discolored. Joints become stiff because of swelling, but function of the fingers returns when inflammation subsides.

During the cellular response of inflammation, WBCs arrive at the site. WBCs pass through blood vessels and into the tissues. Phagocytosis is a process that involves the destruction and absorption of bacteria. Through the process of phagocytosis, specialized WBCs, called neutrophils and monocytes, ingest and destroy microorganisms or other small particles. If inflammation becomes systemic, other signs and symptoms develop. Leukocytosis, or an increase in the number of circulating WBCs, is the response of the body to WBCs leaving blood vessels. In the adult a serum WBC count is normally 5,000 to 10,000/mm³ but typically rises to 15,000 to 20,000/mm³ and higher during inflammation. Fever is caused by phagocytic release of pyrogens from bacterial cells, which causes a rise in the hypothalamic set point (see [Chapter 29](#)).

Inflammatory Exudate

Accumulation of fluid, dead tissue cells, and WBCs forms an exudate at the site of inflammation. Exudate may be serous (clear, like plasma), sanguineous (containing red blood cells), or purulent (containing WBCs and bacteria). Usually the exudate is cleared away through lymphatic drainage. Platelets and plasma proteins such as fibrinogen form a meshlike matrix at the site of inflammation to prevent its spread.

Tissue Repair

When there is injury to tissue cells, healing involves the defensive, reconstructive, and maturative stages (see [Chapter 48](#)). Damaged cells eventually are replaced with healthy new cells. The new cells undergo a gradual maturation until they take on the same structural characteristics and appearance as the previous cells. If inflammation is chronic, tissue defects sometimes fill with fragile granulation tissue that eventually takes the form of a scar at the completion of the healing process. The scar and surrounding tissues are not as strong as normal tissue and may be more susceptible to injury from pressure, shear, or friction, which increase the risk for pressure injury development (see [Chapter 48](#)).

Health Care–Associated Infections

Patients in health care settings, especially hospitals and long-term care facilities, have an increased risk of acquiring infections. **Health care–associated infections (HAIs)** result from the delivery of health services in a health care agency. They occur as the result of invasive procedures, antibiotic administration, the presence of **multidrug-resistant organisms (MDROs)**, and breaks in infection prevention and control activities. The number of health care employees having direct contact with a patient, the type and number of invasive procedures, the therapy received, and the length of hospitalization further influence the risk of infection. Major sites for HAIs include surgical or traumatic wounds, urinary and respiratory tracts, and the bloodstream ([Box 28.3](#)).

Box 28.3 Examples of Sites for and Causes of Health Care–Associated Infections

Improperly performing hand hygiene increases patient risk for all types of health care–associated infections.

Urinary Tract

- Unsterile insertion of urinary catheter
- Improper positioning of the drainage tubing
- Open drainage system
- Catheter and tube becoming disconnected
- Drainage bag port touching contaminated surface
- Improper specimen collection technique
- Obstructing or interfering with urinary drainage
- Urine in catheter or drainage tube being allowed to reenter bladder (reflux)
- Repeated catheter irrigations
- Improper perineal hygiene

Surgical or Traumatic Wounds

- Improper skin preparation before surgery (e.g., shaving versus clipping hair; not performing a preoperative bath or shower)
- Failure to clean skin surface properly
- Failure to use aseptic technique during operative procedures and dressing changes
- Use of contaminated antiseptic solutions

Respiratory Tract

- Contaminated respiratory therapy equipment
- Failure to use aseptic technique while suctioning airway
- Improper disposal of secretions

Bloodstream

- Contamination of intravenous (IV) fluids by tubing
- Insertion of drug additives to IV fluid
- Addition of connecting tube or stopcocks to IV system

- Improper care of needle insertion site
- Contaminated needles or catheters
- Failure to change IV access at first sign of infection or at recommended intervals
- Improper technique during administration of multiple blood products
- Improper care of peritoneal or hemodialysis shunts
- Improperly accessing an IV port

HAI significantly increase the cost of health care. This is especially true in older adults, who have increased susceptibility to these infections because of their affinity to chronic disease and the aging process ([Box 28.4](#)). Extended stays in health care institutions, increased disability, increased costs of antibiotics, and prolonged recovery times add to the expenses both of the patient and the health care institution and funding bodies (e.g., Medicare). Costs for HAIs are often not reimbursed; as a result, prevention has a beneficial financial impact and is an important part of patient care. TJC lists several national safety goals focusing on the care of older adults (e.g., ensuring that older adults receive influenza and pneumonia vaccines, preventing infection after surgery) ([TJC, 2020](#)).

Box 28.4 Focus on Older Adults Risks for Infection

- An age-related functional deterioration in immune system function, termed immune senescence, increases the susceptibility of the body to infection and slows overall immune response (Meiner and Yeager, 2019; Pawelec, 2018).
- Older adults are less capable of producing lymphocytes to combat challenges to the immune system. When antibodies are produced, the duration of their response is shorter, and fewer cells are produced (Roach, 2018).
- Risks associated with the development of infections or health care-associated infections in older patients include poor nutrition, unintentional weight loss, lack of exercise, poor social support, and low serum albumin levels (Meiner and Yeager, 2019).
- Flu and pneumonia vaccinations are recommended for the older adult population to reduce their risk for infectious diseases.

- Teach older adults and their families how to reduce the risk for infections by using proper hand hygiene practices.

Patients who develop HAIs often have multiple illnesses, are older adults, or are poorly nourished and may have a compromised immune system; thus, they are more susceptible to infections. In addition, many patients have a lowered resistance to infection because of underlying medical conditions (e.g., diabetes mellitus or cancer) that impair or damage the immune response of the body. Invasive treatment devices such as IV catheters or indwelling urinary catheters impair or bypass the natural defenses of the body against microorganisms. Critical illness increases patients' susceptibility to infections, especially multidrug-resistant bacteria. Meticulous hand hygiene practices, the use of chlorhexidine washes for bathing and personal hygiene care, advances in intensive care unit (ICU) infection prevention, and the creation of evidence-based bundles help to prevent these infections ([Donskey and Deshpande, 2016](#); [Mehta et al., 2014](#)).

HAI infections are either exogenous or endogenous. An **exogenous infection** comes from microorganisms found outside the individual, such as *Salmonella*, *Clostridium tetani*, and *Aspergillus*. These microorganisms do not exist as normal floras. An **endogenous infection** occurs when part of the patient's flora becomes altered and an overgrowth occurs (e.g., staphylococci, enterococci, yeasts, and streptococci). This often happens when a patient receives broad-spectrum antibiotics that alter the normal floras. When sufficient numbers of microorganisms normally found in one body site move to another site, an endogenous infection develops. The number of microorganisms needed to cause an HAI depends on the virulence of the organism, the susceptibility of the host, and the body site affected.

Iatrogenic infections are a type of HAI caused by an invasive diagnostic or therapeutic procedure. For example, procedures such as a bronchoscopy and treatment with broad-spectrum antibiotics increase the risk for certain infections ([Arnold, 2018](#); [Day, 2018](#)). Use critical thinking when practicing aseptic techniques during the performance of procedures. Follow basic infection prevention and control policies and procedures to reduce the risk of HAIs. Always consider the patient's risks for infection and anticipate how the approach to care increases or decreases the risk.

REFLECT NOW

What are the nursing strategies you can use to break the chain of infection when you care for a patient at risk for a urinary tract infection?

Nursing Knowledge Base

Body substances such as feces, urine, and wound drainage contain potentially infectious microorganisms. Health care workers are at risk for exposure to microorganisms in the hospital and/or home setting (Fiutem, 2018). The meticulous use of specific infection prevention practices reduces the risk of cross-contamination and transmission of infection to noninfected patients when caring for a patient with a known or suspected infection.

Serious infections are ongoing challenges to clinicians, and they create feelings of anxiety, frustration, loneliness, and anger in patients and/or their families (Nesher et al., 2014). These feelings worsen when patients are isolated to prevent transmission of a microorganism to other patients or health care staff. Isolation disrupts normal social relationships with visitors and caregivers. Patient safety is usually an additional risk for a patient on isolation precautions (Monsees, 2018). For example, an older patient with a chronic illness is more at risk for an HAI. When family members fear the possibility of developing the infection, they may avoid contact with the patient. Some patients perceive the simple procedures of proper hand hygiene and gown and glove use as evidence of rejection. Help patients and families reduce some of these feelings by discussing the disease process; explaining isolation procedures; and maintaining a friendly, understanding manner.

When establishing a plan of care, it is important to know how a patient reacts to an infection or infectious disease. The challenge is to identify and support behaviors that maintain human health or prevent infection.

Factors Influencing Infection Prevention and Control

Multiple factors influence a patient's susceptibility to infection. It is important to understand how each of these factors alone or in combination increases this risk. When more than one factor is present, a patient's susceptibility often increases, which affects length of stay, recovery time, and/or overall level of health following an illness. Understanding these factors helps you to assess and care for a patient who has an infection or is at risk for one.

Age

Throughout life a person's susceptibility to infection changes. For example, an infant has immature defenses against infection. Born with only the antibodies provided by the mother, an infant's immune system is incapable of producing the necessary immunoglobulins and WBCs to adequately fight some infections. However, breastfed infants often have greater immunity than bottle-fed infants because they receive their mother's antibodies through the breast milk. As the child grows, the immune system matures but the child is still susceptible to organisms that cause the common cold, intestinal infections, and infectious diseases such as mumps, measles, and chickenpox (if not vaccinated). Since 2000, there has been a major effort to vaccinate all children against all infectious diseases for which vaccines are available. Vaccine-preventable disease levels are at or near record lows ([CDC, 2018c](#)).

The young or middle-age adult has refined defenses against infection. Viruses are the most common cause of communicable illness in young or middle-age adults. Young women are most likely to develop urinary tract infections (UTIs), vaginal yeast infections, and human papillomavirus (HPV). Although UTIs are relatively uncommon in men, prostatitis (infection of the prostate gland) affects men of all ages but tends to be more common in men 50 or younger ([Mayo Clinic, 2018](#)).

Defenses against infection change with aging ([Roach, 2018](#)). The immune response, particularly cell-mediated immunity, declines. Older adults also undergo alterations in the structure and function of the skin, urinary tract, and lungs. For example, the skin loses its turgor, and the epithelium thins. As a result, it is easier to tear or abrade the skin, which increases the potential for invasion by pathogens. In addition, older adults who are hospitalized or reside in an assisted-living or residential care facility are at risk for airborne infections. Ensuring that health care workers are vaccinated against influenza reduces the transmission of this illness in older adults ([Thomas et al., 2013](#)).

Sex

Women and men differ in their immune responses to infections. This applies to infections with viruses, bacteria, and parasites, including the pathogens such as malaria, TB, AIDS, hepatitis, and influenza ([Lunzen and Altfeld, 2014](#)). Only recently have the biological pathways responsible for these sex-based differences in the manifestations of infectious diseases been researched. Besides genetic factors, these differences can be explained through the greatly divergent and changing levels of sex steroid hormones and their interplay with the immune system. Estrogens promote (but

androgens suppress) immune responses during infections and after vaccination. They also increase the risk for autoimmune diseases (Giefing-Kröll, et al., 2015). In vaccinated adults, sex-related differences have been observed in immunogenicity (ability of an antigen to provoke an immune response in the body of a human) and clinical effectiveness of influenza, pneumococcal polysaccharide, hepatitis A and B, tetanus, diphtheria, measles, rabies, and smallpox vaccines (Giefing-Kröll, et al., 2015).

Nutritional Status

A patient's nutritional health directly influences susceptibility to infection. A reduction in the intake of protein and other nutrients such as carbohydrates and fats reduces body defenses against infection and impairs wound healing (see Chapter 48). Patients with illnesses or problems that increase protein requirements, such as extensive burns and febrile conditions, are at further risk. For example, patients who have undergone surgery require increased protein. A thorough diet history is necessary. Determine a patient's normal daily nutrient intake and whether preexisting problems such as nausea, impaired swallowing, or oral pain alter food intake. Confer with a registered dietitian to assist in calculating the calorie count of foods ingested.

Stress

The body responds to emotional or physical stress by the general adaptation syndrome (see Chapter 37). During the alarm stage the basal metabolic rate increases as the body uses energy stores.

Adrenocorticotrophic hormone increases serum glucose levels and decreases unnecessary antiinflammatory responses through the release of cortisone. If stress continues or becomes intense, elevated cortisone levels result in decreased resistance to infection. Continued stress leads to exhaustion, which causes depletion in energy stores, and the body has no resistance to invading organisms. The same conditions that increase nutritional requirements, such as surgery or trauma, also increase physiological stress.

Disease Process

Patients with diseases of the immune system are at particular risk for infection. Leukemia, AIDS, lymphoma, and aplastic anemia are conditions that compromise a host by weakening defenses against infectious organisms. For example, patients with leukemia are unable to produce

enough WBCs to fight off infection. Patients with HIV are often unable to ward off simple infections and are prone to opportunistic infections.

Patients with chronic diseases such as diabetes mellitus and multiple sclerosis are also more susceptible to infection because of general debilitation and nutritional impairment. Diseases that impair body system defenses such as emphysema and bronchitis (which impair ciliary action and thicken mucus), cancer (which alters the immune response), and peripheral vascular disease (which reduces blood flow to injured tissues) increase susceptibility to infection. Patients with burns have a high susceptibility to infection because of the damage to skin surfaces. The greater the depth and extent of the burns, the higher is the risk for infection.

REFLECT NOW

Consider the care of an older adult patient who is receiving chemotherapy for a recent cancer diagnosis. What risk factors for infection would you need to address when planning care for this patient?

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ Assessment

Perform a thorough assessment of each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care. You will assess a patient's current condition as well as review any history of previous health problems involving infection. As you conduct your assessment, apply knowledge of the infectious process and the patient's diagnosed medical problem(s) to focus on your physical examination.

Through the Patient's Eyes

Determine how the patient feels about his or her illness or risk for infection. Has the patient had experiences in the past that will affect expectations for care? For example, a patient undergoing a second surgical procedure might have different expectations than a first-time surgery patient regarding the prevention of wound infection. Assess a patient's knowledge of his or her risk factors that increase the susceptibility for developing an infection ([Table 28.3](#)) to help you plan appropriate patient education.

TABLE 28.3**Host Characteristics Influencing Susceptibility To and Severity of Disease**

Characteristic	Examples
Age	"Childhood diseases" (e.g., measles, chickenpox) are seen more frequently in children, whereas chronic diseases, such as heart disease or chronic obstructive pulmonary disease, occur more frequently in older patients.
Sex	Reproductive diseases are sex-specific. Sex influences immune response and susceptibility to certain infections.
Ethnicity	Tay-Sachs disease occurs in Jews of European descent.
Socioeconomic status	Socioeconomic status influences the ability to purchase food, pay for immunizations, and obtain health care services
Marital status	Some studies of stress-related diseases have shown marital status to be a factor influencing susceptibility.
Lifestyle	Homelessness increases susceptibility due to poor nutrition and exposure to pathogens.
Heredity	Sickle cell anemia influences susceptibility.
Nutritional status	Inadequate nutrition reduces immune function.
Occupation	Coal miners are at risk for black lung. Prison guards or social workers involved with immigrants or asylum seekers originating from areas with a high tuberculosis (TB) prevalence are at risk for contacting TB.
Immunization status	Those who have not been vaccinated for measles are at risk for the disease.
Diagnostic/therapeutic procedures	Transplant patients have an increased risk of infection.
Medications	Steroid use increases the risk of infection.
Pregnancy	Tuberculosis-positive women who are pregnant are more likely to reactivate.
Trauma	Injury may provide a portal of entry for organisms and triggers an inflammatory response that may increase the risk of infection.

Modified from Tweeten SM: General principles of epidemiology. In Grota P, editor: *APIC text of infection control and epidemiology*, Washington, DC, 2018, Association for Professionals in Infection Control and Epidemiology.

Some patients with infection have a variety of problems, including physical, psychological, social, or economic needs. Patients with chronic or serious infection, especially communicable infections such as TB or AIDS, experience psychological and social problems from self-imposed isolation or rejection by friends and family. Ask the patient how an infection affects the ability to maintain relationships and perform activities of daily living. Determine whether chronic infection has drained the patient's financial resources. Ask about his or her expectations of care (e.g., how a procedure should be performed) and determine how much he or she wants to be involved in planning care. Some patients and their families wish to know

more about the disease process, whereas others only want to know the interventions necessary to treat the infection. Encourage patients to verbalize their expectations so that you are able to establish interventions to meet patients' priorities.

Risk Factors

A review of a patient's clinical condition can begin with the identification of risk factors. Ask specific questions to determine the patient's and family's awareness of any risks for infection (Box 28.5). Assess the patient's age, nutritional status, presence of chronic illnesses or stress, and presence of disease processes to identify factors that influence susceptibility to infection. Gather information about each factor through your interview and the patient's medical history.

Box 28.5 Nursing Assessment Questions

Risk Factors

- Do you have any recent cuts or lacerations? Show me the location.
- Describe for me any illnesses or diseases that you have and those for which you receive treatment.
- Tell me about any recent diagnostic testing you have undergone, such as colonoscopy or cystoscopy?

Possible Existing Infections

- Do you have or feel as if you have a fever?
- Do you have any cuts or wounds with drainage?
- Do you have any pain/burning during urination?
- Do you have a cough? Is there any sputum?

Recent Travel History

- Have you traveled outside the United States in the past 6 months?

- Are you a resident of or have you traveled within the past 21 days to a country where an Ebola outbreak is occurring (CDC, 2015b)?
- Were any of the people you visited or traveled with ill?

Medication History

- List for me the medications you are currently taking.
- Describe for me the doses of each medication you are supposed to take daily.
- Describe any over-the-counter medications or herbals that you are currently taking.

Stressors

- Tell me about any major lifestyle change occurring, such as the loss of employment or place of residence, divorce, or disability.

Clinical Appearance

Perform a physical assessment (see [Chapter 30](#)) of a patient, examining areas involved in an infection as well as areas where risk of infection exists. The signs and symptoms of infection may be local or systemic. Localized infections are most common in areas of skin or mucous membrane breakdown, such as surgical and traumatic wounds, pressure injuries, oral lesions, and abscesses.

To assess an area for localized infection, first inspect it for redness, warmth, and swelling caused by inflammation. Because there may be drainage from open lesions or wounds, wear clean gloves. Infected drainage may be yellow, green, or brown depending on the pathogen. For example, green nasal secretions often indicate a sinus infection. Ask the patient about pain or tenderness around the site. Some patients complain of tightness and pain caused by edema. If the infected area is large enough, movement is restricted. Gentle palpation of an infected area usually results in some degree of tenderness. Wear protective eyewear and a surgical mask when there is a risk for splash or spray with blood or body fluids.

Systemic infections cause more generalized symptoms than local infection. These symptoms often include fever, fatigue, nausea/vomiting,

and malaise. Lymph nodes that drain the area of infection often become enlarged, swollen, and tender during palpation. For example, an abscess in the peritoneal cavity causes enlargement of lymph nodes in the groin. An infection of the upper respiratory tract causes cervical lymph node enlargement. If an infection is serious and widespread, all major lymph nodes may enlarge.

Systemic infections sometimes develop after treatment for localized infection has failed. Be alert for changes in a patient's level of activity and responsiveness. As systemic infections develop, an elevation in body temperature can lead to episodes of increased heart and respiratory rates and low blood pressure. Involvement of major body systems produces specific symptoms. For example, a pulmonary infection results in a productive cough with purulent sputum. A UTI results in cloudy, foul-smelling urine.

An infection does not always present with typical signs and symptoms in all patients. For example, in some older adults an infection may be advanced before it is identified. Because of the aging process, there is a reduced inflammatory and immune response. Older adults have increased fatigue and diminished pain sensitivity. A reduced or absent fever response often occurs from chronic use of aspirin or nonsteroidal antiinflammatory drugs. Atypical symptoms such as confusion, incontinence, or agitation may be the only symptoms of an infectious illness (Roach, 2018). For example, as many as 20% of older adults with pneumonia do not have the typical signs and symptoms of fever, shaking, chills, and colored productive sputum. Often the only symptoms are an unexplained increase in heart rate, confusion, or generalized fatigue. A pneumonia vaccine is available and recommended for all people with chronic respiratory problems and those over 65 years of age.

Status of Defense Mechanisms

As you conduct your physical assessment, determine the status of normal defense mechanisms against infection. For example, any break in the skin such as an ulcer on the foot of a patient who has diabetes is a potential site for infection. Any reduction in the primary or secondary defenses of the body against infection such as a weakened ability to cough places a patient at increased risk.

Medical Therapy

Some drugs and medical therapies compromise immunity, increasing the risk for infection. Assess your patient's medication history to determine whether he or she takes any medications that increase infection susceptibility (see [Box 28.5](#)). This includes any over-the-counter medications and herbal supplements. A review of therapies received within the health care setting further reveals risks. For example, adrenal corticosteroids, prescribed for several conditions, are antiinflammatory drugs that cause protein breakdown and impair the inflammatory response against bacteria and other pathogens. Corticosteroids and TNF (tumor necrosis factor) inhibitors are two medications that increase the chance of getting a fungal infection ([CDC, 2017e](#)). Cytotoxic and antineoplastic drugs attack cancer cells but also cause the side effects of bone marrow depression and normal cell toxicity, which affects the response of the body against pathogens.

Travel History

Conduct a review of a patient's recent travel history to determine possible exposure to communicable diseases. Also assess if any immediate family members have traveled and presented risks to the patient (see [Box 28.5](#)). A person's exposure depends on the presence of infectious agents in the area visited. The risk of becoming infected will vary according to the purpose of the trip and the itinerary within the area; the standards of accommodation, hygiene, and sanitation; and the behavior of the traveler ([WHO, 2019a](#)).

Laboratory Data

Review laboratory data as soon as the results are available. Laboratory values such as increased WBCs and/or a positive blood culture often indicate infection ([Table 28.4](#)). However, laboratory values are not enough to detect infection. It is possible that a contaminated specimen was collected because of poor technique (e.g., a blood sample is mixed with IV fluid because it is improperly collected from an indwelling line; a urine specimen is contaminated because of poor perineal cleansing). You need to assess other clinical signs of infection. A culture result may show growth of an organism in the absence of infection. For example, in the older adult bacterial growth in urine without clinical symptoms does not always indicate the presence of a UTI ([Roach, 2018](#)). Also know that laboratory values often vary from laboratory to laboratory. Be sure to know the standard range of laboratory values for the laboratory in your facility.

TABLE 28.4**Laboratory Tests To Screen for Infection**

Laboratory Value	Normal (Adult) Values	Indication of Infection
White blood cell (WBC) count	5000-10,000/mm ³	Increased in acute infection, decreased in certain viral or overwhelming infections
Erythrocyte sedimentation rate	Up to 15 mm/hr for men and 20 mm/hr for women	Elevated in presence of inflammatory process
Iron level	80-180 mcg/mL for men 60-160 mcg/mL for women	Decreased in chronic infection
Cultures of urine and blood	Normally sterile, without microorganism growth	Presence of infectious microorganism growth
Cultures and Gram stain of wound, sputum, and throat	No WBCs on Gram stain, possible normal flora	Presence of infectious microorganism growth and WBCs on Gram stain
Differential Count (Percentage of Each Type of White Blood Cell)		
Neutrophils	55%-70%	Increased in acute suppurative (pus-forming) infection, decreased in overwhelming bacterial infection (older adult)
Lymphocytes	20%-40%	Increased in chronic bacterial and viral infection, decreased in sepsis
Monocytes	2%-8%	Increased in protozoan, rickettsial, and tuberculosis infections
Eosinophils	1%-4%	Increased in parasitic infection
Basophils	0.5%-1.5%	Normal during infection

Adapted from Pagana KD, et al: *Mosby's diagnostic and laboratory test reference*, ed 13, St Louis, 2017, Elsevier.

REFLECT NOW

What questions would you ask a patient who just returned from a mission trip from another country when assessing for a possible infection?

• Nursing Diagnosis

During assessment gather objective data such as inspection of an open incision or a reduced caloric intake record and subjective data such as a patient's complaint of tenderness over a surgical wound site. Review the data carefully, looking for clusters of assessment findings or risk factors that create a pattern. This pattern suggests a specific nursing diagnosis

(Box 28.6). The following are examples of nursing diagnoses that often apply to patients with infection:

Box 28.6 Nursing Diagnostic Process **Risk for Infection**

Assessment Activities	Assessment Findings
Check results of laboratory tests.	WBC count 5000/mm ³
Review current medications.	Patient receiving antibiotics and oral antidiabetic medications
Identify potential sites of infection.	IV catheter in right forearm, in place for 3 days Foley catheter draining cloudy amber-colored urine

IV, Intravenous; WBC, white blood cell.

- *Risk for Infection*
- *Impaired Nutritional Status: Deficient Food Intake*
- *Impaired Oral Mucous Membrane*
- *Social Isolation*
- *Impaired Tissue Integrity*

It is necessary to validate data such as inspecting the integrity of a wound more carefully and to review laboratory findings to confirm a diagnosis. Success in planning appropriate nursing interventions depends on the accuracy of the diagnostic statement and the ability to meet the patient's needs. A patient will have assessment findings for a problem-focused or a negative diagnosis. You individualize the diagnosis with the addition of an accurate *related* factor in the diagnostic statement. For example, minimizing the risk for infection in a patient with a diagnosis of *Impaired Oral Mucous Membrane related to mouth breathing* requires frequent and proper oral hygiene measures. Minimizing the risk for infection in a patient with a nursing diagnosis of *Impaired Nutritional Status: Deficient Food Intake related to inability to absorb nutrients* requires good nutritional support and fluid balance. At-risk diagnoses such as *Risk for Infection* require careful identification of relevant risk factors.

Planning

Goals and Outcomes

The patient's care plan is based on each nursing diagnosis and any related or risk factors (see the [Nursing Care Plan](#)). Develop a plan that sets realistic outcomes, so interventions are purposeful, direct, and measurable. For example, when you care for a patient with broken skin and obesity, the nursing diagnosis of *Risk for Infection* requires you to implement skin and wound care measures to promote healing. The expected outcome of "absence of drainage" sets an expected outcome for measuring the patient's improvement. A goal for this situation would be "Patient remains free of infection at discharge." Additional goals of care applicable to patients with infection often include the following:

- Preventing further exposure to infectious organisms
- Controlling or reducing the extent of infection
- Maintaining resistance to infection
- Verbalizing understanding of infection prevention and control techniques (e.g., hand hygiene)

REFLECT NOW

How would you begin setting goals with a patient in the hospital who is experiencing an infection?

Patients often have multiple nursing diagnoses that are interrelated, and one diagnosis often affects other diagnoses. A concept map for the patient, Mrs. Andrews, helps to show the relationships among multiple nursing diagnoses ([Fig. 28.2](#)).

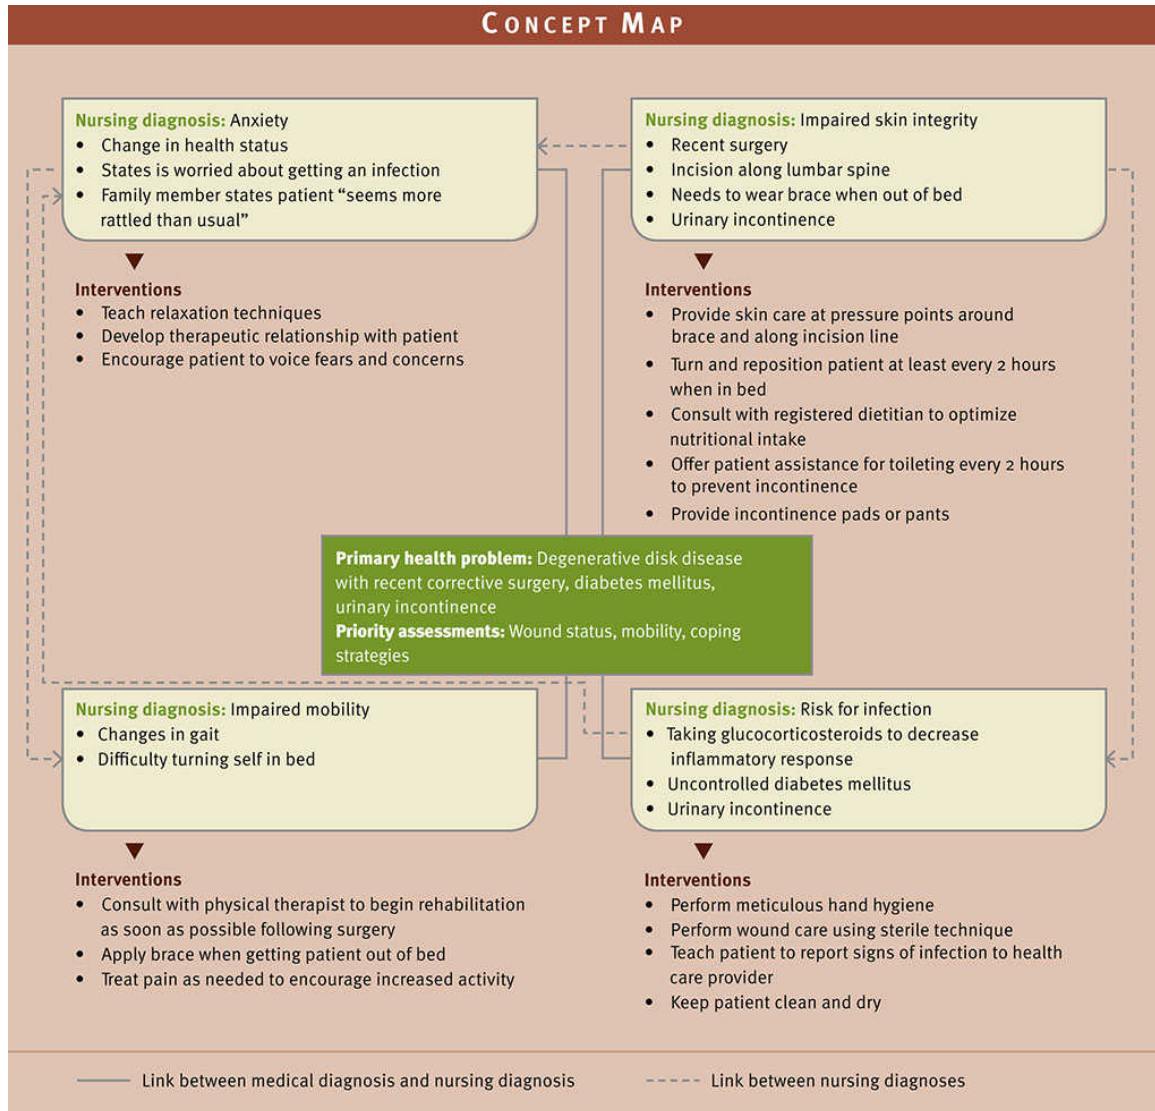

FIG. 28.2 Concept map for Mrs. Andrews.

Setting Priorities

Establish priorities for each diagnosis and related goals of care. For example, you are caring for a patient with cancer who develops an open wound and is unable to tolerate solid foods. The priority of administering therapies to promote wound healing such as improved nutritional intake overrides the goal of educating the patient to assume self-care therapies at home. When the patient's condition improves, the priorities change, and patient education will then become an essential intervention. Patient priorities change quickly, especially in the acute care environment. In the home setting, priorities may remain appropriate for weeks at a time.

Teamwork and Collaboration

The development of a care plan includes prevention and infection control practices provided by multiple disciplines. Select interventions in collaboration with the patient, the family caregiver, and health care providers such as the registered dietitian or respiratory therapist. Know the patient's sociocultural preferences to help you identify the most appropriate types of interventions (Box 28.7). In addition, consult with an expert in infection control in planning the patient's care. Before discharge, consult with case management to complete a home assessment and identify home health needs. Case managers work with the patient, family, and home care services to ensure that the transition from the hospital goes smoothly and that a safe discharge plan is in place.

Box 28.7 Cultural Aspects of Care Implications for Infection Control and Isolation Procedures

IV, Intravenous.

Various cultural practices and beliefs present challenges to health care providers when infection control and isolation procedures are needed. Patients' health care practices and beliefs influence their decisions to seek treatment for an infection or to use methods to prevent infections. In the United States cities and rural areas have immigrant populations that hold on to the health care practices of their countries of origin. Some members of the immigrant population may come from war-torn countries where health care was limited and infections were rampant. In addition, some of these patients may fear isolation equipment, which for some may indicate that they have a deadly disease or that harm will come to them or their families. It is important to meet the cultural needs of the patients but also to integrate best practices related to infection control and, when needed, isolation procedures. Although gender-congruent caregivers are important for many cultures, the cultural aspects of care for infection control must expand beyond that premise (San Patten and Associates, 2016).

Implications for Patient-Centered Care

- Assess a patient's literacy level and identify the best method for communication and patient teaching for the patient and family. This

may include a community elder, an interpreter, or a family member.

- Determine initially whether the patient has any signs of fear, anxiety, or confusion about his condition and treatment plan.
- Reinforce that infection control and isolation procedures are designed for patient safety. Use simple language to explain.
- Explain each item used for infection control and isolation procedures, and obtain feedback from the patient to determine his or her level of understanding.
- Be aware that in some cultures touch from a person who is not a family member is not appropriate. Prepare the patient by explaining why you need to touch; when possible, ask permission. For example, say, "I need to check your arm that has an IV line. May I do that now?"
- If the patient seems fearful of the isolation equipment, continually reinforce why you are wearing the equipment.
- Culturally sensitive care is necessary to identify unique approaches to help patients who are on isolation precautions to understand why the precautions are necessary, answer any questions, and allay patient's and/or family's fear.

When care continues into the patient's home, the home health nurse plans to ensure that the home environment supports good infection prevention and control practices. For example, if a patient does not have running water yet requires wound care, even simple hand hygiene with soap and water is difficult to achieve. Home health nurses instruct patients to perform hand hygiene with either bottled water and soap or alcohol-based hand products. In addition, in the home it is common to use clean instead of sterile asepsis. Consult with the patient's health care provider if you have questions about proper aseptic technique.

• Implementation

By identifying relevant nursing diagnoses and implementing a plan of care with appropriate evidence-based measures, you can effectively reduce the risk of infection.

Health Promotion

Use your critical thinking skills to prevent an infection from developing or spreading. In the home and community settings, review with and teach

patients and their family caregivers about ways to strengthen a potential host's defenses against infection. Nutritional support, rest, personal hygiene, maintenance of physiological protective mechanisms, and recommended immunizations protect patients. Explain how to perform infection prevention and control principles such as hand hygiene and methods for proper disposal of medical waste. Based on your assessment of a patient's cultural practices, integrate infection prevention and control measures into the patient's daily lifestyle practices.

Nutrition

Nutritional requirements for your patients will vary depending on their age and condition. A proper diet helps the immune system function and consists of a variety of foods from all food groups (see [Chapter 45](#)). Collaborate with registered dietitians, the patient, and the family to select the correct foods. Recommend ways to prepare foods that the patient will enjoy. Teach patients the importance of a proper diet in maintaining immunity and preventing infection.

Hygiene

Personal hygiene measures (see [Chapter 40](#)) reduce microorganisms on the skin and maintain the integrity of mucous membranes such as the mouth and vagina. Patients and family caregivers need to understand techniques for cleansing the skin and how to avoid the spread of microorganisms in body secretions or excretions. For example, teach female patients how to wash their perineum from clean to dirty, from the urethra down toward the rectum, using a clean washcloth with each wipe. Another example is to teach patients the proper technique to cleanse around a wound (see [Chapter 48](#)).

Nursing Care Plan

Risk for Infection

Assessment

Mrs. Andrews has diabetes mellitus, urinary incontinence, and degenerative disk disease. She had surgery on her lower spine yesterday and is now experiencing pain along her incision and difficulty walking. Mrs. Andrews needs to wear a brace when she is out of bed and needs an

incisional dressing change because of contamination from urinary incontinence. The health care provider removes the dressing, leaving the incision open to air. The physical therapist plans to help Mrs. Andrews transfer to a chair after breakfast.

Assessment Activities	Assessment Findings ^a
Review Mrs. Andrews' chart for laboratory data that reflects infection (e.g., white blood cell [WBC] count).	The WBC count is 9500/mm ³ .
Inspect incision area.	Incision edges are slightly pink; edges approximated but edematous; no drainage noted.
Review risk factors for infection.	Has had diabetes mellitus for past 16 years; states blood sugars have been "poorly controlled" for the past year. Dietary assessment reflects malnutrition before surgery. Is taking a glucocorticosteroid , which reduces inflammation and suppresses the immune system.

^a **Assessment Findings** are shown in bold type.

Nursing Diagnosis:

Risk for infection

Planning

Goals	Expected Outcomes (NOC) ^b
	<i>Immune Status</i>
Mrs. Andrews will remain free from symptoms of infection.	Mrs. Andrews has no signs or symptoms of infection (e.g., remains afebrile; incision intact; edges approximated; no redness, swelling, or drainage).
	<i>Knowledge: Infection Management</i>
Mrs. Andrews will describe ways to prevent infection before discharge.	Mrs. Andrews demonstrates appropriate hand hygiene before discharge. Mrs. Andrews identifies who will help assess incisional site when she goes home.

^b Outcome classification labels from Moorhead S, et al.: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Interventions (NIC) ^c	
Infection Protection	Rationale
Teach Mrs. Andrews how to perform hand hygiene correctly.	Meticulous hand hygiene reduces bacterial counts on the hands (Hass, 2018). Patient can easily come in contact with organisms in the health care environment that can cause infection.
Monitor Mrs. Andrews frequently to prevent urine contamination of the incision site. Provide Mrs. Andrews with incontinence panties that she wears at home.	Offer bedpan/restroom hourly to decrease risk for incontinence. Absorbent padding will wick away urine from Mrs. Andrew's incision.
Help Mrs. Andrews identify a family member to check the incision until it is healed and teach Mrs. Andrews and the family member signs and symptoms of infection.	Mrs. Andrews will be unable to visualize incision since it is on her back; she will need a family member to help monitor healing of the surgical site.

^c Intervention classification labels from Butcher HK, et al.: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Compare Mrs. Andrews' body temperature with baseline.	Mrs. Andrews has an oral temperature of 38°C (100.4°F).	Mrs. Andrews is suspected to have infection at this time.
Ask Mrs. Andrews to describe signs and symptoms to report to health care provider.	Mrs. Andrews is unable to identify temperature range to report; unable to identify signs of wound infection.	Mrs. Andrews has minimal understanding of signs and symptoms to report. Will require additional instruction and include an information sheet on signs and symptoms of infection. Family member caring for Mrs. Andrews incision will also need instruction on signs and symptoms to report.
Observe for signs of infection at incisional site (e.g., redness, warmth, and wound discharge).	Incision shows signs of infection: redness, warmth, and a small amount of tan drainage.	Incision is showing signs of infection at this time.

Immunization

The CDC's Advisory Committee on Immunization Practices recommends routine vaccination by age 24 months against 14 potentially serious

illnesses (CDC, 2018). Immunization programs for infants and children have historically decreased the occurrence of childhood diphtheria, whooping cough, and measles. In 2017, coverage with most recommended vaccines among children 19 to 35 months of age remained stable and high, but coverage was lower in more rural areas and among children who were uninsured or on Medicaid (CDC, 2018). A small but increasing proportion of children received no vaccines by age 24 months (CDC, 2018d).

More recently developed vaccines for meningococcal pneumonia and rotavirus provide immunity to adults and children. Another important vaccine for adults is the shingles vaccine. Recombinant zoster vaccine (RZV, Shingrix) has been in use since 2017 and is recommended by the CDC's Advisory Committee on Immunization Practices (ACIP) as the preferred shingles vaccine (CDC, 2018f). Inform patients that their risk of shingles and **postherpetic neuralgia** (PHN) increases as they get older and that just because they may have had shingles does not mean they cannot acquire the virus a second time. Advise parents about the advantages of immunizations but also make them aware of the contraindications for certain vaccines, especially in pregnant and lactating women. You can access the most current immunization schedules at <http://www.cdc.gov/vaccines/schedules/hcp/index.html>.

Adequate Rest and Regular Exercise

Adequate rest and regular exercise help prevent infection. Physical exercise increases lung capacity, circulation, energy, and endurance. It also decreases stress and improves appetite, sleeping, and elimination. Help patients with a schedule that balances regular exercise with the need for rest and sleep.

Acute Care

Treatment of an infectious process includes eliminating the infectious organisms and supporting a patient's defenses. To identify the causative organisms, you will collect specimens of body fluids such as sputum or drainage from infected body sites for lab cultures. When the disease process or causative organism is identified, the health care provider prescribes the most effective treatment (e.g., antimicrobials).

Systemic infections require measures to prevent complications of fever (see **Chapter 29**). Maintaining intake of fluids prevents dehydration resulting from diaphoresis. The patient's increased metabolic rate requires

an adequate nutritional intake, which may be provided through IV parenteral nutrition. Rest preserves energy for the healing process.

Localized infections often require measures to assist removal of debris to promote healing. You apply principles of wound care to remove infected drainage from wound sites and support the integrity of healing wounds (see [Chapter 48](#)). When changing a dressing, wear a mask and goggles or a mask with a face shield if splashing or spraying with blood or body fluids is anticipated. Apply gloves to reduce the transmission of microorganisms into the wound. Apply special dressings to facilitate removal of drainage and promote healing of wound margins. Sometimes a surgeon will insert drainage tubes to remove infected drainage from body cavities (see [Chapter 48](#)). Use medical and surgical aseptic techniques appropriately to manage wounds and ensure correct handling of all drainage or body fluids.

During the course of infection, support the patient's body defense mechanisms. For example, if a patient has diarrhea, maintain skin integrity by frequent cleansing of the skin, application of a skin-barrier cream, and frequent repositioning to prevent breakdown and the entrance of additional microorganisms. Other routine hygiene measures such as cleaning the oral cavity and bathing protect the skin and mucous membranes from invasion and overgrowth of organisms.

Medical Asepsis

Asepsis is the absence of pathogenic (disease-producing) microorganisms. Aseptic technique refers to the practices/procedures that help reduce the risk for infection. The two types of aseptic technique are medical and surgical asepsis. Basic medical aseptic techniques break the chain of infection. Use these techniques for all patients, even when no infection is diagnosed. Aggressive preventive measures are highly effective in reducing HAIs. Hand hygiene, barrier techniques, and routine environmental cleaning are examples of **medical asepsis**. Principles of medical asepsis are also commonly followed in the home; examples are performing hand hygiene with soap and water before preparing food, after using the bathroom, or after touching what are interpreted as dirty objects. It is important to include cultural or social beliefs of the patient and family.

Control or Elimination of Infectious Agents

With the increased use of disposable equipment, nurses are often less aware of disinfection and sterilization procedures. The proper cleaning, disinfection, and sterilization of contaminated objects significantly reduce and/or eliminate microorganisms (Chetan, 2018). In health care agencies a sterile processing department is responsible for the disinfection and sterilization of reusable supplies and equipment. However, nurses sometimes need to perform these functions in the home care setting. Many principles of cleaning and disinfection also apply to the home, so it is important to educate patients and family caregivers on these techniques.

Cleaning

Cleaning is the removal of organic material (e.g., blood) or inorganic material (e.g., soil) from objects and surfaces (Chetan, 2018). In general, cleaning involves the use of water, a detergent/disinfectant, and proper mechanical scrubbing. Cleaning occurs before disinfection and sterilization procedures.

When an object comes in contact with an infectious or potentially infectious material, it is contaminated. If the object is disposable, it is discarded. Reusable objects need to be cleaned thoroughly before reuse and then either disinfected or sterilized according to manufacturer recommendations. Failure to follow manufacturer recommendations transfers liability from the manufacturer to the health care agency if an infection results from improper processing.

Apply protective eyewear (or a face shield) and utility (dishwashing style) gloves when cleaning equipment that is soiled by organic material such as blood, fecal matter, mucus, or pus. Protective barriers provide protection from potentially infectious organisms. A brush and detergent or soap are necessary for cleaning. The following steps ensure that an object is clean:

1. Rinse the contaminated object or article with cold running water to remove organic material. Hot water causes the protein in organic material to coagulate and stick to objects, making removal difficult.
2. After rinsing, wash the object with soap and warm water. Soap or detergent reduces the surface tension of water and emulsifies dirt or remaining material. Rinse the object thoroughly.
3. Use a brush to remove dirt or material in grooves or seams. Friction dislodges contaminated material for easy removal. Open hinged items for cleaning.
4. Rinse the object in warm water.

5. Dry the object and prepare it for disinfection or sterilization if indicated by classification of the item (i.e., critical, semicritical, or noncritical).
6. The brush, gloves, and sink used to clean the equipment are considered contaminated and are cleaned and dried according to policy.

Disinfection and Sterilization

Disinfection and sterilization use both physical and chemical processes that disrupt the internal functioning of microorganisms by destroying cell proteins. **Disinfection** describes a process that eliminates many or all microorganisms, with the exception of bacterial spores, from inanimate objects (Chetan, 2018). There are two types of disinfection: (1) the disinfection of surfaces, and (2) high-level disinfection, which is required for some patient care items such as endoscopes and bronchoscopes. **Sterilization** eliminates or destroys all forms of microbial life, including spores (Chetan, 2018). Sterilization methods include processing items using steam, dry heat, hydrogen peroxide plasma, or ethylene oxide (ETO). The decision to clean, clean and disinfect, or sterilize depends on the intended use of a contaminated item (Box 28.8). Be familiar with the policies and procedures of your health care agency for cleaning, handling, and delivering care items for eventual disinfection and sterilization. Workers in the central processing area who are specially trained in disinfection and sterilization perform most of the procedures. The following factors influence the efficacy of the disinfecting or sterilizing method:

Box 28.8 Categories for Sterilization, Disinfection, and Cleaning

Critical Items

Items that enter sterile tissue or the vascular system present a high risk of infection if they are contaminated with microorganisms, especially bacterial spores. *Critical items* must be *sterile*. These items include:

- Surgical instruments
- Cardiac or intravascular catheters

- Urinary catheters
- Implants

Semicritical Items

Items that come in contact with mucous membranes or nonintact skin also present a risk. These objects must be free of all microorganisms (except bacterial spores). *Semicritical items* must be *high-level disinfected (HLD)* or *sterilized*. These items include:

- Respiratory and anesthesia equipment
- Endoscopes
- Endotracheal tubes
- GI endoscopes
- Diaphragm fitting rings

After rinsing, dry items and store in a manner to protect from damage and contamination.

Noncritical Items

Items that come in contact with intact skin, but not mucous membranes must be clean. *Noncritical items* must be *disinfected*. These items include:

- Bedpans
- Blood pressure cuffs
- Bedrails
- Linens
- Stethoscopes
- Bedside trays and patient furniture
- Food utensils

- *Concentration of solution and duration of contact.* A weakened concentration or shortened exposure time lessens its effectiveness.
- *Type and number of pathogens.* The greater the number of pathogens on an object, the longer the required disinfecting time.
- *Surface areas to treat.* All dirty surfaces and areas need to be fully exposed to disinfecting and sterilizing agents. The type of surface is an important factor. Is the surface porous or nonporous?

- *Temperature of the environment.* Disinfectants tend to work best at room temperature.
- *Presence of soap.* Soap causes certain disinfectants to be ineffective. Thorough rinsing of an object is necessary before disinfecting.
- *Presence of organic material.* Disinfectants become inactivated unless blood, saliva, pus, or body excretions are washed off.

Table 28.5 lists processes for disinfection and sterilization and their characteristics. Some delicate instruments requiring sterilization cannot tolerate steam and must be processed with gas or plasma.

TABLE 28.5

Examples of Disinfection and Sterilization Processes

Characteristics	Examples of Use
Moist Heat	
Steam is moist heat under pressure. When exposed to high pressure, water vapor reaches a temperature above boiling point to kill pathogens and spores.	Autoclave sterilizes heat-tolerant surgical instruments and semicritical patient care items.
Chemical Sterilants—High-Level Disinfection (HLD)	
A number of chemical disinfectants are used in health care. These include alcohols, chlorines, formaldehyde, glutaraldehyde, hydrogen peroxide, iodophors, phenolics, and quaternary ammonium compounds. Each product performs in a unique manner and is used for a specific purpose.	Chemicals disinfect heat-sensitive instruments and equipment such as endoscopes and respiratory therapy equipment.
Ethylene Oxide (ETO) Gas	
This gas destroys spores and microorganisms by altering the metabolic processes of cells. Fumes are released within an autoclave-like chamber. ETO gas is toxic to humans, and aeration time varies with products.	This gas sterilizes most medical materials.
Boiling Water	
Boiling is least expensive for use in the home. Bacterial spores and some viruses resist boiling. It is not used in health care facilities.	Boiling is commonly used in the home for items such as urinary catheters, suction tubes, and drainage collection devices.

Protection of the Susceptible Host

A patient’s resistance to infection improves as you protect normal body defenses against infection. Intervene to maintain the normal reparative processes of the body (Box 28.9). Nurses also protect themselves and others through the use of isolation precautions.

Box 28.9 Infection Prevention and Control:

Protecting the Susceptible Host

Protecting Natural Defense Mechanisms

- Regular bathing removes transient microorganisms from the surface of the skin. Lubrication helps keep the skin hydrated and intact. In many intensive care settings, a chlorhexidine (CHG) bath is recommended if there is a risk for *methicillin-resistant Staphylococcus aureus* (MRSA) or other resistant bacteria (CDC, 2013b; Popovich, 2017)).
- Perform regular oral hygiene. Saliva contains enzymes that promote digestion and has a bactericidal action to maintain control of bacteria. Flossing removes tartar and plaque that cause germ infection.
- Maintenance of adequate fluid intake promotes normal urine formation and a resultant outflow of urine to flush the bladder and urethral lining of microorganisms.
- For patients who are physically dependent or immobilized, encourage routine coughing and deep breathing to keep lower airways clear of mucus.
- Encourage proper immunization of children or adult patients who are exposed to certain infectious microorganisms. Children are vaccinated for measles, mumps, rubella, chickenpox, diphtheria, and other vaccine-preventable diseases. Adults receive one booster of tetanus-diphtheria-acellular pertussis (Tdap), annual flu vaccine, and others as recommended by the Centers for Disease Control and Prevention (CDC) (2010). Older adults should receive a pneumococcal vaccine, shingles vaccine, and an annual influenza vaccine.

Maintaining Healing Processes

- Promote intake of adequate fluids and a well-balanced diet containing essential proteins, vitamins, carbohydrates, and fats. Use measures to increase the patient's appetite.
- Promote a patient's comfort and sleep so that energy stores are replaced daily.
- Help the patient learn techniques to reduce stress.

Control or Elimination of Reservoirs of Infection

To control or eliminate the numbers and types of organisms in reservoir sites, eliminate sources of body fluids, drainage, or solutions that possibly harbor microorganisms. Eliminating reservoirs of infection (e.g., emptying urinary drainage bags), controlling portals of exit and entry (e.g., using

antiseptic wipes on IV tubing ports), and avoiding actions that transmit microorganisms prevent bacteria from finding a new site in which to grow (Box 28.10). Be aware of the state regulations for the handling and disposal of medical (infectious) waste. Occupational Safety and Health Administration (OSHA) regulations address the handling and disposal of blood and body fluids that potentially pose a risk for the transmission of bloodborne pathogens. These regulations defer to state laws and regulations (OSHA, 2012a).

Box 28.10 Infection Prevention and Control to Reduce Reservoirs of Infection

Bathing

- Use soap and water to remove drainage, dried secretions, or excess perspiration.

Dressing Changes

- Change dressings that become wet and/or soiled (see Chapter 48).

Contaminated Articles

- Place tissues, soiled dressings, or soiled linen in fluid-resistant bags for proper disposal.

Contaminated Sharps

- Place all needles, safety needles, and needleless systems into puncture-proof containers, which should be located at the site of use. Federal law requires the use of needle-safe technology. Blood tube holders are single use only (OSHA, 2012a).

Bedside Unit

- Keep table surfaces clean and dry.

Bottled Solutions

- Do not leave bottled solutions open.
- Keep solutions tightly capped.
- Date bottles when opened and discard in 24 hours.

Surgical Wounds

- Keep drainage tubes and collection bags patent to prevent accumulation of serous fluid under the skin surface.

Drainage Bottles and Bags

- Wear gloves and protective eyewear if splashing or spraying with contaminated blood or body fluids is anticipated.
- Empty and dispose of drainage suction bottles according to agency policy.
- Empty all drainage systems on each shift unless otherwise ordered by a health care provider.
- Never raise a drainage system (e.g., urinary drainage bag) above the level of the site being drained unless it is clamped off.

Control of Portals of Exit/Entry

To control organisms exiting via the respiratory tract, cover your mouth or nose when coughing or sneezing. Teach patients, health care staff, patient's families, and visitors about respiratory hygiene or **cough etiquette**. The use of posters and written material explaining cough etiquette to learners is beneficial. Cough etiquette has become more important because of concern for transmission of respiratory infections such as *Mycobacterium tuberculosis*, severe acute respiratory syndrome (SARS), and H1N1 influenza (CDC, 2007). The elements of respiratory hygiene and cough etiquette are summarized in [Table 28.6 \(CDC, 2007\)](#).

TABLE 28.6

Centers for Disease Control and Prevention Isolation Guidelines

Standard Precautions (Tier One) for Use With All Patients	
<ul style="list-style-type: none"> • Standard Precautions apply to blood, blood products, all body fluids, secretions, excretions (except sweat), nonintact skin, and mucous membranes. • Perform hand hygiene before direct contact with patients; between patient contacts; after contact with blood, body fluids, secretions, and excretions and with equipment or articles contaminated by them; and immediately after gloves are removed. • When hands are visibly soiled or contaminated with blood or body fluids, wash them with either a nonantimicrobial soap or antimicrobial soap and water. • When hands are not visibly soiled or contaminated with blood or body fluids, use an alcohol-based hand rub to perform hand hygiene. • Wash hands with nonantimicrobial or antimicrobial soap and water if contact with spores (e.g., <i>Clostridium difficile</i>) is likely to have occurred. • Do not wear artificial fingernails or extenders if duties include direct contact with patients at high risk for infection and associated adverse outcomes. • Wear gloves when touching blood, body fluids, secretions, excretions, nonintact skin, mucous membranes, or contaminated items or surfaces. Remove and dispose of gloves and perform hand hygiene between patient care encounters and when going from a contaminated to a clean body site. • Wear PPE when your anticipated patient interaction is likely to involve contact with blood or body fluids. • A private room is unnecessary. Check with the infection prevention and control professional of your agency. • Discard all contaminated sharp instruments and needles in a puncture-resistant container. Health care facilities must make needleless devices available. Activate the mechanical safety device, if present. If needle recapping is necessary, use the one-handed scoop method and dispose of the capped needle as soon as possible. • Respiratory hygiene and cough etiquette: Have patients cover the nose or mouth when sneezing or coughing; use tissues to contain respiratory secretions and dispose in nearest waste container; perform hand hygiene after contact with respiratory secretions and contaminated objects or materials; contain respiratory secretions with procedure or surgical mask; sit at least 3 feet away from others if coughing. 	
Transmission-Based Precautions (Tier Two) for Use With Specific Types of Patients	

Centers for Disease Control and Prevention Isolation Guidelines

Category	Disease	Barrier Protection
Airborne Precautions (Droplets <5 µm)	Measles, chickenpox (varicella), disseminated herpes zoster, <i>Mycobacterium tuberculosis</i> , rubeola	Private room; negative-pressure airflow of at least 6-12 exchanges per hour via HEPA filtration; mask or respiratory protection device, N95 respirator
Droplet Precautions (Droplets >5 µm; being within 3 feet of the patient)	Influenza, adenovirus, group A streptococcus, <i>Neisseria meningitides</i> , pertussis, rhinovirus, mycoplasma pneumoniae, pertussis, diphtheria, pneumonic plague, rubella, mumps, respiratory syncytial virus	Private room or cohort patients; mask or respirator (refer to agency policy)
Contact Precautions (Direct patient or environmental contact)	Colonization or infection with multidrug-resistant organisms, such as VRE and MRSA, <i>Clostridium difficile</i> , shigella and other enteric pathogens, major wound infections, herpes simplex, scabies, varicella zoster (disseminated), respiratory syncytial virus	Private room or cohort patients (see agency policy); gloves, gowns
Protective environment	Allogeneic hematopoietic stem cell transplants	Private room; positive airflow with ≥12 air exchanges per hour; HEPA filtration for incoming air; mask, gloves, gowns

HEPA, High-efficiency particulate air; MRSA, methicillin-resistant *Staphylococcus aureus*; PPE, personal protective equipment; VRE, vancomycin-resistant enterococcus.

Modified from Centers for Disease Control and Prevention (CDC) Hospital Infection Control Practice Advisory Committee: *Guidelines for isolation*

precautions in hospitals, 2017; Association of periOperative Registered Nurses (AORN): *AORN guidelines for perioperative practice*, Denver, 2019; US Food and Drug Administration (FDA): *What to do if you can't find a sharps disposal container*, 2016, <https://www.fda.gov/medicaldevices/productsandmedicalprocedures/homehealthandconsumer/consumerproducts/sharps/default.htm>.

Another way of controlling the exit of microorganisms is by using Standard Precautions (see [Table 28.6](#)) when handling body fluids such as urine, feces, and wound drainage. Wear clean gloves if there is any chance of contact with any blood or body fluids, and perform hand hygiene after providing care. Be sure to bag contaminated items (e.g., linen placed in fluid-resistant linen bags) appropriately.

Many measures that control the exit of microorganisms also control their entrance. Maintaining the integrity of skin and mucous membranes reduces the chances of microorganisms reaching a host. Keep a patient's skin well lubricated by using lotion as appropriate. Patients who are immobilized and debilitated are particularly susceptible to skin breakdown. Do not position patients on tubes or objects that cause breaks in the skin. It is important to turn and position patients before their skin becomes reddened. Frequent oral hygiene prevents the drying of mucous membranes. A water-soluble ointment keeps a patient's lips well lubricated.

After elimination instruct women to clean the rectum and perineum by wiping from the urinary meatus toward the rectum. Cleaning in a direction from the least to the most contaminated area helps reduce GU infections. Meticulous and frequent perineal care is especially important in older-adult women who wear disposable incontinence pads.

Another cause for entrance of microorganisms into a host is improper handling and management of urinary catheters and drainage sets (see [Chapter 46](#)) ([Box 28.11](#)). Keep the point of connection between a catheter and drainage tube closed and intact. If such systems are closed, their contents are considered sterile. Outflow spigots on drainage bags should also remain closed to prevent entrance of bacteria. Minimize movement of the catheter at the urethra by stabilizing it with tape or a securing device to reduce the chance of microorganisms ascending the urethra into the bladder. Do not share urine-measuring containers among patients. Sometimes you care for patients with closed drainage systems that collect wound drainage, bile, or other body fluids. Make sure that the site from which a drainage tube exits remains clear of excess moisture or

accumulated drainage. Keep all tubing connected throughout use and open drainage receptacles only when it is necessary to discard or measure the volume of drainage (see [Chapter 46](#)).

Box 28.11 Evidence-Based Practice Daily Unit Rounds to Reduce CAUTI

PICOT Question: Does the implementation of routine root cause analysis compared with routine daily rounds reduce the incidence of catheter-associated urinary tract infections?

Evidence Summary

Among urinary tract infections (UTI) acquired in the hospital, approximately 75% are associated with a urinary catheter, and between 15% and 25% of hospitalized patients receive urinary catheters during their hospital stay (CDC, 2017b). The most important risk factor for developing a catheter-associated urinary tract infection (CAUTI) is prolonged use of the urinary catheter. CAUTIs are a common infection in hospitals across the United States, with many hospitals demonstrating high CAUTI rates and high urinary catheter utilization rate for several years. CAUTIs are usually preventable, so numerous studies have examined strategies for decreasing CAUTI rates. Strategies have included the development of CDC guidelines for the prevention of CAUTIs (CDC, 2009), the use of a CAUTI guide with questions regarding proper indwelling catheter use (Fletcher et al., 2016), and a quality improvement collaboration of health care centers throughout the United States (Fakih et al., 2014). One successful strategy implemented by Graziano-Husser and colleagues (2018) involved implementing daily huddle rounds for urinary catheter justification. The project team started to implement mini root cause analyses (RCAs) to review CAUTI cases, identify issues that contributed to the CAUTI, and educate nurses and nursing assistants to generate awareness of why and how CAUTIs occur and strategies to prevent them. After a CAUTI was found, the chart was reviewed by unit staff for key factors, including necessity of catheter, appropriate culturing, and appropriate care and maintenance. Findings were then discussed among the unit staff on challenges and concerns related to the urinary catheter and maintenance and opportunities for improvement. Through the intervention, the unit's CAUTI rate was decreased by 38.5%.

Application to Nursing Practice

- Insert catheters only for appropriate indications, such as acute urinary retention or strict output monitoring (Graziano-Husser et al, 2018).
- Leave catheters in place only as long as needed and remove within 24 hours unless there are appropriate indications for continued use (Fakih et al, 2014).
- Ensure that only properly trained persons insert and maintain urinary catheters (Fakih et al, 2014).
- Insert urinary catheters using aseptic technique and sterile equipment (CDC, 2009).
- Following aseptic insertion, maintain a closed drainage system (CDC, 2009).
- Use hand hygiene and Standard (or appropriate isolation) Precautions.

Control of Transmission

Effective prevention and control of infection requires you to remain aware of the modes of transmission of microorganisms and ways to control them. The use of Standard Precautions ([Table 28.6](#)) for all patients is a step toward preventing transmission of infection. In any health care setting a patient usually has a personal set of care items. Sharing bedpans, urinals, bath basins, and eating utensils among patients easily leads to cross-infection by indirect contact. When using a stethoscope, always wipe off the bell, diaphragm, and ear tips with a disinfectant such as an alcohol wipe before proceeding to the next patient. Diaphragms and ear tips are a common location for staphylococcal organisms ([Adesanya et al., 2017](#)). In facilities where HAI diarrhea occurs, electronic thermometers are not recommended for rectal temperatures. You usually use oral or tympanic thermometers to assess temperature. Do not use electronic thermometers for patients on contact isolation.

Always be careful when handling exudate such as urine, feces, emesis, and blood. Contaminated fluids easily splash while being discarded in toilets or hoppers. Urinals and bedpans need to be emptied at water level to reduce the risk of splash or splatter, and gloves and protective eyewear are worn. Appropriately dispose of disposable soiled items in trash bags. Dispose of items contaminated with large amounts of blood in biohazard bags. Know the location of biohazard bags; it will differ among facilities. Handle laboratory specimens from all patients as if they were infectious and place them in designated biohazard containers or bags for transport or disposal. Because certain microorganisms travel easily through the air, do

not shake linens or bedclothes. Dust with a treated or dampened cloth to prevent dust particles from entering the air.

To prevent transmission of microorganisms through indirect contact, do not allow soiled items and equipment to touch your clothing. A common error is to carry dirty linen in the arms against your uniform. Use fluid-resistant linen bags or carry soiled linen with hands held out from the body. Cover laundry hampers and empty them before they become overloaded. **Never put clean or soiled linens on the floor.**

Hand Hygiene

The most effective basic technique in preventing and controlling the transmission of infection is hand hygiene (see Skill 28.1) (Hass, 2018; WHO, 2017). **Hand hygiene** is a general term that applies to four techniques: handwashing, antiseptic hand wash, antiseptic hand rub, or surgical hand antisepsis. **Handwashing** is defined by the CDC (2008) as the vigorous, brief rubbing together of all surfaces of lathered hands followed by rinsing under a stream of warm water for 15 seconds. The fundamental principle behind handwashing is removing microorganisms mechanically from the hands and rinsing with water. Handwashing does not kill microorganisms.

An antiseptic hand wash means washing hands with warm water and soap or other detergents containing an antiseptic agent; some antiseptics kill bacteria and some viruses. An antiseptic hand rub means applying an antiseptic hand-rub product to all surfaces of the hands to reduce the number of microorganisms present. Ethanol-based hand antiseptics containing 60% to 90% alcohol appear to be the most effective against common pathogens found on the hands (CDC, 2008). Alcohol-based products are more effective for standard handwashing or hand antisepsis (nonsoiled hands) by health care workers than regular soap or antimicrobial soaps (CDC, 2008). Surgical hand antisepsis is an antiseptic hand-wash or hand-rub technique that surgical personnel perform before surgery to eliminate transient and reduce resident hand flora. Antiseptic detergent preparations have persistent antimicrobial activity (CDC, 2008; WHO, 2009).

According to the WHO (2009), hand cleansing practices are likely to be established in the first 10 years of a person's life. This imprinting affects an individual's attitudes about hand cleansing throughout life. This is called inherent hand hygiene (WHO, 2009). Attitudes toward handwashing in situations such as the delivery of health care are called elective handwashing practices (WHO, 2009). In many patient populations,

inherent and elective handwashing is influenced by cultural factors. Thus, hand hygiene is often performed for hygienic reasons, rituals, and symbolic reasons. It is important to learn the significance hand hygiene holds for an individual.

The use of alcohol-based hand rubs is recommended by the [CDC \(2008\)](#) to improve hand hygiene practices, protect health care workers' hands, and reduce the transmission of pathogens to patients and personnel in health care settings. Alcohols have excellent germicidal activity and are as effective as soap and water. However, alcohol-based hand antiseptics are not effective on hands that are visibly dirty or are contaminated with organic material ([CDC, 2013a](#)). [WHO \(2017\)](#) recommends the following hand hygiene guidelines:

1. When hands are visibly dirty, when hands are soiled with blood or other body fluids, before eating, and after using the toilet, wash hands with water and either a nonantimicrobial or antimicrobial soap.
2. Wash hands if exposed to spore-forming organisms such as *C. difficile*, *Bacillus anthracis*, or *Norovirus* ([CDC, 2014](#)).
3. If hands are not visibly soiled ([WHO, 2017](#)), use an alcohol-based, waterless antiseptic agent for routinely decontaminating hands in the following clinical situations:
 - Before, after, and between direct patient contact (e.g., taking a pulse, lifting a patient)
 - Before putting on sterile gloves and before inserting invasive devices such as a peripheral vascular catheter or urinary catheter
 - After contact with body fluids or excretions, mucous membranes, nonintact skin, and wound dressings (even if gloves are worn)
 - When moving from a contaminated to a clean body site during care
 - After contact with surfaces or objects in the patient's room (e.g., overbed table, IV pump)
 - After removing gloves ([CDC, 2008](#))

Remember, contaminated hands of health care workers are a primary source of infection transmission in health care settings. It is recommended that health care workers have well-manicured nails and refrain from wearing artificial nails to reduce microorganism transmission.

Infection can easily be transmitted by visitors of patients in health care settings. A study by [Birnbach and colleagues \(2015\)](#) included hand hygiene observations of visitors and collection of cultures as visitors entered patient rooms. Thirty-five of 55 visitors did not perform hand hygiene before entering the patient room, and all 55 visitors agreed to providing hand cultures. All of the cultures from visitors not doing hand hygiene grew a significantly higher number of bacteria than the cultures from visitors doing hand hygiene. The study demonstrates the need for education of visitors on the importance of hand hygiene and evaluation of corresponding changes in hand hygiene behavior. Instruct patients and visitors about proper hand hygiene technique, the reason for it, and the times for performing it. If health care is to continue at home, teach patients and family caregivers to wash their hands before eating or handling food; after handling contaminated equipment, linen, or organic material; and after elimination. In health care settings, encourage visitors to wash their hands before eating or handling food; after coming in contact with infected patients; and after handling contaminated equipment, patient furniture, or organic material ([Gould et al., 2011](#)).

You are responsible for providing the patient and family with a safe environment. The [CDC \(2015d\)](#) launched a Clean Hands Save Lives Campaign that highlights for consumers the five simple and effective steps (Wet, Lather, Scrub, Rinse, Dry) to take to reduce the spread of diarrheal and respiratory illnesses and thus to stay healthy. Many hospitals encourage patients to follow the recommendations of TJC's "Speak Up" campaign. TJC together with the Centers for Medicare and Medicaid Services urges patients to take a role in preventing health care errors by becoming active, involved, and informed participants on the health care team. The program features brochures, posters, and buttons on a variety of patient safety topics. One recommendation is to have patients speak up to be sure the health care provider has cleaned his or her hands or wears gloves when providing care.

The effectiveness of infection prevention practices such as hand hygiene depends on the conscientiousness and consistency in using proper technique by all health care providers. It is human nature to forget key procedural steps or, when hurried, to take shortcuts that break aseptic procedures. However, failure to adhere to basic procedures places patients at risk for infections that can seriously impair recovery or lead to death.

Isolation and Isolation Precautions

In 2007 the Hospital Infection Control Practices Advisory Committee (HICPAC) of the CDC published revised guidelines for isolation precautions. HICPAC recommended that facilities modify the guidelines according to need and as dictated by federal, state, or local regulations. The guidelines contain recommendations for respiratory hygiene/cough etiquette as part of Standard Precautions. The CDC recommendations contain two tiers of precautions (see [Table 28.6](#)). The first and most important tier is called *Standard Precautions*, which are designed to be used for the care of all patients, in all settings, regardless of risk or presumed infection status. Standard Precautions are the primary strategies (including barrier precautions) for prevention of infection transmission and apply to contact with blood, body fluids, nonintact skin, mucous membranes, and equipment or surfaces contaminated with potentially infectious materials. In the acute care setting, nurses follow Standard Precautions in all aspects of care. This includes barrier precautions and the appropriate use of PPE such as gowns, gloves, masks, eyewear, and other protective devices or clothing. The choice of barriers depends on the task being performed and the patient's disease. Standard Precautions apply to all patients because every patient has the potential to transmit infection via blood and body fluids, and the risk for infection transmission is unknown. Respiratory hygiene/cough etiquette applies to any person with signs of respiratory infection, including cough, congestion, rhinorrhea, or increased production of respiratory secretions, when entering a health care site. Educating health care staff, patients, and visitors to follow respiratory hygiene/cough etiquette protects both patients and health care workers.

The second tier of precautions (see [Table 28.6](#)) includes precautions designed for the care of patients who are known or suspected to be infected or colonized with microorganisms transmitted by droplet, airborne, or contact routes ([Berends and Walesa, 2018](#); [CDC, 2007](#)). There are four types of transmission-based precautions, which are based on the mode of transmission of a disease: *Airborne*, *Droplet*, *Contact*, and *Protective Environment Precautions*. These precautions are for patients with highly transmissible pathogens. The protective environment category is designed for patients who have undergone transplants and gene therapy, making them highly vulnerable to infection([CDC, 2007](#)).

- *Contact Precautions*: Used for direct and indirect contact with patients and their environment. Direct contact refers to the care and handling of contaminated body fluids. Contact Precautions require a gown and gloves. An example includes blood or other

body fluids from an infected patient that enter the health care worker's body through direct contact with compromised skin or mucous membranes. Indirect contact involves the transfer of an infectious agent through a contaminated intermediate object such as contaminated instruments or hands of health care workers. The health care worker may transmit microorganisms from one patient site to another if hand hygiene is not performed between patients (CDC, 2007).

- *Droplet Precautions*: Focus on diseases that are transmitted by large droplets (greater than 5 microns) expelled into the air and by being within 3 feet of a patient. Droplet Precautions require the wearing of a surgical mask when within 3 feet of the patient, proper hand hygiene, and some dedicated-care equipment. An example is a patient with influenza.
- *Airborne Precautions*: Focus on diseases that are transmitted by smaller droplets, which remain in the air for longer periods of time. Airborne Precautions require a specially equipped room with a negative airflow referred to as an *airborne infection isolation room*. Air is not returned to the inside ventilation system but is filtered through a high-efficiency particulate air (HEPA) filter and exhausted directly to the outside. For example, all health care personnel wear an N95 respirator every time they enter the room of a patient with TB.
- *Protective environment*: Focuses on a very limited patient population, all of whom are highly susceptible to infection. This form of isolation requires a specialized room with positive airflow. The airflow rate is set at greater than 12 air exchanges per hour, and all air is filtered through a HEPA filter. One example of a patient requiring a protective environment is a patient who received a kidney transplant. The patient wears a mask when out of his or her room during transportation to x-ray.

Health care facilities are required to have the capability of isolating patients. However, not all communicable diseases require placing a patient in a special private room. You can conduct many isolation practices in standard rooms using barrier precautions.

Because of the resurgence of TB, the CDC (2007) developed guidelines to prevent its transmission to health care workers and stresses the importance of isolation for the patient with known or suspected TB in a special negative-pressure room. Close the doors to the patient's room to

control the direction of airflow. You must wear a special high-filtration particulate respirator on entering a respiratory isolation room. A respirator must be fitted to your facial size and characteristics. When worn correctly, particulate respirators and masks have a tighter face seal and filter at a higher level than routine surgical masks.

MDROs such as methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-resistant enterococcus (VRE) and *C. difficile* are more common as a cause of colonization and HAIs. MDROs have developed a resistance to one or more broad-spectrum antibiotics, making the organisms hard to treat effectively. Major efforts have been in place for a number of years to reduce the incidence of HAIs caused by these dangerous organisms. For example, evidence shows that the percentage of central line bloodstream infections (see [Chapter 42](#)) caused by MRSA, VRE, and gram-negative bacteria has declined ([CDC, 2011](#)). Unlike MRSA and VRE, *C. difficile* (which is transmitted by the fecal-oral route) is harder to eliminate from the environment. It is a spore-forming microorganism, meaning it can remain on surfaces (e.g., bedside table, stethoscope) in a dormant state for long periods. To reduce the risk of cross-contamination among patients, use Contact Precautions in addition to Standard Precautions when caring for patients with MDROs.

Regardless of the type of isolation or barrier protection you use, follow these basic principles when caring for patients:

- Understand how certain diseases are transmitted and which protective barriers to use.
- Use thorough hand hygiene before entering and leaving the room of a patient in isolation.
- Dispose of contaminated supplies and equipment in a manner that prevents spread of microorganisms to other people as indicated by the mode of transmission of the organism.
- Protect all people who might be exposed during transport of a patient outside the isolation room.

Psychological Implications of Isolation

Consider the psychological effects of being in an isolation room. Many patients find positive aspects of being in a single room; however, the overall experience of isolation is commonly viewed negatively ([Mehrotra et al., 2013](#)). Isolation imposes barriers to the expression of a patient's identity and normal interpersonal relationships and affects the delivery of

quality care. When a patient requires isolation in a private room, a sense of loneliness sometimes develops because normal social relationships become disrupted. This situation can be psychologically harmful, especially for children. A study noted that patients in isolation experienced more depression and anxiety and were less satisfied with their care (Sprague et al., 2016). Patients' body images become altered as a result of the infectious process. Some feel unclean, rejected, lonely, or guilty. Infection prevention and control practices further intensify these beliefs of difference or undesirability. Isolation disrupts normal social relationships with visitors and caregivers. Take the opportunity to listen to a patient's concerns or interests. If you rush care or show a lack of interest in a patient's needs, he or she feels rejected and even more isolated.

Before you institute isolation measures, the patient and family need to understand the nature of the disease or condition, the purposes of isolation, and steps for following specific precautions. If they are able to participate in maintaining infection prevention and control practices, the chances of reducing the spread of infection increase. Teach the patient and family to perform hand hygiene and use barrier protection if appropriate. Demonstrate each procedure; be sure to give the patient and family an opportunity for practice. It is also important to explain how infectious organisms are transmitted so that the patient and family understand the difference between contaminated and clean objects. Explaining and demonstrating these procedures, especially hand hygiene, help the family to consistently practice correct hand hygiene and prescribed isolation measures (Gould et al., 2011).

Take measures to improve a patient's sensory stimulation during isolation. Make sure that the room environment is clean and pleasant. Open drapes or shades and remove excess supplies and equipment. Listen to the patient's concerns or interests. Mealtime is a particularly good opportunity for conversation. Providing comfort measures such as repositioning, a back massage, or a warm sponge bath increases physical stimulation. Depending on the patient's condition, encourage him or her to walk around the room or sit up in a chair. Recreational activities such as board games, reading, and playing cards are options for keeping a patient mentally stimulated.

Explain to the family the patient's risk for depression or loneliness. Encourage visiting family members to avoid expressions or actions that convey revulsion or disgust related to infection prevention and control practices. Discuss ways to provide meaningful stimulation.

The Isolation Environment

Private rooms used for isolation sometimes provide negative-pressure airflow to prevent infectious particles from flowing out of a room to other rooms and the air handling system. Special rooms with positive-pressure airflow are also used for patients who are immunocompromised, such as recipients of transplanted organs. On the door or wall outside the room a nurse posts a card listing precautions for the isolation category in use according to health care agency policy. The card is a handy reference for health care personnel and visitors and alerts anyone who enters the room that special precautions must be followed.

An area immediately outside an isolation room or an adjoining anteroom needs to contain hand hygiene and PPE supplies. Soap and antiseptic (antimicrobial) solutions also should be available. Personnel and visitors perform hand hygiene before entering a patient's room and again before leaving the room. If toilet facilities are unavailable, there are special procedures for handling portable commodes, bedpans, or urinals.

All patient care rooms, including those used for isolation, should contain an impervious bag for soiled or contaminated linen and a trash container with plastic liners. Impervious receptacles prevent transmission of microorganisms by preventing leaking and soiling of the outside surface. A disposable rigid container needs to be available in the room to discard used sharps such as safety needles and syringes.

Remain aware of infection prevention and control techniques while working with patients in protected environments. You need to feel comfortable performing all procedures and yet remain conscious of infection prevention and control principles. Depending on the microorganism and mode of transmission, evaluate which articles or equipment to take into an isolation room. For example, the [CDC \(2017c\)](#) recommends the dedicated use of articles such as stethoscopes, sphygmomanometers, and thermometers in the isolation room of a patient infected or colonized with VRE. Do not use these devices on other patients unless they are first adequately cleaned and disinfected.

Personal Protective Equipment

The PPE, specialized clothing or equipment (e.g., gowns, masks or respirators, protective eyewear, and gloves) that you wear for protection against exposure to infectious materials, should be readily available in a patient care area ([CDC, 2017c](#)). You choose the equipment to use depending on the task to be performed.

Gowns

The primary reason for gowning is to prevent soiling clothes during contact with a patient. Gowns or cover-ups protect health care personnel and visitors from coming in contact with infected material and blood or body fluids. Gowns are often required, depending on the expected amount of exposure to infectious material. Gowns used for barrier protection are made of a fluid-resistant material. Change gowns immediately if damaged or heavily contaminated.

Isolation gowns usually open at the back and have ties or snaps at the neck and waist to keep the gown closed and secure. Gowns need to be long enough to cover all outer garments. Long sleeves with tight-fitting cuffs provide added protection. No special technique is required for applying clean gowns if they are fastened securely. However, carefully remove gowns to minimize contamination of the hands and uniform and discard them after removal.

Masks

Masks provide respiratory protection. Wear full-face protection (with eyes, nose, and mouth covered) when you anticipate splashing or spraying of blood or body fluid into the face. Also wear masks when working with a patient placed on Airborne or Droplet Precautions. If a patient is on Airborne Precautions for TB, apply an OSHA-approved respirator-style mask. The mask protects you from inhaling microorganisms and small-particle droplet nuclei that remain suspended in the air from a patient's respiratory tract. The surgical mask protects a wearer from inhaling large-particle aerosols that travel short distances (3 feet). When caring for patients on Droplet or Airborne Precautions, apply a mask (surgical or respirator) when entering the isolation room.

At times, a patient who is susceptible to infection wears a mask to prevent inhalation of pathogens. Patients on Droplet or Airborne Precautions who are transported outside their rooms need to wear a surgical mask to protect other patients and personnel. Masks prevent transmission of infection by direct contact with mucous membranes ([CDC, 2005a](#)). A mask discourages the wearer from touching the eyes, nose, or mouth ([Box 28.12](#)).

Box 28.12 Procedural Guidelines **Applying a Disposable Mask**

Delegation and Collaboration

The skill of applying a surgical mask can be delegated when assistive personnel (AP) are trained in required sterile procedure. The nurse informs AP to:

- Put on the mask following the appropriate steps.
- Change the mask if it becomes moist or contaminated.
- Remove the mask when leaving the patient's room.

Equipment

Disposable mask

Steps

1. Find top edge of mask (some have a thin metal strip along edge).
Pliable metal fits snugly against bridge of nose. Others offer an occlusive fit that does not require an adjustment.
2. Hold mask by top two strings or loops. Secure two top ties at top of back of head (see illustration), with ties above ears. (*Alternative:* Slip loops over each ear.)

STEP 2 Securing top two ties of a tie-on mask.

3. Tie two lower ties snugly around neck with mask well under chin (see illustration).
4. Gently pinch upper metal band around bridge of nose.
Note: Change mask when it becomes wet, moist, or contaminated.
5. Remove mask by untying *bottom* mask strings and then top strings; pull mask away from face and drop into trash receptacle. (Do not touch outer surface of mask.)

STEP 3 Securing lower ties of a tie-on mask.

If a person wears glasses, the top edge of the mask fits below the glasses so that they do not cloud over as the person exhales. Keep talking to a minimum while wearing a mask to reduce respiratory airflow. A mask that becomes moist does not provide a barrier to microorganisms and is ineffective. You need to discard it. Never reuse a disposable mask. Warn patients and family members that a mask can cause a sensation of smothering. If family members become uncomfortable, they should leave the room and discard the mask.

Specially fitted respiratory protective devices (N95 respirator masks) are required when caring for patients on Airborne Precautions such as patients with known or suspected TB ([Fig. 28.3](#)) ([CDC, 2005a](#)). The mask must have a higher filtration rating than regular surgical masks and be fitted snugly to prevent leakage around the sides. Be aware of health care agency policy regarding the type of respiratory protective device required. Special fit testing is required to establish the size and ability of the nurse to wear this type of mask ([CDC, 2005a](#)).

FIG. 28.3 N95 respirator mask.
Courtesy of Halyard Health, Inc., Alpharetta, GA.

Eye Protection

Use either special glasses or goggles when performing procedures that generate splash or splatter. Examples of such procedures include irrigation of a large abdominal wound or insertion of an arterial catheter when the nurse assists a health care provider. A nurse who wears prescription glasses uses removable, reusable, or disposable side shields over them ([OSHA, 2011](#)). Eyewear is available in the form of plastic glasses or goggles. The eyewear needs to fit snugly around the face so that fluids cannot enter between the face and the glasses.

Gloves

Gloves help to prevent the transmission of pathogens by direct and indirect contact. The [CDC \(2007\)](#) notes that you need to wear clean gloves when touching blood, body fluid, secretions, excretions (except sweat), moist mucous membranes, nonintact skin, and contaminated items or surfaces. Follow these guidelines:

- Change and dispose of gloves and perform hand hygiene between tasks and procedures on the same patient after contact with material that contains a high concentration of microorganisms.
- Remove and dispose of gloves promptly after use, before touching noncontaminated items and environmental surfaces, and before going to another patient.
- Perform hand hygiene immediately after removing gloves to avoid transfer of microorganisms to other patients or environments.

To reduce the incidence of health care providers developing a sensitivity or allergy to the latex in gloves, health care agencies provide nonlatex gloves to employees. Most health care agencies are working to become latex free to protect health care providers and patients.

Box 28.13 describes the steps to follow for applying full PPE. During a procedure, be sure PPE remains in place. If you notice a break or tear in a glove while providing care, change gloves. If you do not plan to have additional contact with a patient after a care activity, reapplying gloves is unnecessary. Perform hand hygiene when gloves are removed.

Box 28.13 Procedural Guidelines **Caring for a Patient on Isolation Precautions**

Delegation and Collaboration

The skill of caring for a patient on isolation precautions can be delegated to assistive personnel (AP). However, it is the nurse who assesses the patient's status and isolation indications. Instruct AP about:

- Reason patient is on isolation precautions
- Use of the correct personal protective equipment (PPE) for the specific isolation type
- Precautions about bringing equipment into the patient's room
- Reporting abnormal findings and any high-risk behaviors (e.g., patient does not adhere to secretion control when coughing)
- Special precautions regarding individual patient needs such as transportation to diagnostic tests.

Equipment

PPE—gloves, gowns, masks, protective eyewear, or face shield—is determined by the type of isolation that is needed. Other patient care equipment depends on procedures performed in room (e.g., hygiene items; disposable blood pressure (BP) cuff, thermometer, and stethoscope; sharps container; soiled linen bag; and trash receptacle).

Steps

1. Assess patient's health history for isolation indications (e.g., tuberculosis [TB], diarrhea, major draining wound or purulent cough).
2. Review laboratory test results (e.g., wound culture; acid-fast bacillus [AFB] smears) to identify the type of microorganism for which the patient is isolated and whether the patient is immunocompromised.
3. Review agency policies and precautions necessary for the specific isolation system, and consider care measures you will perform and necessary equipment to use while in the patient's room.
4. Review nurses' notes or speak with colleagues regarding patient's emotional state and adjustment to isolation.
5. Determine whether patient has latex allergy to avoid sensitivity or allergic reaction. If allergy exists, refer to agency policy to provide full latex-free care.
6. Perform hand hygiene and prepare all equipment that you need to take into patient's room. In some cases, equipment remains in the room (stethoscope or BP cuff).
7. Prepare for entrance into isolation room. Ideally, before applying PPE, step into patient's room and stay by door. Introduce yourself and explain the care that you are providing. If this is not possible, apply PPE outside of room.
 - a. Apply cover gown, being sure that it covers all outer garments. Pull sleeves down to wrist. Tie securely at neck and waist (see illustration).

STEP 7a Tie gown at waist.

b. Apply either surgical mask or fitted respirator around mouth and nose. (Type depends on type of precautions)

- and agency policy.) You must have a medical evaluation and be fit tested before using a respirator (OSHA, 2011).
- c. If needed, apply eyewear, goggles, or face shield securely around face and eyes. If prescription glasses are worn, side shield may be used.
 - d. Apply clean gloves. (NOTE: Wear unpowdered latex-free gloves if you, patient, or another health care worker has a history of latex allergy.) Secure glove cuffs over edge of gown sleeves (see illustration).

STEP 7d Apply gloves over gown sleeves.

8. Enter patient's room. Arrange supplies and equipment. (If equipment will be removed from room for reuse, place on clean paper towel.)
9. Identify patient using at least two identifiers (e.g., name and birthday, or name and medical record number) according to agency policy.
10. Assess patient's or family caregiver's knowledge, experience, and health literacy level.
11. Explain purpose of isolation and necessary precautions for patient and family to take. Offer opportunity to ask questions. Discuss types of activities patient may wish to do to try to stay occupied. Assess

for evidence of emotional problems that can occur from isolation. If TB precautions are in use, instruct patient to cover mouth with tissue when coughing and to wear disposable surgical mask when leaving room.

12. Assess vital signs (see Chapter 29).

- a. If patient is infected or colonized with a resistant organism (e.g., vancomycin-resistant enterococci, methicillin-resistant *Staphylococcus aureus* or *Clostridium difficile*), use disposable equipment that remains in room. This includes thermometer, stethoscope, and BP cuff.
- b. If stethoscope is to be reused, clean diaphragm or bell with alcohol. Set aside on clean surface.
- c. Use individual electronic or disposable thermometer.

CLINICAL DECISION: If disposable thermometer indicates a fever, assess for other signs/symptoms. Confirm fever using an alternative thermometer. Do not use electronic thermometer if patient is suspected or confirmed to have *C. difficile* (Amitra et al., 2018).

13. Administer medications (see Chapter 31).

- a. Give oral medication in wrapper or cup.
- b. Dispose of wrapper or cup in plastic-lined receptacle.
- c. Wear gloves when administering an injection.
- d. Discard safety needle and syringe or uncapped needle into sharps container.
- e. Place reusable syringe (e.g., Carpujet) on a clean towel for eventual removal and disinfection.
- f. If you are not wearing gloves and hands come into contact with contaminated article or body fluids, perform hand hygiene as soon as possible.

14. Administer hygiene, encouraging patient to discuss questions or concerns about isolation. Provide informal teaching at this time.

- a. Avoid allowing isolation gown to become wet. Carry wash basin out away from gown; avoid leaning against any wet surface.
- b. Help patient remove own gown; discard in leakproof linen bag.
- c. Remove linen from bed; avoid contact with isolation gown. Place in linen bag according to agency policy.
- d. Provide clean bed linen and a set of towels.

- e. Remove and dispose of gloves, perform hand hygiene, and reglove if further care is necessary.
15. Collect specimens.
- a. Place specimen containers on clean paper towel in patient's bathroom. Follow procedure for collecting specimen of body fluids.
 - b. Transfer specimen to container without soiling outside of container. Label specimen in front of patient. All specimen containers must be placed in a double-sided, self-sealing polythene bag with one compartment containing the laboratory request form and the other the specimen (Nukifora, 2015).
 - c. Perform hand hygiene and reglove if additional procedures are needed.
 - d. Check label on specimen for accuracy. Send to laboratory. Be sure containers are labeled with a biohazard label (see illustration).

STEP 15d Specimen container placed in biohazard bag.

16. Assist patient to comfortable position. Place nurse call system in an accessible location within patient's reach.

Instruct patient in its use.

17. Raise side rails (as appropriate) and lower bed to lowest position.

18. Dispose of linen, trash, and disposable items.

a. Empty trash bag as it becomes full.

b. Use sturdy, moisture-resistant single bags to contain soiled articles. Use double bag if outside of bag is contaminated.

c. Tie bags securely at top in knot (see illustration).

STEP 18c Tie trash bag securely.

19. Retrieve and clean nondedicated reusable equipment. Clean any contaminated surfaces (see health care agency policy).

20. Resupply room as needed. Have a staff member outside the isolation room hand you new supplies.
21. Explain to patient when you plan to return to room. Ask whether patient requires any personal care items, books, or magazines.
22. Leave isolation room. The order for removing PPE depends on what was needed for the type of isolation. The sequence listed is based on full PPE being required.
 - a. Remove and dispose of gloves. Remove one glove by grasping cuff and pulling glove inside out over hand. With ungloved hand tuck finger inside cuff of remaining glove and pull it off, inside out (see illustration).

STEP 22a Remove glove.

- b. Remove eyewear/face shield or goggles.
- c. Untie waist and neck strings of gown. Allow gown to fall from shoulders. Remove hands from sleeves without touching outside of gown. Hold gown inside at shoulder seams and fold inside out. Discard in laundry bag if fabric or in trash can if gown is disposable.
- d. Remove mask: If mask loops over your ears, remove from ears and pull away from face. For a tie-on mask, untie *top* mask strings; hold strings; untie bottom strings, pull mask away from face, and drop it into trash receptacle. Do not touch outer surface of mask (see illustrations).

STEP 22d Remove mask.

- e. Perform hand hygiene.
- f. Leave room and close door if necessary. (Make sure that door is closed if patient is on airborne precautions.)
- g. Dispose of all contaminated supplies and equipment in a manner that prevents spread of microorganisms to other people (see health care agency policy).

Instruct family members visiting patients on isolation precautions on how to apply gloves properly. Demonstrate the application of gloves to family members, and explain the reason for the use of gloves. Emphasize the importance of performing hand hygiene after removing gloves.

Specimen Collection

Many laboratory studies are often necessary when a patient is suspected of having an infectious or communicable disease ([Box 28.14](#)). You collect body fluids and secretions suspected of containing infectious organisms for culture and sensitivity tests. After a specimen is sent to a laboratory, the laboratory technologist identifies the microorganisms growing in the culture. Additional test results indicate the antibiotics to which the organisms are resistant or sensitive. Sensitivity reports determine which antibiotics used in treatment are effective and need to be ordered for treatment.

Box 28.14 Specimen Collection Techniques^a

o Ensure that all specimen containers used have the biohazard symbol on the outside (Pagana et al., 2018). Also follow agency policy in confirming proper labeling of all specimen containers (i.e., labeling in front of patient (TJC, 2020)).

Wound Specimen

Perform hand hygiene and apply clean gloves. Clean site with sterile water or saline before wound specimen collection with a clean swab. Wipe from edges outward to remove old exudate (see Chapter 48). Remove and dispose of gloves, perform hand hygiene, and apply gloves and use sterile cotton-tipped swab or syringe to collect as much drainage as possible. Have clean test tube or culture tube on clean paper towel. After swabbing center of wound site, grasp collection tube with a paper towel. Carefully insert swab without touching outside of tube. After securing top of tube, label specimen container with patient name and identifying information, then transfer tube into labeled biohazard bag for transport and perform hand hygiene.

Blood Specimen

(This procedure is often performed by a laboratory technician.)

Wearing gloves, clean venipuncture site with antiseptic swab; move the first swab back and forth on horizontal plane, another swab on the vertical plane, and the last swab in a circular motion from site outward for 5 cm (2 inches), lasting a total of 30 seconds. Allow area to dry. Clean tops of culture bottles for 15 seconds with agency-approved cleansing solution. Use a 20-mL needle-safe syringe and collect up to 10 to 15 mL of blood per culture bottle (check health care agency policy). Perform venipuncture at two different sites to decrease likelihood of both specimens being contaminated with skin flora. Place blood culture bottles on a clean paper towel on bedside table or other surface; swab off bottle tops with alcohol. Inject an appropriate amount of blood into each bottle. If collecting aerobic and anaerobic specimens, inject blood into the aerobic bottle first and the anaerobic bottle second. Transfer labeled specimen into clean, labeled biohazard bag for transport. Remove and dispose of gloves and perform hand hygiene.

Stool Specimen

Wearing gloves, use clean cup with seal top (need not be sterile) and a tongue blade to collect a small amount, approximately 2 to 3 cm (1 inch) of stool. Place cup on clean paper towel in patient's bathroom. Using

tongue blade, collect needed amount of feces from patient's bedpan. Transfer feces to cup without touching outside surface of cup. Dispose of tongue blade and place seal on cup. Transfer labeled specimen into clean labeled biohazard bag for transport. Remove and dispose of gloves and perform hand hygiene.

Urine Specimen

Apply gloves, cleanse needleless port on urinary catheter and, using a needleless safety syringe, collect 1 to 5 mL of urine. Fill sterile specimen tube and place on clean towel in patient's bathroom. Instruct patient to follow procedure to obtain a clean voided specimen (see Chapter 46) if not catheterized. Secure top of transfer container, label container in front of patient, and place in a biohazard bag with label attached. Remove and dispose of gloves and perform hand hygiene.

^a Health care agency policies may differ on types of containers and amounts of specimen material required.

Obtain all culture specimens using clean gloves and sterile equipment. Blood cultures are taken from two separate venipuncture sites and before initiation of antimicrobials. Collecting fresh material such as wound drainage from the site of infection ensures that neighboring microbes do not contaminate a specimen. Seal all specimen containers tightly to prevent spillage and contamination of the outside of the container.

Bagging Trash or Linen

Bagging contaminated items prevents accidental exposure of personnel and contamination of the surrounding environment. Double bagging is not recommended (CDC, 2007). The use of a single intact, standard-size linen bag that is not overfilled and that is tied securely is adequate to prevent infection transmission. Check the color code of bag that your agency uses for bagging these items.

Transporting Patients

Before transferring patients to wheelchairs or stretchers, give them clean gowns to serve as robes. Patients infected with organisms transmitted by the airborne route normally leave their rooms only for essential purposes such as diagnostic procedures or surgery. When a patient has an airborne

infection, he or she must wear a mask when leaving the room. Notify personnel in diagnostic or procedural areas or the operating room of the type of isolation precautions the patient requires. Some patients being transported drain body fluids onto a stretcher or wheelchair. Use an extra layer of sheets to cover the stretcher or seat of the wheelchair. Be sure to clean the equipment with an approved germicide after patient use and before another patient uses the shared equipment.

Building Competency in Evidence-Based Practice

You are asked to participate on a unit-based team to help your fellow health care workers be more adherent to hand hygiene before and after patient care. Your unit's current rate of adherence to hand hygiene is 74%, and the unit manager has been directed by administration to improve the rate by the next quarter. Your team meets, and many team members offer opinions on how best to improve the unit hand hygiene adherence rates, but no one is sure where to start. You know that implementing an evidence-based plan will be more successful than a trial and error approach. How can you guide the team in a way that will provide an evidence-based approach to the problem?

Role of the Infection Control Professional

An infection control professional is a valuable resource for helping nurses control HAIs. These professionals are specially trained in infection prevention and control. They are responsible for advising health care personnel regarding infection prevention and control practices and monitoring infections within the hospital. An infection control professional's responsibilities often include ([Friedman, 2018](#)):

- Collection and analysis of infection data
- Evaluation of products and procedures
- Development and review of policies and procedures
- Consultation on infection risk assessment, prevention, and control strategies (includes activities related to occupational health, construction, and emergency management)
- Educational efforts directed at interventions to reduce infection risks

- Education of patients and families
- Implementation of changes mandated by regulatory, accrediting, and licensing agencies (includes reporting communicable diseases to health departments)
- Application of epidemiological principles, including activities directed at improving patient outcomes using implementation science
- Antimicrobial management
- Participation in research projects
- Monitoring antibiotic-resistant organisms in the institution

Infection Prevention and Control for Hospital Personnel

Health care workers are continually at risk for exposure to infectious microorganisms. Numerous efforts have been made by health care agencies to improve health care provider adherence to hand hygiene, including increased access to automatic alcohol-based hand sanitizers, posted reminders, and sensor monitoring of sanitizer use. The WHO recently released a new initiative for improving adherence of health care workers to hand hygiene. The WHO's Five Moments for Hand Hygiene has emerged from the WHO Guidelines on Hand Hygiene in Health Care to add value to any hand hygiene improvement strategy ([WHO, 2019b](#)). The Five Moments defines the key moments for hand hygiene, overcoming misleading language and complicated descriptions ([Fig. 28.4](#)).

FIG. 28.4 Five Moments for Hand Hygiene.
 From World Health Organization: *About SAVE Lives: Clean Your Hands: 5 moments for hand hygiene*, 2017,
<http://www.who.int/gpsc/5may/background/5moments/en/>.

Patient Education

Often patients need to learn to use infection prevention and control practices at home (Box 28.15). Preventive technique becomes almost second nature to the nurse who practices it daily. However, patients are less aware of factors that promote the spread of infection or ways to prevent its transmission. The home environment may not always lend itself to infection prevention and control. Often you help a patient adapt according to the resources available to maintain hygienic techniques. Generally, patients in a home care setting have a decreased risk of infection because of decreased exposure to resistant organisms such as those found in a health care setting and fewer invasive procedures. However, it is important to educate patients and their family caregivers about infection prevention and control techniques.

Box 28.15 Patient Teaching Infection Prevention and Control

Objective

- Patient and/or caregiver will use proper infection prevention and control practices when performing a clean dressing change.

Teaching Strategies

- Demonstrate proper hand hygiene, explaining that patient and/or caregiver needs to perform it before and after all treatments and when infected body fluids are contacted.
- Instruct patient and/or caregiver about the signs and symptoms of wound infection and when to notify the health care provider.
- Instruct patient and/or caregiver to place contaminated dressings and other disposable items containing infectious body fluids in impervious plastic or brown paper bags. Place needles in metal or hard plastic containers, such as coffee cans or laundry detergent bottles, and tape the openings shut. *Some states have specific requirements for sharps disposal. Check local regulations.*
- Instruct patient and/or caregiver to separate linen soiled with wound drainage from other laundry. Wash in warm water with detergent. There are no special recommendations for setting a dryer temperature (CDC, 2007).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me how what you will do to decrease the transmission of infection at home. Show me how you do hand hygiene before the dressing change.
- Show me how you would change your dressing.
- Tell me three signs or symptoms of wound infection that you will watch for. Tell me the signs and symptoms that you might develop

that would require you to call your health care provider.

Surgical Asepsis

Surgical asepsis or sterile technique prevents contamination of an open wound, serves to isolate an operative or procedural area from an unsterile environment, and maintains a sterile field for surgery or procedural intervention. Surgical asepsis includes procedures used to eliminate all microorganisms, including pathogens and spores, from an object or area (Chetan, 2018). In surgical asepsis an area or object is considered contaminated if touched by any object that is not sterile. It demands the highest level of aseptic technique and requires that all areas be kept free of infectious microorganisms.

Use surgical asepsis in the following situations:

- During procedures that require intentional perforation of the patient's skin, such as insertion of peripheral IV catheters or a central IV line
- When the integrity of the skin is broken as a result of trauma, surgical incision, or burns
- During invasive procedures, such as the insertion of a urinary catheter or the insertion of surgical instruments into sterile body cavities (e.g., placement of a wound drain)

Although surgical asepsis is common in the operating room, labor and delivery area, and major diagnostic/procedural areas, you also use surgical aseptic techniques at the patient's bedside (e.g., when inserting IV or urinary catheters, suctioning the tracheobronchial airway, and sterile dressing changes). A nurse in an operating room follows a series of steps to maintain sterile technique, including applying a mask, protective eyewear, and a cap; performing a surgical hand scrub; and applying a sterile gown and gloves. In contrast, a nurse performing a dressing change at a patient's bedside only performs hand hygiene and applies sterile gloves. For certain procedures (e.g., changing a central line dressing) the nurse also uses a mask and gown (see agency policy). Regardless of the procedures followed or the setting, the nurse always recognizes the importance of strict adherence to aseptic principles (Iwamoto and Post, 2018).

Patient Preparation for a Sterile Procedure

Because surgical asepsis requires exact techniques, you need to have the patient's full cooperation. Therefore, assess a patient's understanding of the sterile procedure, and explain the reasons for not moving or interfering with the procedure. Certain patients fear moving or touching objects during a sterile procedure, whereas others try to help. Explain how you will perform a procedure and what the patient can do to avoid contaminating sterile items, including the following:

- Avoid sudden movements of body parts covered by sterile drapes.
- Refrain from touching sterile supplies, drapes, or the nurse's gloves and gown.
- Avoid coughing, sneezing, or talking over a sterile area.

Certain sterile procedures last an extended time. Assess a patient's needs and anticipate factors that may disrupt a procedure. If a patient is in pain, administer ordered analgesics about a half an hour before a sterile procedure begins. Ask a patient whether he or she needs to use the bathroom or a bedpan. Often patients have to assume relatively uncomfortable positions during sterile procedures. Help a patient assume the most comfortable position possible. Finally, a patient's condition sometimes results in actions or events that contaminate a sterile field. For example, a patient with a respiratory infection transmits organisms by coughing or talking. Anticipate such a problem and place a surgical mask on him or her before the procedure begins.

Principles of Surgical Asepsis

Performing sterile aseptic procedures requires a work area in which objects can be handled with minimal risk of contamination. A sterile field provides a sterile surface for placement of sterile equipment. It is an area considered free of microorganisms and consists of a sterile kit or tray, a work surface draped with a sterile towel or wrapper, or a table covered with a large sterile drape (Murphy, 2018). When beginning a surgically aseptic procedure, nurses follow certain principles to ensure maintenance of asepsis. Failure to follow these principles places patients at risk for infection. The following principles are important:

1. *A sterile object remains sterile only when touched by another sterile object.* This principle guides a nurse in placement of sterile objects and how to handle them.

- a. Sterile touching sterile remains sterile (e.g., use sterile gloves or sterile forceps to handle objects on a sterile field).
 - b. Sterile touching clean becomes contaminated (e.g., if the tip of a syringe or other sterile object touches the surface of a clean disposable glove, the object is contaminated).
 - c. Sterile touching contaminated becomes contaminated (e.g., when a nurse touches a sterile object with an ungloved hand, the object is contaminated).
 - d. Sterile state is questionable (e.g., when you find a tear or break in the covering of a sterile object). Discard it regardless of whether the object itself appears untouched.
2. *Only sterile objects may be placed on a sterile field.* All items are properly sterilized before use. Sterile objects are kept in clean, dry storage areas. The package or container holding a sterile object must be intact and dry. A package that is torn, punctured, wet, or open is considered unsterile.
 3. *A sterile object or field out of the range of vision or an object held below a person's waist is contaminated.* Nurses never turn their back on a sterile field or tray or leave it unattended. Contamination can occur accidentally by a dangling piece of clothing or an unknowing patient touching a sterile object. Any object held below waist level is considered contaminated because it cannot always be viewed. Keep sterile objects in front with the hands as close together as possible.
 4. *A sterile object or field becomes contaminated by prolonged exposure to air.* Avoid activities that create air currents such as excessive movements or rearranging linen after a sterile object or field becomes exposed. When you open sterile packages, it is important to minimize the number of people walking into an area. Microorganisms also travel by droplet through the air. Do not talk, laugh, sneeze, or cough over a sterile field or when gathering and using sterile equipment. When opening sterile packages, hold the item or piece of equipment as close as possible to the sterile field without touching the sterile surface.
 5. When a sterile surface comes in contact with a wet, contaminated surface, the sterile object or field becomes contaminated by capillary action. If moisture leaks through the protective covering of a sterile package, microorganisms travel to the sterile object.

When stored sterile packages become wet, discard the objects immediately or send the equipment for resterilization. When working with a sterile field or tray, you may have to pour sterile solutions. Any spill is a source of contamination unless on a sterile surface that moisture cannot penetrate. Urinary catheterization trays contain sterile supplies that rest in a sterile, plastic container. In contrast, if you place a piece of sterile gauze in its wrapper on a patient's bedside table and the table surface is wet, the gauze is considered contaminated.

6. *Fluid flows in the direction of gravity.* A sterile object becomes contaminated if gravity causes a contaminated liquid to flow over the surface of the object. To avoid contamination during a surgical hand scrub, hold your hands above your elbows. This allows water to flow downward without contaminating your hands and fingers. The principle of water flow by gravity is also the reason for drying from fingers to elbows, with hands held up, after the scrub.
7. *The edges of a sterile field or container are considered to be contaminated.* Frequently you place sterile objects on a sterile towel, drape, or tray (Fig. 28.5). Because the edge of the drape touches an unsterile surface such as a table or bed linen, a 2.5-cm (1-inch) border around the drape is considered contaminated. Objects placed on the sterile field need to be *inside* this border. The edges of sterile containers become exposed to air after they are open and thus are contaminated. After you remove a sterile needle from its protective cap or forceps from a container, the objects must not touch the edge of the container.

FIG. 28.5 Placing sterile item on sterile field.

Performing Sterile Procedures

Assemble all the equipment that will be needed before a procedure. Have a few extra supplies available in case objects accidentally become contaminated. Do not leave a sterile area, because you will not know if the area was contaminated during your absence. Before a sterile procedure, explain each step so that the patient can cooperate fully. If an object becomes contaminated during the procedure, do not hesitate to discard it immediately.

Donning and Removing Caps, Masks, and Eyewear

Wear a surgical mask and eyewear without a cap for any sterile procedures on a general nursing unit. Eyewear is worn as a part of Standard Precautions if there is a risk of fluid or blood splashing into your eyes. For sterile surgical procedures, you first apply a clean cap that covers all your hair and then the surgical mask and eyewear. A mask must fit snugly around the face and nose. After wearing a mask for several hours, the area over the mouth and nose often becomes moist. Because moisture promotes the growth of microorganisms, change the mask if it becomes moist.

Protective glasses or goggles fit snugly around the forehead and face to fully protect the eyes. Wear eyewear only for procedures that create the risk of body fluids splashing into the eyes. Remove PPE in the following

order: gloves, face shield or goggles, gown, and mask or respirator ([CDC, 2005b](#)). After removing all PPE, perform hand hygiene.

Opening Sterile Packages

Sterile items such as syringes, gauze dressings, or catheters are packaged in paper or plastic containers and are impervious to microorganisms as long as they are dry and intact. These items have expiration labels on the packages. Do not use an item after the expiration date. Some institutions wrap reusable supplies (e.g., operating room instruments) in a double thickness of paper, linen, or muslin. These packages are permeable to steam and thus allow for steam autoclaving. Sterile items are kept in clean, enclosed storage cabinets and separated from dirty equipment.

Sterile supplies that have been autoclaved have chemical tapes indicating that a sterilization process has taken place. The tapes change color during the process. Failure of the tapes to change color means that the item is not sterile. Health care agencies follow the principles of event-related sterility, a concept that items are considered sterile if the packaging is uncompromised ([Jefferson and Young, 2018](#)). Never use a sterile item if the packaging is open or soiled, shows evidence that the package has been wet, or has dropped to the floor. Before opening a sterile item, perform hand hygiene. Inspect the supplies for package integrity and sterility and assemble the supplies in the work area such as the bedside table or treatment room before opening packages. A bedside table or countertop provides a large, clean working area for opening items. Keep the work area above waist level. Do not open sterile supplies in a confined space where contamination might occur.

Opening a Sterile Item on a Flat Surface

You must open sterile packages without contaminating the contents. Commercially packaged items are usually designed so that you only have to tear away or separate the paper or plastic cover. Hold the item in one hand while pulling the wrapper away with the other ([Fig. 28.6](#)). Take care to keep the inner contents sterile before use. You may use a sterile wrapper from a commercial kit or a sterile paper or linen wrapper from an institutional pack to create a sterile field on which to work. Use the inner surface of the package (except for the 2.5-cm [1-inch] border around the edges) as a sterile field to add sterile items. You can grasp the 2.5-cm (1-inch) border to maneuver the field on a table surface (see Skill 28.2).

FIG. 28.6 Nurse opens sterile package on work area above waist level.

Opening a Sterile Item While Holding It

To open a small sterile item, hold the package in your nondominant hand while opening the top flap and pulling it away from you. Using the dominant hand, carefully open the sides and innermost flap away from the enclosed sterile item in the same order as opening a sterile item on a flat surface (see Skill 28.2). You open the item in a hand so that you can pass it to a person wearing sterile gloves or transfer it to a sterile field.

Preparing a Sterile Field

When performing sterile procedures, you need a sterile work area that provides room for handling and placing sterile items. A **sterile field** is an area free of microorganisms and prepared to receive sterile items. You prepare the field by using the inner surface of a sterile wrapper as the work surface or by using a sterile drape or dressing tray. After creating the surface for the sterile field, add sterile items by placing them directly on the field or transferring them with sterile forceps (see Skill 28.2). Discard an object that comes in contact with the 2.5-cm (1-inch) border.

Sometimes you will wear sterile gloves while preparing items on a sterile field. If you do this, you can touch the entire drape, but sterile items must be handed over by an assistant. The gloves cannot touch the wrappers of sterile items.

Pouring Sterile Solutions

Often you need to pour sterile solutions into sterile containers. A bottle containing a sterile solution is sterile on the inside and contaminated on

the outside; the neck of the bottle is also contaminated, but the inside of the bottle cap is considered sterile. After you remove the cap or lid, hold it in your hand or place its sterile side (inside) up on a *clean* surface. This means that you can see the inside of the lid as it rests on the table surface. Never rest a bottle cap or lid on a sterile surface. The outer edge of the cap is unsterile and contaminates the surface. Placing a sterile cap down on an unsterile surface increases the chances of the inside of the cap becoming contaminated.

Hold the bottle with its label in the palm of the hand to prevent the possibility of the solution wetting and fading the label. Keep the edge of the bottle away from the edge or inside of the receiving container. Pour the solution slowly to avoid splashing the underlying drape or field. Never hold the bottle so high above the container that even slow pouring causes splashing. Hold the bottle outside the edge of the sterile field. Any remaining fluids should be discarded. The edge of a container is considered contaminated after the contents have been poured. Reuse of open containers may contaminate solutions due to drops contacting unsterile areas and then running back over container openings ([AORN, 2019](#)).

Surgical Scrub

Patients undergoing operative procedures are at an increased risk for infection. Nurses working in operating rooms perform surgical hand antisepsis (see Skill 28.3) to decrease and suppress the growth of skin microorganisms under gloved hands in case of glove tears. A surgical hand scrub must eliminate the transient flora and reduce the resident flora on the hands. For maximum elimination of bacteria, remove all jewelry and keep the nails clean and short. Do not wear chipped nail polish, artificial nails, or extenders because they often hold a greater number of bacteria ([AORN, 2019](#); [WHO, 2009](#)). Nurses who have active skin infections, open lesions or cuts, or respiratory infections should be excluded from the surgical or procedure team.

During surgical hand antisepsis the nurse scrubs from fingertips to elbows with an antiseptic soap before each surgical procedure. Research studies vary on the optimum duration of a surgical hand scrub ([WHO, 2009](#)). Chlorhexidine gluconate has been found to be more effective than povidone-iodine as a cleansing agent, although both can be found in health care agencies. Thus, the type of product used for cleansing will influence the time required for hand antisepsis ([CDC, 2008](#); [WHO 2009](#)). The traditional scrub time in the United States for both the initial and the

subsequent scrub is 5 minutes, but research has shown effectiveness can be gained when scrubs are performed for 2, 3, and 6 minutes (WHO, 2009). Follow the manufacturer recommendation for scrub solutions. For many years preoperative handwashing protocols required nurses to scrub with a brush. However, this practice damages the skin. Scrubbing with a disposable sponge or combination sponge-brush reduces bacterial counts on the hands as effectively as scrubbing with a brush. However, several studies suggest that neither a brush nor a sponge is necessary to reduce bacterial counts on the hands, especially when using an alcohol-based product (CDC, 2008).

Applying Sterile Gloves

Sterile gloves are an additional barrier to bacterial transfer. There are two gloving methods: open and closed. Nurses who work on general nursing units use open gloving before procedures such as dressing changes or urinary catheter insertions. The glove cuffs are placed over a gown sleeve (when worn). The closed-gloving method, which you perform after applying a sterile gown, is practiced in operating rooms and special procedure areas (see Skills 28.4 and 28.5). In this case, the glove cuffs remain under the surgical gown cuffs. Make sure to select the proper glove size; the glove should not stretch so tightly that it can tear easily, yet it must be tight enough that you can pick up objects easily.

Donning a Sterile Gown

Nurses wear sterile gowns when assisting at the sterile field in the operating room, delivery room, and special procedure areas. It allows the nurse to handle sterile objects and also be comfortable with less risk of contamination. The sterile gown acts as a barrier to decrease shedding of microorganisms from skin surfaces into the air and thus prevents wound contamination. Nurses caring for patients with large open wounds or assisting health care providers during major invasive procedures (e.g., inserting an arterial catheter) also wear sterile gowns. The circulating nurse generally does not wear one.

The nurse does not apply a sterile gown until after applying a mask and surgical cap and completing surgical handwashing. He or she picks up the gown from a sterile pack, or an assistant hands the gown to the nurse. Only a certain portion of the gown (i.e., the area from the anterior waist to, but not including, the collar and the anterior surface of the sleeves) is considered sterile. The back of the gown, the area under the arms, the

collar, the area below the waist, and the underside of the sleeves are not sterile because the nurse cannot keep these areas in constant view and ensure their sterility (see Skill 28.4).

Exposure Issues

Patients and health care personnel, including housekeepers and maintenance personnel, are at risk for acquiring infections from accidental needlesticks. In the past, a stray needle lying in bed linen or carelessly thrown into a wastebasket served as a prime source for exposure to bloodborne pathogens. With the passage of the Needlestick Safety and Prevention Act in 2000 (OSHA, 2012b) and the implementation of safety needle devices, the incidence rate of sharps injuries has decreased. All sharps must now be either needle safe or needleless. After administering an injection or inserting an IV catheter, place the used needle safety device in a puncture-resistant box (see Chapter 31). Sharps boxes must be at the site of use; this is an OSHA requirement (OSHA, 2012b).

HBV and HCV are the infections most commonly transmitted by contaminated needles (Box 28.16). Report any contaminated needlestick immediately. Additional criteria for exposure reporting include blood or other potentially infectious materials (OPIMs) that come into direct contact with an open area of the skin, blood or OPIM that is splashed into a health care worker's eye or mouth or up the nose, and cuts with a sharp object that is covered with blood or OPIM.

Box 28.16 Hepatitis B Vaccination and Postexposure

Follow-Up After Hepatitis C and Human Immunodeficiency Virus Exposure

CDC, Centers for Disease Control and Prevention; *RNA*, ribonucleic acid; *PEP*, postexposure prophylaxis.

- Health care employers shall make available the hepatitis B vaccine and vaccination series to all employees who may have occupational exposures. If an employee declines the vaccine, he or she must sign a declination form. Evaluation and follow-up care is available to all employees who have been exposed.

- Hepatitis B vaccinations are made available to employees within 10 working days of assignment—this means before starting to provide patient care and after receiving education and training on the vaccine.
- A blood test (titer) is offered in some facilities 1 to 2 months after completing the three-dose vaccine series (check the health care agency policy).
- Vaccine is offered at no cost to employees. At present the vaccine does not require any boosters.
- After exposure no treatment is needed if there is a positive blood titer on file. If no positive titer is on file, follow CDC guidelines.

Exposure to Hepatitis C Virus

- If the source patient is positive for hepatitis C virus (HCV), the employee receives a baseline test.
- At 4 weeks after exposure the employee should be offered an HCV-RNA test to determine whether he or she contracted HCV.
- If positive, the employee starts treatment.
- There is no prophylactic treatment for HCV after exposure.
- Early treatment for infection can prevent chronic infection.

Exposure to Human Immunodeficiency Virus

- If the patient is positive for human immunodeficiency virus (HIV) infection, a viral load study should be performed to determine the amount of virus present in the blood.
- If the exposure meets the CDC criteria for HIV PEP, it should be started as soon as possible, preferably within 24 hours after the exposure (CDC, 2013c).

All medical evaluations and procedures, including the vaccine and vaccination series and evaluation after exposure (prophylaxis), are made available at no cost to at-risk employees.

A confidential written medical evaluation will be available to employees with exposure incidents.

From Occupational Safety and Health Administration: Occupational Safety and Health Act of 2001, 2001, 2005, <http://www.cdc.gov>.

Follow-up for risk of acquiring infection begins with source patient testing. Access to testing the source patient is stated in the testing law for each state. Some states have deemed consent, which means that the state has granted the patient's consent to be tested. Other states require that the patient consent to testing for the presence of bloodborne pathogens. Know the testing policies in the agency and state in which you practice. Health care agencies and workers' compensation require exposed employees to complete an injury report and seek appropriate treatment if needed. The need for treatment is linked to the results of a risk assessment and the testing of the patient. Test the patient for HIV, HBV, and HCV. If positive for HIV or HCV, testing for syphilis may be indicated because of the incidence of coinfection ([CDC, 2015e](#)). It is required that an exposed employee be given the patient's testing results. This is *not* a violation of the Health Insurance Portability and Accountability Act (HIPAA) of 1996. Both the CDC and OSHA state that this information must be given to the exposed health care worker contingent on the health care worker's willingness to be tested.

Testing the exposed employee at the time of the exposure is not needed immediately unless required by the state testing law. If the patient tests positive for a bloodborne pathogen or if the source patient is unknown, prophylactic treatment is recommended for the employee.

Exposures also occur involving nonbloodborne pathogens. Airborne and droplet diseases pose a risk to the nonimmune nurse. The [CDC \(2016\)](#) has published a list of recommended immunizations and vaccinations for health care workers, including hepatitis B vaccine; TB testing; annual influenza vaccine; measles, mumps, and rubella (MMR); chickenpox vaccine; and tetanus, diphtheria, and pertussis. Employee health should review your health history and offer appropriate prevention. Declination forms are needed if these are declined ([OSHA, 2011](#))

• Evaluation

Measure the success of infection prevention and control techniques by determining whether you achieved the goals for reducing or preventing infection. Document the patient's response to therapies for infection prevention and control. A clear description of any signs and symptoms of systemic or local infection is necessary to give all nurses a baseline for comparative evaluation.

Through the Patient's Eyes

Patients generally expect to be safe and protected when receiving health care. Ask patients about whether their expectations for care have been met. A patient at risk for infection needs to understand the measures needed to reduce or prevent microorganism growth and spread. Providing patients and/or family caregivers the opportunity to discuss infection prevention and control measures or to demonstrate procedures such as hand hygiene reveals their ability to adhere to therapy. Be sure that you understand the patient's perceptions of how infection spreads, his or her expectations for self-care, and how it can affect him or her as you evaluate the results of your instruction. Sometimes patients require new information, or previously instructed information needs reinforcement.

Patient Outcomes

A comparison of a patient's response before and after an infection control measure, such as the absence of fever or wound infection, is an example of an expected outcome for measuring the success of nursing interventions. Observe wounds during dressing changes to determine the degree of wound healing. Monitor patients, especially those at risk, for signs and symptoms of infection. For example, a patient who has undergone a surgical procedure is at risk for infection at the surgical site and other invasive sites such as the venipuncture site or central line sites. In addition, the patient is at risk for a respiratory tract infection as a result of decreased mobility and for a UTI if an indwelling catheter is present. Observe all invasive and surgical sites for swelling, erythema (redness), or purulent drainage. Monitor breath sounds for changes and observe sputum character for change in color or consistency. Review laboratory test results for leukocytes. For example, leukocytosis in the urine often indicates a UTI. The absence of signs or symptoms of infection is the expected outcome of infection prevention and control.

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with members of the health care team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

- Apply Standard Precautions when performing all nursing care activities.
- Use clean gloves when you anticipate contact with body fluids and nonintact skin or mucous membranes when there is a risk of drainage.
- Use gown, mask, and eye protection when there is a risk for splash.
- Keep bedside table surfaces clutter-free, clean, and dry when performing aseptic procedures.
- Clean all equipment that is shared between patients.
- Ensure that patients cover mouth and nose when coughing or sneezing, use tissues to contain respiratory secretions, and dispose of tissues in waste receptacle.

Skill 28.1. Hand Hygiene ◦

Delegation and Collaboration

The skill of hand hygiene is performed by all caregivers. Hand hygiene is not optional.

Equipment

- Antiseptic hand rub
 - Alcohol-based waterless antiseptic
- Handwashing
 - Easy-to-reach sink with warm running water
 - Antimicrobial or regular soap
 - Paper towels
 - Disposable nail cleaner (*optional*)

Step	Rationale
Assessment	
1. Inspect surface of hands for breaks or cuts in skin or cuticles. Cover any skin lesions with a dressing before providing care. If lesions are too large to cover, you may be restricted from direct patient care.	Open cuts or wounds can harbor high concentrations of microorganisms. Agency policy may prevent nurses from caring for high-risk patients if open lesions are present on hands (WHO, 2017).
2. Inspect hands for visible soiling.	Visible soiling requires handwashing with soap and water (CDC, 2017a).
3. Inspect condition of nails. Natural tips should be no longer than 0.625 cm (¼ inch) long. Be sure that fingernails are short, filed, and smooth.	Microorganisms can live under artificial nails after handwashing and using an alcohol-based sanitizer and should not be worn by health care providers having direct contact with patients (CDC, 2017b).
Planning	
1. Ensure that a filled hand sanitizer dispenser is available and/or a sink with running water and soap.	Having needed hand hygiene supplies readily available and visible increases hand hygiene adherence.
Implementation	
1. Push wristwatch and long uniform sleeves above wrists. Avoid wearing rings. If worn, remove during hand hygiene.	Provides complete access to fingers, hands, and wrists. The skin underneath jewelry may carry a higher bacterial count (AORN, 2019).
2. Antiseptic hand rub	
a. Following manufacturer directions, dispense ample amount of product into palm of one hand (see illustration).	Use enough product to cover hands thoroughly.
b. Rub hands together covering all surfaces of hands and fingers with antiseptic (see illustration).	Ensures even bacteriostatic action.
c. Rub hands together (approximately 20 seconds) until alcohol is dry. Allow hands to dry completely before applying gloves.	Provides enough time for product to work (CDC, 2017a).
3. Handwashing using regular or antimicrobial soap:	
a. Stand in front of sink, keeping hands and uniform away from sink surface. (If hands touch sink during handwashing, repeat sequence.)	Inside of sink is a contaminated area. Reaching over sink increases risk of touching edge, which is contaminated.
b. Turn on water. Turn on faucet (see illustration). It is best if sinks have knee, foot, or electronic sensor controls.	Knee pads within operating room and treatment areas are preferred to prevent hand contact with faucet. Faucet handles are likely to be contaminated with organic debris and microorganisms (AORN, 2019).
c. Avoid splashing water against uniform.	Microorganisms travel and grow in moisture.
d. Regulate flow of water so that temperature is warm.	Warm water removes less of protective oils on hands than hot water.
e. Wet hands and wrists thoroughly under running water. Keep hands and forearms lower than elbows during washing.	Hands are most contaminated parts to wash. Water flows from least to most contaminated area, rinsing microorganisms into sink.
f. Apply the amount of antiseptic soap recommended by the manufacturer and rub hands together (see illustration).	Ensure that all surfaces of hands and fingers are cleaned.
 <p data-bbox="358 1478 561 1493">Step 2a Apply waterless antiseptic to hands.</p>	 <p data-bbox="927 1457 1057 1472">Step 2b Rub hands thoroughly.</p>

Table Continued

Step	Rationale
CLINICAL DECISION: The decision whether to use an antiseptic soap or an alcohol-based hand rub depends on whether the hands are visibly soiled, the type of infectious microorganism, the procedure you will perform, and the patient's immune status.	
g. Perform hand hygiene using plenty of lather and friction for at least 15 seconds. Interlace fingers and rub palms and back of hands with circular motion at least five times each. Keep fingertips down to facilitate removal of microorganisms.	Soap cleans by emulsifying fat and oil and lowering surface tension. Friction and rubbing mechanically loosen and remove dirt and transient bacteria. Interlacing fingers and thumbs ensures that all surfaces are cleaned. Adequate time is needed to expose skin surfaces to antimicrobial agent.
h. Areas underlying fingernails are often soiled. Clean them with fingernails of other hand and additional soap or with disposable nail cleaner.	Area under nails can be highly contaminated, which increases risk for transmission of infection from nurse to patient.
i. Rinse hands and wrists thoroughly, keeping hands down and elbows up (see illustration).	Rinsing mechanically washes away dirt and microorganisms.
j. Dry hands thoroughly from fingers to wrists with paper towel or single-use cloth.	Drying from cleanest (fingertips) to least clean (wrist) avoids contamination. Drying hands prevents chapping and roughened skin. Do not tear or cut skin under or around nail.
k. If paper towel is used, discard in proper receptacle.	Prevents transfer of microorganisms.
l. To turn off hand faucet, use clean, dry paper towel; avoid touching handles with hands (see illustration). Turn off water with foot or knee pedals (if applicable).	Wet towel and hands allow transfer of pathogens from faucet by capillary action.
m. If hands are dry or chapped, use small amount of lotion or barrier cream.	Helps to minimize skin dryness. Only use lotions or creams approved by your health care agency as they have been selected to not interact with hand sanitizing products (CDC, 2017a).
 <p>Step 2b Turn on water.</p>	 <p>Step 2f Lather hands thoroughly.</p>
 <p>Step 2g Rinse hands.</p>	 <p>Step 2h Turn off faucet.</p>

Table Continued

Step	Rationale
Evaluation	
1. Inspect surface of hands for obvious signs of dirt or other contaminants.	Determines if hand hygiene is adequate.
2. Inspect hands for dermatitis or cracked skin.	Breaks in skin integrity increase risk for transmission of microorganisms.
Unexpected Outcomes and Related Interventions	
<p>1. Hands or areas under fingernails remain soiled.</p> <ul style="list-style-type: none"> Repeat handwashing with soap and water. <p>2. Repeated use of soaps or antiseptics causes dermatitis or cracked skin.</p> <ul style="list-style-type: none"> Rinse and dry hands thoroughly after using soap and water; avoid excessive amounts of soap or antiseptic; try various products. Use approved hand lotions or barrier creams that will not interfere with hand sanitizing products (CDC, 2017a). 	
Recording and Reporting	
<ul style="list-style-type: none"> It is unnecessary to document handwashing. Report dermatitis, psoriasis, and/or cuts to your agency's employee health or infection control department. 	
Home Care Considerations	
<ul style="list-style-type: none"> Evaluate the handwashing facilities in a patient's home, including the availability of warm running water and soap, to determine the potential for contamination, how close the facilities are to the patient, and available supplies in the area. Anticipate the need for alternative handwashing products such as alcohol-based hand rubs and/or detergent-containing towels. Instruct the patient and primary caregiver in proper techniques and situations for handwashing. Use teach-back to confirm learning. 	

Skill 28.2. Preparation of Sterile Field

Delegation and Collaboration

Nurses prepare sterile fields for some sterile procedures, such as urinary catheter insertion and performing tracheostomy care and suctioning, while other health care providers usually prepare sterile fields in the operating room (see agency's policy). The skill of preparing a sterile field cannot be delegated to assistive personnel (AP). The nurse can direct the AP to:

- Help with patient positioning and obtain any necessary supplies.

Equipment

- Sterile pack (commercial or facility wrapped)
- Sterile drape or kit that will be used as a sterile field
- Sterile gloves (if not included in kit)
- Sterile solution and equipment specific to procedure
- Waist-high table/countertop surface
- Appropriate personal protective equipment (PPE): gown, mask, cap, protective eyewear (see agency policy)

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Assess type of aseptic technique needed for procedure.	Some procedures require medical, whereas others require surgical aseptic technique.
3. Assess patient's comfort, positioning, oxygen requirements, and elimination needs before preparing for procedure.	Certain procedures requiring a sterile field may last a long time. Anticipates patient's needs so that patient can relax and avoid any unnecessary movement that might disrupt procedure.
4. Assess patient for latex allergies.	A review of the patient's health history may reveal a latex allergy. Determine the need to use latex-free supplies.
5. Check sterile package integrity for punctures, tears, discoloration, moisture, or any other signs of contamination. Check the expiration date. Check sterile package for sterilization indicator (marker that changes color when exposed to heat or steam).	Inspection of packaging ensures that sterile field is not contaminated (AORN, 2019).
6. Anticipate supplies needed for procedure.	Not all sterile kits contain sufficient amounts or types of supplies needed for all procedures. Failure to have the proper supplies may cause you to leave sterile field, increasing risk for contamination and potential need to set up another sterile field.
7. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
8. Instruct patient (and family caregiver, if present) not to touch work surface or equipment during procedure.	Prevents contamination of sterile field. Promotes patient understanding and cooperation.
Table Continued	

Step	Rationale
Planning	
1. Complete all other nursing interventions (e.g., medication administration, hygiene) before beginning procedure.	Prepare sterile field as close as possible to time of use to reduce potential for contamination (AORN, 2019).
2. Suggest that visitors step out of room briefly during procedure. Discourage movement of staff assisting with procedure.	Traffic or movement can increase potential for contamination through spread of microorganisms by air currents.
3. Provide privacy. Arrange equipment/supplies at bedside or in a location convenient to the procedure.	Surgical preparation often includes full or partial skin exposure before draping. Ensures availability of equipment before procedure and prevents break in sterile technique. (Note: Povidone-iodine and chlorhexidine are not considered sterile solutions and require separate work surfaces for preparation).
4. Position patient comfortably for specific procedure to be performed. If a body part is to be examined or treated, position patient so area is accessible. Have AP help with positioning as needed.	Patient should be able to lie still in one position comfortably during procedure. Movement can disrupt the sterile field.
5. Provide an explanation of procedure.	Preparing patient for procedure improves adherence and decreases patient stress.
Implementation	
1. Perform hand hygiene (see Skill 28.1.)	Hand hygiene reduces number of microorganisms on hands, thus reducing transmission to patient. Do not allow rinse water to run down arms onto clean hands (i.e., arms are considered dirty).
2. Apply PPE as needed (check agency policy).	PPE controls microorganism transmission.
3. Select a clean, flat, dry work surface above waist level.	A dry surface is needed for a sterile field. A sterile object placed below a person's waist is considered contaminated.
4. Prepare sterile work surface.	
a. Use sterile commercial kit or package containing sterile items.	
(1) Place sterile kit or package on the prepared work surface.	
(2) Open outside cover (see illustration) and remove package from dust cover. Place on work surface.	Outside of kit is not sterile. Inner kit remains sterile.
(3) Grasp outer surface of tip of outermost flap.	Outer surface of package is considered unsterile. There is a 2.5-cm (1-inch) border around any sterile drape or wrap that is considered contaminated and can be touched with clean fingers.
(4) Open outermost flap away from body, keeping arm outstretched and away from sterile field (see illustration).	Reaching over sterile field contaminates it.
(5) Grasp outside surface of edge of first side flap.	Outer border is considered unsterile.
(6) Open side flap, pulling to side, allowing it to lie flat on table surface. Keep arm to side and not over sterile surface (see illustration).	Drape or wrapper should lie flat, so it does not accidentally rise up and contaminate inner surface or sterile contents.
(7) Repeat Step (6) for second side flap (see illustration).	
 <p>Step 4a(2) Open outside cover of sterile kit.</p>	 <p>Step 4a(4) Open outermost flap of sterile kit away from body.</p>

Table Continued

Step	Rationale
<p>(8) Grasp outside border of last and innermost flap (see illustration). Stand away from sterile package and pull flap back, allowing it to fall flat on table. Kit is ready to be used.</p>	<p>Outer border is considered unsterile. Never reach over a sterile field.</p>
<p>b. Open sterile linen-wrapped package.</p>	
<p>(1) Place package on clean, dry, flat work surface above waist level.</p>	<p>Sterile items placed below waist level are considered contaminated.</p>
<p>(2) Remove sterilization tape seal and unwrap both layers following same steps (see Steps 4a [2] through 4a [8]) as for sterile kit (see illustration).</p>	<p>Linen-wrapped items have two layers. The first is a dust cover. The second layer must be opened to view sterilization indicator.</p>
<p>(3) Use opened package wrapper as sterile field.</p>	<p>Inside of package wrapper is considered sterile.</p>
 <p>Step 4a(6) Open first side flap, pulling to side.</p>	 <p>Step 4a(7) Open second side flap, pulling to side.</p>
 <p>Step 4a(8) Open Last and Innermost flap.</p>	 <p>Step 4b(2) Open sterile linen-wrapped package.</p>

Table Continued

Step	Rationale
c. Prepare sterile drape.	
(1) Place pack containing sterile drape on flat, dry surface and open as described (see Steps 4a [2] through 4a[8]) for sterile package.	Packaged drape remains sterile.
(2) Apply sterile gloves (optional, see agency policy). The outer 2.5-cm (1-inch) border of drape may be touched without wearing gloves.	Sterile object remains sterile only when touched by another sterile object. Gloves are not necessary as long as fingers grasp the 2.5-cm (1-inch) unsterile border of the drape.
(3) Using fingertips of one hand, pick up folded top edge of drape along 2.5-cm (1-inch) border. Gently lift drape up from its wrapper without touching any object. Discard wrapper with other hand.	If sterile object touches any nonsterile object, it becomes contaminated.
(4) With other hand, grasp an adjacent corner of drape and hold it straight up and away from body. Allow drape to unfold, keeping it above waist and work surface and away from body (see illustration).	An object held below a person's waist or above chest is contaminated. Drape can now be placed properly with two hands.
(5) Holding drape, position bottom half over top half of intended work surface (see illustration).	Proper positioning prevents nurse from reaching over sterile field.
(6) Allow top half of drape to be placed over bottom half of work surface (see illustration). Sterile field is ready to use.	Proper positioning creates flat, sterile work surface for placement of sterile supplies.
CLINICAL DECISION: Use slow movements when setting up sterile drapes. Fast movements can stir up dust, lint, and infectious microorganisms, which can contaminate the sterile field.	
5. Add sterile items to sterile field.	
a. Open sterile item (following package directions) while holding outside wrapper in nondominant hand.	Use of nondominant hand frees dominant hand for unwrapping outer wrapper.
b. Carefully peel wrapper over nondominant hand.	Item remains sterile. Inner surface of wrapper covers hand, making it sterile.
c. Be sure that the wrapper does not fall onto the sterile field. Place the item onto the field at an angle (see illustration). Do not hold arms over sterile field.	Secured wrapper edges prevent flipping wrapper and contaminating contents of sterile field (AORN, 2019). Skin is a source of bacteria and shedding.
d. Dispose of outer wrapper.	Disposal prevents accidental contamination of sterile field.
6. Pour sterile solutions.	
a. Verify contents and expiration date of solution.	Verification ensures proper solution and sterility of contents.
b. Place receptacle for solution near table/work surface edge. Sterile kits have cups or plastic molded sections into which fluids can be poured.	Proper placement prevents reaching over sterile field during pouring of solution.
c. Remove sterile seal and cap from bottle in upward motion.	Upward movement prevents contamination of bottle lip.
d. With solution bottle held away from field and bottle lip 2.5 to 5 cm (1 to 2 inches) above inside of sterile receiving container, slowly pour needed amount of solution into container. Hold bottle with label facing palm of hand (see illustration).	Edge and outside of bottle are considered contaminated. Slow pouring prevents splashing. Sterility of contents cannot be ensured if cap is replaced. Prevents label from becoming wet and illegible.

Step	Rationale
	

STEP 4c(4) Grasp corners of sterile drape, then hold up and away from body.

Step

Rationale

STEP 4c(5) Position bottom half of sterile drape over top half of work space.

Step	Rationale
	 <p data-bbox="354 1077 703 1094">STEP 4c(6) Allow top half of drape to be placed over bottom half of work surface.</p>
Table Continued	

Step	Rationale
CLINICAL DECISION: When liquids permeate sterile field or barrier, it is called a strikethrough, resulting in contamination of the sterile field .	
7. Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of infection.
Evaluation	
1. Observe for breaks in sterile technique throughout the procedure.	A break in sterile technique requires you to repeat the procedure.
2. Use Teach-Back: "I want to be sure I explained the procedure that I just performed and steps I took to prevent any infection. Please tell me in what way the procedure will help you." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<ol style="list-style-type: none"> 1. Sterile field comes in contact with contaminated object or liquid splatters onto drape, causing strikethrough. <ul style="list-style-type: none"> • Discontinue field preparation and start over with new equipment. 2. Sterile item falls off sterile field. <ul style="list-style-type: none"> • Open another package containing new sterile item and add to field. Apply a new pair of sterile gloves. If field becomes contaminated, a new sterile field needs to be established. Apply a new pair of sterile gloves. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record the procedure performed and that sterile technique was used. • Discuss with nurses and other pertinent health care providers the sterile procedure performed, outcome, patient's response, and any necessary follow-up. This assures quality continuation of care and provides for optimal patient outcomes. 	

Skill 28.3. Surgical Hand Asepsis

Delegation and Collaboration

The skill of surgical hand asepsis can be delegated to properly trained surgical technicians (know the state Nurse Practice Act).

Equipment

- Deep sink with foot or knee controls for dispensing water and soap (faucets should be high enough for hands and forearms to fit comfortably)
- Antimicrobial agent approved by the health care agency
- Surgical scrub sponge with plastic nail pick (*optional*)
- Paper face mask, cap or hood, surgical shoe covers
- Sterile towel
- Sterile pack containing sterile gown
- Protective eyewear (glasses or goggles)

Step	Rationale
<p>1. Consult manufacturer policy regarding required length of time and antiseptic to use for hand antisepsis. Chlorhexidine has been found to be more effective than povidone iodine (WHO, 2009).</p>	<p>Guidelines vary regarding ideal time needed and antiseptic to use for surgical scrub. Most facilities in the United States follow 5 minutes for hand scrub (WHO, 2015).</p>
<p>2. Remove bracelets, rings, and watches.</p>	<p>Jewelry may harbor or protect microorganisms from removal. Allergic skin reactions may occur as a result of scrub agent or glove powder accumulating under jewelry (Association of Surgical Technologists [AST], 2017).</p>
<p>3. Be sure that fingernails are short, clean, and healthy. Artificial nails should be removed. Natural nails should be less than ¼ inch long from fingertip.</p>	<p>Long nails and chipped or old polish increase number of bacteria residing on nails. Long fingernails can puncture gloves, causing contamination. Artificial nails are known to harbor gram-negative microorganisms and fungus (AORN, 2019; CDC, 2008).</p>
<div data-bbox="358 527 695 730" data-label="Image"> </div> <p data-bbox="358 737 509 751">Step 5c Add items to sterile field.</p>	<div data-bbox="862 527 1284 804" data-label="Image"> </div> <p data-bbox="862 810 1117 825">Step 6d Pour solution into receiving container on sterile field.</p>
<p>Table Continued</p>	

Step	Rationale
CLINICAL DECISION: Remove nail polish if chipped or worn longer than 4 days because it is likely to harbor microorganisms (AORN, 2019).	
4. Inspect condition of cuticles, hands, and forearms for abrasions, cuts, or open lesions.	These conditions increase likelihood of more microorganisms residing on skin surfaces. Broken skin permits microorganisms to enter layers of the skin, providing deeper microbial breeding grounds (AORN, 2019).
5. Apply surgical shoe covers, cap or hood, face mask, and protective eyewear (depends on procedure; see agency policy).	Mask prevents escape into air of microorganisms that can contaminate hands. Other protective wear prevents exposure to blood and body fluid splashes during the procedure.
6. Turn on water using knee or foot controls and adjust to comfortable temperature.	Knee or foot controls prevent contamination of hands after scrub.
7. Prescrub wash/rinse: Wet hands and arms under running lukewarm water and lather with detergent to 5 cm (2 inches) above elbows. (Hands need to be above elbows at all times.)	Water runs by gravity from fingertips to elbows. Hands become cleanest part of upper extremity. Keeping hands elevated allows water to flow from least to most contaminated areas. Washing a wide area reduces risk of contaminating overlying gown that the nurse later applies.
8. Rinse hands and arms thoroughly under running water. Remember to keep hands above elbows.	Rinsing removes transient bacteria from fingers, hands, and forearms.
9. Under running water clean under nails of both hands with nail pick. Discard after use (see illustration).	Removes dirt and organic material that harbor large numbers of microorganisms.
10. Surgical hand scrub (with sponge)	
a. Wet clean sponge and apply antimicrobial agent. Visualize each finger, hand, and arm as having four sides. Wash all four sides effectively. Scrub the nails of one hand with 15 strokes. Scrub the palm, each side of thumb and fingers, and posterior side of hand with 10 strokes each.	Friction loosens resident bacteria that adhere to skin surfaces. Ensures coverage of all surfaces. Scrubbing is performed from cleanest area (hands) to marginal area (upper arms).
b. Divide the arm mentally into thirds: scrub each third 10 times (AORN, 2019) (see illustration). Some health care agency policies require scrub by total time (e.g., 5 minutes) rather than number of strokes. Rinse sponge and repeat sequence for the other arm. A two-sponge method may be substituted (check health care agency policy).	Eliminates transient microorganisms and reduces resident hand flora.
c. Discard sponge. Flex arms and rinse from fingertips to elbows in one continuous motion, allowing water to run off at elbow (see illustration).	Hands remain the cleanest part of upper extremities.
d. Turn off water with foot or knee control, with hands elevated in front of and away from body. Enter operating room suite by backing into room.	Keeps hands free of microorganisms.
e. Approach sterile setup; grasp sterile towel, taking care not to drip water onto sterile setup.	Water contaminates sterile setup.

Step 9 Clean under fingernails.

Table Continued

Step	Rationale
f. Bending slightly at waist, keeping hands and arms above waist and outstretched, grasp one end of sterile towel and dry one hand, moving from fingers to elbow in a rotating motion (see illustrations).	Avoids sterile towel from contacting unsterile scrub attire and transferring contamination to hands. Dry skin from cleanest (hands) to least clean (elbows).
g. Repeat drying method for other hand by carefully reversing towel or using a new sterile towel.	Prevents accidental contamination.
h. Drop towel into linen hamper or circulating nurse's hand.	Prevents accidental contamination.
11. Optional: Brushless antiseptic hand rub	
a. After prescrub wash (see Step 7), dry hands and forearms thoroughly with paper towel.	Promotes reduction in microorganisms on all surfaces of hands and arms.
b. Dispense 2 mL of antimicrobial agent hand preparation into palm of one hand. Dip fingertips of opposite hand into hand preparation and work it under nails. Spread remaining hand preparation over hand and up to just above elbow, covering all surfaces (see illustrations).	
c. Using another 2 mL of hand preparation, repeat with other hand.	
d. Dispense another 2 mL of hand preparation into either hand and reapply to all aspects of both hands up to wrist. Allow to dry thoroughly before donning gloves.	Ensures complete antiseptic coverage of all hand surfaces.
12. Proceed with sterile gowning (see agency policy).	

Step 10b Scrub forearms.

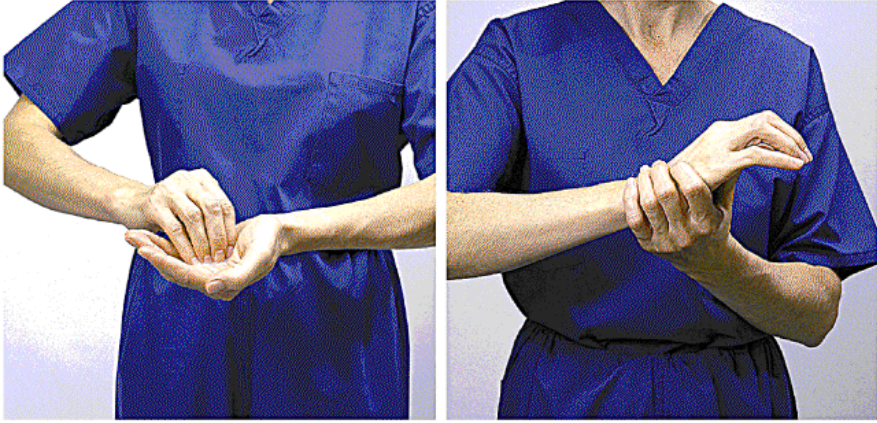

Step 10c Rinse arms.

Step 10f A, Grasp sterile towel. B, Drying sequence.

Table Continued

Step	Rationale
 <p data-bbox="354 678 914 695">Step 11b Application of antimicrobial agent for brushless hand scrub. Nurse using 3M Avagard. (Photos courtesy 3M Health Care.)</p>	
<p data-bbox="267 716 440 737">Recording and Reporting</p> <ul data-bbox="289 739 824 787" style="list-style-type: none"> <li data-bbox="289 739 625 760">• It is not necessary to record or report this procedure. <li data-bbox="289 762 824 787">• Report any skin dermatitis to employee health or infection control per agency policy. 	

Skill 28.4. Open Gloving ◦

Delegation and Collaboration

Assisting with skills that include the application and removal of sterile gloves may be delegated to assistive personnel (AP). However, most procedures that require the use of sterile gloves cannot be delegated to AP. The nurse instructs the AP about:

- The reason sterile gloves are being used for a specific procedure.

Equipment

- Package of proper-size sterile gloves, latex or synthetic nonlatex. If patient has a latex allergy, ensure that gloves are latex free and powder free.

Step	Rationale
Assessment	
1. Consider the type of procedure to be performed and consult agency policy on use of sterile gloves. In some facilities, double gloving is recommended for the operating room and if exposure to blood, body fluids, or infectious microorganisms is anticipated (AORN, 2019).	Ensures proper use of sterile gloves. Evidence supports the use of double gloving and double gloving with an indicator glove system to decrease the risk of percutaneous injury and therefore be an effective barrier to bloodborne pathogen exposure (AORN, 2019).
2. Consider patient's risk for infection (e.g., preexisting condition, immunosuppressed, type of procedure).	Knowledge of risk directs you to follow necessary precautions (e.g., use of additional protective barriers) if necessary.
3. Select correct size and type of gloves and examine glove package to determine if it is dry and intact with no visible stains.	Torn or wet package is considered contaminated. Visible stains on package indicate previous contamination by water or other liquid.
4. Use nonpowdered gloves.	The FDA passed a ruling that powdered gloves may no longer be used due to increased risks of hypersensitivity and allergic reactions (FDA, 2016).
5. Inspect condition of hands for cuts, hangnails, open lesions, or abrasions. In some settings, you can cover any open lesion with a sterile, impervious transparent dressing (check agency policy). In some cases, presence of such lesions may prevent you from participating in a procedure.	Cuts, abrasions, and hangnails tend to ooze serum, which possibly contains pathogens. Breaks in skin integrity permit microorganisms to enter and increase the risk for infection for both patient and nurse (AORN, 2019).
6. Assess patient for the following risk factors before applying latex gloves:	Risk factors determine level of patient's risk for latex allergy.
a. Previous reaction to the following items within hours of exposure: adhesive tape, dental or face mask, golf club grip, ostomy bag, rubber band, balloon, bandage, elastic underwear, intravenous (IV) tubing, rubber gloves, condom.	Items are known to lead to latex allergy.
b. Personal history of asthma, contact dermatitis, eczema, urticaria, rhinitis.	Patients with a history of these conditions are at higher risk of having a reaction.
c. History of food allergies, especially avocado, banana, peach, chestnut, raw potato, kiwi, tomato, papaya.	Patients with a history of food allergies are at higher risk of developing a reaction.
d. Previous history of adverse reactions during surgery or dental procedure.	Previous history suggests allergic response.
e. Previous reaction to latex product.	Previous reaction suggests allergic response.
7. Assess patient's or family caregiver's knowledge, experience and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).

Table Continued

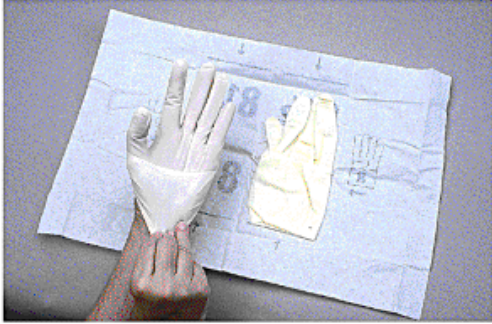

Step	Rationale
Planning	
1. Provide privacy.	Assures patient is comfortable answering assessment questions.
2. Set up equipment.	Having needed supplies readily available decreases time patient needs to be exposed.
3. Explain procedure.	Preparing patient for procedure improves adherence and decreases patient stress.
Implementation	
1. Apply sterile gloves.	
a. Remove outer glove package wrapper by carefully separating and peeling apart sides (see illustration).	Proper removal prevents inner glove package from accidentally opening and touching contaminated objects.
b. Grasp inner package and place on clean, dry, flat surface at waist level. Open package, keeping gloves on inside surface of wrapper (see illustration).	Sterile object held below waist is contaminated. Inner surface of glove package is sterile.
c. Identify right and left glove. Each glove has a cuff approximately 5 cm (2 inches) wide. Glove dominant hand first.	Proper identification of gloves prevents contamination by improper fit. Gloving of dominant hand first improves dexterity.
d. With thumb and first two fingers of nondominant hand, grasp glove for dominant hand by touching only inside surface of cuff.	Inner edge of cuff will lie against skin and thus is not sterile.
e. Carefully pull glove over dominant hand, leaving a cuff and being sure that cuff does not roll up wrist. Be sure that thumb and fingers are in proper spaces (see illustration).	If outer surface of glove touches hand or wrist, it is contaminated.
f. With gloved dominant hand, slip fingers underneath cuff of second glove (see illustration).	Cuff protects gloved fingers. Sterile touching sterile prevents glove contamination.
g. Carefully pull second glove over fingers of nondominant hand (see illustration).	Contact of gloved hand with exposed hand results in contamination.
h. After second glove is on, interlock hands together and hold away from body above waist level until beginning procedure (see illustration).	Ensures smooth fit over fingers and prevents contamination.
 <p data-bbox="355 1272 558 1287">Step 1a Open outer glove package wrapper.</p>	 <p data-bbox="1024 1127 1247 1142">Step 1b Open inner glove package on work surface.</p>
 <p data-bbox="355 1671 854 1696">Step 1c Pick up glove at cuff of dominant hand and insert fingers. Pull glove completely over dominant hand (example is for left-handed person).</p>	 <p data-bbox="1024 1524 1224 1539">STEP 1d Pick up glove for nondominant hand.</p>

Table Continued

Step	Rationale
 <p data-bbox="354 659 591 674">Step 1g Pull second glove over nondominant hand.</p>	 <p data-bbox="1159 352 1269 380">Step 1h Interlock gloved hands.</p>
<p data-bbox="266 699 1333 741">CLINICAL DECISION: Do not allow fingers and thumb of gloved dominant hand to touch any part of exposed nondominant hand. Keep thumb of dominant hand abducted back.</p>	
<p data-bbox="289 753 435 768">2. Perform procedure.</p>	
<p data-bbox="289 783 509 798">3. Remove and dispose of gloves.</p>	
<p data-bbox="302 814 797 829">a. Grasp outside of one cuff with other gloved hand; avoid touching wrist.</p>	<p data-bbox="1078 814 1317 856">Procedure minimizes contamination of underlying skin.</p>

<ul data-bbox="289 1497 1240 1560" style="list-style-type: none"> • No recording or reporting is required for sterile gloving. • Record the procedure performed and patient's response. • Discuss with nurses and other pertinent health care providers the sterile procedure performed, patient's response, outcome, and any necessary follow-up. 	
<p data-bbox="1252 1570 1351 1585" style="text-align: right;">Table Continued</p>	

Step

Rationale

Step 3: Remove second glove by turning it inside out.

Key Points

- Transmission of infection can occur if the six elements of the infection chain are present and uninterrupted.
- Prevention of infection involves breaking an element of the chain of transmission.
- The severity of an infection determines the level and type of nursing care provided.
- Normal body flora and body system defenses help the body resist infection by reducing the number of pathogenic organisms.
- The inflammatory response neutralizes and eliminates pathogens and promotes healing to the damaged cells and tissue.
- Health care–associated infections can lead to adverse patient events and higher health care costs.
- Advanced age, poor nutrition, stress, inherited conditions, chronic disease, and treatments that compromise the immune response increase susceptibility to infection.
- Surgical asepsis requires more stringent techniques than medical asepsis.
- Standard Precautions are applied in all patient care activities to prevent patients and health care workers from transmitting infection.
- Hand hygiene is the most effective basic technique in preventing and controlling infection transmission.

- Transmission-based precautions are used in addition to Standard Precautions for patients with highly transmissible pathogens.
- Educating patients and caregivers on infection prevention in the home should include adaptations made for the home environment.
- Proper application of protective personal equipment protects the patient and health care worker from transmission of pathogens.
- Understanding and practicing infection prevention and control decreases the risk of the health care worker to infectious organisms.
- Understanding the postexposure process allows health care workers to access early intervention and decrease risk of transmission.

Reflective Learning

- Per best practice guidelines, hand hygiene is required before donning both clean and sterile gloves. How would you explain the rationale to a co-worker who states that hand hygiene is not necessary when wearing gloves?
- What would you include in an assessment of a patient with a large, stapled abdominal wound that is open to air?
- What are some infection-related factors to consider when providing care to older adults?

Review Questions

1. A patient who has been placed on Contact Precautions for *Clostridium difficile* (*C. difficile*) asks you to explain what he should know about this organism. What is the most appropriate information to include in patient teaching? (Select all that apply.)
 1. The organism is usually transmitted through the fecal-oral route.
 2. Hands should always be cleaned with soap and water versus alcohol-based hand sanitizer.
 3. Everyone coming into the room must be wearing a gown and gloves.
 4. While the patient is in Contact Precautions, he cannot leave the room.
 5. *C. difficile* dies quickly once outside the body.
2. A patient is diagnosed with meningitis. Which type of isolation precaution is *most* appropriate for this patient?
 1. Reverse isolation
 2. Droplet Precautions
 3. Standard Precautions
 4. Contact Precautions
3. A patient is placed on Airborne Precautions for pulmonary tuberculosis. The nurse notes that the patient seems to be angry, but he knows that this is a normal response to isolation. Which is the best intervention?
 1. Provide a dark, quiet room to calm the patient.
 2. Reduce the level of precautions to keep the patient from becoming angry.

3. Explain the reasons for isolation procedures and provide meaningful stimulation.
4. Limit family and other caregiver visits to reduce the risk of spreading the infection.
4. Which type of personal protective equipment should the nurse wear when caring for a pediatric patient who is placed on Airborne Precautions for confirmed chickenpox/herpes zoster? (Select all that apply.)
 1. Disposable gown
 2. N95 respirator mask
 3. Face shield or goggles
 4. Disposable mask
 5. Gloves
5. The infection control nurse has asked the staff to work on reducing the number of iatrogenic infections on the unit. Which of the following actions on your part would contribute to reducing health care–acquired infections? (Select all that apply.)
 1. Teaching correct handwashing to assigned patients
 2. Using correct procedures in starting and caring for an intravenous infusion
 3. Providing perineal care to a patient with an indwelling urinary catheter
 4. Isolating a patient on antibiotics who has been having loose stool for 24 hours
 5. Decreasing a patient’s environmental stimuli to decrease nausea

6. Which of the following actions by the nurse demonstrate the practice of core principles of surgical asepsis? (Select all that apply.)
 1. The front and sides of the sterile gown are considered sterile from the waist up.
 2. Keep the sterile field in view at all times.
 3. Consider the outer 2.5 cm (1 inch) of the sterile field as contaminated.
 4. Only health care personnel within the sterile field must wear personal protective equipment.
 5. After cleansing the hands with antiseptic rub, apply clean disposable gloves.
7. Put the following steps for removal of protective barriers after leaving an isolation room in order.
 1. Remove and dispose of gloves.
 2. Perform hand hygiene.
 3. Remove eyewear or goggles.
 4. Untie top and then bottom mask strings and remove from face.
 5. Untie waist and neck strings of gown. Remove gown, rolling it onto itself without touching the contaminated side.
8. A patient is diagnosed with a multidrug-resistant organism (MDRO) in his surgical wound and asks the nurse what this means. What is the nurse's best response? (Select all that apply.)
 1. There is more than one organism in the wound that is causing the infection.

2. The antibiotics the patient has received are not strong enough to kill the organism.
 3. The patient will need more than one type of antibiotic to kill the organism.
 4. The organism has developed a resistance to one or more broad-spectrum antibiotics, indicating that the organism will be hard to treat effectively.
 5. There are no longer any antibiotic options available to treat the patient's infection.
9. Which of these statements are true regarding disinfection and cleaning? (Select all that apply.)
1. Proper cleaning requires mechanical removal of all soil from an object or area.
 2. General environmental cleaning is an example of medical asepsis.
 3. When cleaning a wound, wipe around the wound edge first and then clean inward toward the center of the wound.
 4. Cleaning in a direction from the least to the most contaminated area helps reduce infections.
 5. Disinfecting and sterilizing medical devices and equipment involve the same procedures.
10. Patient-to-patient transmission of infection cannot occur if gloves are routinely used.
1. True
 2. False
- Answers:** 1.1, 2, 3; 2.2; 3.3; 4.1, 2, 5; 5.1, 2, 3; 6.2, 3; 7.1, 3, 5, 4, 2; 8.2, 4; 9.1, 2, 4; 10. 2.

Vital Signs

OBJECTIVES

- Explain the principles and mechanisms of thermoregulation.
- Describe nursing measures that promote heat loss and heat conservation.
- Discuss physiological changes associated with fever.
- Describe factors that cause variations in body temperature, pulse, oxygen saturation, respirations, capnography, and blood pressure measurement.
- Describe an ethnic variation with blood pressure assessment.
- Identify ranges of acceptable vital sign values for an infant, a child, and an adult.
- Explain variations in technique used to assess an infant's, a child's, and an adult's vital signs.
- Describe the benefits and precautions involving self-measurement of blood pressure.
- Identify when to measure vital signs.
- Accurately record and report vital sign measurements.
- Appropriately delegate measurement of vital signs to assistive personnel.

Systolic pressure, p. 484

Tachycardia, p. 479

Thermogenesis, p. 469

Thermoregulation, p. 469

Ventilation, p. 480

Vital signs, p. 467

The most frequent and routine measurements obtained by health care providers are those of temperature, pulse, blood pressure (BP), respiratory rate, and oxygen saturation. As indicators of health status, these measures indicate the effectiveness of circulatory, respiratory, neural, and endocrine body functions. Because of their importance, they are referred to as **vital signs** (VS). Pain, a subjective symptom, is often called another vital sign and is frequently measured with the others (see [Chapter 44](#)).

Measurement of vital signs provides data to determine a patient's usual state of health (baseline data). Many factors such as the temperature of the environment, the patient's physical exertion, and the effects of illness cause vital signs to change, sometimes outside an acceptable range. An alteration in vital signs signals a change in physiological function. Assessment of vital signs provides data to identify nursing diagnoses, implement planned interventions, and evaluate outcomes of care.

Vital signs are a quick and efficient way of monitoring a patient's condition or identifying problems and evaluating his or her response to intervention. When you learn the physiological variables

influencing vital signs and recognize the relationship of their changes to one another and to other physical assessment findings, you can make precise determinations about a patient's health status and the need for medical or nursing interventions. Vital signs and other physiological measurements are the basis for clinical decision making and problem solving. Many agencies adopt Early Warning Scores (EWS) determined by vital signs data entered into the electronic medical record (EMR) to alert nurses to potential changes in a patient's condition. An EWS system responds to multiple vital sign parameters at the same time and identifies at-risk patients at the first sign of a subtle change in vital signs ([IHI, 2018](#)).

Guidelines for Measuring Vital Signs

Vital signs are a part of the assessment database. You include them in a complete physical assessment (see [Chapter 30](#)), routinely per a health care provider's order, or obtain them individually to assess a patient's condition. Establishing a database of vital signs during a routine physical examination serves as a baseline for future assessments. A patient's condition determines when, where, how, and by whom vital signs are measured. You need to measure them correctly, and at times you appropriately delegate their measurement. You also need to know expected values ([Box 29.1](#)), interpret your patient's values, communicate findings appropriately, and begin interventions as needed. Use the following guidelines to incorporate measurements of vital signs into nursing practice:

Box 29.1 Vital Signs Acceptable Ranges for

Adults

Temperature Range

Average temperature range: 36° to 38°C (96.8° to 100.4°F)

Average oral/tympanic: 37°C (98.6°F)

Average rectal: 37.5°C (99.5°F)

Axillary: 36.5°C (97.7°F)

Pulse

60 to 100 beats/min, strong and regular

Pulse Oximetry (SpO₂)

Normal: SpO₂ ≥95%

Respirations

12 to 20 breaths/min, deep and regular

Blood Pressure

Systolic <120 mm Hg

Diastolic <80 mm Hg

Pulse pressure: 30 to 50 mm Hg

Capnography (EtCO₂)

Normal: 35-45 mm Hg

- Measuring vital signs is your responsibility. You may delegate these measurements in selected situations (e.g., in stable patients). However, it is your responsibility to review vital sign data, interpret their significance, and critically think through decisions about interventions.
- Assess equipment to ensure that it is working correctly to provide accurate findings.
- Select equipment on the basis of the patient's condition and characteristics (e.g., do not use an adult-size BP cuff for a child).
- Know the patient's usual range of vital signs. These values can differ from the acceptable range for a patient's age or health status. The patient's usual values serve as a baseline for comparison with later findings. Thus you are able to detect a change in condition over time.
- Know your patient's health history, therapies, and prescribed and over-the-counter medications. Some illnesses or treatments cause predictable changes in vital signs. Some medications affect one or more vital signs.

- Control or minimize environmental factors that affect vital signs. For example, assessing a patient's temperature in a warm, humid room may yield a value that is not a true indicator of his or her condition.
- Use an organized, systematic approach. Each vital sign procedure requires a step-by-step approach to ensure accuracy.
- On the basis of a patient's condition, collaborate with health care providers to decide the frequency of vital sign assessment. In the hospital health care providers order a minimum frequency of vital sign measurements for each patient. As a patient's physical condition worsens, it is often necessary to monitor more frequently, such as every 5 to 10 minutes. The nurse is responsible for judging whether more frequent assessments are necessary ([Box 29.2](#)).

Box 29.2 When to Measure Vital Signs

- On admission to a health care facility
- When assessing a patient during home care visits
- In a clinic setting before a health care provider examines the patient and after any invasive procedures
- In a hospital on a routine schedule according to the health care provider's order or hospital standards of practice
- Before, during, and after a surgical procedure or invasive diagnostic/treatment procedure
- Before, during, and after a transfusion of any type of blood product
- Before, during, and after the administration of medication or therapies that affect cardiovascular, respiratory, or temperature-control functions
- When a patient's general physical condition changes (e.g., loss of consciousness or increased intensity of pain)

- Before, during, and after nursing interventions influencing a vital sign (e.g., before a patient previously on bed rest ambulates or before a patient performs range-of-motion exercises)
 - When a patient reports nonspecific symptoms of physical distress (e.g., feeling “funny” or “different”)
-
- Use vital sign measurements to determine indications for medication administration. For example, give certain cardiac drugs only within a range of pulse or BP values. Administer antipyretics when temperature is elevated outside the acceptable range for the patient. Know the acceptable vital sign ranges for your patients before administering medications.
 - Analyze the results of vital sign measurements on the basis of patient’s condition and past health history.
 - Verify and communicate significant changes in vital signs. Baseline measurements provide a starting point for identifying and accurately interpreting possible changes. When VS appear abnormal, have another nurse or health care provider repeat the measurement to verify readings. Inform the charge nurse or health care provider immediately, document findings in your patient’s record, and report changes to nurses during hand-off communication ([TJC, 2020](#)).
 - Educate the patient or family caregiver in vital sign assessment and the significance of findings.

Body Temperature

Physiology

Body temperature is the difference between the amount of heat produced by body processes and the amount lost to the external environment.

$$\text{Heat Produced} - \text{Heat Lost} = \text{Body Temperature}$$

Despite extremes in environmental conditions and physical activity, temperature-control mechanisms of humans keep body **core temperature** (temperature of the deep tissues) relatively constant (Fig. 29.1). However, surface temperature varies, depending on blood flow to the skin and the amount of heat lost to the external environment. Body tissues and cells function efficiently within a narrow range, from 36° to 38°C (96.8° to 100.4°F), but no single temperature is normal for all people.

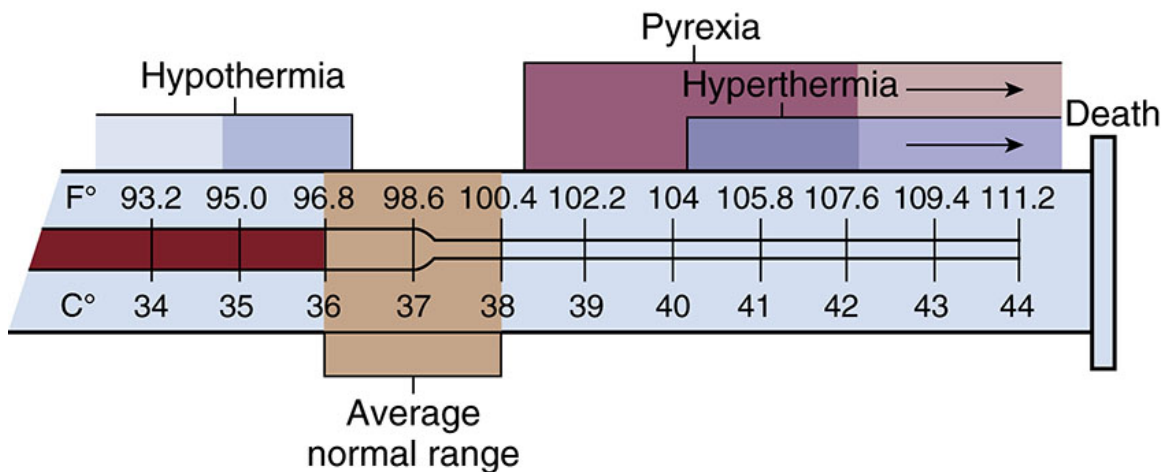

FIG. 29.1 Ranges of normal temperature values and abnormal body temperature alterations.

The site of temperature measurement (oral, rectal, tympanic membrane, temporal artery, esophageal, pulmonary artery, axillary, or even urinary bladder) is one factor that determines a patient's temperature. For healthy young adults the average oral temperature is 37°C (98.6°F). In the elderly population the average core temperature ranges from 35° to 36.1°C (95° to

97°F) as a result of changes in temperature regulation. The time of day also affects body temperature, with the lowest temperature at 6:00 AM and the highest temperature at 4:00 PM in healthy people. Invasive measurements obtained with a pulmonary artery or esophageal catheter are considered core temperatures, whereas axillary temperatures are reflective of the surface temperature of the body. It is important to remember that a consistent body temperature measurement from a single site allows you to monitor patterns of your patient's body temperature. As you assess and document these temperature trends, you collaborate with the health care team to determine whether a specific body temperature measurement site is more appropriate.

Body Temperature Regulation

Physiological and behavioral mechanisms regulate the balance between heat lost and heat produced, or **thermoregulation**. For the body temperature to stay constant and within an acceptable range, various mechanisms maintain the relationship between heat production and heat loss. Apply knowledge of temperature-control mechanisms to promote temperature regulation.

Neural and Vascular Control

The hypothalamus, located between the cerebral hemispheres, controls body temperature the same way a thermostat works in the home. A comfortable temperature is the "set point" at which a heating system operates. In the home a drop in environmental temperature activates the furnace, whereas a rise in temperature shuts the system down.

The hypothalamus senses minor changes in body temperature. The anterior hypothalamus controls heat loss, and the posterior hypothalamus controls heat production. When nerve cells in the anterior hypothalamus become heated beyond the set point, impulses are sent out to reduce body temperature. Mechanisms of heat loss include sweating, vasodilation (widening) of blood vessels, and inhibition of heat production. The body redistributes blood to surface vessels to promote heat loss.

If the posterior hypothalamus senses that body temperature is lower than the set point, the body initiates heat-conservation mechanisms. Vasoconstriction (narrowing) of blood vessels reduces blood flow to the skin and extremities to reduce heat loss. Compensatory heat production is stimulated through voluntary muscle contraction and muscle shivering. When vasoconstriction is ineffective in preventing additional heat loss,

shivering begins. Disease or trauma to the hypothalamus or the spinal cord, which carries hypothalamic messages, causes serious alterations in temperature control.

Heat Production

Temperature regulation depends on normal heat production processes. Heat produced by the body is a by-product of metabolism, which is the chemical reaction in all body cells. Activities requiring additional chemical reactions increase the metabolic rate. As metabolism increases, additional heat is produced. When metabolism decreases, less heat is produced. Heat production occurs during rest, voluntary movements, involuntary shivering, and nonshivering **thermogenesis**.

- Basal metabolism accounts for the heat produced by the body at absolute rest. The average basal metabolic rate (BMR) depends on the body surface area. Thyroid hormones also affect the BMR. By promoting the breakdown of body glucose and fat, thyroid hormones increase the rate of chemical reactions in almost all cells of the body. When large amounts of thyroid hormones are secreted, the BMR can increase 100% above normal. The absence of thyroid hormones reduces the BMR by half, causing a decrease in heat production. The male sex hormone testosterone increases BMR. Men have a higher BMR than women.
- Voluntary movements such as muscular activity during exercise require additional energy. The metabolic rate increases during activity, sometimes causing heat production to increase up to 50 times normal.
- **Shivering** is an involuntary body response to temperature differences in the body. The skeletal muscle movement during shivering requires significant energy. Shivering sometimes increases heat production 4 to 5 times greater than normal. The heat that is produced helps equalize the body temperature, and the shivering ceases. In vulnerable patients shivering seriously drains energy sources, resulting in further physiological deterioration.
- **Nonshivering thermogenesis** occurs primarily in neonates because they cannot shiver ([Hockenberry et al, 2019](#)). A limited amount of vascular brown tissue, present at birth, is metabolized for heat production.

Heat Loss

Heat loss and heat production occur simultaneously. The structure of the skin and exposure to the environment result in constant, normal heat loss through radiation, conduction, convection, and evaporation.

Radiation is the transfer of heat from the surface of one object to the surface of another without direct contact between the two. As much as 85% of the surface area of the human body radiates heat to the environment. Peripheral vasodilation increases blood flow from the internal organs to the skin to increase radiant heat loss. Peripheral vasoconstriction minimizes radiant heat loss. Radiation increases as the temperature difference between the objects increases. Radiation heat loss can be considerable during surgery when the patient's skin is exposed to a cool environment. However, if the environment is warmer than the skin, the body absorbs heat through radiation.

The patient's position enhances radiation heat loss (e.g., standing exposes a greater radiating surface area, and lying in a fetal position minimizes heat radiation). Help promote heat loss through radiation by removing clothing or blankets. Covering the body with dark, closely woven clothing decreases the amount of heat lost from radiation.

Conduction is the transfer of heat from one object to another with direct contact. Solids, liquids, and gases conduct heat through contact. When the warm skin touches a cooler object, heat is lost. Conduction normally accounts for a small amount of heat loss. Applying an ice pack or bathing a patient with a cool cloth increases conductive heat loss. Applying several layers of clothing reduces conductive loss. The body loses heat by conduction when it makes contact with materials cooler than skin temperature (e.g., application of an ice pack).

Convection is the transfer of heat away by air movement. A fan promotes heat loss through convection. The rate of heat loss increases when moistened skin comes into contact with slightly moving air.

Evaporation is the transfer of heat energy when a liquid is changed to a gas. The body continuously loses heat by evaporation. Approximately 600 to 900 mL a day evaporates from the skin and lungs, resulting in water and heat loss. By regulating perspiration or sweating, the body promotes additional evaporative heat loss. When body temperature rises, the anterior hypothalamus signals the sweat glands to release sweat through tiny ducts on the surface of the skin. During physical exercise over 80% of the heat produced is lost by sweat evaporation.

Diaphoresis is visible perspiration primarily occurring on the forehead and upper thorax, although it occurs in other places on the body. For each

hour of exercise in hot conditions up to 2 L of body fluid can be lost in sweat. Excessive evaporation causes skin scaling and itching and drying of the nares and pharynx. A lowered body temperature inhibits sweat gland secretion. People who have a congenital absence of sweat glands or a serious skin disease that impairs sweating are unable to tolerate warm temperatures because they cannot cool themselves adequately.

Skin in Temperature Regulation

The skin regulates temperature through insulation of the body, vasoconstriction (which affects the amount of blood flow and heat loss to the skin), and temperature sensation. The skin, subcutaneous tissue, and fat keep heat inside the body. People with more body fat have more natural insulation than do slim and muscular people.

The way the skin controls body temperature is similar to the way an automobile radiator controls engine temperature. An automobile engine generates a great deal of heat. Water is pumped through the engine to collect the heat and carry it to the radiator, where a fan transfers the heat from the water to the outside air. In the human body the internal organs produce heat; during exercise or increased sympathetic stimulation (such as in the stress response) the amount of heat produced is greater than the usual core temperature. Blood flows from the internal organs, carrying heat to the body surface. The skin has many blood vessels, especially the areas of the hands, feet, and ears. Blood flow through these vascular areas of the skin varies from minimal flow to as much as 30% of the blood ejected from the heart. Heat transfers from the blood, through vessel walls, and to the surface of the skin and is lost to the environment through heat-loss mechanisms. The core temperature of the body remains within safe limits.

The degree of vasoconstriction determines the amount of blood flow and heat loss to the skin. If the core temperature is too high, the hypothalamus inhibits vasoconstriction, thus blood vessels dilate, and more blood reaches the surface of the skin. On a hot, humid day the blood vessels in the hands are dilated and easily visible. In contrast, if the core temperature becomes too low, the hypothalamus initiates vasoconstriction, and blood flow to the skin lessens to conserve heat.

Behavioral Control

Healthy individuals maintain a comfortable body temperature when exposed to temperature extremes. The ability of a person to control body

temperature depends on (1) the degree of temperature extreme, (2) the person's ability to sense feeling comfortable or uncomfortable, (3) thought processes or emotions, and (4) the person's mobility or ability to remove or add clothes. Individuals are less able to control body temperature if any of these abilities are lost. For example, infants are able to sense uncomfortable warm conditions but need help to change their environment. Older adults sometimes need help to detect cold environments and minimize heat loss. Illnesses, a decreased level of consciousness, or impaired thought processes result in an inability to recognize the need to change behavior for temperature control. When temperatures become extremely hot or cold, health-promoting behaviors such as removing or adding clothing have a limited effect on controlling temperature.

Factors Affecting Body Temperature

Many factors affect body temperature. Changes in body temperature within an acceptable range occur when physiological or behavioral mechanisms alter the relationship between heat production and heat loss. Be aware of these factors when assessing temperature variations and evaluating deviations from normal.

Age

At birth the newborn leaves a warm, relatively constant environment and enters one in which temperatures fluctuate widely. Temperature-control mechanisms are immature. An infant's temperature responds drastically to changes in the environment. Take extra care to protect newborns from environmental temperatures. A newborn loses up to 30% of body heat through the head and therefore needs to wear a cap to prevent heat loss (Hockenberry et al., 2019). When protected from environmental extremes, the newborn's body temperature is usually within 35.5° to 37.5°C (95.9° to 99.5°F).

Temperature regulation is unstable until children reach puberty. The usual temperature range gradually drops as individuals approach older adulthood. The older adult has a narrower range of body temperatures than the younger adult. Oral temperatures of 35°C (95°F) are sometimes found in older adults in cold weather. However, the average body temperature of older adults is approximately 35° to 36.1°C (95° to 97°F). Older adults are particularly sensitive to temperature extremes because of deterioration in control mechanisms, particularly poor vasomotor control

(control of vasoconstriction and vasodilation), reduced amounts of subcutaneous tissue, reduced sweat gland activity, and reduced metabolism.

Exercise

Muscle activity requires an increased blood supply and carbohydrate and fat breakdown. Any form of exercise increases metabolism and heat production and thus body temperature. Prolonged strenuous exercise such as long-distance running temporarily raises body temperature.

Hormone Level

Women generally experience greater fluctuations in body temperature than men. Hormonal variations during the menstrual cycle cause body temperature fluctuations. Progesterone levels rise and fall cyclically during the menstrual cycle. When progesterone levels are low, the body temperature is a few tenths of a degree below the baseline level. The lower temperature persists until ovulation occurs. During ovulation greater amounts of progesterone enter the circulatory system and raise the body temperature to previous baseline levels or higher. These temperature variations help to predict a woman's most fertile time to achieve pregnancy.

Body temperature changes also occur in women during menopause (cessation of menstruation). Women who have stopped menstruating often experience periods of intense body heat and sweating lasting from 30 seconds to 5 minutes. During these periods skin temperature can increase as much as 4°C (7.2°F), referred to as hot flashes. This is caused by the instability of the vasomotor controls for vasodilation and vasoconstriction.

Circadian Rhythm

Body temperature normally changes 0.5° to 1°C (0.9° to 1.8°F) during a 24-hour period. However, temperature is one of the most stable rhythms in humans. The temperature is usually lowest between 1:00 and 4:00 AM (Fig. 29.2). During the day body temperature rises steadily to a maximum temperature value at about 4:00 PM and then declines to early-morning levels. Temperature patterns are not automatically reversed in people who work at night and sleep during the day. It takes 1 to 3 weeks for the cycle to reverse. In general the circadian temperature rhythm does not change with age.

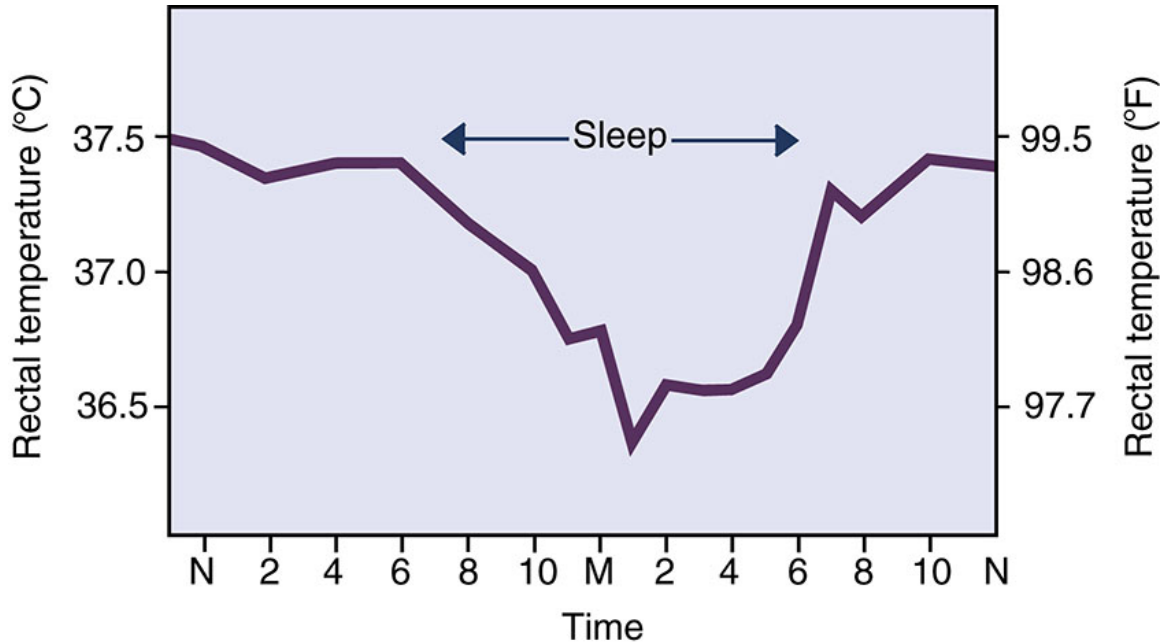

FIG. 29.2 Temperature cycle for 24 hours.

Stress

Physical and emotional stress increase body temperature through hormonal and neural stimulation (see [Chapter 37](#)). These physiological changes increase metabolism, which increases heat production. A patient who is anxious about entering a hospital or a health care provider's office often has a higher normal temperature.

Environment

Environment influences body temperature. When placed in a warm room a patient may be unable to regulate body temperature by heat-loss mechanisms, and the body temperature may elevate. If the patient is outside in the cold without warm clothing, body temperature may be low as a result of extensive radiant and conductive heat loss. Environmental temperatures affect infants and older adults more often because their temperature-regulating mechanisms are less efficient.

Temperature Alterations

Changes in body temperature outside the usual range are related to excessive heat production, excessive heat loss, minimal heat production, minimal heat loss, or any combination of these alterations.

Fever

Fever, or **pyrexia**, occurs because heat-loss mechanisms are unable to keep pace with excessive heat production, resulting in an abnormal rise in body temperature. In general, a fever is a temperature above 100.4° F (38° C) for an adult or child, depending on the type of thermometer used (Ward, 2019; Mayo Clinic, 2017). The height of a child's fever is not always the best indicator of whether the child needs to be treated. Instead, it is important to note how a child behaves and appears because fever is usually accompanied by other symptoms (Ward, 2019). These are the cutoffs for fever in children using different types of thermometers (Seattle Children's Hospital, 2019):

- Rectal (bottom), ear, or forehead temperature: 100.4° F (38.0° C) or higher
 - Caution: Ear temperatures are not accurate before 6 months of age.
- Oral (mouth) temperature: 100° F (37.8° C) or higher
- Under the arm (armpit) temperature: 99° F (37.2° C) or higher

A single temperature reading does not always indicate a fever (Bijur et al., 2016). In addition to physical signs and symptoms of infection, fever determination is also based on several temperature readings at different times of the day compared with the usual value for that person at that time.

A true fever results from an alteration in the hypothalamic set point. **Pyrogens** such as bacteria and viruses elevate body temperature by acting as antigens to trigger the immune system. The hypothalamus reacts to raise the set point, and the body responds by producing and conserving heat. Several hours pass before the body temperature reaches the new set point. During this period a person experiences the physical signs and symptoms of chills, shivers, and feeling cold, even though the body temperature is rising (Fig. 29.3). The chill phase resolves when the new set point, a higher temperature, is achieved. During the next phase, the plateau, the chills subside, and the person feels warm and dry. If the new set point is "overshot" or the pyrogens are removed (e.g., destruction of bacteria by antibiotics), the third phase of a **febrile** episode occurs. The hypothalamus set point drops, initiating heat-loss responses. The skin becomes warm and flushed because of vasodilation. Diaphoresis assists in

evaporative heat loss. When the fever “breaks,” the patient becomes **afebrile**.

FIG. 29.3 Effect of changing set point of hypothalamic temperature control during a fever.

Modified from Guyton AC, Hall JE: *Textbook of medical physiology*, ed 13, Philadelphia, 2016, Saunders.

Fever is an important defense mechanism. Mild temperature elevations as high as 39° C (102.2° F) enhance the immune system of the body. However, during a fever cellular metabolism increases; for every 1° C rise in body temperature, the body’s chemical reactions increase 10% (Mordiffi et al., 2016). During a febrile episode white blood cell production is stimulated. Increased temperature reduces the concentration of iron in the blood plasma, suppressing the growth of bacteria. Fever also fights viral infections by stimulating interferon, the natural virus-fighting substance of the body.

The body responds to the increase in metabolic needs during a fever by increasing heart and respiratory rates. The increased metabolism uses energy to produce additional heat. If a patient has a cardiac or respiratory problem, the stress of a fever is great. A prolonged fever weakens a patient by exhausting energy stores. Increased metabolism requires additional

oxygen. If the body cannot meet the additional oxygen demand, cellular hypoxia (inadequate oxygen) occurs. Myocardial hypoxia produces angina (chest pain). Cerebral hypoxia produces confusion. When water loss through increased respiration and diaphoresis is excessive, the patient is at risk for fluid volume deficit. Dehydration is a serious problem for older adults and children with low body weight. Maintaining optimum fluid volume status is an important nursing action (see [Chapter 42](#)).

Fevers and fever patterns serve a diagnostic purpose. Fever patterns differ, depending on the causative pyrogen ([Box 29.3](#)). The increase or decrease in pyrogen activity results in fever spikes and declines at different times of the day. The duration and degree of fever depend on the strength of the pyrogen and the ability of the individual to respond. The term **fever of unknown origin (FUO)** refers to a fever with an undetermined cause.

Box 29.3 Patterns of Fever

Sustained: A constant body temperature continuously above 38°C (100.4°F) that has little fluctuation

Intermittent: Fever spikes interspersed with usual temperature levels (Temperature returns to acceptable value at least once in 24 hours.)

Remittent: Fever spikes and falls without a return to acceptable temperature levels.

Relapsing: Periods of febrile episodes and periods with acceptable temperature values (Febrile episodes and periods of normothermia are often longer than 24 hours.)

Hyperthermia

An elevated body temperature related to the inability of the body to promote heat loss or reduce heat production is **hyperthermia**. Whereas fever is an upward shift in the set point, hyperthermia results from an overload of the thermoregulatory mechanisms. Any disease or trauma to the hypothalamus impairs heat-loss mechanisms. **Malignant hyperthermia** is a hereditary condition of uncontrolled heat production that occurs when susceptible people receive certain anesthetic drugs (see [Chapter 50](#)).

Heatstroke

Heat depresses hypothalamic function. Prolonged exposure to the sun or a high environmental temperature overwhelms the heat-loss mechanisms of the body. These conditions cause **heatstroke**, defined as a body temperature of 40°C (104°F) or more accompanied by hot, dry skin and central nervous system abnormalities, such as delirium, convulsions, or coma (Hifumi et al., 2018). Heatstroke is a dangerous heat emergency with a high mortality rate. There are two groups of heatstroke. Exertional heatstroke develops in able-bodied individuals, such as athletes, soldiers, or laborers who are performing rigorous physical activities. In contrast, nonexertional heatstroke can develop during low-level physical activities among elderly, ambulatory individuals with comorbidities (e.g., diabetes or cardiovascular disease) (Gaudio and Grissom, 2016). Also at risk are those who take medications that decrease the ability of the body to lose heat (e.g., phenothiazines, anticholinergics, diuretics, amphetamines, and beta-adrenergic receptor antagonists).

Signs and symptoms of heatstroke include giddiness, confusion, delirium, excessive thirst, nausea, muscle cramps, visual disturbances, and even incontinence. Vital signs reveal a body temperature sometimes as high as 45°C (113°F), with an increase in heart rate (HR) and lowering of BP. The most important sign of heatstroke is hot, dry skin. Victims of heatstroke do not sweat because of severe electrolyte loss and hypothalamic malfunction. If the condition progresses, a patient with heatstroke becomes unconscious, with fixed, nonreactive pupils. Permanent neurological damage occurs unless cooling measures are rapidly started.

Heat Exhaustion

Heat exhaustion occurs when profuse diaphoresis results in excess water and electrolyte loss. Caused by environmental heat exposure, a patient exhibits signs and symptoms of deficient fluid volume (see [Chapter 42](#)).

Hypothermia

Heat loss during prolonged exposure to cold overwhelms the ability of the body to produce heat, causing hypothermia. **Hypothermia** is classified by core temperature measurements ([Table 29.1](#)). Hypothermia contributes to poor patient outcomes such as increased infection complications, clotting disorders, and prolonged length of hospitalization (Salota et al., 2016).

Preventing hypothermia increases patient comfort and prevents complications.

TABLE 29.1

Classification of Hypothermia by Core Temperature

	Celsius	Fahrenheit
Mild	32°-35°	90.0°-95°
Moderate	28°-32°	82°-90°
Severe	<28°	<82°

From Zafren K, Mechem CC: *Accidental hypothermia in adults*, UpToDate, 2018, <https://www.uptodate.com/contents/accidental-hypothermia-in-adults>.

Hypothermia can be unintentional, such as falling through the ice of a frozen lake, or intentionally induced during surgical or emergency procedures to decrease metabolism and the body's need for oxygen. Accidental hypothermia usually develops gradually and goes unnoticed for several hours. Older adults are more susceptible to accidental hypothermia (Salota et al., 2016). When skin temperature drops below 34°C (93.2°F), the patient suffers uncontrolled shivering, loss of memory, depression, and poor judgment. As the body temperature falls, HR, respiratory rate, and BP also fall. The skin becomes cyanotic. Patients experience cardiac dysrhythmias and loss of consciousness and are unresponsive to painful stimuli if hypothermia progresses. In severe cases a person demonstrates clinical signs similar to those of death (e.g., lack of response to stimuli and extremely slow respirations and pulse). Assessment of core temperature is critical when you suspect hypothermia. A special low-reading thermometer is required because standard devices do not register below 35°C (95° F).

Frostbite occurs when the body is exposed to subnormal temperatures. Ice crystals form inside the cells, and permanent circulatory and tissue damage occurs. Areas particularly susceptible to frostbite are the earlobes, tip of the nose, and fingers and toes. The injured area becomes white, waxy, and firm to the touch. The patient loses sensation in the affected area. Interventions include gradual warming measures, analgesia, and protection of the injured tissue.

◆ Nursing Process

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

Knowledge of the physiology of body temperature regulation is essential to assess and evaluate a patient's response to temperature alterations and to intervene safely. Implement independent nursing measures to increase or minimize heat loss, promote heat conservation, and increase comfort. These measures complement the effects of medically ordered therapies during illness. You also provide education to family members, parents of children, or other caregivers.

◆ Assessment

During the assessment process thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes

Identify your patient's values, beliefs, current treatments, and expectations regarding fever management. When possible, select the temperature site preferred by the patient. Include the patient's preferences when selecting nonpharmacological interventions for hyperthermia (e.g., cooling blankets, tepid baths, fans).

Temperature Measurement Sites

Core and surface body temperature can be measured at several sites. Intensive care units use the core temperatures of the pulmonary artery, esophagus, and urinary bladder. These measurements require the use of continuous invasive devices placed in body cavities or organs and continually display readings on an electronic monitor.

Use a thermometer for the mouth, rectum, tympanic membrane, or temporal artery to obtain intermittent temperature measurements. Axillary temperature measurements, obtained by placing a thermometer under the axillae, require longer measurement time and are only reliable for stable infants ([Charafeddine et al., 2014](#)). You can apply noninvasive chemically

prepared thermometer patches to the skin to screen for temperature alterations.

Oral, rectal, and skin temperature sites rely on effective blood circulation at the measurement site. The heat of the blood is conducted to the thermometer probe. Tympanic temperature relies on the radiation of body heat to an infrared sensor. Because the tympanic membrane shares the same arterial blood supply as the hypothalamus, it is a core temperature. Temporal artery measurements detect the temperature of cutaneous blood flow.

To ensure accurate temperature readings, measure each site correctly (see [Skill 29.1](#)). The temperature obtained varies, depending on the site used, but it is usually between 36° C (96.8° F) and 38°C (100.4° F). Rectal temperatures are usually 0.5° C (0.9° F) higher than oral temperatures. Each of the common temperature measurement sites has advantages and disadvantages ([Table 29.2](#)). Choose the safest and most accurate site for each patient. When possible, use the same site when repeated measurements are necessary.

TABLE 29.2

Advantages and Disadvantages of Select Temperature Measurement Sites

Site Advantages	Site Limitations
Oral	
<p>Easily accessible—requires no position change</p> <p>Comfortable for patient</p> <p>Provides accurate surface temperature reading</p> <p>Reflects rapid change in core temperature</p> <p>Reliable route to measure temperature in patients who are intubated</p>	<p>Causes delay in measurement if patient recently ingested hot/cold fluids or foods, smoked, or is receiving oxygen by mask/cannula</p> <p>Not for patients who had oral surgery, trauma, history of epilepsy, or shaking chills</p> <p>Not for infants, small children, or patients who are confused, unconscious, or uncooperative</p> <p>Risk of body fluid exposure</p>
Tympanic Membrane	
<p>Easily accessible site</p> <p>Found to be most accurate method in critically ill patients when compared with oral, axillary, and rectal (Asadian et al., 2016).</p> <p>Minimal patient repositioning required</p> <p>Obtained without disturbing, waking, or repositioning patients</p> <p>Used for patients with tachypnea without affecting breathing</p> <p>Sensitive to core temperature changes</p> <p>Very rapid measurement (2 to 5 seconds)</p> <p>Unaffected by oral intake of food or fluids or smoking</p> <p>Not influenced by environmental temperatures</p>	<p>More variability of measurement than with other core temperature devices</p> <p>Requires removal of hearing aids before measurement</p> <p>Requires disposable sensor cover with only one size available</p> <p>Otitis media and cerumen impaction distorts readings</p> <p>Not used in patients who have had surgery of the ear or tympanic membrane</p> <p>Does not accurately measure core temperature changes during and after exercise</p> <p>Does not obtain continuous measurement</p> <p>Affected by ambient temperature devices such as incubators, radiant warmers, and facial fans</p> <p>Use in infants older than 6 months (Seattle Children's Hospital, 2019) and children under 3 years of age; use care to position device correctly because anatomy of ear canal makes it difficult to position.</p> <p>Inaccuracies reported caused by incorrect positioning of handheld unit</p>
Rectal	
<p>Argued to be more reliable when oral temperature is difficult or impossible to obtain</p>	<p>Lags behind core temperature during rapid temperature changes</p> <p>Not for patients with diarrhea, rectal disorders, or bleeding tendencies or those who had rectal surgery</p> <p>Requires positioning and is often source of patient embarrassment and anxiety</p> <p>Risk of body fluid exposure and injury to rectal lining</p> <p>Requires lubrication</p> <p>Not for routine vital signs in newborns</p> <p>Readings influenced by impacted stool</p>
Skin	
<p>Inexpensive</p> <p>Provides continuous reading</p> <p>Safe and noninvasive</p> <p>Used for neonates</p>	<p>Measurement lags behind other sites during temperature changes, especially during hyperthermia</p> <p>Adhesion impaired by diaphoresis or sweat</p> <p>Reading affected by environmental temperature</p> <p>Cannot be used for patients with allergy to adhesives</p>
Temporal Artery	
<p>Easy to access without position change</p> <p>Very rapid measurement</p> <p>Comfortable with no risk of injury to patient or nurse</p> <p>Eliminates need to disrobe or be unbundled</p> <p>Comfortable for patient</p> <p>Used in premature infants, newborns, and children (Reynolds et al., 2014)</p> <p>Reflects rapid change in core temperature</p> <p>Sensor cover not required</p>	<p>Inaccurate with head covering or hair on forehead</p> <p>Affected by skin moisture such as diaphoresis or sweating</p>
Axillary	
<p>Safe and inexpensive</p> <p>Reliable in stable term and preterm infants (Charafeddine et al., 2014)</p>	<p>Long measurement time</p> <p>Requires continuous positioning</p> <p>Measurement lags behind core temperature during rapid temperature changes</p> <p>Not recommended for detecting fever</p> <p>Requires exposure of thorax that can result in temperature loss, especially in newborns</p> <p>Affected by exposure to environment, including time to place the thermometer</p> <p>Underestimates core temperature</p>

Thermometers

Two types of thermometers are available for measuring body temperature: electronic and disposable. The mercury-in-glass thermometer, once the standard device, has been eliminated from health care facilities because of the environmental hazards of mercury. However, some patients still use mercury-in-glass thermometers at home. When you find a mercury-in-glass thermometer in the home, teach the patient about safer temperature devices and encourage the disposal of mercury products at appropriate neighborhood hazardous disposal locations. Disposable digital thermometers are readily available for use in the home setting. Home disposable thermometers are useful for temperature screening but are not as accurate as nondisposable electronic thermometers.

Each device measures temperature using the Celsius or Fahrenheit scale. Electronic thermometers convert the temperature scales by activating a switch. When it is necessary to convert temperature readings, use the following formulas:

1. To convert Fahrenheit to Celsius, subtract 32 from the Fahrenheit reading and multiply the result by $\frac{5}{9}$.

$$C = (F - 32) \times \frac{5}{9}$$

$$\text{Example : } 40^{\circ} \text{ C} = (104^{\circ} \text{ F} - 32) \times \frac{5}{9}$$

2. To convert Celsius to Fahrenheit, multiply the Celsius reading by $\frac{9}{5}$ and add 32 to the product.

$$F = \left(\frac{9}{5} \times ^\circ\text{C}\right) + 32$$

$$\text{Example : } 104^\circ \text{ F} = \left(\frac{9}{5} \times 40^\circ\text{C}\right) + 32^\circ$$

Electronic Thermometer

The electronic thermometer consists of a rechargeable battery-powered display unit, a thin wire cord, and a temperature-processing probe covered by a disposable probe cover (Fig. 29.4A). Separate unbreakable reusable probes with single-use disposable covers are available for oral and rectal use. Electronic thermometers provide two modes of operation: a 4-second predictive temperature and a 3-minute standard temperature. Nurses use the 4-second predictive mode, which improves measurement accuracy. A sound signals, and a reading appears on the display unit when the peak temperature reading has been measured.

FIG. 29.4 **A**, Electronic thermometer with disposable probe. **B**, Genius 3 Tympanic Thermometer. **C**, Temporal artery thermometer. **D**, Chemical dot disposable single-use thermometer. **A**, Courtesy Hillrom; **B**, Copyright © 2018 Courtesy of Cardinal Health UK Ltd.; **C**, photo courtesy Exergen.

Another form of electronic thermometer is used exclusively for tympanic temperature. An otoscope-like speculum with an infrared sensor tip detects heat radiated from the tympanic membrane (Fig. 29.4B). The tip is covered by a single patient-use cover. Within seconds of placement in the auditory canal, a sound signals, and a reading appears on the display unit when the peak temperature reading has been measured.

There is an electronic thermometer that measures the temperature of the superficial temporal artery. A handheld scanner with an infrared sensor tip detects the temperature of cutaneous blood flow by sweeping the sensor across the forehead and just behind the ear (Fig. 29.4C). After scanning is complete, a reading appears on the display unit. Temporal artery temperature is a reliable noninvasive measure of core temperature.

The greatest advantages of electronic thermometers are that their readings appear within seconds and they are easy to read. The plastic sheath is unbreakable and ideal for children. Their expense is a major disadvantage. Maintaining cleanliness of the probes is an important consideration. For example, if not properly cleaned between patients, gastrointestinal contamination of a rectal probe causes disease transmission. Wipe the thermometer device daily with alcohol and the thermometer probe with an alcohol swab after each patient, paying

particular attention to the ridges where the probe cover is secured to the probe.

Chemical Dot Thermometers

Single-use or reusable chemical dot thermometers (Fig. 29.4D) are thin strips of plastic with a temperature sensor at one end. The sensor consists of a matrix of chemically impregnated dots that change color at different temperatures. In the Celsius version there are 50 dots, each representing a temperature increment of 0.1°C , over a range of 35.5°C to 40.4°C . The Fahrenheit version has 45 dots with increments of 0.2°F and a range of 96°F to 104.8°F . Chemical dots on the thermometer change color to reflect temperature reading, usually within 60 seconds. Most are for single use. In one reusable brand for a single patient, the chemical dots return to the original color within a few seconds. Chemical dot thermometers are for oral use and are useful for screening temperatures, especially in infants, young children, and patients who are intubated. Chemical dot thermometers often underestimate oral temperature by 0.4°C (0.7°F) or more. Use an electronic thermometer to confirm measurements made with a chemical dot thermometer when treatment decisions are involved. Chemical dot thermometers are useful when caring for patients who have sores in the mouth or who are on protective isolation to avoid the need to take electronic instruments into patient rooms (see Chapter 28).

Another disposable thermometer useful for screening temperature is a temperature-sensitive patch or tape. Applied to the forehead or abdomen, chemical-sensitive areas of the patch change color at different temperatures. This type of thermometer can also be affected by environmental temperature.

REFLECT NOW

You are planning interventions for a patient with hyperthermia who has entered the emergency department. How will the patient's characteristics influence your care plan?

Nursing Diagnosis

After concluding your assessment, cluster assessment findings to form a nursing diagnosis (Box 29.4). For example, a decrease in body temperature, shivering, skin cool to touch, tachycardia and lowered SpO₂ indicate the nursing diagnosis of *Hypothermia*. State a nursing diagnosis as either an at-risk or problem-focused (negative) temperature alteration. Implement actions to minimize or eliminate risk factors if the patient has an at-risk diagnosis. Examples of nursing diagnoses for patients with body temperature alterations include the following:

Box 29.4 Nursing Diagnostic Process Impaired Thermoregulation Related to Aging and Inability to Adapt to Environmental Temperature

Assessment Activities	Assessment Findings
Obtain vital signs, including temperature, pulse (see Skill 29.2), respirations (see Skill 29.3), SpO ₂ (see Skill 29.4).	Increased body temperature above usual range Tachycardia Tachypnea
Palpate skin.	Warm, dry skin
Observe patient's appearance and behavior while talking and resting.	Confusion Mild shivering Flushed skin
Review health history.	Found in unventilated apartment during heat wave; 85 years old with history of dementia

- *Risk for Impaired Thermoregulation*
- *Hyperthermia*
- *Hypothermia*
- *Impaired Thermoregulation*
- *Fever*

Once you determine a diagnosis, accurately select the related factor for problem-focused (negative) diagnoses. The related factor allows you to develop/set appropriate patient goals and select appropriate nursing interventions. In the example of hyperthermia, a related factor of *vigorous*

activity results in interventions that are much different from those used with a related factor of *decreased ability to perspire*.

Planning

During planning integrate the knowledge gathered from assessment and the patient history to develop an individualized plan of care. Match the patient's needs with interventions that are supported and recommended in the clinical research literature.

Goals and Outcomes

The plan of care for a patient with alteration in temperature includes realistic and individualized goals along with relevant outcomes. This requires collaboration with the patient and family in setting patient-centered goals and outcomes while selecting nursing interventions. Establish expected outcomes to gauge progress toward returning the body temperature to an acceptable range. In cases in which the temperature alteration requires helping patients modify their environment, goals may be long term (e.g., obtaining appropriate clothing to wear in cold weather). Short-term goals such as regaining normal range of body temperature improve patient health. In the example of a patient who has an elevated fever and excessive diaphoresis, the goal of care is attaining fluid and electrolyte balance. The outcome is that the patient's intake and output are balanced for the next 24 hours.

Setting Priorities

Set priorities of care with regard to the extent that the temperature alteration affects a patient. The severity of a temperature alteration and its effects, together with the patient's general health status, influence your priorities in his or her care. Safety is a top priority. Often other medical problems complicate the care plan. For instance, body temperature imbalance affects body requirements for fluids. Patients with heart problems often have difficulty tolerating required fluid replacement therapy.

Teamwork and Collaboration

Patients at risk for imbalanced body temperature require an individualized care plan directed at maintaining normothermia and reducing risk factors. For example, it is important to establish the outcome

that a patient who is homeless can explain appropriate actions to take (e.g., fluid intake, type of clothing) and available community resources to use (e.g., cooling stations) during a heat wave. In contrast, an older adult living at home may need encouragement and reminders from family to use fans or window air conditioner units and to drink appropriate amounts of fluids. Teach the patient and caregiver the importance of thermoregulation and actions to take during excessive environmental heat. Education is particularly important for parents, who need to know how to take action at home and whom to call (e.g., health care provider's office, home care nurse) when an infant or child develops a temperature imbalance.

• Implementation

Health Promotion

By maintaining balance between heat production and heat loss you promote the health of patients at risk for imbalanced body temperature. Consider patient activity, temperature of the environment, and appropriate clothing. Teach patients to avoid strenuous exercise in hot, humid weather; to drink fluids such as water or clear fruity juices before, during, and after exercise; and to wear lightweight, loose-fitting, light-colored clothes. Also teach patients to avoid exercising in areas with poor ventilation, to wear a protective covering over the head when outdoors, and to expose themselves to hot climates gradually.

Prevention is key for patients at risk for hypothermia. It involves educating patients, family members, and friends. Patients at risk include the very young; the very old; and people debilitated by trauma, stroke, diabetes, drug or alcohol intoxication, and sepsis. Patients who are mentally ill or handicapped sometimes fall victim to hypothermia because they are unaware of the dangers of cold conditions. People with inadequate home heating, shelter, diet, or clothing are also at risk. Fatigue, dark skin color, malnutrition, and hypoxemia contribute to the risk of frostbite.

Prevention is also the focus for individuals at risk for heatstroke, with prevention strategies such as using air conditioners; limiting outdoor activities during the daytime; consuming ample fluids; wearing loose-fitting and light-colored clothing; being aware of medication side effects that may cause fluid losses, decrease sweating, or decrease heart rate; and never leaving impaired adults or children in a car unattended (Peiris et al., 2017).

Acute Care

Fever

When an elevated body temperature develops, initiate interventions to treat fever. The objective of therapy is to increase heat loss, reduce heat production, and prevent complications. The choice of interventions depends on the cause; adverse effects; and the strength, intensity, and duration of the temperature elevation. The health care provider attempts to determine the cause of the elevated temperature by isolating the causative pyrogen. Sometimes it is necessary to obtain culture specimens for laboratory analysis such as urine, blood, sputum, and wound sites (see [Chapter 28](#)). Some antibiotic medications are ordered to be given after the cultures have been obtained. Administering antibiotics destroys pyrogenic bacteria and eliminates body stimulus for the elevated temperature. Nurses are essential in assessing and implementing temperature-reducing strategies ([Box 29.5](#)).

Box 29.5 Nursing Interventions for Patients With a Fever

Interventions (Unless Contraindicated by Medical Condition)

- Obtain cultures of body fluids such as urine, sputum, or blood (before beginning antibiotics) if ordered. Obtain blood specimens to coincide with temperature spikes, when the antigen-producing organism is most prevalent.
- Minimize heat production: reduce frequency of activities that increase oxygen demand such as excessive turning and ambulation; allow rest periods; limit physical activity.
- Maximize heat loss: reduce external covering on patient's body without causing shivering; keep patient, clothing, and bed linen dry.
- Satisfy requirements for increased metabolic rate: provide supplemental oxygen therapy as ordered to improve oxygen delivery to body cells; provide measures to stimulate appetite and offer well-balanced meals; provide fluids (at least 8 to 10 [8-oz] glasses for

patients with normal cardiac and renal function) to replace fluids lost through insensible water loss and sweating.

- Promote patient comfort: encourage oral hygiene because oral mucous membranes dry easily from dehydration; control temperature of the environment without inducing shivering; apply damp cloth to patient's forehead.
- Identify onset and duration of febrile episode phases: examine previous temperature measurements for trends.
- Initiate health teaching as indicated.
- Control environmental temperature to 21° to 27°C (70° to 80°F).

Most fevers in children are of a viral origin, last only briefly, and have limited effects. However, children still have immature temperature-control mechanisms, and temperatures can rise rapidly. Dehydration and febrile seizures occur during rising temperatures of children between 6 months and 3 years of age. Febrile seizures are unusual in children over 5 years old. The extent of the temperature, often exceeding 38.8°C (101.8°F), seems to be a more important factor in regard to seizures than the rapidity of the temperature increase. Children are at particular risk for fluid volume deficit because they can quickly lose large amounts of fluids in proportion to their body weight. It is important to maintain accurate intake and output records, weigh the patient daily, encourage fluids, and provide regular mouth/oral care.

Sometimes a fever is a hypersensitivity response to a drug. Drug fevers are often accompanied by other allergy symptoms such as rash or pruritus (itching). Treatment involves withdrawing the medication, treating any skin integrity impairment, and educating the patient and family about the allergy.

Antipyretics are medications that reduce fever. Acetaminophen and nonsteroidal antiinflammatory drugs such as ibuprofen, salicylates, and indomethacin reduce fever by increasing heat loss. Although not used to treat fever, corticosteroids reduce heat production by interfering with the hypothalamic response. It is important to remember that steroids mask signs and symptoms of infection ([Frenkel et al., 2018](#)). Therefore patients who are prescribed steroids need to be monitored closely, especially if they are at risk for infection.

Nonpharmacological therapies for fever increase heat loss by evaporation, conduction, convection, or radiation. Make sure that nursing measures to enhance body cooling do not stimulate shivering. Shivering is

counterproductive and increases energy expenditure up to 400%. Tepid sponge baths, bathing with alcohol-water solutions, applying ice packs to axillae and groin areas, and cooling fans were previously used to reduce fever; however, *avoid these therapies because they lead to shivering*. There is no advantage of these methods over antipyretic medications.

Blankets cooled by circulating water delivered by motorized units increase conductive heat loss. Follow manufacturer instructions for applying these hypothermia blankets because of the risk for skin breakdown and “freeze burns.” Placing a bath blanket between the patient and the hypothermia blanket and wrapping distal extremities (fingers, toes, and genitalia) reduces the risk of injury to the skin and tissue from hypothermia therapy. Wrapping the patient’s extremities reduces the incidence and intensity of shivering. Medications such as meperidine or butorphanol reduce shivering.

Heatstroke

Heatstroke is an emergency situation, First aid treatment includes moving the patient to a cooler environment; removing excess body clothing; placing cool, wet towels over the skin; and using oscillating fans to increase convective heat loss. Emergency medical treatment also includes administering intravenous (IV) fluids, irrigating the stomach and lower bowel with cool solutions, and applying hypothermia blankets.

Hypothermia

The priority treatment for hypothermia is to prevent a further decrease in body temperature. Removing wet clothes, replacing them with dry ones, and wrapping patients in blankets are key nursing interventions. In emergencies away from a health care setting, have the patient lie under blankets next to a warm person. A conscious patient benefits from drinking hot liquids such as soup and by avoiding alcohol and caffeinated fluids. It is also helpful to keep the head covered, place the patient near a fire or in a warm room, or place heating pads next to areas of the body (head and neck) that lose heat the quickest.

REFLECT NOW

You implement an order for acetaminophen for an elderly patient with a fever of 100.6°F. What additional measures can you implement to improve comfort care? What vital sign changes do you expect if your interventions are successful?

Restorative and Continuing Care

Educate the patient with a fever about the importance of taking and continuing any antibiotics as directed until the course of treatment is completed. Children and older adults are at risk for deficient fluid volume because they can quickly lose large amounts of fluids in proportion to their body weight. Provide education on signs of dehydration such as dry mouth, sunken eyes, and decreased urine output. Identifying preferred fluids and encouraging oral fluid intake are important ongoing nursing interventions.

Evaluation

Through the Patient's Eyes

Evaluate your patient's perspectives about the care provided. Is he or she satisfied with the outcomes of care or does the care plan need to be modified? Including the patient in the evaluation demonstrates that you value his or her perspective and contributes to patient safety.

Patient Outcomes

Evaluate all nursing interventions by comparing the patient's actual response to the expected outcomes of the care plan. Determine whether goals of care were met and make revisions to the care plan when necessary. After an intervention, measure the patient's temperature to evaluate for change. In addition, use other evaluative measures such as palpating the skin and assessing pulse and respirations. If therapies are effective, body temperature returns to an acceptable range, other vital signs stabilize, and the patient reports a sense of comfort.

Pulse

The pulse is the palpable bounding of blood flow in a peripheral artery. Blood flows through the body in a continuous circuit. The pulse is an indirect indicator of circulatory status.

Physiology and Regulation

Electrical impulses originating from the sinoatrial (SA) node travel through heart muscle to stimulate cardiac contraction.

Approximately 60 to 70 mL of blood enters the aorta with each ventricular contraction (stroke volume [SV]). With each SV ejection, the walls of the aorta distend, creating a pulse wave that travels rapidly toward the distal ends of the arteries. The pulse wave moves 15 times faster through the aorta and 100 times faster through the small arteries than the ejected volume of blood. When a pulse wave reaches a peripheral artery, you can feel it by palpating the artery lightly against underlying bone or muscle. The number of pulsing sensations occurring in 1 minute is the pulse rate.

The volume of blood pumped by the heart during 1 minute is the cardiac output, the product of HR and the ventricular SV. In an adult the heart normally pumps 5000 mL of blood per minute. A change in HR or SV does not always change the output of the heart or the amount of blood in the arteries. For example, if a person's HR is 70 beats/min and the SV is 70 mL, the cardiac output is 4900 mL/min (70 beats/min \times 70 mL/beat). If the HR drops to 60 beats/min and the SV rises to 85 mL/beat, the cardiac output increases to 5100 mL or 5.1 L/min (60 beats/min \times 85 mL/beat).

Mechanical, neural, and chemical factors regulate the strength of ventricular contraction and the SV. SV depends on the time available to fill the ventricle with blood. When the contraction strength or SV cannot be altered, a change in HR causes a change in cardiac output. As HR increases, there is less time for the ventricular chambers of the heart to fill. When SV cannot change when the HR increases, the BP will decrease. As HR slows, filling time is increased, and BP increases.

An abnormally slow, rapid, or irregular pulse alters cardiac output. Assess the ability of the heart to meet the demands of body tissue for nutrients by palpating a peripheral pulse or using a stethoscope to listen to heart sounds (apical pulse) (see [Skill 29.2](#)).

❖ Nursing Process

• Assessment of Pulse

You can assess any artery for pulse rate, but you typically use the radial artery because it is easy to palpate. When a patient's condition suddenly worsens, the carotid artery site is recommended for quickly finding and assessing the pulse. The heart continues to deliver blood through the carotid artery to the brain as long as possible. When cardiac output declines significantly, peripheral pulses weaken and are difficult to palpate.

The radial and apical locations are the most common sites for pulse rate assessment. Use the radial pulse to teach patients how to monitor their own HRs (e.g., athletes, people taking heart medications, and patients starting a prescribed exercise regimen). If the radial pulse is abnormal or intermittent resulting from dysrhythmias or if it is inaccessible because of a dressing or cast, assess the apical pulse. When a patient takes medication that affects the HR, the apical pulse provides a more accurate assessment of heart function. The brachial or apical pulse is the best site for assessing an infant's or a young child's pulse because other peripheral pulses are deep and difficult to palpate accurately.

Assessment of other peripheral pulse sites such as the brachial or femoral artery is unnecessary when routinely obtaining vital signs. You assess other peripheral pulses when conducting a complete physical, when surgery or treatment has impaired blood flow to a body part, or when there are clinical indications of impaired peripheral blood flow (see [Chapter 30](#)). [Table 29.3](#) summarizes pulse sites and criteria for measurement.

TABLE 29.3**Pulse Sites**

Site	Location	Assessment Criteria
Temporal	Over temporal bone of head, above and lateral to eye	Easily accessible site used to assess pulse in children
Carotid	Along medial edge of sternocleidomastoid muscle in neck	Easily accessible site used during physiological shock or cardiac arrest when other sites are not palpable
Apical	Fourth to fifth intercostal space at left midclavicular line	Site used to auscultate for apical pulse
Brachial	Groove between biceps and triceps muscles at antecubital fossa	Site used to assess status of circulation to lower arm and to auscultate blood pressure
Radial	Radial or thumb side of forearm at wrist	Common site used to assess character of pulse peripherally and status of circulation to hand
Ulnar	Ulnar or little finger side of forearm at wrist	Site used to assess status of circulation to hand; also used to perform an Allen's test
Femoral	Below inguinal ligament, midway between symphysis pubis and anterior superior iliac spine	Site used to assess character of pulse during physiological shock or cardiac arrest when other pulses are not palpable; used to assess status of circulation to leg
Popliteal	Behind knee in popliteal fossa	Site used to assess status of circulation to lower leg
Posterior tibial	Inner side of ankle, below medial malleolus	Site used to assess status of circulation to foot
Dorsalis pedis	Along top of foot, between extension tendons of great and first toe	Site used to assess status of circulation to foot

Use of a Stethoscope

Assessing the apical rate requires a stethoscope. The five major parts of the stethoscope are the earpieces, binaurals, tubing, bell chest piece, and diaphragm chest piece (Fig. 29.5). The plastic or rubber earpieces should fit snugly and comfortably in your ears. The binaurals should be angled and strong enough that the earpieces stay firmly in the ears without causing discomfort. To ensure the best reception of sound, the earpieces follow the contour of the ear canal, pointing toward the face when the stethoscope is in place.

FIG. 29.5 Parts of stethoscope.

The polyvinyl tubing is flexible and 30 to 40 cm (12 to 18 inches) in length. Longer tubing decreases the transmission of sound waves. Thick-walled and moderately rigid tubing eliminates the transmission of environmental noise and prevents the tubing from kinking, which distorts sound-wave transmission. Stethoscopes have single or dual tubes.

The chest piece consists of a bell and a diaphragm that you rotate into position. The diaphragm or bell needs to be in proper position during use to hear sounds through the stethoscope. With the earpieces in your ears, tap lightly on the diaphragm to determine which side of the chest piece is functioning. The diaphragm is the circular, flat portion of the chest piece covered with a thin plastic disk. It transmits high-pitched sounds created by the high-velocity movement of air and blood. Auscultate bowel, lung, and heart sounds with the diaphragm. Place the stethoscope directly on the skin because clothing obscures the sound. Position the diaphragm to make a tight seal and press firmly against the patient's skin ([Fig. 29.6A](#)). Do not use your thumb to hold the diaphragm in place because you may hear the pulse being transmitted through it.

FIG. 29.6 **A**, Place the diaphragm firmly and securely when auscultating high-pitched lung and bowel sounds. **B**, The bell must be placed lightly on the skin to hear low-pitched vascular and heart sounds.

The bell is the bowl-shaped chest piece usually surrounded by a rubber ring. The ring avoids chilling patients with cold metal when placed on the skin. The bell transmits low-pitched sounds created by the low-velocity movement of blood. Auscultate heart and vascular sounds with the bell. Apply the bell lightly, resting the chest piece on the skin (Fig. 29.6B).

Compressing the bell against the skin reduces low-pitched sound amplification and creates a “diaphragm of skin.” Some stethoscopes have one chest piece that combines features of the bell and diaphragm. When you use light pressure, the chest piece is a bell; exerting more pressure converts the bell into a diaphragm.

The stethoscope is a delicate instrument and requires proper care for optimal function. Remove the earpieces regularly and clean them of cerumen (earwax). Clean the bell and diaphragm between patients thoroughly with an antiseptic swab to remove microorganisms. Clean the tubing regularly with mild soap and water. A study examined the cross-contamination of physicians’ hands with MRSA microorganisms following a physical examination of patients. The study showed that the contamination level of the stethoscope was substantial after a single physical examination and comparable to the contamination of parts of the physician’s dominant hand (Longtin et al., 2014)

Character of the Pulse

Assessment of the radial pulse includes measuring the rate, rhythm, strength, and equality. When auscultating an apical pulse, assess rate and rhythm only.

Rate

Before measuring a pulse, review the patient’s baseline rate for comparison (Table 29.4). Some practitioners prefer to make baseline measurements of the pulse rate as a patient assumes a sitting, standing, and lying position. Postural changes affect the pulse rate because of alterations in blood volume and sympathetic activity. The

HR temporarily increases when a person changes from a lying to a sitting or standing position.

TABLE 29.4

Acceptable Ranges of Heart Rate

Age	Heart Rate (beats/min)
Infant	120-160
Toddler	90-140
Preschooler	80-110
School-age child	75-100
Adolescent	60-90
Adult	60-100

When assessing the pulse, consider the variety of factors influencing the heart rate (Table 29.5). A single factor or a combination of these factors often causes significant changes. If you detect an abnormal rate while palpating a peripheral pulse, the next step is to assess the apical rate. The apical rate requires auscultation of heart sounds, which provides a more accurate assessment of cardiac contraction.

TABLE 29.5**Factors Influencing Heart Rate**

Factor	Increases Pulse Rate	Decreases Pulse Rate
Exercise	Short-term exercise	Heart conditioned by long-term exercise, resulting in lower resting pulse and quicker return to resting level after exercise (AHA, 2015)
Temperature	Fever and heat	Hypothermia
Acute pain	Increased sympathetic activity increases heart rate, stroke volume, and peripheral resistance, all of which increase myocardial work and oxygen demand.	Effect of chronic pain on heart rate varies; parasympathetic stimulation increased by unrelieved severe pain lowers heart rate
Emotions	Sympathetic stimulation increased by anxiety affects heart rate.	
Medications	Positive chronotropic drugs such as epinephrine	Negative chronotropic drugs such as digitalis; beta-adrenergic and calcium channel blockers
Hemorrhage	Sympathetic stimulation increased by loss of blood	
Postural changes	Standing or sitting	Lying down
Pulmonary conditions	Diseases causing poor oxygenation such as asthma, chronic obstructive pulmonary disease (COPD)	

Assess the apical rate by listening to heart sounds (see [Chapter 30](#)). Identify the first and second heart sounds (S_1 and S_2). At normal slow rates S_1 is low pitched and dull, sounding like a “lub.” S_2 is higher pitched and shorter, creating the sound “dub.” Count each set of “lub-dub” as one heartbeat. Using the diaphragm or bell of the stethoscope, count the number of lub-dubs occurring in 1 minute.

Peripheral and apical pulse rate assessment often reveals variations in HR. Two common abnormalities in pulse rate are tachycardia and bradycardia. **Tachycardia** is an abnormally elevated HR, above 100 beats/min in adults. **Bradycardia** is a slow rate, below 60 beats/min in adults.

An inefficient contraction of the heart that fails to transmit a pulse wave to the peripheral pulse site creates a **pulse deficit**. To assess a pulse deficit you and a colleague assess radial and apical rates simultaneously and then compare rates (see Skill 29.2). The difference between the apical and radial pulse rates is the pulse deficit. For example, an apical rate of 92 with a radial rate of 78 leaves a pulse

deficit of 14 beats. Pulse deficits are often associated with abnormal rhythms.

Rhythm

Normally a regular interval occurs between each pulse or heartbeat. An interval interrupted by an early or late beat or a missed beat indicates an abnormal rhythm, or **dysrhythmia**. A dysrhythmia threatens the ability of the heart to provide adequate cardiac output, particularly if it occurs repetitively. You identify a dysrhythmia by palpating an interruption in successive pulse waves or auscultating an interruption between heart sounds. If a dysrhythmia is present, assess the regularity of its occurrence and auscultate the apical rate (see [Chapter 30](#)). Dysrhythmias are described as regularly irregular or irregularly irregular.

To document a dysrhythmia, the health care provider often orders an electrocardiogram (ECG), Holter monitor, or telemetry monitor. An ECG records the electrical activity of the heart for a 12-second interval. This test requires placement of electrodes across a patient's chest followed by recording of the heart rhythm. A patient wears the Holter monitor, which records and stores 24 hours of electrical activity. Access to the information recorded is not available until after the 24 hours have passed and the data are reviewed. Cardiac telemetry provides continuous monitoring of the electrical activity of the heart transmitted to a stationary monitor. Telemetry permits continuous observation of heart rhythm during all of a patient's daily activities and thus allows for immediate treatment if the rhythm becomes erratic or unstable.

Children often have a sinus dysrhythmia, which is an irregular heartbeat that speeds up with inspiration and slows with expiration. This is a normal finding that you can verify by having the child hold his or her breath; the HR usually becomes regular.

Strength

The strength or amplitude of a pulse reflects the volume of blood ejected against the arterial wall with each heart contraction and the condition of the arterial vascular system leading to the pulse site. Normally the pulse strength remains the same with each heartbeat.

Document the pulse strength as bounding (4); full or strong (3); normal and expected (2); diminished or barely palpable (1); or absent (0). Include assessment of pulse strength in the assessment of the vascular system (see [Chapter 30](#)).

Equality

Assess radial pulses on both sides of the peripheral vascular system, comparing the characteristics of each. A pulse in one extremity is sometimes unequal in strength or absent in many disease states (e.g., thrombus [clot] formation). Assess all symmetrical pulses simultaneously except for the carotid pulse. Never measure the carotid pulses simultaneously because excessive pressure occludes blood supply to the brain.

• Nursing Diagnosis

Pulse assessment determines the general state of cardiovascular health and the response of the body to other system imbalances. Tachycardia, bradycardia, and dysrhythmias are assessment findings found for many nursing diagnoses, including the following:

- *Activity Intolerance*
- *Dehydration*
- *Hypervolaemia*
- *Impaired Cardiac Function*
- *Impaired Peripheral Tissue Perfusion*

• Planning and Implementation

The nursing care plan includes independent nursing interventions based on the nursing diagnosis identified and the risk factors or related factors. For example, the assessment findings of an abnormal HR in response to activity, exertional dyspnea, and a patient's verbal report of fatigue lead to a diagnosis of *Activity Intolerance*. When the related factor is *inactivity following a prolonged illness*, interventions focus on increasing the patient's daily exercise routine. If the diagnosis has a related factor of *sedentary lifestyle*, interventions include an

exercise routine with adaptations during activities of daily living that increase the patient's overall activity level. [Chapter 38](#) details standards for promoting early activity and exercise. A patient-centered plan of care is key to developing an exercise plan to which a patient will adhere. Also educate patients about the benefits of exercise and how to measure heart rate during exercise. Patients who are placed on medications to improve heart function should also learn how to measure their own pulse.

A patient's nursing diagnoses (e.g., *Activity Intolerance*) will often develop as a result of medical conditions, such as heart failure, chronic lung diseases, or myocardial infarction. Therefore the plan of care includes dependent interventions that focus on the timely administration of medications (e.g., cardiotonics, beta-adrenergic blocking agents, and oxygen) and careful management of fluid balance.

• Evaluation

Patient Outcomes

Once a plan of care is implemented, evaluate the patient's outcomes, which will involve evaluation of the character of the pulse in response to interventions. For example, if a patient is beginning to ambulate after prolonged immobility, measure the pulse as the patient ambulates and when ambulation is completed to identify any change. Basically the patient's goal is to stay within 10 to 20 beats above normal resting rate ([AHA, 2015](#)). Exercise intensity is a subjective measure of how hard physical activity feels to a person while he or she is exercising ([Mayo Clinic, 2019](#)). It is important to always ask patients how they feel, especially when exercising the first time after a prolonged illness or surgery. For example, during low to moderate exercise a patient may perceive that breathing quickens, but he or she is not out of breath. The patient may develop a light sweat after about 10 minutes of activity ([Mayo Clinic, 2019](#)). A more objective measure of activity tolerance is measuring a patient's actual heart rate compared with his or her target heart rate. The target heart rate is useful for evaluating a patient's exercise intensity and tolerance (see [Chapter 50](#)).

Respiration

Human survival depends on the ability of oxygen (O_2) to reach body cells and carbon dioxide (CO_2) to be removed from the cells. Respiration is the mechanism the body uses to exchange gases between the atmosphere and the blood and the blood and the cells. Respiration involves **ventilation** (the movement of gases in and out of the lungs), diffusion (the movement of oxygen and carbon dioxide between the alveoli and the red blood cells), and perfusion (the distribution of red blood cells to and from the pulmonary capillaries). Analyzing respiratory efficiency requires integrating assessment data from all three processes. Assess ventilation by determining respiratory rate, depth, rhythm, and end-tidal carbon dioxide ($EtCO_2$) value. Assess diffusion and perfusion by determining oxygen saturation (SpO_2).

Physiological Control

Breathing generally is a passive process. Normally a person thinks little about it. The respiratory center in the brainstem regulates the involuntary control of respirations. Adults normally breathe in a smooth, uninterrupted pattern 12 to 20 times a minute.

The body regulates ventilation using levels of CO_2 , O_2 , and hydrogen ion concentration (pH) in the arterial blood. The most important factor in the control of ventilation is the level of CO_2 in the arterial blood. An elevation in the CO_2 level causes the respiratory control system in the brain to increase the rate and depth of breathing. The increased ventilatory effort removes excess CO_2 (hypercarbia) by increasing exhalation.

However, patients with chronic lung disease have ongoing hypercarbia. For these patients chemoreceptors in the carotid artery and aorta become sensitive to **hypoxemia**, or low levels of arterial O_2 . When arterial oxygen levels fall, these receptors signal the brain to increase the rate and depth of ventilation. Hypoxemia thus helps to control ventilation in patients with chronic lung disease. However, when arterial oxygen levels fall below 88%, supplemental low dose oxygen may be required. Continuous long-term oxygen administration improves survival of patients with COPD (Koczulla et al., 2018)

Mechanics of Breathing

Although breathing is normally passive, muscular work is involved in moving the lungs and chest wall. Inspiration is an active process. During inspiration the respiratory center sends impulses along the phrenic nerve, causing the diaphragm to contract. Abdominal organs move downward and forward, increasing the length of the chest cavity to move air into the lungs. The diaphragm moves approximately 1 cm (4/10 inch), and the ribs retract upward from the midline of the body approximately 1.2 to 2.5 cm (1/2 to 1 inch). During a normal, relaxed breath, a person inhales 500 mL of air. This amount is referred to as the tidal volume. During expiration the diaphragm relaxes, and the abdominal organs return to their original positions. The lung and chest wall return to a relaxed position (Fig. 29.7). Expiration is a passive process. Sighing interrupts the normal rate and depth of ventilation, *eupnea*. The sigh, a prolonged deeper breath, is a protective physiological mechanism for expanding small airways and alveoli not ventilated during a normal breath.

FIG. 29.7 Illustration of diaphragmatic and chest wall movement during inspiration and expiration.

The accurate assessment of respirations depends on the recognition of normal thoracic and abdominal movements. During quiet breathing the chest wall gently rises and falls. Contraction of the intercostal muscles between the ribs or contraction of the muscles in the neck and shoulders (the accessory muscles of breathing) is not visible. During normal quiet breathing diaphragmatic movement causes the abdominal cavity to rise and fall slowly.

◆ Nursing Process

◆ Assessment of Ventilation

Respirations are the easiest of all vital signs to assess, but they are often the most haphazardly measured. Do not estimate respirations. Accurate measurement requires observation and palpation of chest wall movement.

A sudden change in the character of respirations is important. Because respiration is tied to the function of numerous body systems, consider all variables when changes occur (Box 29.6). For example, a decrease in respirations occurring in a patient after head trauma often signifies injury to the brainstem.

Box 29.6 Factors Influencing Character of Respirations

Exercise

- Exercise increases rate and depth to meet the need of the body for additional oxygen and to rid the body of CO₂.

Acute Pain

- Pain alters rate and rhythm of respirations; breathing becomes shallow.
- Patient inhibits or splints chest wall movement when pain is in area of chest or abdomen.

Anxiety

- Anxiety increases respiration rate and depth as a result of sympathetic stimulation.

Smoking

- Chronic smoking changes pulmonary airways, resulting in increased rate of respirations at rest when not smoking.

Body Position

- A straight, erect posture promotes full chest expansion.
- A stooped or slumped position impairs ventilatory movement.
- Lying flat prevents full chest expansion.

Medications

- Opioid analgesics, general anesthetics, and sedative hypnotics depress rate and depth.
- Amphetamines and cocaine sometimes increase rate and depth.
- Bronchodilators slow rate by causing airway dilation.

Neurological Injury

- Injury to brainstem impairs respiratory center and inhibits respiratory rate and rhythm.

Hemoglobin Function

- Decreased hemoglobin levels (anemia) reduce oxygen-carrying capacity of the blood, which increases respiratory rate.
- Increased altitude lowers amount of saturated hemoglobin, which increases respiratory rate and depth.
- Abnormal blood cell function (e.g., sickle cell disease) reduces ability of hemoglobin to carry oxygen, which increases respiratory rate and depth.

Do not let a patient know that you are assessing respirations. Quietly observe the patient's breathing and when appropriate begin to count the rate. A patient aware of the assessment can alter the rate and depth of breathing (Hill et al., 2018). Assess respirations immediately after

measuring pulse rate, with your hand still on the patient’s wrist as it rests over the chest or abdomen. In children, measure respirations first, before other vital signs. When assessing a patient’s respirations, keep in mind the patient’s usual ventilatory rate and pattern, the influence any disease or illness has on respiratory function, the relationship between respiratory and cardiovascular function, and the influence of therapies on respirations. The objective measurements of respiratory status include the rate and depth of breathing and the rhythm of ventilatory movements (see [Skill 29.3](#)).

Respiratory Rate

Observe a full inspiration and expiration when counting ventilation or respiration rate. The usual respiratory rate varies with age ([Table 29.6](#)). The usual range of respiratory rate declines throughout life. A patient’s respiratory rate can be used to help predict a risk for cardiac arrest. For example a respiratory rate greater than 27 breaths/min in an adult is a better predictor of cardiac arrest within 72 hours than heart rate or blood pressure ([Kelly, 2018](#)).

TABLE 29.6

Acceptable Ranges of Respiratory Rate

Age	Rate (breaths/min)
Newborn	30-60
Infant (6 months)	30-50
Toddler (2 years)	25-32
Child	20-30
Adolescent	16-20
Adult	12-20

The apnea monitor is a device that aids respiratory rate assessment. This device uses leads attached to a patient’s chest wall; the leads sense movement. The absence of chest wall movement triggers the apnea alarm. Apnea monitoring is used often with infants in the hospital and at home to observe the risk for prolonged apneic events.

Ventilatory Depth

Assess the depth of respirations by observing the degree of excursion or movement of the chest. Describe ventilatory movements as deep or

shallow, normal or labored. A deep respiration involves a full expansion of the lungs with full exhalation. Respirations are shallow and difficult to observe when only a small quantity of air passes through the lungs. Use more objective techniques if you observe that chest excursion is unusually shallow (see [Chapter 30](#)). [Table 29.7](#) summarizes types of breathing patterns.

TABLE 29.7

Alterations in Breathing Pattern

Alteration	Description
Bradypnea	Rate of breathing is regular but abnormally slow (less than 12 breaths/min).
Tachypnea	Rate of breathing is regular but abnormally rapid (greater than 20 breaths/min).
Hyperpnea	Respirations are labored, increased in depth, and increased in rate (greater than 20 breaths/min) (occurs normally during exercise).
Apnea	Respirations cease for several seconds. Persistent cessation results in respiratory arrest.
Hyperventilation	Rate and depth of respirations increase. Hypocarbica sometimes occurs.
Hypoventilation	Respiratory rate is abnormally low, and depth of ventilation is depressed. Hypercarbica sometimes occurs.
Cheyne-Stokes respiration	Respiratory rate and depth are irregular, characterized by alternating periods of apnea and hyperventilation. Respiratory cycle begins with slow, shallow breaths that gradually increase to abnormal rate and depth. The pattern reverses; breathing slows and becomes shallow, concluding as apnea before respiration resumes.
Kussmaul’s respiration	Respirations are abnormally deep, regular, and increased in rate.
Biot’s respiration	Respirations are abnormally shallow for two to three breaths, followed by irregular period of apnea.

Ventilatory Rhythm

Determine breathing pattern by observing the chest or the abdomen. Diaphragmatic breathing results from the contraction and relaxation of the diaphragm, and you observe it best by watching abdominal movements. Healthy men and children usually demonstrate diaphragmatic breathing. Women tend to use thoracic muscles to breathe, assessed by observing movements in the upper chest. Labored respirations usually involve the accessory muscles of respiration visible in the neck. When something such as a foreign body interferes with the movement of air in and out of the lungs, the intercostal spaces retract during inspiration. A longer expiration phase is evident when the outward flow of air is obstructed (e.g., asthma, chronic obstructive pulmonary disease (COPD)).

With normal breathing a regular time interval occurs after each respiratory cycle. Infants tend to breathe less regularly. A young child often breathes slowly for a few seconds and then suddenly breathes more rapidly. Respiration is regular or irregular in rhythm.

• Assessment of Diffusion and Perfusion

Assess the respiratory processes of diffusion and perfusion by measuring the oxygen saturation of the blood. Blood flow through the pulmonary capillaries delivers red blood cells for oxygen attachment. After oxygen diffuses from the alveoli into the pulmonary blood, most of the oxygen attaches to hemoglobin molecules in red blood cells. Red blood cells carry the oxygenated hemoglobin molecules through the left side of the heart and out to the peripheral capillaries, where the oxygen detaches, depending on the needs of the tissues.

The percent of hemoglobin that is bound with oxygen in the arteries is the percent of saturation of hemoglobin (or SaO_2). It is usually between 95% and 100%. It is affected by factors that interfere with ventilation, perfusion, or diffusion (see [Chapter 41](#)). The saturation of venous blood (SvO_2) is lower because the tissues have removed some of the oxygen from the hemoglobin molecules. Factors that interfere with or increase tissue oxygen demand affect the usual value for SvO_2 , which is 70%.

Measurement of Arterial Oxygen Saturation

A pulse oximeter permits the indirect measurement of **oxygen saturation** (see [Skill 29.4](#)) by measuring the hemoglobin saturation in peripheral blood. The pulse oximeter is a probe with a light-emitting diode (LED) connected by a cable to an oximeter ([Fig. 29.8](#)). The LED emits light wavelengths that the oxygenated and deoxygenated hemoglobin molecules absorb differently. A photodetector in the probe detects the amount of oxygen bound to hemoglobin molecules, and the oximeter calculates the peripheral saturation (SpO_2). SpO_2 is a reliable estimate of SaO_2 when the SaO_2 is over 70%. A saturation greater than 93% is acceptable while a saturation of less than 90% is a clinical emergency ([WHO, 2011](#)). Values obtained with pulse oximetry are less accurate at saturations less than 70%.

FIG. 29.8 Portable pulse oximeter with digit probe.

Selecting the appropriate pulse oximeter probe is important to reduce measurement error. Digit probes are spring-loaded and conform to various sizes. Earlobe probes have greater accuracy at lower saturations and are least affected by peripheral vasoconstriction. You can apply disposable sensor pads to a variety of sites, including the forehead, the bridge of an adult's nose, or the sole of an infant's foot. These pads are less likely than the spring-loaded probes to cause pressure injuries. Oxygen saturation measurement using a forehead probe is quicker than finger probes and more accurate in conditions that decrease blood flow. Factors that affect light transmission or peripheral arterial pulsations affect the ability of the photodetector to measure SpO_2 correctly (Box 29.7). An awareness of these factors allows accurate interpretation of abnormal SpO_2 measurements.

Box 29.7 Factors Affecting Determination of Pulse Oxygen Saturation (SpO_2)

Interference with Light Transmission

- Outside light sources interfere with ability of oximeter to process reflected light.
- Carbon monoxide (caused by smoke inhalation or poisoning) artificially elevates SpO₂ by absorbing light similar to oxygen.
- Patient motion interferes with ability of oximeter to process reflected light.
- Jaundice interferes with ability of oximeter to process reflected light.
- Intravascular dyes (methylene blue) absorb light similar to deoxyhemoglobin and artificially lower saturation.
- Black or brown nail polish or metal studs in nails and thickened nails (e.g., artificial) can interfere with light absorption and the ability of the oximeter to process reflected light.
- Dark skin pigment sometimes results in signal loss or overestimation of saturation.

Interference with Arterial Pulsations

- Peripheral vascular disease (atherosclerosis) reduces pulse volume.
- Hypothermia at assessment site decreases peripheral blood flow.
- Pharmacological vasoconstrictors (e.g., epinephrine) decrease peripheral pulse volume.
- Low cardiac output and hypotension decrease blood flow to peripheral arteries.
- Peripheral edema obscures arterial pulsation.
- Tight probe records venous pulsations in finger that compete with arterial pulsations.

Capnography

Capnography is the measurement of exhaled carbon dioxide throughout exhalation. At the end of exhalation, the EtCO₂ measurement approximates the PaCO₂ in a healthy patient, normally 35 to 45 mm Hg. In nonintubated patients EtCO₂ can be obtained from a special nasal cannula (see [Chapter 41](#)) connected to a monitor that detects the percentage of carbon dioxide exhaled at the end of each respiratory cycle. The EtCO₂ can be used to assess respiratory and cardiac status, whereas interpretation of a continuous recording, or capnogram, can detect changes in ventilation.

• Nursing Diagnosis

Measurement of respiratory rate, pattern, and depth, along with SpO₂, assesses ventilation, diffusion, and perfusion. You also conduct other assessments to measure respiratory status (see [Chapter 30](#)). Use assessment data to determine the nature of a patient's problem. Respiratory assessment data are assessment findings for many nursing diagnoses, including the following:

- *Activity Intolerance*
- *Impaired Airway Clearance*
- *Impaired Breathing*
- *Impaired Gas Exchange*

• Planning and Implementation

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the assessment findings of tachycardia, dyspnea, restlessness, and an increase in CO₂ level lead to a diagnosis of *Impaired Gas Exchange*. Related factors could include *alveolar capillary membrane changes from infection or a ventilator-perfusion imbalance*.

You select interventions (e.g., coughing, positioning, and fluid management) on the basis of the related factor. As in the case of pulse alterations, medical diagnoses associated with respiratory changes require dependent nursing interventions. [Chapter 41](#) details oxygen therapies.

• Evaluation

Patient Outcomes

After providing interventions designed to improve a patient's activity tolerance, breathing pattern, and/or gas exchange, evaluate patient outcomes by evaluating the respiratory rate, ventilatory depth, rhythm, and SpO₂. Consider the physiological changes expected from nursing interventions as you evaluate patient outcomes. For example, after suctioning secretions from a patient's airway, the respiratory rate should decrease and the respiratory depth should increase. The administration of bronchodilators, which relax constricted airways, can reduce respiratory rate and improve respiratory depth.

Blood Pressure

Blood pressure is the force exerted on the walls of an artery by the pulsing blood under pressure from the heart. Systemic or arterial BP, the BP in the system of arteries in the body, is a good indicator of cardiovascular health. Blood flows throughout the circulatory system because of pressure changes. It moves from an area of high pressure to one of low pressure. The contraction of the heart forces the blood under high pressure into the aorta. The peak of maximum pressure when ejection occurs is the **systolic pressure**. When the ventricles relax, the heart fills, and the pressure of blood in the arteries is the **diastolic pressure**. Diastolic pressure is the minimal pressure exerted against the arterial walls at all times.

The standard unit for measuring BP is millimeters of mercury (mm Hg). The measurement indicates the height to which the BP raises a column of mercury. Record BP with the systolic reading before the diastolic reading (e.g., 120/80). The difference between systolic and diastolic pressure is the **pulse pressure**. For example, for a BP of 120/80, the pulse pressure is 40.

Physiology of Arterial Blood Pressure

Blood pressure reflects the interrelationships of cardiac output, peripheral vascular resistance, blood volume, blood viscosity, and artery elasticity. Your knowledge of these hemodynamic variables helps in the assessment of BP alterations.

Cardiac Output

The BP depends on the cardiac output. When volume increases in an enclosed space such as a blood vessel, the pressure in that space rises. Thus as cardiac output increases, more blood is pumped against arterial walls, causing the BP to rise. Cardiac output increases as a result of an increase in HR, greater heart muscle contractility, or an increase in blood volume. Changes in HR occur faster than changes in heart muscle contractility or blood volume. A rapid or significant increase in HR decreases the filling time of the heart, which decreases the volume in the left ventricle, and BP decreases.

Peripheral Resistance

The BP depends on peripheral vascular resistance. Blood circulates through a network of arteries, arterioles, capillaries, venules, and veins. Arteries and arterioles are surrounded by smooth muscle that contracts or relaxes to change the size of the lumen. The size of arteries and arterioles changes to adjust blood flow to the needs of local tissues. For example, when a major organ needs more blood, the peripheral arteries constrict, decreasing their supply of blood. More blood becomes available to the major organ because of the resistance change in the periphery. Normally arteries and arterioles remain partially constricted to maintain a constant flow of blood. Peripheral vascular resistance is the resistance to blood flow determined by the tone of vascular musculature and diameter of blood vessels. The smaller the lumen of a vessel, the greater is the peripheral vascular resistance to blood flow. As resistance rises, arterial BP rises. When vessels dilate and resistance falls, arterial BP falls.

Blood Volume

Blood pressure depends on the volume of circulating blood. Most adults have a circulating blood volume of 5000 mL. Normally the blood volume remains constant. However, an increase in blood volume exerts more pressure against arterial walls. For example, the rapid, uncontrolled infusion of IV fluids elevates BP. When a person's circulating blood volume falls, as in the case of hemorrhage or dehydration, the BP also falls.

Viscosity

The thickness or viscosity of blood affects the ease with which blood flows through small vessels. The **hematocrit**, or percentage of red blood cells in the blood, determines blood viscosity. When the hematocrit rises and blood flow slows, arterial BP increases. The heart contracts more forcefully to move the viscous blood through the circulatory system.

Elasticity

Normally the walls of an artery are elastic and easily distensible. As pressure within the arteries increases, the diameter of vessel walls increases to accommodate the pressure change. The ability of arteries to dilate prevents wide fluctuations in BP. However, in certain diseases such as arteriosclerosis, the vessel walls lose their elasticity and are replaced by fibrous tissue that cannot stretch well. Reduced elasticity results in greater resistance to blood flow. As a result, when the left ventricle ejects its SV, the vessels no longer yield to pressure. Instead a given volume of blood is forced through the rigid arterial walls, and the systemic pressure rises. Systolic pressure is more significantly elevated than diastolic pressure as a result of reduced arterial elasticity.

Each hemodynamic factor significantly affects the others. For example, as arterial elasticity declines, peripheral vascular resistance increases. The complex control of the cardiovascular system normally prevents any single factor from permanently changing the BP. For example, if the blood volume falls, the body compensates with an increased vascular resistance.

Factors Influencing Blood Pressure

Blood pressure is not constant. With many influencing factors one BP measurement cannot adequately reflect a patient's health status. Even under the best conditions, BP changes from heartbeat to heartbeat. BP trends, not individual measurements, guide nursing interventions. Understanding these factors ensures a more accurate interpretation of BP readings.

Age

Normal BP levels vary throughout life ([Table 29.8](#)). BP increases during childhood. You assess the level of a child's or adolescent's BP with respect to their percentile of height and their age ([Hockenberry et al., 2019](#)). Larger children (heavier and/or taller) have higher BPs than smaller children of the same age. During adolescence BP continues to vary according to body size. An adult's BP tends to rise with advancing age. The optimal BP for a healthy, middle-age adult is less than 120/80 mm Hg. A systolic value of 120 to 129 and a

diastolic greater than 80 is considered to be an elevated blood pressure.

TABLE 29.8

Average Optimal Blood Pressure for Age

Age	Blood Pressure (mm Hg)
Newborn (3000 g [6.6 lb])	40 (mean)
1 month	85/54
1 year	95/65
6 years ^a	105/65
10-13 years ^a	110/65
14-17 years ^a	119/75
18 years and older	<120/<80

^a In children and adolescents, hypertension is defined as blood pressure that on repeated measurement is at the 95th percentile or greater adjusted for age, height, and gender.

From James PA et al: Evidence-based guideline for the management of high blood pressure in adults: report by the panel appointed to the Eighth Joint National Committee (JNC 8), *JAMA* 31:507, 2014.

Stress

Emotional stress (e.g., anxiety and fear) and acute pain result in sympathetic stimulation, which increases HR, cardiac output, and vascular resistance. The effect of sympathetic stimulation increases BP.

Ethnicity and Genetics

Ethnic and genetic characteristics influence blood pressure. The prevalence of hypertension (high blood pressure) in African Americans in the United States is among the highest in the world. In addition, more than 40% of non-Hispanic African-American men and women have high blood pressure (AHA, 2016). However, other ethnic groups are at risk as well. A study by Carson and colleagues (2011) has shown that among adults 45 to 84 years of age there is a

higher incidence of hypertension among Hispanics compared with whites; however, hypertension incidence did not differ for Chinese and white participants. In a study involving prevalence of hypertension among Asian and Hispanics adults in New York City, two major racial/ethnic minority groups had higher odds of hypertension than non-Hispanic whites: non-Hispanic black and Asian individuals (Fei et al., 2017). There is the need for specifically targeted interventions for hypertension, because of ethnic differences (Fei et al., 2017). Genetic factors also contribute to a patient's blood pressure. Assess the patient's family history for early hypertension and any complications related to hypertension. Individuals with a family history of high blood pressure may share common environments and other potential factors that increase their risk of hypertension (CDC, 2014).

Gender

There is no clinically significant difference in BP levels between boys and girls. After puberty males tend to have higher BP readings. After menopause women tend to have higher BP levels than men of similar age. There are no specific guidelines for treating hypertension in men and women. However, numerous human studies have shown differences in the mechanisms responsible for blood pressure control between the sexes (Reckelhoff, 2018). Both men and women require education on the risk for hypertension and hypertension-related complications.

Daily Variation

Blood pressure varies throughout the day, with lower BP during sleep between midnight and 3:00 AM. Between 3:00 AM and 6:00 AM there is a slow and steady rise in BP. When a patient awakens, there is an early-morning surge. It is highest during the day between 10:00 AM and 6 PM. No two people have the same pattern or degree of variation.

Medications

Some medications directly or indirectly affect BP. Before BP assessment ask whether the patient is receiving antihypertensive, diuretic, or other cardiac medications, which lower BP (Table 29.9). Another class of medications that lower BP is opioid analgesics. Vasoconstrictors and an excess volume of IV fluids increase BP.

TABLE 29.9

Antihypertensive Medications

Medication Type	Example	Action
Diuretics	Furosemide, spironolactone, metolazone, polythiazide, hydrochlorothiazide	Lower blood pressure by reducing resorption of sodium and water by the kidneys, thus lowering circulating fluid volume
Beta-adrenergic blockers	Atenolol, nadolol, timolol maleate, metoprolol	Combines with beta-adrenergic receptors in the heart, arteries, and arterioles to block response to sympathetic nerve impulses; reduces heart rate and thus cardiac output
Vasodilators	Hydralazine hydrochloride, minoxidil	Acts on arteriolar smooth muscle to cause relaxation and reduce peripheral vascular resistance
Calcium channel blockers	Diltiazem, verapamil hydrochloride, nifedipine, nicardipine	Reduces peripheral vascular resistance by systemic vasodilation
Angiotensin-converting enzyme (ACE) inhibitors	Captopril, enalapril, lisinopril, benazepril	Lowers blood pressure by blocking the conversion of angiotensin I to angiotensin II, preventing vasoconstriction; reduces aldosterone production and fluid retention, lowering circulating fluid volume
Angiotensin-II receptor blockers (ARBs)	Losartan, olmesartan	Lowers blood pressure by blocking the binding of angiotensin II, which prevents vasoconstriction

Activity and Weight

A period of exercise can reduce BP for several hours afterward. An increase in oxygen demand by the body during activity increases BP. Inadequate exercise frequently contributes to weight gain, and obesity is a factor in the development of hypertension.

Smoking

Smoking results in vasoconstriction, a narrowing of blood vessels. BP rises when a person smokes and returns to baseline about 15 minutes after stopping smoking.

Hypertension

The most common alteration in BP is **hypertension**. Hypertension is often asymptomatic. An elevated blood pressure or hypertension is diagnosed in adults when an average of two or more readings on at least two subsequent health care visits is above 120/80 mm Hg. One elevated BP measurement does not qualify as a diagnosis of hypertension. A systolic blood pressure between 120 and 129 with a diastolic blood pressure less than 80 is considered elevated. Hypertension is classified as Stage 1 or Stage 2, depending on systolic and diastolic values ([Table 29.10](#)). Hypertension increases the risk of hypertension-related illness, including stroke, heart attack, and damage to kidneys, retinas, and the peripheral nervous system. The categories of hypertension determine nonpharmacological and pharmacological intervention. [Table 29.11](#) summarizes recommended follow-up for patients diagnosed with BP alterations.

TABLE 29.10

Categories of BP in Adults^a

Bp Category	Sbp		Dbp
Normal	<120 mm Hg	and	<80 mm Hg
Elevated	120-129 mm Hg	and	<80 mm Hg
Hypertension			
Stage 1	130-139 mm Hg	or	80-89 mm Hg
Stage 2	≥140 mm Hg	or	≥90 mm Hg

BP indicates blood pressure (based on an average of ≥2 careful readings obtained on ≥2 occasions, as detailed in diastolic blood pressure (DBP) and systolic blood pressure (SBP)).

^a Individuals with SBP and DBP in 2 categories should be designated to the higher BP category.

Data from Whelton et al: Guideline for the prevention, detection, evaluation, and management of high blood pressure in adults, *J Am Coll Cardiol* 71(19):2199-2269, 2018.

TABLE 29.11**Recommendations for Blood Pressure Follow-Up**

Initial Blood Pressure	Follow-Up Recommended ^a
Normal	Recheck in 1 year.
Elevated	Recheck in 3-6 months. ^b
Stage 1 hypertension	Evaluate therapy within 3-6 months. ^b
Stage 2 hypertension	Evaluate therapy within 1 month. ^b For those with higher pressure (e.g., >180/110 mm Hg), evaluate and treat immediately or within 1 week, depending on clinical situation and complications.

^a Modify the scheduling of follow-up according to reliable information about past blood pressure measurements, other cardiovascular risk factors, or target organ damage.

^b Provide advice about lifestyle modifications.

Data from Whelton et al: Guideline for the prevention, detection, evaluation, and management of high blood pressure in adults-executive summary, *J Am Coll Cardiol* 71:(19): 2199, 2018.

Hypertension is associated with thickening and loss of elasticity in the arterial walls. Peripheral vascular resistance increases within thick and inelastic vessels. The heart continually pumps against greater resistance. As a result blood flow to vital organs such as the heart, brain, and kidney decreases with untreated or chronic hypertension.

Multiple risk factors are associated with hypertension. Modifiable risk factors include obesity, cigarette smoking, heavy alcohol consumption, and high sodium (salt) intake. Sedentary lifestyle and continued exposure to stress are also linked to hypertension. The incidence of hypertension is greater in patients with diabetes and in older adults. Hypertension contributes to deaths from strokes and myocardial infarctions (heart attacks).

Hypotension

Hypotension is present when the systolic BP falls to 90 mm Hg or below. Although some adults have a low BP normally, for most

people low BP is an abnormal finding associated with illness.

Hypotension occurs because of the dilation of the arteries in the vascular bed, the loss of a substantial amount of blood volume (e.g., hemorrhage), or the failure of the heart muscle to pump adequately (e.g., myocardial infarction). Hypotension associated with pallor, skin mottling, clamminess, confusion, increased HR, or decreased urine output is life threatening and is reported to a health care provider immediately.

When a healthy individual changes from a lying-to sitting-to standing position, the peripheral blood vessels in the legs constrict. When standing, the lower-extremity vessels constrict, preventing the pooling of blood in the legs caused by gravity. Thus an individual normally does not feel any symptoms when standing. **Orthostatic hypotension**, also referred to as **postural hypotension**, occurs when a normotensive person develops symptoms and a drop in systolic pressure by at least 20 mm Hg or a drop in diastolic pressure by at least 10 mm Hg within 3 minutes of rising to an upright position (Shibao et al., 2013). Orthostatic hypotension occurs when patients are unable to constrict their lower extremity blood vessels to maintain their BP. Patients who are dehydrated, anemic, or have experienced prolonged bed rest or recent blood loss are at risk for orthostatic hypotension, particularly in the morning (Shibao et al., 2013). Some medications cause orthostatic hypotension, especially in older adults or young patients.

❖ Nursing Process

• Assessment of Blood Pressure

Arterial BP measurements are obtained either directly (invasively) or indirectly (noninvasively). The direct method requires the insertion of a thin catheter into an artery. Tubing connects the catheter with electronic hemodynamic monitoring equipment. The monitor displays a constant arterial pressure waveform and reading. Because of the risk of sudden blood loss from an artery, invasive BP monitoring is used only in intensive care settings. The common indirect methods require either a sphygmomanometer and stethoscope with auscultation or an automated oscillometric device without auscultation. The use of a sphygmomanometer and stethoscope has been considered the gold standard for BP measurement when properly used and maintained (Stergiou, 2012). The technique for measuring BP by auscultation is described in [Skill 29.5](#).

Blood Pressure Equipment for Auscultation

Before assessing BP, make sure that you are comfortable using the equipment. For more than half a century health care settings relied on a sphygmomanometer and stethoscope to measure BP by auscultation. A **sphygmomanometer** includes a pressure manometer, an occlusive cuff that encloses an inflatable rubber bladder, and a pressure bulb with a release valve that inflates the bladder manually. The aneroid manometer has a glass-enclosed circular gauge containing a needle that registers millimeter calibrations. Before using the aneroid model, make sure that the needle points to zero and that the manometer is correctly calibrated. Aneroid sphygmomanometers require biomedical calibration every 6 months to verify their accuracy.

An occlusive cuff comes in different sizes. The size selected is proportional to the circumference of the limb being assessed ([Fig. 29.9](#)). Ideally the width of the cuff is 40% of the circumference (or 20% wider than the diameter) of the midpoint of the limb on which the cuff is used to measure BP. The inflatable bladder, contained in the occlusive cuff, encircles at least 80% of the upper arm of an adult and the entire arm of a child.

FIG. 29.9 Guidelines for proper blood pressure cuff size. Cuff width 20% more than upper-arm diameter or 40% of circumference and two-thirds of arm length.

Measure a blood pressure in the arm by placing the lower edge of the cuff above the antecubital fossa, allowing room for positioning the stethoscope bell or diaphragm over the brachial artery. Many adults require a large adult cuff. Using the forearm when a larger cuff is not readily available is not recommended and can result in an overestimate of systolic blood pressure up to 20 mm Hg (Schimanski et al., 2014). An improperly fitting cuff causes inaccurate BP measurements (Table 29.12). The release valve of the sphygmomanometer needs to be clean and freely movable in either direction. A closed valve holds the pressure constant. A sticky valve makes pressure cuff deflation hard to regulate.

TABLE 29.12**Common Errors in Blood Pressure Assessment**

Error	Effect
Bladder or cuff too wide	False-low reading
Bladder or cuff too narrow or too short	False-high reading
Cuff wrapped too loosely or unevenly	False-high reading
Deflating cuff too slowly	False-high diastolic reading
Deflating cuff too quickly	False-low systolic and false-high diastolic reading
Arm below heart level	False-high reading
Arm above heart level	False-low reading
Arm not supported	False-high reading
Stethoscope that fits poorly or impairment of examiner's hearing, causing sounds to be muffled	False-low systolic and false-high diastolic reading
Stethoscope applied too firmly against antecubital fossa	False-low diastolic reading
Inflating too slowly	False-high diastolic reading
Repeating assessments too quickly	False-high systolic reading
Inadequate inflation level	False-low systolic reading
Multiple examiners using different sounds for diastolic readings	False-high systolic and false-low diastolic reading

Auscultation

The best environment for BP measurement by auscultation is a quiet room at a comfortable temperature. Although the patient may lie or stand, sitting is the preferred position. In most cases BP readings obtained with the patient in the supine, sitting, and standing positions are similar.

The patient's position during routine BP determination needs to be the same during each measurement to permit a meaningful comparison of values. Before obtaining the patient's BP, attempt to control factors responsible for artificially high readings such as pain, anxiety, or exertion. The patient's perception that the physical or interpersonal environment is stressful affects the BP measurement. BP measurements taken at the patient's place of employment or in a health care provider's office are often higher than those taken at the patient's home.

During the initial assessment obtain and record the BP in both arms. Normally there is a difference of 5 to 10 mm Hg between the arms. In subsequent assessments, measure the BP in the arm with the higher

pressure. Pressure differences greater than 10 mm Hg indicate vascular problems and are reported to the health care provider or nurse in charge.

Ask the patient to state his or her usual BP. If the patient does not know, inform him or her after measuring and recording it. This is a good opportunity to educate a patient about optimal values of BP, risk factors for developing hypertension, and dangers of hypertension.

Indirect measurement of arterial BP works on a basic principle of pressure. Blood flows freely through an artery until an inflated cuff applies pressure to tissues and causes the artery to collapse. After release of the cuff pressure, the point at which blood flow returns and sound appears through auscultation is the systolic pressure.

In 1905 Korotkoff, a Russian surgeon, first described the sounds heard over an artery distal to the BP cuff when the cuff was deflated. The first sound is a clear rhythmical tapping corresponding to the pulse rate that gradually increases in intensity. *Onset of the sound corresponds to the systolic pressure.* A blowing or swishing sound occurs as the cuff continues to deflate, resulting in the second sound. As the artery distends there is turbulence in blood flow. The third sound is a crisper and more intense tapping. The fourth sound becomes muffled and low pitched as the cuff is further deflated. At this point the cuff pressure has fallen below the pressure within the vessel walls; *this sound is the diastolic pressure in infants and children.* The fifth sound marks the disappearance of sound. *In adolescents and adults the fifth sound corresponds with the diastolic pressure (Fig. 29.10).* In some patients the sounds are clear and distinct. In others only the beginning and ending sounds are clear.

FIG. 29.10 The sounds auscultated during blood pressure measurement can be differentiated into five phases. In this example blood pressure is 140/90 mm Hg.

The manual auscultatory method for BP measurement is prone to observer bias and requires clinical skill (MHRA, 2013). Obtaining an accurate measurement is essential because BP assessment results in many medical decisions and nursing interventions. There are several sources for error (see Table 29.12). When you are unsure of a reading, have a colleague reassess the BP.

The American Heart Association recommends recording two numbers for a BP measurement: the point on the manometer when you hear the first sound for systolic and the point on the manometer when you hear the fifth sound for diastolic. Some institutions recommend recording the point when you hear the fourth sound as well, especially for patients with hypertension. Divide the numbers by slashed lines (e.g., 120/70 or 120/100/70). Note the arm used to measure the BP (e.g., right arm [RA] 130/70) and the patient's position (e.g., sitting).

Orthostatic Hypotension

Assess for orthostatic hypotension during measurements of vital signs by obtaining BP and pulse in sequence with the patient supine, sitting, and standing. Obtain BP readings within 3 minutes after the patient changes position. In most cases orthostatic hypotension is detected within a minute of standing. If it occurs, help the patient to a lying position and notify the health care provider or nurse in charge. While obtaining orthostatic measurements, monitor for changes in pulse rate and observe for other symptoms of hypotension such as fainting, weakness, blurred vision, or light-headedness. Orthostatic hypotension is a risk factor for falls, especially among elderly patients with hypertension (Angelousi et al., 2014). When recording orthostatic BP measurements, record the patient's position in addition to the BP measurement (e.g., 140/80 mm Hg supine, 132/72 mm Hg sitting, 108/60 mm Hg standing). The skill of orthostatic measurements requires critical thinking and ongoing nursing judgment when determining a patient's response to repositioning. Do not delegate this procedure.

Ultrasonic Stethoscope

When you are unable to auscultate sounds because of a weakened arterial pulse, you can use an ultrasonic stethoscope (see Chapter 30). This stethoscope allows you to hear low-frequency systolic sounds. You frequently use this device when measuring the BP of infants and children or low BP in adults.

Palpation

Indirect measurement of BP by palpation is useful for patients whose arterial pulsations are too weak to create sounds that are audible by auscultation. Severe blood loss and decreased heart contractility are examples of conditions that result in BPs too low to auscultate accurately. In these cases you can assess the systolic BP by palpation (see Skill 29.5, Step 10). The diastolic BP is difficult to determine by palpation. When using the palpation technique, record the systolic value and how you measured it (e.g., RA 90/-, palpated, supine).

In some patients with hypertension the sounds usually heard over the brachial artery when the cuff pressure is high disappear as pressure is reduced and then reappear at a lower level. This temporary disappearance of sound is the **auscultatory gap**. It typically occurs between the first and second sounds. The gap in sound covers a range of 40 mm Hg and thus causes an underestimation of systolic pressure or overestimation of diastolic pressure. The examiner needs to be certain to inflate the cuff high enough to hear the true systolic pressure before the auscultatory gap. Palpation of the radial artery helps to determine how high to inflate the cuff. The examiner inflates the cuff 30 mm Hg above the pressure at which the radial pulse was palpated. Record the range of pressures in which the auscultatory gap occurs (e.g., BP RA 180/94 mm Hg with an auscultatory gap from 180 to 160 mm Hg, sitting).

Equipment for Oscillometric Measurement

More common today is the use of automated electronic oscillometric devices that do not require use of a stethoscope for auscultation. The devices include an electronic monitor with a pressure sensor, a digital display, and an upper arm cuff (Fig. 29.11). An electrically driven pump raises the pressure in the cuff (MHRA, 2013). There are also devices that fit around a patient's wrist. Devices usually have an adjustable set inflation pressure or they will automatically inflate to the appropriate level, usually about 30 mm Hg above an estimated systolic reading (MHRA, 2013). When started, the device automatically inflates, then deflates the cuff and displays the systolic and diastolic values. These devices rely on oscillometric principle to measure mean blood pressure and apply a manufacturer- and device-specific algorithm to estimate systolic and diastolic blood pressure (Stergiou, 2012).

FIG. 29.11 Automatic blood pressure monitor.

Blood Pressure Measurement Using Oscillometric Device

Many different styles of electronic oscillometric devices are available to determine BP automatically. The arm cuff is placed around the upper arm, just above the brachial artery. A push of a button activates the inflation of the cuff. The electronic pressure sensor detects the vibrations caused by the rush of blood through an artery (Box 29.8). Once a BP is sensed, a reading will be shown on the electronic display. Oscillometric devices are mercury-free, lightweight, compact, portable, easy to use, and offer no observer bias (MHRA, 2013). More of these devices can be found in physician offices and clinics and even on hospital inpatient units. The devices are particularly useful when frequent BP assessment is necessary, such as in patients who are critically ill or unstable, during or after invasive procedures, or when therapies require frequent monitoring (e.g., IV heart and BP medications). Box 29.9 lists conditions that are not appropriate for automatic BP devices. If a BP result is questionable based on a patient's condition, ensure accurate BP measurement by obtaining manual measurements using auscultation with a sphygmomanometer

Box 29.8 Procedural Guidelines **Electronic Blood Pressure Measurement**

Delegation and Collaboration

The skill of blood pressure measurement using an electronic blood pressure machine can be delegated to assistive personnel (AP) unless the patient is considered unstable (i.e., hypotensive). The nurse instructs the AP by:

- Explaining the frequency and the extremity to use for measurement.
- Reviewing how to select appropriate-size blood pressure cuff for designated extremity and appropriate cuff for the machine.
- Reviewing patient's usual blood pressure and directing AP to report significant changes or abnormalities to the nurse.

Equipment

Electronic oscillometric blood pressure device; blood pressure cuff of appropriate size as recommended by machine manufacturer; pen and vital sign flow sheet in chart or electronic health record (EHR)

Steps

1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number), according to agency policy (TJC, 2020).
2. Assess need to measure blood pressure (see Skill 29.5 Assessment Steps 2, 3, and 5), and determine patient's baseline blood pressure.
3. Determine appropriateness of using electronic blood pressure measurement. Patients with irregular heart rate, known hypertension, peripheral vascular disease, seizures, tremors, and shivering are not candidates for the device (Wang et al., 2016).
4. Collect and bring appropriate equipment to patient's bedside. Select appropriate cuff size for patient extremity. Electronic blood pressure cuff and device must be matched by manufacturer and are not interchangeable.
5. Perform hand hygiene and determine best site for cuff placement; inspect condition of extremities.
6. Assist patient to comfortable position, either lying or sitting. Plug device into electrical outlet and place it near patient, ensuring that connector hose between cuff and machine reaches.
7. Locate on/off switch and turn on machine to enable device to self-test computer systems.
8. Remove constricting clothing to ensure proper cuff application.
9. Prepare blood pressure cuff by manually squeezing all the air out of the cuff and connecting it to connector hose.
10. Wrap flattened cuff snugly around extremity, verifying that only one finger can fit between cuff and patient's skin. Make sure that "artery" arrow marked on outside of cuff is placed correctly (see illustration).

STEP 10 Aligning blood pressure cuff arrow with brachial artery.

11. Verify that connector hose between cuff and machine is not kinked. Kinking prevents proper inflation and deflation of cuff.
12. Following manufacturer directions, set frequency control for automatic or manual and press the start button. The first blood pressure measurement pumps cuff to a peak pressure of approximately 180 mm Hg. After this pressure is reached, the machine begins a deflation sequence that determines the blood pressure. The first reading determines peak pressure inflation for additional measurements.
13. When deflation is complete, digital display provides most recent values and flashes time in minutes that have elapsed since the measurement occurred (see illustration).

STEP 13 Digital electronic blood pressure display.
Image courtesy of Hillrom.

CLINICAL DECISION: If unable to obtain blood pressure with electronic device, verify machine connections (e.g., plugged into working electrical outlet, hose-cuff connections tight, machine on, correct cuff). Repeat electronic blood pressure; if unable to obtain, use auscultatory technique (see Skill 29.5).

14. Set frequency of measurements and upper and lower alarm limits for systolic, diastolic, and mean blood pressure readings. Intervals between measurements can be set from 1 to 90 minutes. A nurse determines frequency and alarm limits on the basis of patient's acceptable range of blood pressure, nursing judgment, and health care provider order.
15. Obtain additional readings at any time by pressing the start button. Pressing the cancel button immediately deflates the cuff.

16. If frequent measurements are required, the cuff may be left in place. Remove it at least every 2 hours to assess underlying skin integrity and, if possible, alternate measurement sites.

CLINICAL DECISION: Frequent measurement by electronic blood pressure machines increases the risk of extremity pressure injuries, especially in vulnerable elders. Patients with abnormal bleeding tendencies are at risk for microvascular rupture from repeated inflations. Inspect the skin under the blood pressure cuff at regular intervals, depending on the frequency of use.

17. When patient no longer requires frequent blood pressure monitoring:
 - a. Assist patient in return to comfortable position and cover upper arm or leg if previously clothed to restore comfort and provide sense of well-being.
 - b. Place nurse call system within reach and instruct patient in its use to promote safety and prevent falls.
 - c. Raise side rails (as appropriate) and lower bed to lowest position to promote safety and prevent falls.
 - d. Wipe cuff with agency-approved disinfectant to reduce transmission of infection. Clean and store electronic blood pressure machine.
18. Perform hand hygiene.
19. Compare electronic blood pressure readings with auscultatory measurements to verify accuracy of electronic device. Electronic measurements can underestimate measurements (Drawz, 2017).
20. **Use Teach-Back:** "I want to be sure I explained why you need to keep your arm straight while the machine is taking your blood pressure. Tell me why it is important to remain still." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.
21. Record blood pressure, site assessed, and use of electronic device; record any signs or symptoms of blood pressure alterations.
22. Notify nurse in charge or health care provider of abnormal findings.

Box 29.9 Patient Conditions Not Appropriate for Electronic Blood Pressure Measurement

- Irregular heart rate
- Known hypertension
- Peripheral vascular obstruction (e.g., clots, narrowed vessels)
- Shivering
- Seizures
- Excessive tremors
- Inability to cooperate
- Blood pressure less than 90 mm Hg systolic

Blood Pressure Assessment in Children

Blood pressure measurement in the ambulatory setting begins at 3 years of age during every wellness visit. For otherwise healthy children, BP need only be measured annually rather than during every health care encounter (Flynn et al., 2017). If a child has obesity, diabetes, renal disease, or vascular problems, obtain readings during every health encounter (Flynn et al., 2017). BP in children changes with growth and development. The prevalence of BP elevations and hypertension in children, especially among children who are overweight, has increased (Flynn et al., 2017). Help parents understand the importance of routine BP screening to detect children who are at risk for hypertension. The measurement of BP in infants and children is difficult for several reasons:

- Different arm size requires careful and appropriate cuff size selection. Do not choose a cuff on the basis of the name of the cuff. An “infant” cuff can be too small for some infants.
- Readings are difficult to obtain in restless or anxious infants and children. Allow at least 15 minutes for children to recover from recent activities and become less apprehensive. The child’s cooperation is increased when you or the parent have prepared him or her for the unusual sensation of the BP cuff. Most children understand the analogy of a “tight hug on your arm.”
- Placing the stethoscope too firmly on the antecubital fossa causes errors in auscultation. Sounds are difficult to hear in children

because of low frequency and amplitude. A pediatric stethoscope bell is often helpful.

Lower-Extremity Blood Pressure

Dressings, casts, IV catheters, or arteriovenous fistulas or shunts make the upper extremities inaccessible for BP measurement. You then need to obtain the BP in a lower extremity. Comparing upper-extremity BP with that in the legs is also necessary for patients with certain cardiac and BP abnormalities. The popliteal artery, palpable behind the knee in the popliteal space, is the site for auscultation or oscillometric measurement. The cuff needs to be wide and long enough to allow for the larger girth of the thigh. Placing the patient in a prone position is best. If such a position is impossible, ask the patient to flex the knee slightly for easier access to the artery. Position the cuff 2.5 cm (1 inch) above the popliteal artery, with the bladder over the posterior aspect of the midthigh ([Fig. 29.12](#)). The procedure is identical to brachial artery measurement. Systolic pressure in the legs is usually higher by 10 to 40 mm Hg than in the brachial artery, but the diastolic pressure is the same.

FIG. 29.12 Lower-extremity blood pressure cuff positioned above popliteal artery at midhigh with knee flexed.

Self-Measurement of Blood Pressure

Electronic monitoring devices allow individuals to measure their own BPs in their home with the push of a button. The devices are mercury-free, lightweight, compact, portable, easy to use, and have no observer bias (MHRA, 2013). The most common portable home devices are electronic digital readout devices that do not require use of a stethoscope. The electronic devices are easy to manipulate but require frequent recalibration, more than once a year.

Stationary automatic BP devices are often found in public places such as grocery stores, fitness clubs, airports, or work sites. Users simply rest their arms within the inflatable cuff of the machine, which contains a pressure sensor. A visual display tells users their BP within 60 to 90 seconds. The reliability of the stationary machines is limited. BP values can vary by 5 to 10 mm Hg or more (for both systolic and diastolic values) compared with pressures taken with a manual sphygmomanometer.

Self-measurement of BP has several benefits. Sometimes elevated BP is detected in people previously unaware of a problem. People with prehypertension provide information about the pattern of BP values to

their health care provider. Patients with hypertension benefit from participating actively in their treatment through self-monitoring, which helps adherence with treatment. The disadvantages of self-measurement include improper use of the device and risk of inaccurate readings. Some patients are needlessly alarmed with one elevated reading. Some patients with hypertension become overly conscious of their BP and inappropriately self-adjust medications.

• Nursing Diagnosis

The assessment of BP along with pulse assessment evaluates the general state of cardiovascular health and responses to other system imbalances. Hypotension, hypertension, orthostatic hypotension, and narrow or wide pulse pressures are assessment findings of certain nursing diagnoses, including the following:

- *Activity Intolerance*
- *Anxiety*
- *Impaired Cardiac Output*
- *Fluid Imbalance*
- *Acute Pain*

• Planning and Implementation

The nursing care plan includes interventions based on the nursing diagnosis identified and the related factors. For example, the assessment findings of hypotension, bradycardia or tachycardia, edema, fatigue, or weight gain lead to a diagnosis of *Impaired Cardiac Output*. Related factors might include deconditioning or altered fluid intake. The related factor guides the choice of nursing interventions.

Health Promotion

The emphasis on health promotion and maintenance and early discharge from hospital settings has resulted in an increase in the need for patients and their families to monitor vital signs in the home and to know how to take medications correctly for management of cardiovascular problems. Teaching considerations affect all vital sign measurements. Incorporate them within the patient's plan of care ([Box 29.10](#)).

Box 29.10 Patient Teaching Health Promotion

Objective

- Patient identifies measures to promote cardiovascular health.

Teaching Strategies

- Instruct patient about the importance of diet, exercise, and remaining tobacco free.
- Demonstrate self-assessment of heart rate using the carotid pulse. Patients taking certain prescribed cardiac medications need to learn to assess their own pulse rate to detect side effects of medications. Patients undergoing cardiac rehabilitation need to learn to assess their own pulse rate to determine their response to exercise.
- Instruct patient about normal blood pressure values, risk factors for hypertension, and usual lack of hypertension symptoms.
- Demonstrate how to obtain blood pressure to the patient/patient's family caregiver using an appropriate-size blood pressure cuff for home use:
 - Do not take a measurement over clothing (AHA, 2017).
 - Sit correctly with your back straight and supported (on a dining chair, rather than a sofa). The feet should be flat on the floor and the legs should not be crossed (AHA, 2017).
 - Measure at the same time each day, after patient has had a brief rest, and in the same position and arm each time pressure is taken.
 - Take two or three readings 1 minute apart, and record the results at each measurement (AHA, 2017).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me three activities you will do to promote cardiovascular health.
- Observe patient obtaining carotid pulse rate.

- Observe patient or family caregiver's measurement of blood pressure.

When patients are diagnosed with an elevated blood pressure or hypertension, educate them about BP values, long-term follow-up care and therapy, the usual lack of symptoms (the fact that it may not be “felt”), the ability of therapy to control but not cure high BP, and a consistently followed treatment plan that ensures a relatively normal lifestyle (James et al., 2014).

Consumers can learn to use self-measurement devices if they have the information needed to perform the procedure correctly and if they know when to seek a health care provider. Advise patients of possible inaccuracies in the BP devices, help them understand the meaning and implications of readings, and teach them proper measurement techniques. Encourage them to record the date of their BP readings to assess BP over time and share findings with their health care provider.

When considering how to teach patients and their families about vital sign measurements and their importance and significance, a patient's age is an important factor. With an increase in the older-adult population there is a greater need for family caregivers to be aware of changes that are unique to older adults. Box 29.11 identifies some of these variations.

Box 29.11 Focus on Older Adults

Factors Affecting Vital Signs of Older Adults

Temperature

- The temperature of older adults is at the lower end of the normal temperature range, 36° to 36.8°C (96.8° to 98.3°F) orally and 36.6° to 37.2°C (98° to 99°F) rectally. Therefore temperatures considered within normal range sometimes reflect a fever in an older adult. In an older adult fever is present when a single oral temperature is over 37.8°C (100°F); repeated oral temperatures are over 37.2°C (99°F); rectal temperatures are over 37.5°C (99.5°F); or temperature has increased more than 1°C (2°F) over baseline.
- Older adults are very sensitive to slight changes in environmental temperature because their thermoregulatory systems are not as efficient.

- A decrease in sweat gland reactivity in the older adult results in a higher threshold for sweating at high temperatures, which leads to hyperthermia and heatstroke.
- Be especially attentive to subtle temperature changes and other manifestations of fever in this population such as tachypnea, anorexia, falls, delirium, and overall functional decline.
- Older adults without teeth or with poor muscle control may be unable to close their mouths tightly to obtain accurate oral temperature readings.

Pulse Rate

- If it is difficult to palpate the pulse of an obese older adult, a Doppler device provides a more accurate reading.
- Pedal pulses are often difficult to palpate in older adults.
- The older adult has a decreased heart rate at rest.
- It takes longer for the heart rate to rise in the older adult to meet sudden increased demands that result from stress, illness, or excitement. Once elevated, the pulse rate takes longer to return to normal resting rate.
- Heart sounds are sometimes muffled or difficult to hear in older adults because of an increase in air space in the lungs.

Blood Pressure

- Older adults who have lost upper arm mass, especially the frail elderly, require special attention to selection of a smaller-size blood pressure cuff.
- Older adults sometimes have an increase in systolic pressure related to decreased vessel elasticity, whereas the diastolic pressure remains the same, resulting in a wider pulse pressure.
- Instruct older adults to change position slowly and wait after each change to avoid postural hypotension and prevent injuries.
- Skin of older adults is more fragile and susceptible to cuff pressure during frequent measurements. More frequent assessment of skin under the cuff or rotating blood pressure sites is recommended.

Respirations

- Aging causes ossification of costal cartilage and downward slant of ribs, resulting in a more rigid rib cage, which reduces chest wall expansion. Kyphosis and scoliosis that occur in older adults also restrict chest expansion and decrease tidal volume.
- Older adults depend more on accessory abdominal muscles during respiration than on weaker thoracic muscles.
- The respiratory system matures by the time a person reaches 20 years of age and begins to decline in healthy people after the age of 25. Despite this decline older adults are able to breathe effortlessly as long as they are healthy. However, sudden events that require an increased demand for oxygen (e.g., exercise, stress, illness) create shortness of breath in the older adult.
- Identifying an acceptable pulse oximeter probe site is difficult with older adults because of the likelihood of peripheral vascular disease, decreased cardiac output, cold-induced vasoconstriction, and anemia.

Box 29.12 Evidence-Based Practice Reliability in

Assessing Respiratory Rate

PICOT Question: Do nurses who count respirations for 15 or 30 seconds accurately assess the respiratory rate compared with nurses who count respirations for 60 seconds?

Evidence Summary

Respiratory rate is a strong predictor of adverse events and strongly correlated with in-hospital mortality. Some experts believe that respiratory rate is a stronger predictor of mortality than blood pressure or pulse. Many Early Warning Scores include respiratory rate measurements. Therefore it is important that respiratory rate be measured accurately and reliably. Brabrand and colleagues (2018) presented experienced nurses with five 60-second patient videos and asked them to measure respiratory rate. In each case measurements had a wide range of more than 10 breaths per minute. Daw et al (2017) conducted a similar study using 169 emergency room pediatric patients. Three health care professionals, a nurse, physician, and respiratory therapist, measured respiratory rate. Measurements varied from 11 breaths below to 18 breaths above the

known respiratory rate. Higher respiratory rates resulted in less agreement. Nurses who count for 15 seconds and multiply by 4 or count for 30 seconds and multiply by 2 round down or round up, which contributes to the measurement error. Convenient electronic devices exist for pulse, blood pressure, oxygen saturation, and temperature for prompt and accurate measurement. Respiratory rate remains a subjective assessment full of human error.

Application to Nursing Practice

- 15-second assessments of respiratory rates are not reliable.
- High respiratory rates require a 60-second assessment of respiratory rate.
- Abnormal respiratory rates should be reassessed before initiating therapies.

Evaluation

Patient Outcomes

Know a patient's baseline trend when evaluating blood pressure values in response to therapies. Know the expected effects of an intervention for blood pressure alterations. For example, if a patient is receiving an antihypertensive medication or an increased infusion of IV fluids, has the BP responded appropriately? The antihypertensive medication should lower BP while an increase in fluids can raise the BP. Evaluate outcomes of teaching interventions by having patients or family caregivers explain the importance of BP measurement and BP medications. Request a demonstration of the blood pressure measurement device.

Recording Vital Signs

Special electronic and paper graphic flow sheets exist for recording vital signs (see [Chapter 26](#)). Identify institution procedure for documenting on a graphic. In addition to the actual vital sign values, record in the nurses' notes any accompanying or precipitating symptoms such as chest pain and dizziness with changes in pulse rate, abnormal BP, shortness of breath with abnormal respirations, or flushing and diaphoresis with elevated temperature. Document any interventions initiated as a result of vital sign measurement such as administration of oxygen therapy, cooling blankets, or an antihypertensive medication.

Patients being managed on critical paths often have vital sign values listed as outcomes. If a vital sign value is above or below the anticipated outcome, write a variance note to explain the nature of the variance and the nursing course of action. For example, a path for a patient who has undergone lung surgery often has an outcome during the postoperative period of “afebrile.” If the patient has a fever, the nurse’s variance note addresses possible sources of fever (e.g., retained pulmonary secretions) and nursing interventions (e.g., increased suctioning, postural drainage, or hydration).

Building Competency in Informatics

The team leader notifies you that your patient has achieved a critical Early Warning Score, a computer-generated value that reflects a patient’s condition on the basis of the vital signs entered by the assistive personnel within the past 15 minutes. After completing a focused assessment of the patient, you review the vital signs and compare the most recent with baseline readings. Which vital signs that are included in the Early Warning Score indicate a potential change in the patient’s condition? Which actions should you take next?

Baseline Vital Signs	Vital Signs During the Past 15 Minutes
Heart rate 86 and regular	Heart rate 92 and regular
Blood pressure 120/84 in right arm via electronic blood pressure machine	Blood pressure 92/76 in right arm via electronic blood pressure machine
Oxygen saturation 95% on 2 L nasal cannula	Oxygen saturation 89% on 2 L nasal cannula
Respiratory rate 16, regular and deep	Respiratory rate 22, regular and deep
Temperature 37.2° C via temporal artery	Temperature 37.6° C via temporal artery

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of the professional nurse. To ensure patient safety, communicate clearly with the members of the health care team, assess and incorporate the patient’s priorities of care and preferences, and use the best evidence when making decisions about your

patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient-centered care.

- Devices for measuring vital signs are often shared among patients. Cleaning each device carefully between patients decreases patients' risk of infection.
- Blood pressure cuffs and pulse oximetry sensors can apply excessive pressure on fragile skin. Rotating sites during repeated measurements decreases risk for skin breakdown.
- Analyze trends for measuring vital signs, and report abnormal findings to the health care provider.
- Determine frequency of measuring vital signs on the basis of the patient's condition.
- Determine a patient's status before delegating a vital sign skill.

SKILL 29.1. Measuring Body Temperature

Delegation and Collaboration

The skill of temperature measurement can be delegated to assistive personnel (AP). The nurse instructs the AP by:

- Communicating the appropriate route, device, and frequency of temperature measurement.
- Explaining any precautions needed in positioning the patient (e.g., for rectal temperature measurement).
- Reviewing the patient's usual temperature values and significant changes to report to the nurse.

Equipment

- Thermometer (selected on the basis of site used)
- Soft tissue or wipe
- Alcohol swab
- Water-soluble lubricant (for rectal measurements only)
- Pen and vital sign flow sheet, record form, or electronic health record (EHR)

- Clean gloves (*optional*), plastic thermometer sleeve, disposable probe or sensor cover
- Towel

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
Table Continued	

Step	Rationale
2. Obtain data from patient's electronic health record (EHR) to determine need to measure patient's body temperature:	
a. Note patient's risks for temperature alterations: <ul style="list-style-type: none"> • Expected or diagnosed infection • Open wounds or burns • White blood cell count below 5000/mm³ or above 12,000/mm³ • Immunosuppressive drug therapy • Injury to hypothalamus • Exposure to temperature extremes • Blood product infusion • Hypothermia or hyperthermia therapy 	Certain conditions place patients at risk for temperature alterations and require more frequent temperature measurement and nursing assessment.
b. Perform hand hygiene. Assess for signs and symptoms that indicate a temperature alteration: <ul style="list-style-type: none"> • <i>Hyperthermia</i>: Decreased skin turgor, dry mucous membranes; tachycardia; hypotension; decreased venous filling; concentrated urine • <i>Heatstroke</i>: Body temperature of 40° C (104° F) or more (Hifumi et al., 2018); hot, dry skin; tachycardia; hypotension; excessive thirst; muscle cramps; visual disturbances; confusion or delirium • <i>Hypothermia</i>: Pale skin; skin cool or cold to touch; bradycardia and dysrhythmias; uncontrollable shivering; reduced level of consciousness; shallow respirations 	Reduces transmission of microorganisms. Physical signs and symptoms alert you to alterations in body temperature.
c. Assess for factors that normally influence temperature:	Allows you to accurately assess for presence and significance of temperature alteration.
• Age	Older adults have narrower range of temperature than younger adults.
CLINICAL DECISION: No single temperature is normal for all people. A temperature within an acceptable range in an adult may reflect a fever in an older adult. Undeveloped temperature-control mechanisms in infants and children cause temperature to rise and fall rapidly.	
• Exercise	Muscle activity increases metabolism, which increases heat production and raises temperature.
• Hormones	Women have wider temperature fluctuations than men because of menstrual cycle hormonal changes, because body temperature varies during menopause, and because women have thicker layer of subcutaneous fat.
• Stress	Stress elevates temperature.
• Environmental temperature	Infants and older adults are more sensitive to environmental temperature changes.
• Medications	Some drugs impair or promote sweating, vasoconstriction, or vasodilation or interfere with ability of hypothalamus to regulate temperature.
• Daily fluctuations	Body temperature normally changes 0.5° to 1° C (0.9° to 1.8° F) during 24-hour period. Temperature is lowest during early morning. Most patients have maximum temperature elevation between 4 PM and 7 PM; temperature falls gradually during night.
3. Determine appropriate measurement site and device for patient (Table 29.2). Use disposable thermometer for patient on isolation precautions.	Determines whether patient's status contraindicates selection of a specific method or site.
4. Determine previous baseline temperature and measurement site (if available) from patient's electronic health record.	Allows you to assess for change in condition. Provides comparison with future temperature measurements.
5. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Provide privacy; draw curtain around bed and/or close room door. Prepare bedside environment for patient safety.	Maintains patient comfort and removes barriers that may interfere with procedure.
2. Collect and bring appropriate supplies to the patient's bedside.	Ensures an organized approach for body temperature measurement.
3. If measuring oral temperature, verify that patient has not had anything to eat or drink and has not chewed gum or smoked within the past 20 minutes.	Oral food and fluids, smoking, and gum can alter oral temperature measurement.
4. Explain to patient the way you will measure temperature and the importance of maintaining proper position until reading is complete.	Promotes patient cooperation.
Implementation	
1. Perform hand hygiene.	Reduces transmission of infection.
2. Help patient to a comfortable position that provides easy access to temperature measurement site. <ul style="list-style-type: none"> a. Sitting or lying supine (oral, tympanic, temporal, axillary) b. Side lying with upper leg flexed (rectal) 	Ensures patient's comfort and accuracy of temperature reading.

Table Continued

Step	Rationale
3. Obtain temperature reading.	
a. Oral temperature (electronic):	
(1) <i>Optional</i> : Apply clean gloves when there is risk for exposure to respiratory secretions or facial or mouth wound drainage.	An oral probe cover is removable without physical contact; thus does not require gloves.
(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on ejection button.	Charging provides battery power. Ejection button releases plastic cover from probe stem.
(3) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place (see illustrations).	Soft plastic cover will not break in patient's mouth and prevents transmission of infection between patients.
(4) Ask patient to open mouth; gently place thermometer probe under tongue in posterior sublingual pocket lateral to center of lower jaw (see illustration).	Heat from superficial blood vessels in sublingual pocket results in temperature reading. With electronic thermometer, temperatures in right and left posterior sublingual pocket are significantly higher than in area under front of tongue.
(5) Ask patient to hold thermometer probe with lips closed.	Maintains proper position of thermometer during recording.
(6) Leave thermometer probe in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from under patient's tongue.	Probe must stay in place until signal occurs to ensure accurate reading.
(7) Push ejection button on thermometer probe stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of infection.

STEP 3A(3) Disposable plastic cover is placed over probe.
Copyright © Mosby's Clinical Skills: Essentials Collection.

Step	
	

STEP 3A(4) Probe placed under tongue in posterior sublingual pocket.

Table Continued

Step	Rationale
(8) If wearing gloves, remove, dispose in appropriate receptacle, and perform hand hygiene.	Reduces transmission of infection.
(9) Return thermometer probe stem to storage position of thermometer unit.	Protects probe stem from damage. Returning thermometer probe stem automatically causes digital reading to disappear.
b. Rectal temperature (electronic):	
(1) Move aside bed linen to only expose anal area. Keep patient's upper body and lower extremities covered with sheet or blanket.	Maintains patient's privacy, minimizes embarrassment, and promotes comfort.
(2) Apply clean gloves. Cleanse anal region when feces and/or secretions are present. Remove soiled gloves, perform hand hygiene, and reapply clean gloves.	Maintains Standard Precautions when exposed to items soiled with body fluids (e.g., feces).
(3) Remove thermometer pack from charging unit. Attach rectal thermometer probe stem (red tip) to thermometer unit. Grasp top of probe stem, being careful not to apply pressure on ejection button.	Ejection button releases plastic cover from probe stem.
(4) Slide disposable plastic probe cover over thermometer probe stem until cover locks in place.	Soft plastic probe cover prevents transmission of infection between patients.
(5) Using a single-use package, squeeze a liberal amount of lubricant on tissue. Dip probe cover of thermometer, blunt end, into lubricant, covering 2.5 to 3.5 cm (1 to 1½ inches) for adult.	Lubrication minimizes trauma to rectal mucosa during insertion. Using a tissue allows adequate lubrication of probe.
(6) With nondominant hand separate patient's buttocks to expose anus. Ask patient to breathe slowly and relax.	Fully exposes anus for thermometer insertion. Relaxes anal sphincter for easier thermometer insertion.
(7) Gently insert thermometer into anus in direction of umbilicus 3.5 cm (1½ inches) for adult. Do not force thermometer.	Ensures adequate exposure against blood vessels in rectal wall.
(8) If you feel resistance during insertion, withdraw immediately. Never force thermometer.	Prevents trauma to mucosa.
CLINICAL DECISION: <i>If you cannot adequately insert thermometer into rectum or resistance is felt during insertion, remove thermometer and consider alternative method for obtaining temperature.</i>	
(9) Once positioned, hold thermometer probe in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from anus (see illustration).	Probe must stay in place until signal occurs to ensure accurate reading.
(10) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle. Wipe probe stem with alcohol swab, paying particular attention to ridges where probe stem connects to probe.	Reduces transmission of infection.
(11) Return thermometer stem to storage position of recording unit.	Protects probe stem from damage. Returning thermometer stem automatically causes digital reading to disappear.
(12) Wipe patient's anal area with soft tissue to remove lubricant or feces and discard tissue. Perform perineal hygiene as needed.	Provides for comfort and hygiene.
(13) Remove and dispose of gloves in appropriate receptacle. Perform hand hygiene.	Reduces transmission of infection.

Step	Rationale
	

STEP 3B(9) Probe inserted into anus.

Step	Rationale
c. Axillary temperature (electronic):	
(1) Move clothing or gown away from shoulder and arm.	Exposes axilla for correct thermometer probe placement.
(2) Remove thermometer pack from charging unit. Attach oral thermometer probe stem (blue tip) to thermometer unit. Grasp top of thermometer probe stem, being careful not to apply pressure on ejection button.	Charging provides battery power. Ejection button releases plastic cover from probe stem.
(3) Slide disposable plastic probe cover over thermometer stem until cover locks in place.	Soft plastic probe cover prevents transmission of infection between patients.
(4) Raise patient's arm away from torso. Inspect for skin lesions and excessive perspiration; if needed, dry axilla or select alternative site. Place thermometer probe into center of axilla (see illustration), lower arm over probe, and place arm across patient's chest.	Maintains proper position of thermometer against blood vessels in axilla.
CLINICAL DECISION: Do not use axilla if skin lesions are present because local temperature can be altered, and area may be painful to touch.	
(5) Once thermometer probe is positioned, hold it in place until audible signal indicates completion and patient's temperature appears on digital display; remove thermometer probe from axilla.	Thermometer probe must stay in place until signal occurs to ensure accurate reading.
(6) Push ejection button on thermometer stem to discard plastic probe cover into appropriate receptacle.	Reduces transmission of microorganisms.
(7) Return thermometer stem to storage position of recording unit.	Returning thermometer stem to storage position automatically causes digital reading to disappear. Protects stem from damage.
(8) Replace linen or gown.	Restores comfort and sense of well-being.
(9) Perform hand hygiene.	Reduces transmission of infection.
d. Tympanic membrane temperature:	
(1) Instruct patient to turn head toward side, away from you. If patient has been lying on one side, use upper ear. Note if there is an obvious presence of cerumen (earwax) in patient's ear canal.	Ensures comfort and facilitates exposure of auditory canal for accurate temperature measurement. Heat trapped in ear facing down causes false-high temperature reading. Cerumen impedes lens cover of speculum. Switch to other ear or select alternative measurement site.
(2) Obtain temperature from patient's right ear if you are right-handed. Obtain temperature from patient's left ear if you are left-handed.	The less acute the angle of approach, the better the probe seal.

STEP 3C(4) Insert thermometer probe into center of axilla.

Table Continued

Step	Rationale
(3) Remove thermometer handheld unit from charging base, being careful not to apply pressure to ejection button.	Charging base provides battery power. Removal of handheld unit from base prepares it to measure temperature. Ejection button releases plastic probe cover from thermometer tip.
(4) Slide disposable speculum cover over otoscope-like lens tip until it locks in place. Be careful not to touch lens cover.	Soft plastic probe cover prevents transmission of infection between patients. Lens cover should not have dust, fingerprints, or cerumen obstructing optical pathway.
(5) Insert speculum into ear canal following manufacturer instructions for tympanic probe positioning (see illustration):	Correct positioning of probe with respect to ear canal allows maximal exposure of tympanic membrane.
(a) Pull ear pinna backward, up, and out for an adult. For children less than 3 years of age, pull pinna down and back; point covered probe toward midpoint between eyebrow and sideburns. For children older than 3 years, pull pinna up and back (Hockenberry et al., 2019).	Ear tug straightens external auditory canal, allowing maximum exposure of tympanic membrane and therefore correctly positioning speculum (Hockenberry et al., 2019).
(b) Fit speculum tip snug in canal, pointing toward nose.	Gentle pressure seals ear canal from ambient air temperature, which alters readings as much as 2.8° C (5° F).
<i>Optional: Move thermometer in figure-eight pattern.</i>	Some manufacturers recommend movement of speculum tip in figure-eight pattern that allows sensor to detect maximum tympanic membrane heat radiation.
(6) Once positioned, press scan button on handheld unit. Leave speculum in place until audible signal indicates completion and patient's temperature appears on digital display.	Pressing scan button causes detection of infrared energy. Speculum probe tip must stay in place until device has detected infrared energy noted by audible signal.
(7) Carefully remove speculum from auditory meatus. Note temperature. Push ejection button on handheld unit to discard speculum cover into appropriate receptacle.	Reduces transmission of infection. Automatically causes digital reading to disappear.
(8) If temperature is abnormal or second reading is necessary, replace probe cover and wait 2 minutes before repeating in same ear or repeat measurement in other ear. Consider an alternative temperature site or instrument.	Lens cover must be free of cerumen to maintain optical path. Time allows ear canal to regain usual temperature.
(9) Return handheld unit to thermometer base.	Protects sensor tip from damage.
(10) Perform hand hygiene and assist patient to a comfortable position.	Reduces transmission of infection.
e. Temporal artery temperature:	
(1) Ensure that forehead is dry; dry with towel if needed.	Moisture interferes with thermometer sensor.
(2) Place sensor firmly on patient's forehead.	Firm contact avoids measurement of ambient temperature.
(3) Press red scan button with your thumb. Slowly slide thermometer straight across forehead while keeping sensor flat and firmly on skin (see illustration). Keeping scan button depressed, lift sensor after sweeping forehead and touch sensor on neck just behind earlobe. Read temperature when clicking sound during scanning stops. Release scan button.	Thermometer continuously scans for highest temperature when scan button is depressed. Area behind earlobe is less affected by diaphoresis and verifies temperature.
(4) Gently clean sensor with alcohol swab, return to storage unit, and perform hand hygiene.	Prevents transmission of infection.
(5) Return thermometer to charger.	Maintains battery charge of thermometer unit.
4. Assist patient to comfortable position.	Ensures comfort and well-being.
5. Inform patient of temperature reading and record per agency policy.	Promotes participation in care and understanding of health status
6. Place nurse call system within reach; instruct patient in use.	Promotes safety and prevents falls.
7. Raise side rails (as appropriate) and place bed in lowest position.	Promotes safety and prevents falls.

Step	Rationale
	

STEP 3D(5) Tympanic thermometer with probe cover inserted into auditory canal.

Scanning the forehead with a temporal artery thermometer.

Table Continued

Step	Rationale
Evaluation	
1. If you are assessing temperature for the first time, establish it as baseline if it is within acceptable range.	Used to compare future temperature measurements.
2. Compare temperature reading with patient's previous baseline and acceptable temperature range for patient's age-group.	Body temperature fluctuates within narrow range; comparison reveals presence of abnormality. Improper placement or movement of thermometer can cause inaccuracies. Second measurement confirms initial findings of abnormal body temperature.
3. If patient has fever, take temperature approximately 30 minutes after administering antipyretics and every 4 hours until temperature stabilizes.	Determines whether temperature begins to fall in response to therapy.
4. Use Teach-Back. "I want to be sure I explained how to check your child's temperature at home. Show me how to swipe his forehead using the temporal thermometer." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is unable to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient has temperature 1° C (1.8° F) or more above usual range. Initiate measures to lower body temperature:</p> <ul style="list-style-type: none"> • Cool room environment. • Reduce external covering on patient's body to promote heat loss, but do not induce shivering. • Keep clothing and bed linen dry. • Apply hypothermia blanket as ordered. • Limit physical activity and sources of emotional stress. • Administer antipyretics as ordered. • Increase fluid intake to at least 3 L daily (unless contraindicated). 	
<p>2. Patient has temperature 1° C (1.8° F) or more below usual range. Initiate measures to raise body temperature:</p> <ul style="list-style-type: none"> • Apply warm blankets and, unless contraindicated, offer warm liquids. • Apply hyperthermia blankets if ordered. • Remove wet clothing or linen. 	
<p>3. Unable to obtain temperature.</p> <ul style="list-style-type: none"> • Reassess correct placement of temperature probe or sensor. • Choose alternative temperature measurement site. • Obtain alternative temperature measurement device. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record temperature and route and any signs or symptoms of temperature alteration in the EHR. • Record temperature after administration of specific therapies, such as blood or blood product transfusions. • Document your evaluation of patient learning. • Report type of temperature, abnormal findings and any measures used to reduce or increase temperature to health care provider. 	
Home Care Considerations	
<ul style="list-style-type: none"> • Assess temperature and ventilation of patient's environment to determine existence of any environmental condition that influences patient's temperature. 	

Skill 29.2. Assessing Apical and Radial Pulse Delegation and Collaboration

The skill of apical pulse measurement cannot be delegated to assistive personnel (AP). This measurement is often taken when you suspect an irregularity in the radial pulse or when a patient's condition requires more accurate pulse assessment.

The skill of radial pulse measurement can be delegated to assistive personnel (AP) if a patient's condition is stable. The skill cannot be delegated when a patient's condition is unstable because the patient is at high risk for acute or serious cardiac problems or when the nurse is evaluating a patient's response to a treatment or medication. The nurse instructs the AP by:

- Indicating the appropriate site for measuring pulse rate; frequency of measurement; and factors related to the patient history such as risk for abnormally slow, rapid, or irregular pulse.
- Reviewing patient's usual pulse rate and specific changes or abnormalities to report to the nurse.

Equipment

- Stethoscope
- Wristwatch with second hand or digital seconds display
- Pen and vital sign flow sheet in chart or electronic health record (EHR)
- Alcohol swab

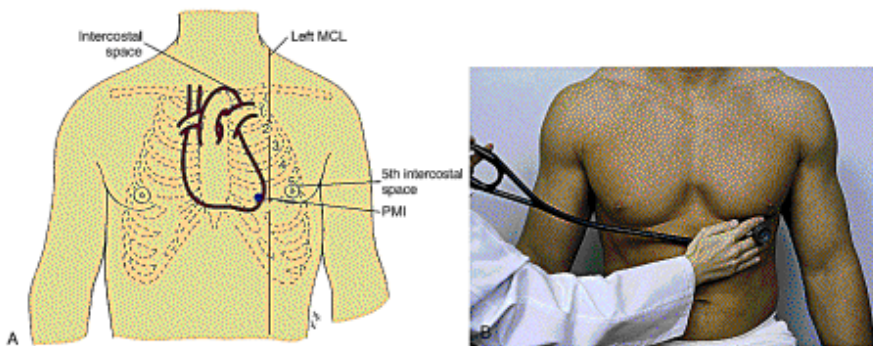

Step	Rationale
Assessment	
Apical pulse or radial pulse:	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Obtain data from patient's EHR to determine need to assess pulse:	
a. Assess for history of the following: heart or peripheral vascular disease, onset of sudden chest pain or acute pain from any site, invasive cardiovascular diagnostic tests, surgery, sudden infusion of large volume of intravenous (IV) fluid, internal or external hemorrhage, administration of medications that alter heart function.	Certain conditions are risk factors for pulse alterations. A history of peripheral vascular disease often alters pulse rate and quality.
b. Perform hand hygiene. Assess for signs and symptoms of altered cardiac function such as dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of dependent body parts.	Reduces transmission of infection. Physical signs and symptoms indicate alteration in conduction of cardiac electrical impulses, cardiac output, or stroke volume, all of which can affect radial pulse and rhythm.
c. Assess for factors that normally influence pulse rate and rhythm:	Allows you to anticipate factors that alter pulse, ensuring an accurate interpretation.
• Age	Newborn's heart rate (HR) ranges from 120-140 beats/min at rest; by age 2 pulse rate slows to 70 to 120 beats/min; by adolescence rate varies between 60 and 90 beats/min and remains so throughout adulthood (Hockenberry et al., 2019).
• Exercise	Physical activity increases HR; a well-conditioned patient may have a slower-than-usual resting HR that returns more quickly to resting rate after exercise.
• Position changes	HR increases temporarily when changing from lying to sitting or standing position.
• Medications	Antidysrhythmics, sympathemimetics, and cardiotonics affect rate and rhythm of pulse; large doses of opioid analgesics can slow HR; general anesthetics slow HR; central nervous system stimulants such as caffeine can increase HR.
• Temperature	Fever or exposure to warm environments increases HR; HR declines with hypothermia.
• Sympathetic stimulation	Emotional stress, anxiety, or fear stimulates sympathetic nervous system, which increases HR.
d. Determine previous baseline pulse rate (if available).	Allows you to assess for change in condition.
3. If obtaining apical pulse, determine any report of latex allergy. If patient has latex allergy, ensure that stethoscope is latex free.	Reduces risk of allergic reaction to stethoscope.
4. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Provide privacy for patient; if necessary, draw curtain around bed and/or close door.	Maintains privacy and minimizes embarrassment, helping patient relax.
2. Collect appropriate equipment and bring to patient's bedside.	Ensures an organized approach for assessing pulse.
3. Explain to patient that you will assess radial pulse rate or apical pulse rate. Encourage patient to relax as much as possible. If patient has been active, wait 5 to 10 minutes before assessing pulse rate. If patient has been smoking or ingesting caffeine, wait 15 minutes before assessing pulse rate.	Anxiety, activity, smoking and caffeine elevate heart rate.
Implementation	
1. Apical pulse	
a. Perform hand hygiene.	Reduces transmission of infection.
b. Have patient assume a sitting or supine position. Locate anatomical landmarks to identify point of maximal impulse (PMI), also called apical impulse (see Chapter 30). The heart is located behind and to left of sternum with base at top and apex at bottom. Find angle of Louis just below suprasternal notch between sternal body and manubrium; it feels like a bony prominence (see illustration A). Slip fingers down each side of angle to find second intercostal space (ICS) (see illustration B). Carefully move fingers down left side of sternum to fifth ICS and laterally to left midclavicular line (MCL) (see illustration C). A light tap felt within area 1 to 2.5 cm (½ to 1 inch) of PMI is reflected from apex of heart (see illustration D).	Provides easy access to pulse sites. Use of anatomical landmarks allows correct placement of stethoscope over apex of heart. This position enhances ability to hear heart sounds clearly. If unable to palpate PMI, reposition patient on left side. In presence of serious heart disease, you may locate PMI to left of MCL or at sixth ICS. PMI may not be palpated in obese adults or patients with severe pulmonary disease that has changed shape of thorax.
c. Place diaphragm of stethoscope in palm of hand for 5 to 10 seconds.	Warming of metal or plastic diaphragm prevents patient from being startled and promotes comfort.
Step	
d. Place diaphragm of stethoscope over PMI at fifth ICS, at left MCL, and auscultate for normal S ₁ and S ₂ heart sounds (heard as "lub-dub") (see illustrations).	Allow stethoscope tubing to extend straight without kinks that would distort sound transmission. Normal sounds S ₁ and S ₂ are high pitched and best heard with diaphragm.

Table Continued

Step	Rationale
e. When you hear S ₁ and S ₂ with regularity, use second hand of watch and begin to count rate; when sweep hand hits number on dial, start counting with zero, then one, two, and so on.	Apical rate is determined accurately only after you are able to auscultate sounds clearly. Timing begins with zero. Count of one is first sound auscultated after timing begins.
f. If apical rate is regular, count for 30 seconds and multiply by 2.	You can assess regular apical rate within 30 seconds.

STEP 9 A, Nurse locates sternal notch. B, Nurse locates second intercostal space. C, Nurse locates fifth intercostal space. D, Nurse locates point of maximal impulse at fifth intercostal space at left midclavicular line.

STEP 10 A, Location of point of maximal impulse (PMI) in adult. B, listening to PMI in adult.

Table Continued

Step	Rationale
g. If HR is irregular or patient is receiving cardiovascular medication, count for a full 60 seconds.	Irregular rate is more accurately assessed when measured over longer interval.
h. Note regularity of any dysrhythmia (S ₁ and S ₂ occurring early or late after previous sequence of sounds) (e.g., every third or every fourth beat is skipped).	Regular occurrence of dysrhythmia within 1 minute indicates inefficient contraction of heart and potential alteration in cardiac output.
CLINICAL DECISION: <i>If apical rate is abnormal or irregular, repeat measurement or have another nurse conduct measurement. Original measurement may be incorrect. Second measurement confirms initial findings of an abnormal HR.</i>	
i. Replace patient's gown and bed linen.	Restores comfort and promotes sense of well-being.
2. Radial pulse	
a. Perform hand hygiene.	Reduces transmission of infection.
b. Help patient to assume a supine or sitting position.	Provides easy access to pulse sites.
c. If patient is supine, place his or her forearm straight alongside or across lower chest or upper abdomen (see illustration A). If sitting, bend patient's elbow 90 degrees and support lower arm on chair or on your arm. Place tips of first two or middle three fingers of hand over groove along radial or thumb side of patient's inner wrist (see illustration B). Slightly extend or flex wrist with palm down until you note strongest pulse.	Fingertips are most sensitive parts of hand to palpate arterial pulsation. Your thumb has pulsation that interferes with accuracy.
d. Lightly compress pulse against radius, losing pulse initially; relax pressure so that pulse becomes easily palpable.	Pulse assessment is more accurate when using moderate pressure. Too much pressure occludes pulse and impairs blood flow.
e. Determine strength of pulse. Note whether thrust of vessel against fingertips is bounding (4+); full, strong (3+); expected (2+); barely palpable, diminished (1+); or absent, not palpable (0).	Strength reflects volume of blood ejected against arterial wall with each heart contraction. Accurate description of strength improves communication among nurses and other health care providers.
f. After palpating a regular pulse, look at watch second hand and begin to count rate. Count the first beat after the second hand hits the number on the dial; count as one, then two, and so on.	Rate is determined accurately only after pulse has been palpated. Timing begins with zero. Count of one is first beat palpated after timing begins.
(1) If pulse is regular, count rate for 30 seconds and multiply total by 2.	A 30-second count is accurate for rapid, slow, or regular pulse rates.
(2) If pulse is irregular, count rate for a full 60 seconds. Assess frequency and pattern of irregularity.	Inefficient contraction of heart fails to transmit pulse wave, resulting in irregular pulse. Longer time ensures accurate count.
(3) When pulse is irregular, compare radial pulses bilaterally and compare with apical pulse.	A marked difference between pulses indicates that arterial flow is compromised to one extremity; as a nurse you need to take action.
3. Assist patient to comfortable position.	Promotes comfort and sense of well-being.
4. Discuss findings with patient	Promotes participation in care and understanding of health status.
5. Place nurse call system within reach; instruct patient in use.	Promotes safety and prevents falls.
6. Raise side rails (as appropriate) and lower bed to lowest position.	Promotes safety and prevent falls.
7. Store reusable equipment. Perform hand hygiene.	Reduces transmission of infection.
Evaluation	
1. If assessing pulse for first time, establish apical or radial rate as baseline if it is within an acceptable range.	Used to compare future pulse assessments.
2. Compare apical or radial rate and character with patient's previous baseline and acceptable range of HR for patient's age.	Allows you to assess for change in patient's condition and for presence of cardiac alteration.

STEP 2C A, Pulse check with patient's forearm at side with wrist extended. B, Hand placement for pulse check.

Table Continued

Step	Rationale
3. Use Teach-Back: "I want to be sure I explained why it is important to check your heart rate at home. Tell me which medication you are taking that would decrease your heart rate." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS	
1. Adult patient's apical or radial pulse is greater than 100 beats/min (tachycardia). <ul style="list-style-type: none"> Identify related data, including fever, pain, fear or anxiety, recent exercise, low blood pressure, blood loss, or inadequate oxygenation. Observe for signs and symptoms associated with abnormal cardiac function, including dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of body parts. 	
2. Patient's apical or radial pulse is less than 60 beats/min (bradycardia). <ul style="list-style-type: none"> Assess for factors that decrease HR such as beta blockers and antiarrhythmic drugs. Observe for signs and symptoms associated with abnormal cardiac function, including dyspnea, fatigue, chest pain, orthopnea, syncope, palpitations, edema of body parts, or dizziness. Have another nurse assess apical pulse. Report findings to nurse in charge and/or health care provider. It may be necessary to withhold prescribed medications that alter HR until health care provider can evaluate need to adjust dosage. 	
3. Patient's apical pulse is irregular. <ul style="list-style-type: none"> Assess for signs and symptoms of decreased cardiac output. Report findings to nurse in charge and/or health care provider, who may order an electrocardiogram to detect cardiac conduction alteration. 	
4. Patient's radial pulse is irregular. <p>Assess for Pulse Deficit.</p> <ul style="list-style-type: none"> One nurse auscultates apical pulse while a second provider palpates radial pulse; one nurse begins 60-second pulse count by calling out loud when both should begin to count pulses. The two pulse rates are compared. If pulse count differs by more than 2, a deficit exists. Assess for other signs and symptoms of decreased cardiac output (see Chapter 30). 	
RECORDING AND REPORTING	
<ul style="list-style-type: none"> Record pulse rate and character routinely and after administration of specific therapies in the EHR. Record any signs and symptoms of alteration in cardiac function. Document your evaluation of patient learning. Report bradycardia, tachycardia, or irregular pulse to nurse in charge or health care provider immediately. 	
HOME CARE CONSIDERATIONS	
<ul style="list-style-type: none"> Assess home environment to determine room that affords quiet environment for auscultating apical rate. 	

Skill 29.3. Assessing Respirations

Delegation and Collaboration

The skill of counting respirations can be delegated to assistive personnel (AP) unless the patient is considered unstable (i.e., complaints of dyspnea). The nurse instructs the AP by:

- Communicating the frequency of measurement and factors related to patient history or risk for increased or decreased respiratory rate or irregular respirations.
- Reviewing any unusual respiratory values and significant changes to report to the nurse.

Equipment

- Wristwatch with second hand or digital seconds display
- Pen and vital sign flow sheet in chart or electronic health record (EHR)

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Obtain data from patient's electronic health record (EHR) to assess for factors that influence character of patient's respirations:	Allows you to anticipate factors that influence respirations, ensuring a more accurate interpretation.
Table Continued	

Step	Rationale
• Fever	Elevated body temperature increases oxygen demand and increases respiration rate and depth.
• Exercise	Respirations increase in rate and depth to meet need for additional oxygen and rid body of carbon dioxide.
• Anxiety	Increases oxygen demand, respiratory rate and depth because of sympathetic nervous system stimulation.
• Diseases/trauma of chest wall or muscles	Certain conditions (e.g., fractured ribs, thoracic surgery, asthma, chronic lung disease) affect inspiration and/or expiration.
• Constrictive chest or abdominal dressings	Dressings can restrict ease with which a patient is able to breathe deeply.
• Acute pain	Pain increases oxygen demand and alters rate and rhythm of respirations; breathing becomes shallow. Patient inhibits or splints chest wall movement when pain is in area of chest or abdomen.
• Smoking	Chronic smoking changes pulmonary airways, resulting in increased respiratory rate at rest when not smoking.
• Medications	Opioid analgesics, general anesthetics, and sedative hypnotics depress rate and depth; amphetamines and cocaine increase rate and depth; bronchodilators cause dilation of airways, which ultimately slows respiratory rate.
• Body position	Standing or sitting erect promotes full ventilatory movement and lung expansion; stooped or slumped posture impairs ventilatory movement; lying flat prevents full chest expansion.
• Neurological injury	Damage to brainstem impairs respiratory center and inhibits rate and rhythm.
• Anemia, decreased hemoglobin	Decreased hemoglobin levels lower amount of oxygen carried in blood, which results in increased respiratory rate to increase oxygen delivery.
• Increased altitude	An increase in altitude lowers the amount of saturated hemoglobin, which increases respiratory rate and depth.
3. Perform hand hygiene. Assess for signs and symptoms of respiratory alterations such as: • Bluish or cyanotic appearance of nail beds, lips, mucous membranes, and skin • Restlessness, irritability, confusion, reduced level of consciousness • Pain during inspiration • Labored or difficult breathing • Orthopnea • Use of accessory muscles • Adventitious breath sounds (see Chapter 30) • Inability to breathe spontaneously • Thick, frothy, blood-tinged, or copious sputum production	Reduces transmission of infection. Physical signs and symptoms indicate alterations in respiratory status (see Chapter 30).
4. Review EHR and assess pertinent laboratory/clinical values:	
a. Arterial blood gases (ABGs): Normal ranges (values vary slightly among agencies) (Pagana et al., 2019): • pH, 7.35–7.45 • PaCO ₂ , 35–45 mm Hg • HCO ₃ ⁻ , 21–28 mEq/L • PaO ₂ , 80–100 mm Hg • SaO ₂ , 95%–100%	ABG values measure arterial blood pH, partial pressure of oxygen and carbon dioxide, and arterial oxygen saturation, which reflect patient's ventilation and oxygenation status (see Chapter 41).
b. Pulse oximetry (SpO ₂): Normal SpO ₂ ≥ 95%–100%; less than 90% is a clinical emergency (see Skill 29.4).	SpO ₂ less than 90% is often accompanied by changes in respiratory rate, depth, and rhythm.
c. Complete blood count (CBC): Normal ranges for adults (values vary among agencies)(Pagana et al., 2019): • Hemoglobin: 14–18 g/100 mL, males; 12–16 g/100 mL, females • Hematocrit: 42%–52%, males; 37%–47%, females • Red blood cell count: 4.7–6.1 million/mm ³ , males; 4.2–5.4 million/mm ³ , females	CBC measures red blood cell count; volume of red blood cells; and concentration of hemoglobin, which reflects patient's capacity to carry oxygen.
5. Determine previous baseline respiratory rate (if available in the EHR).	Assesses for change in condition. Provides comparison with future respiratory measurements.

Table Continued

Step	Rationale
6. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Provide privacy; close curtains or room door.	Promotes relaxation and provides privacy.
2. If patient has been active, wait 5 to 10 minutes before assessing respirations.	Exercise increases respiratory rate and depth. Assessing respirations while patient is at rest allows for objective comparison of values.
3. In an adult, assess respirations after pulse rate; in children assess respirations first.	Inconspicuous assessment after pulse assessment prevents patients from consciously or unintentionally altering rate and depth of breathing. Assess respirations before invasive procedures in children, which may cause anxiety.
4. Position patient in a comfortable position, preferably sitting or lying with the head of the bed elevated 45 to 60 degrees.	Sitting erect promotes full ventilator movement. A position of discomfort causes patient to breath more rapidly.
<i>CLINICAL DECISION: Assess patients with difficulty breathing, dyspnea, heart failure, or abdominal ascites and patients in the late stages of pregnancy in the position of greatest comfort. Repositioning may increase the work of breathing, which increases respiratory rate.</i>	
Implementation	
1. Perform hand hygiene.	Prevents transmission of infection.
2. Be sure that patient's chest is visible. If necessary, move bed linen or gown.	Ensures clear view of chest wall and abdominal movements.
3. Place patient's arm in relaxed position across abdomen or lower chest or place your hand directly over patient's upper abdomen.	A similar position used during pulse assessment allows respiratory rate assessment to be inconspicuous. Patient awareness of monitoring reduces respiratory rate by 2 breaths per minute (Hill et al., 2018). The patient's or your hand rises and falls during respiratory cycle.
4. Observe complete respiratory cycle (one inspiration and one expiration).	Rate is accurately determined only after viewing a complete respiratory cycle.
5. After observing a cycle, look at second hand of watch and begin to count rate: when sweep hand hits number on dial, begin time frame, counting one with first full respiratory cycle.	Timing begins with count of one. Respirations occur more slowly than pulse; thus timing does not begin with zero.
6. If rhythm is regular, count number of respirations in 30 seconds and multiply by 2. If rhythm is irregular, less than 12, or greater than 20, count for 1 full minute (Box 29.12).	Respiratory rate is equivalent to number of respirations per minute. Suspected irregularities require assessment for at least 1 minute (Table 29.7).
Table Continued	

Step	Rationale
7. Note depth of respirations by observing degree of chest wall movement while counting rate. In addition, assess depth by palpating chest wall excursion or auscultating posterior thorax after you have counted rate (see Chapter 30). Describe depth as shallow, normal, or deep.	Character of ventilatory movement reveals specific disease states restricting volume of air from moving into and out of lungs.
8. Note rhythm of ventilatory cycle. Normal breathing is regular and uninterrupted. Do not confuse sighing with abnormal rhythm.	Character of ventilations reveals specific types of alterations. Periodically people unconsciously take single deep breaths or sighs to expand small airways prone to collapse.
CLINICAL DECISION: Any irregular respiratory pattern or periods of apnea (cessation of respiration over 5 seconds) are symptoms of underlying disease in an adult; report this to the health care provider or nurse in charge. Further assessment and immediate intervention are often necessary.	
9. Replace bed linen and patient's gown.	Restores comfort and promotes sense of well-being.
10. Assist patient to comfortable position.	Promotes comfort and sense of well-being.
11. Place nurse call system within reach and instruct patient in use.	Promotes safety and prevents falls.
12. Raise side rails (as appropriate) and lower bed to lowest position.	Promotes safety and prevents falls.
13. Perform hand hygiene.	Reduces transmission of infection.
14. Discuss results with patient.	Promotes participation in care and understanding of health.
Evaluation	
1. If assessing respirations for the first time, establish rate, rhythm, and depth as baseline if within acceptable range.	Used to compare future respiratory assessments.
2. Compare respirations with patient's previous baseline and usual rate, rhythm, and depth.	Allows you to assess for changes in patient's condition and presence of respiratory alterations.
3. Correlate respiratory rate, depth, and rhythm with data obtained from pulse oximetry and ABG measurements if available.	Evaluation of ventilation, perfusion, and diffusion is interrelated.
4. Use Teach-Back: "I want to be sure I explained why you need to take deep breaths after your surgery. Tell me why deep breathing is important." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Adult patient's respiratory rate is below 12 breaths/min (bradypnea) or above 20 breaths/min (tachypnea). Breathing pattern is irregular (see Table 29.7). Depth of respirations is increased or decreased. Patient complains of dyspnea.</p> <ul style="list-style-type: none"> Assess for related factors, including obstructed airway, abnormal breath sounds, productive cough, restlessness, anxiety, and confusion (see Chapter 30). Help patient to supported sitting position (semi- or high-Fowler's) unless contraindicated. Provide oxygen as ordered (see Chapter 41). Assess for environmental factors that influence patient's respiratory rate such as secondhand smoke, poor ventilation, or gas fumes. Notify health care provider or nurse in charge if alteration continues. 	
<p>2. Patient demonstrates Kussmaul's, Cheyne-Stokes, or Biot's respirations (see Table 29.7).</p> <ul style="list-style-type: none"> Notify health care provider for additional evaluation and possible medical intervention. 	
Recording and Reporting	
<ul style="list-style-type: none"> Record respiratory rate and character, noting any abnormalities. Record respiratory rate after administration of specific therapies. Record type and amount of oxygen therapy if used by patient during assessment. Document your evaluation of patient learning. Report bradypnea, tachypnea, abnormal depth or rhythm to nurse in charge or health care provider immediately. 	
Home Care Considerations	
<ul style="list-style-type: none"> Assess for environmental factors in the home that influence respiratory rate such as secondhand smoke, poor ventilation, gas or fireplace fumes, dust, and pets. 	

Skill 29.4. Measuring Oxygen Saturation (Pulse Oximetry)

Delegation and Collaboration

The skill of SpO₂ measurement can be delegated to assistive personnel (AP). The nurse instructs the AP by:

- Communicating specific factors related to the patient that can falsely lower SpO₂.

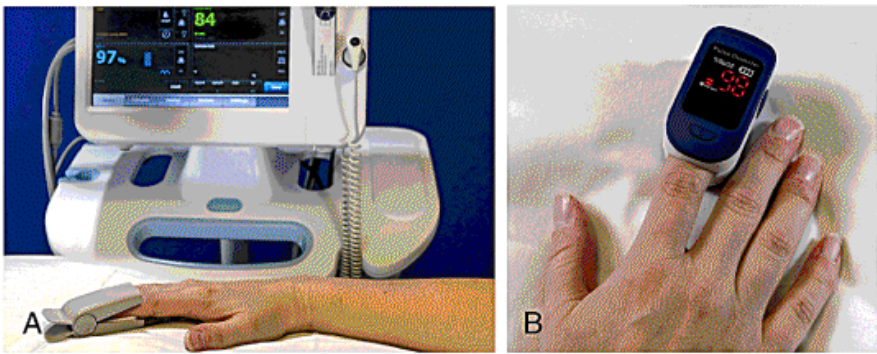

- Informing AP about appropriate sensor site and probe and about reporting any skin irritation from probe placement to nurse.
- Notifying about frequency of SpO₂ measurements for a specific patient.
- Informing AP to notify the nurse immediately of any reading lower than SpO₂ of 95% or value for specific patient.
- Instructing to refrain from using pulse oximetry to obtain heart rate because oximeter will not detect an irregular pulse.

Equipment

- Oximeter
- Oximeter probe appropriate for patient and recommended by oximeter manufacturer
- Acetone or nail-polish remover if needed
- Pen and vital sign flow sheet in chart or the EHR

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Determine previous baseline SpO ₂ (if available) from patient's medical record.	Provides basis for comparison and assists in the assessment of current status and evaluation of interventions.
3. Determine need to assess patient's oxygen saturation: a. Review the EHR to identify conditions that can cause decreased oxygen saturation, including acute or chronic compromised respiratory function, recovery from general anesthesia or conscious sedation, traumatic injury to chest wall, collapse of lung tissue, ventilator dependence, or a change in oxygen therapy.	Certain conditions place patients at risk for decreased oxygen saturation.
b. Perform hand hygiene. Assess for signs and symptoms of alteration in oxygen saturation such as altered respiratory rate, depth or rhythm; abnormal breath sounds (see Chapter 30); cyanotic appearance of nail beds, lips, mucous membranes; restlessness, irritability, confusion; reduced level of consciousness; and labored or difficult breathing.	Reduces transmission of infection. Physical signs and symptoms often indicate low oxygen saturation.
4. Assess for factors that influence measurement of SpO ₂ (e.g., oxygen therapy, respiratory therapy such as postural drainage and percussion, hemoglobin level, hypotension, temperature, nail polish, and medications such as bronchodilators).	Allows you to accurately assess oxygen saturation variations.
5. Determine if patient has a latex allergy.	Disposable adhesive sensors may contain latex.
6. Determine most appropriate patient-specific probe site (e.g., finger, toe, earlobe, forehead, nose) for sensor placement by evaluating capillary refill (see Chapter 30). If capillary refill is greater than 2 seconds, select alternative site.	Sensor requires pulsating vascular bed to identify light-absorbing hemoglobin molecules. Patients requiring vasopressors or who are critically ill may have increased peripheral capillary refill; forehead sensors are preferred. Moisture and black or brown nail polish alter readings. Motion artifact is the most common cause of inaccurate measurements. Clip-on probe may be too small for obese patient.
7. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Provide privacy and prepare bedside environment for patient safety.	Maintains patient comfort and removes barriers that may interfere with procedure.
2. Collect and bring appropriate supplies to the patient's bedside.	Ensures an organized approach for oxygen saturation measurement.
3. Explain to patient the way you will measure oxygen saturation and the importance of breathing normally until reading is complete.	Promotes patient cooperation and increases adherence. Prevents large fluctuations in minute ventilation and possible error in SpO ₂ readings
Implementation	
1. Perform hand hygiene.	Prevents transmission of infection.
2. Position patient in a comfortable position, preferably sitting or lying with the head of the bed elevated 45 to 60 degrees.	Sitting erect promotes full ventilation. A position of discomfort causes patient to breath more rapidly.
3. Attach sensor to monitoring site (see illustrations). If using finger, remove fingernail polish from digit with acetone or polish remover. Instruct patient that clip-on probe will feel like a clothes pin on the finger but will not hurt.	Nail polish falsely alters saturation.
CLINICAL DECISION: Do not attach probe to finger, ear, or bridge of nose if area is edematous or skin integrity is compromised. Do not use earlobe and bridge of nose sensors for infants and toddlers because of skin fragility. Do not attach sensor to fingers that are hypothermic. Select ear or bridge of nose if adult patient has a history of peripheral vascular disease. Do not use disposable adhesive sensors if patient has a latex allergy. Do not place sensor on same extremity as electronic blood pressure cuff because blood flow to finger will be interrupted temporarily when cuff inflates and cause inaccurate reading that can trigger alarms.	
4. Once sensor is in place, turn on oximeter by activating power. Observe pulse waveform/intensity display and audible beep. Correlate oximeter pulse rate with patient's radial pulse.	Pulse waveform and audible beep enables detection of valid pulse. Pitch of audible beep is proportional to SpO ₂ value. Correlating pulse rates ensures oximeter accuracy; difference requires reassessment of sensor placement site.
5. Leave sensor in place 10 to 30 seconds or until oximeter readout reaches constant value and pulse display reaches full strength during each cardiac cycle. Inform patient that oximeter alarm will sound if sensor falls off or patient moves it. Read SpO ₂ on digital display.	Sensor alarm may frighten patient or visitors.

Table Continued

Step	Rationale
6. For continuous SpO₂ monitoring: <ul style="list-style-type: none"> • Verify SpO₂ alarm limits preset by manufacturer at a low of 85% and a high of 100%. • Determine limits for SpO₂ and pulse rate as indicated by patient's condition. • Verify that alarms are on. • Assess skin integrity under sensor probe every 2 hours; relocate sensor at least every 4 hours and more frequently if skin integrity is altered or tissue perfusion compromised. 	Sensor tension and sensitivity to disposable sensor adhesive cause skin irritation and lead to disruption of skin integrity.
7. If you plan intermittent checking or spot-checking of SpO₂, remove probe and turn oximeter power off. Clean sensor and store sensor in appropriate location.	Prevents transmission of infection. Sensor probes are vulnerable to damage.
8. Assist patient to comfortable position.	Restores comfort and promotes a sense of well-being.
9. Place nurse call system within patient's reach and instruct patient in use.	Promotes safety and prevents falls.
10. Raise side rails (as appropriate) and lower bed to lowest position.	Promotes safety and prevents falls.
11. Perform hand hygiene.	Prevents transmission of infection.
12. Discuss results with patient.	Promotes participation in care and understanding of health.
Evaluation	
1. If assessing oxygen saturation for the first time, establish it as baseline if within acceptable range.	Used to compare future SpO ₂ measurements.
2. Compare SpO₂ reading with patient's previous baseline and acceptable values. Note use of oxygen therapy, which can affect SpO₂.	Allows you to assess for changes in patient's condition and presence of respiratory alterations.
3. Correlate SpO₂ with SaO₂ obtained from ABG measurements if available.	Documents reliability of noninvasive assessment.
4. Correlate reading with data obtained from respiratory rate, depth and rhythm assessment (see Skill 29.3).	Measurements assessing ventilation, perfusion, and diffusion are interrelated.
5. Use Teach Back: "I want to be sure I explained the reasons for a low oxygen saturation. Can you tell me two actions that could improve the oxygen level in your blood?" Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is unable to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS	
1. SpO₂ is less than 90%. <ul style="list-style-type: none"> • Verify that oximeter sensor is intact and properly applied. • Observe for signs and symptoms of decreased oxygenation such as anxiety, restlessness, tachycardia. • Verify that supplemental oxygen is delivered as ordered and that system is functioning properly. • Assist patient to a position that maximizes ventilator effort (e.g., position an obese patient in a high-Fowler position). • Report SpO₂ to nurse in charge or health care provider to initiate appropriate evaluation and treatment. 	
 <p>STEP 3 A, Pulse oximetry machine. B, Clip-on pulse oximetry sensor.</p>	
Table Continued	

Step	Rationale
2. Sensor device results in pressure injury. <ul style="list-style-type: none"> • Rotate oximetry probe sites more frequently. • Change type or location of sensor device. • Increase frequency of skin assessment under sensor. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record type and amount of oxygen therapy used by patient during assessment, SpO₂ readings, and any signs or symptoms of alterations in oxygenation in EHR. • Document your evaluation of patient learning. • Report alterations in SpO₂ to health care provider. 	

Skill 29.5. Measuring Blood Pressure by Auscultation Delegation and Collaboration

The skill of BP measurement can be delegated to assistive personnel (AP) unless the patient is considered unstable (i.e., hypotensive). The nurse instructs the AP by:

- Explaining the appropriate limb for measurement, BP cuff size, and equipment (manual or electronic) to be used.
- Communicating the frequency of measurement and factors related to the patient's history such as risk for orthostatic hypotension.
- Reviewing the patient's usual BP values and significant changes or abnormalities to report to the nurse.

Equipment

- Aneroid sphygmomanometer
- Cloth or disposable vinyl pressure cuff of appropriate size for patient's extremity (see Planning Step 2)
- Stethoscope
- Alcohol swab
- Pen and vital sign flow sheet in chart or electronic health record (EHR)

Step	Rationale
Assessment	
1. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
2. Obtain data from the patient's electronic record (EHR) to: a. Assess for presence of • History of cardiovascular disease • Renal disease • Diabetes mellitus • Circulatory shock (hypovolemic, septic, cardiogenic, or neurogenic) • Acute or chronic pain • Rapid intravenous (IV) infusion of fluids or blood products • Increased intracranial pressure • Postoperative status • Toxemia of pregnancy	Certain conditions place patients at risk for BP alteration.
b. Assess for factors that influence BP:	Allows you to anticipate factors that influence BP, ensuring a more accurate interpretation.
• Age	Acceptable values for BP vary throughout life. Older patients experience greater "white coat" effect as BP increases when in the presence of a provider (Kallioinen et al., 2017).
• Gender	During and after menopause women often have higher BPs than men of same age.
• Daily (diurnal) variation	BP varies throughout day; pressure is highest during the day between 10:00 AM and 6:00 PM and lowest in early morning.
• Position	BP falls as person moves from lying to sitting or standing position; acceptable postural variations are less than 10 mm Hg (Hale et al., 2017).
• Exercise	Increases in oxygen demand by body during activity increases BP. BP can be increased if patient does not rest at least 15 minutes before measurement (Kallioinen et al., 2017).
• Weight	Obesity is an independent predictor of hypertension.
• Sympathetic stimulation	Pain, anxiety, or fear stimulates sympathetic nervous system, causing BP to rise. A full bladder increases systolic and diastolic BP (Kallioinen et al., 2017).
• Medications	Antihypertensives, diuretics, beta-adrenergic blockers, vasodilators, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), and antidysrhythmics lower BP; opioids and general anesthetics also cause a drop in BP (Soyal et al., 2016).

Table Continued

Step	Rationale
• Smoking	Smoking results in vasoconstriction, a narrowing of blood vessels. SBP and DBP rises acutely and returns to baseline approximately 20-30 minutes after stopping smoking, 30 minutes after snuff chewing, and 40-60 minutes after a nicotine tablet (Kallioinen et al., 2017).
• Ethnicity	Incidence of hypertension is higher in African-Americans and Hispanics than in European Americans. African-Americans tend to develop more severe hypertension at an earlier age and have twice the risk for the complications of hypertension (i.e., stroke and heart attack). Hypertension-related deaths are also higher among African-Americans (Moughrabi, 2017).
• Temperature	Cold exposure increases systolic BP (Kallioinen et al., 2017).
3. Perform hand hygiene. Assess for signs and symptoms of BP alterations (especially patients at high risk for hypertension): headache (usually occipital), flushing of face, nosebleed, and fatigue in older adults. Hypotension is associated with dizziness; mental confusion; restlessness; pale, dusky, or cyanotic skin and mucous membranes; and cool, mottled skin over extremities.	Reduces transmission of infection. Physical signs and symptoms indicate alterations in BP. Hypertension is often asymptomatic until pressure is very high.
4. Determine best site for BP assessment. Avoid applying cuff to extremity when IV fluids are infusing, an arteriovenous shunt or fistula is present, or breast or axillary surgery has been performed on that side. In addition, avoid applying cuff to traumatized or diseased extremity or one that has a cast or bulky bandage. Use lower extremities when brachial arteries are inaccessible.	Inappropriate site selection may result in poor amplification of sounds, causing inaccurate readings. Application of pressure from inflated cuff bladder temporarily impairs blood flow and can further compromise circulation in extremity that already has impaired blood flow.
5. Determine previous baseline BP and site (if available). Determine any report of latex allergy.	Assesses for change in condition. Provides comparison with future BP measurements. If patient has latex allergy, verify that stethoscope and BP cuff are latex free.
6. Assess patient's or family caregiver's knowledge, experience, and health literacy level.	Ensures patient has the capacity to obtain, communicate, process, and understand basic health information (CDC, 2019).
Planning	
1. Provide privacy and prepare bedside environment for patient safety.	Maintains patient comfort and removes barriers that may interfere with procedure.
2. Select appropriate cuff size (see Fig. 29.9) and insure that sphygmomanometer is in patient's room.	Use of improper cuff can cause measurement errors (see Table 29.12).
3. Ensure that patient has not exercised, ingested caffeine, or smoked for 30 minutes before assessing BP.	Exercise causes false elevation in BP. Smoking increases BP immediately and up to 15 minutes. Caffeine increase BP for up to 3 hours (James et al., 2014).
4. Explain to patient that you will be measuring blood pressure. Have patient rest at least 5 minutes before measuring lying or sitting BP and one minute before measuring standing BP. Ask patient to uncross legs and not to speak when BP being measured.	Promotes patient cooperation and increases adherence. Crossed legs or talking during assessment increases BP (AACN Practice Alert, 2016).
Implementation	
1. Perform hand hygiene. Clean stethoscope earpieces and diaphragm with alcohol swab.	Reduces transmission of infection.
2. Position Patient	
a. Upper extremity: With patient sitting or lying, position his or her forearm at heart level with palm turned up (see illustration). Support arm on a table or under your arm. If sitting, support back and instruct patient to keep feet flat on floor without legs crossed. If supine, patient should not have legs crossed.	If arm is extended and not supported, patient will perform isometric exercise that can increase diastolic pressure. Placement of arm above level of heart causes false-low reading; arm below the level of the heart creates a false-high reading (Kallioinen et al., 2017). Not supporting the arm can falsely elevate systolic BP (Gunes and Efteli, 2016). BP readings measured with the back unsupported are higher than those with the back supported (Ringrose et al., 2017). Legs crossed at the knees can significantly increase BP (Kallioinen et al., 2017).
b. Lower extremity: With patient prone, position patient so that knee is slightly flexed. If the patient cannot be placed in prone position, position him or her supine with knee slightly bent.	
3. Expose extremity (arm or leg) fully by removing constricting clothing. Cuff may be placed over a sleeve as long as stethoscope rests on skin (Kallioinen et al., 2017).	Ensures proper cuff application.
4. Palpate brachial artery in arm (see illustration A) or popliteal artery in leg. With cuff fully deflated, apply bladder of cuff above artery by centering arrows marked on cuff over artery (see illustration B). If cuff does not have any center arrows, estimate center of bladder and place this center over artery. Position cuff 2.5 cm (1 inch) above site of pulsation (antecubital or popliteal space). With cuff fully deflated, wrap it evenly and snugly around upper arm (see illustration C) or leg (see illustration D).	Brachial artery is along groove between biceps and triceps muscles above elbow at antecubital fossa. Popliteal artery is just below patient's thigh, behind knee. Placing bladder directly over artery ensures that you apply proper pressure during inflation. Loose-fitting cuff causes false-high readings.

STEP 4 A, Palpating brachial artery. B, Aligning blood pressure cuff arrow with brachial artery. C, Blood pressure cuff wrapped around upper arm. D, Blood pressure cuff applied around thigh. (A-C Copyright © Mosby's Clinical Skills Essentials Collection.)

Table Continued

Step	Rationale
5. Position manometer gauge vertically at eye level. You should be no farther than 1 meter (approximately 1 yard) away.	Looking up or down at scale can result in distorted readings.
6. Measure BP.	
a. Two-step method: (1) Relocate brachial or popliteal pulse. Palpate artery distal to cuff with fingertips of nondominant hand while inflating cuff rapidly to pressure 30 mm Hg above point at which pulse disappears. Slowly deflate cuff and note point when pulse reappears. Deflate cuff fully and wait 30 seconds.	Estimating prevents false-low readings. Determine maximal inflation point for accurate reading by palpation. If unable to palpate artery because of weakened pulse, use ultrasonic stethoscope (see Chapter 30). Deflating the cuff completely prevents venous congestion and false-high readings.
(2) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Ensure that each earpiece follows angle of ear canal to facilitate hearing.
(3) Relocate artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures best sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false-low systolic and false-high diastolic readings. The bell provides better sound reproduction, whereas the diaphragm is easier to secure with fingers and covers a larger area. Placing the stethoscope under the cuff increases the systolic and decreases the diastolic BP measurement (Kallioinen et al., 2017).
(4) Close valve of pressure bulb clockwise until tight. Quickly inflate cuff to 30 mm Hg above patient's estimated systolic pressure.	Tightening valve prevents air leak during inflation. Rapid inflation ensures accurate measurement of systolic pressure.
(5) Slowly release pressure bulb valve and allow manometer needle to fall at rate of 2 to 3 mm Hg/second.	Too-rapid a decline decreases systolic BP and increases diastolic BP measurement (Kallioinen et al., 2017).
(6) Note point on manometer when you hear first clear sound. Sound will slowly increase in intensity.	First sound reflects systolic BP.
(7) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Note pressure to nearest 2 mm Hg. Listen for 20 to 30 mm Hg after last sound and allow remaining air to escape quickly.	Beginning of last or fifth sound is indication of diastolic pressure in adults (Thomas and Pohl, 2017). In children distinct muffling of sounds indicates diastolic pressure (Thomas and Pohl, 2017).
b. One-step method:	
(1) Place stethoscope earpieces in ears and be sure that sounds are clear, not muffled.	Earpieces should follow angle of ear canal to facilitate hearing.
(2) Relocate brachial or popliteal artery and place bell or diaphragm chest piece of stethoscope over it. Do not allow chest piece to touch cuff or clothing.	Proper stethoscope placement ensures optimal sound reception. Stethoscope improperly positioned causes muffled sounds that often result in false readings. Bell provides better sound reproduction, whereas diaphragm is easier to secure with fingers and covers a larger area. Placing the stethoscope under the cuff increases the systolic and decreases the diastolic BP measurement (Kallioinen et al., 2017).
(3) Close valve of pressure bulb clockwise until tight. Quickly inflate cuff to 30 mm Hg above patient's usual systolic pressure.	Tightening valve prevents air leak during inflation. Inflation above systolic level ensures accurate measurement of systolic pressure.
(4) Slowly release pressure bulb valve and allow manometer needle to fall at rate of 2 to 3 mm Hg/second. Note point on manometer when you hear first clear sound. Sound will slowly increase in intensity.	A too-rapid decline decreases systolic BP and increases diastolic BP measurement (Kallioinen et al., 2017). First sound reflects systolic pressure.
(5) Continue to deflate cuff gradually, noting point at which sound disappears in adults. Note pressure to nearest 2 mm Hg. Listen for 10 to 20 mm Hg after last sound, and allow remaining air to escape quickly.	Beginning of fifth sound is indication of diastolic pressure in adults (Thomas and Pohl, 2017). In children distinct muffling of sounds indicates diastolic pressure (Thomas and Pohl, 2017).
7. The American Heart Association recommends average of two sets of BP measurement, 2 minutes apart. Use second set of BP measurements as baseline. If readings are different by more than 5 mm Hg, additional readings are necessary.	Two sets of BP measurements help to prevent false-positive readings based on patient's sympathetic response (alert reaction). Averaging minimizes effect of anxiety, which often causes first reading to be higher than subsequent measures (Kallioinen et al., 2017).
8. Remove cuff from patient's arm or leg unless patient condition requires repeated measurements.	Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of patient's arm/leg.
9. If this is first assessment of patient, repeat procedure on other arm or leg.	Comparison of BP in both arms and legs detects circulatory problems. (Normal difference of 5 to 10 mm Hg exists between arms.) Use arm with higher pressure for repeated measurements (AACN Practice Alert, 2016).
10. Assess systolic BP by palpation:	
a. Follow Steps 2-5.	
b. Locate and then continually palpate brachial, radial, or popliteal artery with fingertips of one hand. Inflate cuff to pressure 30 mm Hg above point at which you can no longer palpate pulse.	Ensures accurate detection of true systolic pressure once pressure valve is released.

Step	Rationale
	Table Continued

Step	Rationale
CLINICAL DECISION: <i>If unable to palpate artery because of weakened pulse, use a Doppler ultrasonic stethoscope (see Chapter 30).</i>	
c. Slowly release valve and deflate cuff, allowing manometer needle to fall at rate of 2 mm Hg/second. Note point on manometer when pulse is again palpable, which indicates systolic pressure.	A too-rapid decline decreases systolic BP and increases diastolic BP measurement (Kallioinen et al., 2017). Palpation helps identify systolic pressure only.
d. Deflate cuff rapidly and completely. Remove cuff from patient's extremity unless patient condition requires repeated measurements.	Continuous cuff inflation causes arterial occlusion, resulting in numbness and tingling of extremity.
11. Assist patient return to comfortable position and cover upper arm or leg if previously clothed.	Restores comfort and provides sense of well-being.
12. Discuss results with patient.	Promotes participation in care and understanding of health.
13. Place nurse call system within reach and instruct patient in use.	Promotes safety and prevents falls.
14. Raise side rails (as appropriate) and lower bed to lowest position.	Promotes safety and prevents falls.
15. Wipe cuff with agency-approved disinfectant if used between patients.	Reduces transmission of infection.
16. Clean earpieces and diaphragm of stethoscope with alcohol swab.	Reduces transmission of infection when nurses share stethoscope.
17. Perform hand hygiene.	Reduces transmission of infection.
Evaluation	
1. If assessing BP for first time, establish baseline BP if it is within acceptable range.	Used to compare future BP measurements.
2. Compare BP reading with patient's previous baseline and usual BP for patient's age.	Allows you to assess for change in condition. Provides comparison with future BP measurements.
3. Use Teach-Back "I want to be sure I explained why it is important to stand up slowly since you are taking blood pressure medications. Tell me which of your medications might make you dizzy if you stand up too fast." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
UNEXPECTED OUTCOMES AND RELATED INTERVENTIONS	
<p>1. Patient's BP is above acceptable range.</p> <ul style="list-style-type: none"> Repeat measurement in other extremity and compare findings. When a clinically significant difference greater than 10 mm Hg exists, use the arm with the higher pressure (AACN Practice Alert, 2016). Verify correct size and placement of BP cuff. Have another nurse repeat measurement in 1 to 2 minutes. Observe for related symptoms that are not apparent unless BP is extremely high, including headache, facial flushing, nosebleed, and fatigue in an older patient. Report BP to nurse in charge or health care provider to initiate appropriate evaluation and treatment. Administer antihypertensive medications as ordered. 	
<p>2. Patient's BP is below acceptable range.</p> <ul style="list-style-type: none"> Compare BP value with baseline. Position patient in supine position to enhance circulation and restrict activity that decreases BP further. Assess for signs and symptoms associated with hypotension, including tachycardia; weak, thready pulse; weakness; dizziness; confusion; and cool, pale, dusky, or cyanotic skin. Assess for factors that contribute to low BP, including hemorrhage, dilation of blood vessels resulting from hyperthermia, anesthesia, or medication side effects. Report BP to nurse in charge or health care provider to initiate appropriate interventions. Increase rate of IV infusion or administer vasoconstriction drugs if ordered. If patient stabilizes, assess for postural hypotension. 	
<p>3. Unable to obtain BP reading.</p> <ul style="list-style-type: none"> Determine that no immediate crisis is present by obtaining pulse and respiratory rate. Assess for signs and symptoms of decreased cardiac output; if present, notify nurse in charge or health care provider immediately. Use alternative sites or procedures to obtain BP: use Doppler ultrasonic instrument (see Chapter 30); palpate systolic BP. 	
Recording and Reporting	
<ul style="list-style-type: none"> Record BP, extremity assessed, method of assessment, and any signs and symptoms of BP alterations in EHR. Record measurement of BP after administration of specific therapies. Document assessment of patient learning. Report elevated or low blood pressure, a difference of more than 20 mm Hg between extremities or more than 20 mm Hg drop in systolic blood pressure or a 10 mm Hg drop in diastolic blood pressure when rising from a supine to a sitting or standing position. 	
Home Care Considerations	
<ul style="list-style-type: none"> Assess home noise level to determine room that provides most quiet environment for assessing BP. Consider use of an electronic BP cuff for home if patient has hearing difficulties, sufficient financial resources, and adequate dexterity. Blood pressure taken in the home may differ from the measurements assessed in a health care facility because the equipment and environment are different. Home blood pressure readings predict cardiovascular events and are particularly useful for monitoring the effects of treatment. 	

Key Points

- For the body temperature to stay constant and within an acceptable range, various mechanisms maintain the relationship between heat production and heat loss.
- Body temperature will decrease using measures that increase radiation, evaporation, convection, and conduction of heat.
- Fever serves as an important mechanism to enhance the immune system's ability to fight infection.
- Fever increases metabolism, which requires additional energy and oxygen.
- Vital sign assessment requires an organized approach.
- Patient age, gender, activity, medications, and health status influence vital signs.
- Measurement location and time of day influence vital signs.
- Hypertension occurs more frequently among African Americans.
- Acceptable vital signs fall within a normal range, with infant and children values higher for pulse and respirations and lower in blood pressure, compared with adults.
- Changes related to aging influence the vital sign values of older adults.
- Assessment of a child's vital signs requires you to consider that the brachial or apical pulse is the best site for assessing

an infant's or a young child's pulse, and when measuring respirations, infants tend to breathe less regularly.

- Self-measurement of blood pressure helps patients adhere to treatment regimens, but findings should not be used for treatment decisions.
- Report route and site when measuring temperature, blood pressure, pulse, and oxygen saturation.
- When vital signs are above or below expected values, enter a note in the patient's record regarding the finding, any intervention, and the patient's response.
- Vital signs can be delegated to assistive personnel when the patient's condition is stable; however, the skill of apical pulse measurement cannot be delegated.

Reflective Learning

- Consider your experience with vital sign delegation and how you met the rights of delegation.
- Consider the vital sign measurement equipment you used and describe how you prevented the spread of infection.
- Consider a patient you cared for today and provide your rationale for the frequency and order of the vital sign measurements you completed.

Review Questions

1. A 52-year-old woman is admitted with pneumonia, dyspnea, and discomfort in her left chest when taking deep breaths. She has smoked for 35 years and recently lost over

10 lb. She is started on intravenous antibiotics, high-protein shakes, and 2 L O₂ via nasal cannula. Her most recent vital signs are HR 112, BP 138/82, RR 22, tympanic temperature 37.9°C (100.2° F), and oxygen saturation 94%. Which vital signs reflect a positive outcome of the treatment interventions? (Select all that apply.)

1. Temperature: 37° C (98.6° F)
 2. Radial pulse: 98
 3. Respiratory rate: 18
 4. Oxygen saturation: 96%
 5. Blood pressure: 134/78
2. The licensed practical nurse (LPN) provides you with the change-of-shift vital signs on four of your patients. Which patient does the nurse need to assess first?
1. 84-year-old man recently admitted with pneumonia, RR 28, SpO₂ 89%
 2. 54-year-old woman admitted after surgery for repair of a fractured arm, BP 160/86 mm Hg, HR 72
 3. 63-year-old man with venous ulcers from diabetes, temperature 37.3° C (99.1° F), HR 84
 4. 77-year-old woman with left mastectomy 2 days ago, RR 22, BP 148/62
3. A patient has been hospitalized for the past 48 hours with a fever of unknown origin. His medical record indicates tympanic temperatures of 38.7°C (101.6°F) at 0400, 36.6°C (97.9°F) at 0800, 36.9°C (98.4°F) at 1200, 37.6°C (99.6°F) at 1600, and 38.3°C (100.9°F) at 2000. How would the nurse describe this pattern of temperature measurements?
1. Usual range of circadian rhythm measurements

2. Sustained fever pattern
 3. Intermittent fever pattern
 4. Resolving fever pattern
4. A patient presents in the clinic with dizziness and fatigue. The assistive personnel (AP) reports a slow but regular radial pulse of 44. Place the following care activities in priority order.
1. Direct the AP to obtain a blood pressure.
 2. Request that the patient lie on the clinical stretcher.
 3. Assess the patient's apical pulse for a full minute.
 4. Prepare to administer cardiac-stimulating medications.
5. Which of the following patients are at most risk for tachypnea? (Select all that apply.)
1. Patient just admitted with four rib fractures
 2. Woman who is 9 months' pregnant
 3. A patient admitted with hypothermia
 4. Postoperative patient waking from general anesthesia
 5. Three-pack-per-day smoker with pneumonia
6. Which number marks the location where the nurse would auscultate the point of maximal impulse (PMI)?

7. During admission of an obese patient with heart failure the assistive personnel (AP) reports to the nurse that the blood pressure (BP) is 140/76 on the left arm and 128/72 on the right arm. What actions do you take on the basis of this information? (Select all that apply.)

1. Notify the health care provider immediately.
2. Repeat the measurements on both arms using a stethoscope.
3. Ask the patient if she has taken her blood pressure medications recently.

4. Obtain blood pressure measurements on lower extremities.
5. Verify that the correct cuff size was used during the measurements.
6. Review the patient's record for her baseline vital signs.
7. Compare right and left radial pulses for strength.
8. The assistive personnel (AP) informs the nurse that the electronic blood pressure machine on the patient who has recently returned from surgery after removal of her gallbladder is flashing a blood pressure of 65/46 and alarming. Place the care activities in priority order.
 1. Press the start button of the electronic blood pressure machine to obtain a new reading.
 2. Obtain a manual blood pressure with a stethoscope.
 3. Check the patient's pulse distal to the blood pressure cuff.
 4. Assess the patient's mental status.
 5. Remind the patient not to bend her arm with the blood pressure cuff.
9. A healthy adult patient tells the nurse that he obtained his blood pressure in "one of those quick machines in the mall" and was alarmed that it was 152/72 when his normal value ranges from 114/72 to 118/78. The nurse obtains a blood pressure of 116/76. What would account for the blood pressure of 152/92? (Select all that apply.)
 1. Cuff too small
 2. Arm positioned above heart level
 3. Slow inflation of the cuff by the machine
 4. Patient did not remove his long-sleeved shirt

5. Insufficient time between measurements

10. A patient is admitted for dehydration caused by pneumonia and shortness of breath. He has a history of heart disease and cardiac dysrhythmias. The assistive personnel reports his admitting vital signs to the nurse. Which measurements should the nurse reassess? (Select all that apply.)

1. Right arm BP: 118/72

2. Radial pulse rate: 72 and irregular

3. Temporal temperature: 37.4°C (99.3°F)

4. Respiratory rate: 28

5. Oxygen saturation: 99%

Answers: 1.1, 2, 3, 4; 2.1; 3.3; 4.2, 1, 3, 5, 4; 5. 1, 2, 5; 6.5; 7.2, 6; 8.4, 1, 3, 2, 5; 9.1, 5; 10.2, 4, 5.

Health Assessment and Physical Examination

OBJECTIVES

- Discuss the purpose of a physical assessment.
- Discuss how cultural diversity influences a nurse's approach to and findings from a health assessment.
- List techniques for preparing a patient physically and psychologically before and during an examination.
- Describe interview techniques used to enhance communication during history taking.
- Make environmental preparations before an examination.
- Identify data to collect from the nursing history before an examination.
- Demonstrate the techniques used with each physical assessment skill.
- Discuss normal physical findings in a young, middle-age, and older adult.
- Discuss ways to incorporate health promotion and health teaching into an examination.
- Identify ways to use physical assessment skills during routine nursing care.
- Describe physical measurements made in assessing each body system.
- Identify self-screening examinations commonly performed by patients.
- Identify preventive screenings and the appropriate age(s) for each screening to occur.

Completing a health assessment and physical examination is an important step toward providing safe and competent nursing care. The nurse is in a unique position to determine each patient's current health status, distinguish variations from the norm, and recognize improvements or deterioration in the patient's condition. Nurses

must be able to recognize and interpret each patient's behavioral and physical presentation. You perform health assessments and physical examinations to identify health patterns and evaluate each patient's response to treatments and therapies.

You gather assessment data about patients' past and current health conditions in a variety of ways, using a comprehensive or focused approach, depending on the patient situation. Nurses perform assessments at health fairs, at screening clinics, in a health provider's office, in acute care agencies, or in patients' homes. Depending on the outcome of an assessment, a nurse considers evidence-based recommendations for care based on a patient's values, the health provider's clinical expertise, or personal experience.

A complete health assessment involves a nursing history (see [Chapter 16](#)) and behavioral and physical examination. Through the health history interview you gather subjective data about a patient's condition. Objective data is obtained while observing a patient's behavior and overall presentation. Gather additional objective data through a head-to-toe body system review during the physical examination. You make clinical judgments based on all of the gathered data to create a plan of care for each situation. With accurate data you create a patient-centered care plan, identifying the nursing diagnoses, desired patient outcomes, and nursing interventions.

Purposes of the Physical Examination

Nurses conduct physical examinations for many reasons, such as an initial evaluation in triage for emergency care; for routine screening to promote wellness behaviors and preventive health care measures; to determine eligibility for health insurance, military service, or a new job; or to admit a patient to a hospital or long-term care facility. After considering a patient's current condition, a nurse selects a focused physical examination on a specific system or area. For example, when a patient is having a severe asthma episode, the nurse first focuses on the pulmonary and cardiovascular systems so that treatments can begin immediately. When the patient is no longer at risk for a poor outcome or injury, the nurse performs a more comprehensive examination of the other body systems.

For patients who are hospitalized, a nurse integrates the collection of physical assessment data during routine patient care, validating findings with what is known about the patient's health history. For example, on entering a patient's room a nurse may notice behavioral patient cues that indicate sadness or may observe swallowing difficulties while administering medications. Use physical examination to do the following:

- Gather baseline data about a patient's health status.
- Supplement, confirm, or refute subjective data obtained.
- Identify and confirm nursing diagnoses.
- Make clinical decisions about a patient's changing health status and management.
- Evaluate the outcomes of care.

Cultural Sensitivity

Respect the cultural differences among patients from a variety of backgrounds when completing an examination. It is important to remember that cultural differences influence patient behaviors. Consider the patient's health beliefs, use of alternative therapies, nutritional habits, relationships with family, and comfort with physical closeness during the examination and history. These factors

will affect both your approach and the type of findings you might expect.

Be culturally aware and avoid stereotyping based on gender, race, education, or other cultural factors. There is a difference between cultural and physical characteristics. Learn to recognize common characteristics and disorders among members of ethnic populations within the community. It is equally important to recognize variations in physical characteristics such as in the skin and musculoskeletal system. Recognize the impact of cultural difference in racial and ethnic aspects. Be aware of cultural humility and recognize your own knowledge deficits related to different cultures. Consider how the illness may impact the patient, adaptations that may be needed for the physical assessment, mode of communication, health beliefs and practices, familial relationships and nutritional practices. (Ball et al., 2019). By addressing cultural diversity, you show respect for each patient's uniqueness, leading to higher-quality care and improved clinical outcomes (see [Chapter 9](#)).

Preparation for Examination

Physical examination is a routine and integral part of a nurse's patient assessment. In many care settings a head-to-toe physical assessment is required daily. You perform a reassessment when a patient's condition changes, as it improves or worsens. In some health care settings, such as during a home health visit, a focused physical examination is preferred. A proper physical examination will take into consideration cultural aspects, infection control, preparation of the environment, patient position, age of the patient, equipment, and explanation of assessment procedures. This will provide a smooth physical examination with few interruptions. A disorganized approach could cause errors and incomplete findings. Safety for patients who are confused should be a priority; never leave a patient who is confused or combative alone during an examination.

Infection Control

Some patients present with open skin lesions, infected wounds, or other communicable diseases. Use Standard Precautions throughout an examination (see [Chapter 28](#)). When an open sore or microorganism is present, wear gloves to reduce contact with contaminants. If a patient has excessive drainage or there is a risk of splattering from a wound, use additional personal protective equipment, such as an isolation gown or eye shield. Follow the agency's hand hygiene policies before initiating and after completing a physical assessment.

Although most health care agencies make nonlatex gloves available, it is your responsibility to identify latex allergies in patients and use equipment items that are latex free. By recognizing risk factors for latex allergies, patients remain free of a natural rubber latex (NRL) allergy. Three types of allergic responses appear with NRL. The most immediate is an immunological reaction. This is a type 1 response, for which the body develops antibodies known as *immunoglobulin E* that can lead to an anaphylactic response. The second is type IV (delayed-type) hypersensitivity, which is T cell-mediated and appears 48 to 96 hours after exposure ([AAFA, 2015](#)).

Irritant contact dermatitis is a nonallergic reaction and presents with dry, irritated, or fissured skin. The severity of the response varies among individuals. [Table 30.1](#) provides a short list of products that contain latex and suggests available alternatives.

TABLE 30.1**Products Containing Latex and Nonlatex Substitutes^a**

Products Containing Latex	Nonlatex Substitutes
Medical Equipment	
Disposable gloves	Vinyl, nitrile, or neoprene gloves
Blood pressure cuffs	Covered cuffs
Stethoscope tubing	Covered tubing
Intravenous injection ports	Needleless system, stopcocks, covered latex ports
Tourniquets	Latex-free or cloth-covered tourniquets
Syringes	Glass syringes
Adhesive tape	Nonlatex tapes
Oral and nasal airways	Nonlatex tubes
Endotracheal tubes	Hard plastic tubes
Catheters	Silicone catheters
Eye goggles	Silicone eye goggles
Anesthesia masks	Silicone masks
Respirators	Nonlatex respirators
Rubber aprons	Cloth-covered aprons
Wound drains	Silicone drains
Medication vial stoppers	Stoppers removed
Household Items	
Rubber bands	String; latex-free bands
Erasers	Silicone erasers
Motorcycle and bicycle handgrips	Handgrips removed or covered
Carpeting	Other types of flooring
Swimming goggles	Silicone construction
Shoe soles	Leather shoes
Expandable fabric (e.g., waistbands)	Fabric removed or covered
Dishwashing gloves	Vinyl gloves
Condoms	Nonlatex condoms
Diaphragms	Synthetic rubber diaphragms
Balloons	Mylar balloons
Pacifiers and baby bottle nipples	Silicone, plastic, or nonlatex pacifiers and nipples

^a This list is intended to provide examples of products and alternatives. It is not complete.

Modified from Ball JW, et al: *Mosby's guide to physical examination*, ed 9, St Louis, 2019, Elsevier; and U.S. National Library of Medicine Medline Plus: *Latex allergies: for hospital patients*, 2019.

Environment

A respectful, considerate physical examination requires privacy. In the acute setting nurses perform assessments in a patient's room while examination rooms are used in clinics or offices. In the home the examination is performed in a space where privacy can be established such as the patient's bedroom.

Examination spaces need to be well equipped for any procedures. Adequate lighting is necessary to properly illuminate body parts. The hospital room can be secured for privacy so that patients are comfortable discussing their condition. Eliminate extra noise and take precautions to prevent interruptions from others. The room must be warm enough to maintain comfort.

Depending on the body part being assessed, it may be difficult to perform a selected assessment skill when a patient is in bed or on a stretcher. Special examination tables make positioning easier and body areas more easily accessible. By helping patients on and off examination tables, injury can be avoided. Examination tables can be uncomfortable; elevate the head of the table about 30 degrees. A small pillow helps with head and neck comfort. If the examination is completed in the patient room, raise the height of the patient's bed to be able to reach the patient more comfortably.

Equipment

Perform hand hygiene thoroughly before handling equipment and starting an examination. Arrange any necessary equipment so that it is readily available and easy to use. Prepare equipment as appropriate (e.g., warm the diaphragm of the stethoscope between the hands before applying it to the skin). Be sure that equipment functions properly before using it (e.g., ensure that the ophthalmoscope and otoscope have good batteries and light bulbs). [Box 30.1](#) lists typical equipment used during a physical examination.

Box 30.1 Equipment and Supplies for Physical Assessment

- Cervical brush or broom devices (if needed)
- Cotton applicators
- Disposable pad/paper towels
- Drapes/cover
- Eye chart (e.g., Snellen chart)
- Flashlight and spotlight
- Forms (e.g., physical, laboratory)
- Nonlatex gloves (clean)
- Gown for patient
- Ophthalmoscope
- Otoscope
- Papanicolaou (Pap) liquid preparation (if needed)
- Percussion (reflex) hammer
- Pulse oximeter

- Ruler
- Scale with height measurement rod
- Specimen containers, slides, wooden or plastic spatula, and cytological fixative (if needed)
- Sphygmomanometer and cuff
- Sterile swabs
- Stethoscope
- Tape measure
- Thermometer
- Tissues
- Tongue depressors
- Tuning fork
- Vaginal speculum (if needed)
- Water-soluble lubricant
- Watch with second hand or digital display

Physical Preparation of the Patient

Show respect for a patient by ensuring that physical comfort needs, such as using the restroom, are met before starting the exam. An empty bladder and bowel facilitate a more comfortable examination of the abdomen, genitalia, and rectum. Collect urine or fecal specimens at this time if needed.

Physical preparation involves making certain that patient privacy is maintained with proper dress and draping. The patient in the hospital is probably wearing a hospital gown. In the clinic or health care provider's office the patient needs to undress and usually is provided a disposable paper cover or gown. If the examination is limited to certain body systems, it is not always necessary for the patient to undress completely. Provide the patient privacy and plenty of time to undress to lessen the patient's anxiety. After changing, the patient sits or lies down on the examination table with a light drape over the lap or lower trunk. Make sure that drafts are eliminated, temperature is controlled, and blankets are provided. Routinely ask whether he or she is comfortable.

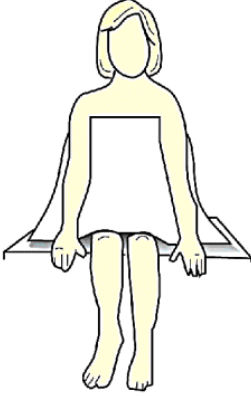

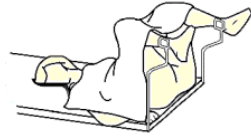

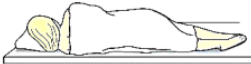

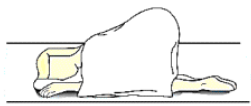

Positioning

During the examination ask the patient to assume proper positions so that body parts are accessible and he or she stays comfortable. [Table](#)

30.2 lists the preferred positions for each part of the examination and contains figures illustrating the positions. Patients' abilities to assume positions depend on their physical strength, mobility, ease of breathing, age, and degree of wellness. After explaining a position, help the patient to assume it correctly. Take care to maintain respect and show consideration by adjusting the drapes so that only the area examined is accessible. During the examination a patient may need to assume more than one position. To decrease the number of position changes, organize the examination so that all techniques requiring a sitting position are completed first, followed by those that require a supine position next, and so forth. Use extra care when positioning older adults with disabilities and limitations.

TABLE 30.2

Positions for Examination

Position	Areas Assessed	Rationale	Limitations
Sitting 	Head and neck, back, posterior thorax and lungs, anterior thorax and lungs, breasts, axillae, heart, vital signs, and upper extremities	Sitting upright provides full expansion of lungs and better visualization of symmetry of upper body parts.	Physically weakened patient sometimes is unable to sit. Use supine position with head of bed elevated instead.
Supine 	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen, extremities, pulses	This is normally a relaxed position. It provides easy access to pulse sites.	If patient becomes short of breath easily, raise head of bed.
Dorsal recumbent 	Head and neck, anterior thorax and lungs, breasts, axillae, heart, abdomen	Position is for abdominal assessment because it promotes relaxation of abdominal muscles.	Patients with painful disorders are more comfortable with knees flexed.
Lithotomy^a 	Female genitalia and genital tract	Position provides maximal exposure of female genitalia and facilitates insertion of vaginal speculum.	Lithotomy position is embarrassing and uncomfortable; thus examiner minimizes time that patient spends in it. Keep patient well draped.
Sims' 	Rectum and vagina	Flexion of hip and knee improves exposure of rectal area.	Joint deformities hinder patient's ability to bend hip and knee.
Prone 	Musculoskeletal system	Position is only for assessing extension of hip joint, skin, and buttocks.	Patients with respiratory difficulties do not tolerate this position well.
Lateral recumbent 	Heart	Position aids in detecting murmurs.	Patients with respiratory difficulties do not tolerate this position well.
Knee-chest^a 	Rectum	Position provides maximal exposure of rectal area.	This position is embarrassing and uncomfortable.

^a Some patients with arthritis or other joint deformities are unable to assume this position.

Psychological Preparation of a Patient

Many patients find an examination stressful or tiring, or they experience anxiety about possible findings. A thorough explanation of the purpose and steps of each assessment lets a patient know what to expect and how to cooperate. Adapt your explanations to the patient's level of understanding, and encourage him or her to ask questions and comment on any discomfort. Convey an open, professional approach while remaining relaxed. A quiet, formal demeanor inhibits a patient's ability to communicate, but a style that is too casual may cause him or her to doubt an examiner's competence (Ball et al., 2019).

Consider cultural or social norms when performing an examination on a person of the opposite gender. When this situation occurs, another person of the patient's gender or a culturally approved family member needs to be in the room. By taking this step you demonstrate cultural awareness for a patient's individual needs. As a side benefit, the second person acts as a witness to the conduct of the examiner and the patient should any question arise.

During the examination watch the patient's emotional responses by observing whether his or her facial expressions show fear or concern or whether body movements indicate anxiety. When you remain calm, the patient is more likely to relax. Especially if the patient is weak or elderly, it is necessary to pace the examination, pausing at intervals to ask how he or she is tolerating the assessment. If the patient feels all right, the examination can proceed. However, do not force the patient to cooperate based on your schedule. Postpone the examination when needed; your findings may be more accurate when the patient can cooperate and relax.

Assessment of Age-Groups

Use different interview styles and approaches to physical examination for patients of different age-groups. When assessing children, show sensitivity and anticipate a child's perception of the

examination as a strange and unfamiliar experience. Routine pediatric examinations focus on health promotion and illness prevention, particularly for well children who receive competent parenting and have no serious health problems (Hockenberry and Wilson, 2019). This examination focuses on growth and development, sensory screening, dental examination, and behavioral assessment. When examining children, the following tips help in data collection:

- Gather all or part of the history on infants and children from parents or guardians. Use open-ended questions to allow parents to share more information and describe more of the children's situation. This will allow observation of parent-child interactions. Older children can be interviewed and provide details about their health history and severity of symptoms.
- Gain a child's trust before doing any type of an examination. Perform the examination in a nonthreatening area. Talk and play with the child first. Do the visual parts of the examination before touching the child. Start the examination from the periphery and then move to the center (e.g., start with the extremities before moving to the chest).
- Because parents sometimes think the examiner is testing them, offer support during the examination and do not pass judgment.
- Call children by their first names and address the parents as "Mr., Mrs., or Ms." rather than by their first names unless instructed differently.
- Treat adolescents as adults and individuals because they tend to respond best when treated as such. Remember that adolescents have the right to confidentiality. After talking with parents about historical information, speak alone with adolescents.

A comprehensive health assessment and examination of older adults includes physical data; family relationships; religious and occupational pursuits; and a review of the patient's cognitive, affective, and social level. An important aspect is to assess the

patient's ability to perform basic activities of daily living (e.g., bathing, grooming) and complex instrumental activities of daily living (e.g., making a phone call).

Throughout an examination, recognize that older adults often present with subtle or atypical signs and symptoms (Touhy and Jett, 2017). Principles to follow during examination of an older adult include the following:

- Do not stereotype about aging patients' level of cognition. Most older adults are reliable historians and are able to adapt to change and learn about their health.
- Recognize that some older adults have sensory or physical limitations that affect how quickly they can be interviewed and examinations can be conducted. It might be necessary to plan for more than one examination session. Sometimes it helps to give patients an initial health questionnaire before they come to a clinic or office.
- Perform the examination with adequate space; this is especially important for patients with mobility aids such as a cane or walker.
- During the examination use patience, allow for pauses, and observe for details. Recognize normal physiological and behavioral changes that are characteristic of later life.
- Giving certain types of health information is stressful for older patients. Some view illness as a threat to independence and a step toward institutionalization.
- Be aware of the location of the closest bathroom in case the patient has an urgent need to eliminate.
- Be alert to signs of increasing fatigue such as sighing, grimacing, irritability, leaning against objects for support, and drooping head and shoulders.

REFLECT NOW

As the nurse preparing to begin the physical examination, verbalize your opening statement to your older adult patient. Reflect on your knowledge of culture, aging, and developing a safe environment of trust. What nursing strategies should you use during the physical examination?

Organization of the Examination

Assess each body system during a physical examination. Use judgment to ensure that an examination is relevant and includes the correct assessments. Patients with focused symptoms or needs require only parts of an examination; thus, when a patient comes to a clinic with symptoms of a severe chest cold, a neurological assessment is not usually required. When a patient is admitted to the hospital, you perform a complete examination at the time of admission and at least once each day to maintain and monitor the patient's baseline. Agency guidelines may define the components of a complete examination (see agency policy). A patient in the community seeks screening for specific conditions, often dependent on his or her age or health risks listed in [Table 30.3](#).

TABLE 30.3

Recommended Preventive Screenings

Disease/Condition	Age-Group	Screening Measures
Breast cancer ^a (Women at average risk)	Ages 40-44	Should have the choice to start annual breast cancer screening with mammograms if they wish to do so. The risks of screening as well as the potential benefits should be considered. Monthly BSE dependent on health care provider recommendations (not recommended by ACS)
	Ages 45-54	Monthly BSE dependent upon health care provider recommendations (not recommended by ACS) Should get mammogram every year
	Ages 55 and older	Should switch to mammograms every 2 years or have the choice to continue yearly screening.
	Women with a personal history of breast cancer, a family history of breast cancer, a genetic mutation known to increase the risk of breast cancer (such as <i>BRCA</i>), and women who have had radiation therapy to the chest before the age of 30 are at a higher risk for breast cancer, not average risk. These women require earlier and more extensive screening.	
Colon/rectal cancer ^b	Ages 45 and older	Men and women need to have one of the following sensitive tests that look for signs of cancer: fecal occult blood test (FOBT) or flexible sigmoidoscopy (FSIG) or colonoscopy. Earlier screening is necessary if risk factors exist.
Ear disorders	All ages	Periodic hearing checks as needed
	Over age 65	Regular hearing checks
Eye disorders	Age 40 and under	Complete eye examination every 3 to 5 years (more if positive history for eye disease [e.g., diabetes])
	Ages 40 to 64	Complete eye examination every 2 years to screen for conditions that may go unnoticed (e.g., glaucoma) Annual eye examinations if patient has diabetes
	Age 65 and older	Complete eye examination every year
Heart/vascular disorders	Men age 45 to 65	Regular measurement of total blood cholesterol levels, lipids, and triglycerides; blood pressure screenings (If patient has risk factors for coronary artery disease [CAD], blood pressure screening needs to begin at age 20-35 for men, 20-45 for women.)
	Women age 45 to 65	
Obesity	All ages	Periodic height and weight measurements
Oral cavity/pharyngeal disorders/cancer	All ages (children, adults, older adults)	Regular dental examinations every 6 months
Ovarian cancer ^c	Age 18 and up or on becoming sexually active	Annual pelvic examinations by health care provider (This screening rarely detects ovarian cancer unless it is in its advanced stage. Those at high risk need to have a thorough pelvic examination, a transvaginal ultrasound, and a blood test [tumor marker CA 125]) (ACS, 2018d).
Prostate cancer ^b	Ages 50 and up	Men who have at least a 10-year life expectancy need to have a digital rectal examination (DRE) and prostate-specific antigen (PSA) blood test annually. Men at high risk require earlier screening.
Skin cancer ^b	Ages 20 to 40	See specialist every 3 years
	Over 40	Annual skin checkups with biopsy of suspicious lesions
Testicular cancer ^b	Age 15 and up	Monthly testicular self-examination (TSE)
Uterine cancer ^b	Screening begins 3 years after having vaginal intercourse but not later than age 21	^d Annual pelvic examination by health care provider plus annual Papanicolaou (Pap) test
Cervical cancer	An annual Pap test is no longer recommended by the American Cancer Society (ACS, 2016).	
	Ages 21-29	Pelvic examination by health care provider plus Pap test with cytology every 3 years; human papillomavirus (HPV) needed only if Pap test is abnormal (ACS, 2016)
	Ages 30-65	Preferred screening is with a Pap test combined with an HPV test every 5 years. This is called co-testing (ACS, 2016).
	Over 65	No testing needed if previous regular testing was completed and normal. If a high risk for cervical cancer or previous perchance then screening should be continued (ACS, 2016).
Endometrial cancer	Same as for cervical cancer	Endometrial biopsy at age 35 for high-risk patients (those with or at risk for hereditary nonpolyposis colon cancer [HNPCC]) (At menopause women at average and high risk need to be informed about signs and symptoms to report.)

Follow a systematic routine when you perform a physical examination to avoid missing important findings. A head-to-toe approach includes all body systems, and the examiner recalls and performs each step in a predetermined order. For an adult the examination begins with an assessment of the head and neck and progresses methodically down the body to incorporate all body systems. The following tips help keep an examination well organized:

- Compare both sides of the body for symmetry. A degree of asymmetry is occasionally normal (e.g., the biceps muscles in the dominant arm are sometimes more developed than the same muscles in the nondominant arm).
- If the patient is seriously ill, first assess the systems of the body most at risk for being abnormal. For example, complete a cardiovascular assessment first when caring for a patient with chest pain.
- If the patient becomes fatigued, offer rest periods between assessments.
- Perform painful procedures near the end of an examination.
- Record assessments in specific terms in the electronic or paper record. A standard form allows for recording information in the same sequence that it is gathered.
- Use common and accepted medical terms and abbreviations to keep notes accurate, brief, and concise.
- Record quick notes during the examination to avoid delays. Complete any larger documentation notes at the end of the

examination.

Techniques of Physical Assessment

The four techniques used in a physical examination are inspection, palpation, percussion, and auscultation.

Inspection

To inspect, carefully look, listen, and smell to distinguish normal from abnormal findings. To do so, you must be aware of any personal visual, hearing, or olfactory deficits. It is important to deliberately practice this skill and learn to recognize all the possible pieces of data that can be gathered through inspection alone. **Inspection** occurs when interacting with a patient, watching for nonverbal expressions of emotional and mental status and assessing physical movements and structural components. Most important, be deliberate and pay attention to detail. Follow these guidelines to achieve the best results during inspection:

- Make sure that adequate lighting is available, either direct or indirect.
- Use a direct lighting source (e.g., a penlight or lamp) to inspect body cavities.
- Inspect each area for size, shape, color, symmetry, position, and abnormality.
- Position and expose body parts as needed so that all surfaces can be viewed but privacy can be maintained.
- When possible, check for side-to-side symmetry by comparing each area with its match on the opposite side of the body.
- Validate findings with the patient.

While assessing a patient, recognize the nature and source of body odors ([Table 30.4](#)). An unusual odor often indicates an underlying pathology. **Olfaction** helps to detect abnormalities. For example, when a patient's breath has a sweet, fruity odor, assess for signs of diabetes. Continue to inspect various parts of the body during the entire physical examination. Palpation may be used concurrently with inspection, or it may follow in a more deliberate fashion.

TABLE 30.4**Assessment of Characteristic Odors**

Odor	Site or Source	Potential Causes
Alcohol	Oral cavity	Ingestion of alcohol, diabetes
Ammonia	Urine	Urinary tract infection, renal failure
Body odor	Skin, particularly in areas where body parts rub together (e.g., underarms and under breasts)	Poor hygiene, excess perspiration (hyperhidrosis), foul-smelling perspiration (bromhidrosis)
	Wound site	Wound abscess
	Vomitus	Abdominal irritation, contaminated food
Feces	Vomitus/oral cavity (fecal odor)	Bowel obstruction
	Rectal area	Fecal incontinence
Foul-smelling stools in infant	Stool	Malabsorption syndrome
Halitosis	Oral cavity	Poor dental and oral hygiene, gum disease
Sweet, fruity ketones	Oral cavity	Diabetic acidosis
Stale urine	Skin	Uremic acidosis
Sweet, heavy, thick odor	Draining wound	<i>Pseudomonas</i> (bacterial) infection
Musty odor	Casted body part	Infection inside cast
Fetid, sweet odor	Tracheostomy or mucus secretions	Infection of bronchial tree (<i>Pseudomonas</i> bacteria)

Palpation

Palpation involves using the sense of touch to gather information. Through touch you make judgments about expected and unexpected findings of the skin or underlying tissue, muscle, and bones. For example, you palpate the skin for temperature, moisture, texture, turgor, tenderness, and thickness and the abdomen for tenderness, distention, or masses. Use different parts of the hand to detect different characteristics (Table 30.5). The palmar surface of the hand and finger pads is more sensitive than the fingertips and is used to determine position, texture, size, consistency, masses, fluid, and crepitus (Fig. 30.1A). Assess body temperature by using the dorsal surface or back of the hand (Fig. 30.1B). Vibration is best felt on the palmar surface of the hand and fingers (Fig. 30.1C).

TABLE 30.5**Examples of Characteristics Measured By Palpation**

Area Examined	Criteria Measured	Portion of Hand To Use
Skin	Temperature	Dorsum of hand/fingers
	Moisture	Palmar surface
	Texture	Palmar surface
	Turgor and elasticity	Grasping with fingertips
	Tenderness	Finger pads/palmar surface of fingers
	Thickness	Palmar surface
Organs (e.g., liver and intestine)	Size Shape Tenderness Absence of masses	Entire palmar surface of hand or palmar surface of fingers
Glands (e.g., thyroid and lymph)	Swelling	Pads of fingertips
	Symmetry and mobility	
Blood vessels (e.g., carotid or femoral artery)	Pulse amplitude Elasticity Rate Rhythm	Palmar surface/pads of fingertips
Thorax	Excursion	Palmar surface
	Tenderness	Finger pads/palmar surface of fingers
	Fremitus	Palmar or ulnar surface of entire hand

FIG. 30.1 **A**, Radial pulse is detected with pads of fingertips, the most sensitive part of the hand. **B**, Dorsum of hand detects temperature variations in skin. **C**, Bony part of palm at base of fingers detects vibrations.

Touching a patient is a personal experience for both you and the patient. Display respect and concern throughout an examination. Before palpating consider the patient's condition and ability to tolerate the assessment techniques, paying close attention to areas that are painful or tender. In addition, always be conscious of the environment and any threats to the patient's safety.

Prepare for palpation by warming hands, keeping fingernails short, and using a gentle approach. Palpation proceeds slowly, gently, and deliberately. Encourage the patient to relax, and help the patient feel

comfortable since tense muscles make assessment more difficult. To promote relaxation, have him or her take slow, deep breaths and place both arms along the sides of the body. Ask the patient to point to more sensitive areas, watching for nonverbal signs of discomfort. *Palpate tender areas last.*

Two types of palpation, light and deep, are used for physical examination. Perform light palpation by placing the hand on the body part being examined; it also involves pressing inward about 1 cm (½inch). Light, superficial palpation of structures such as the abdomen gives the patient the chance to identify areas of tenderness (Fig. 30.2A). Inquire about areas of tenderness and assess them further for potentially serious pathologies. Use deep palpation to examine the condition of organs such as those in the abdomen (Fig. 30.2B). Depress the area under examination approximately 4 cm (2 inches) (Ball et al., 2019), using one or both hands (bimanually). When using bimanual palpation, relax one hand (sensing hand) and place it lightly over the patient's skin. The other hand (active hand) helps apply pressure to the sensing hand. The lower hand does not exert pressure directly and thus remains sensitive to detect organ characteristics. For safety deep palpation should be used with caution in a patient with discomfort in the area to be palpated.

FIG. 30.2 **A**, During light palpation gentle pressure against underlying skin and tissues can detect areas of irregularity and tenderness. **B**, During deep palpation depress tissue to assess condition of underlying organs.

Percussion

Percussion involves tapping the skin with the fingertips to vibrate underlying tissues and organs. The vibration travels through body tissues,

and the character of the resulting sound reflects the density of the underlying tissue. The denser the tissue, the quieter is the sound. By knowing how various densities influence sound, it is possible to locate organs or masses, map their edges, and determine their size. An abnormal sound from what is expected in that area suggests a mass or substance such as air or fluid within an organ or body cavity. The skill of percussion is used more often by advanced practice nurses than by nurses in daily practice at the bedside.

Auscultation

Auscultation involves listening to sounds the body makes to detect variations from normal. Some sounds such as speech and coughing can be heard without additional equipment, but a stethoscope is necessary to hear internal body sounds.

Internal body sounds are created by blood, air, or gastric contents as they move against the body structures. For example, normal heart sounds are created when the heart valves close, moving blood to the next part of the cardiovascular system. Normal sounds for each body system are discussed later in this chapter. Learn to recognize abnormal sounds after learning normal variations. Becoming more proficient in auscultation occurs by knowing the types of sounds each body structure makes and the location in which the sounds are heard best.

To auscultate internal sounds, you need to hear well, have a good stethoscope, and know how to use it properly. Nurses with hearing disorders can obtain stethoscopes with extra sound amplification. There are two aspects to the stethoscope. The bell is best for hearing low-pitched sounds such as vascular and certain heart sounds, and the diaphragm is best for listening to high-pitched sounds such as bowel and lung sounds.

By practicing with the stethoscope, you become proficient at using it and realize when sounds are clear and when there are extraneous sounds. Extraneous sounds created by rubbing against the tubing or chest piece interfere with auscultation of body organ sounds. By deliberately producing these sounds, you learn to recognize and disregard them during the actual examination. [Box 30.2](#) contains ways to practice using the stethoscope and techniques for caring for the stethoscope. Describe any sound you hear using the following characteristics:

Box 30.2 Use and Care of the Stethoscope

- Ensure that the earpiece follows the contour of the ear canals. Learn which fit is best for you by comparing amplification of sounds with the earpieces in both directions.
- Place the earpieces in your ears with the tips turned toward the face. *Lightly* blow into the diaphragm. Again, place the earpieces in your ears, this time with the ends turned toward the back of the head. *Lightly* blow into the diaphragm. You will find that you hear clearer sounds with the earpiece turned toward the face. After you have learned the right fit for the loudest amplification, wear the stethoscope the same way each time.
- Put on the stethoscope and *lightly* blow into the diaphragm. If the sound is barely audible, *lightly* blow into the bell. Sound is carried through only one part of the chest piece at a time. If the sound is greatly amplified through the diaphragm, the diaphragm is in position for use. If the sound is barely audible through the diaphragm, the bell is in position for use. Rotation of the diaphragm and bell places the chest piece in the desired position. Leave the diaphragm in position for the next exercise.
- Place the diaphragm over the anterior part of your chest. Ask a friend to speak in a normal conversational tone. Environmental noise seriously detracts from hearing the noise created by body organs. When using a stethoscope, the patient and the examiner need to remain quiet.
- Put on the stethoscope and gently tap the tubing. It is often difficult to avoid stretching or moving the stethoscope tubing. The examiner is in a position so that the tubing hangs free. Moving or touching the tubing creates extraneous sounds.
- *Care of the stethoscope:* Remove earpieces regularly and clean; remove cerumen (earwax). Keep the bell and diaphragm free of dust, lint, and body oils. Keep the tubing away from any body oils. Avoid draping the stethoscope around the neck next to the skin. Clean daily or after soiling by wiping the entire stethoscope (e.g., diaphragm, tubing) with alcohol. Be sure to dry all parts thoroughly. Follow manufacturer recommendations.
- *Infection control:* Harmful bacteria such as gram-positive bacilli, methicillin-resistant *Staphylococcus aureus* (MRSA), nonaureus

Staphylococcus, *Enterobacter cloacae*, and methicillin-sensitive *S. aureus* can be transferred from patient to patient when using portable equipment such as stethoscopes. Clean the stethoscope (diaphragm/bell) *before* reuse on another patient. Using a disinfectant such as isopropyl alcohol (with or without chlorhexidine), benzalkonium, or sodium hypochlorite is effective in reducing the number of bacterial colonies. Hand foam serves this purpose well. Earpieces of stethoscopes are sources of transferable bacteria. When you inadvertently touch your ears and care for the patient, potential pathogens could contaminate the earpieces. Using hand hygiene before and after patient contact decreases the risk of transmitting microorganisms from your ear to your patient. Follow the institution's infection control guidelines, especially Contact Precautions, to decrease this risk.

- Frequency indicates the number of sound wave cycles generated per second by a vibrating object. The higher the frequency, the higher the pitch of a sound and vice versa.
- Loudness refers to the amplitude of a sound wave. Auscultated sounds range from soft to loud.
- Quality refers to sounds of similar frequency and loudness from different sources. Terms such as *blowing* or *gurgling* describe the quality of sound.
- Duration means the length of time that sound vibrations last. The duration of sound is short, medium, or long. Layers of soft tissue dampen the duration of sounds from deep internal organs.

Auscultation requires concentration and practice. While listening, know which sounds are expected in certain parts of the body and what causes the sounds. Expected sounds are discussed in each body system section of this chapter. After understanding the cause and character of normal auscultated sounds, it becomes easier to recognize abnormal sounds and their origins.

General Survey

When a patient first enters an examination room, observe his or her walk and general appearance and be attentive to his or her behavior and dress. A general survey, or appraisal, of the patient's presentation and behavior provides information about characteristics of an illness, the patient's ability to function independently, body image, emotional state, recent changes in weight, and developmental status. If there are abnormalities or problems, assess the affected body system more closely during the full examination.

General Appearance and Behavior

Assess appearance and behavior while preparing the patient for the examination. For this review include:

- *Gender and race:* A person's gender affects the type of examination performed and the order of the assessments. Different physical features are related to gender and race. Certain illnesses are more likely to affect a specific gender or race (e.g., the incidence of skin cancer is more common in whites than in blacks, prostate cancer is higher in black men than in white men, and cancer of the bladder is higher in men than in women) ([ACS, 2018b](#)).
- *Age:* Age influences normal physical characteristics and a person's ability to participate in some parts of the examination.
- *Signs of distress:* Sometimes obvious signs or symptoms indicate pain (grimacing, splinting painful area), difficulty breathing (shortness of breath, sternal retractions), or anxiety. Set priorities and examine the related physical areas first.
- *Body type:* Observe whether the patient appears trim and muscular, obese, or excessively thin. Body type reflects the level of health, age, and lifestyle.
- *Posture:* Normal standing posture shows an upright stance with parallel alignment of the hips and shoulders. Normal sitting posture involves some degree of rounding of the shoulders. Observe whether the patient has a slumped, erect, or bent posture, which reflects mood or pain. Changes in older adult physiology often result in a stooped, forward-bent posture, with the hips and knees somewhat flexed and the arms bent at the elbows.

- *Gait*: Observe as the patient walks into the room or stands at the bedside (if the patient is ambulatory). Note whether movements are coordinated or uncoordinated. A person normally walks smoothly, with the arms swinging freely at the sides and the head and face leading the body.
- *Body movements*: Observe whether movements are purposeful, noting any tremors involving the extremities. Determine whether any body parts are immobile.
- *Hygiene and grooming*: Note the patient's level of cleanliness by observing the appearance of the hair, skin, and fingernails. Determine whether his or her clothes are clean. Grooming depends on the patient's cognitive and emotional function, daily or social activities, and occupation. Observe for excessive use of cosmetics or colognes that could indicate a change in self-perception.
- *Dress*: Culture, lifestyle, socioeconomic level, and personal preference affect the selection and wearing of clothing. However, you assess whether the clothing is appropriate for the temperature, weather conditions, or setting. People who are depressed or mentally ill may not be able to select proper clothing, and an older adult might tend to wear extra clothing because of sensitivity to cold.
- *Body odor*: An unpleasant body odor can result from physical exercise, poor hygiene, or certain disease states. Validate any odors that might indicate a health problem.
- *Affect and mood*: Affect is how a person appears to others. Patients express mood or emotional state verbally and nonverbally. Determine whether verbal expressions match nonverbal behavior and whether the mood is appropriate for the situation. By maintaining eye contact you can observe facial expressions while asking questions.
- *Speech*: Normal speech is understandable and moderately paced and shows an association with the person's thoughts. However, emotions or neurological impairment sometimes causes rapid or slowed speech. Observe whether the patient speaks in a normal tone with clear inflection of words.
- *Signs of patient abuse*: During the examination observe whether the patient fears his or her spouse or partner, a caregiver, a parent, or an adult child. Abuse of children, women, and older adults is a growing health problem. Consider any obvious physical injury or

neglect as signs of possible abuse (e.g., evidence of malnutrition or presence of bruising on the extremities or trunk) (WHO, 2018). Abuse occurs in many forms: physical, mental or emotional, sexual, social, and financial or economic. Observe the behavior of the individual for any signs of frustration, explanations that do not fit his or her physical presentation, or signs of injury. Most states mandate a report to a social service center when abuse or neglect is suspected (Box 30.3). It is difficult to detect abuse because victims often do not report that they are in abusive situations. If you suspect abuse, find a way to interview the patient in private; patients are more likely to reveal any problems when the suspected abuser is absent from the room. It is imperative that you, the health care team, and the proper authorities help the patient find safe housing or seek protection from the abuser since the risk for further abuse is high once the victim has reported it or tries to leave the abusive situation.

Box 30.3 Clinical Indicators of Abuse

Physical Findings	Behavioral Findings
Child Abuse	
Vaginal or penile discharge Blood on underclothing Pain, itching, or unusual odor in genital area Genital injuries Difficulty sitting or walking Pain while urinating; recurrent urinary tract infections Foreign bodies in rectum, urethra, or vagina Sexually transmitted infections Pregnancy in young adolescent	Problem sleeping or eating, anxiety, depression Fear of certain people or places Play activities recreate the abuse situation Regressed behavior Sexual acting out Knowledge of explicit sexual matters Preoccupation with others' or own genitals Profound and rapid personality changes Rapidly declining school performance Poor relationship with peers
Intimate Partner Violence	
Injuries and trauma inconsistent with reported cause Multiple injuries involving head, face, neck, breasts, abdomen, and genitalia (black eyes, orbital fractures, broken nose, fractured skull, lip lacerations, broken teeth, vaginal tears) X-ray films showing old and new fractures in different stages of healing Abrasions, lacerations, bruises/welts Burns from cigarettes or other Human bites Unexplained injuries (e.g., bruises, fractures, and welts) Strangulation marks on neck from rope burns or bruises; throat pain, voice changes, trouble swallowing; damage to hyoid bone Stress-related disorders such as irritable bowel syndrome, exacerbation of asthma, or chronic pain	Overuse of health services Thoughts of or attempted suicide Eating or sleeping disorders Anxiety and panic attacks Pattern of substance abuse (follows physical abuse) Low self-esteem Depression, problems with eating or sleeping Sense of helplessness Guilt Smoking Stress-related complaints (headache, anxiety) Financial dependence on abuser Isolation from others Unsafe sexual behaviors
Older-Adult Abuse	
Injuries and trauma inconsistent with reported cause (scratch, bruise, or bite) Hematomas, bruises at various stages of resolution Unexplained bruises or welts, pattern bruises Burns Bruises, chafing, excoriation on wrist or legs (restraints) Fractures inconsistent with cause described Dried blood Overmedication or undermedication Exposure to severe weather, cold or hot Torn, bloody underwear or vaginal and anal bruises Sunken eyes or loss of weight Extreme thirst Bed sores	Dependent on caregiver Physically and/or cognitively impaired Combative, verbally aggressive Wandering Minimal social support Prolonged interval between injury and medical treatment Life circumstances do not match size of patient's estate Uncommunicative or isolated

Data from Cooper C, et al: The prevalence of elder abuse and neglect: a systematic review, *Age Aging* 37(2):151, 2008; Hockenberry MJ, Wilson P: *Wong's nursing care of infants and children*, ed 10, St Louis, 2019, Mosby; World Health Organization (WHO): *Intimate partner violence*, 2012, http://www.who.int/reproductivehealth/publications/violence/rhr12_36/en/index.html. Accessed October 27, 2018.

- **Substance abuse:** Unusual or inconsistent behavior may be an indicator of substance abuse, which can affect all socioeconomic groups. Although a single patient visit to a clinic does not always reveal the problem, investigate unusual behaviors further with a well-focused history and physical examination. Always approach the patient in a caring and nonjudgmental way; substance abuse involves both emotional and lifestyle issues. **Box 30.4** lists characteristics of patients who should be further assessed for

potential substance abuse. A tool such as the online Tobacco, Alcohol, Prescription medication, and other Substance use (TAPS) tool can be used to assess a patient's risk for substance abuse (NIDA, 2018). If you suspect that alcohol abuse is a major problem, the CAGE questionnaire provides a useful set of questions to guide assessment. CAGE is an acronym for the following:

Box 30.4 Behaviors That Are Suspicious for Substance Abuse

Among adolescents and adults: Agitation; inappropriate behavior; problems thinking clearly, remembering, and paying attention; poor coordination; seizure; respiratory depression; coma; asphyxiation; aspiration; pulmonary edema; cardiac arrhythmias; immune system impairment; self-inflicted trauma; and suicidal ideation

Red flags:

- The risk of suicide, seizures, and violent behavior is high among substance abusers.
- Intoxicated patients, particularly those with phencyclidine (PCP) or methamphetamine intoxication, are at significant risk for becoming agitated and violent, placing themselves and others at risk for injury.

Observe for combinations or repetition of these behaviors:

- Frequently misses appointments
- Frequently requests written excuses for absence from school or work
- Drops out of school
- Chief complaints of insomnia, "bad nerves," or pain that do not fit a particular pattern
- Reports lost prescriptions (e.g., tranquilizers or pain medications) or asks for frequent refills
- Frequent emergency department visits
- History of changing health care providers or brings in medication bottles prescribed by several different providers
- History of gastrointestinal bleeds, peptic ulcers, pancreatitis, cellulitis, or frequent pulmonary infections
- Frequent sexually transmitted infections (STIs), complicated pregnancies, multiple abortions, or sexual dysfunction
- Complaints of chest pains or palpitations or has a history of admissions to rule out heart attacks

- History of activities that place the patient at risk for human immunodeficiency virus (HIV) infection (multiple partners, multiple rapes)
- Family history of addiction; history of childhood sexual, physical, or emotional abuse; or social and financial or marital problems
- Intimate partner violence

Data from American Psychiatric Association: *Diagnostic and statistical manual of mental disorders*, ed 5, text revision, Washington, DC, 2013, The Association; American Society of Addiction Medicine and Widlitz M, Marin D: Substance abuse in older adults: an overview, *Geriatrics* 57(12):29, 2002; and Walsh K, et al: Examining the interface between substance misuse and intimate partner violence, *Substance Abuse Res Treatment* 3:25, 2009; and National Institute on Drug Abuse: *Drugs, brains and behavior: the science of addiction*, 2018, <https://www.drugabuse.gov/publications/drugs-brains-behavior-science-addiction/introduction>. Accessed January 22, 2019.

- Have you ever felt the need to **Cut down** on your drinking or drug use?
- Have people **Annoyed** you by criticizing your drinking or drug use?
- Have you ever felt bad or **Guilty** about your drinking or drug use?
- Have you ever used or had a drink first thing in the morning as an **Eye-opener** to steady your nerves or feel normal?

Among older adults, risk factors for development of alcohol-related problems include chronic medical disorders, sleep disorders, social isolation, loneliness, bereavement, and acute or chronic pain. When assessing adolescents there are brief online tools to screen substance use, such as the Brief Screener for Tobacco, Alcohol, and other Drugs (BSTAD) and Screening to Brief Intervention (S2BI) ([NIDA, 2017](#)).

Vital Signs

After completing the general survey, measure the patient's vital signs. Measurement of vital signs is more accurate if completed before beginning positional changes or movements. If there is a chance that the vital signs are inaccurate when you first take them, recheck them later during the rest of the examination. Assess for pain, the fifth vital sign, whenever you take a patient's vital signs.

Height and Weight

The relationship of height and weight reflects a person's general health status. Assess every patient to identify whether he or she is at a healthy weight, underweight, overweight, or obese. Weight is routinely measured during health screenings, visits to physicians' offices or clinics, and on admission to the hospital. Infants and children are measured for both height and weight at each health care visit to assess for healthy growth and development. If older adults are underweight, difficulty with feeding and other functional activities is a possibility. Measuring height and weight of older adults, along with obtaining a dietary history (Box 30.5), shows risk factors for chronic diseases.

Box 30.5 Dietary History for Older Adults

- Does the older adult need or have help shopping for or preparing meals?
- Is income adequate for food purchasing? Food stamps or public assistance required?
- Does the patient ever skip meals?
- Are the five primary food groups from MyPlate (fruits, grains, protein, vegetables, dairy) represented in the daily diet (see Chapter 45) (USDA, 2018)?
- Does the older adult take nutritional supplements such as multivitamins?
- Does the older adult take any medication affecting appetite or absorption of nutrients?
- Does the older adult have any religious or cultural beliefs and practices that influence diet?
- Does the older adult have a special diet, food intolerances, or allergies? Does the patient's diet contain an unusual amount of alcohol, sweets, or fried food?
- Does the older adult have problems with chewing, swallowing, or salivation?
- Does the older adult have gastrointestinal problems that interfere with food intake?

Data from Meiner SE, Yeager JJ: *Gerontologic nursing*, ed 6 , St Louis, 2019, Elsevier; and US Department of Agriculture and US Department of Health and Human Services: *2015-2020 Dietary guidelines for Americans*, ed 8, Washington, DC, 2015, https://health.gov/dietaryguidelines/2015/resources/2015-2020_Dietary_Guidelines.pdf. Accessed September 22, 2019.

Evaluate a patient's weight and height, and assess for trends in weight changes. Assessments screen for abnormal weight changes. A patient's weight normally varies daily because of fluid loss or retention. Use the nursing history to identify possible causes for a change in weight (Table 30.6). For example, a downward trend in an older adult who is frail indicates a serious reduction in nutritional reserves. Ask the patient to report current height and weight, along with a history of any substantial weight gain or loss. A weight gain of 2 to 3 lb (0.9-1.4 kg) in 1 day indicates fluid-retention problems. A weight loss is considered significant if the patient has lost more than 5% of body weight in a month or 10% in 6 months.

TABLE 30.6**Nursing History for Weight Assessment**

Assessment	Rationale
Ask about total weight lost or gained; compare with usual weight; note time period for loss and whether it was planned (e.g., gradual, sudden, desired, or undesired).	Assessment determines severity of problem and reveals whether weight change is related to disease process, change in eating pattern, or pregnancy.
If weight loss desired, ask about eating habits, diet plan followed, food preparation, calorie intake, appetite, exercise pattern, support group participation, weight goal.	Assessment helps to determine appropriateness of diet plan followed.
If weight loss undesired, ask about anorexia; vomiting; diarrhea; thirst; frequent urination; and change in lifestyle, activity, and stress levels.	Assessment focuses on problems that cause weight loss (e.g., gastrointestinal problems).
Assess whether patient has noted changes in social aspects of eating; more meals in restaurants, rushing to eat meals, stress at work, or skipping meals.	Lifestyle changes sometimes contribute to weight changes.
Assess whether patient takes chemotherapy, diuretics, insulin, fluoxetine, prescription and nonprescription appetite suppressants, laxatives, oral hypoglycemics, or herbal supplements (weight loss); steroids, oral contraceptives, antidepressants, insulin (weight gain).	Weight gain or loss is a side effect of these medications.
Assess for preoccupation with body weight or body shape such as fasting, never feeling thin enough, unusually strict caloric intake or restrictions, laxative abuse, induced vomiting, amenorrhea, excessive exercise, alcohol intake.	Excesses indicate an eating disorder.

When a patient is hospitalized, daily weight is measured at the same time of day and on the same scale (Ball et al., 2019). This allows an objective comparison of subsequent weights. Accuracy of weight measurement is important because health care providers base medical and nursing decisions (e.g., drug dosage, medications) on changes.

Several different scales are available for use. Patients capable of bearing their own weight use a standing scale. You calibrate a standard platform scale by moving the large and small weights to zero. By adjusting the calibrating knob, the balance beam is leveled and steadied. The patient stands on the scale platform and remains still as the nurse adjusts the largest solid weight to the 50-lb or 22.5-kg increment under the patient's weight. Next the smaller weight is moved to balance the scale at the nearest $\frac{1}{4}$ lb or 0.1 kg (Ball et al., 2019). Electronic scales are calibrated automatically each time they are used and automatically display the weight within seconds.

Bed and chair scales are available for patients who are unable to bear weight. Newer electronic hospital beds have built-in electronic scales for

weighing patients who are not able to get out of bed.

You can use a basket or platform scale to weigh infants. Keep the room warm to prevent chills. Before weighing the infant, clean the infant scale and place a light cloth or paper cover on the surface to prevent cross-infection from urine or feces. Place a dry diaper on the scale and zero the scale so that the weight of the items on the scale will not be represented in the infant's weight. Once the scale is at zero, the naked infant can be placed on the scale and the diaper secured. When placing an infant in a basket or on a platform, hold a hand lightly above him or her to detect movements and prevent accidental falls. Measure an infant's weight in both ounces and grams.

In patients who can stand, measure height by having them remove their shoes. The standing surface should be clean. Use a measuring rod attached vertically to a weight scale, or use a tape ruler on the wall. As the patient stands erect, place a flat surface on his or her head that is even with the vertical measure. Then read the number on the scale or ruler that indicates his or her height in centimeters or inches.

Remove the shoes of a patient who cannot bear weight, and position the patient (such as an infant) supine on a firm surface. When measuring an infant, hold his or her head and make sure that his or her legs are straight at the knees. After positioning the infant, use a tape measure to measure length from the head to the bottom of the feet (Fig. 30.3). Record the infant's length to the nearest 0.5 cm ($\frac{1}{4}$ inch).

FIG. 30.3 Measurement of infant length.

From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing*, ed 7, St Louis, 2019, Elsevier.

Skin, Hair, and Nails

The integumentary system refers to the skin, hair, scalp, and nails. To assess, you first gather a health history to guide your examination and use the techniques of inspection and palpation.

Skin

Begin an assessment of the skin by focusing on the health history questions found in [Table 30.7](#). Then inspect all visible skin surfaces; assess less visible surfaces when you examine other body systems. Use the senses of sight, smell, and touch while inspecting and palpating the skin.

TABLE 30.7

Nursing History for Skin Assessment

Assessment	Rationale
Ask patient about history of changes in skin: dryness, pruritus, sores, rashes, lumps, color, texture, odor, and lesion that does not heal.	Patient is best source to recognize change. Usually skin cancer is first noticed as a localized change in skin color.
Consider whether patient has the following history: fair, freckled, ruddy complexion; light-colored hair or eyes; tendency to burn easily.	Characteristics are risk factors for skin cancer.
Determine whether patient works or spends excessive time outside. If so, ask whether patient wears sunscreen and the level of protection.	Exposed areas such as face and arms are more pigmented than rest of body. The American Cancer Society (2018b) recommends sun safety and use of sunscreen and lip balm with broad-spectrum protection and a sun protection factor (SPF) of 30 or higher and not sunbathing or indoor tanning.
Determine whether patient has noted lesions, rashes, or bruises.	Most skin changes do not develop suddenly. Change in character of lesion can indicate cancer. Bruising indicates trauma or bleeding disorder.
Question patient about frequency of bathing and type of soap used.	Excessive bathing and use of harsh soaps cause dry skin.
Ask whether patient has had recent trauma to skin.	Some injuries cause bruising and changes in skin texture.
Determine whether patient has history of allergies.	Skin rashes commonly occur from allergies.
Ask whether patient uses topical medications or home remedies on skin.	Incorrect use of topical agents causes inflammation or irritation.
Ask whether patient goes to tanning parlors, uses sunlamps, or takes tanning pills.	Overexposure of skin to these irritants can cause skin cancer.
Ask whether patient has family history of serious skin disorders such as skin cancer or psoriasis.	Family history can reveal information about patient's condition.
Determine whether patient works with creosote, coal, tar, petroleum products, arsenic compounds, or radium.	Exposure to these agents creates risk for skin cancer.

Assessment of the skin reveals the patient's health status related to oxygenation, circulation, nutrition, local tissue damage, and hydration. Check the condition of the patient's skin to determine the need for nursing care. If there is an alteration in integumentary status, then adequate nutrition and hydration may become priority goals of therapy (see [Chapter 45](#)).

Every patient has a risk for skin impairment in a hospital setting. This risk increases in certain situations, such as pressure against the skin when the patient is immobile, reactions to various medications used in treatment, and moisture if the patient is incontinent or has wound drainage. Patients at high risk are those who have neurological impairments, chronic illnesses, decreased mental status, poor tissue oxygenation, low cardiac output, or inadequate nutrition or those who have had orthopedic or vascular injuries. Patients who are homebound, in nursing homes, or in extended-care facilities are often at risk for pressure injuries, depending on their level of mobility and the presence of chronic illness. Routinely assess the skin of all patients, especially those at risk, to look for primary or initial lesions that develop. Without identification and appropriate care, primary lesions can quickly deteriorate to become secondary lesions that require more extensive nursing care. For example, the

development of a pressure injury lengthens a hospital stay unless it is prevented or discovered and treated early (see [Chapter 48](#)).

Adequate lighting is required when assessing the skin. Daylight is the best choice for identifying variations in skin color, especially for detecting skin changes in patients with dark skin. When sunlight is unavailable, fluorescent lighting is the next best choice. Room temperature also affects skin assessment. A room that is too warm causes superficial vasodilation, resulting in increased redness of the skin. A cool environment causes a sensitive patient to develop cyanosis around the lips and nail beds ([Ball et al., 2019](#)).

Although you inspect the skin over each part of the body during an examination, it is helpful to make a brief but careful overall visual sweep of the entire body. This approach provides a good idea of the distribution and extent of any lesions and the overall symmetry of skin color. Inspect all skin surfaces, making a point to do so when examining other body systems. Often overlooked, inspection of the feet is absolutely essential for patients with poor circulation or diabetes. If any abnormalities are found during an examination, palpate the involved areas. Use disposable gloves for palpation if open, moist, or draining lesions are present.

Throughout the examination remain alert for skin odors. Black and white adolescents and adults ordinarily have body odor because they have a greater number of functioning apocrine glands. In contrast, Asians and Native Americans/American Indians often do not ([Ball et al., 2019](#)). [Fig. 30.4](#) illustrates a normal cross-section of the skin.

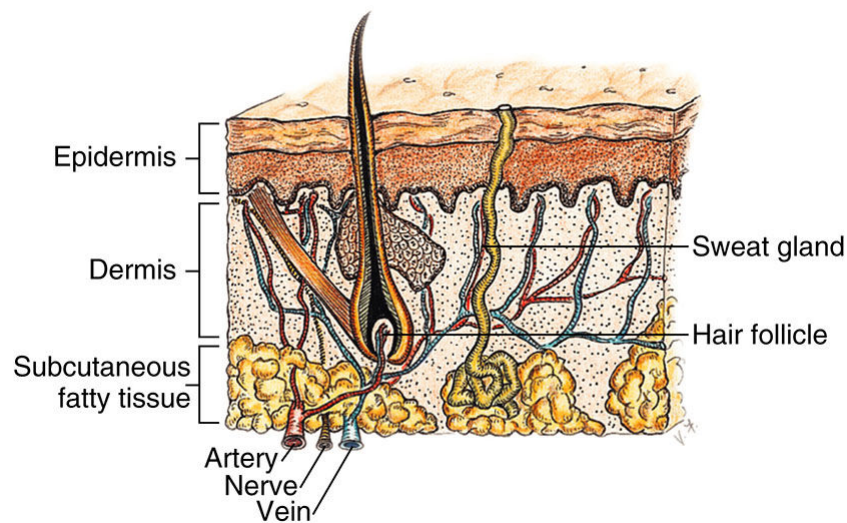

FIG. 30.4 Cross-section of skin reveals three layers: epidermis, dermis, and subcutaneous fatty tissues.

Color

Skin color varies from body part to body part and from person to person. Despite individual variations, it is usually uniform over the body. [Table 30.8](#) lists common variations. Normal skin pigmentation ranges in tone from ivory or light pink to ruddy pink in light skin and from light to deep brown or olive in dark skin. In older adults, pigmentation increases unevenly, causing discolored skin. While inspecting the skin, be aware that cosmetics or tanning agents sometimes mask normal skin color.

TABLE 30.8

Skin Color Variations

Color	Condition	Causes	Assessment Locations
Bluish (cyanosis)	Increased amount of deoxygenated hemoglobin (associated with hypoxia)	Heart or lung disease, cold environment	Nail beds, lips, mouth, skin (severe cases)
Pallor (decrease in color)	Reduced amount of oxyhemoglobin	Anemia	Face, conjunctivae, nail beds, palms of hands
	Reduced visibility of oxyhemoglobin resulting from decreased blood flow	Shock	Skin, nail beds, conjunctivae, lips
Loss of pigmentation	Vitiligo	Congenital or autoimmune condition causing lack of pigment	Patchy areas on skin over face, hands, arms
Yellow-orange (jaundice)	Increased deposit of bilirubin in tissues	Liver disease, destruction of red blood cells	Sclera, mucous membranes, skin
Red (erythema)	Increased visibility of oxyhemoglobin caused by dilation or increased blood flow	Fever, direct trauma, blushing, alcohol intake	Face, area of trauma, sacrum, shoulders, other common sites for pressure injuries
Tan-brown	Increased amount of melanin	Suntan, pregnancy	Areas exposed to sun: face, arms, areolas, nipples

The assessment of color first involves areas of the skin not exposed to the sun such as the palms of the hands. Note whether the skin is unusually pale or dark. Areas exposed to the sun such as the face and arms are darker. It is more difficult to note changes such as pallor or cyanosis in patients with dark skin. Usually color hues are most evident in the palms, soles of the feet, lips, tongue, and nail beds. Areas of increased (hyperpigmentation) and decreased (hypopigmentation) color are common. Skin creases and folds are darker than the rest of the body in patients with dark skin.

Inspect sites where abnormalities are more easily identified. For example, pallor is more evident in the face, buccal (mouth) mucosa, conjunctiva, and nail beds. Observe for cyanosis (bluish discoloration) in the lips, nail beds, palpebral conjunctivae, and palms. In recognizing pallor in a patient with dark skin, observe that normal brown skin appears to be yellow-brown and normal black skin appears to be ashen gray. Also assess the lips, nail beds, and mucous membranes for generalized pallor; if pallor is present, the mucous membranes are ashen gray. Assess for cyanosis in a patient with dark skin in areas where pigmentation occurs the least (conjunctiva, sclera, buccal mucosa, tongue, lips, nail beds, and palms and soles). In addition, verify these findings with clinical manifestations (Ball et al., 2019).

Discoloration of the skin occurs on different areas of the body for varying reasons. A patient’s sclera is the best site to inspect for **jaundice** (yellow-orange discoloration). Normal reactive hyperemia, or redness, is most often seen in regions exposed to pressure such as the sacrum, heels, and greater trochanter. Inspect for any patches or areas of skin color variation. Localized skin changes such as pallor or **erythema** (red discoloration) indicate circulatory changes. It is difficult to observe erythema in a patient with dark skin; thus palpate the area for heat and warmth to note the presence of skin inflammation. For example, you notice an area of erythema in a patient with dark skin that is caused by localized vasodilation resulting from a sunburn, inflammation, or fever. Compare the area with a different part of the skin to detect a difference in temperature. An area of an extremity that appears unusually pale results from arterial occlusion or edema. Be sure to ask whether the patient has noticed any changes in skin coloring.

There is also a pattern of findings associated with patients who are chemically dependent or abuse intravenous (IV) drugs (Table 30.9). It is sometimes difficult to recognize signs and symptoms through an isolated examination. A patient who takes repeated IV injections has edematous, reddened, and warm areas along the arms and legs. This pattern suggests recent injections. Areas of old injection sites appear as hyperpigmented and shiny or scarred.

TABLE 30.9**Physical Findings of the Skin Indicative of Substance Abuse**

Skin Finding	Commonly Associated Drug
Diaphoresis	Sedative hypnotic (including alcohol)
Spider angiomas	Alcohol, stimulants
Burns (especially fingers)	Alcohol
Needle marks	Opioids
Contusion, abrasions, cuts, scars	Alcohol, other sedative hypnotics, intravenous (IV) opioids
“Homemade” tattoos	Cocaine, IV opioids (prevents detection of injection sites)
Vasculitis	Cocaine
Red, dry skin	Phencyclidine (PCP)

Modified from Burchum J, Rosenthal L, *Lehne’s pharmacology for nursing care*, ed 10, St Louis, 2019, Saunders; Ries R, Wilford B: *Principles of addiction medicine*, ed 5, Chevy Chase, MD, 2014, Lippincott Williams & Wilkins.

Moisture

The hydration of skin and mucous membranes helps to reveal body fluid imbalances, changes in the environment of the skin, and regulation of body temperature. Moisture refers to wetness and oiliness. The skin is normally smooth and dry. Skinfolds such as the axillae are normally moist. Minimal perspiration or oiliness is often present (Ball et al., 2019). Increased perspiration can be associated with activity, exposure to warm environments, obesity, anxiety, or excitement. Use ungloved fingertips to palpate skin surfaces. Observe for dullness, dryness, crusting, and flaking that resembles dandruff when the skin surface is lightly rubbed. Excessively dry skin is common in older adults because their sebaceous and sweat gland activity decreases, reducing perspiration (Ball et al., 2019). Other factors causing dry skin include lack of humidity, exposure to sun, smoking, stress, excessive perspiration, and dehydration. Excessive dryness worsens existing skin conditions such as eczema and dermatitis. Patients with large abdominal skinfolds are at high risk for moisture within the skinfolds. Excessive moisture may cause maceration of the skin or softening of the tissues, resulting in an increased risk for breakdown (see Chapter 48).

Temperature

The temperature of the skin depends on the amount of blood circulating through the dermis. Increased or decreased skin temperature indicates an increase or decrease in blood flow. An increase in skin temperature often accompanies localized erythema or redness of the skin. A reduction in skin temperature often accompanies pallor and reflects a decrease in blood flow. Remember that a cold or excessively warm examination room can cause changes in the patient’s skin temperature and color.

Accurately assess temperature by palpating the skin with the dorsum or back of the hand and compare symmetrical body parts. Normally the skin temperature is warm. Sometimes it is the same throughout the body, and other times it varies in one area. Always assess skin temperature for patients at risk of having impaired circulation such as after a cast application or vascular surgery. A stage I pressure injury can be identified early by noting warmth over an area of erythema on the skin (see Chapter 48).

Texture

Texture refers to the appearance of the surface of the skin and how the deeper layers feel. By palpating lightly with the fingertips, you determine whether the patient’s skin is smooth or rough, thin or thick, tight or supple, and **indurated** (hardened) or soft. The texture of the skin is normally smooth, soft, even, and flexible in children and adults. However, the texture is usually not uniform throughout, with thicker texture over the palms of the hand and soles of the feet. In older adults the skin becomes wrinkled and leathery because of a decrease in collagen, subcutaneous fat, and sweat glands.

Localized skin changes result from trauma, surgical wounds, or lesions. When there are irregularities in texture such as scars or indurations, ask the patient about recent injury to the skin. Deeper palpation sometimes reveals irregularities such as tenderness or localized areas of induration, which can be caused by an injury or repeated injections.

Turgor

Turgor refers to the elasticity of the skin. To assess skin turgor, grasp a fold of skin on the back of the forearm or sternal area with the fingertips and release (Fig. 30.5). Normally the skin loses its elasticity with age, but fluid balance can also affect skin turgor. Edema or dehydration diminishes turgor and makes the skin tauter. Since the skin on the back of the hand is normally loose and thin, turgor is not assessed reliably at that site (Ball et al., 2019). Normally the skin lifts easily and falls immediately back to its resting position. When turgor is poor, it stays pinched and shows tenting. Evaluate the ease with which the skin moves and the speed at which it returns to its resting state. Failure of the skin to reassume its normal contour or shape indicates dehydration. A patient with poor skin turgor does not have resilience to the normal wear and tear on the skin, and a decrease in turgor predisposes him or her to skin breakdown.

FIG. 30.5 Assessment for skin turgor.

Vascularity

The circulation of the skin affects color in localized areas and leads to the appearance of superficial blood vessels. Vascularity occurs in localized pressure areas when patients remain in one position. Vascularity appears reddened, pink, or pale (see Chapter 48). With aging, capillaries become fragile and more easily injured. **Petechiae** are nonblanching, pinpoint-size, red or purple spots on the skin caused by small hemorrhages in the skin layers. Many petechiae have no known cause; but some may indicate serious blood-clotting disorders, drug reactions, or liver disease.

Edema

Edema is present when areas of the skin become swollen or edematous from a buildup of fluid in the tissues. Direct trauma and impairment of venous return are two common causes of edema. Inspect edematous areas for location, color, and shape. The formation of edema separates the surface of the skin from the pigmented and vascular layers, masking skin color. Edematous skin also appears stretched and shiny. Palpate edematous areas to determine mobility, consistency, and tenderness. When pressure from the examiner's fingers leaves an indentation in the edematous area, it is called pitting edema. To assess

the degree of pitting edema, press the edematous area firmly with the thumb for several seconds and release. The depth of pitting, recorded in millimeters, determines the degree of edema (Ball et al., 2019). For example, 1+ edema equals a 2-mm depth, 2+ edema equals a 4-mm depth, 3+ equals 6 mm, and 4+ equals 8 mm (Fig. 30.6).

FIG. 30.6 Assessing for pitting edema.
From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Lesions

The term *lesion* refers broadly to any unusual finding of the skin surface. Normally the skin is free of lesions, except for common freckles or age-related changes such as skin tags, senile keratosis (thickening of skin), cherry angiomas (ruby red papules), and atrophic warts. Lesions that are primary occur as an initial spontaneous sign of a pathological process such as with an insect bite. Secondary lesions result from later formation or trauma to a primary lesion such as a pressure injury. When you find a lesion, collect standard information about its color, location, texture, size, shape, type, grouping (clustered or linear), and distribution (localized or generalized). Next observe for any exudate, odor, amount, and consistency. Measure the size of the lesion in centimeters by using a small, clear, flexible ruler. Measure each lesion for height, width, and depth.

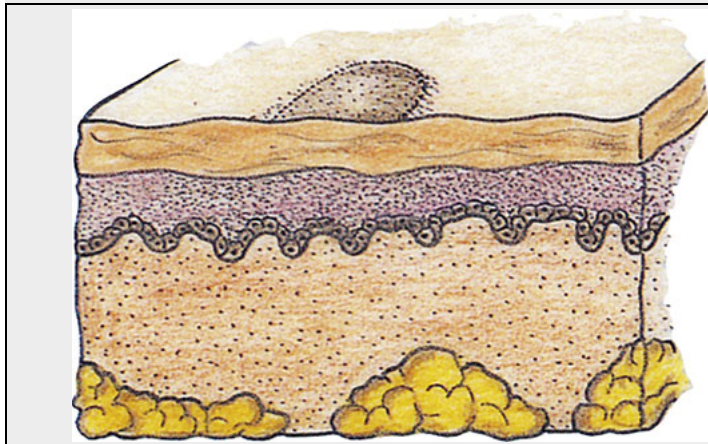

Palpation helps determine the mobility, contour (flat, raised, or depressed), and consistency (soft or indurated) of a lesion. Certain types of lesions present characteristic patterns. For example, a tumor is usually an elevated, solid lesion larger than 2 cm (1 inch). Primary lesions such as macules and nodules come from some stimulus to the skin (Box 30.6). Secondary lesions such as ulcers occur as alterations in primary lesions. After you identify a lesion, closely inspect it in good lighting. Palpate gently, covering the entire area of the lesion. If it is moist or draining fluid, wear gloves during palpation and pay attention to whether the patient identifies any areas of tenderness.

Box 30.6 Types of Primary Skin Lesions

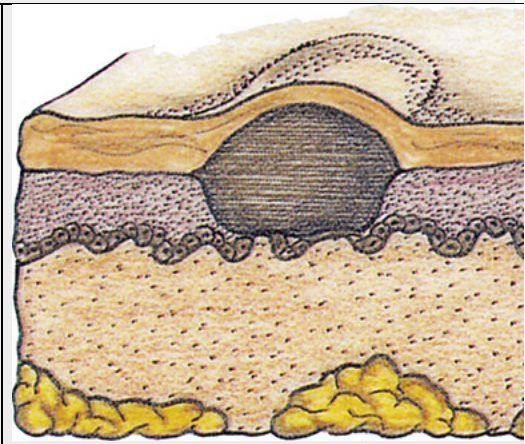

Nine types of primary skin lesions are:

- **Macule:** Flat, nonpalpable change in skin color; smaller than 1 cm (e.g., freckle, petechiae).
- **Papule:** Palpable, circumscribed, solid elevation in skin; smaller than 1 cm (e.g., elevated nevus).
- **Nodule:** Elevated solid mass, deeper and firmer than papule; 1-2 cm (e.g., wart).
- **Tumor:** Solid mass that extends deep through subcutaneous tissue; larger than 1-2 cm (e.g., epithelioma).
- **Wheal:** Irregularly shaped, elevated area or superficial localized edema; varies in size (e.g., hive, mosquito bite).
- **Vesicle:** Circumscribed elevation of skin filled with serous fluid, smaller than 1 cm (e.g., herpes simplex, chickenpox).
- **Pustule:** Circumscribed elevation of skin similar to vesicle but filled with pus; varies in size (e.g., acne, staphylococcal

infection). • Ulcer: Deep loss of skin surface that extends to dermis and frequently bleeds and scars; varies in size (e.g., venous stasis ulcer). • Atrophy: Thinning of skin with loss of normal skin furrow, with skin appearing shiny and translucent; varies in size (e.g., arterial insufficiency).

Macule: Flat, nonpalpable change in skin color; smaller than 1 cm (e.g., freckle, petechiae)

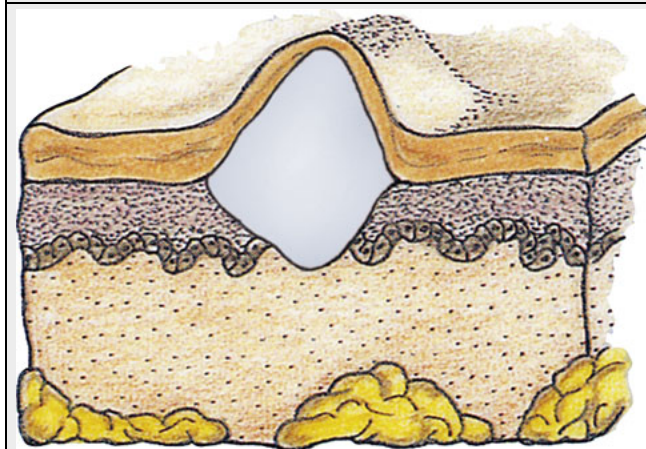

Papule: Palpable, circumscribed, solid elevation in skin; small (e.g., elevated nevus)

Tumor: Solid mass that extends deep through subcutaneous tissue; larger than 1-2 cm (e.g., epithelioma)

Wheal: Irregularly shaped, elevated area or superficial localization; varies in size (e.g., hive, mosquito bite)

Pustule: Circumscribed elevation of skin similar to vesicle but filled with pus; varies in size (e.g., acne, staphylococcal infection)

Ulcer: Deep loss of skin surface that extends to dermis and subcutaneous tissue and scars; varies in size (e.g., venous stasis ulcer)

Skin (cutaneous) malignancies are the most common neoplasms. For this reason you need to complete a thorough skin assessment on all patients. Cancerous lesions have distinct features and over time undergo changes in color and size (Box 30.7). Basal cell carcinoma is most common in areas exposed to the sun and frequently occurs with a history of sun damage; it almost never spreads to other parts of the

body. Squamous cell carcinoma is more serious than basal cell and develops on the outer layers of sun-exposed skin; these cells may travel to lymph nodes and throughout the body. Malignant melanoma, a skin cancer that develops from melanocytes, begins as a mole or other area that has changed in appearance and is usually located on normal skin. (Note: Melanoma also can originate in noncutaneous primary sites, including mucosal epithelium [GI tract], retinas, and leptomeninges.) In African Americans (more than in other races) it can also appear under fingernails or on the palms of the hands and soles of the feet. Use the *ABCD* mnemonic to assess the skin for any type of carcinoma (ACS, 2018b):

Box 30.7 Skin Malignancies

Basal Cell Carcinoma

- 0.5- to 1-cm crusted lesion that is flat or raised and has a rolled, somewhat scaly border
- Frequent appearance of underlying, widely dilated blood vessels within the lesion

Squamous Cell Carcinoma

- Occurs more often on mucosal surfaces and nonexposed areas of skin than basal cell

- 0.5- to 1.5-cm scaly lesion sometimes ulcerated or crusted; appears frequently and grows more rapidly than basal cell

Melanoma

- 0.5- to 1-cm brown, flat lesion; appears on sun-exposed or nonexposed skin; variegated pigmentation, irregular borders, and indistinct margins
- Ulceration, recent growth, or recent changes in long-standing mole are ominous signs

Illustrations from Belcher AE: *Cancer nursing*, St Louis, 1992, Mosby; Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 3, St Louis, 1996, Mosby; and Zitelli BJ, et al: *Zitelli and Davis' atlas of pediatric physical diagnosis*, ed 7, St Louis, 2018, Saunders.

- Asymmetry—Look for an uneven shape. One half of mole does not match the other half.
- Border irregularity—Look for edges that are blurred, notched, or ragged.
- Color—Look for pigmentation that is not uniform; variegated areas of blue, black, and brown and areas of pink, white, gray, blue, or red are abnormal.
- Diameter—Look for areas greater than 6 mm (about the size of a typical pencil eraser).

Report abnormal lesions to the health care provider for further examination. Since ultraviolet light of the sun or tanning beds increases the risk for development of skin cancers, teach patients about the risks that exist. In addition, using individualized teaching materials, teach patients how to perform a skin self-examination.

Hair and Scalp

Assess a patient's hair during all parts of the examination. Two types of hair cover the body: soft, fine, vellus hair, which covers the body; and coarse, long, thick terminal hair, which is easily visible on the scalp, axillae, and pubic areas and in the facial beard on men. First obtain health history information listed in [Table 30.10](#). Prepare to inspect the condition and distribution of hair and the integrity of the scalp by first obtaining a good light source.

TABLE 30.10

Nursing History for Hair and Scalp Assessment

Assessment	Rationale
Ask patient whether he or she is wearing a wig or hairpiece; if so, ask him or her to remove it.	Wigs or hairpieces interfere with inspection of hair and scalp. (Patient sometimes requests to omit this part of examination.)
Determine whether patient has noted change in growth, loss of hair, or change in texture or color.	Change often occurs slowly over time.
Identify type of hair-care products used for grooming.	Excessive use of chemical agents and burning of hair causes drying and brittleness.
Determine whether patient has had chemotherapy (drugs that cause hair loss) recently or taken a vasodilator (minoxidil) for hair growth.	Chemotherapeutic agents kill cells that rapidly multiply such as tumor and normal hair cells. Minoxidil causes excessive hair growth.
Has patient noted changes in diet or appetite?	Nutrition influences condition of hair.

Inspection

During inspection explain that it is necessary to separate parts of the hair to detect abnormalities. Wear a pair of clean gloves if open lesions or lice are noted.

First inspect the color, distribution, quantity, thickness, texture, and lubrication of body hair. Scalp hair is coarse or fine and curly or straight; it should be shiny, smooth, and pliant. While separating sections of scalp hair, observe characteristics of color and coarseness. Color varies from very light blond to black to gray and is sometimes altered by rinses or dyes. In older adults the hair sometimes becomes dull gray, white, or yellow.

Be aware of the normal distribution of hair growth in a man and a woman. At puberty an increase in the amount and distribution of hair occurs for both genders. During the aging process the hair may thin over the scalp, axillae, and pubic areas. Facial hair of older men decreases. A woman with hirsutism has hair growth on the upper lip, chin, and cheeks, with vellus hair becoming coarser over the body; this may be related to an endocrine disorder. For some a change in hair growth negatively affects body image and emotional well-being. The amount of hair covering the extremities is sometimes reduced as a result of aging, or it could result from arterial insufficiency that could reduce hair growth over the lower extremities. In the United States and some other cultures, women commonly shave their legs and axilla, although shaving remains a matter of personal preference among women from all cultures.

Assess for causes of changes in the thickness, texture, and lubrication of scalp hair. At times these are a result of febrile illnesses or scalp diseases that result in hair loss. Conditions such as thyroid disease alter the condition of the hair, making it fine and brittle. Hair loss (**alopecia**) or thinning of the hair is usually related to genetic tendencies, endocrine disorders such as diabetes, thyroiditis, and menopause. Poor nutrition causes stringy, dull, dry, and thin hair. The oil of sebaceous glands lubricates the hair, but excessively oily hair is associated with androgen hormone stimulation. Dry, brittle hair occurs with aging and excessive use of chemical agents.

Normally the scalp is smooth and inelastic with even coloration. Carefully separate strands of hair and thoroughly inspect the scalp for lesions, which are not easy to notice in thick hair. Note the characteristics of any scalp lesion. For lumps or bruises, ask whether the patient has experienced recent head trauma. Moles on the scalp are common, but they can bleed as a result of vigorous combing or brushing. Dandruff or psoriasis frequently causes scaliness or dryness of the scalp.

Careful inspection of hair follicles on the scalp and pubic areas can reveal lice or other parasites. The three types of lice are *Pediculus humanus capitis* (head lice), *Pediculus humanus corporis* (body lice), and *Pediculus pubis* (crab lice). The presence of lice does not mean that a person practices poor hygiene. Lice spread easily, especially among children who play closely together. Head and crab lice attach their eggs to hair. The tiny eggs look like oval particles of dandruff, although the lice themselves are difficult to see (Fig. 30.7). Head and body lice are very small with grayish-white bodies, whereas crab lice have red legs. To better identify infestations, observe for small, red, pustular eruptions in the hair follicles and areas where skin surfaces meet, such as behind the ears and in the groin. A person often has intense itching of the scalp, especially on the back of the head or neck. Combing with a fine-tooth comb reveals the small oval-shaped lice; discovery of lice requires immediate treatment. Teach the patient to perform hair and scalp hygiene practices (Box 30.8).

FIG. 30.7 Head lice infestation.

From Habif TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 4, Philadelphia, 2004, Mosby.

Box 30.8 Patient Teaching Hair and Scalp Assessment

Objective

- Patient will perform proper hygiene practices for care of hair and scalp.

Teaching Strategies

- Instruct patient about basic hygiene practices for hair and scalp care.
- Instruct patients who have head lice to shampoo thoroughly with pediculicide (shampoo available at drugstores) in cold water at a basin or sink. Do not use a tub or shower, where the medication can reach other body parts. Comb thoroughly with a fine-tooth comb (following product directions) and discard comb. *Caution: Do not use products containing Lindane, a toxic ingredient known to cause adverse reactions.* Repeat shampoo treatment 12 to 24 hours later.
- After shampooing, remove any detectable nits or nit cases with tweezers or a metal nit comb. A dilute solution of vinegar and water helps loosen nits.
- Instruct patients and parents about ways to reduce transmission of lice:

- Do not share hairbrushes, combs, hairpieces, hats, bedding, towels, or clothing with someone who has head lice.
- Vacuum all rugs, car seats, pillows, furniture, and flooring thoroughly and discard vacuum bag.
- Seal nonwashable items in plastic bags for 14 days if unable to dry-clean or vacuum.
- Use thorough hand hygiene practices.
- Launder all clothing, linen, and bedding in hot water and detergent; then dry in a hot dryer for at least 31 minutes. Dry clean nonwashable items.
- Do not use insecticide.
- Instruct patient to notify his or her partner if lice were sexually transmitted.
- Avoid physical contact with infested individuals and their belongings, especially clothing and bedding.
- Soak any comb or brush used to remove lice for 15 minutes in very hot ammonia water (1 tsp ammonia to 2 cups hot water) or boiling water for 10 minutes.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me how you care for your hair and scalp.
- Explain to me the steps you will take to reduce lice transmission in your home.

Nails

The condition of the nails reflects a person's general health, state of nutrition, occupation, and habits of self-care. Before assessing the nails, gather a brief history (Table 30.11). The most visible part of the nail is the nail plate, the transparent layer of epithelial cells covering the nail bed (Fig. 30.8). The vascularity of the nail bed creates the underlying color of the nail. The semilunar whitish area at the base of the nail bed is called the *lunula*, from which the nail plate grows.

TABLE 30.11

Nursing History for Nail Assessment

Assessment	Rationale
Ask whether patient has experienced recent trauma or changes in nails (splitting, breaking, discoloration, thickening).	Trauma changes shape and growth of nail. Systemic conditions cause changes in color, growth, and shape.
Has patient had other symptoms of pain, swelling, presence of systemic disease with fever, or psychological or physical stress?	Alterations sometimes occur slowly over time.
Question patient's nail care practices. Determine whether patient has acrylic nails or silk wraps.	Change in nails can be caused by local or systemic problem. Acrylic nails and silk wraps are areas for fungal growth.
Determine whether patient has risks for nail or foot problems (e.g., diabetes, peripheral vascular disease, older adulthood, obesity).	Chemical agents cause drying of nails. Improper care damages nails and cuticles. Vascular changes associated with diabetes and peripheral vascular disease reduce blood flow to peripheral tissues; foot lesions and thickened nails are common. Some older adults have trouble performing foot and nail care because of poor vision, lack of coordination, or inability to bend over. Patients who are obese often have difficulty bending.

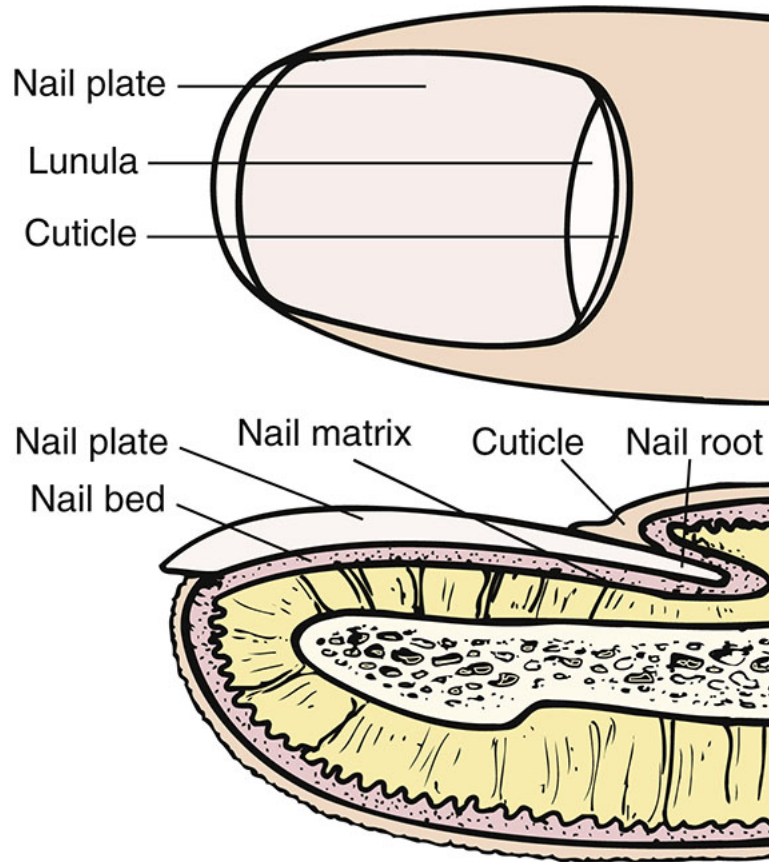

FIG. 30.8 Components of nail unit.
From Lewis SL, et al: *Medical-surgical nursing*, ed 9, St Louis, 2014, Mosby.

Inspection and Palpation

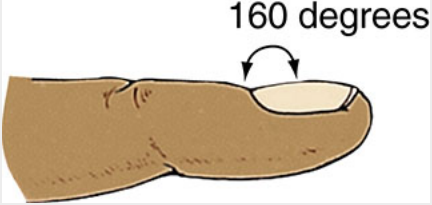

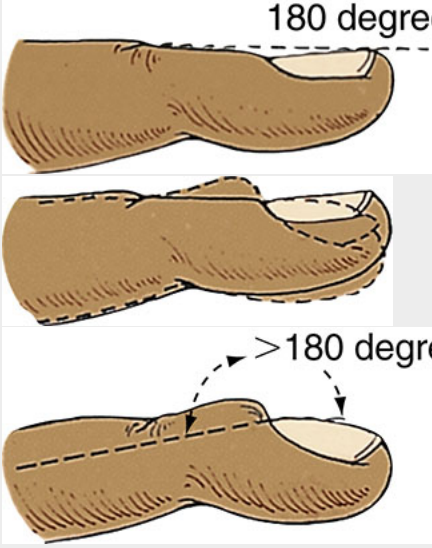

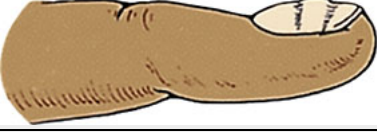

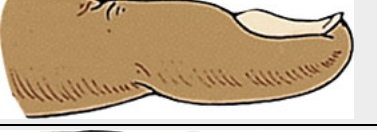

Inspect the nail bed for color, length, symmetry, cleanliness, and configuration. The shape and condition of the nails can give clues to pathophysiological problems. Assess the thickness and shape of the nail, its texture, the angle between the nail and the nail bed, and the condition of the lateral and proximal nail folds around the nail. When inspecting the nails, you gather a sense of a patient's hygiene practices. The nails are normally transparent, smooth, well rounded, and convex, with a nail bed angle of about 160 degrees (Box 30.9). A larger angle and softening of the nail bed indicate chronic oxygenation problems. The surrounding cuticles are smooth, intact, and without inflammation. When you assess for basic care of the nails, you recognize that nail biting, stains, and jagged edges either represent poor nail care or are caused by habits or occupational exposure to grease or dirt. Jagged, bitten, or broken nail edges or cuticles predispose a patient to localized infection.

Box 30.9 Abnormalities of the Nail Bed

Illustration of finger depicts abnormalities of nail beds and their causes as:

1. Normal Nail: Approximately 160-degree angle between nail plate and nail.
2. Clubbing: Change in angle between nail and nail base (eventually larger than 180 degrees); nail bed softening with nail flattening; often enlargement of fingertips Causes: Chronic lack of oxygen: heart or pulmonary disease.
3. Beau's lines: Transverse

depressions in nails indicating temporary disturbance of nail growth (nail grows out over several months). Causes: Systemic illness such as severe infection; nail injury⁴. Koilonychia (spoon nail): Concave curves. Causes: Iron deficiency anemia, syphilis, use of strong detergents.⁵ Splinter hemorrhages: Red or brown linear streaks in nail bed. Causes: Minor trauma, sub acute bacterial endocarditis, trichinosis.⁶ Paronychia: Inflammation of skin at base of nail. Causes: Local infection, trauma.

 <p>160 degrees</p>	<p>Normal nail: Approximately 160-degree angle between nail plate and nail</p>
 <p>180 degrees</p> <p>>180 degrees</p>	<p>Clubbing: Change in angle between nail and nail base (eventually larger than 180 degrees); nail bed softening with nail flattening; often enlargement of fingertips <i>Causes:</i> Chronic lack of oxygen: heart or pulmonary disease</p>
	<p>Beau's lines: Transverse depressions in nails indicating temporary disturbance of nail growth (nail grows out over several months). <i>Causes:</i> Systemic illness such as severe infection; nail injury</p>
	<p>Koilonychia (spoon nail): Concave curves <i>Causes:</i> Iron deficiency anemia, syphilis, use of strong detergents</p>
	<p>Splinter hemorrhages: Red or brown linear streaks in nail bed <i>Causes:</i> Minor trauma, subacute bacterial endocarditis, trichinosis</p>
	<p>Paronychia: Inflammation of skin at base of nail <i>Causes:</i> Local infection, trauma</p>

When palpating, expect to find a firm nail base, and check for any abnormalities such as erythema or swelling. For patients with impaired circulation, especially observe for early signs of infection or open lesions. To palpate, gently grasp the patient's finger and observe the color of the nail bed. The nail bed and nails appear pink with white nail tips in white patients. In patients with darker skin, the nail beds are darkly pigmented with a blue or reddish hue. A brown or black pigmentation is normal with longitudinal streaks (Fig. 30.9). Trauma, cirrhosis, diabetes mellitus, and hypertension cause splinter hemorrhages while vitamin, protein, and electrolyte changes cause various lines or bands to form on the nail beds.

FIG. 30.9 Pigmented bands in nail of patient with dark skin.
From Habib TP: *Clinical dermatology: a color guide to diagnosis and therapy*, ed 5, St Louis, 2010, Mosby.

Nails normally grow at a constant rate, but direct injury or generalized disease changes growth patterns. With aging the nails of the fingers and toes become harder and thicker, longitudinal striations develop, and the rate of nail growth slows. In older adults with insufficient calcium nails become more brittle, dull, turn opaque-yellow and the cuticle becomes thick and wide.

Calluses and corns commonly are found on the toes or fingers. A callus is flat and painless, resulting from a thickening of the epidermis. Friction and pressure from shoes cause corns, usually over bony prominences. During the examination instruct the patient in proper nail care (Box 30.10).

Box 30.10 PATIENT TEACHING **Nail Assessment**

Objective

- Patient will properly care for fingernails, feet, and toenails.

Teaching Strategies

- Instruct patient to cut nails only after soaking them about 10 minutes in warm water. (*Exception:* Patients with diabetes or peripheral vascular disease are warned against soaking nails because this can cause maceration of the skin, leading to infection. Long-term soaking also dries out the hands and feet; dry, cracked skin leads to infection.)
- Caution patient against over-the-counter preparations to treat corns, calluses, or ingrown toenails.
- Instruct patient to cut nails straight across and even with tops of fingers or toes. If patient has diabetes, tell him or her to file rather than cut nails (see Chapter 40).
- Instruct patient to shape nails with a file or emery board.
- If patient has diabetes:
 - Wash feet daily in warm water and carefully dry them, especially between toes. Inspect feet each day in good lighting, looking for dry places and cracks in skin. Soften dry feet by applying a cream or lotion such as Nivea, Eucerin, or Alpha Keri.
 - Do not put lotion between toes; moisture between toes allows microorganisms to grow, leading to infections.
 - Caution patient against using sharp objects to poke or dig under toenail or around the cuticle.
 - Have patient see a podiatrist for treatment of ingrown toenails and nails that are thick or tend to split.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Show me how you are going to clean and moisturize your hands and feet.
- Explain the measures that you will take to avoid injury to your feet.

Head and Neck

An examination of the head and neck includes assessment of the head, eyes, ears, nose, mouth, pharynx, and neck (lymph nodes, carotid arteries, thyroid gland, and trachea). Assessment of the head and neck uses inspection, palpation, and auscultation. Many times, you will inspect and palpate the head and neck at the same time.

Head

Inspection and Palpation

The nursing history screens for intracranial injury and local or congenital deformities (Table 30.12). Inspect the patient’s head, noting the position, size, shape, and contour. The head is normally held upright and midline to the trunk. A patient who tilts the head to one side may have unilateral hearing or visual loss or muscle weakness in the neck. A horizontal jerking or bobbing may indicate a tremor.

TABLE 30.12

Nursing History for Head Assessment

Assessment	Rationale
Determine whether patient experienced recent head trauma. If so, assess state of consciousness after injury (immediately on return and 5 minutes later), duration of unconsciousness, and predisposing factors (e.g., seizure, poor vision, blackout).	Trauma is major cause for lumps, bumps, cuts, bruises, or deformities of scalp or skull. Loss of consciousness following head injury indicates possible brain injury.
Ask whether patient has history of headache; note onset, duration, character, pattern, and associated symptoms.	Character of headache helps to reveal causative factors such as sinus infection, migraine, or neurological disorders.
Determine length of time patient has experienced neurological symptoms.	Duration of signs or symptoms reveals severity of problem.
Review patient’s occupational history for use of safety helmets.	Nature of some occupations creates a risk for head injury.
Ask whether patient participates in contact sports, cycling, rollerblading, or skateboarding.	These activities require use of safety helmets.

Note the patient’s facial features, looking at the eyelids, eyebrows, nasolabial folds, and mouth for shape and symmetry. It is normal for slight asymmetry to exist. If there is facial asymmetry, note whether all features on one side of the face are affected or if only a part of the face is involved. Various neurological disorders (e.g., facial nerve paralysis) affect different nerves that innervate muscles of the face.

Examine the size, shape, and contour of the skull. The skull is generally round with prominences in the frontal area anteriorly and the occipital area posteriorly. Trauma typically causes local skull deformities. In infants a large head results from congenital anomaly or the buildup of cerebrospinal fluid in the ventricles (hydrocephalus). Some adults have enlarged jaws and facial bones resulting from acromegaly, a disorder caused by excessive secretion of growth hormone. Palpate the skull for nodules or masses. Gently rotate the fingertips down the midline of the scalp and along the sides of the head to identify abnormalities. Palpate the temporomandibular joint (TMJ) space bilaterally. Place the fingertips just anterior to the tragus of each ear. The fingertips should slip into the joint space as the patient's mouth opens to gently palpate the joint spaces. Normally the movements should be smooth, although it is not unusual to hear or feel a clicking, grating, or snapping in the TMJ, indicating degenerative joint disease ([Ball et al., 2019](#)).

Eyes

Examination of the eyes includes assessment of visual acuity, visual fields, extraocular movements, and external and internal eye structures. [Fig. 30.10](#) shows a cross-section of the eye. The eye assessment detects visual alterations and determines the general level of assistance that patients require when ambulating or performing self-care activities. Some patients with visual problems also need special aids for reading educational materials or instructions (e.g., medication labels). [Table 30.13](#) reviews the nursing history for an eye examination. [Box 30.11](#) describes common types of visual problems.

FIG. 30.10 Cross-section of eye.

TABLE 30.13**Nursing History for Eye Assessment**

Assessment	Rationale
Determine whether patient has history of eye disease (e.g., glaucoma, retinopathy, cataracts), eye trauma, diabetes, hypertension, or eye surgery.	Some diseases or trauma cause risk for partial or complete visual loss. Patient may have had surgery for a visual disorder.
Determine problems that prompted patient to seek health care. Ask patient about eye pain, photophobia (sensitivity to light), burning or itching, excess tearing or crusting, diplopia (double vision) or blurred vision, awareness of a “film” or “curtain” over field of vision, floaters (small black spots that seem to float across field of vision), flashing lights, or halos around lights.	Common symptoms of eye disease indicate need for health care provider.
Determine whether there is family history of eye disorders or diseases.	Certain eye problems such as glaucoma or retinitis pigmentosa are inherited.
Review patient’s occupational history and recreational hobbies. Are safety glasses worn?	Performance of close, intricate work causes eye fatigue. Working with computers causes eye strain. Certain occupational tasks (e.g., working with chemicals) and recreational activities (e.g., fencing, motorcycle riding) place people at risk for eye injury unless they take precautions.
Ask patient whether he or she wears glasses or contacts and, if so, how often.	Patients need to wear glasses or contacts during certain parts of examination for accurate assessment.
Determine when patient last visited ophthalmologist or optometrist.	Date of last eye examination reveals level of preventive care patient takes.
Assess medications patient is taking, including eyedrops or ointment.	Determines need to assess patient’s knowledge of medications. Certain medications cause visual symptoms.

Box 30.11 Common Eye and Vision Problems**Hyperopia**

Hyperopia is farsightedness, a refractive error in which rays of light enter the eye and focus behind the retina. People are able to clearly see distant objects but not close objects.

Myopia

Myopia is nearsightedness, a refractive error in which rays of light enter the eye and focus in front of the retina. People are able to clearly see close objects but not distant objects.

Presbyopia

Presbyopia is impaired near vision in middle-age and older adults caused by loss of elasticity of the lens and associated with the aging process.

Retinopathy

Retinopathy is a noninflammatory eye disorder resulting from changes in retinal blood vessels. It is a leading cause of blindness.

Strabismus

Strabismus is a (congenital) condition in which both eyes do not focus on an object simultaneously; these eyes appear crossed. Impairment of the extraocular muscles or their nerve supply causes strabismus.

Cataracts

A cataract is an increased opacity of the lens, which blocks light rays from entering the eye. Cataracts sometimes develop slowly and progressively after age 35 or suddenly after trauma. They are one of the most common eye disorders. Most older adults (65 years old and older) have some evidence of visual impairment from cataracts.

Glaucoma

Glaucoma is intraocular structural damage resulting from elevated intraocular pressure. Obstruction of the outflow of aqueous humor causes this. Without treatment the disorder leads to blindness.

Macular Degeneration

Macular degeneration is associated with aging and results in severe loss of a patient's central vision. It is the leading cause of blindness and low vision in the United States in those 65 years of age and older (CDC, 2018b). There is no cure, but there are injections and laser treatments that may slow the progression.

Visual Acuity

Assessing visual acuity (i.e., the ability to see small details) tests central vision. The easiest way to assess near vision is to ask patients to read printed material under adequate lighting. If patients wear glasses, make sure that they wear them during the assessment. Asking patients to read aloud helps to determine literacy. If the patient has difficulty reading, move to the next step.

Assessment of distant vision requires using a Snellen chart (paper chart or projection screen). The chart should be well lit. Test vision without corrective lenses first. Have the patient sit or stand 6.1 m (20 feet) away from the chart and try to read all of the letters beginning at any line with

both eyes open. Then have the patient read the line with each eye separately (patient covers the opposite eye with an index card or eye cover to avoid applying pressure to the eye). Note the smallest line for which the patient can read all of the letters correctly and record the visual acuity for that line. Repeat the test with the patient wearing corrective lenses. Complete the test rapidly enough so that the patient does not memorize the chart (Ball et al., 2019). If a patient is unable to read, use an E chart or one with pictures of familiar objects. Instead of reading letters, patients tell which direction each E is pointing or the name of the object.

The Snellen chart has standardized numbers at the end of each line of the chart. The numerator is the number 20, or the distance the patient stands from the chart. The denominator is the distance from which the normal eye is able to read the chart. Normal visual acuity is 20/20. The larger the denominator, the poorer the patient's visual acuity. For example, a value of 20/40 means that the patient, standing 20 feet away, can read a line that a person with normal vision can read from 40 feet away. Record visual acuity for each eye and both eyes and record whether the test was performed with or without correction (including glasses or contact lenses).

If patients cannot read even the largest letters or figures of a Snellen chart, test their ability to count upraised fingers or to distinguish light. Hold a hand 31 cm (1 foot) from the patient's face and have him or her count the upraised fingers. To check light perception, shine a penlight into the eye and turn off the light. If the patient notes when the light is turned on or off, light perception is intact.

Assess near vision by asking the patient to read a handheld card containing a vision screening chart. The patient holds the card a comfortable distance (31.7 to 35.5 cm [about 12½ to 14 inches]) from the eyes and reads the smallest line possible. This part of the examination is a good time to discuss the need for routine eye examinations (Box 30.12).

Box 30.12 Patient Teaching Eye Assessment

Objective

- Patient will follow recommendations for regular eye examinations and prevention of injury.

Teaching Strategies

- Explain recommended frequency for eye testing with a Snellen chart and examination (see Table 30.3).
- Describe the typical symptoms of eye disease.
- Instruct older adult to take the following precautions because of normal vision changes: avoid or use caution while driving at night, increase lighting in the home to reduce risk of falls, and paint the first and last steps of a staircase and the edge of each of the other steps a bright color to aid depth perception.
- Remind patient that wearing protective eyewear prevents injury from debris and splashes.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me how often you should schedule an eye examination.
- Describe for me the symptoms you should watch for and when you should call the health care provider.
- Tell me what changes you are making in your home that will improve your safety.

Modified from Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Extraocular Movements

Six small muscles guide the movement of each eye. Both eyes move parallel to one another in each of the six directions of gaze (Fig. 30.11). To assess extraocular movements, a patient sits or stands, and the nurse faces the patient from 60 cm (2 feet) away. The nurse holds a finger at a comfortable distance (15 to 31 cm [6 to 12 inches]) from the patient's eyes. While the patient maintains his or her head in a fixed position facing forward, the nurse directs him or her to follow with the eyes only as the nurse's finger moves to the right, left, and diagonally up and down to the left and right. The nurse moves the finger smoothly and slowly within the normal field of vision.

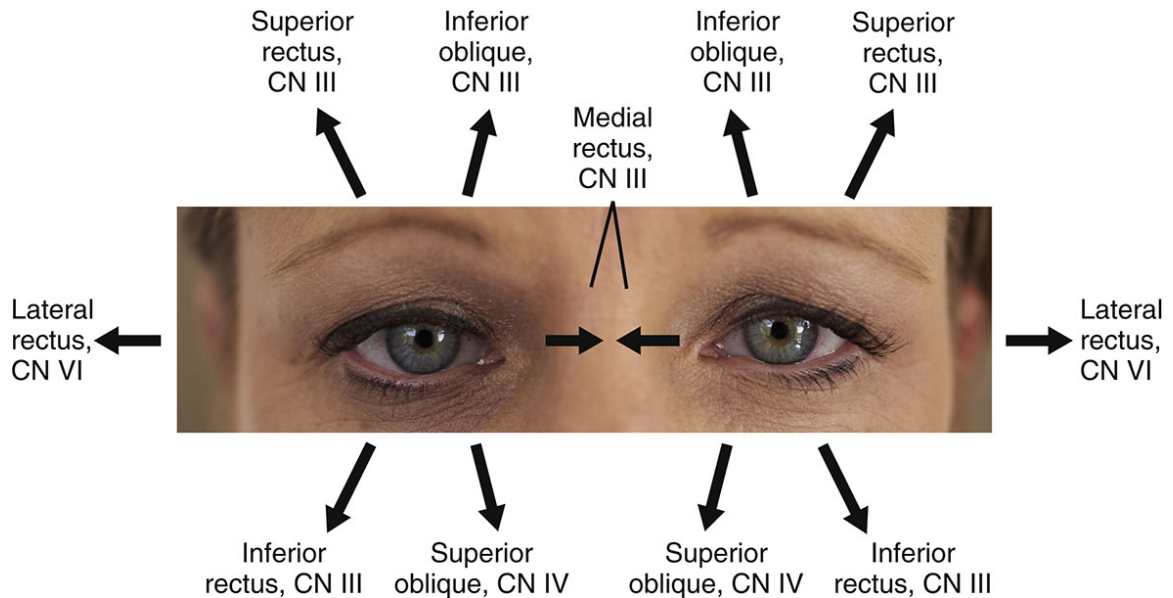

FIG. 30.11 Six directions of gaze. Direct patient to follow finger movement through each gaze. CN, Cranial nerve.

As the patient gazes in each direction, observe for parallel eye movement, the position of the upper eyelid in relation to the iris, and the presence of abnormal movements. As the eyes move through each direction of gaze, the upper eyelid covers the iris only slightly. **Nystagmus**, an involuntary, rhythmical oscillation of the eyes, occurs as a result of local injury to eye muscles and supporting structures or a disorder of the cranial nerves innervating the muscles. Initiate nystagmus in patients with normal eye movements by having them gaze to the far left or right.

Visual Fields

As a person looks straight ahead, he or she normally can see all objects in the periphery. To assess visual fields, direct the patient to stand or sit 60 cm (2 feet) away at eye level. The patient gently closes or covers one eye (e.g., the left) and looks at your eye directly opposite. You close your opposite eye (in this case the right) so that the field of vision is superimposed on that of the patient. Next move a finger equidistant between you and the patient outside the field of vision and slowly bring it back into the visual field. The patient reports when he or she can see the finger. If you see the finger before the patient does, a part of the patient's visual field is reduced. To test temporal field vision, hold an object or your finger slightly behind the patient. Repeat the procedure for each field of vision for the other eye. Patients with visual field problems are at risk for

injury because they cannot see all of the objects in front of them. Older adults commonly have loss of peripheral vision caused by changes in the lens.

External Eye Structures

To inspect external eye structures, stand directly in front of the patient at eye level and ask him or her to look at your face.

Position and Alignment

Assess the position of the eyes in relation to one another. Normally they are parallel to one another. Bulging eyes (exophthalmos) usually indicate hyperthyroidism. Crossed eyes (strabismus) result from neuromuscular injury or inherited abnormalities. Tumors or inflammation of the orbit often cause abnormal eye protrusion.

For the remainder of the eye examination have the patient remove contact lenses.

Eyebrows

Inspect the eyebrows for size, extension, texture of hair, alignment, and movement. Normally the eyebrows are symmetrical. Coarseness of hair and failure to extend beyond the temporal canthus possibly reveals hypothyroidism. Thin brows may be a result of waxing or plucking. Aging causes loss of the lateral third of the eyebrows. To assess movement, ask the patient to raise and lower the eyebrows. The brows normally raise and lower symmetrically. An inability to move them indicates a facial nerve paralysis (cranial nerve VII).

Eyelids

Inspect the eyelids for position; color; condition of the surface; condition and direction of the eyelashes; and the patient's ability to open, close, and blink. When the eyes are open in a normal position, the lids cover the sclera above the iris but not the pupil. The lids are also close to the eyeball. An abnormal drooping of the lid over the pupil is called **ptosis** (pronounced "toe-sis") and is caused by edema or impairment of the third cranial nerve. In the older adult ptosis results from a loss of elasticity that accompanies aging. An older adult frequently has lid margins that turn out (**ectropion**) or in (**entropion**). Entropion sometimes leads to the lashes of the lid irritating the conjunctiva and cornea, increasing the risk of infection. Normally the eyelashes are distributed evenly and curved

outward away from the eye. An erythematous or yellow lump (hordeolum or sty) on the follicle of an eyelash indicates an acute suppurative inflammation.

To inspect the surface of the upper lids, ask the patient to close his or her eyes while observing for lid tremors. Normally the lids are smooth and the same color as the surrounding skin. Redness indicates inflammation or infection. Lid edema is sometimes caused by allergies or heart or kidney failure. Edema of the eyelids prevents them from closing. Inspect any lesions for typical characteristics and discomfort or drainage. Wear clean gloves if drainage is present.

The lids normally close symmetrically. Their failure to close exposes the cornea to drying. This condition is common in unconscious patients or those with facial nerve paralysis. To inspect the lower lids, ask the patient to open the eyes again while you look for the same characteristics noted for the upper lids. Normally a patient blinks involuntarily and bilaterally up to 20 times a minute. The blink reflex lubricates the cornea. Report absent, infrequent, rapid, or monocular (one-eyed) blinking.

Lacrimal Apparatus

The lacrimal gland ([Fig. 30.12](#)), located in the upper outer wall of the anterior part of the orbit, is responsible for tear production. Tears flow from the gland across the surface of the eye to the lacrimal duct, which is in the nasal corner or inner canthus of the eye. The lacrimal gland is sometimes the site of tumors or infections and should be inspected for edema and redness. Palpate the gland gently to detect tenderness; normally tenderness cannot be felt.

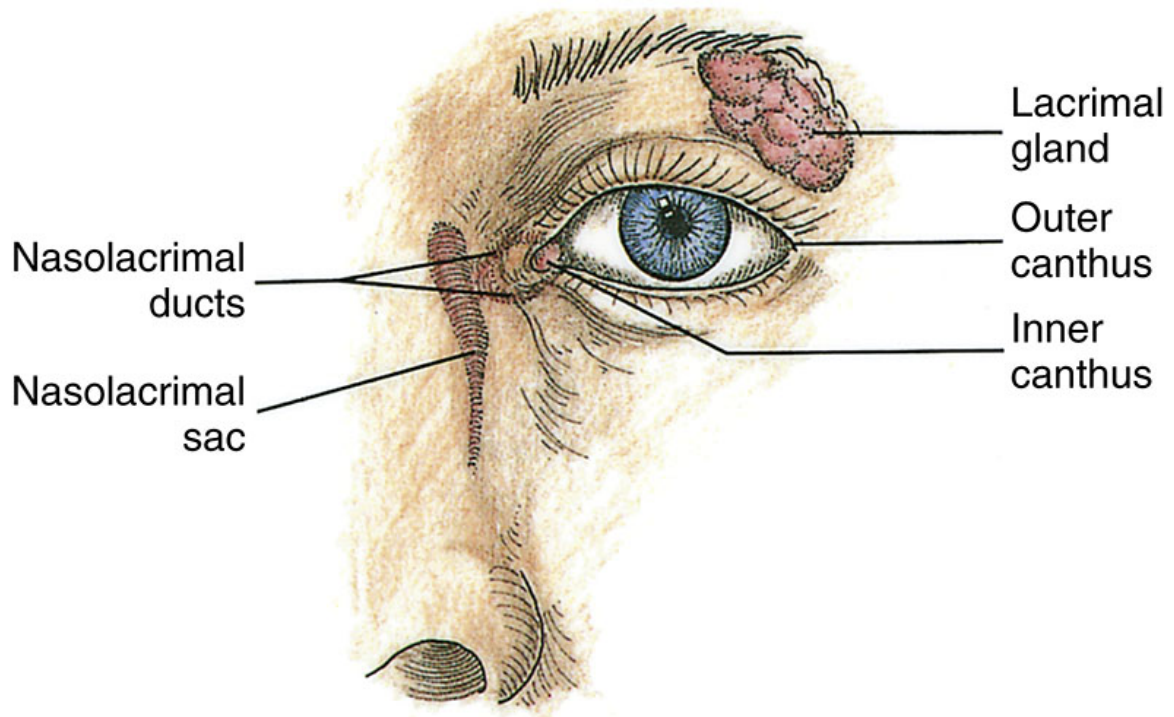

FIG. 30.12 The lacrimal apparatus secretes and drains tears, which moisten and lubricate eye structures.

The nasolacrimal duct sometimes becomes obstructed, blocking the flow of tears. Observe for evidence of edema in the inner canthus. Gentle palpation of the duct at the lower eyelid just inside the lower orbital rim causes a regurgitation of tears.

Conjunctivae and Sclerae

The bulbar conjunctiva covers the exposed surface of the eyeball up to the outer edge of the cornea. Observe the sclera under the bulbar conjunctiva; normally it has the color of white porcelain in patients with light skin and is light yellow in patients with dark skin. Sclerae become pigmented and appear either yellow or green if liver disease is present.

Take care when inspecting the conjunctivae. For adequate exposure of the bulbar conjunctiva, retract the eyelids without placing pressure directly on the eyeball. Gently retract both lids, with the thumb and index finger pressed against the lower and upper bony orbits. Ask the patient to look up, down, and from side to side. Many patients begin to blink, making the examination difficult. Inspect for color, texture, and the presence of edema or lesions. Normally the conjunctivae are free of erythema. The presence of redness indicates an allergic or infectious **conjunctivitis**. Bright red blood in a localized area surrounded by normal-

appearing conjunctiva usually indicates subconjunctival hemorrhage. Conjunctivitis is a highly contagious infection. It is easy to spread the crusty drainage that collects on eyelid margins from one eye to the other. When drainage is present wear clean gloves during the examination and perform proper hand hygiene before and after the eye examination.

Corneas

The cornea is the transparent, colorless part of the eye covering the pupil and iris. From a side view it looks like the crystal of a wristwatch. While the patient looks straight ahead, inspect the cornea for clarity and texture while shining a penlight obliquely across its entire surface. The cornea is normally shiny, transparent, and smooth. In older adults it loses its luster. Any irregularity in the surface indicates an abrasion or tear that requires further examination by a health care provider. Both conditions are very painful. Note the color and details of the underlying iris. In an older adult the iris becomes faded. A thin white ring along the margin of the iris, called an **arcus senilis**, is common with aging but is abnormal in anyone under age 40. To test for the corneal blink reflex, see the cranial nerve test section of this chapter.

Pupils and Irises

Observe the pupils for size, shape, equality, accommodation, and reaction to light. They are normally black, round, regular, and equal in size (3 to 7 mm in diameter) (Fig. 30.13). The iris should be clearly visible.

FIG. 30.13 Chart depicting pupillary size in millimeters.

Cloudy pupils indicate cataracts. Dilated pupils result from glaucoma, trauma, neurological disorders, eye medications (e.g., atropine), or withdrawal from opioids. Inflammation of the iris or use of drugs (e.g., pilocarpine, morphine, or cocaine) causes constricted pupils. Pinpoint pupils are a common sign of opioid intoxication. Shining a beam of light through the pupil and onto the retina stimulates the third cranial nerve,

causing the muscles of the iris to constrict. Any abnormality along the nerve pathways from the retina to the iris alters the ability of the pupils to react to light. Changes in intracranial pressure, lesions along the nerve pathways, locally applied ophthalmic medications, and direct trauma to the eye alter pupillary reaction.

Test pupillary reflexes (to light and accommodation) in a dimly lit room. Instruct the patient to avoid looking directly at the light. While the patient looks straight ahead, bring a penlight from the side of his or her face, directing the light onto the pupil (Fig. 30.14). A directly illuminated pupil constricts, and the opposite pupil constricts consensually. Observe the quickness and equality of the reflex. Repeat the examination for the opposite eye.

FIG. 30.14 **A**, To check pupillary reflexes the nurse first holds penlight to side of patient's face. **B**, Illumination of pupil causes pupillary constriction.

To test for accommodation, ask the patient to gaze at a distant object (the far wall) and then at a test object (finger or pencil) held approximately 10 cm (4 inches) from the bridge of his or her nose. The pupils normally converge and accommodate by constricting when looking at close objects. The pupillary responses are equal. Testing for accommodation is important only if the patient has a defect in the pupillary response to light (Ball et al., 2019). If assessment of pupillary reaction is normal in all tests, record the abbreviation **PERRLA** (pupils equal, round, reactive to light, and accommodation).

Internal Eye Structures

The examination of the internal eye structures through the use of an ophthalmoscope is beyond the scope of new graduate nurses' practice. Advanced nurse practitioners use the ophthalmoscope to inspect the fundus (Fig. 30.15), which includes the retina, choroid, optic nerve disc, macula, fovea centralis, and retinal vessels. Patients in greatest need of an examination are those with diabetes, hypertension, and intracranial disorders.

FIG. 30.15 Fundus of white patient (A) and black patient (B).
Courtesy of MEDCOM, Cypress, CA.

Ears

The ear assessment determines the integrity of ear structures and hearing acuity. The three parts of the ear are the external, middle, and inner ear (Fig. 30.16). Inspect and palpate external ear structures, which consist of the auricle, outer ear canal, and tympanic membrane (eardrum). The ear canal is normally curved and approximately 2.5 cm (1 inch) long in an adult. It is lined with skin containing fine hairs, nerve endings, and glands secreting cerumen. The middle ear is inspected with an otoscope. It is an air-filled cavity containing the three bony ossicles (malleus, incus, and stapes). The eustachian tube connects the middle ear to the nasopharynx. Pressure between the outer atmosphere and the middle ear is stabilized through this tube. Finally, the inner ear is tested by measuring a patient's hearing acuity. The inner ear contains the cochlea, vestibule, and semicircular canals. Assessing the ears determines the integrity of ear structures and the condition of hearing. Use nursing history data to identify patients' risks for hearing disorders (Table 30.14).

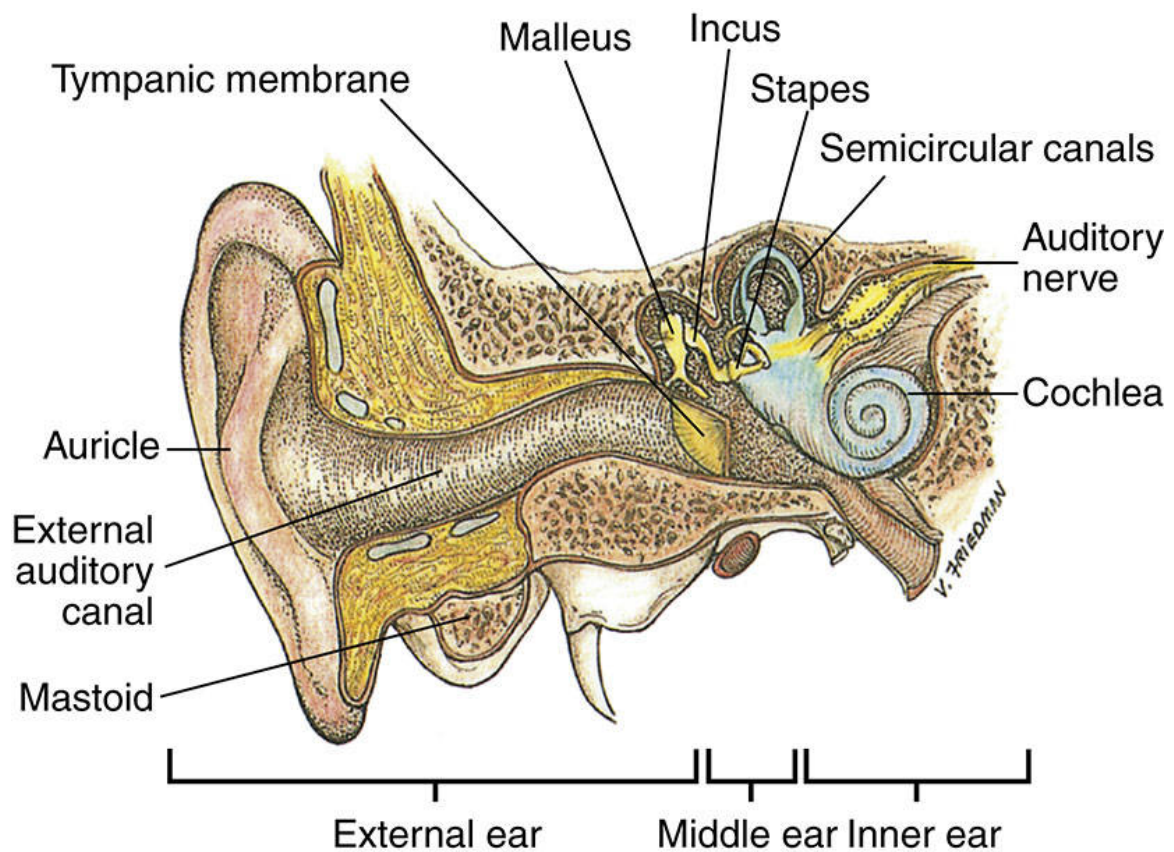

FIG. 30.16 Structures of external, middle, and inner ear.

TABLE 30.14**Nursing History for Ear Assessment**

Assessment	Rationale
Ask whether patient has experienced ear pain, itching, discharge, vertigo, tinnitus (ringing in ears), or change in hearing.	These signs and symptoms indicate infection or hearing loss.
<p>Assess risks for hearing problem.</p> <p><i>Infants/children:</i> Hypoxia at birth, meningitis, birth weight less than 1500 g, family history of hearing loss, congenital anomalies of skull or face, nonbacterial intrauterine infections (rubella, herpes), maternal drug use, excessively high bilirubin, head trauma</p> <p><i>Adolescents:</i> Frequent exposure to loud music from concerts, car radios, and cell phone or iPods while wearing headphone, earbuds, or other devices</p> <p><i>Adults:</i> Exposure to industrial or recreational noise, genetic disease (Ménière's disease), neurodegenerative disorder</p>	Risk factors predispose patient to permanent hearing loss. It is difficult to assess infant's hearing status with examination only.
Determine patient's exposure to loud noises at work and availability of protective devices.	Prolonged noise exposure causes temporary or permanent hearing loss.
Note behaviors indicative of hearing loss such as failure to respond when spoken to, requests to repeat comments, leaning forward to hear, and child's inattentiveness or use of a monotonous voice tone.	People with hearing loss cope with sensory deficit through a variety of behavioral cues.
Assess whether patient takes large doses of aspirin or other ototoxic drugs (e.g., aminoglycosides, furosemide, streptomycin, cisplatin, ethacrynic acid).	Medications have side effects of hearing loss.
Determine whether patient uses hearing aid.	Determination allows you to assess patient's ability to care for device and adjust voice tone to communicate.
If patient had recent hearing problem, note onset, contributing factors, affected ear, and effect on activities of daily living.	Helps determine nature and severity of hearing problem.
Determine whether patient has repeated history of cerumen buildup in ear.	Cerumen impaction is common cause for conduction deafness.

Understanding the mechanisms for sound transmission helps identify the nature of hearing disorders. Sound travels through the ear by air and bone conduction. Nerve impulses from the cochlea travel to the auditory nerve (eighth cranial nerve) and the cerebral cortex. Disorders of the ear result from several types of problems, including mechanical dysfunction (blockage by cerumen or foreign body), trauma (foreign bodies or noise exposure), neurological disorders (auditory nerve damage), acute illnesses (viral infection), and toxic effects of medications.

Auricles

With the patient sitting comfortably, inspect the size, shape, symmetry, landmarks, position, and color of the auricle (Fig. 30.17). The auricles are normally of equal size and level with each other. The upper point of attachment is in a straight line with the lateral canthus, or corner of the eye. The position of the auricle is almost vertical. Ears that are low set or at an unusual angle are a sign of chromosomal abnormality such as Down syndrome. Ear color is usually the same as that of the face, without moles, cysts, deformities, or nodules. Redness is a sign of inflammation or fever. Extreme pallor indicates frostbite.

FIG. 30.17 Anatomical structures of auricle.

Palpate the auricles for texture, tenderness, and skin lesions. Auricles are normally smooth and without lesions. If a patient has pain, gently pull the auricle, press on the tragus, and palpate behind the ear over the mastoid process. If palpating the external ear increases the pain, an external ear infection is likely. If palpating the auricle and tragus does not influence the

pain, the patient may have a middle ear infection. Tenderness in the mastoid area indicates mastoiditis.

Inspect the opening of the ear canal for size and presence of discharge. If discharge is present, wear clean gloves. A swollen or occluded meatus is not normal. A yellow, waxy substance called **cerumen** is common. Yellow or green, foul-smelling discharge indicates infection or a foreign body.

Ear Canals and Eardrums

Observe the deeper structures of the external and middle ear with the use of an otoscope. A special ear speculum attaches to the handle of the ophthalmoscope. For best visualization select the largest speculum that fits comfortably in the patient's ear. Before inserting the speculum, check for foreign bodies in the opening of the auditory canal.

Make sure that the patient avoids moving the head during the examination to avoid damage to the canal and tympanic membrane. Infants and young children might need to be held securely to prevent movement. Lay infants supine with head turned to one side and arms held securely at the sides. Have young children sit on their parents' laps with their legs held between the parents' knees.

Turn on the otoscope by rotating the dial at the top of the handle. To insert the speculum properly, ask the patient to tip the head slightly toward the opposite shoulder. Hold the handle of the otoscope in the space between the thumb and index finger, supported on the middle finger. This leaves the ulnar side of the hand to rest against the patient's head, stabilizing the otoscope as you insert it into the canal (Ball et al., 2019). There are two ways to grip the otoscope: (1) hold the handle along the patient's face with the fingers against the face or neck, and (2) lightly brace the inverted otoscope against the side of the patient's head or cheek. This latter grip, used with children, prevents accidental movement of the otoscope deeper into the ear canal. Insert the scope while pulling the auricle upward and backward in the adult and older child (Fig. 30.18). This maneuver straightens the ear canal. For infants the auricle should be pulled down and back.

FIG. 30.18 Otoscopic examination.

From Wilson S, Giddens J: *Health assessment for nursing practice*, ed 6, St Louis, 2016, Elsevier.

Insert the speculum slightly down and forward 1 to 1.5 cm ($\frac{1}{2}$ inch) into the ear canal. Take care not to scrape the sensitive lining, which is painful. The ear canal normally has little cerumen and is uniformly pink with tiny hairs in the outer third of the canal. Observe for color, discharge, scaling, lesions, foreign bodies, and cerumen. Normally cerumen is dry (light brown to gray and flaky) or moist (dark yellow or brown) and sticky. Dry cerumen is common in Asians and Native Americans (Ball et al., 2019). A reddened canal with discharge is a sign of inflammation or infection. In other adults accumulated cerumen is a common problem; buildup creates a mild hearing loss. During the examination ask the patient about methods he or she uses to clean the ear canal (Box 30.13).

Box 30.13 PATIENT TEACHING Ear Assessment Objective

- Patient will follow preventive guidelines for screening of hearing loss and proper cleaning technique for the ears.

Teaching Strategies

- Explain that noise-induced hearing loss can lead to communication difficulties, learning difficulties, pain or ringing in the ears (tinnitus), distorted or muffled hearing, and an inability to hear some environmental sounds and warning signals.
- Encourage patients to adopt behaviors to protect their hearing (CDC, 2017):
 - Avoid or limit exposure to excessively loud sounds.
 - Turn down the volume of music systems.
 - Move away from the source of loud sounds when possible.
 - Use hearing protection devices when it is not feasible to avoid exposure to loud sounds or to reduce them to a safe level.
- Instruct patient in the proper way to clean the outer ear (see Chapter 40), avoiding use of cotton-tipped applicators and sharp objects such as hairpins, which cause impaction of cerumen deep in the ear canal or trauma.
- Tell patient to avoid inserting pointed objects into the ear canal.
- Encourage patients over age 65 to have regular hearing checks. Explain that a reduction in hearing is a normal part of aging (see Chapter 49).
- Instruct family members of patients with hearing loss to avoid shouting; to speak in slower, low tones; and to be sure that the patient is able to see the speaker's face.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe two ways to protect hearing while you are home.
- Show me how you will safely clean your ears.
- Tell me how often you will get your hearing checked.

The light from the otoscope allows visualization of the tympanic membrane. Know the common anatomical landmarks and their appearances (Fig. 30.19). Gently move the otoscope so that the entire tympanic membrane and its periphery are visible. Because the tympanic membrane is angled away from the ear canal, the light from the otoscope appears as a cone shape rather than a circle. A ring of fibrous cartilage surrounds the oval membrane. The umbo is near the center of the membrane, behind which is the attachment of the malleus. The underlying short process of the malleus creates a knoblike structure at the top of the drum. Check carefully to make sure that there are no tears or breaks in the membrane. The normal tympanic membrane is translucent, shiny, and pearly gray. It is free from tears or breaks. A pink or red bulging membrane indicates inflammation. A white color reveals pus behind it. The membrane is taut, except for the small triangular pars flaccida near the top. If cerumen is blocking the tympanic membrane, warm water irrigation safely removes the wax.

FIG. 30.19 Normal right tympanic membrane.

University of Illinois, Chicago.

Hearing Acuity

A patient with a hearing loss often fails to respond to conversation. The three types of hearing loss are conduction, sensorineural, and mixed. A conduction loss interrupts sound waves as they travel from the outer ear to the cochlea of the inner ear because the sound waves are not transmitted through the outer and middle ear structures. Causes of a conduction loss include swelling of the auditory canal and tears in the tympanic membrane. A sensorineural loss involves the inner ear, auditory nerve, or hearing center of the brain. Sound is conducted through the outer and middle ear structures, but the continued transmission of sound becomes interrupted at some point beyond the bony ossicles. A mixed loss involves a combination of conduction and sensorineural loss. Patients working or living around loud noises and those who listen to loud music are at risk for hearing loss.

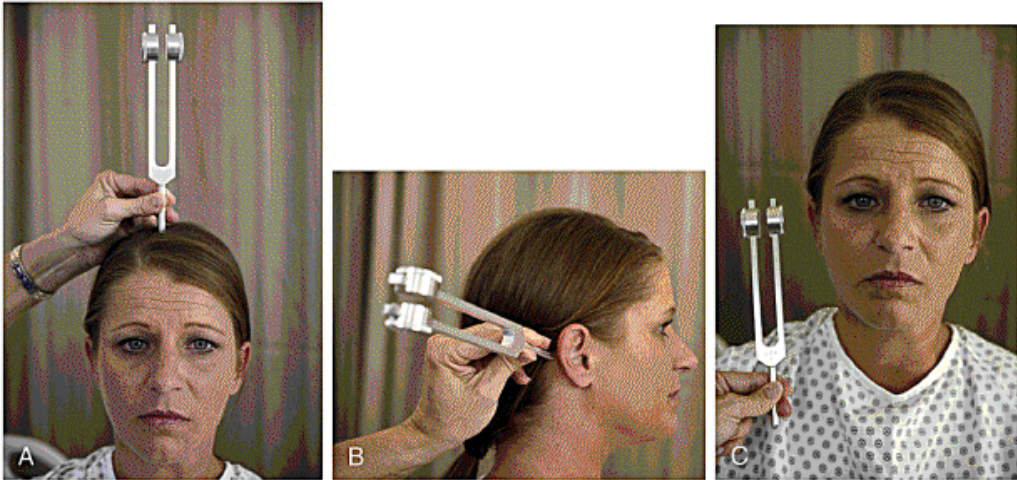

Older adults experience an inability to hear high-frequency sounds and consonants (e.g., *S*, *Z*, *T*, and *G*). Deterioration of the cochlea and thickening of the tympanic membrane cause older adults to gradually lose hearing acuity. They are especially at risk for hearing loss caused by **ototoxicity** (injury to auditory nerve) resulting from high maintenance doses of antibiotics (e.g., aminoglycosides).

To conduct a hearing assessment, have the patient remove any hearing aid if worn. Note his or her response to questions. Normally he or she responds without excessive requests to have the questions repeated. If a hearing loss is suspected, check the patient's response to the whispered voice. Test one ear at a time while the patient occludes the other ear with a finger. Ask him or her to gently move the finger up and down during the test in response to the whispered sound. While standing 31 to 60 cm (1 to 2 feet) from the testing ear, speak while covering the mouth so that the patient is unable to read lips. After exhaling fully, whisper softly toward the unoccluded ear, reciting random numbers with equally accented syllables, such as *nine-four-ten*. If necessary, gradually increase voice intensity until the patient correctly repeats the numbers. Then test the other ear for comparison. [Ball et al. \(2019\)](#) report that patients normally hear numbers clearly when whispered, responding correctly at least 50% of the time.

If a hearing loss is present, test the hearing using a tuning fork. A tuning fork of 256 to 512 hertz (Hz) is most commonly used. The tuning fork allows for comparison of hearing by bone conduction with that of air conduction. Hold the base of the tuning fork with one hand without touching the tines. Tap the fork lightly against the palm of the other hand to set it in vibration ([Table 30.15](#)).

TABLE 30.15

Tuning Fork Tests

Tests and Steps	Rationale
Weber's Test (Lateralization of Sound)	
<p>Hold fork at its base and tap it lightly against heel of palm.</p> <p>Place base of vibrating fork on midline vertex of patient's head or middle of forehead (see illustration A).</p> <p>Ask patient whether he or she hears the sound equally in both ears or better in one ear (lateralization).</p>	<p>Patient with normal hearing hears sound equally in both ears. In conduction deafness sound is heard best in impaired ear. In sensorineural hearing loss, sound is heard better in normal ear.</p>
Rinne Test (Comparison of Air and Bone Conduction)	
<p>Place stem of vibrating tuning fork against patient's mastoid process (see illustration B).</p> <p>Begin counting the interval with your watch.</p> <p>Ask patient to tell you when he or she no longer hears the sound; note number of seconds. Quickly place still-vibrating tines 1 to 2 cm ($\frac{1}{2}$ to 1 inch) from ear canal and ask patient to tell you when he or she no longer hears the sound (see illustration C).</p> <p>Continue counting time the sound is heard by air conduction.</p> <p>Compare number of seconds the sound is heard by bone conduction versus air conduction.</p>	<p>Patient should hear air-conducted sound twice as long as bone-conducted sound (2:1 ratio). For example, if patient hears bone-conducted sound for 10 seconds, he or she should hear air-conducted sound for an additional 10 seconds. In conduction deafness patient hears bone conduction longer than air conduction in affected ear. In sensorineural loss patient hears air conduction longer than bone conduction in affected ear, but at less than a 2:1 ratio (Ball et al., 2019).</p>
	

Nose and Sinuses

Use inspection and palpation to assess the integrity of the nose and sinuses. The patient sits during the examination. A penlight allows for gross examination of each naris. A more detailed examination requires use of a nasal speculum to inspect the deeper nasal turbinates. Do not use a speculum unless a qualified practitioner such as a nurse educator or an

advanced practice nurse is present. [Table 30.16](#) lists components of the nursing history.

TABLE 30.16

Nursing History for Nose and Sinus Assessment

Assessment	Rationale
Ask whether patient has had trauma to nose.	Trauma causes septal deviation and asymmetry of external nose.
Ask whether patient has history of allergies, nasal discharge, epistaxis (nosebleeds), or postnasal drip.	History is useful in determining source or nature of nasal and sinus drainage.
If there is history of nasal discharge, assess color, amount, odor, duration, and associated symptoms (e.g., sneezing, nasal congestion, obstruction, or mouth breathing).	Aids in ruling out presence of infection, allergy, or drug use.
Assess for history of nosebleed, including site, frequency, amount of bleeding, treatment, and difficulty stopping bleeding.	Characteristics sometimes reveal trauma, medication use, or excessive dryness as causative factors.
Ask whether patient uses nasal spray or drops, including amount, frequency, and duration of use.	Overuse of over-the-counter nasal preparations causes physical change in mucosa.
Ask whether patient snores at night or has difficulty breathing.	Difficulty breathing or snoring indicates septal deviation or obstruction.

Nose

When inspecting the external nose, observe for shape, size, skin color, and the presence of deformity or inflammation. The nose is normally smooth and symmetrical with the same skin color as the face. Recent trauma sometimes causes edema and discoloration. If swelling or deformities exist, gently palpate the ridge and soft tissue of the nose by placing one finger on each side of the nasal arch and gently moving the fingers from the nasal bridge to the tip. Note any tenderness, masses, or underlying deviations. Nasal structures are usually firm and stable.

Air normally passes freely through the nose when a person breathes. To assess patency of the nares, place a finger on the side of the patient’s nose and occlude one naris. Ask the patient to breathe with the mouth closed. Repeat the procedure for the other naris.

While illuminating the anterior nares, inspect the mucosa for color, lesions, discharge, swelling, and evidence of bleeding. If discharge is present, apply gloves. Normal mucosa is pink and moist without lesions. Pale mucosa with clear discharge indicates allergy. A mucoid discharge indicates rhinitis. An infection (viral or bacterial) results in yellowish or

greenish discharge. Habitual use of intranasal cocaine and opioids causes puffiness and increased vascularity of the nasal mucosa. For the patient with a nasogastric tube, routinely check for local skin breakdown (**excoriation**) of the naris, characterized by redness and skin sloughing.

To view the septum and turbinates, have the patient tip the head back slightly to provide a clear view. Illuminate the septum and observe for alignment, perforation, or bleeding. Normally the septum is close to the midline and thicker anteriorly than posteriorly. The turbinates are covered with mucous membranes that warm and moisten inspired air. Normal mucosa is pink and moist, without lesions. A deviated septum obstructs breathing and interferes with passage of a nasogastric tube. Perforation of the septum often occurs after repeated use of intranasal cocaine. Note any **polyps** (tumorlike growths) or purulent drainage.

Sinuses

Examination of the sinuses involves palpation. In cases of allergies or infection, the interior of the sinuses becomes inflamed and swollen. The most effective way to assess for tenderness is by externally palpating the frontal and maxillary facial areas ([Fig. 30.20](#)). Palpate the frontal sinus by exerting pressure with the thumb up and under the patient's eyebrow. Gentle, upward pressure elicits tenderness easily if sinus irritation is present. Do not apply pressure to the eyes. If sinus tenderness is present, the sinuses may be transilluminated. However, this procedure requires advanced experience. [Box 30.14](#) describes teaching guidelines during nose and sinus assessment.

FIG. 30.20 Palpation of maxillary sinuses.

Box 30.14 Patient Teaching **Nose and Sinus Assessment**

Objective

- Patient will explain self-care measures to address and minimize loss of olfaction.

Teaching Strategies

- Caution patient against overuse of over-the-counter nasal sprays, which leads to “rebound” effect, causing excess nasal congestion.
- Instruct parents in care of a child with nosebleeds: have child sit up and lean forward to avoid aspiration of blood, apply pressure to the anterior nose with the thumb and forefinger as the child breathes through the mouth, and apply ice or a cold cloth to the bridge of the nose if pressure fails to stop bleeding.
- Instruct older adults with loss of olfaction to follow safety precautions:
 - Install smoke detectors on each floor of their home.
 - Ask others to advise them when food smells pungent.
- Instruct older adults to always check dated labels on food to ensure against spoilage.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Show me how you will instill the nasal spray you purchased at the pharmacy.
- Show me the techniques that you will use to stop a nosebleed.
- Show me the smoke detector locations in your home and how you check to make sure they are working properly.

Mouth and Pharynx

Assess the mouth and pharynx to detect signs of overall health. Determine a patient’s oral hygiene needs and therapies needed if he or she has dehydration, restricted intake, oral trauma, or oral airway obstruction. To assess the oral cavity, use a penlight and tongue depressor or gauze

square. Wear clean gloves during the examination. Have the patient sit or lie down. Assess the oral cavity also while administering oral hygiene (see [Chapter 40](#)). [Table 30.17](#) describes the nursing history for assessment of the mouth and pharynx.

TABLE 30.17

Nursing History for Mouth and Pharyngeal Assessment

Assessment	Rationale
Determine whether patient wears dentures or retainers and whether they are comfortable.	Patient needs to remove dentures to visualize and palpate gums. Ill-fitting dentures chronically irritate mucosa and gums.
Determine whether patient has had recent change in appetite or weight.	Symptoms result from painful mouth conditions or poor hygiene.
Determine whether patient uses tobacco products: <ul style="list-style-type: none"> • Smoking cigarettes, cigars, or pipe; smokeless tobacco; chewing tobacco and snuff • E-cigarettes or vapor cigarettes 	Tobacco use in any form (smoked and smokeless) increases the risk for oral-pharyngeal cancer (ACS, 2018b). Long-term smokeless tobacco users have an increased risk for cancer of the gums and cheeks (ACS, 2018b). Electronic nicotine delivery systems (e-cigarettes) are on the rise in adolescence and may contribute to the use of combustible tobacco products because the flavorings desensitize the lungs' negative response to nicotine inhalation (ACS, 2018b ; Cancer.Net, 2018).
Review history for alcohol consumption.	Oral and pharyngeal cancers are more common in people who use alcohol. Those who both smoke and drink have a 15 times greater risk of developing oral cancer than others (ACS, 2018b ; Oral Cancer Foundation, 2018).
Assess dental hygiene practices, including use of fluoride toothpaste, frequency of brushing and flossing, and frequency of dental visits.	Assessment reveals patient's need for education and/or financial support. Periodontal disease has a higher prevalence in older adults who have history of high plaque buildup, use tobacco, and visit the dentist infrequently.
Ask whether patient has pain from chewing or eating. If so, ask whether mouth lesions are present, including duration and associated symptoms.	Pain is often associated with broken tooth, teeth grinding, or temporomandibular joint problems. Extra care is needed during oral hygiene administration.
Review a patient's medical history for a previous diagnosis of the human papilloma virus (HPV).	HPV, particularly HPV16, has been definitively implicated as a risk for oral cancers, particularly those that occur in the back of the mouth (oropharynx, base of tongue, tonsillar pillars and crypt, and the tonsils themselves) (Oral Cancer Foundation, 2018 ; ACS, 2018b).

Lips

Inspect the lips for color, texture, hydration, contour, and lesions. With the patient's mouth closed, view the lips from end to end. Normally they are pink, moist, symmetrical, and smooth ([Fig. 30.21](#)). Lip color in a patient with dark skin varies from pink to plum. Have female patients remove their lipstick before the examination. Anemia causes pallor of the lips, with cyanosis caused by respiratory or cardiovascular problems. Cherry-colored lips indicate carbon monoxide poisoning. When you inspect any lesion, consider the potential of it being an infection, irritation, or skin cancer.

FIG. 30.21 Lips are normally pink, symmetrical, smooth, and moist.

Buccal Mucosa, Gums, and Teeth

Ask the patient to clench the teeth and smile to observe teeth occlusion. The upper molars normally rest directly on the lower molars, and the upper incisors slightly override the lower incisors. A symmetrical smile reveals normal facial nerve function.

Inspect the teeth to determine the quality of dental hygiene ([Box 30.15](#)). Note the position and alignment of the teeth. To examine the posterior surface of the teeth, have the patient open the mouth with the lips relaxed. Use a tongue depressor to retract the lips and cheeks, especially when viewing the molars. Note the color of teeth and presence of dental caries (cavities), tartar, and extraction sites. Normal, healthy teeth are smooth, white, and shiny. A chalky white discoloration of the enamel is an early indication of caries formation. Brown or black discolorations indicate the formation of caries. A stained yellow color is from tobacco use; coffee, tea, and colas cause a brown stain. In the older adult loose or missing teeth are common because bone resorption increases. An older adult's teeth often feel rough when tooth enamel calcifies. Yellow or darkened teeth are also

common in the older adult because of the general wear and tear that exposes the darker underlying dentin.

Box 30.15 PATIENT TEACHING Mouth and Pharyngeal Assessment

Objective

- Patient will practice proper oral hygiene/dental care measures and identify symptoms of oral cancer.

Teaching Strategies

- Discuss proper techniques for oral hygiene, including brushing and flossing (see Chapter 40).
- Explain the early warning signs of oral cavity and pharynx cancer that should be checked by a health care professional, including a mouth sore that bleeds easily and does not heal, a lump or thickening in the cheek, a white or red patch on the mucosa that persists, a sore throat or a feeling that something is caught in the throat, numbness of the tongue or other area of the mouth, or a swelling of the jaw that causes dentures to not fit (Oral Cancer Foundation, 2018).
- Late symptoms of oral cancer are difficulty in chewing, swallowing, or moving the tongue or jaw (ACS, 2018b).
- Encourage regular dental examination every 6 months for children, adults, and older adults.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Show me the technique you use to brush your teeth.
- Explain to me how often you should have regular dental checkups.
- Tell me the warning signs of mouth cancer and when you should call the health care provider.

To view the mucosa and gums, ask the patient to first remove any dental appliance. View the inner oral mucosa by having the patient open and relax the mouth slightly and then gently retract his or her lower lip away from the teeth ([Fig. 30.22](#)). Repeat this process for the upper lip. Inspect the mucosa for color; hydration; texture; and lesions such as ulcers, abrasions, or cysts. Normally the mucosa is glistening, pink, smooth, and moist. Some common small, yellow-white raised lesions on the buccal mucosa and lips are Fordyce spots, or ectopic sebaceous glands ([Ball et al., 2019](#)). If lesions are present, palpate them gently with a gloved hand for tenderness, size, and consistency.

FIG. 30.22 Inspection of inner oral mucosa of lower lip.

To inspect the buccal mucosa, ask the patient to open the mouth and then gently retract the cheeks with a tongue depressor ([Fig. 30.23](#)). View the surface of the mucosa from right to left and top to bottom. A penlight illuminates the most posterior part of the mucosa. Normal mucosa is glistening, pink, soft, moist, and smooth. Varying shades of hyperpigmentation are normal in 10% of whites after age 50 and as many as 90% of blacks by the same age. For patients with normal pigmentation,

the buccal mucosa is a good site to inspect for jaundice and pallor. In older adults the mucosa is normally dry because of reduced salivation. Thick white patches (leukoplakia) are often a precancerous lesion seen in heavy smokers and alcoholics. Palpate for any buccal lesions by placing the index finger within the buccal cavity and the thumb on the outer surface of the cheek. Patients who smoke cigarettes, cigars, or pipes and those who use smokeless tobacco have an increased risk of oral, pharyngeal, laryngeal, and esophageal cancer. These individuals may have leukoplakia or other lesions anywhere in their oral cavity (e.g., lips, gums, or tongue) at an early age. These usually appear as cream-white patches throughout the inner mouth area.

FIG. 30.23 Retraction of buccal mucosa allows for clear visualization.

Inspect the gums (gingivae) for color, edema, retraction, bleeding, and lesions while retracting the cheeks. Healthy gums are pink, smooth, and moist and fit tightly around each tooth. Patients with dark skin often have patchy pigmentation. In older adults the gums are usually pale. Using clean gloves, palpate the gums to assess for lesions, thickening, or masses. Normally there is no tenderness. Spongy gums that bleed easily indicate

periodontal disease and vitamin C deficiency. If a patient has loose or mobile teeth, swollen gums, or pockets containing debris at the tooth margins, a dental referral is necessary to check for periodontal disease or gingivitis.

Tongue and Floor of Mouth

Carefully inspect the tongue on all sides and the floor of the mouth. Have the patient relax the mouth and stick the tongue out halfway. Note any deviation, tremor, or limitation in movement. This tests hypoglossal nerve function. If a patient protrudes the tongue too far, it elicits the gag reflex. When the tongue protrudes, it lays midline. To test for tongue mobility, ask the patient to raise it up and move it from side to side. It should move freely.

Using a penlight for illumination, examine the tongue for color, size, position, texture, and coatings or lesions. A normal tongue is medium or dull red in color, moist, slightly rough on the top surface, and smooth along the lateral margins. The undersurface of the tongue and the floor of the mouth are highly vascular ([Fig. 30.24](#)). Take extra care to inspect this area, a common site for oral cancer lesions. The patient lifts the tongue by placing its tip on the palate behind the upper incisors. Inspect for color, swelling, and lesions such as nodules or cysts. The ventral surface of the tongue is pink and smooth, with large veins between the frenulum folds. To palpate the tongue, explain the procedure and ask the patient to protrude it. Grasp the tip with a gauze square and gently pull it to one side. With a gloved hand palpate the full length of the tongue and the base for any areas of hardening or ulceration. Varicosities (swollen, tortuous veins) are common in the older adult and rarely cause problems.

FIG. 30.24 Undersurface of tongue is highly vascular.

Palate

Have the patient extend the head backward, holding the mouth open to inspect the hard and soft palates. The hard palate, or roof of the mouth, is located anteriorly. The whitish hard palate is dome shaped. The soft palate extends posteriorly toward the pharynx. It is normally light pink and smooth. Observe the palates for color, shape, texture, and extra bony prominences or defects ([Fig. 30.25](#)). A bony growth, or exostosis, between the two palates is common.

FIG. 30.25 Hard palate is located anteriorly in roof of mouth.

Pharynx

Perform an examination of pharyngeal structures to rule out infection, inflammation, or lesions. Have the patient tip the head back slightly, open the mouth wide, and say “ah” while you place the tip of a tongue depressor on the middle third of the tongue. Take care not to press the lower lip against the teeth. By placing the tongue depressor too far anteriorly, the posterior part of the tongue mounds up, obstructing the view. Placing the tongue depressor on the posterior tongue elicits the gag reflex.

With a penlight first inspect the uvula and soft palate ([Fig. 30.26](#)). Both structures, which are innervated by the tenth cranial (vagus) nerve, should rise centrally as the patient says “ah.” Examine the anterior and posterior pillars, soft palate, and uvula. View the tonsils in the cavities between the anterior and posterior pillars and note the presence or absence of tissue. The posterior pharynx is behind the pillars. Normally pharyngeal tissues are pink and smooth and well hydrated. Small irregular spots of lymphatic tissue and small blood vessels are normal. Note edema, petechiae (small hemorrhages), lesions, or exudate. Patients with chronic sinus problems

frequently exhibit a clear exudate that drains along the wall of the posterior pharynx. Yellow or green exudate indicates infection. A patient with a typical sore throat has a red and edematous uvula and tonsillar pillars with possible presence of yellow exudate.

FIG. 30.26 Penlight and tongue depressor allow visualization of uvula and posterior soft palate.

Neck

Assessment of the neck includes assessing the neck muscles, lymph nodes of the head and neck, carotid arteries, jugular veins, thyroid gland, and trachea (Fig. 30.27). You may postpone the examination of the jugular veins and carotid arteries until the vascular system assessment. Inspect and palpate the neck to determine the integrity of its structures and examine the lymphatic system. An abnormality of superficial lymph nodes sometimes reveals the presence of an infection or **malignancy**. Examine the lymphatic system region by region during the assessment of other body systems (head and neck, breast, genitalia, and extremities).

Examination of the thyroid gland and trachea also aids in ruling out malignancies. Perform this examination with the patient sitting. The sternocleidomastoid and trapezius muscles outline the areas of the neck, dividing each side of the neck into two triangles. The anterior triangle contains the trachea, thyroid gland, carotid artery, and anterior cervical lymph nodes. The posterior triangle contains the posterior lymph nodes. [Table 30.18](#) reviews the nursing history for the head and neck examination.

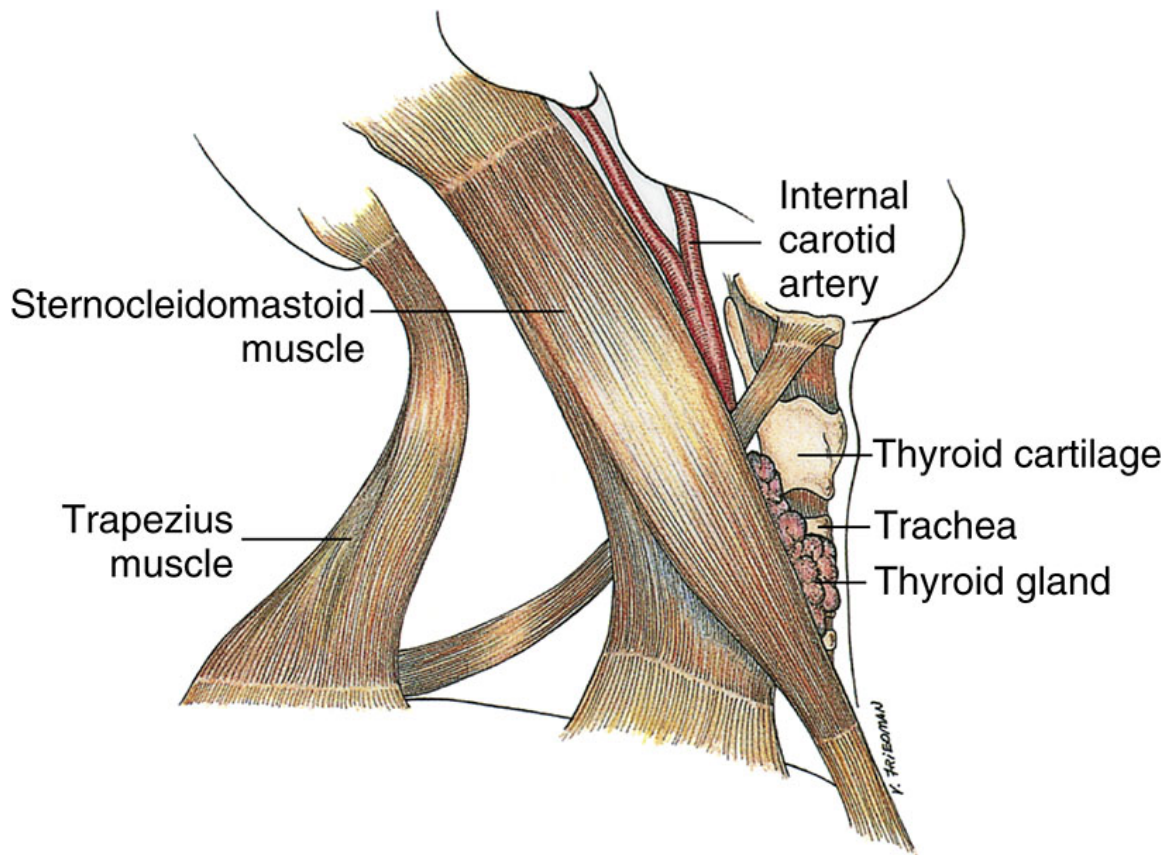

FIG. 30.27 Anatomical position of major neck structures. Note triangles formed by sternocleidomastoid muscle, lower jaw, and anterior neck anteriorly and sternocleidomastoid muscle, trapezius muscle, and lower neck posteriorly.

TABLE 30.18**Nursing History for Neck Assessment**

Assessment	Rationale
Assess for history of recent cold, infection, or enlarged lymph nodes or exposure to radiation or toxic chemicals.	Colds or infections cause temporary or permanent lymph node enlargement. Lymph nodes are also enlarged in various diseases such as cancer.
If there is an enlarged lymph node, consider reviewing history of intravenous drug use, hemophilia, sexual contact with people infected with human immunodeficiency virus (HIV), history of blood transfusion, multiple and indiscriminate sexual contacts, or male with homosexual or bisexual activities.	These are risk factors for HIV infection.
Ask whether patient has had history of neck pain with restriction in movement.	This indicates muscle strain, head injury, local nerve injury, or enlarged or swollen lymph node.
Ask whether patient has had change in temperature preference (more or less clothing); swelling in neck; change in texture of hair, skin, or nails; or change in emotional stability.	Symptoms indicate thyroid disease.
Ask whether patient has history of hypothyroidism or hyperthyroidism, takes thyroid medication, or has a family history of thyroid disease.	Disease or medications influence tissue growth of gland.
Review medical history of pneumothorax (collapsed lung) or bronchial tumor.	Conditions place patient at risk for tracheal displacement or lateral deviation.

Neck Muscles

First inspect the neck in the usual anatomical position, with slight hyperextension. Observe for symmetry of the neck muscles. Ask the patient to flex the neck with the chin to the chest, hyperextend the neck backward, and move the head laterally to each side and then sideways with the ear moving toward the shoulder. This tests the sternocleidomastoid and trapezius muscles. The neck normally moves without discomfort. Perform other tests for muscle strength and function during assessment of the musculoskeletal system.

Lymph Nodes

An extensive system of lymph nodes collects lymph from the head, ears, nose, cheeks, and lips (Fig. 30.28). The immune system protects the body from foreign antigens, removes damaged cells from the circulation, and provides a partial barrier to growth of malignant cells within the body. Assessing the lymph nodes requires competence when caring for patients

with a compromised immune system, which is often linked to allergies, human immunodeficiency virus (HIV) infection, autoimmune disease (e.g., lupus erythematosus), or serious infection.

FIG. 30.28 Palpable lymph nodes in head and neck.
 From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

With the patient's chin raised and head tilted slightly, first inspect the area where lymph nodes are distributed and compare both sides. This position stretches the skin slightly over any possible enlarged nodes. Inspect visible nodes for edema, erythema, or red streaks. Nodes normally are not visible.

Use a methodical approach to palpate the lymph nodes to avoid overlooking any single node or chain. The patient relaxes with the neck flexed slightly forward. Inspect and palpate both sides of the neck for comparison. During palpation either face or stand to the side of the patient for easy access to all nodes. Use the pads of the middle three fingers of

each hand to gently palpate in a circular motion over the nodes (Fig. 30.29). Check each node methodically in the following sequence: occipital nodes at the base of the skull, postauricular nodes over the mastoid, preauricular nodes just in front of the ear, retropharyngeal nodes at the angle of the mandible, submandibular nodes, and submental nodes in the midline behind the mandibular tip. Try to detect enlargement and note the location, size, shape, surface characteristics, consistency, mobility, tenderness, and warmth of the nodes. If the skin is mobile, move it over the area of the nodes. It is important to press underlying tissue in each area and not simply move the fingers over the skin. However, if you apply excessive pressure, you miss small nodes and destroy palpable nodes.

FIG. 30.29 **A**, Palpation of preauricular lymph nodes. **B**, Palpation of supraclavicular lymph nodes.

To palpate supraclavicular nodes, ask the patient to bend the head forward and relax the shoulders. Palpate these nodes by hooking the index and third finger over the clavicle lateral to the sternocleidomastoid muscle. Palpate the deep cervical nodes only with the fingers hooked around the sternocleidomastoid muscle.

Normally lymph nodes are not easily palpable. However, small, mobile, nontender nodes are common. Lymph nodes that are large, fixed, inflamed, or tender indicate a problem such as local infection, systemic disease, or neoplasm (Ball et al., 2016) (Box 30.16). When you find enlarged nodes, explore the adjacent areas and regions that they drain. Tenderness almost always indicates inflammation. A problem involving a lymph node of the head and neck means an abnormality in the mouth, throat, abdomen, breasts, thorax, or arms. These are the areas drained by the head and neck nodes.

Box 30.16 Patient Teaching Neck Assessment

HIV, Human immunodeficiency virus.

Objective

- Patient will take proper preventive action if he or she notices a mass in the neck.

Teaching Strategies

- Stress the importance of regular adherence with the medication schedule to patients with thyroid disease.
- Instruct patient about the lymph nodes and how infection commonly causes node tenderness and mild enlargement.
- Instruct patient to call a health care provider when he or she notices a fixed, enlarged lump or mass in the neck.
- Teach patient the risk factors for HIV infection and other sexually transmitted diseases.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me what signs and symptoms in the neck area would require you to contact your health care provider.

Thyroid Gland

The thyroid gland lies in the anterior lower neck, in front of and to both sides of the trachea. The gland is fixed to the trachea, with the isthmus overlying the trachea and connecting the two irregular, cone-shaped lobes (Fig. 30.30). Inspect the lower neck overlying the thyroid gland for obvious masses, symmetry, and any subtle fullness at the base of the neck. Ask the patient to hyperextend the neck, which helps tighten the skin for better visualization. Offer the patient a glass of water, and, while observing the neck, have him or her swallow. This maneuver helps to visualize an abnormally enlarged thyroid. Normally the thyroid cannot be visualized. Advanced practice nurses examine the thyroid by palpating for more subtle masses.

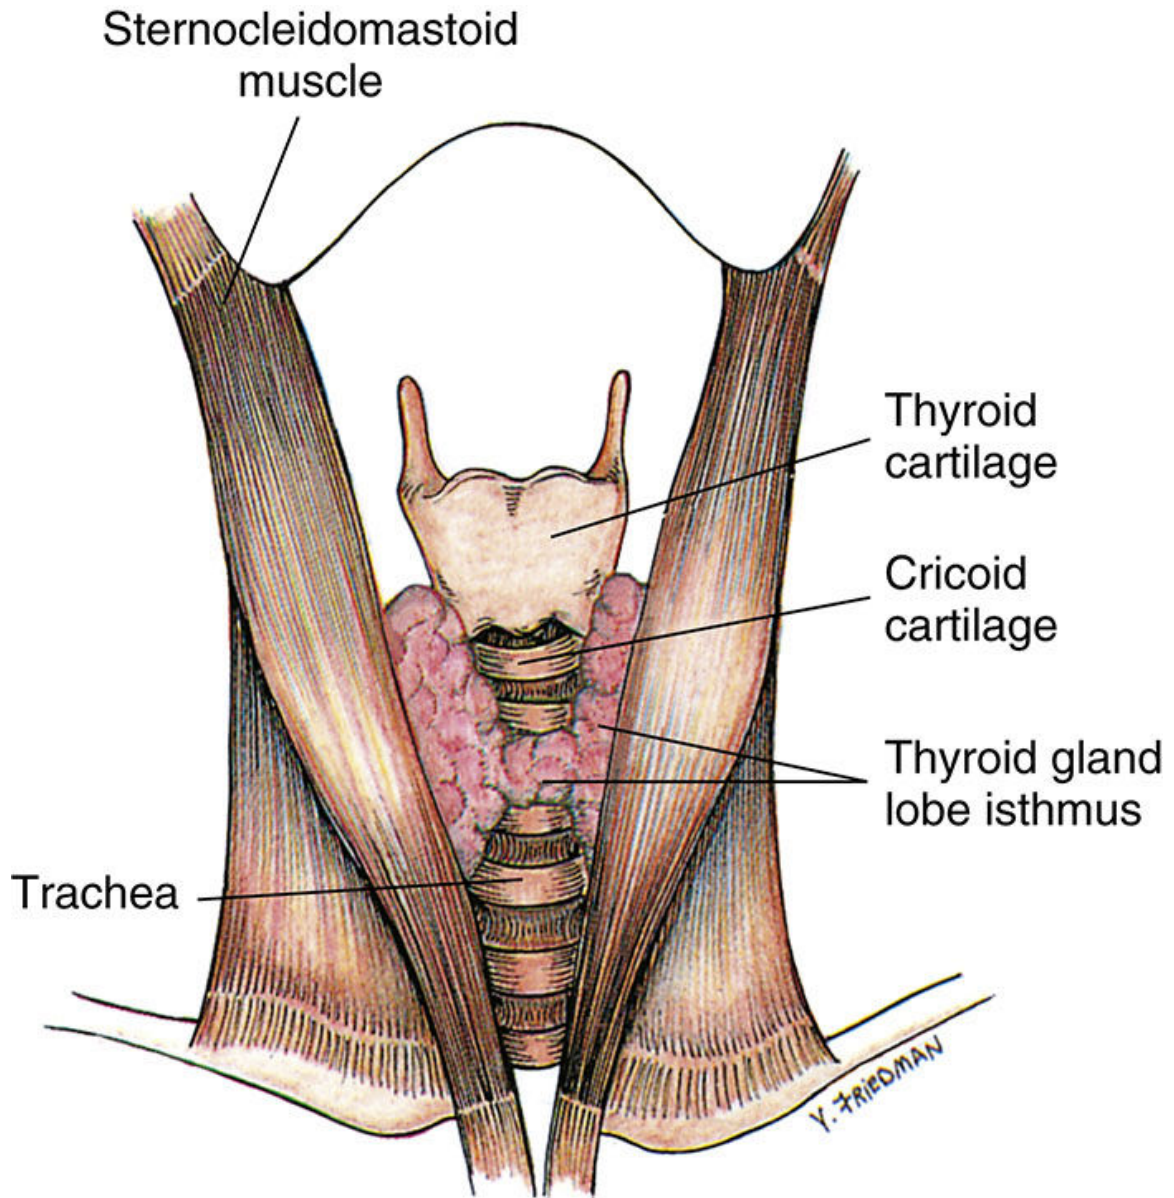

FIG. 30.30 Anatomical position of thyroid gland.

Carotid Artery and Jugular Vein

This part of the examination is described under examination of the vascular system (see later section).

Trachea

The trachea is a part of the upper respiratory system that you directly palpate. It is normally located in the midline above the suprasternal notch.

Masses in the neck or mediastinum and pulmonary abnormalities cause displacement laterally. Have the patient sit or lie down during palpation. Determine the position of the trachea by palpating at the suprasternal notch, slipping the thumb and index fingers to each side. Note if the finger and thumb shift laterally. Do not apply forceful pressure because this elicits coughing.

Thorax and Lungs

Accurate physical assessment of the thorax and lungs requires review of the ventilatory and respiratory functions of the lungs. Diseases of the lungs affect other body systems. For example, the brain is very sensitive to oxygen levels. When a patient has reduced oxygenation, changes in level of consciousness and mental alertness result. Use data from all body systems to determine the nature of pulmonary alterations. You use inspection, palpation, and auscultation to examine the thorax and lungs. Diagnostic equipment such as x-ray films, magnetic resonance imaging (MRI), and computed tomography (CT) scans create little need for the use of percussion as an assessment measure. Risk factors for lung disease are reviewed at the time of respiratory assessment ([Box 30.17](#)).

Box 30.17 Patient Teaching Lung Assessment

COPD, Chronic obstructive pulmonary disease.

Objective

- The patient will practice preventive care measures for lung health.

Teaching Strategies

- Explain risk factors for chronic lung disease and lung cancer, including cigarette smoking; history of smoking for over 20 years; exposure to environmental pollution; and radiation exposure from occupational, medical, and environmental sources. Exposure to radon and asbestos also increases risk. Other risk factors include exposure to certain metals (e.g., arsenic, cadmium, chromium), some organic chemicals, and tuberculosis. Exposure to secondhand cigarette smoke increases risk for nonsmokers (ACS, 2018b).
- Share brochures on lung cancer, asthma, and COPD from American Cancer Society with patient and family.
- Instruct patient with asthma to identify and tell family members and friends which triggers cause asthma episodes.

- Discuss warning signs of lung cancer such as a persistent cough, sputum streaked with blood, chest pains, and recurrent attacks of pneumonia or bronchitis.
- Counsel older adult about benefits of receiving influenza and pneumonia vaccinations because of a greater susceptibility to respiratory infection.
- Instruct patient with COPD how to perform coughing and pursed-lip breathing exercises.
- Refer people at risk for tuberculosis to visit clinics or health care centers for skin testing.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me three risk factors for lung disease and lung cancer.
- Describe for me the warning signs of lung cancer.
- Explain to me the importance of receiving a pneumonia and annual influenza vaccine.
- Show me how you perform your deep breathing and coughing exercises.

First identify the landmarks of the chest to assess the thorax and lungs correctly (Fig. 30.31A-C). A patient's nipples, angle of Louis, suprasternal notch, costal angle, clavicles, and vertebrae are key landmarks that provide a series of imaginary lines for sign identification. Keep a mental image of the location of the lobes of the lung and the position of each rib (Fig. 30.32A-C). Your understanding of the anatomical structures ensures a thorough assessment of the anterior, lateral, and posterior thorax.

FIG. 30.31 Anatomical chest wall landmarks. **A**, Posterior chest landmarks. **B**, Lateral chest landmarks. **C**, Anterior chest landmarks.

Locate the position of each rib to visualize the lobe of the lung being assessed. To begin, find the angle of Louis at the manubriosternal junction. The angle is a visible and palpable angulation of the sternum and is the point at which the second rib articulates with the sternum. Count the ribs and intercostal spaces (between the ribs) from this point. The number of each intercostal space corresponds with that of the rib just above it. The spinous process of the third thoracic vertebra and the fourth, fifth, and sixth ribs help to locate the lobes of the lung laterally. The lower lobes project laterally and anteriorly (see [Fig. 30.32B](#)). Posteriorly the tip or inferior margin of the scapula lies approximately at the level of the seventh rib (see [Fig. 30.32C](#)). After identifying the seventh rib, count upward to locate the third thoracic vertebra and align it with the inner borders of the scapula to locate the posterior lobes.

FIG. 30.32 Position of lung lobes in relation to anatomical landmarks. **A**, Anterior position. **B**, Lateral position. **C**, Posterior position. From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Ensure the patient is undressed to the waist, and ensure the room has good lighting when performing your assessment. Begin with the patient sitting to assess the posterior and lateral chest if possible. Have him or her sit or lie down for assessment of the anterior chest. [Table 30.19](#) reviews the nursing history for lung examination.

TABLE 30.19**Nursing History for Lung Assessment**

Assessment	Rationale
Assess history of tobacco or marijuana use, including type of tobacco, duration, and amount (Pack-years = Number of years smoking × Number of packs per day), age started, efforts to quit, and length of time since smoking stopped.	Smoking is a risk factor for lung cancer, heart disease, cerebrovascular disease, emphysema, or chronic bronchitis. It accounts for a significant percentage of all cancer deaths. It increases the risk for 12 types of cancer (ACS, 2018b).
Ask whether patient has had a <i>persistent cough</i> (productive or nonproductive), <i>sputum streaked with blood</i> , <i>voice change</i> , <i>chest pain</i> , <i>shortness of breath</i> , <i>orthopnea</i> , <i>dyspnea during exertion or at rest</i> , <i>poor activity tolerance</i> , or <i>recurrent attacks of pneumonia or bronchitis</i> .	Symptoms of cardiopulmonary alterations help localize objective physical findings. (Warning signals for lung cancer are in italic type.) The diaphragm of the lungs expands more easily when the individual is sitting upright, as for patients who must be in an upright position to breathe.
Determine whether patient works in environment containing pollutants (e.g., asbestos, arsenic, coal dust) or requiring exposure to radiation. Does patient have exposure to secondhand smoke?	These risk factors increase chance for various lung diseases.
Review history for known or suspected human immunodeficiency virus (HIV) infection; substance abuse; low income; or being homeless, a resident or employee of a nursing home or shelter, a recent prison inmate, a family member of a tuberculosis (TB) patient, or an immigrant to the United States from a country where TB is prevalent.	These are risk factors for TB.
Ask whether patient has history of persistent cough, hemoptysis, unexplained weight loss, fatigue, night sweats, or fever.	These are risk factors for both TB and HIV infection.
Does patient have history of chronic hoarseness?	Hoarseness indicates laryngeal disorder or abuse of cocaine or opioids (sniffing).
Assess history of allergies to pollens, dust, or other airborne irritants and to foods, drugs, or chemical substances.	Symptoms such as choking feeling, bronchospasm with respiratory stridor, wheezes on auscultation, and dyspnea are often caused by allergic response.
Review family history for cancer, TB, allergies, or chronic obstructive pulmonary disease.	Conditions place patient at risk for lung disease.
Ask whether patient has had a pneumonia or influenza vaccine and a TB test; if not, educate him or her on need to do so.	The very young, the very old, and those with chronic respiratory problems or immunosuppressive diseases are at increased risk for respiratory disease.

Posterior Thorax

Begin examination of the posterior thorax by observing for any signs or symptoms in other body systems that indicate pulmonary problems. Reduced mental alertness, nasal flaring, somnolence, and cyanosis are

examples of assessed signs that indicate oxygenation problems. Inspect the posterior thorax by observing the shape and symmetry of the chest from the patient's back and front. Note the anteroposterior diameter. Body shape or posture significantly impairs ventilatory movement. Normally the chest contour is symmetrical, with the anteroposterior diameter one-third to one-half of the transverse, or side-to-side, diameter. A barrel-shaped chest (anteroposterior diameter equals transverse diameter) characterizes aging and chronic lung disease. Infants have an almost round shape. Congenital and postural alterations cause abnormal contours in which a patient may lean over a table or splint the side of the chest because of a breathing problem. Pain sometimes causes a patient to splint or hold the chest wall and bend toward the affected side, resulting in impaired ventilatory movement.

Standing at a midline position behind the patient, look for deformities, position of the spine, slope of the ribs, retraction of the intercostal spaces during inspiration, and bulging of the intercostal spaces during expiration. The scapulae are normally symmetrical and closely attached to the thoracic wall. The normal spine is straight without lateral deviation. Posteriorly the ribs tend to slope across and down. The ribs and intercostal spaces are easier to see in a thin person. Normally no bulging or active movement occurs within the intercostal spaces during breathing. Bulging indicates that a patient is using great effort to breathe.

Also assess the rate and rhythm of breathing. Observe the thorax as a whole. It normally expands and relaxes regularly with equal movement bilaterally. In healthy adults the normal respiratory rates vary from 12 to 20 respirations per minute.

Palpation of the posterior thorax provides further information about a patient's health status. Palpate the thoracic muscles and skeleton for lumps, masses, pulsations, and unusual movement. If the patient voices pain or tenderness, avoid deep palpation. Fractured rib fragments could be displaced against vital organs. Normally the chest wall is not tender. If there is a suspicious mass or swollen area, lightly palpate it for size, shape, and the typical qualities of a lesion.

To measure chest excursion or depth of breathing, stand behind the patient and place the thumbs along the spinal processes at the 10th rib, with the palms lightly contacting the posterolateral surfaces. Place thumbs 5 cm (2 inches) apart, pointing toward the spine with fingers pointing laterally ([Fig. 30.33A](#)). Press the hands toward the spine so that a small skinfold appears between the thumbs. Do not slide the hands over the skin. Instruct the patient to exhale and then take a deep breath. Note

movement of the thumbs during inhalation (see [Fig. 30.33B](#)). Chest excursion is symmetrical, separating the thumbs 3 to 5 cm (1¼ to 2 inches). Reduced chest excursion may be caused by pain, postural deformity, or fatigue. In older adults chest movement normally declines because of costal cartilage calcification and respiratory muscle atrophy.

FIG. 30.33 A, Hand position for palpation of posterior thorax excursion. B, As patient inhales, movement of chest excursion separates thumbs.

During speech the sound created by the vocal cords is transmitted through the lungs to the chest wall. The sound waves create vibrations that you palpate externally. These vibrations are called **vocal or tactile fremitus**. The accumulation of mucus, the collapse of lung tissue, or the presence of one or more lung lesions blocks the vibrations from reaching the chest wall.

To palpate for tactile fremitus, use a firm, light touch and place the palmar surfaces of the fingers or the ulnar part of the hand over symmetrical intercostal spaces, beginning at the lung apex ([Fig. 30.34A](#)). Ask the patient to say “ninety-nine” or “one-one-one.” Palpate both sides simultaneously and symmetrically (from top to bottom) for comparison or use one hand, quickly alternating between the two sides ([Ball et al., 2019](#)). Normally a faint vibration is present as a patient speaks. If fremitus is faint, ask the patient to speak in a louder or lower tone of voice. Normally fremitus is symmetrical. Vibrations are strongest at the top, near the level of the tracheal bifurcation. Strong vibrations through the chest wall occur in crying infants.

FIG. 30.34 A to C, Systematic pattern (posterior-lateral-anterior) is followed when palpating and auscultating thorax.

Use auscultation to assess the movement of air through the tracheobronchial tree and detect mucus or obstructed airways. Normally air flows through the airways in an unobstructed pattern. Recognizing the sounds created by normal airflow allows you to detect sounds caused by airway obstruction. Follow the same systematic approach you used for palpation when auscultating the lungs (see [Fig. 30.34A](#)).

Place the diaphragm of the stethoscope firmly on the skin, over the posterior chest wall between the ribs ([Fig. 30.35](#)). Have the patient fold the arms in front of the chest and keep the head bent forward while taking slow, deep breaths with the mouth slightly open. Listen to an entire inspiration and expiration at each position of the stethoscope. If sounds are faint, as in a patient who is obese, ask the patient to breathe harder and faster temporarily. Breath sounds are much louder in children because of their thin chest walls. The bell works best in children because of a child's small chest. Auscultate for normal breath sounds and abnormal or **adventitious sounds** ([Fig. 30.36](#)). Normal breath sounds differ in character, depending on the area you are auscultating and the age of the patient. Bronchovesicular and vesicular sounds are normally heard over the posterior thorax ([Table 30.20](#)).

FIG. 30.35 Use diaphragm of stethoscope to auscultate breath sounds.

FIG. 30.36 Schema of breath sounds in the ill and well patient.
From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

TABLE 30.20**Normal Breath Sounds**

Description	Location	Origin
Vesicular		
Vesicular sounds are soft, breezy, and low pitched. Inspiratory phase is 3 times longer than expiratory phase.	Best heard over periphery of lung (except over scapula)	Created by air moving through smaller airways
Bronchovesicular		
Bronchovesicular sounds are blowing sounds that are medium pitched and of medium intensity. Inspiratory phase is equal to expiratory phase.	Best heard posteriorly between scapulae and anteriorly over bronchioles lateral to sternum at first and second intercostal spaces	Created by air moving through large airways
Bronchial		
Bronchial sounds are loud and high pitched with hollow quality. Expiration lasts longer than inspiration (3:2 ratio).	Heard only over trachea	Created by air moving through trachea close to chest wall

Abnormal sounds result from air passing through moisture, mucus, or narrowed airways. They also result from alveoli suddenly reinflating or an inflammation between the pleural linings of the lung. Adventitious sounds often occur superimposed over normal sounds. The four types of adventitious sounds are crackles, rhonchi, wheezes, and pleural friction rub (see [Fig. 30.36](#)). Each sound has a specific cause and typical auditory features ([Table 30.21](#)). During auscultation note the location and characteristics of the sounds and listen for the absence of breath sounds (found in patients with collapsed or surgically removed lobes).

TABLE 30.21**Adventitious Breath Sounds**

Sound	Site Auscultated	Cause	Character
Crackles	Most common in dependent lobes: right and left lung bases	Random, sudden reinflation of groups of alveoli; disruptive passage of air through small airways	Fine crackles are high-pitched fine, short, interrupted crackling sounds heard during end of inspiration; usually not cleared with coughing. Medium crackles are lower, moister sounds heard during middle of inspiration; not cleared with coughing. Coarse crackles are loud, bubbly sounds heard during inspiration; not cleared with coughing.
Rhonchi (sonorous wheeze)	Primarily heard over trachea and bronchi; if loud enough, able to be heard over most lung fields	Muscular spasm, fluid, or mucus in larger airways; new growth or external pressure causing turbulence	Loud, low-pitched, rumbling, coarse sounds are heard either during inspiration or expiration; sometimes cleared by coughing.
Wheezes (sibilant wheeze)	Heard over all lung fields	High-velocity airflow through severely narrowed or obstructed airway	High-pitched, continuous musical sounds are like a squeak heard continuously during inspiration or expiration; usually louder on expiration.
Pleural friction rub	Heard over anterior lateral lung field (if patient is sitting upright)	Inflamed pleura; parietal pleura rubbing against visceral pleura	Dry, rubbing, or grating quality is heard during inspiration or expiration; does not clear with coughing; heard loudest over lower lateral anterior surface.

Data from Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

If there are abnormalities in tactile fremitus or auscultation, perform the vocal resonance tests (spoken and whispered voice sounds). Place the stethoscope over the same locations used to assess breath sounds and have the patient say “ninety-nine” in a normal voice tone. Normally the sound is muffled. If fluid is compressing the lung, the vibrations from the patient’s voice are transmitted to the chest wall, and the sound becomes clear (bronchophony). Then ask the patient to whisper “ninety-nine.” The whispered voice is usually faint and indistinct. Certain lung abnormalities cause the whispered voice to become clear and distinct (whispered pectoriloquy).

Lateral Thorax

After assessing the posterior thorax, move to the lateral sides of the chest. The patient sits during examination of the lateral chest whenever possible. Have the patient raise the arms to improve access to lateral thoracic structures. Use inspection, palpation, and auscultation skills to examine the lateral thorax (see [Fig. 30.34B](#)). Do not assess excursion laterally. Normally the breath sounds you hear are vesicular.

Anterior Thorax

Inspect the anterior thorax for the same features as the posterior thorax. The patient sits or lies down with the head elevated. Observe the accessory muscles of breathing: sternocleidomastoid, trapezius, and abdominal muscles. The accessory muscles move little with normal passive breathing. However, patients who use a great deal of effort to breathe as a result of strenuous exercise or pulmonary disease (e.g., chronic obstructive pulmonary disease) rely on the accessory and abdominal muscles to contract to inhale and exhale. Some patients who require great effort produce a grunting sound.

Observe the width of the costal angle. It is usually larger than 90 degrees between the two costal margins. Observe a patient's breathing pattern. Normal breathing is quiet and barely audible near the open mouth. You most often assess respiratory rate and rhythm anteriorly. The male patient's respirations are usually diaphragmatic, whereas a female's are more costal. Accurate assessment occurs as the patient breathes passively.

Palpate the anterior thoracic muscles and skeleton for lumps, masses, tenderness, or unusual movement. The sternum and xiphoid are relatively inflexible. Place the thumbs parallel approximately along the costal margin 6 cm (2½ inches) apart with the palms touching the anterolateral chest. Push the thumbs toward the midline to create a skinfold. As the patient inhales deeply, the thumbs normally separate approximately 3 to 5 cm (1¼ to 2 inches), with each side expanding equally.

Assess tactile fremitus over the anterior chest wall. Anterior findings differ from posterior findings because of the heart and female breast tissue. Fremitus is felt next to the sternum at the second intercostal space, at the level of the bronchial bifurcation. It decreases over the heart, lower thorax, and breast tissue.

Auscultation of the anterior thorax follows a systematic pattern (see [Fig. 30.34C](#)) comparing right and left sides. This allows you to compare lung sounds in one region on one side of the body with sounds in the same region on the opposite side of the body.

If possible, have the patient sit to maximize chest expansion. Give special attention to the lower lobes, where mucus secretions commonly gather. Listen for bronchovesicular and vesicular sounds above and below the clavicles and along the lung periphery. In addition, auscultate for bronchial sounds, which are loud, high pitched, and hollow sounding, with expiration lasting longer than inspiration (3:2 ratio). This sound is normally heard over the trachea.

Heart

Compare your assessment of a patient's heart with findings from the vascular assessment (see later section). Alterations in either system sometimes manifest as changes in the other. Some patients with signs or symptoms of heart (cardiac) problems have a life-threatening condition requiring immediate attention. In this case act quickly and conduct only the parts of the examination that are necessary. Conduct a more thorough assessment when the patient is more stable. The nursing history ([Table 30.22](#)) provides data to help interpret physical findings.

TABLE 30.22**Nursing History for Heart Assessment**

Assessment	Rationale
Determine history of smoking, alcohol intake, caffeine intake, use of prescriptive and recreational drugs, exercise habits, and dietary patterns and intake (including fat and sodium intake).	Smoking; alcohol ingestion; cocaine use; lack of regular exercise; intake of foods high in carbohydrates, fats, and cholesterol are risk factors for cardiovascular disease. Caffeine can cause heart dysrhythmias.
Determine whether patient is taking medications for cardiovascular function (e.g., antidysrhythmics, antihypertensives) and whether he or she knows their purpose, dosage, and side effects.	Knowledge allows nurse to assess adherence with drug therapies. Medications sometimes affect vital sign values.
Assess for chest pain or discomfort, palpitations, excess fatigue, cough, dyspnea, leg pain or cramps, edema of feet, cyanosis, fainting, and orthopnea. Ask whether symptoms occur at rest or during exercise.	These are key symptoms of heart disease. Cardiovascular function is sometimes adequate during rest but not during exercise. Positions affect how well lungs can expand.
If patient reports chest pain, determine whether it is cardiac in nature. Anginal pain is usually a deep pressure or ache that is substernal and diffuse, radiating to one or both arms, neck, or jaw.	Assessment determines nature of pain and need to initiate care immediately.
Determine whether patient has stressful lifestyle. Which physical demands and/or emotional stress exist?	Repeated exposure to stress increases risk for heart disease.
Assess family history for heart disease, diabetes, high cholesterol levels, hypertension, stroke, or rheumatic heart disease.	Factors increase risk for heart disease.
Ask patient about history of heart trouble (e.g., heart failure, congenital heart disease, coronary artery disease, dysrhythmias, murmurs).	Knowledge reveals patient's level of understanding of condition. Preexisting condition influences examination techniques used and findings to expect.
Determine whether patient has preexisting diabetes, lung disease, obesity, or hypertension.	These disorders alter heart function.

Assess cardiac system through the anterior thorax. Form a mental image of the exact location of the heart ([Fig. 30.37](#)). In the adult it is located in the center of the chest (precordium), behind and to the left of the sternum, with a small section of the right atrium extending to the right of the sternum. The base of the heart is the upper part, and the apex is the bottom tip. The surface of the right ventricle composes most of the anterior surface of the heart. A section of the left ventricle shapes the left anterior side of the apex. The apex touches the anterior chest wall at approximately the

fourth to fifth intercostal space just medial to the left midclavicular line. This is the **apical impulse or point of maximal impulse (PMI)**.

FIG. 30.37 Anatomical position of heart.

An infant's heart is positioned more horizontally. The apex of the heart is at the third or fourth intercostal space, just to the left of the midclavicular line. By the age of 7 a child's PMI is in the same location as the adult's. In tall, slender people the heart lies more vertically and centrally. In shorter or stockier individuals, the heart tends to lie more to the left and horizontally (Ball et al., 2019).

To assess the heart, you need a clear understanding of the cardiac cycle and associated physiological events (Fig. 30.38). The heart normally pumps blood through its four chambers in a methodical, even sequence. Events on the left side occur just before those on the right. As blood flows through each chamber, the valves open and close, the pressures within chambers rise and fall, and the chambers contract. Each event creates a physiological sign. Both sides of the heart function in a coordinated fashion.

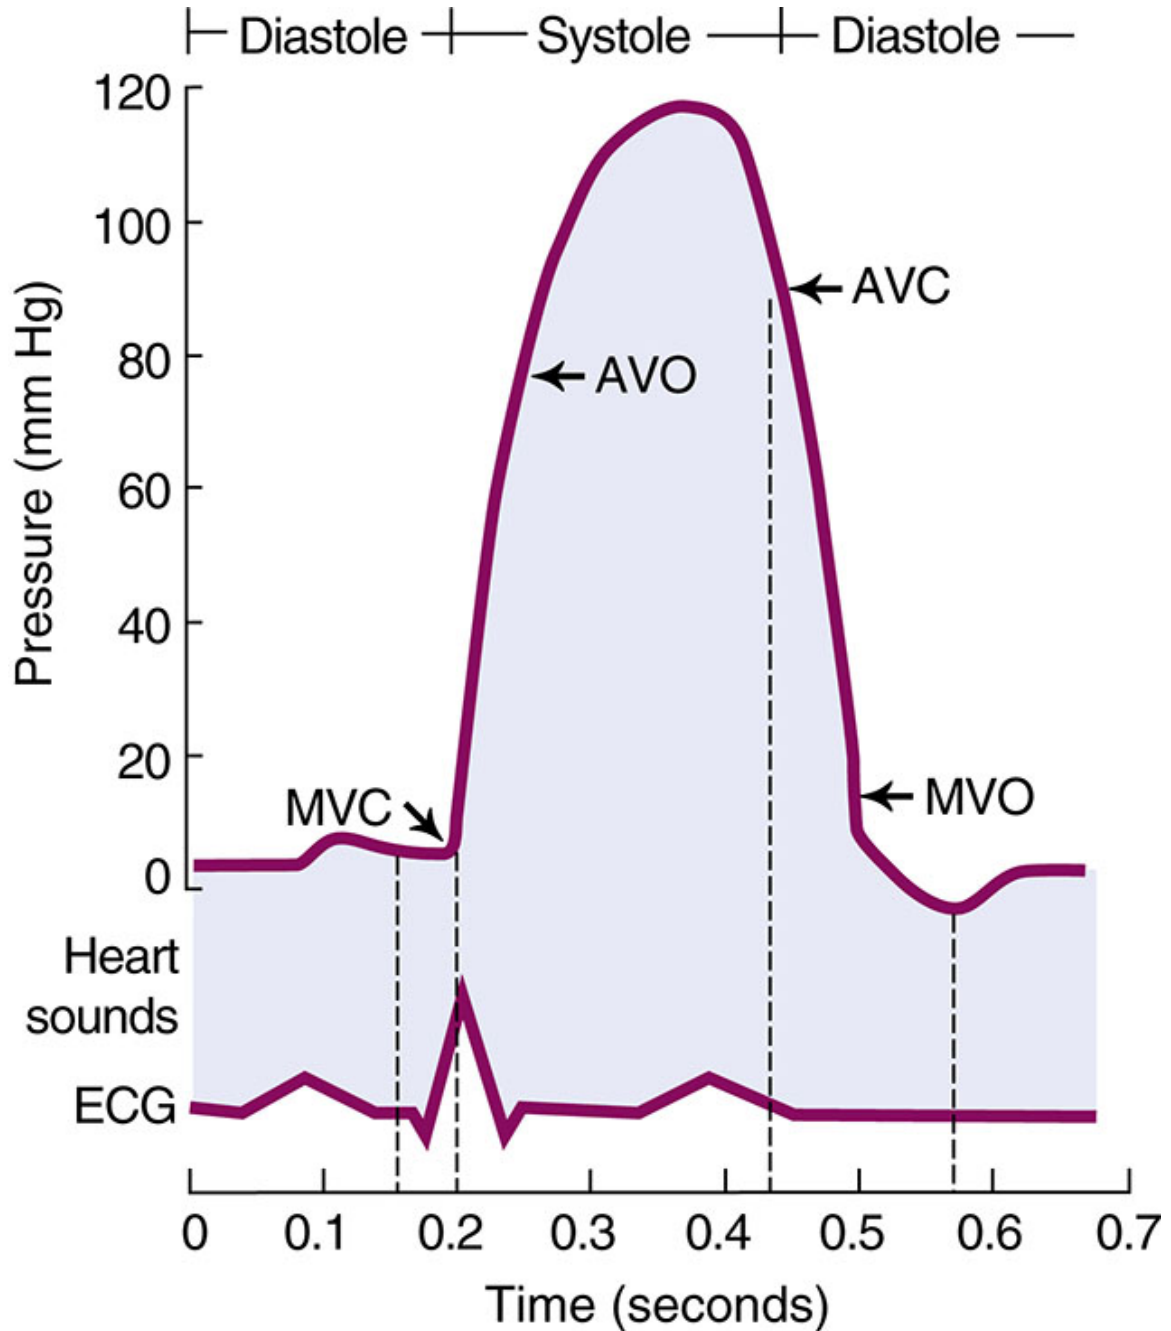

FIG. 30.38 Cardiac cycle. *AVC*, Aortic valve closes; *AVO*, aortic valve opens; *ECG*, electrocardiogram; *MVC*, mitral valve closes; *MVO*, mitral valve opens.

There are two phases to the cardiac cycle: systole and diastole. During systole the ventricles contract and eject blood from the left ventricle into the aorta and from the right ventricle into the pulmonary artery. During diastole the ventricles relax, and the atria contract to move blood into the ventricles and fill the coronary arteries.

Heart sounds occur in relation to physiological events in the cardiac cycle. As systole begins, ventricular pressure rises and closes the mitral and tricuspid valves. Valve closure causes the first heart sound (S_1), often described as “lub.” The ventricles then contract, and blood flows through the aortic and pulmonary valves into circulation. After the ventricles empty, ventricular pressure falls below that in the aorta and pulmonary artery. This allows the aortic and pulmonic valves to close, causing the second heart sound (S_2), described as “dub.” As ventricular pressure continues to fall, it drops below that of the atria. The mitral and tricuspid valves reopen to allow ventricular filling. When the heart attempts to fill an already distended ventricle, a third heart sound (S_3) can be heard, as with heart failure. An S_3 is considered abnormal in adults over 31 years of age but can often be heard normally in children and young adults. It can also be present among women in the late stages of pregnancy. A fourth heart sound (S_4) occurs when the atria contract to enhance ventricular filling. An S_4 is often heard in healthy older adults, children, and athletes, but it is not normal in adults. Because S_4 also indicates an abnormal condition, report it to a health care provider.

Inspection and Palpation

Provide a relaxed and comfortable environment for the examination. Explain the assessment procedure to help decrease a patient’s anxiety. An anxious or uncomfortable patient can have mild tachycardia, which leads to inaccurate findings.

Use the skills of inspection and palpation simultaneously. Begin the examination with the patient in the supine position or with the upper body elevated 45 degrees. Patients with heart disease frequently experience shortness of breath while lying flat. Stand at the patient’s right side. Do not let the patient talk, especially when auscultating heart sounds. Good lighting in the room is essential.

Direct your attention to the anatomical sites best suited for assessment of the cardiac area. During inspection and palpation look for visible pulsations and exaggerated lifts and palpate for the apical impulse and any source of vibrations (thrills). Follow an orderly sequence, beginning with assessment of the base of the heart (top) and moving toward the apex (bottom). First inspect the angle of Louis, which lies between the sternal body and manubrium, and feel the ridge in the sternum approximately 5 cm (2 inches) below the sternal notch. Slip the fingers along the angle on

each side of the sternum to feel adjacent ribs. The intercostal spaces are just below each rib. The second intercostal space allows identification of each of the six anatomical landmarks (Fig. 30.39). The second intercostal space on the right is the *aortic area*, and the left second intercostal space is the *pulmonic area*. You need to use deeper palpation to feel the spaces in obese or heavily muscled patients. After locating the pulmonic area, move the fingers down the patient's left sternal border to the third intercostal space, called the *second pulmonic area*. The *tricuspid area* is located at the fourth or fifth intercostal space along the sternum. To find the *apical* or *mitral area*, locate the fifth intercostal space just to the left of the sternum and move the fingers laterally to the left midclavicular line. Locate the apical area with the palm of the hand or the fingertips. Normally you feel the apical impulse as a light tap in an area 1 to 2 cm ($\frac{1}{2}$ to 1 inch) in diameter at the apex (Fig. 30.40). Another landmark is the epigastric area at the tip of the sternum. Palpate there if you suspect aortic abnormalities.

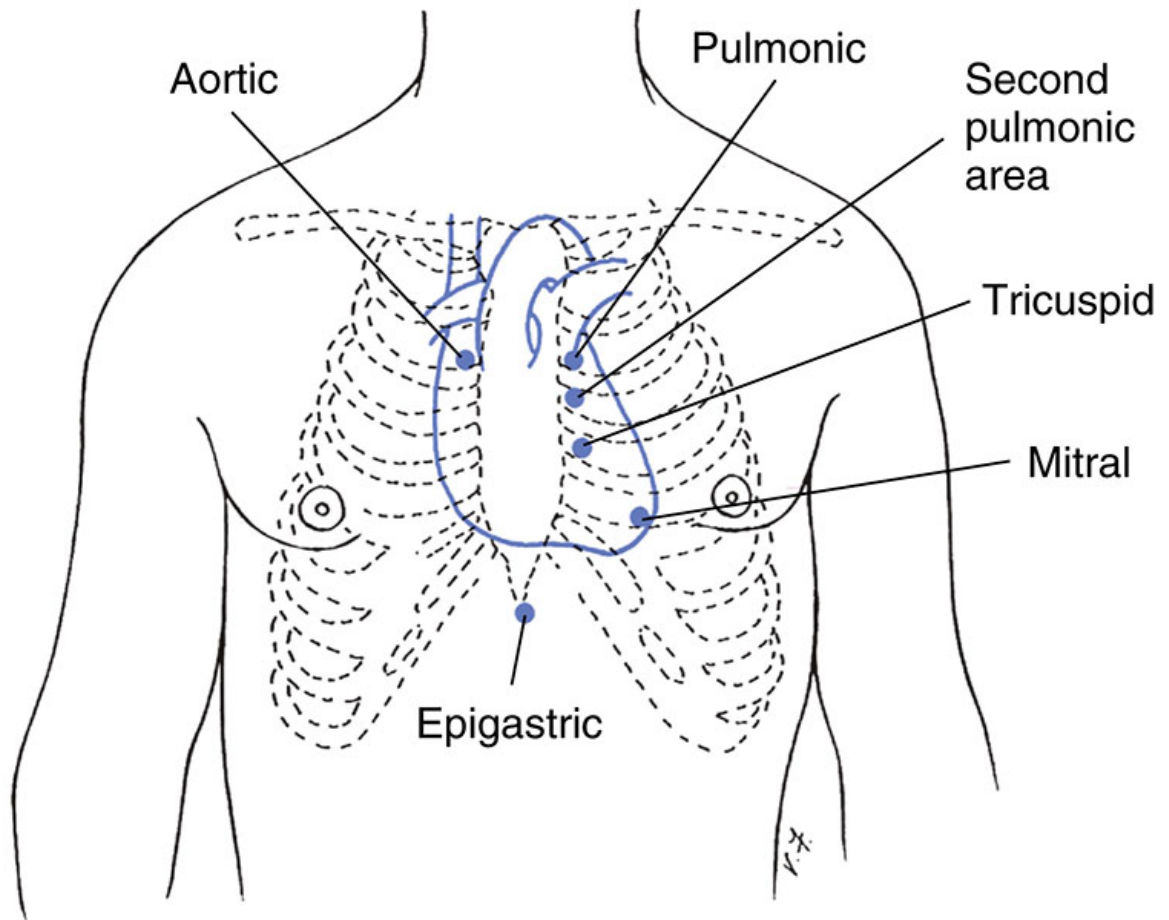

FIG. 30.39 Anatomical sites for assessment of cardiac function.

FIG. 30.40 Palpation of apical pulse.

Locate the six anatomical landmarks of the heart and inspect and palpate each area. Look for the appearance of pulsations, viewing each area over the chest at an angle to the side. Normally you do not see pulsations except perhaps at the PMI in thin patients or at the epigastric area as a result of abdominal aorta pulsation. Use the proximal halves of the four fingers together and alternate this with the ball of the hand to palpate for pulsations. Touch the areas gently to allow movements to lift the hand. Normally no pulsations or vibrations are felt in the second, third, or fourth intercostal spaces. Loud murmurs cause a vibration.

Just medial to the left midclavicular line, at the fourth or fifth intercostal space, is the PMI. If you cannot locate it with the patient in a supine position, have him or her roll onto the left side, moving the heart closer to the chest wall. Estimate the size of the heart by noting the diameter of the PMI and its position relative to the midclavicular line. In cases of serious heart disease, the cardiac muscle enlarges, with the PMI found more to the left of the midclavicular line. The PMI is sometimes difficult to find in the older adult because the chest deepens in its anteroposterior diameters. It is also difficult to find in muscular or overweight patients. An infant's PMI is located near the third or fourth intercostal space. It is easy to palpate because of the child's thin chest wall.

Auscultation

You may hear normal heart sounds, extra heart sounds, and/or murmurs during auscultation of the heart. Concentrate on detecting the normal low-intensity sounds created by valve closures. Before auscultating the heart, eliminate all sources of room noise and explain the procedure to reduce the patient's anxiety. Follow a systematic pattern, beginning at the aortic area and inching the stethoscope across each of the anatomical sites. Listen for the complete cycle ("lub-dub") of heart sounds clearly at each location. Repeat the sequence with the bell of the stethoscope. Sometimes you will have a patient assume three different positions during the examination to hear sounds clearly ([Fig. 30.41A-C](#)): sitting up and leaning forward (good for all areas and to hear high-pitched murmurs), supine (good for all areas), and left lateral recumbent (good for all areas; best position to hear low-pitched sounds in diastole).

FIG. 30.41 Sequence of patient positions for heart auscultation. **A**, Sitting. **B**, Supine. **C**, Left lateral recumbent.

Learn to identify the first (S_1) and second (S_2) heart sounds. At normal rates S_1 occurs after the long diastolic pause and before the short systolic pause. S_1 is high pitched, dull in quality, and heard best at the apex. If it is difficult to hear S_1 , time it in relation to the carotid pulsation. S_2 follows the short systolic pause and precedes the long diastolic pause; it is best heard at the aortic area.

Auscultate for rate and rhythm after hearing both sounds clearly. Each combination of S_1 and S_2 or “lub-dub” counts as one heartbeat. Count the rate for 1 minute and listen for the interval between S_1 and S_2 and then the time between S_2 and the next S_1 . A regular rhythm involves regular intervals of time between each sequence of beats. There is a distinct silent pause between S_1 and S_2 . Failure of the heart to beat at regular successive intervals is a **dysrhythmia**. Some dysrhythmias are life threatening.

When assessing an irregular heart rhythm, compare apical and radial pulse rates simultaneously to determine whether a pulse deficit exists. Auscultate the apical pulse first and then immediately palpate the radial pulse (one examiner present). When two examiners are present, assess the apical and radial rates at the same time. When a patient has a pulse deficit, the radial pulse is slower than the apical pulse because ineffective contractions fail to send pulse waves to the periphery. Report a difference in pulse rates to the health care provider immediately.

Assess for extra heart sounds at each auscultatory site. Use the bell of the stethoscope and listen for low-pitched extra heart sounds such as S_3 and S_4 gallops, clicks, and rubs. Auscultate over all anatomical areas. S_3 , or a **ventricular gallop**, occurs after S_2 . It is caused by a premature rush of blood into a ventricle that is stiff or dilated as a result of heart failure and hypertension. The combination of S_1 , S_2 , and S_3 sounds like “Ken-TUCK-y.”

S_4 , or an atrial gallop, occurs just before S_1 or ventricular systole. The sound of an S_4 is similar to that of “TEN-nes-see” Physiologically it is caused by an atrial contraction pushing against a ventricle that is not accepting blood because of heart failure or other alterations. You can hear extra heart sounds more easily with the patient lying on the left side and the stethoscope at the apical site.

The final part of the auscultation examination includes assessment for heart murmurs. **Murmurs** are sustained swishing or blowing sounds heard at the beginning, middle, or end of the systolic or diastolic phase. They are caused by increased blood flow through a normal valve, forward

flow through a stenotic valve or into a dilated vessel or heart chamber, or backward flow through a valve that fails to close. A murmur is asymptomatic or a sign of heart disease (Box 30.18). It is common in children. Keep the following factors in mind when auscultating to detect murmurs:

Box 30.18 Patient Teaching Heart Assessment

Objective

- Patient will describe risk factors for heart disease and take appropriate steps to eliminate risks from lifestyle.

Teaching Strategies

- Explain risk factors for heart disease, including high dietary intake of saturated fat or cholesterol, lack of regular aerobic exercise, smoking, excess weight, stressful lifestyle, hypertension, and family history of heart disease.
- Refer patient (if appropriate) to resources available for controlling or reducing risks (e.g., nutritional counseling, exercise class, stress-reduction programs).
- Teach patient to eat a well-rounded healthy diet. Explain that a healthy pattern emphasizes variety, including fruits and vegetables, whole grains, low-fat dairy products, skinless poultry and fish, nuts and legumes, and nontropical vegetable oils. Limit saturated and trans fats, sodium, red meats, sweets, and sugar-sweetened beverages (AHA, 2015).
- Encourage patient who is over 20 years old to have his or her cholesterol checked every 4 to 6 years. A complete cholesterol test, also called a lipid profile, will give the results of HDL (good), LDL (bad), triglycerides, and total blood cholesterol. The health care provider will look at these numbers in relation to your other risk factors to assess overall cardiovascular risk (AHA, 2017).
- Encourage patient to discuss with health care provider the need for periodic C-reactive protein (CRP) testing. CRP levels assess a patient's risk for cardiovascular disease.

- Advise patient to avoid cigarette smoke because nicotine causes vasoconstriction.
- Advise patient to quit smoking to lower the risk for coronary heart disease and coronary vascular disease.
- Patients who are at risk benefit from taking a daily low dose of aspirin. Consult health care provider before starting therapy.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- List for me the risk factors for heart disease.
- Show me the meal plan you developed that helps you follow a diet low in cholesterol and saturated fat.
- Describe for me how you have reduced risk factors for heart disease in your life.

- When a murmur is detected, auscultate the mitral, tricuspid, aortic, and pulmonic valve areas for placement in the cardiac cycle (timing); the place it is heard best (location); radiation; loudness; pitch; and quality.
- If a murmur occurs between S_1 and S_2 , it is a systolic murmur.
- If it occurs between S_2 and the next S_1 , it is a diastolic murmur.
- The location of a murmur is not necessarily directly over the valves. Experience with hearing murmurs helps with better understanding of where each type of murmur is best heard. For example, mitral murmurs are best heard at the apex of the heart.
- To assess for radiation, listen over other areas in addition to where it is heard best. Murmurs can also be heard over the neck or back.
- Intensity or loudness is related to the rate of blood flow through the heart or the amount of blood regurgitated. Feel for a thrust or intermittent palpable sensation at the auscultation site in serious murmurs. A **thrill** is a continuous palpable sensation that resembles the purring of a cat. Intensity is recorded using the following grades (Ball et al., 2019):
 - *Grade 1*: Barely audible in a quiet room
 - *Grade 2*: Quiet but clearly audible
 - *Grade 3*: Moderately loud

- *Grade 4*: Loud, with associated thrill
- *Grade 5*: Very loud; thrill easily palpable
- *Grade 6*: Very loud; audible with stethoscope not in contact with chest; thrill palpable and visible
- A murmur is low, medium, or high in pitch, depending on the velocity of blood flow through the valves. A low-pitched murmur is best heard with the bell of the stethoscope. If the murmur is best heard with the diaphragm, it is high pitched.

The quality of a murmur refers to its characteristic pattern and sound. A crescendo murmur starts softly and builds in loudness. A decrescendo murmur starts loudly and becomes less intense.

Vascular System

Examination of the vascular system includes measuring the blood pressure and assessing the integrity of the peripheral vascular system. [Table 30.23](#) reviews the nursing history data collected before the examination. Use the skills of inspection, palpation, and auscultation. Perform parts of the vascular examination during other body system assessments. For example, check the carotid pulse after palpating the cervical lymph nodes. Assess the skin, as part of the vascular system, for signs and symptoms of arterial and venous insufficiency.

TABLE 30.23

Nursing History for Vascular Assessment

Assessment	Rationale
Determine whether patient experiences leg cramps; numbness or tingling in extremities; sensation of cold hands or feet; pain in legs; or swelling or cyanosis of feet, ankles, or hand.	These signs and symptoms indicate vascular disease.
If patient experiences leg pain or cramping in lower extremities, ask whether walking or standing for long periods or sleeping aggravates or relieves it.	Relationship of symptoms to exercise clarifies whether problem is vascular or musculoskeletal. Pain caused by vascular condition tends to increase with activity. Musculoskeletal pain usually is not relieved when exercise ends.
Ask patients whether they wear tight-fitting garters, socks, or hosiery and sit or lie in bed with legs crossed.	Tight hosiery around lower extremities and crossing legs can impair venous return.
Reconsider previous heart risk factors (e.g., smoking, exercise, nutritional problems).	These predispose patient to vascular disease.
Assess medical history for heart disease, hypertension, phlebitis, diabetes, or varicose veins.	Circulatory and vascular disorders influence findings gathered during examination.

Blood Pressure

When auscultating blood pressure, know that readings between the arms vary by as much as 10 mm Hg and tend to be higher in the right arm ([Ball et al., 2019](#)). Always record the higher reading. Repeated systolic readings that differ by 15 mm Hg or more suggest atherosclerosis or disease of the aorta.

Carotid Arteries

When the left ventricle pumps blood into the aorta, the arterial system transmits pressure waves. The carotid arteries reflect heart function better than peripheral arteries because their pressure correlates with that of the aorta. The

carotid artery supplies oxygenated blood to the head and neck (Fig. 30.42). The overlying sternocleidomastoid muscle protects it.

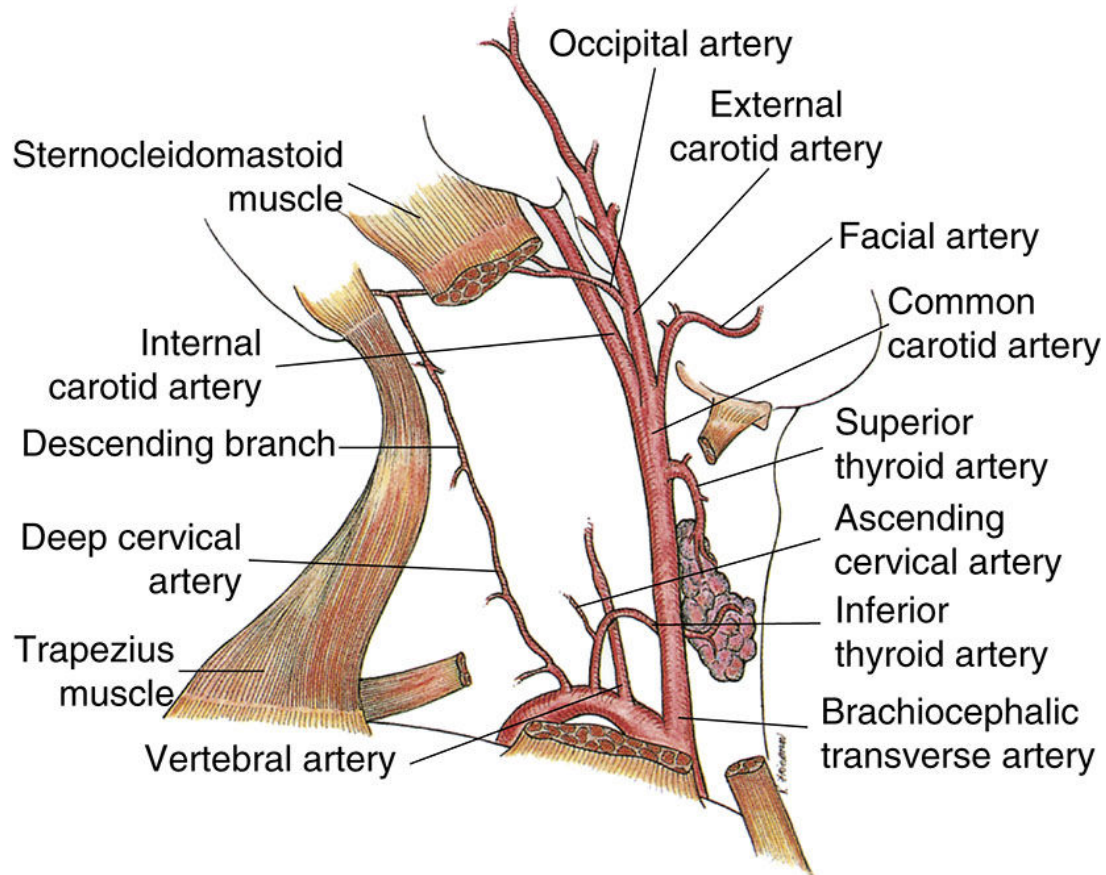

FIG. 30.42 Anatomical position of carotid artery.

To examine the carotid arteries, have the patient sit or lie supine with the head of the bed elevated 30 degrees. Examine one carotid artery at a time. If both arteries are occluded simultaneously during palpation, the patient loses consciousness as a result of inadequate circulation to the brain. *Do not palpate or massage the carotid arteries vigorously* because the carotid sinus is located at the bifurcation of the common carotid arteries in the upper third of the neck. This sinus sends impulses along the vagus nerve. Stimulating it causes a reflex drop in heart rate and blood pressure, which causes **syncope** or circulatory arrest. This is a particular problem for older adults.

Begin inspection of the neck for obvious pulsation of the artery. Have the patient turn the head slightly away from the artery being examined. Sometimes the wave of the pulse is visible. The carotid is the only site for assessing the quality of a pulse wave. An absent pulse wave indicates arterial occlusion (blockage) or **stenosis** (narrowing).

To palpate the pulse, ask the patient to look straight ahead or turn the head slightly toward the side you are examining. Turning relaxes the sternocleidomastoid muscle. Slide the tips of the index and middle fingers around the medial edge of the sternocleidomastoid muscle. Gently palpate to avoid occlusion of circulation (Fig. 30.43).

FIG. 30.43 Palpation of internal carotid artery along margin of sternocleidomastoid muscle.

The normal carotid pulse is localized and strong rather than diffuse. It has a thrusting quality. As a patient breathes, no change occurs. Rotating the neck or going from a sitting to a supine position does not change the quality of the carotid impulse. Both carotid arteries are normally equal in pulse rate, rhythm, and strength and are equally elastic. Diminished or unequal carotid pulsations indicate atherosclerosis or other forms of arterial disease.

The carotid is the most commonly auscultated pulse. Auscultation is especially important for middle-age or older adults or patients suspected of having cerebrovascular disease. When the lumen of a blood vessel is narrowed, it disturbs blood flow. As blood passes through the narrowed section, it creates turbulence, causing a blowing or swishing sound. The blowing sound is called a **bruit** (pronounced “brew-ee”) (Fig. 30.44).

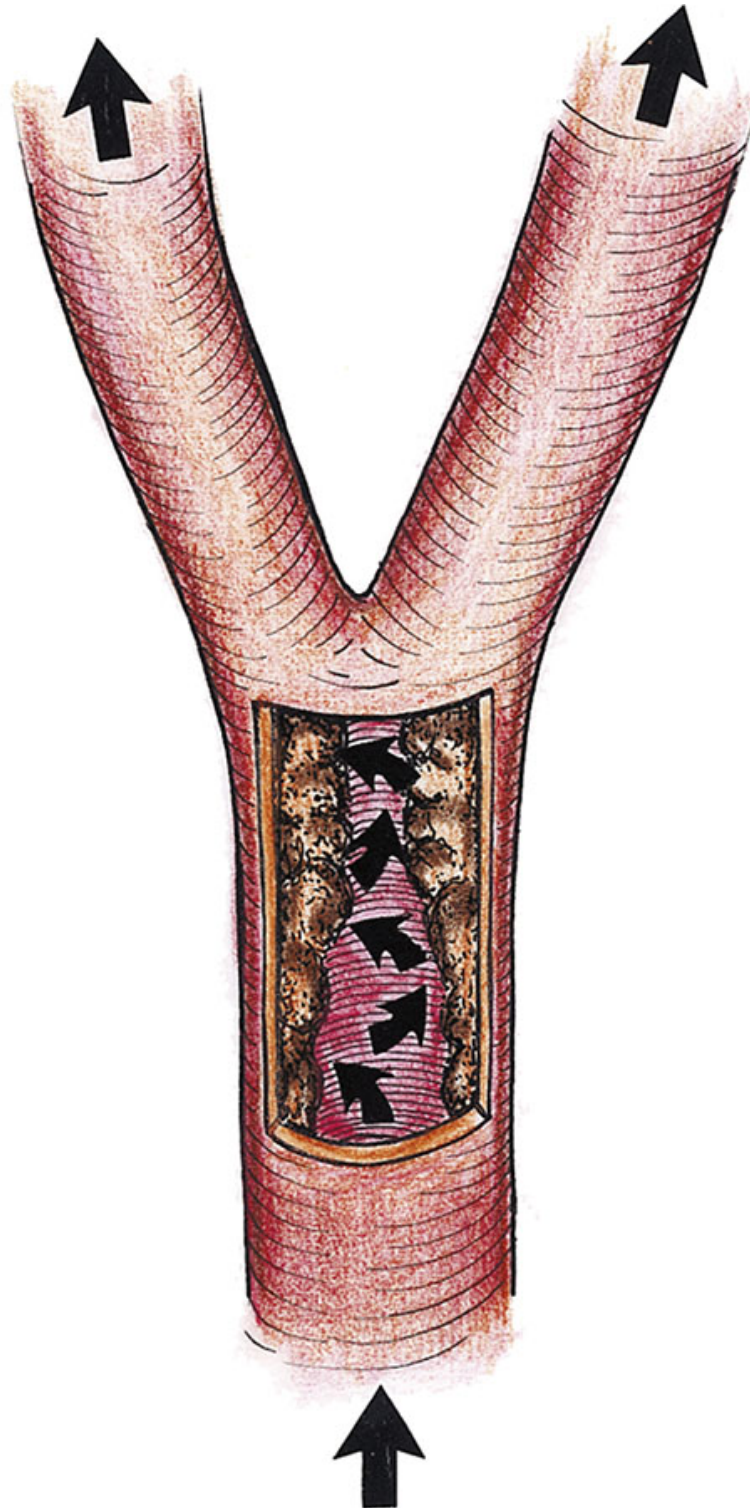

FIG. 30.44 Occlusion or narrowing of the carotid artery disrupts normal blood flow. The resultant turbulence creates a sound (bruit) that is auscultated.

Place the bell of the stethoscope over the carotid artery at the lateral end of the clavicle and the posterior margin of the sternocleidomastoid muscle. Have

the patient turn his or her head slightly away from the side being examined (Fig. 30.45). Ask him or her to hold the breath for a moment so that breath sounds do not obscure a bruit. Normally you do not hear any sounds during carotid auscultation. Palpate the artery lightly for a thrill (palpable bruit) if you hear a bruit.

FIG. 30.45 Auscultation for carotid artery bruit.

Jugular Veins

The most accessible veins for examination are the internal and external jugular veins in the neck. Both veins drain bilaterally from the head and neck into the superior vena cava. The external jugular vein lies superficially and is just above the clavicle. The internal jugular vein lies deeper, along the carotid artery.

It is best to examine the right internal jugular vein because it follows a more direct anatomical path to the right atrium of the heart. The column of blood inside the internal jugular vein serves as a manometer, reflecting pressure in the right atrium. The higher the column, the greater is the venous pressure. Raised venous pressure reflects right-sided heart failure.

Normally, when a patient lies in the supine position, the external jugular vein distends and becomes easily visible. In contrast, the jugular veins normally flatten when the patient changes to a sitting or standing position. However, for some patients with heart disease the jugular veins remain distended when sitting.

Venous pressure is influenced by blood volume (i.e., the capacity of the right atrium to receive blood and send it to the right ventricle and the ability of the right ventricle to contract and force blood into the pulmonary artery). Any factor resulting in greater blood volume within the venous system results in elevated jugular venous pressure. You can observe for elevation in jugular venous pressure by using the following steps:

1. Have the patient lie flat in the supine position. Expose the neck and upper thorax. Use a pillow to align the head. Avoid neck hyperextension or flexion to ensure that the vein is not stretched or kinked ([Fig. 30.46](#)). Observe for engorgement of the jugular veins.

FIG. 30.46 Position of patient to assess jugular vein distention.
 From Thompson JM, et al: *Mosby's manual of clinical nursing*, ed 5, St Louis, 2001, Mosby.

2. Gradually raise the head of the bed until the jugular venous pulsations become evident between the angle of the jaw and the clavicle. **Note:** Palpating a carotid pulse helps to distinguish venous pulsations from carotid palpations. The jugular pulse can only be visualized, not palpated.
3. Inspect the jugular veins. Usually pulsations are not evident with the patient sitting up. As he or she slowly leans back into a supine position, the level of venous pulsations begins to rise above the level of the manubrium as much as 1 or 2 cm ($1/2$ to 1 inch) as the patient reaches a 45-degree angle.

Peripheral Arteries and Veins

To examine the peripheral vascular system, first assess the adequacy of blood flow to the extremities by measuring arterial pulses and inspecting the condition of the skin and nails. Next assess the integrity of the venous system. Assess the arterial pulses in the extremities to determine sufficiency of the entire arterial circulation.

Factors such as coagulation disorders, local trauma or surgery, constricting casts or bandages, and systemic diseases impair circulation to the extremities

(Table 30.24). Discuss risk factors and ways to monitor for circulatory problems with the patient (Box 30.19).

TABLE 30.24

Indicators for Assessing Local Blood Flow

Indicator	Rationale
Systemic diseases (e.g., arteriosclerosis, atherosclerosis, diabetes)	Diseases result in changes in integrity of walls of arteries and smaller blood vessels.
Coagulation disorders (e.g., thrombosis, embolus)	Blood clot causes mechanical obstruction to blood flow.
Local trauma or surgery (e.g., contusion, fracture, vascular surgery)	Direct manipulation of vessels or localized edema impairs blood flow.
Application of constricting devices (e.g., casts, dressings, elastic bandages, restraints)	Constriction causes tourniquet effect, impairing blood flow to areas below site of constriction.

Box 30.19 Patient Teaching Vascular Assessment

Objective

- Patient with vascular insufficiency will avoid activities that worsen circulatory status.

Teaching Strategies

- Instruct patient with risk or evidence of vascular insufficiency in the lower extremities to avoid tight clothing over the lower body or legs, to avoid sitting or standing for long periods, to avoid sitting with legs crossed, to walk regularly, and to elevate feet when sitting.
- Advise patient to avoid or stop the smoking of cigarettes, cigars, or pipes or the use of nicotine products (e.g., chewing tobacco, nicotine patches or gum) because nicotine causes vasoconstriction. Offer a referral to a reliable stop-smoking program.
- Instruct patient with hypertension about the benefits of regular monitoring of blood pressure (daily, weekly, or monthly). Teach patient how to use home monitoring kits.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Explain to me what precautions you are taking to avoid further decrease in your peripheral circulation.
- Explain to me what your normal limits for blood pressure are. Tell me when you would contact your health care provider.
- Show me how you take your blood pressure at home.

Peripheral Arteries

Examine each peripheral artery using the distal pads of your second and third fingers. The thumb helps anchor the brachial and femoral artery. Apply firm pressure but avoid occluding a pulse. When a pulse is difficult to find, it helps to vary pressure and feel all around the pulse site. Be sure not to palpate your own pulse.

Routine vital signs usually include assessment of the rate and rhythm of the radial artery because it is easily accessible. Count the pulse for either 30 seconds or a full minute, depending on the character of the pulse. Always count an irregular pulse for 60 seconds. With palpation, the pulse waves are normally felt at regular intervals. When an interval is interrupted by an early, a late, or a missed beat, the pulse rhythm is irregular. During cardiac emergencies health care providers usually assess the carotid artery because it is accessible and most useful in evaluating heart activity. To check local circulatory status of tissues (e.g., when a leg cast is in place or following vascular surgery), palpate the peripheral arteries long enough to note that a pulse is present.

Assess each peripheral artery for elasticity of the vessel wall, strength, and equality. The arterial wall normally is elastic, making it easily palpable. After depressing the artery, it springs back to shape when the pressure is released. An abnormal artery is hard, inelastic, or calcified.

The strength of a pulse is a measurement of the force at which blood is ejected against the arterial wall. Some examiners use a scale rating from 0 to 4 for the strength of a pulse ([Ball et al., 2019](#)):

- 0: Absent, not palpable
- 1: Pulse diminished, barely palpable
- 2: Expected
- 3: Full, increased
- 4: Bounding, aneurysmal

Measure all peripheral pulses for equality and symmetry. Compare the left radial pulse with that of the right and so on. Lack of symmetry indicates impaired circulation such as a localized obstruction or an abnormally positioned artery.

In the upper extremities the brachial artery channels blood to the radial and ulnar arteries of the forearm and hand. If circulation in this artery becomes blocked, the hands do not receive adequate blood flow. If circulation in the radial or ulnar arteries becomes impaired, the hand still receives adequate perfusion. An interconnection between the radial and ulnar arteries guards against arterial occlusion (Fig. 30.47A).

FIG. 30.47 A, Anatomical positions of brachial, radial, and ulnar arteries. B, Palpation of radial pulse. C, Palpation of ulnar pulse. D, Palpation of brachial pulse.

To locate pulses in the arm, have the patient sit or lie down. Find the radial pulse along the radial side of the forearm at the wrist. Thin individuals have a groove lateral to the flexor tendon of the wrist. Feel the radial pulse with light palpation in the groove (see Fig. 30.47B). The ulnar pulse is on the opposite

side of the wrist and feels less prominent (see Fig. 30.47C). Palpate the ulnar pulse when evaluating arterial insufficiency to the hand.

To palpate the brachial pulse, find the groove between the biceps and triceps muscle above the elbow at the antecubital fossa (see Fig. 30.47D). The artery runs along the medial side of the extended arm. Palpate it with the fingertips of the first three fingers in the muscle groove.

The femoral artery is the primary artery in the leg, delivering blood to the popliteal, posterior tibial, and dorsalis pedis arteries (Fig. 30.48A). An interconnection between the posterior tibial and dorsalis pedis arteries guards against local arterial occlusion.

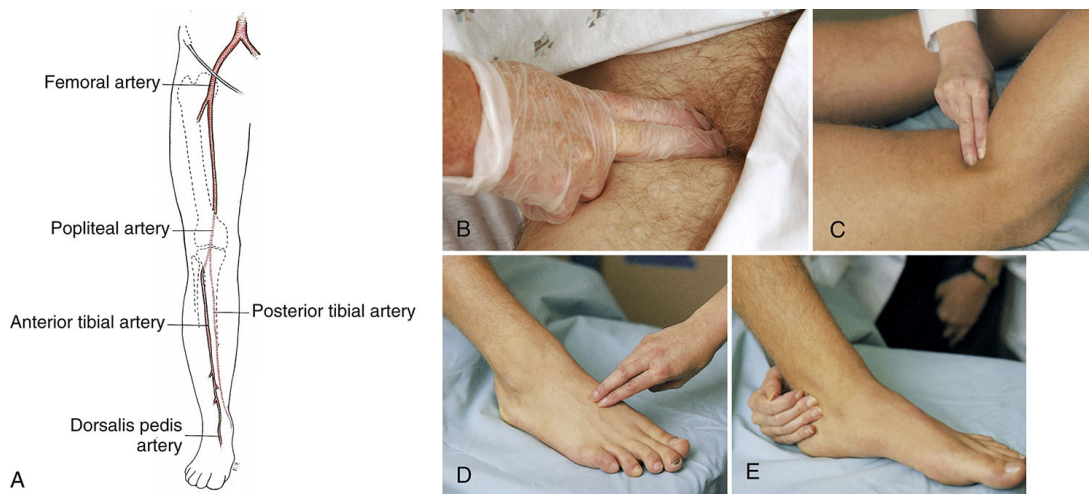

FIG. 30.48 A, Anatomical position of femoral, popliteal, dorsalis pedis, and anterior and posterior tibial arteries. B, Palpation of femoral pulse. C, Palpation of popliteal pulse. D, Palpation of dorsalis pedis pulse. E, Palpation of posterior tibial pulse.

Find the femoral pulse with the patient lying down with the inguinal area exposed (see Fig. 30.48B). The femoral artery runs below the inguinal ligament, midway between the symphysis pubis and the anterosuperior iliac spine. Sometimes deep palpation is necessary to feel the pulse. Bimanual palpation is effective in patients who are obese. Place the fingertips of both hands on opposite sides of the pulse site. Feel a pulsatile sensation when the arterial pulsation pushes the fingertips apart.

The popliteal pulse runs behind the knee. Have the patient slightly flex the knee with the foot resting on the examination table or assume a prone position with the knee slightly flexed (see Fig. 30.48C) and leg muscles relaxed. Palpate with the fingers of both hands deeply into the popliteal fossa, just lateral to the midline. The popliteal pulse is difficult to locate.

With the patient's foot relaxed, locate the dorsalis pedis pulse. The artery runs along the top of the foot in line with the groove between the extensor

tendons of the great toe and first toe (see [Fig. 30.48D](#)). To find the pulse, place the fingertips between the first and second toes and slowly move up the dorsum of the foot. This pulse is sometimes congenitally absent.

Find the posterior tibial pulse on the inner side of each ankle ([Fig. 30.48E](#)). Place the fingers behind and below the medial malleolus (ankle bone). With the foot relaxed and slightly extended, palpate the artery.

Ultrasound Stethoscopes

If a pulse is difficult to palpate, an ultrasound (Doppler) stethoscope is a useful tool that amplifies the sounds of a pulse wave. Factors that weaken a pulse or make palpation difficult include obesity, reduction in the stroke volume of the heart, diminished blood volume, or arterial obstruction. Apply a thin layer of transmission gel to the patient's skin at the pulse site or directly onto the transducer tip of the probe. Turn on the volume control and place the tip of the transducer at a 45- to 90-degree angle on the skin ([Fig. 30.49](#)). Move the transducer until you hear a pulsating "whooshing" sound that indicates that arterial blood flow is present.

REFLECT NOW

How would you respond if while completing an assessment you found a severe abnormality in a body system? Think through your body language, facial expression, and the conversation you would have with the patient through this situation. What further assessments might you need to complete?

FIG. 30.49 Ultrasound stethoscope in position on the pedal pulse.

Tissue Perfusion

The condition of the skin, mucosa, and nail beds offers useful data about the status of circulatory blood flow. Examine the face and extremities, looking at the color of the skin, lips, mucosa, and nail beds. Bluish color of lips or nail

beds or decrease in pallor sometimes indicate cyanosis. When cyanosis is present, obtain a patient’s oxygen saturation to determine the severity of the problem. Health care providers sometimes order additional blood tests to further evaluate oxygenation status. Examination of the nails involves inspection for **clubbing**, a bulging of the tissues at the nail base, which causes an abnormal curvature of the nail. Clubbing suggests a chronic problem such as emphysema and congenital heart disease.

Inspect the lower extremities for changes in color, temperature, and condition of the skin, indicating either arterial or venous alterations (Table 30.25). Ask if the patient has pain in the legs. If an arterial occlusion is present, the patient will experience pain distal to the occlusion. The five *Ps*—pain, pallor, pulselessness, paresthesias, and paralysis—characterize an occlusion. Venous congestion causes tissue changes that indicate an inadequate circulatory flow back to the heart.

TABLE 30.25

Signs of Venous and Arterial Insufficiency

Assessment Criterion	Venous	Arterial
Color	Normal or cyanotic	Pale; worsened by elevation of extremity; dusky red when extremity is lowered
Temperature	Normal	Cool (blood flow blocked to extremity)
Pulse	Normal	Decreased or absent
Edema	Often marked	Absent or mild
Skin changes	Brown pigmentation around ankles	Thin, shiny skin; decreased hair growth; thickened nails

While examining the lower extremities, also inspect skin and nail texture; hair distribution on the lower legs, feet, and toes; the venous pattern; and scars, pigmentation, or ulcers. Absence of hair on the legs may indicate circulatory insufficiency; remember to consider whether the patient has shaved legs or wears tight socks, which can lead to a decrease in hair on the legs. Chronic recurring ulcers of the feet or lower legs are a serious sign of circulatory insufficiency and require a health care provider’s intervention. Palpate the legs and feet for color, temperature, and edema. Capillary refill is used to determine adequacy of peripheral blood flow to the digits (Ball et al., 2019).

Peripheral Veins

Assess the status of the peripheral veins by asking the patient to assume sitting and standing positions. Assessment includes inspection and palpation for varicosities, peripheral edema, and phlebitis. Varicosities are superficial veins that become dilated, especially when the legs are in a dependent position. They are common in older adults because the veins normally fibrose, dilate, and

stretch. They are also common in people who stand for prolonged periods. Varicosities in the anterior or medial part of the thigh and the posterolateral part of the calf are abnormal.

Dependent edema around the area of the feet and ankles is a sign of venous insufficiency or right-sided heart failure. It is common in older adults and people who spend a lot of time standing (e.g., waitresses, security guards, and nurses). To assess for pitting edema, use the index finger to press firmly for several seconds and release over the medial malleolus or the shins. A depression left in the skin indicates edema. Grading 1+ through 4+ characterizes the severity of the edema (see [Fig. 30.6](#)).

Phlebitis is an inflammation of a vein that occurs commonly after trauma to the vessel wall, infection, immobilization, and prolonged insertion of IV catheters. To assess for phlebitis in the leg, inspect the calves for localized redness, tenderness, and swelling over vein sites. Gentle palpation of calf muscles reveals warmth, tenderness, and firmness of the muscle. Unilateral edema of the affected leg is one of the most reliable findings of phlebitis. The Homan sign is not a reliable indicator of phlebitis or deep vein thrombosis (DVT) and is present in other conditions ([Ambesh, 2017](#)). To confirm DVT, other diagnostic tests are used whether or not the Homan sign is positive ([Ambesh, 2017](#)).

Lymphatic System

Assess the lymphatic drainage of the lower extremities during examination of the vascular system or during the female or male genital examination. Superficial and deep nodes drain the legs, but only two groups of superficial nodes are palpable. With the patient supine, palpate the area of the superficial inguinal nodes in the groin area ([Fig. 30.50A](#)). Then move the fingertips toward the inner thigh, feeling for any inferior nodes. Use a firm but gentle pressure when palpating over each lymphatic chain. Multiple nodes normally are not palpable, although a few soft nontender nodes are not unusual. Enlarged, hardened, tender nodes reveal potential sites of infection or metastatic disease.

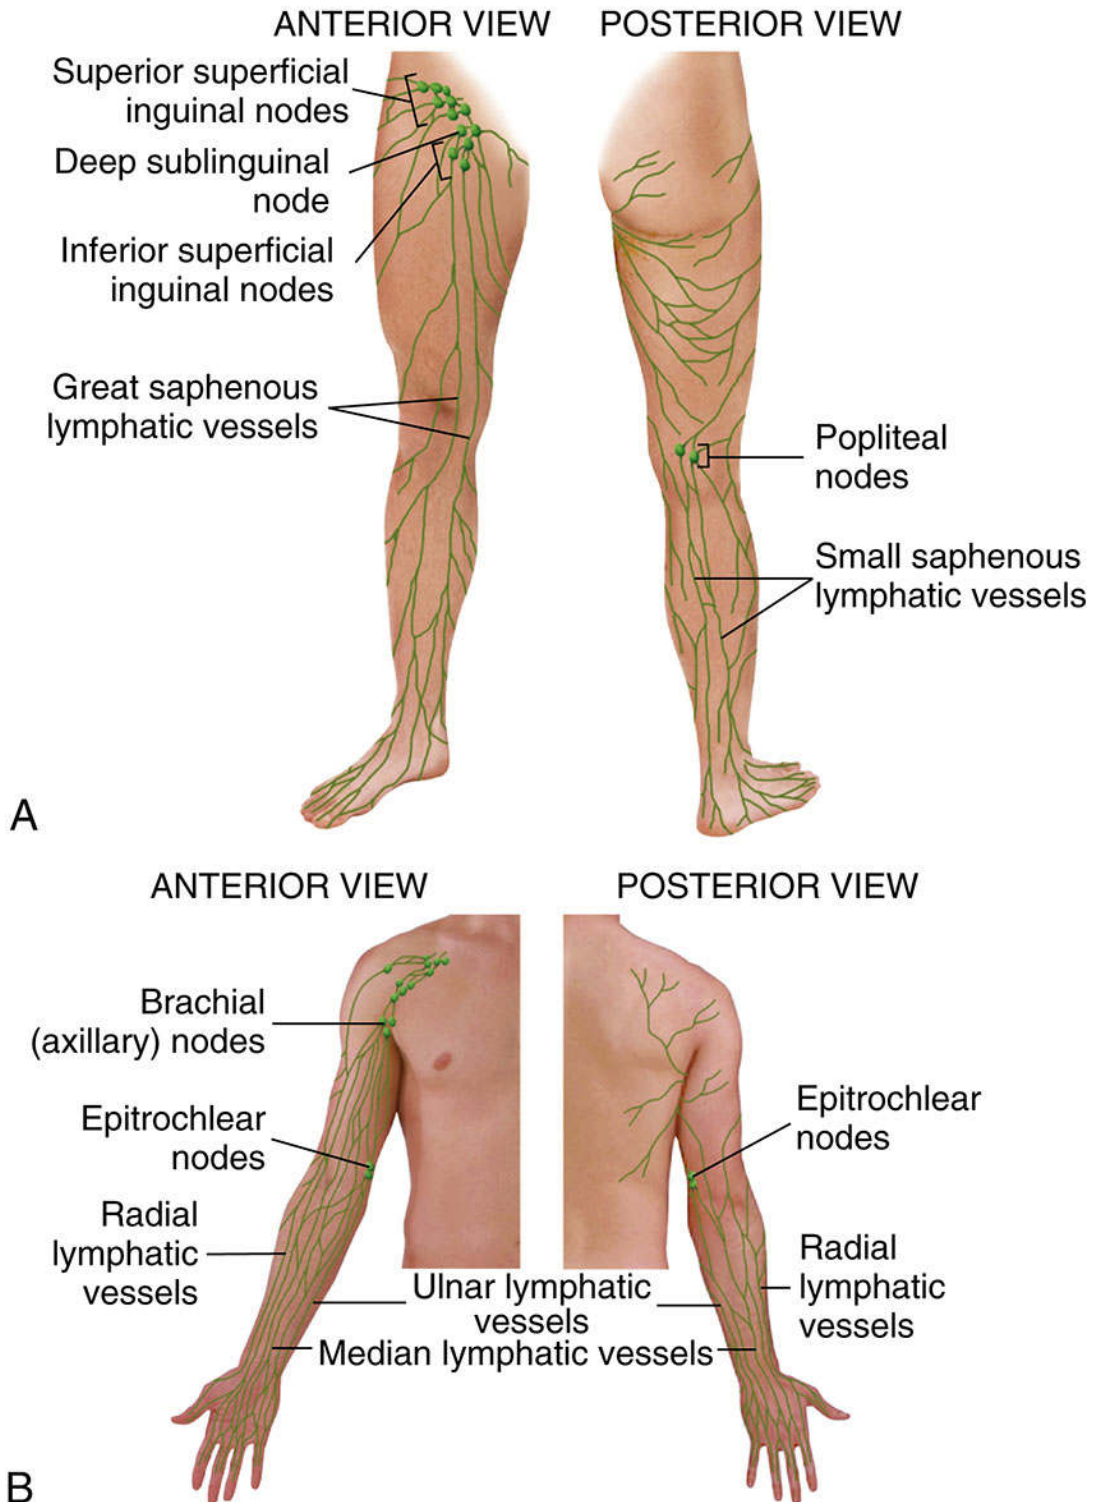

FIG. 30.50 **A**, Lymphatic drainage for lower extremities. **B**, Lymphatic drainage for upper extremities.

From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

In the upper extremities, lymph is carried by the collecting ducts from the upper extremities to the subclavian lymphatic trunk. To assess this lymph system, gently palpate the epitrochlear nodes, located on the medial aspect of the arms near the antecubital fossa (see [Fig. 30.50B](#)). The proximal part of the upper-extremity lymph system is located in the axilla and is usually assessed during examination of the breasts.

Breasts

It is important to examine the breasts of both female and male patients. Men have a small amount of glandular tissue in the breast, which is a potential site for the growth of cancer cells. In contrast, the majority of the female breast is glandular tissue.

Female Breasts

New cases of invasive breast cancer were predicted to affect an estimated 231,840 women in the United States during 2015; about 2,350 new cases were expected in men ([ACS, 2018b](#)). The disease is second to lung cancer as the leading cause of death in women with cancer. Early detection is the key to cure.

[Table 30.3](#) outlines the American Cancer Society ([ACS, 2018a](#)) guidelines for the early detection of breast cancer in women at average risk. The [ACS \(2018b\)](#) recommends that women who are at high risk for breast cancer based on certain factors should get an MRI and a mammogram every year. This includes women who:

- Have a lifetime risk of breast cancer of about 20% to 25% or greater, according to risk assessment tools that are based mainly on family history
- Have a known *BRCA1* or *BRCA2* gene mutation
- Have a first-degree relative (parent, brother, sister, or child) with a *BRCA1* or *BRCA2* gene mutation and have not had genetic testing themselves
- Had radiation therapy to the chest when they were between 10 and 30 years of age

Monthly breast self-examination (BSE) is no longer recommended by the [ACS \(2018a\)](#) for women at any age because there is limited evidence to benefits in locating cancerous tumors, but other health organizations encourage BSE as an important option for women ([National Breast Cancer Foundation, 2016](#)). Encourage women to ask their personal physician what he or she recommends. If a female patient chooses to perform BSE, assess the method she uses and when she does the examination in relation to her menstrual cycle ([Box 30.20](#)). The best time for a BSE is the fourth through seventh day of the menstrual cycle or right after the menstrual cycle ends, when the breasts are no longer swollen or tender from hormone

elevations. If the woman does not menstruate (e.g., due to pregnancy or menopause), advise her to check her breasts on the same day each month.

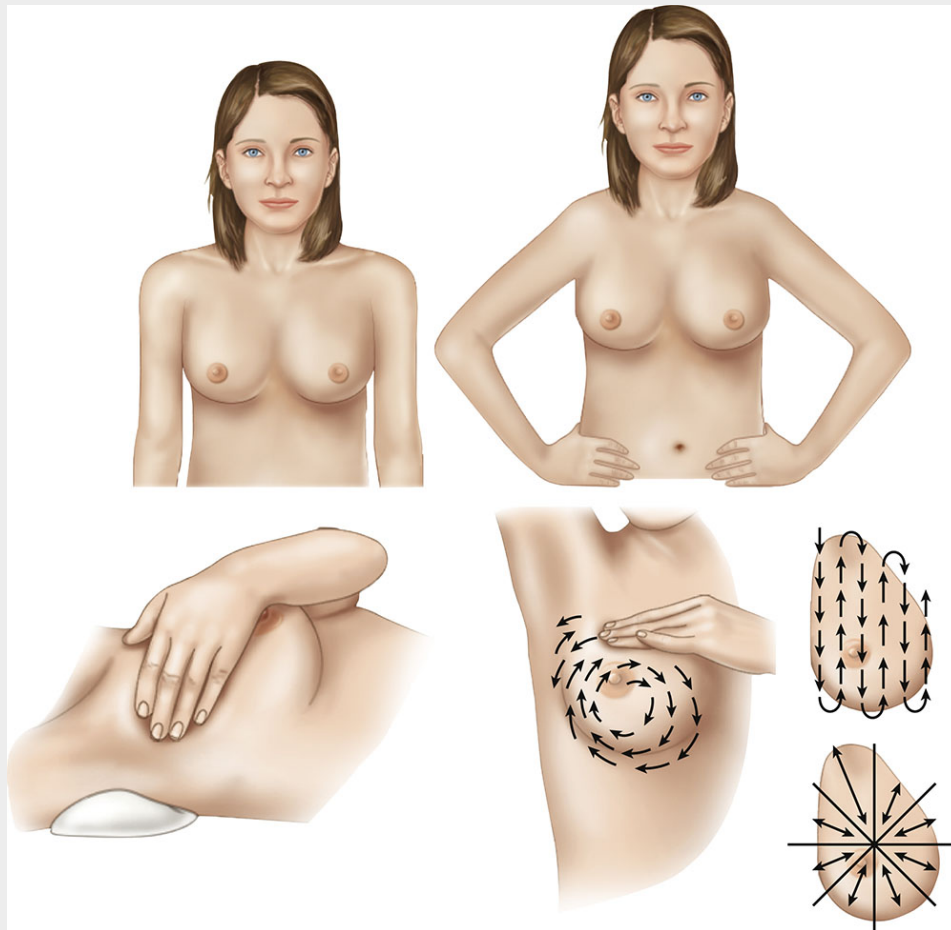

Box 30.20 Breast Self-Examination

Procedure

- Help patient identify the appropriate time of the month to perform breast self-examination (BSE).
- Describe normal findings and what findings require notification of health care provider.
- Teach patient the steps to perform BSE:
 1. Examine your right breast. Lie on your back and place your right arm behind your head. The examination is best completed lying down, not standing up, because when you lie down the breast tissue spreads evenly over the chest wall and is as thin as possible, making it much easier to feel all of it.
 2. Use finger pads of the three middle fingers on your left hand to feel for lumps in the right breast. Use overlapping dime-size circular motions of the finger pads to feel the breast tissue. Use three different levels of pressure to feel all the breast tissue. Light pressure is needed to feel the tissue closest to the skin, medium pressure to feel a little deeper, and firm pressure to feel the tissue closest to the chest and ribs. It is normal to feel a firm ridge in the lower curve of each breast, but you should tell your health care provider if you feel anything else out of the ordinary. If you are not sure how hard to press, discuss this with your health care provider. Use each pressure level to feel the breast tissue before moving on to the next spot.
 3. Move around the breast in an up-and-down pattern starting at an imaginary line drawn straight down your side from the underarm and moving across the breast to the middle of the chest bone (sternum or breastbone). Be sure to check the entire breast area, going down until you feel only ribs and up to the neck or collarbone (clavicle). Evidence shows that

the up-and-down pattern is the most effective pattern for covering the entire breast.

4. Repeat self-examination in the left breast, putting your left arm behind your head and examining the left breast as noted in Steps 1 to 3.
5. While standing in front of a mirror with your hands pressing firmly down on your hips, look at your breasts, observing for any changes in size, shape, contour, dimpling, redness, or scaliness of the nipple or breast tissue. Pressing down on your hips contracts the chest wall muscles and enhances any breast changes.
6. Examine each underarm while sitting or standing and with your arm only slightly raised so that you can feel any lumps or changes in this area easily. Raising your arm straight tightens the tissue in this area, making it harder to examine.
 - **Note:** If implants are present, help the patient determine the edges of each implant and how to evaluate each breast.
7. Instruct patient to call the health care provider if she finds a lump or other abnormality.
8. **Use Teach Back:** "I want to be sure I explained to you how to conduct a breast self-examination. Can you show me how to conduct an examination on both of your breasts?" Document your evaluation of patient learning. Revise your instruction or develop a plan for revised patient teaching to be implemented at an appropriate time if patient is not able to teach back correctly.

Images from Silvestri LA, Silvestri AE: *Saunders comprehensive review for the NCLEX-PN® Examination*, ed 7, St Louis, 2019, Elsevier.

Older women require special attention when reviewing the need for regular BSE. Unfortunately, many older women ignore changes in their breasts, assuming that they are a part of aging. In addition, physiological factors affect the ease with which older women perform a BSE. Musculoskeletal limitations, diminished peripheral sensation, reduced eyesight, and changes in joint range of motion (ROM) limit palpation and inspection abilities.

The patient's history ([Table 30.26](#)) reveals normal developmental changes and signs of breast disease. Because of its glandular structure, the breast undergoes changes during a woman's life. Knowing these changes ([Box 30.21](#)) allows complete and accurate assessment. Encourage both men and women to observe their breasts for changes and to report any changes to their health care provider.

TABLE 30.26**Nursing History for Breast Assessment**

Assessment	Rationale
Determine whether woman is over age 40; has a personal or family history of breast cancer, especially with the <i>BRCA1</i> or <i>BRCA2</i> inherited gene mutations; early-onset menarche (before age 12) or late-age menopause (after age 55); has never had children or gave birth to first child after age 31; or has recently used oral contraceptives.	These are risk factors for breast cancer (ACS, 2018a; ACS, 2018b).
Ask whether patient (both sexes) has noticed lump, thickening, pain, or tenderness of breast; discharge, distortion, retraction, or scaling of the nipple; or change in size of breast.	Potential signs and symptoms of breast cancer allow nurse to focus on specific areas of breast during assessment.
Determine patient's use of medications (oral contraceptives, digitalis, diuretics, steroids, or estrogen). Determine his or her caffeine intake.	Some medications cause nipple discharge. Hormones and caffeine cause fibrocystic changes in breast.
Determine patient's level of activity, alcoholic intake, and weight.	Breast cancer incidence rates correlate with being overweight or obese (postmenopausal), physical inactivity, and consumption of alcoholic beverages (ACS, 2018b).
Ask whether patient performs monthly breast self-examination (BSE). If so, determine time of month she performs examination in relation to menstrual cycle. Have her describe or demonstrate method used.	Nurse's role is to educate patient about breast cancer and correct techniques for BSE.
If patient reports a breast mass, ask about length of time since she first noticed the lump. Does lump come and go, or is it always present? Have there been changes in the lump (e.g., size, relationship to menses), and are there associated symptoms?	Assessment helps to determine nature of mass (e.g., breast cancer versus fibrocystic disease).

Box 30.21 Normal Changes in the Breast During a Woman's Life Span

Puberty (8 to 20 Years)

Breasts mature in five stages. One breast may grow more rapidly than the other. The ages at which changes occur and rate of developmental progression vary.

Stage 1 (Preadolescent)

This stage involves elevation of the nipple only.

Stage 2

The breast and nipple elevate as a small mound, and the areolar diameters enlarge.

Stage 3

There is further enlargement and elevation of the breast and areola, with no separation of contour.

Stage 4

The areola and nipple project into the secondary mound above the level of the breast (does not occur in all girls).

Stage 5 (Mature Breast)

Only the nipple projects, and the areola recedes (varies in some women).

Young Adulthood (20 to 31 Years)

Breasts reach full (nonpregnant) size. Shape is generally symmetrical. Breasts are sometimes unequal in size.

Pregnancy

Breast size gradually enlarges to two to three times the previous size. Nipples enlarge and become erect. Areolas darken, and diameters increase. Superficial veins become prominent. The nipples expel a yellowish fluid (colostrum).

Menopause

Breasts shrink. Tissue becomes softer, sometimes flabby.

Older Adulthood

Breasts become elongated, pendulous, and flaccid as a result of glandular tissue atrophy. The skin of the breasts tends to wrinkle, appearing loose and flabby.

Nipples become smaller and flatter and lose erectile ability. They sometimes invert because of shrinkage and fibrotic changes.

Data from Touhy TA, Jett KF: *Ebersole and Hess' gerontological nursing & healthy aging*, ed 5, St Louis, 2019, Elsevier; Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children*, ed 10, St Louis, 2017, Elsevier; and Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Inspection

Have the patient remove the top gown or drape to allow simultaneous visualization of both breasts. Have her stand or sit with her arms hanging loosely at her sides. If the patient chooses to perform BSE, place a mirror in

front of her if possible during inspection so that she sees what to look for when performing a BSE. Describe observations or findings in relation to imaginary lines that divide the breast into four quadrants and a tail. The lines cross at the center of the nipple. Each tail extends outward from the upper outer quadrant (Fig. 30.51).

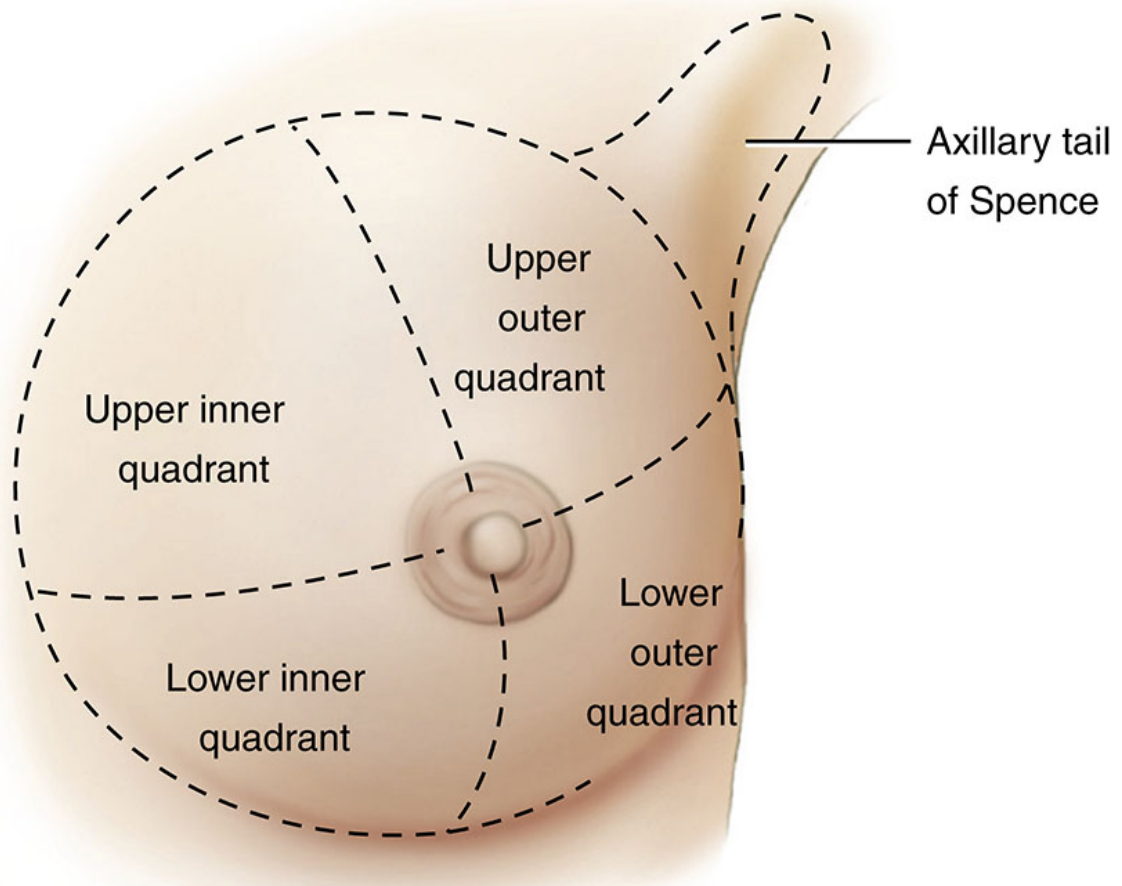

FIG. 30.51 Quadrants of left breast and axillary tail of Spence.
From Shiland BJ: *Medical terminology and anatomy for coding*, ed 3, St Louis, 2017, Mosby.

Inspect the breasts for size and symmetry. Normally they extend from the third to the sixth ribs, with the nipple at the level of the fourth intercostal space. It is common for one breast to be smaller. However, inflammation or a mass causes a difference in size. As a woman ages, the ligaments supporting the breast tissue weaken, causing the breasts to sag and the nipples to lower.

Observe the contour or shape of the breasts and note masses, flattening, retraction, or dimpling. Breasts vary in shape from convex to pendulous or conical. Retraction or dimpling can result from invasion of underlying ligaments by tumors. The ligaments fibrose and pull the overlying skin inward toward the tumor. Edema also changes the contour of the breasts. To bring out retraction or changes in the shape of breasts, ask the patient to assume three positions: raise arms above the head, press hands against the hips, and extend arms straight ahead while sitting and leaning forward. Each maneuver causes a contraction of the pectoral muscles, which accentuates the presence of any retraction.

Carefully inspect the skin for color; venous pattern; and the presence of lesions, edema, or inflammation. Lift each breast when necessary to observe lower and lateral aspects for color and texture changes. The breasts are the color of neighboring skin, and venous patterns are the same bilaterally. Venous patterns are easily visible in thin or pregnant women. Women with large breasts often have redness and excoriation of the undersurfaces caused by rubbing of skin surfaces.

Inspect the nipple and areola for size, color, shape, discharge, and the direction in which the nipples point. The normal areolas are round or oval and nearly equal bilaterally. Color ranges from pink to brown. In light-skinned women the areola turns brown during pregnancy and remains dark. In dark-skinned women the areola is brown before pregnancy (Ball et al., 2019). Normally the nipples point in symmetrical directions, are everted, and have no drainage. If the nipples are inverted, ask whether this has been a lifetime history. A recent inversion or inward turning of the nipple indicates an underlying growth. Rashes or ulcerations are not normal on the breast or nipples. Note any bleeding or discharge from the nipple. Clear yellow discharge 2 days after childbirth is common. While inspecting the breasts, explain the characteristics you see. Teach patients the significance of abnormal signs or symptoms.

Palpation

Use palpation to assess the condition of underlying breast tissue and lymph nodes. Breast tissue consists of glandular tissue, fibrous supportive ligaments, and fat. Glandular tissue is organized into lobes that end in ducts that open onto the surface of the nipple. The largest part of glandular tissue is in the upper outer quadrant and tail of each breast. Suspensory ligaments connect to skin and fascia underlying the breast to support the breast and maintain its upright position. Fatty tissue is located superficially and to the sides of the breast.

A part of the lymph system of the breasts drains into axillary lymph nodes. If cancerous lesions metastasize (spread), the nodes commonly become involved. Study the location of supraclavicular, infraclavicular, and axillary nodes (Fig. 30.52). The axillary nodes drain lymph from the chest wall, breasts, arms, and hands. A tumor of one breast sometimes involves nodes on the same and opposite sides.

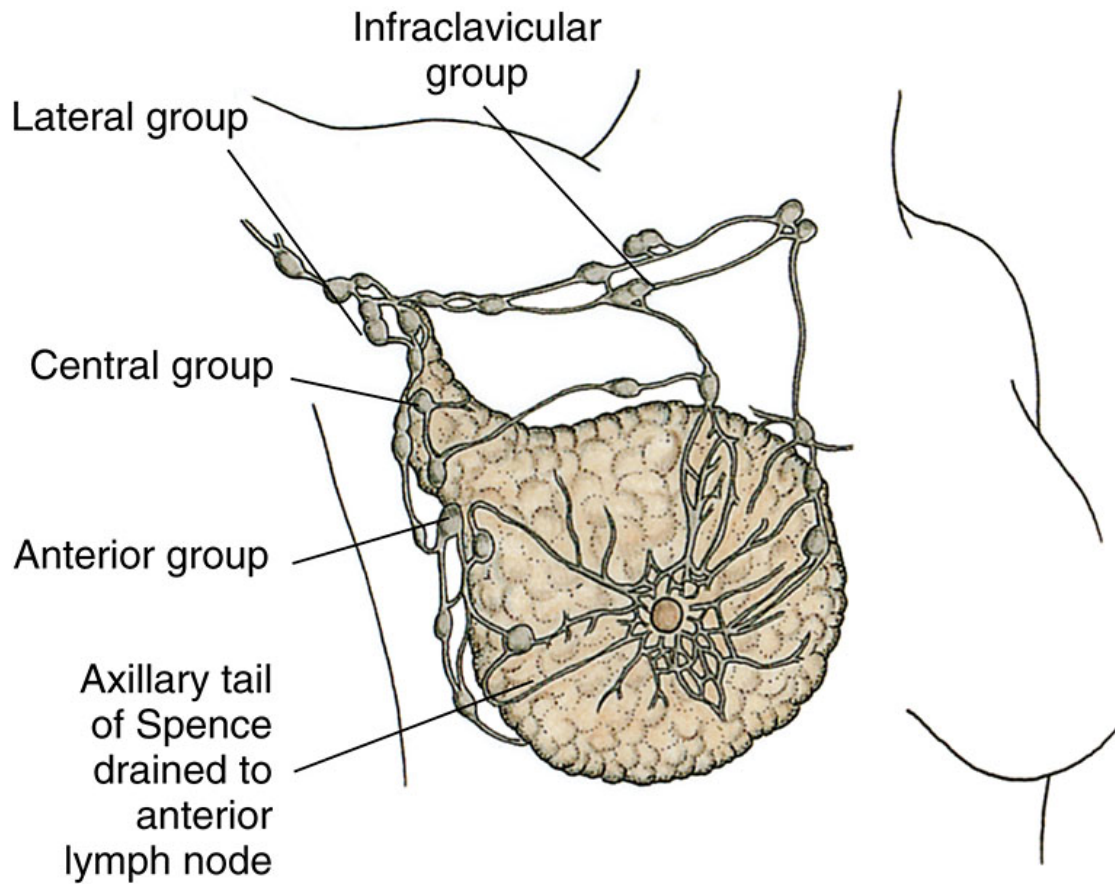

FIG. 30.52 Anatomical position of axillary and clavicular lymph nodes.

To palpate the lymph nodes, have the patient sit with her arms at her sides and muscles relaxed. While facing the patient and standing on the side you are examining, support her arm in a flexed position and abduct it from the chest wall. Place the free hand against the patient's chest wall and high in the axillary hollow. With the fingertips press gently down over the surface of the ribs and muscles. Palpate the four areas of the axilla and the axillary nodes with the fingertips, gently rolling soft tissue (Fig. 30.53).

FIG. 30.53 Support patient's arm and palpate axillary lymph nodes.
From Wilson S, Giddens J: *Health assessment for nursing practice*, ed 6, St Louis, 2016, Elsevier.

Normally lymph nodes are not palpable. Carefully assess each area and note their number, consistency, mobility, and size. One or two small, soft, nontender palpable nodes are normal. An abnormal palpable node feels like a small mass that is hard, tender, and immobile. Continue to palpate along the upper and lower clavicular ridges. Reverse the procedure for the patient's other side.

It is sometimes difficult for a patient to learn to palpate for lymph nodes. Lying down with the arm abducted makes the area more accessible. Instruct the patient to use her left hand for the right axillary and clavicular areas. Take the patient's fingertips and move them in the proper fashion. Then have the patient use her right hand to palpate for nodes on the left side.

With the patient lying supine and one arm under the head and neck (alternating with each breast), palpate her breast tissue ([Fig. 30.54](#)). The supine position allows the breast tissue to flatten evenly against the chest wall. The position of the arm and hand further stretches and positions

breast tissue evenly. Place a small pillow or towel under the patient's shoulder blade to further position breast tissue. Palpate the tail of Spence.

FIG. 30.54 Patient lies flat with arm abducted and hand under head to help flatten breast tissue evenly over chest wall. Each breast is palpated in a systematic fashion.

From Wilson S, Giddens J: *Health assessment for nursing practice*, ed 6, St Louis, 2016, Elsevier.

The consistency of normal breast tissue varies widely. The breasts of a young patient are firm and elastic. In an older patient the tissue sometimes feels stringy and nodular. A patient's familiarity with the texture of her own breasts is very important. Teach patients about strategies to promote breast health ([Box 30.22](#)).

Box 30.22 Patient Teaching **Female Breast Assessment** **Objective**

- Patient will follow prevention and detection practices to ensure breast health.

Teaching Strategies

- Have patient perform return demonstration of breast self-examination (BSE) and offer the opportunity to ask questions (see Box 30.20).
- Explain recommended frequency of mammography and assessment by the patient's health care provider.
- Discuss signs and symptoms of breast cancer.
- Discuss signs and symptoms of benign (fibrocystic) breast disease.
- Inform a woman who is obese or has a family history of breast cancer that she is at higher risk for the disease (ACS, 2018b). Encourage dietary changes, including limiting meat consumption to well-trimmed, lean beef, pork, or lamb; removing skin from cooked chicken before eating it; selecting tuna and salmon packed in water and not oil; and using low-fat dairy products.
- Encourage patient to reduce intake of caffeine and theophyllines. Although this approach is controversial, it can reduce symptoms of benign (fibrocystic) breast disease.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me when was your last mammogram? Explain to me how often you should get a mammogram.
- Describe for me the signs and symptoms of breast cancer and when you should contact your health care provider.

If you or the patient palpate a mass, examine the opposite breast to ensure an objective comparison of normal and abnormal tissue. Use the pads of the first three fingers to compress breast tissue gently against the chest wall, noting tissue consistency. Perform palpation systematically in one of three ways: (1) using a vertical technique with the fingers moving up and down each quadrant; (2) clockwise or counterclockwise, forming small concentric circles with the fingers along each quadrant and the tail;

or (3) palpating from the center of the breast in a radial fashion, returning to the areola to begin each spoke (Fig. 30.55A-C). Whichever approach you use, be sure to cover the entire breast and tail, directing attention to any areas of tenderness. Use a bimanual technique when palpating large, pendulous breasts. Support the inferior part of the breast in one hand while using the other hand to palpate breast tissue against the supporting hand.

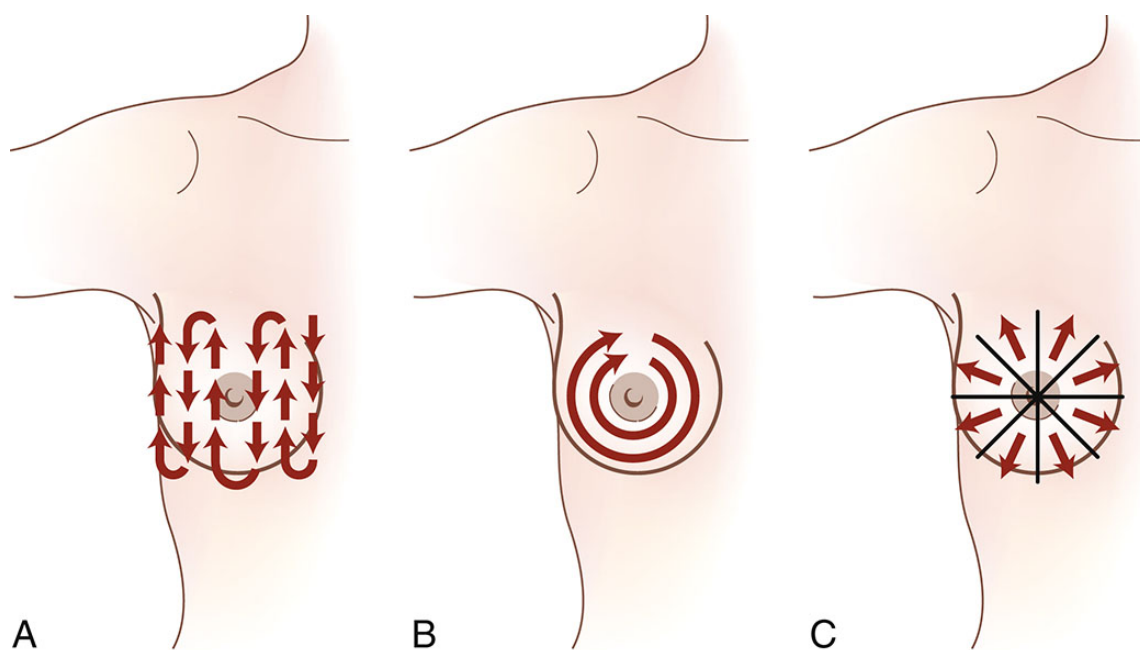

FIG. 30.55 Various methods for palpation of breast. **A**, Palpate from top to bottom in vertical strips. **B**, Palpate in concentric circles. **C**, Palpate out from center in wedge sections.

During palpation note the consistency of breast tissue. It normally feels dense, firm, and elastic. With menopause breast tissue shrinks and becomes softer. The lobular feel of glandular tissue is normal. The lower edge of each breast sometimes feels firm and hard. This is the normal inframammary ridge and not a tumor. It helps to move the patient's hand so that she can feel normal tissue variations. Palpate abnormal masses to determine location in relation to quadrants, diameter in centimeters, shape (e.g., round or discoid), consistency (soft, firm, or hard), tenderness, mobility, and discreteness (clear or unclear boundaries).

Cancerous lesions are hard, fixed, nontender, irregular in shape, and usually unilateral. A common benign condition of the breast is benign (fibrocystic) breast disease. Bilateral lumpy, painful breasts and sometimes

nipple discharge characterize this condition. Symptoms are more apparent during the menstrual period. When palpated, the cysts (lumps) are soft, well differentiated, and movable. Deep cysts feel hard.

Give special attention to palpating the nipple and areola. Palpate the entire surface gently. Use the thumb and index finger to compress the nipple and note any discharge. During the examination of the nipple and areola, the nipple sometimes becomes erect with wrinkling of the areola. These changes are normal. Continue by positioning the patient and examining the other breast.

Male Breasts

Inspect the nipple and areola for nodules, edema, and ulceration. An enlarged male breast results from obesity or glandular enlargement. Breast enlargement in young males results from steroid use. Fatty tissue feels soft, whereas glandular tissue is firm. Use the same techniques to palpate for masses used in examination of the female breast. Because breast cancer in men is relatively rare, routine self-examinations are unnecessary. However, men who have a first-degree relative (e.g., mother or sister) with breast cancer are at risk for breast cancer and may be scheduled by their health care provider for routine mammograms.

Abdomen

The abdominal examination is complex because of the number of organs located within and near the abdominal cavity. A thorough nursing history ([Table 30.27](#)) helps interpret physical signs. The examination includes an assessment of structures of the lower gastrointestinal (GI) tract in addition to the liver, stomach, uterus, ovaries, kidneys, and bladder. Abdominal pain is one of the most common symptoms that patients report when seeking medical care. An accurate assessment requires matching patient history data with a careful assessment of the location of physical symptoms.

TABLE 30.27**Nursing History for Abdominal Assessment**

Assessment	Rationale
If patient has abdominal or low back pain, assess character of pain in detail (location, onset, frequency, precipitating factors, aggravating factors, type of pain, severity, course).	Pattern of characteristics of pain helps determine its source.
Carefully observe patient's movement and position, including lying still with knees drawn up, moving restlessly to find comfortable position, and lying on one side or sitting with knees drawn to chest.	Positions assumed by patient reveal nature and source of pain, including peritonitis, renal stone, and pancreatitis.
Assess normal bowel habits and stool character; ask whether patient uses laxatives.	Data compared with physical findings help identify cause and nature of elimination problems.
Determine whether patient has had abdominal surgery, trauma, or diagnostic tests of gastrointestinal (GI) tract.	Surgical or traumatic alterations of abdominal organs cause changes in expected findings (e.g., position of underlying organs). Diagnostic tests change character of stool.
Assess whether patient has had recent weight changes or intolerance to diet (e.g., nausea, vomiting, cramping, especially in last 24 hours).	Data can indicate alterations in upper GI tract (stomach or gallbladder) or lower colon.
Assess for difficulty in swallowing, belching, flatulence (gas), bloody emesis (hematemesis), black or tarry stools (melena), heartburn, diarrhea, or constipation.	These characteristic signs and symptoms indicate GI alterations.
Ask whether patient takes antiinflammatory medication (e.g., aspirin, ibuprofen, steroids) or antibiotics.	Pharmacological agents cause GI upset or bleeding.
Ask patient to locate tender areas before examination begins.	Assess painful areas last to minimize discomfort and anxiety.
Inquire about family history of cancer, kidney disease, alcoholism, hypertension, or heart disease.	Data can reveal risk for alterations identifiable during examination.
Determine whether female patient is pregnant; note last menstrual period.	Pregnancy causes changes in abdominal shape and contour.
Assess patient's usual intake of alcohol.	Chronic alcohol ingestion causes GI and liver problems, including liver, colon, and pancreatic cancer (ACS, 2018b).
Review patient's history for the following: health care occupation, hemodialysis, intravenous drug user, household or sexual contact with hepatitis B virus (HBV) carrier, heterosexual person with more than one sex partner in previous 6 months, sexually active homosexual or bisexual male, international traveler in area of high HBV infection rate.	Risk factors for HBV exposure.

Assess the organs anteriorly and posteriorly. A system of landmarks helps map out the abdominal region. The xiphoid process (tip of the sternum) is the upper boundary of the anterior abdominal region. The

symphysis pubis marks the lower boundary. Divide the abdomen into four imaginary quadrants ([Fig. 30.56A](#)); refer to assessment findings and record them in relation to each quadrant. Posteriorly the lower ribs and heavy back muscles protect the kidneys, which are located from the T12 to L3 vertebrae (see [Fig. 30.56B](#)). The costovertebral angle formed by the last rib and vertebral column is a landmark used during kidney palpation.

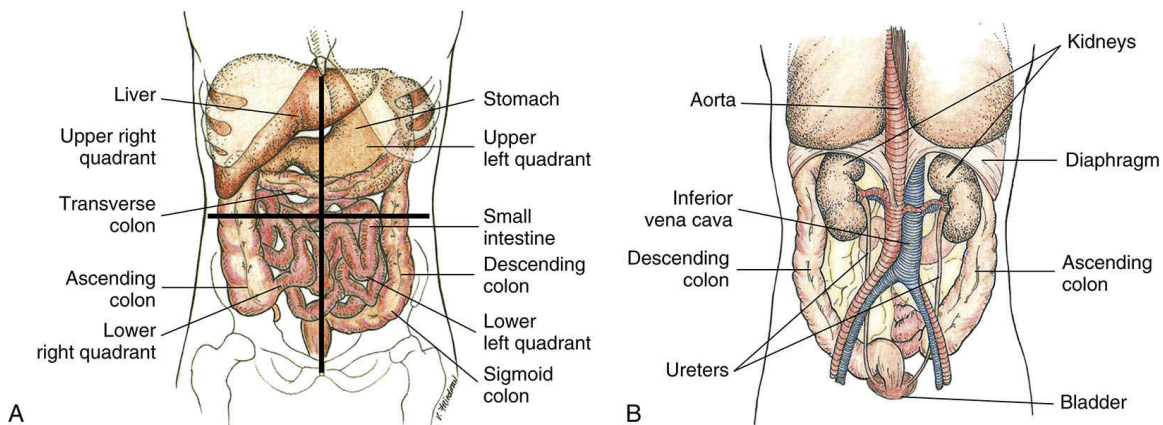

FIG. 30.56 **A**, Anterior view of abdomen divided by quadrants. **B**, Posterior view of abdominal section.

During the abdominal examination the patient needs to relax. A tightening of abdominal muscles hinders palpation. Ask the patient to void before beginning. Be sure that the room is warm and drape upper chest and legs. The patient lies supine or in a dorsal recumbent position with the arms at the sides and knees slightly bent. Place small pillows beneath the knees. If the patient places the arms under the head, the abdominal muscles tighten. Proceed calmly and slowly, being sure that there is adequate lighting. Expose the abdomen from just above the xiphoid process down to the symphysis pubis. Warm hands and stethoscope further promote relaxation. Ask the patient to report pain and point out tender areas. Assess tender areas last.

The order of an abdominal examination differs slightly from previous assessments. Begin with inspection and follow with auscultation. By completing palpation last there is less chance of altering the frequency and character of bowel sounds. Be sure to have a tape measure and marking pen available during the examination.

Inspection

Make it a habit to observe the patient during routine care activities. Note his or her posture and look for evidence of abdominal splinting: lying with the knees drawn up or moving restlessly in bed. A patient free from abdominal pain does not guard or splint the abdomen. To inspect the abdomen for abnormal movement or shadows, stand on the patient's right side and inspect from above the abdomen. After sitting or stooping down to look across the abdomen, assess abdominal contour. Direct the examination light over the abdomen.

Skin

Inspect the skin over the abdomen for color, scars, venous patterns, lesions, and **striae** (stretch marks). The skin is subject to the same color variations as the rest of the body. Venous patterns are normally faint, except in thin patients. Striae result from stretching of tissue by obesity or pregnancy. Artificial openings indicate drainage sites resulting from surgery (see [Chapter 50](#)) or an ostomy (see [Chapters 46](#) and [47](#)). Scars reveal evidence of past trauma or surgery that has created permanent changes in underlying organ anatomy. Bruising indicates accidental injury, physical abuse, or a type of bleeding disorder. If needle marks or bruises are present, ask whether the patient self-administers injections (e.g., low-molecular-weight heparin or insulin). Unexpected findings include generalized color changes such as jaundice or cyanosis. Shiny abdominal skin with a taut (tight) appearance can indicate ascites.

Umbilicus

Note the position; shape; color; and signs of inflammation, discharge, or protruding masses. A normal umbilicus is flat or concave, with the color the same as that of the surrounding skin. Underlying masses cause displacement of the umbilicus. An everted (pouched-out) umbilicus usually indicates distention. Hernias (protrusion of abdominal organs through the muscle wall) cause upward protrusion of the umbilicus. Normally the umbilical area does not emit discharge.

Contour and Symmetry

Inspect for contour, symmetry, and surface motion of the abdomen, noting any masses, bulging, or distention. A flat abdomen forms a horizontal plane from the xiphoid process to the symphysis pubis. A round abdomen protrudes in a convex sphere from the horizontal plane. A concave abdomen appears to sink into the muscular wall. Each of these findings is

normal for the individual patient if the shape of the abdomen is symmetrical. In older adults there is often an overall increased distribution of adipose tissue. The presence of masses on only one side, or asymmetry, can indicate an underlying pathological condition.

Intestinal gas, a tumor, or fluid in the abdominal cavity causes **distention** (swelling). When distention is generalized, the entire abdomen protrudes. The skin often appears taut, as if it were stretched over the abdomen. When gas causes distention, the flanks (side muscles) do not bulge. However, if fluid is the source of the problem, the flanks bulge. Ask the patient to roll onto one side. A protuberance forms on the dependent side if fluid is the cause of the distention. Ask the patient whether the abdomen feels unusually tight. Be careful not to confuse distention with obesity. In obesity the abdomen is large, rolls of adipose tissue are often present along the flanks, and the patient does not complain of tightness in the abdomen. If distention is expected, measure the abdomen by placing a tape measure around it at the level of the umbilicus (this may require the patient to roll side-to-side as you position the tape measure). Consecutive measurements show any increase or decrease in distention. Use a marking pen to indicate the location of the tape measure.

Enlarged Organs or Masses

Observe the contour of the abdomen while asking the patient to take a deep breath and hold it. Normally the contour remains smooth and symmetrical. This maneuver forces the diaphragm downward and reduces the size of the abdominal cavity. Any enlarged organs in the upper abdominal cavity (e.g., liver or spleen) descend below the rib cage to cause a bulge. Perform a closer examination with palpation. To evaluate the abdominal musculature have the patient raise the head. This position causes superficial abdominal wall masses, hernias, and muscle separations to become more apparent.

Movement or Pulsations

Inspect for movement. Normally men breathe abdominally, and women breathe more costally. A patient with severe pain has diminished respiratory movement and tightens the abdominal muscles to guard against the pain. Closely inspect for peristaltic movement and aortic pulsation by looking across the abdomen from the side. These movements are visible in thin patients; otherwise no movement is present.

Auscultation

Auscultate before palpation during the abdominal assessment because manipulation of the abdomen alters the frequency and intensity of bowel sounds. Ask patients not to talk. Patients with GI tubes connected to suction need them temporarily turned off before beginning an examination.

Bowel Motility

Peristalsis, or the movement of contents through the intestines, is a normal function of the small and large intestine. Bowel sounds are the audible passage of air and fluid that peristalsis creates. Place the warmed diaphragm of the stethoscope lightly over each of the four quadrants. Normally air and fluid move through the intestines, creating soft gurgling or clicking sounds that occur irregularly 5 to 35 times per minute (Ball et al., 2019). It normally takes 5 to 20 seconds to hear a bowel sound. However, it takes 5 minutes of continuous listening before determining that bowel sounds are absent (Ball et al., 2019). Auscultate all four quadrants to be sure that you do not miss any sounds. The best time to auscultate is between meals. Sounds are generally described as normal, audible, absent, hyperactive, or hypoactive. Absent sounds indicate a lack of peristalsis, possibly the result of late-stage bowel obstruction; paralytic ileus; or peritonitis. Absent or hypoactive bowel sounds may be normal after surgery following general anesthesia. Hyperactive sounds are loud, “growling” sounds called **borborygmi**, which indicate increased GI motility and can be caused by inflammation of the bowel, anxiety, diarrhea, bleeding, excessive ingestion of laxatives, and reaction of the intestines to certain foods. Assessment findings vary based on patient situation and level of care (Box 30.23). Teach patients practices that promote normal elimination patterns (Box 30.24).

Box 30.23 Evidence-Based Practice **Detection of Gastrointestinal Complications**

PICOT Question: Are patients with general medical problems more at risk for gastrointestinal (GI) complications compared with patients who are critically ill?

Evidence Summary

A well-performed, complete GI assessment can identify changes that lead to complications and guide care of the patient. The subjective component of the GI assessment requires questions to determine history, normal routine, food consumption, elimination patterns, and discomfort. It is recommended to use multiple objective assessment techniques such as auscultation, inspection, and palpation as well as more detailed tests such as computed tomography (CT), ultrasound, endoscopy and real-time bowel sound analysis using acoustic sensors (Goto et al., 2015). Using only one component of the exam, such as auscultation of bowel sounds is not a good indicator of complications (Felder et al., 2014). Bowel sounds can vary greatly depending on the patient situation. An increase in the frequency of bowel sounds can present because the patient is chewing gum (Frazer et al., 2018), or an increase in blood sugar can slow motility and decrease the frequency of bowel sounds (Ladopoulos et al., 2018). Over the years the physical GI exam has been scaled down while imaging techniques have increased (Zuin et al., 2017). Scales such as the sequential failure assessment (SOFA) and GI failure (GIF) can be used in combination with a physical exam to help identify complications (Moonen et al., 2018).

GI complications contribute to a high risk of mortality, increased length of stay, and medical costs (Frazer et al., 2018). Patients in intensive care units are more likely to have more GI devices, such as nasogastric (NG) tubes to suction, a tube for feedings, and parenteral feeding, and require additional monitoring (Jacob, 2017). These aspects of care contribute to a patient in the intensive care area having an increased risk for complications when compared to a general medicine patient. Current and preexisting conditions, such as obesity, advancing age, chronic alcohol use, altered fluid and electrolytes, or kidney issues, make the patient more likely to experience GI complications (Bond and Hallmark, 2018). Patients with a decreased level of consciousness have an increased risk of GI complications; therefore, different assessment techniques may be needed (Li et al., 2014). Goto and colleagues (2015) discuss the use of a real-time bowel sound analysis system for continuous monitoring of bowel sounds through recording equipment and acoustic sensors. This monitoring allows for the initial change in bowel sound to be addressed as soon as possible to assist with the identification of complications.

Application to Nursing Practice

- GI complications are common in patients admitted to the hospital (Jacob, 2017).

- A complete GI assessment needs to be completed, including subjective and objective information because an assessment finding as minor as hiccups can be an indication of a complication (Bond and Hallmark, 2018).
- Auscultation of bowel sounds should be completed but should not be the sole indicator of a complication (Zuin et al., 2017).
- Education should be completed on standard practice for auscultation of bowel sounds and evaluation conducted to make sure standards are being followed (Li et al., 2014).
- Movement can help decrease GI complications in patients (Morisawa et al., 2017).

Box 30.24 Patient Teaching **Abdominal Assessment**

Objective

- Patient will maintain normal bowel elimination.

Teaching Strategies

- Explain factors that promote normal bowel elimination such as diet (fruits, vegetables, fiber), regular exercise, limited use of over-the-counter drugs causing constipation, establishment of regular elimination schedule, and a good fluid intake (see Chapter 47). Stress importance for older adults.
- Caution patients about the dangers of excessive use of laxatives or enemas.
- Instruct patient to have acute abdominal pain evaluated by a health care provider.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe for me your bowel elimination pattern and what the stool looks like.

- Describe for me the high-fiber foods that you have added to your diet.

Vascular Sounds

Bruits indicate narrowing of the major blood vessels and disruption of blood flow. The presence of bruits in the abdominal area can reveal aneurysms or stenotic vessels. Use the bell of the stethoscope to auscultate in the epigastric region and each of the four quadrants. Normally there are no vascular sounds over the aorta (midline through the abdomen) or femoral arteries (lower quadrants). You can hear renal artery bruits by placing the stethoscope over each upper quadrant anteriorly or over the costovertebral angle posteriorly. Report a bruit immediately to a health care provider.

Kidney Tenderness

With the patient sitting or standing erect, use direct or indirect percussion to assess for kidney inflammation. With the ulnar surface of the partially closed fist, percuss posteriorly the costovertebral angle at the scapular line. If the kidneys are inflamed, the patient feels tenderness during percussion.

Palpation

Palpation primarily detects areas of abdominal tenderness, distention, or masses. As your skill base increases, learn to palpate for specific organs by using light and deep palpation.

Use light palpation over each abdominal quadrant to detect areas of tenderness. Initially avoid areas previously identified as problem spots. Lay the palm of the hand with fingers extended and approximated lightly on the abdomen. Explain the maneuver to the patient and, with the palmar surface of the fingers, depress approximately 1.3 cm (½ inch) in a gentle dipping motion (Fig. 30.57). Avoid quick jabs and use smooth, coordinated movements. If the patient is ticklish, first place his or her hand on the abdomen with your hand on the patient's; continue this until the patient tolerates palpation.

FIG. 30.57 Light palpation of abdomen.

Use a systematic palpation approach for each quadrant and assess for muscular resistance, distention, tenderness, and superficial organs or masses. Observe the patient's face for signs of discomfort. The abdomen is normally smooth with consistent softness and nontender without masses. In contrast to firm muscles found among young adults, an older adult often lacks abdominal tone. Guarding or muscle tenseness sometimes occurs while palpating a sensitive area. If tightening remains after the patient relaxes, peritonitis, acute cholecystitis, or appendicitis is sometimes the cause. It is easy to detect a distended bladder with light palpation because the bladder lies below the umbilicus and above the symphysis pubis. Routinely check for a distended bladder if the patient has been unable to void (e.g., because of anesthesia or sedation, has been incontinent, or if an indwelling urinary catheter is not draining well).

With practice and experience perform deep palpation to delineate abdominal organs and detect less obvious masses. You need short fingernails. It is important for the patient to be relaxed while the hands depress approximately 2.5 to 7.5 cm (1 to 3 inches) into the abdomen (Fig. 30.58). Never use deep palpation over a surgical incision, over tender organs, or on abnormal masses. Deep pressure causes tenderness in a

healthy patient over the cecum, sigmoid colon, aorta, and the midline near the xiphoid process (Ball et al., 2019).

FIG. 30.58 Deep palpation of abdomen.

Survey each quadrant systematically. Palpate masses for size, location, shape, consistency, tenderness, pulsation, and mobility. Test for rebound tenderness by pressing a hand slowly and deeply into the involved area and letting go quickly; if discomfort is present, then the test is positive. Be careful with this examination technique if pain is present. Rebound tenderness occurs in patients with peritoneal irritation such as occurs in appendicitis; pancreatitis; or any peritoneal injury causing bile, blood, or enzymes to enter the peritoneal cavity.

Aortic Pulsation

Palpate with the thumb and forefinger of one hand deeply into the upper abdomen just left of the midline to assess aortic pulsation. Normally a pulsation is transmitted forward. If the aorta is enlarged because of an aneurysm (localized dilation of a vessel wall), the pulsation expands laterally. Do not palpate a pulsating abdominal mass. When enlargement

from an aneurysm is present, palpate this area only lightly, referring the finding to the health care provider. In patients who are obese, it is often necessary to palpate with both hands, one on each side of the aorta.

Female Genitalia and Reproductive Tract

Examination of the female genitalia can be embarrassing to a patient unless you use a calm, relaxed approach. The gynecological examination is one of the most difficult experiences for adolescents. A person's cultural background further adds to apprehension. For example, female Mexican Americans have a strong social value that women do not expose their bodies to men or even to other women. Similarly, Chinese Americans believe that the examination of genitalia is offensive. Muslim women value respect for female modesty. Provide a thorough explanation of the reason for the procedures used in an examination. The lithotomy position assumed during the examination is an added source of embarrassment and can increase anxiety. A patient is more comfortable when you use correct positioning and draping. Be sure to explain each part of the examination in advance so that patients anticipate necessary actions. Adolescents sometimes choose to have parents present in the examination room.

Sometimes a patient requires a complete examination of the female reproductive organs, including assessing the external genitalia and performing a vaginal examination. You can examine external genitalia while performing routine hygiene measures or when preparing to insert a urinary catheter. An internal examination is part of each woman's preventive health care because ovarian cancer causes more deaths than any other cancer of the female reproductive system ([ACS, 2018b](#)).

Adolescents and young adults are examined because of the growing incidence of sexually transmitted infections (STIs). The average age of menarche among young girls has declined, and the majority of male and female teenagers are sexually active by age 19 ([Hockenberry and Wilson, 2019](#)). It is important to assess a patient's level of anxiety when obtaining the nursing history ([Table 30.28](#)). Combine rectal and anal assessments with the pelvic examination since the patient is situated in a lithotomy or dorsal recumbent position.

TABLE 30.28**Nursing History for Female Genitalia and Reproductive Tract Assessment**

Assessment	Rationale
Determine whether patient has had previous illness or surgery involving reproductive organs, including STIs.	Illness or surgery influences appearance and position of organs being examined.
Determine whether patient has received HPV vaccine.	HPV increases patient's risk for development of cervical cancer.
Review menstrual history, including age at menarche, frequency and duration of menstrual cycle, character of flow (e.g., amount, presence of clots), presence of dysmenorrhea (painful menstruation), pelvic pain, dates of last two menstrual periods, and premenstrual symptoms.	This information helps to reveal level of reproductive health, including normalcy of menstrual cycle.
Ask patient to describe obstetrical history, including each pregnancy and history of abortions or miscarriages.	Observed physical findings vary, depending on woman's history of pregnancy.
Determine whether patient uses safe sex practices; have patient describe current and past contraceptive practices and problems encountered. Discuss risk of STIs and HIV infection.	Use of certain types of contraceptives influences reproductive health (e.g., sensitivity reaction to spermicidal jelly). Sexual history reveals risk for and understanding of STIs.
Assess whether patient has signs and symptoms of vaginal discharge, painful or swollen perianal tissues, or genital lesions.	These signs and symptoms may indicate STI or other pathological condition.
Determine whether patient has symptoms or history of genitourinary problems, including burning during urination, frequency, urgency, nocturia, hematuria, incontinence, or stress incontinence (see Chapter 46).	Urinary problems are associated with gynecological disorders, including STIs.
Ask whether patient has had signs of bleeding outside of normal menstrual period or after menopause or has had unusual vaginal discharge.	These are warning signs for cervical and endometrial cancer or vaginal infection.
Determine whether patient has history of HPV (condyloma acuminatum, herpes simplex, or cervical dysplasia), has multiple sex partners, smokes cigarettes, has had multiple pregnancies, or was young at first intercourse.	These are risk factors for cervical cancer (ACS, 2018b).

Assessment	Rationale
Ask if patient has a strong personal or family history of breast or ovarian cancer; women who have had breast cancer or who have tested positive for inherited mutations in <i>BRCA1</i> or <i>BRCA2</i> genes are at increased risk. Other medical conditions associated with increased risk include pelvic inflammatory disease and Lynch syndrome. The use of estrogen alone as menopausal hormone therapy has been shown to increase risk. Tobacco smoking increases the risk of mucinous ovarian cancer. Heavier body weight may be associated with increased risk of ovarian cancer.	These are risk factors for ovarian cancer (ACS, 2018b).
Determine whether patient is postmenopausal, is obese, has abdominal fat, or is infertile. Assess whether patient received menopausal estrogen therapy, had late menopause, never had children, and had a history of polycystic ovary syndrome. Tamoxifen, a drug used to reduce breast cancer risk, increases the risk slightly because it has estrogen-like effects on the uterus. Medical conditions that increase the risk include Lynch syndrome and diabetes.	These are risk factors for endometrial cancer (ACS, 2018b).

HIV, Human immunodeficiency virus; *HPV*, human papillomavirus (HPV) vaccine; *STI*, sexually transmitted infection.

Preparation of the Patient

As a new nurse, you are responsible for assisting a patient's health care provider with a pelvic examination. For a complete examination the following equipment is needed: examination table with stirrups, vaginal speculum of correct size, adjustable light source, sink, clean disposable gloves, sterile cotton swabs, glass slides, plastic or wooden spatula, cervical brush or broom device, cytological fixative, and culture plates or media (Ball et al., 2019).

Make sure that the equipment is ready before the examination begins. Ask the patient to empty her bladder so that the uterus and ovaries are readily palpable. Often it is necessary to collect a urine specimen. Help the patient to the lithotomy position in bed or on an examination table for the external genitalia assessment. Assist her into stirrups for a speculum examination. Have a woman stabilize each foot in a stirrup and slide the buttocks down to the edge of the examining table. Place a hand at the edge of the table and instruct the patient to move until touching the hand. The patient's arms should be at her sides or folded across the chest to prevent tightening of abdominal muscles.

Sometimes women who have pain or a deformity of the joints are unable to assume a lithotomy position. In this situation have the patient abduct only one leg or have another person assist in separating the patient's thighs. In addition, use the side-lying position with the patient on the left side with the right thigh and knee drawn up to her chest.

Give the patient a square drape or sheet. She holds one corner over her sternum, the adjacent corners fall over each knee, and the fourth corner covers the perineum. After the examination begins, lift the drape over the perineum. A male examiner always needs to have a female attendant present during the examination, whereas a female examiner may choose to work alone. An additional woman should be present if the patient requests it.

External Genitalia

You can perform this examination independently of a health care provider. Make sure that the perineal area is well illuminated. Follow standard precautions and wear clean gloves to prevent contact with infectious organisms. The perineum is sensitive and tender; do not touch the area suddenly without warning a patient. It is best to touch the inner thigh first before touching the perineum.

While sitting at the end of the examination table or bed, inspect the quantity and distribution of hair growth. Preadolescents have no pubic hair. During adolescence hair grows along the labia, becoming darker, coarser, and curlier. In an adult hair grows in a triangle over the female perineum and along the medial surfaces of the thighs. The underlying skin is free of inflammation, irritation, or lesions.

Inspect surface characteristics of the labia majora. The skin of the perineum is smooth, clean, and slightly darker than other skin. The mucous membranes appear dark pink and moist. The labia majora can be gaping or closed, appear dry or moist, and are usually symmetrical. After childbirth the labia majora separate, causing the labia minora to become more prominent. When a woman reaches menopause, the labia majora become thinned; they become atrophied in older age. The labia majora are normally without inflammation, edema, lesions, or lacerations.

To inspect the remaining external structures, use your nondominant hand and gently place the thumb and index finger inside the labia minora and retract the tissues outwardly (Fig. 30.59). Be sure to have a firm hold to avoid repeated retraction against the sensitive tissues. Use the other hand to palpate the labia minora between the thumb and second finger. On inspection the labia minora are normally thinner than the labia majora, and one side is sometimes larger. The tissue feels soft on palpation and without tenderness. The size of the clitoris varies, but it normally does not exceed 2 cm (1 inch) in length and 0.5 cm ($\frac{1}{4}$ inch) in width. Look for atrophy, inflammation, or adhesions. If inflamed, the clitoris is a bright

cherry red. In young women it is a common site for an abnormal finding such as syphilitic lesions, or chancres, which appear as small open ulcers that drain serous material.

FIG. 30.59 Female external genitalia.

Inspect the urethral orifice carefully for color and position. It is normally intact without inflammation. The urethral meatus is anterior to the vaginal

orifice and is pink. It appears as a small slit or pinhole opening just above the vaginal canal. Note any discharge, polyps, or fistulas.

Inspect the vaginal orifice for inflammation, edema, discoloration, discharge, and lesions. Normally the opening is a thin, vertical slit, and the tissue is moist. While inspecting the vaginal orifice, note the condition of the hymen, which is just inside the opening. In the virgin female the hymen restricts the opening of the vagina, but the tissue retracts or disappears after sexual intercourse or with normal growth in adolescence (Ball et al., 2019).

Inspect the anus, looking for lesions and hemorrhoids (see rectal examination). After completion of the external examination, dispose of examination gloves and offer the patient soft disposable cloths for perineal hygiene.

Patients who are at risk for contracting an STI need to learn to perform a genital self-examination (Box 30.25). The purpose of the examination is to detect any signs or symptoms of an STI. Many people do not know that they have an STI (e.g., chlamydia), and some STIs (e.g., syphilis) remain undetected for years.

Box 30.25 Patient Teaching Female Genitalia and Reproductive Tract Assessment

Objective

- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies

- Instruct patient about purpose and recommended frequency of Papanicolaou (Pap) smears and gynecological examinations. Explain that a pelvic examination is needed yearly for women who are sexually active or over the age of 21. Patients are screened more often if certain risk factors exist such as a weak immune system, multiple sex partners, smoking, and a history of infections (e.g., human papillomavirus [HPV]).

- Counsel patient with an STI about the implications of diagnosis and treatment.
- Counsel young males and females and their parents about genital HPV infection and the need to receive the HPV vaccine before becoming sexually active. The vaccine is recommended for preteen boys and girls at age 11 or 12 (CDC, 2018a). Adolescent boys and girls who did not start or finish the HPV vaccine series when they were younger should get it now. Young women can get an HPV vaccine through age 26, and young men can get vaccinated through age 21 (CDC, 2018b).
- Instruct in genital self-examination (GSE). Using a mirror, position self to examine the area covered by the pubic hair. Spread the hair apart, looking for bumps, sores, or blisters. Also look for any warts, which appear as small, bumpy spots and enlarge to fleshy, cauliflower-like lesions. Next spread the outer vaginal lips apart and look at the clitoris for bumps, blisters, sores, or warts. Look at both sides of the inner vaginal lips. Inspect the area around the urinary and vaginal opening for bumps, blisters, sores, or warts.
- Explain warning signs of STIs: pain or burning on urination, pain during sex, pain in pelvic area, bleeding between menstruation, itchy rash around vagina, and abnormal vaginal discharge.
- Teach measures to prevent STIs: male partner's use of condoms, restricting number of sexual partners, avoiding sex with people who have several other partners, and perineal hygiene measures.
- Tell patients with an STI to inform sexual partners of the need for an examination.
- Reinforce the importance of performing perineal hygiene (as appropriate).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Explain to me the rationale for obtaining the HPV vaccination for your child.
- Explain to me why a routine gynecological examination and Pap test are important.
- Describe measures you can take to prevent transmission of an STI.

- Since you were diagnosed with an STI, describe for me the safe sexual practices that you are using to prevent further infections.

Speculum Examination of Internal Genitalia

An examination of the internal genitalia requires much skill and practice. Advanced nurse practitioners and primary care providers perform this examination. As a nursing student you observe the procedure or assist the examiner by helping the patient with positioning, handing off specimen supplies, and providing emotional support for the patient.

The examination involves use of a plastic or metal speculum consisting of two blades and an adjustment device. The examiner inserts the speculum into the vagina to assess the internal genitalia for cancerous lesions and other abnormalities. During the examination the examiner collects a specimen for a Papanicolaou (Pap) test for cervical and vaginal cancer. The cervix is inspected for color, position, size, surface characteristics, and discharge ([Ball et al., 2019](#)).

Male Genitalia

An examination of the male genitalia assesses the integrity of the external genitalia (Fig. 30.60), inguinal ring, and canal. Because the incidence of STIs in adolescents and young adults is high, an assessment of the genitalia needs to be a routine part of any health maintenance examination for this age-group (Box 30.26). The examination begins by having the patient void. Make sure the examination room is warm. During the examination have the patient stand or lie supine with the chest, abdomen, and lower legs draped. Apply clean gloves.

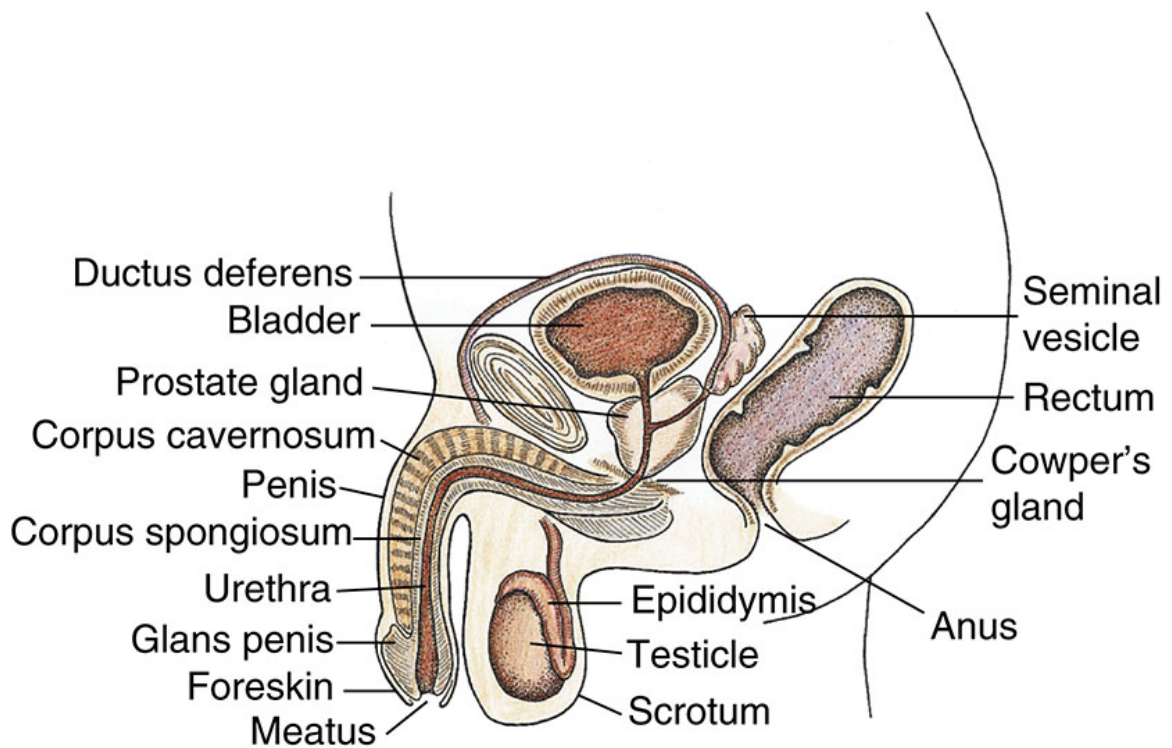

FIG. 30.60 External and internal male sex organs.

Box 30.26 Patient Teaching Male Genitalia

Assessment

Objective

- Patient will use measures to maintain sexual health and prevent acquisition and transmission of sexually transmitted infections (STIs).

Teaching Strategies

- Teach patient how to perform genital self-examination (see Box 30.27).
- Counsel patient who has an STI about diagnosis implications and treatment.
- Explain warning signs of STIs: pain on urination and during sex, abnormal penile discharge (different from usual), swollen lymph nodes, or rash or ulcer on skin or genitalia.
- Teach measures to prevent STIs: HPV immunization, use of condoms, avoiding sex with infected partner, restricting number of sexual partners, avoiding sex with people who have multiple partners, and using regular perineal hygiene.
- Recommend HPV vaccine for preteen boys age 11 or 12; young men can get vaccinated through age 21 (CDC, 2018c).
- Tell patients with an STI to inform their sexual partners of the need to have an examination.
- Instruct patient to seek treatment as soon as possible if partner becomes infected with an STI.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe measures you can take to prevent transmission of an STI.
- Since you were diagnosed with an STI, describe for me the safe sexual practices that you are using to prevent further infections.

Use a calm, gentle approach to lessen the patient's anxiety. The position and exposure of the body during the examination is embarrassing for some men. To minimize his anxiety, it often helps to offer explanation of the steps of examination so that he anticipates all actions. Manipulate the genitalia gently to avoid causing erection or discomfort. Obtain a thorough history ([Table 30.29](#)) before the examination, ensuring that the assessment is complete.

TABLE 30.29**Nursing History for Male Genitalia Assessment**

Assessment	Rationale
Review normal urinary elimination pattern, including frequency of voiding; history of nocturia; character and volume of urine; daily fluid intake; symptoms of burning, urgency, and frequency; difficulty starting stream; and hematuria (see Chapter 46).	Urinary problems are directly associated with genitourinary problems because of anatomical structure of men's reproductive and urinary systems.
Assess patient's sexual history and use of safe sex habits (multiple partners, infection in partners, failure to use condom).	Sexual history reveals risk for and understanding of sexually transmitted diseases (STIs) and human immunodeficiency virus (HIV).
Determine whether patient has received the human papillomavirus (HPV) vaccine.	HPV is associated with genital warts in males and can lead to cervical cancer in females (CDC, 2018a).
Determine whether patient has had previous surgery or illness involving urinary or reproductive organs, including STI.	Alterations resulting from disease or surgery are sometimes responsible for symptoms or changes in organ structure or function.
Ask whether patient has noted penile pain or swelling, genital lesions, or urethral discharge.	These signs and symptoms may indicate STI.
Determine whether patient has noticed heaviness or painless enlargement of testis or irregular lumps.	These signs and symptoms are early warning signs for testicular cancer.
If patient reports an enlargement in inguinal area, assess whether it is intermittent or constant, associated with straining or lifting, and painful; and whether pain is affected by coughing, lifting, or straining at stool.	Signs and symptoms reflect potential inguinal hernia.
Ask whether patient has difficulty achieving erection or ejaculation; also review whether patient is taking diuretics, sedatives, antihypertensives, or tranquilizers.	These medications influence sexual performance.

Sexual Maturity

First note the sexual maturity of the patient by observing the size and shape of the penis and testes; the size, color, and texture of the scrotal skin; and the character and distribution of pubic hair. The testes first increase in size in preadolescence and there is no pubic hair. By the end of puberty, the testes and penis enlarge to adult size and shape, and scrotal skin darkens and becomes wrinkled. Hair becomes coarser and more abundant in the pubic area. The penis has no hair, and the scrotum has very little hair ([Fig. 30.61A-B](#)). Also inspect the skin covering the genitalia for lice, rashes, excoriations, or lesions. Normally it is clear, without lesions.

FIG. 30.61 Appearance of male genitalia. **A**, Circumcised. **B**, Uncircumcised.

From Ball JW et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

Penis

To inspect penile surfaces, manipulate the genitalia or have the patient assist. Inspect the shaft, corona, prepuce (foreskin), glans, and urethral meatus. The dorsal vein is apparent on inspection. In uncircumcised males retract the foreskin to reveal the glans and urethral meatus. The foreskin usually retracts easily. A small amount of white, thick smegma sometimes collects under this foreskin. Obtain a culture if abnormal discharge is present. The urethral meatus is slitlike in appearance and positioned on the ventral surface just millimeters from the tip of the glans. In some congenital conditions the meatus is displaced along the penile shaft. The area between the foreskin and glans is a common site for venereal lesions. Gently compress the glans between the thumb and index finger; this opens the urethral meatus for inspection of lesions, edema, and inflammation. Normally the opening is glistening and pink without discharge. Palpate any lesion gently to note tenderness, size, consistency, and shape. When inspection and palpation of the glans is complete, pull the foreskin down to its original position.

Continue by inspecting the entire shaft of the penis, including the undersurface, looking for lesions, scars, or edema. Palpate the shaft between the thumb and first two fingers to detect localized areas of hardness or tenderness. A patient who has lain in bed for a prolonged time sometimes develops dependent edema in the penis shaft.

It is important for any male patient to learn to perform a genital self-examination to detect signs or symptoms of STIs, especially men who have had more than one sexual partner or whose partner has had other partners. It is common for men to have an STI but not be aware of it; self-examination is a routine part of self-care (Box 30.27).

Box 30.27 Male Genital Self-Examination

All men 15 years and older need to perform this examination monthly using the following steps.	
Genital Examination	
<ul style="list-style-type: none"> • Perform the examination after a warm bath or shower when the scrotal skin is less thick. • Stand naked in front of a mirror, hold the penis in your hand, and examine the head. Pull back the foreskin if uncircumcised to expose the glans. • Inspect and palpate the entire head of the penis in a clockwise motion, looking carefully for any bumps, sores, or blisters (bumps and blisters may be light colored or red, resemble pimples). • Look also for any genital warts. • Look at the opening (urethral meatus) at the end of the penis for discharge (see illustration). • Look along the entire shaft of the penis for the same signs. • Be sure to separate pubic hair at the base of the penis and carefully examine the skin underneath. 	 
Testicular Self-Examination	
<ul style="list-style-type: none"> • Look for swelling or lumps in the skin of the scrotum while looking in the mirror. • Use both hands, placing the index and middle fingers under the testicles and the thumb on top (see illustration). • Gently roll the testicle, feeling for lumps, swelling, soreness, or a harder consistency. • Find the epididymis (a cordlike structure on the top and back of the testicle; it is not a lump). • Feel for small, pea-size lumps on the front and side of the testicle. Abnormal lumps are usually painless. • Call your health care provider for abnormal findings. 	

Illustrations from Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Scrotum

Be particularly cautious while inspecting and palpating the scrotum because the structures lying within the scrotal sac are very sensitive. The scrotum is divided internally into two halves. Each half contains a testicle, epididymis, and the vas deferens, which travels upward into the inguinal ring. Normally the left testicle is lower than the right. Inspect the size, shape, and symmetry of the scrotum while observing for lesions or edema. Gently lift the scrotum to view the posterior surface. The scrotal skin is

usually loose, and the surface is coarse. The scrotal skin is more deeply pigmented than body skin. Tightening of the skin or loss of wrinkling reveals edema. The size of the scrotum normally changes with temperature variations because the dartos muscle contracts in cold and relaxes in warm temperatures. Lumps in the scrotal skin are commonly sebaceous cysts.

Testicular cancer is a solid tumor common in young men ages 18 to 34 years. Early detection is critical. Explain testicular self-examination (see [Box 30.27](#)) while examining the patient. The testes are normally sensitive but not tender. The underlying testicles are normally ovoid and approximately 2 to 4 cm (1 to 1½ inch) in size. Gently palpate the testicles and epididymis between the thumb and first two fingers. The testes feel smooth, rubbery, and free of nodules. The epididymis is resilient. Note the size, shape, and consistency of the organs. The most common symptoms of testicular cancer are a painless enlargement of one testis and the appearance of a small, hard palpable lump, about the size of a pea, on the front or side of the testicle. In the older adult the testicles decrease in size and are less firm during palpation. Continue to palpate the vas deferens separately as it forms the spermatic cord toward the inguinal ring, noting nodules or swelling. It normally feels smooth and discrete.

Inguinal Ring and Canal

The external inguinal ring provides the opening for the spermatic cord to pass into the inguinal canal. The canal forms a passage through the abdominal wall, a potential site for hernia formation. A hernia is a protrusion of a part of intestine through the inguinal wall or canal. Sometimes an intestinal loop enters the scrotum. Have the patient stand during this part of the examination.

During inspection ask the patient to strain or bear down. The maneuver helps to make a hernia more visible. Look for obvious bulging in the inguinal area. Complete the examination by palpating for inguinal lymph nodes. Normally small, nontender, mobile horizontal nodes are palpable. Any abnormality indicates local or systemic infection or malignant disease.

Rectum and Anus

A good time to perform the rectal examination is after the genital examination. Usually this examination is not performed for young children or adolescents. It detects colorectal cancer in its early stages. The rectal examination also detects prostatic tumors in men. Collect a health history (Table 30.30) to detect the patient’s risk for bowel or rectal disease (men and women) or prostate disease (men). Teach the patient about the purpose of the examination (Box 30.28).

TABLE 30.30

Nursing History for Rectal and Anal Assessment

Assessment	Rationale
Determine whether patient has experienced bleeding from rectum, black or tarry stools (melena), rectal pain, or change in bowel habits (constipation or diarrhea).	These are warning signs of colorectal cancer or other gastrointestinal alterations.
Determine whether patient has personal or strong family history of colorectal cancer, polyps, or chronic inflammatory bowel disease. Ask whether patient is over age 40.	These are risk factors for colorectal cancer (ACS, 2018c).
Assess dietary habits, including high fat intake, diet high in processed or red meats, or deficient fiber content (inadequate fruits and vegetables).	Bowel cancer is often linked to dietary intake of fat or insufficient fiber intake (ACS, 2018b).
Determine whether patient is obese, is physically inactive, smokes, or consumes alcohol.	These are risk factors for colorectal cancer (ACS, 2018c).
Determine whether patient has undergone screening for colorectal cancer (digital examination, fecal occult blood test, flexible sigmoidoscopy, and colonoscopy).	Undergoing this screening reflects understanding and adherence with preventive health care measures.
Assess medication history for use of laxatives or cathartic medications.	Repeated use causes diarrhea and eventual loss of intestinal muscle tone.
Assess for use of codeine or iron preparations.	Codeine causes constipation. Iron turns the color of feces black and tarry.
Ask male patient whether he has experienced weak or interrupted urine flow, inability to urinate, difficulty starting or stopping urine flow, polyuria, nocturia, hematuria, or dysuria. Does patient have continuing pain in lower back, pelvis, or upper thighs?	These are warning signs of prostate cancer (ACS, 2018b). Symptoms also suggest infection or prostate enlargement.

Box 30.28 Patient Teaching Rectal and Anal

Assessment

Objective

- Patient will be able to identify symptoms of colorectal and prostatic cancer.

Teaching Strategies

- Discuss the guidelines of the American Cancer Society (ACS, 2018b) for early detection of colorectal cancer. **Beginning at age 45**, both men and women of average risk should use one of these screening tests (ACS, 2018c):
 - Fecal occult blood test (FOBT) or fecal immunochemical test (FIT) annually
 - Stool DNA test performed every 3 years
 - Flexible sigmoidoscopy (FSIG): Visual inspection of the rectum and lower colon with a hollow, lighted tube performed by a health care provider every 5 years OR
 - Double-contrast barium enema every 5 years if recommended by health care provider
 - Colonoscopy every 10 years if recommended
 - Computed tomography (CT) colonoscopy every 5 years if recommended
- Individuals at increased risk should discuss options with their health care provider.
- Discuss warning signs of colorectal cancer (see Table 30.30).
- Discuss with male patient the ACS guidelines (2018b) for early detection of prostate cancer:
 - For men ages 50+, digital rectal examination (DRE) and prostate-specific antigen test (PSA). The ACS recommends that men who have at least a 10-year life expectancy should have an opportunity to make an

informed decision with their health care provider about whether to be screened for prostate cancer after receiving information about the potential benefits, risks, and uncertainties of testing.

- Discuss warning signs of prostate cancer.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me what screening tests for colorectal cancer that you have had done and when they were completed.
- Describe for me the warning signs of colorectal and prostate cancer and when you should contact your health care provider.

The rectal examination is uncomfortable; thus explaining all steps helps a patient relax. Use a calm, slow-paced, gentle approach during the examination. Female patients remain in the dorsal recumbent position following genitalia examination or they assume a side-lying (Sims') position. The best way to examine men is to have the patient stand and bend over forward with hips flexed and upper body resting across an examination table. Examine a patient who cannot stand in the Sims' position. Use nonlatex clean gloves.

Inspection

Using the nondominant hand, gently retract the buttocks to view the perianal and sacrococcygeal areas. Perianal skin is smooth, more pigmented, and coarser than skin over the buttocks. Inspect anal tissue for skin characteristics, lesions, external hemorrhoids (dilated veins that appear as reddened protrusions), ulcers, fissures and fistulas, inflammation, rashes, or excoriation. Anal tissues are moist and hairless, and the voluntary external muscle sphincter holds the anus closed. Next ask a patient to bear down as though having a bowel movement. Any internal hemorrhoids or fissures appear at

this time. Use clock reference (e.g., 3 o'clock or 8 o'clock) to describe location of findings. Normally there is no protrusion of tissue.

Digital Palpation

Examine the anal canal and sphincters with digital palpation, and in male patients palpate the prostate gland to rule out enlargement. Usually advanced practitioners perform this part of the examination. This technique is not discussed here.

Musculoskeletal System

The musculoskeletal assessment can be performed as a separate examination or integrated with other parts of the total physical examination. In addition, you can assess the patient's movements while performing other nursing care measures such as bathing or positioning. The assessment of musculoskeletal function focuses on determining range of joint motion, muscle strength and tone, and joint and muscle condition. Assessing musculoskeletal integrity is especially important when a patient reports pain or loss of function in a joint or muscle. Because muscular disorders are often the result of neurological disease, you may choose to perform a simultaneous neurological assessment.

While examining a patient's musculoskeletal function, visualize the anatomy of bone and muscle placement and joint structure (see [Chapter 38](#)). Joints vary in degree of mobility, depending on the type of joint.

For a complete examination expose the muscles and joints, so they are free to move. Have the patient assume a sitting, supine, prone, or standing position while assessing specific muscle groups. [Table 30.31](#) lists the information gathered in the nursing history.

TABLE 30.31**Nursing History for Musculoskeletal Assessment**

Assessment	Rationale
Determine whether patient is involved in competitive sports (particularly involving collision and contact), fails to warm up adequately, is in poor physical condition, or has had a rapid growth spurt (adolescents).	These are risk factors for sports injury.
<p>Assess for risk factors of osteoporosis.</p> <p>Uncontrollable risk factors:</p> <ul style="list-style-type: none"> • Over age 50 • Female • Nulliparous • Menopause before age 45 • Family history of osteoporosis • Low body weight/being small and thin/constant dieting • Broken bones or height loss <p>Controllable risk factors:</p> <ul style="list-style-type: none"> • Not getting enough calcium (less than 500 mg) and vitamin D • Not eating enough fruits and vegetables • Getting too much protein, sodium, and caffeine • Having an inactive lifestyle • Smoking • Drinking too much alcohol • Losing weight <p>Long-term use of certain medications: aluminum-containing antacids; antiseizure medicines such as phenytoin or phenobarbital; aromatase inhibitors such as anastrozole, exemestane and letrozole; cancer chemotherapeutic drugs; and heparin.</p>	These are risk factors for osteoporosis (USPSTF, 2018).
Ask patient to describe history of problems in bone, muscle, or joint function (e.g., recent fall, trauma, lifting of heavy objects, history of bone or joint disease with sudden or gradual onset, location of alteration).	History helps to assess nature of musculoskeletal problem.
Assess nature and extent of pain, including location, duration, severity, predisposing and aggravating factors, relieving factors, and type.	Pain frequently accompanies alterations in bone, joints, or muscle. This has implications not only for comfort, but also for ability to perform activities of daily living.
Assess patient's normal activity pattern, including type of exercise routinely performed.	Provides baseline in assessment. Sedentary lifestyle and lack of appropriate exercise increase bone loss and risk of fractures.
Determine how alteration influences ability to perform activities of daily living (e.g., bathing, feeding, dressing, toileting, ambulating) and social functions (e.g., household chores, work, recreation, sexual activities).	The extent to which patient is able to perform self-care determines the level of nursing care. Type and degree of restriction in continuing social activities influence topics for patient education and ability of nurse to identify alternative ways to maintain function.
Assess height loss of woman over age 50 by subtracting current height from recall of maximum adult height. Refer to physician for bone density exam (women 65 years and older).	Measurement is useful screening tool to predict osteoporosis. Bone measurement testing recommended by USPSTF (2018).

General Inspection

Observe a patient's gait when he or she enters the examination room. When the patient is unaware of the nature of your observation, gait is more natural. Later have the patient walk in a straight line away from and returning to the point of origin. Note how the patient walks, sits, and rises from a sitting position. Normally patients walk with the arms swinging freely at the sides and the head leading the body. Older adults often walk

with smaller steps and a wider base of support. Note foot dragging, limping, shuffling, and the position of the trunk in relation to the legs.

Observe the patient from the side and while facing him or her in a standing position. The normal standing posture is upright with parallel alignment of the hips and shoulders (Fig. 30.62 A-C). There is an even contour of the shoulders, level scapulae and iliac crests, alignment of the head over the gluteal folds, and symmetry of extremities. While observing from the side of the patient, note the normal cervical, thoracic, and lumbar curves. Holding the head erect is normal. As the patient sits, some degree of rounding of the shoulders is normal. Older adults tend to assume a stooped, forward-bent posture with the hips and knees somewhat flexed and arms bent at the elbows, raising the level of the arms.

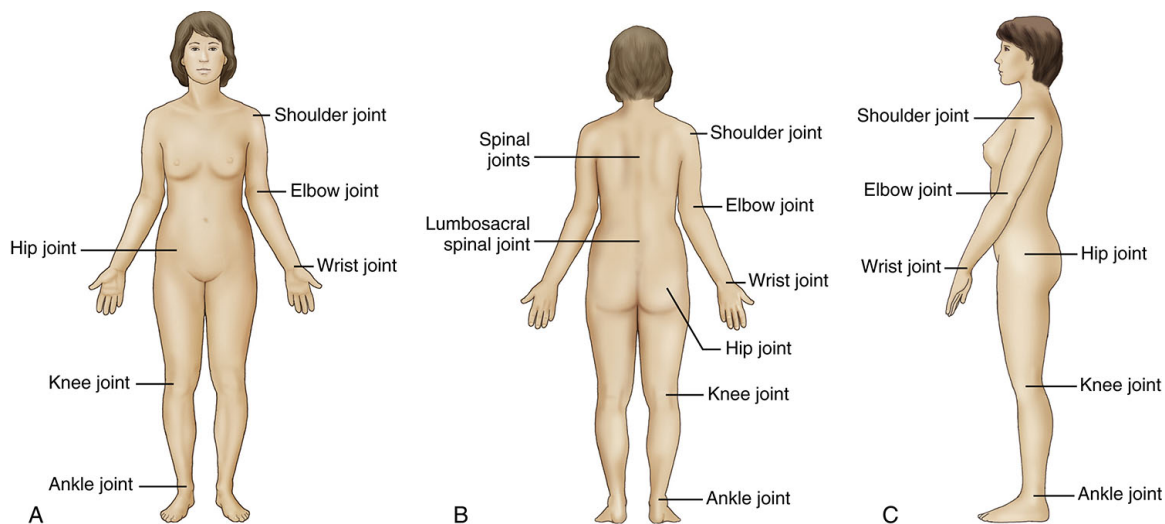

FIG. 30.62 Inspection of overall body posture. **A**, Anterior view. **B**, Posterior view. **C**, Lateral view.

From Muscolino: JE: *Kinesiology: the skeletal system and muscle function*, ed 2, St Louis, 2011, Elsevier.

Common postural abnormalities include kyphosis, lordosis, and scoliosis (Fig. 30.63A-C). **Kyphosis**, or hunchback, is an exaggeration of the posterior curvature of the thoracic spine. This postural abnormality is common in older adults. **Lordosis**, or swayback, is an increased lumbar curvature. A lateral spinal curvature is called **scoliosis**. Loss of height is frequently the first clinical sign of osteoporosis, in which height loss occurs in the trunk as a result of vertebral fracture and collapse. **Osteoporosis** is a systemic skeletal condition that is noted to have both decreased bone mass and deterioration of bone tissue, making bones fragile and at risk for

fracture (Ball et al., 2019). Osteopenia, characterized by low bone mass of the hip, puts people at risk for osteoporosis, fractures, and potential complications later in life. Approximately 80% of people with osteoporosis are women. It can affect any age-group, including children. Teach patients ways to reduce the chance of developing this disease (Box 30.29).

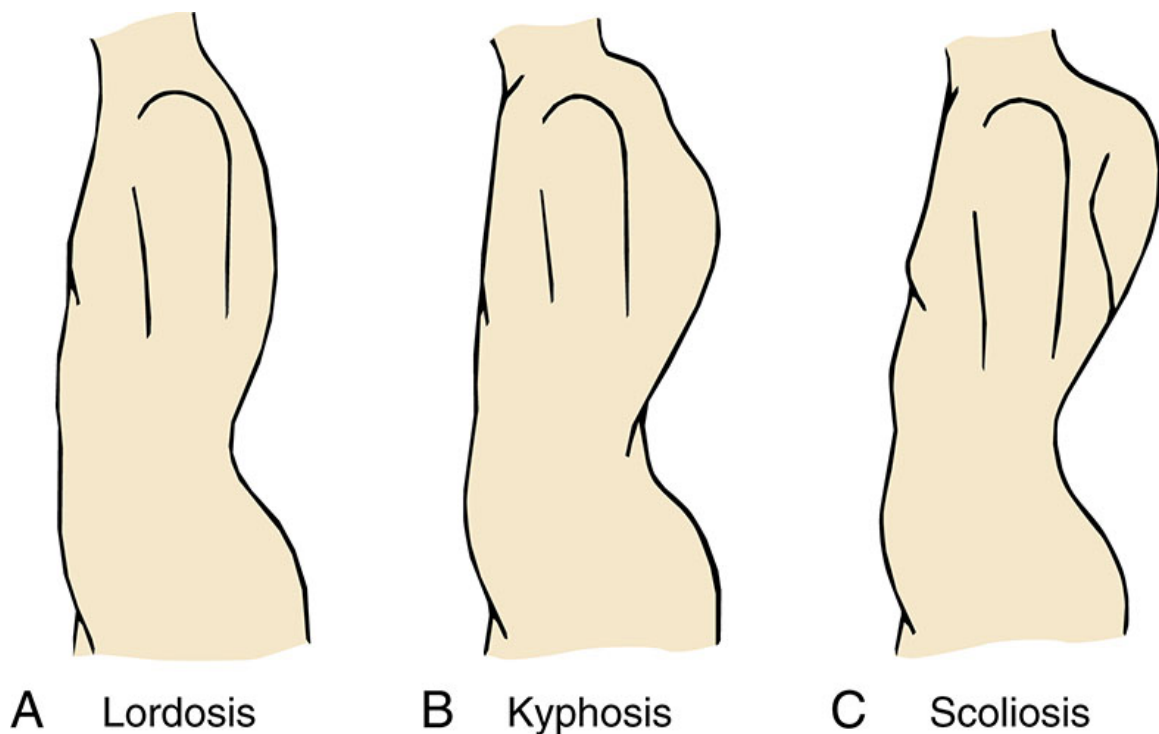

FIG. 30.63 Common postural abnormalities. **A**, Lordosis. **B**, Kyphosis. **C**, Scoliosis.

Box 30.29 Patient TeachingHealth Promotion to Prevent Osteoporosis in Women

Objective

- Patient will follow measures to prevent or minimize osteoporosis.

Teaching Strategies

- Recommend women age 65 and older for routine screening for osteoporosis (USPSTF, 2018). Recommend men for screening as well; they are at risk for development of osteoporosis equally as they age.
- To reduce bone demineralization, instruct older adults in a proper exercise program (e.g., weight-bearing, muscle-strengthening, and balance-training exercises) to be followed 3 or more times a week.
- Encourage intake of calcium to meet the recommended daily allowance. Increased vitamin D aids calcium absorption.
- Recommendation for calcium supplements for adults over age 25 is 1000 to 1500 mg/day. Instruct patient to take no more than 500 mg of calcium at one time.
- Instruct older adults and those with osteoporosis in proper body mechanics and range-of-motion and moderate weight-bearing exercises (e.g., swimming and walking) to minimize trauma and subsequent fracture of bones.
- Instruct older patients to pace activities to compensate for loss in muscle strength.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Show me how you maintain correct posture when you are sitting, standing, and walking.
- Describe for me what therapies you use for preventing osteoporosis.
- Show me how you do your range-of-motion exercises.

During general inspection look at the extremities for overall size, gross deformity, bony enlargement, alignment, and symmetry. Normally there is bilateral symmetry in length, circumference, alignment, and position and in the number of skinfolds ([Ball et al., 2019](#)). A general review can identify areas requiring a more specialized assessment.

Palpation

Apply gentle palpation to all bones, joints, and surrounding muscles during a complete examination. For a focused assessment examine only the involved area. Note any heat, tenderness, edema, or resistance to

pressure. The patient should not feel any discomfort when you palpate. Muscles should be firm.

Range of Joint Motion

The examination includes comparison of both active and passive ROM. Ask the patient to put each major joint through active and passive full ROM (see [Chapter 38](#)). Learn the correct terminology for the movements that the joints can make ([Table 30.32](#)) and teach the patient how to move through each ROM. Demonstrate ROM to the patient when possible. To assess ROM passively, ask the patient to relax and then passively move the extremities through their ROM. Compare the same body parts for equality in movement. [Fig. 30.64A-F](#), shows an example of ROM positions for the hand and wrist. Do not force a joint into a painful position. Know the normal range of each joint and the extent to which you can move the patient's joints. ROM is equal between contralateral joints. Ideally assess the patient's normal range to determine a baseline for assessing later change.

TABLE 30.32**Terminology for Normal Range-Of-Motion Positions**

Term	Range of Motion	Examples of Joints
Flexion	Movement decreasing angle between two adjoining bones; bending of limb	Elbow, fingers, knee
Extension	Movement increasing angle between two adjoining bones	Elbow, knee, fingers
Hyperextension	Movement of body part beyond its normal resting extended position	Head
Pronation	Movement of body part so that front or ventral surface faces downward	Hand, forearm
Supination	Movement of body part so that front or ventral surface faces upward	Hand, forearm
Abduction	Movement of extremity away from midline of body	Leg, arm, fingers
Adduction	Movement of extremity toward midline of body	Leg, arm, fingers
Internal rotation	Rotation of joint inward	Knee, hip
External rotation	Rotation of joint outward	Knee, hip
Eversion	Turning of body part away from midline	Foot
Inversion	Turning of body part toward midline	Foot
Dorsiflexion	Flexion of toes and foot upward	Foot
Plantar flexion	Bending of toes and foot downward	Foot

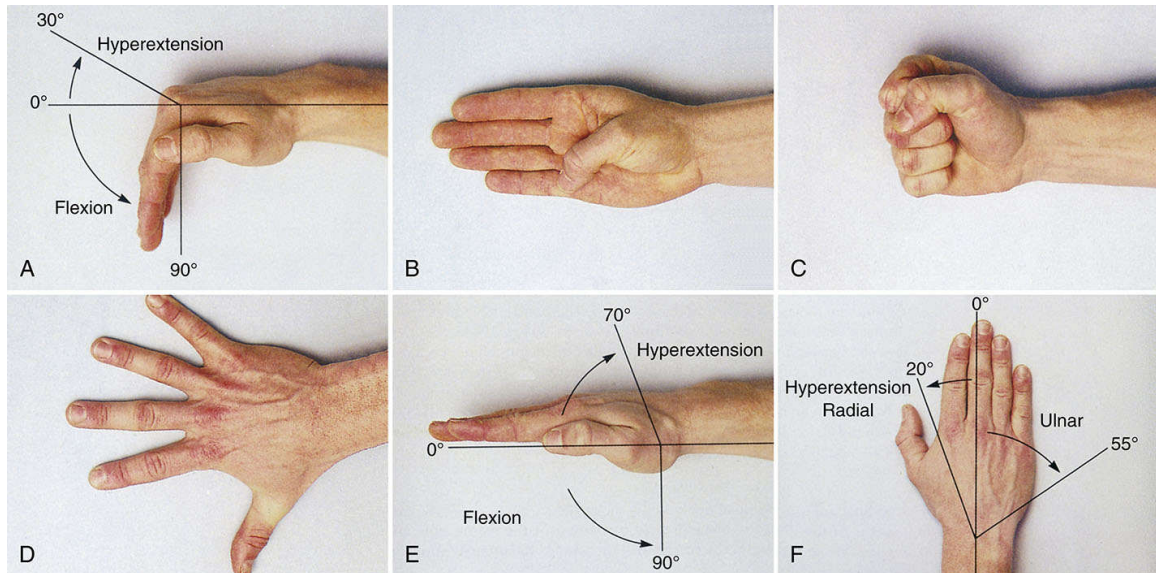

FIG. 30.64 Range of motion of hand and wrist. **A**, Metacarpophalangeal flexion and hyperextension. **B**, Finger flexion: thumb to each fingertip and to base of little finger. **C**, Finger flexion, fist formation. **D**, Finger abduction. **E**, Wrist flexion and hyperextension. **F**, Wrist radial and ulnar movement. From Ball JW et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

Joints are typically free from stiffness, instability, swelling, or inflammation. There should be no discomfort when applying pressure to bones and joints. In older adults, joints often become swollen and stiff, with reduced ROM resulting from cartilage erosion and fibrosis of synovial membranes (see [Chapter 38](#)). If a joint appears swollen and inflamed, palpate it for warmth. A **goniometer** is an instrument with two flexible arms and a 180-degree protractor in the center. It is frequently used by physical and occupational therapists to measure the precise degree of motion in a joint and is mainly for patients who have a suspected reduction in joint movement.

Muscle Tone and Strength

Assess muscle strength and tone during ROM measurement. Integrate these findings with those from the neurological assessment. Note muscle tone, the slight muscular resistance felt as you move the relaxed extremity passively through its ROM.

Ask the patient to allow an extremity to relax or hang limp. This is often difficult, particularly if the patient feels pain in it. Support the extremity and grasp each limb, moving it through the normal ROM ([Fig. 30.65](#)).

Normal tone causes a mild, even resistance to movement through the entire range.

FIG. 30.65 Assessing muscle tone.

If a muscle has increased tone, or **hypertonicity**, there is considerable resistance with any sudden passive movement of a joint. Continued movement eventually causes the muscle to relax. A muscle that has little tone (**hypotonicity**) feels flabby. The involved extremity hangs loosely in a position determined by gravity.

For assessment of muscle strength, have the patient assume a stable position. He or she performs maneuvers demonstrating strength of major muscle groups ([Table 30.33](#)). Use a grading scale of 0 to 5 to compare symmetrical muscle pairs for strength ([Table 30.34](#)). The arm on the dominant side normally is stronger than the arm on the nondominant side. In older adults a loss of muscle mass causes bilateral weakness, but muscle strength remains greater in the dominant arm or leg.

TABLE 30.33**Maneuvers to Assess Muscle Strength**

Muscle Group	Maneuver
Neck (sternocleidomastoid)	Place hand firmly against patient's upper jaw. Ask patient to turn head laterally against resistance.
Shoulder (trapezius)	Place hand over midline of patient's shoulder, exerting firm pressure. Have patient raise shoulders against resistance.
Elbow	
Biceps	Pull down on forearm as patient attempts to flex arm.
Triceps	As you flex patient's arm, apply pressure against forearm. Ask patient to straighten arm.
Hip	
Quadriceps	When patient is sitting, apply downward pressure to thigh. Ask patient to raise leg up from table.
Gastrocnemius	Patient sits while examiner holds shin of flexed leg. Ask patient to straighten leg against resistance.

TABLE 30.34**Muscle Strength**

Muscle Function Level	Scales		
	Grade	% Normal	Lovett Scale
No evidence of contractility	0	0	0 (zero)
Slight contractility, no movement	1	10	T (trace)
Full range of motion, gravity eliminated ^a	2	25	P (poor)
Full range of motion with gravity	3	50	F (fair)
Full range of motion against gravity, some resistance	4	75	G (good)
Full range of motion against gravity, full resistance	5	100	N (normal)

^a Passive movement.

Modified from Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier.

Examine each muscle group. Ask the patient to first flex the muscle you are examining and then to resist when you apply an opposing force against that flexion. It is important to not allow the patient to move the joint. Gradually increase pressure to a muscle group (e.g., elbow extension). Have the patient resist the pressure you apply by attempting to move against resistance (e.g., elbow flexion) until instructed to stop. Vary the amount of pressure applied and observe the joint move. If you identify a weakness, compare the size of the muscle with its opposite counterpart by measuring the circumference of the muscle body with a tape measure. A muscle that has **atrophied** (reduced in size) feels soft and boggy when palpated.

Neurological System

The neurological system is responsible for many functions, including initiation and coordination of movement, reception and perception of sensory stimuli, organization of thought processes, control of speech, and storage of memory. A close integration exists between the neurological system and all other body systems. For example, urine production relies in part on the adequacy of blood flow to the kidneys and on neural control, which affects the size of arterioles supplying the kidneys.

A full assessment of neurological function requires much time and attention to detail. For efficiency, integrate neurological measurements with other parts of the physical examination. For example, test cranial nerve function while assessing the head and neck. Observe mental and emotional status during the initial interview.

Consider many variables when deciding the extent of the neurological examination. A patient's level of consciousness influences his or her ability to follow directions. General physical status influences tolerance to assessment. A patient's chief complaint or presenting problem also helps determine the need for a thorough neurological assessment. If a patient has a headache or a recent loss of function in an extremity, he or she needs a complete neurological review. [Table 30.35](#) lists the data collected in the nursing history. You will need the following items for a complete examination:

TABLE 30.35**Nursing History for Neurological Assessment**

Assessment	Rationale
Determine whether patient uses analgesics, alcohol, sedatives, hypnotics, antipsychotics, antidepressants, nervous system stimulants, or recreational drugs.	These medications alter level of consciousness or cause behavioral changes. Abuse sometimes causes tremors, ataxia, and changes in peripheral nerve function.
Determine whether patient has recent history of seizures/convulsions: clarify sequence of events (aura, fall to ground, motor activity, loss of consciousness); character of any symptoms; and relationship of seizure to time of day, fatigue, or emotional stress.	Seizure activity often originates from central nervous system alteration. Characteristics of seizure help determine its origin.
Screen patient for symptoms of headache, tremors, dizziness, vertigo, numbness or tingling of body part, visual changes, weakness, pain, or changes in speech. Presence of any symptom requires more detailed review (onset, severity, precipitating factors or sequence of events).	These symptoms frequently originate from alterations in central or peripheral nervous system function. Identification of specific patterns aids in diagnosis of pathological condition.
Discuss with patient's family any recent changes in patient's behavior (e.g., increased irritability, mood swings, memory loss, change in energy level).	Behavioral changes sometimes result from intracranial pathological states.
Assess patient for history of change in vision, hearing, smell, taste, or touch.	Major sensory nerves originate from brainstem. These symptoms help to localize nature of problem.
If an older patient displays sudden acute confusion (delirium), review history for drug toxicity (anticholinergics, diuretics, digoxin, cimetidine, sedatives, antihypertensives, antiarrhythmics), serious infections, metabolic disturbances, heart failure, and severe anemia.	Delirium is one of the most common mental disorders in older people. Condition is always potentially reversible (see Box 30.31).
Review past history for head or spinal cord injury, meningitis, congenital anomalies, neurological disease, or psychiatric counseling.	Factors cause neurological symptoms or behavioral changes to develop, focusing assessment on possible cause.

- Reading material
- Vials containing aromatic substances (e.g., vanilla extract and coffee)
- Opposite tip of cotton swab or tongue blade broken in half
- Snellen eye chart
- Penlight
- Vials containing sugar, salt, lemon with applicators
- Tongue blade
- Two test tubes, one filled with hot water and the other with cold water

- Cotton balls or cotton-tipped applicators
- Tuning fork
- Reflex hammer

Mental and Emotional Status

You learn a great deal about mental capacities and emotional state simply by interacting with a patient. Ask questions during an examination to gather data and observe the appropriateness of emotions and thoughts. Special assessment tools are designed to assess a patient's mental status. The Mini-Mental State Examination (MMSE) is an instrument developed by [Folstein et al. \(1975\)](#) that measures orientation and cognitive function. The questions in [Box 30.30](#) offer examples of questions found on the MMSE. The maximum score on the MMSE is 31. Patients with scores of 21 or less generally reveal cognitive impairment requiring further evaluation.

Box 30.30 Mini-Mental State Examination Sample Questions

- Orientation to time
"What is the date?"
- Registration
"Listen carefully. I am going to say three words. Say them back after I stop.
Ready? Here they are . . .
HOUSE (pause), CAR (pause), LAKE (pause). Now repeat these words back to me."
(Repeat up to 5 times but score only the first trial.)
- Naming
"What is this?" (Point to a pencil or pen.)
- Reading
"Please read this and do what it says." (Show examinee the words on the stimulus form.)

To ensure an objective assessment, consider a patient's cultural and educational background, values, beliefs, and previous experiences. Such factors influence response to questions. An alteration in mental or emotional status reflects a disturbance in cerebral functioning. The cerebral cortex controls and integrates intellectual and emotional functioning. Primary brain disorders, medication, and metabolic changes are examples of factors that change cerebral function.

Delirium is an acute mental disorder that occurs among patients who are hospitalized. Obtain a thorough history of a patient's behavior before delirium develops to recognize the condition early. Family members are usually a good resource. It is characterized by confusion, disorientation, and restlessness. It is often a sign of an impending or underlying physical illness in older adults; it may be related to serious injury, impaired senses, poor pain management, medications, or restraint use (Ball et al., 2019). The acute condition differs from dementia, a more progressive, organic mental disorder such as Alzheimer's disease. You need to recognize the difference so that you can try to learn the underlying cause of delirium. Fortunately, the condition often reverses when it is correctly assessed and the underlying cause is treated (i.e., central nervous system [CNS], metabolic, or cardiopulmonary disorders; systemic illnesses; or sensory deprivation or overload). To avoid misdiagnosis, you need to adequately assess mental status. Frequently patients who develop delirium are labeled with "sundown syndrome" because the delirium frequently worsens at night. Many practitioners mistake this as being common with old age. Children can also be vulnerable to delirium due to illness, medications, trauma, or surgeries (Hockenberry and Wilson, 2019). Box 30.31 summarizes clinical criteria for delirium.

Box 30.31 Clinical Criteria for Delirium

Definition: An acute disturbance of consciousness that is accompanied by a change in cognition. It is not caused by a preexisting or evolving dementia. Delirium develops over a short period of time, usually hours to days, and tends to fluctuate during the course of the day. It is usually a direct physiological consequence of a general medical condition. It is most common in older adults but occasionally occurs in younger patients.

- There is reduced clarity of awareness of the environment.
- Ability to focus, sustain, or shift attention is impaired (questions must be repeated).
- Irrelevant stimuli easily distract the person.
- There is an accompanying change in cognition (memory impairment, disorientation, or language disturbance).
- Recent memory commonly is affected.
- Disorientation usually occurs, with patient disoriented to time, place, or person.
- Language disturbance involves impaired ability to name objects or ability to write; speech is sometimes rambling.
- Perceptual disturbances include misinterpretations, delusions, or visual and auditory hallucinations. Neurological signs include tremor, unsteady gait, asterixis, or myoclonus.

Level of Consciousness

A person's level of consciousness exists along a continuum from full awakening, alertness, and cooperation to unresponsiveness. Talk with the patient, asking questions about events involving his or her concerns about any health problems. A fully conscious patient responds to questions quickly and expresses ideas logically. With a lowering of a patient's consciousness, use the Glasgow Coma Scale (GCS) for an objective measurement of consciousness on a numerical scale ([Table 30.36](#)). The patient needs to be as alert as possible before testing. Take care when using the scale if the patient has sensory losses (e.g., vision or hearing). The GCS allows evaluation of a patient's neurological status over time. The higher the score, the better the patient's neurological function. Ask short, simple

questions such as “What is your name?” “Where are you?” and “What day is this?” Also ask the patient to follow simple commands such as “Move your toes.”

TABLE 30.36

Glasgow Coma Scale

(The total score is the sum of the scores in the three categories.)		
Action	Response	Score
Eyes open	Spontaneously	4
	To speech	3
	To pain	2
	None	1
Best verbal response	Oriented	5
	Confused	4
	Inappropriate words	3
	Incomprehensible sounds	2
	None	1
Best motor response	Obeys commands	6
	Localized pain	5
	Flexion withdrawal	4
	Abnormal flexion	3
	Abnormal extension	2
	Flaccid	1
	TOTAL SCORE	3 to 15

If the patient is not conscious enough to follow commands, try to elicit the pain response. Apply firm pressure with the thumb over the root of the patient’s fingernail. The normal response to the painful stimuli is withdrawal of the body part from the stimulus. A patient with serious neurological impairment exhibits abnormal posturing in response to pain. A flaccid response indicates the absence of muscle tone in the extremities and severe injury to brain tissue.

Behavior and Appearance

Behavior, moods, hygiene, grooming, and choice of dress reveal pertinent information about mental status. Remain perceptive of a patient’s mannerisms and actions during the entire physical assessment. Note nonverbal and verbal behaviors. Does the patient respond appropriately to directions? Does his or her mood vary with no apparent cause? Does he or she show concern about appearance? Is his or her hair clean and neatly groomed, and are the nails trim and clean? The patient should behave in a manner expressing concern and interest in the examination. He or she

should make eye contact with you and express appropriate feelings that correspond to the situation. Normally the patient shows some degree of personal hygiene.

Choice and fit of clothing reflect socioeconomic background or personal taste rather than deficiency in self-concept or self-care. Avoid being judgmental and focus assessment on the appropriateness of clothing for the weather. Older adults sometimes neglect their appearance because of finances, reduced vision, or a lack of energy.

Language

Normal cerebral function allows a person to understand spoken or written words and express the self through written words or gestures. Assess the patient's voice inflection, tone, and manner of speech. Normally a patient's voice has inflections, is clear and strong, and increases in volume appropriately. Speech is fluent. When communication is clearly ineffective (e.g., omission or addition of letters and words, misuse of words, or hesitations), assess for **aphasia**. Injury to the cerebral cortex results in aphasia.

The two types of aphasia are sensory (or receptive) and motor (or expressive). With receptive aphasia a person cannot understand written or verbal speech. With expressive aphasia a person understands written and verbal speech but cannot write or speak appropriately when attempting to communicate. A patient sometimes suffers a combination of receptive and expressive aphasia. Assess language capabilities when a patient is communicating ineffectively. Some simple assessment techniques include the following:

- Point to a familiar object and ask the patient to name it.
- Ask the patient to respond to simple verbal and written commands such as "Stand up" or "Sit down."
- Ask the patient to read simple sentences out loud.

Normally a patient names objects correctly, follows commands, and reads sentences correctly.

Intellectual Function

Intellectual function includes memory (recent, immediate, and past), knowledge, abstract thinking, association, and judgment. Testing each

aspect of function involves a specific technique. However, because cultural and educational background influences the ability to respond to test questions, do not ask questions related to concepts or ideas with which a patient is unfamiliar.

Memory

Assess immediate recall and recent and remote memory. Patients demonstrate immediate recall by repeating a series of numbers (e.g., 7, 4, 1) in the order they are presented or in reverse order. Patients normally recall a series of five to eight digits forward and four to six digits backward.

First ask to test the patient's memory. Then state clearly and slowly the names of three unrelated objects. After mentioning all three, ask the patient to repeat each. Later in the assessment ask the patient to repeat the three words again. He or she should be able to identify them. Another test for recent memory involves asking the patient to recall events occurring during the same day (e.g., what was eaten for breakfast). Validate information with a family member.

To assess past memory, ask the patient to recall his or her mother's maiden name, a birthday, or a special date in history. It is best to ask open-ended rather than simple yes-or-no questions. A patient usually has immediate recall of such information. With older adults do not interpret hearing loss as confusion. Good communication techniques are essential throughout the examination to ensure that a patient clearly understands all directions and testing.

Knowledge

Assess knowledge by asking how much the patient knows about his or her illness or the reason for seeking health care. A knowledge assessment allows you to determine a patient's ability to learn or understand. If there is an opportunity to teach, test a patient's mental status by asking for feedback during a follow-up visit.

Abstract Thinking

Interpreting abstract ideas or concepts reflects the capacity for abstract thinking. For an individual to explain common phrases such as "A stitch in time saves nine" or "Don't count your chickens before they're hatched" requires a higher level of intellectual function. Note whether a patient's explanations are relevant and concrete. A patient with altered mental

status probably interprets the phrase literally or merely rephrases the words.

Association

Another higher level of intellectual functioning involves finding similarities or associations between concepts: a dog is to a beagle as a cat is to a Siamese. Name related concepts and ask the patient to identify their associations. Ask questions that are appropriate to the patient's level of intelligence, using simple concepts.

Judgment

Judgment requires a comparison and evaluation of facts and ideas to understand their relationships and form appropriate conclusions. Attempt to measure the patient's ability to make logical decisions with questions such as "Why did you seek health care?" or "What would you do if you became ill at home?" Normally a patient makes logical decisions.

Cranial Nerve Function

To assess cranial nerve function, you may test all 12 cranial nerves, a single nerve, or a related group of nerves. A dysfunction in one nerve reflects an alteration at some point along the distribution of the cranial nerve. Measurements used to assess the integrity of organs within the head and neck also assess cranial nerve function. A complete assessment involves testing the 12 cranial nerves in their numerical order. To remember the order of the nerves, use this simple phrase: "On old Olympus' towering tops, a Finn and German viewed some hops." The first letter of each word in the phrase is the same as the first letter of the names of the cranial nerves listed in order ([Table 30.37](#)).

TABLE 30.37**Cranial Nerve Function and Assessment**

Number	Name	Type	Function	Method
I	Olfactory	Sensory	Sense of smell	Ask patient to identify different nonirritating aromas such as coffee and vanilla.
II	Optic	Sensory	Visual acuity	Use Snellen chart or ask patient to read printed material while wearing glasses.
III	Oculomotor	Motor	Extraocular eye movements: inward, up and inward, up and outward, down and outward	Assess six directions of gaze.
			Pupil constriction and dilation	Measure pupillary reaction to light reflex and accommodation.
			Opening the eye	
IV	Trochlear	Motor	Downward, inward eye movements	Assess six directions of gaze.
V	Trigeminal	Sensory and motor	Sensory nerve to skin of face	Lightly touch cornea with wisp of cotton. Assess corneal reflex. Measure sensation of light pain and touch across skin of face.
			Motor nerve to muscles of jaw	Palpate temples as patient clenches teeth.
VI	Abducens	Motor	Lateral movement of eyeballs	Assess six directions of gaze.
VII	Facial	Sensory and motor	Facial expression	As patient smiles, frowns, puffs out cheeks, and raises and lowers eyebrows, look for asymmetry.
			Taste	Have patient identify salty or sweet taste on front of tongue.
VIII	Auditory	Sensory	Hearing	Assess ability to hear spoken word.
IX	Glossopharyngeal	Sensory and motor	Taste	Ask patient to identify sour or sweet taste on back of tongue.
			Ability to swallow	Use tongue blade to elicit gag reflex.
X	Vagus	Sensory and motor	Sensation of pharynx	Ask patient to say "ah." Observe movement of palate and pharynx.
			Movement of vocal cords	Assess speech for hoarseness.
			Parasympathetic innervation to glands of mucous membranes of the pharynx, larynx, organs in the neck, thorax (heart and lungs), and abdomen	Assess heart rate, presence of peristalsis.
XI	Spinal accessory	Motor	Movement of head and shoulders	Ask patient to shrug shoulders and turn head against passive resistance.
XII	Hypoglossal	Motor	Position of tongue	Ask patient to stick out tongue to midline and move it from side to side.

Sensory Function

The sensory pathways of the CNS conduct sensations of pain, temperature, position, vibration, and crude and finely localized touch. Different nerve pathways relay the sensations. Most patients require only a quick screening of sensory function unless there are symptoms of reduced sensation, motor impairment, or paralysis. The risk of skin breakdown is greater in a patient with impaired sensation. When assessing decreased sensation, complete a skin assessment of the area affected by the sensory loss. In addition, teach the patient to avoid pressure, thermal, and/or chemical trauma to the area.

Normally a patient has sensory responses to all stimuli that are tested. He or she feels sensations equally on both sides of the body in all areas. Assess the major sensory nerves by knowing the sensory dermatome zones ([Fig. 30.66A-B](#)). Some areas of the skin are innervated by specific dorsal root cutaneous nerves. For example, if assessment reveals reduced sensation when checking for light touch along an area of the skin (e.g., the lower neck), this determines in general where a neurological lesion exists (e.g., fourth cervical spinal cord segment).

FIG. 30.66 Dermatomes of body (body surface areas innervated by particular spinal nerves); C1 usually has no cutaneous distribution. **A**, Anterior view. **B**, Posterior view. It appears that there is a distinct separation of surface area controlled by each dermatome, but there is almost always overlap between spinal nerves.

From Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Mosby.

Perform all sensory testing with the patient's eyes closed so that he or she is unable to see when or where a stimulus touches the skin (Table 30.38). Then touch the patient's skin in a random, unpredictable order to maintain his or her attention and prevent detection of a predictable pattern. Ask the patient to describe when, what, and where he or she feels each stimulus. Compare symmetrical areas of the body while applying stimuli to the patient's arms, trunk, and legs.

TABLE 30.38**Assessment of Sensory Nerve Function**

Function	Equipment	Method	Precautions
Pain	End of paper clip or wooden end of cotton applicator	Ask patients to voice when they feel dull or sharp sensation. Alternately apply sharp and blunt ends of the paper clip or broken cotton applicator to surface of skin. Note areas of numbness or increased sensitivity.	Remember that areas where skin is thick such as heel or sole of foot are less sensitive to pain.
Temperature	Two test tubes, one filled with hot water and another with cold	Touch skin with tube. Ask patient to identify hot or cold sensation.	Omit test if pain sensation is normal.
Light touch	Cotton ball or cotton-tip applicator	Apply light wisp of cotton to different points along surface of skin. Ask patients to voice when they feel a sensation.	Apply at areas where skin is thin or more sensitive (e.g., face, neck, inner aspect of arms, top of feet and hands).
Vibration	Tuning fork	Apply stem of vibrating fork to distal interphalangeal joint of fingers and interphalangeal joint of great toe, elbow, and wrist. Have patients voice when and where they feel vibration.	Be sure that patient feels vibration and not merely pressure.
Position		Grasp finger or toe, holding it by its sides with thumb and index finger. Alternate moving finger or toe up and down. Ask patient to state when finger is up or down. Repeat with toes.	Avoid rubbing adjacent appendages as you move finger or toe. Do not move joint laterally; return to neutral position before moving again.
Two-point discrimination	Two ends of paper clips	Lightly apply one or both ends of paper clips simultaneously to the surface of the skin. Ask patients whether they feel one or two pricks. Find the distance at which patient can no longer distinguish two points.	Apply blade tips to same anatomical site (e.g., fingertips, palm of hand, or upper arms). Minimum distance at which patient discriminates two points varies (2 to 8 mm on fingertips).

Motor Function

An examination of motor function includes assessments made during the musculoskeletal examination. In addition, you assess the patient's cerebellar function. The cerebellum coordinates muscular activity, maintains balance and equilibrium, and controls posture.

Coordination

To avoid confusion, demonstrate each maneuver and have the patient repeat it, observing for smoothness and balance in his or her movements (Box 30.32). In older adults, normally slow reaction time causes movements to be less rhythmical.

Box 30.32 PATIENT TEACHING Neurological Assessment Objective

- Patient and family or significant others will understand relationship of patient's behavioral and mental changes to physical status.

Teaching Strategies

- Explain to family caregiver the implications of any behavioral or mental impairment shown by patient.
- If patient has sensory or motor impairments, explain measures to ensure safety (e.g., wearing glasses or hearing aids, use of ambulation aids or safety bars in bathrooms or stairways) (see Chapter 49).
- Teach older adult to plan enough time to complete tasks because reaction time is slow.
- Teach older adult to observe skin surfaces for areas of trauma since pain perception is reduced.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe for me behaviors that can indicate a neurological impairment.
- Describe for me the safety measures you are using to avoid injury because of your sensory and motor limitations.
- Explain to me why it is important as an older adult that you inspect your skin surface regularly.

To assess fine-motor function, have the patient extend the arms out to the sides and touch each forefinger alternately to the nose (first with eyes open, then with eyes closed). Normally a patient alternately touches the nose smoothly. Performing rapid, rhythmical, alternating movements demonstrates coordination in the upper extremities. While sitting, the patient begins by patting the knees with both hands. Then he or she alternately turns up the palm and back of the hands while continuously patting the knees. Normally patients perform the maneuver smoothly and regularly with increasing speed.

An additional maneuver for upper-extremity coordination involves touching each finger with the thumb of the same hand in rapid sequence.

A patient moves from the index finger to the little finger and back, with one hand tested at a time. The dominant hand is slightly less awkward when performing this movement. Movement is smooth and in succession.

Test lower-extremity coordination with the patient lying supine, legs extended. Place a hand at the ball of the patient's foot. The patient taps the hand with the foot as quickly as possible. Test each foot for speed and smoothness. The feet do not move as rapidly or evenly as the hands.

Balance

Use one or two of the following tests to assess balance and gross-motor function. When examining the older adult for balance and equilibrium, be aware of the risk for falls. Some older adults need help with this part of the examination.

Have the patient perform a Romberg's test by standing with feet together, arms at the sides, both with eyes open and eyes closed. Protect the patient's safety by standing at the side; observe for swaying. Expect slight swaying of the body in the Romberg's test. A loss of balance (positive Romberg) causes a patient to fall to the side. Normally he or she does not break the stance.

Have the patient close his or her eyes, with arms held straight at the sides, and stand on one foot and then the other. Normally patients are able to maintain balance for 5 seconds with slight swaying. Another test involves asking the patient to walk a straight line by placing the heel of one foot directly in front of the toes of the other foot.

Reflexes

Eliciting reflex reactions provides data about the integrity of sensory and motor pathways of the reflex arc and specific spinal cord segments. Assessment of reflexes does not determine higher neural center functioning but helps to assess peripheral-spinal nerve function. [Fig. 30.67](#) traces the pathway of the reflex arc. Each muscle contains a small sensory unit called a *muscle spindle*, which controls muscle tone and detects changes in the length of muscle fibers. Tapping a tendon with a reflex hammer stretches the muscle and tendon, lengthening the spindle. The spindle sends nerve impulses along afferent nerve pathways to the dorsal horn of the spinal cord segment. Within milliseconds the impulses reach the spinal cord and synapse to travel to the efferent motor neuron in the spinal cord. A motor nerve sends the impulses back to the muscle, causing the reflex response.

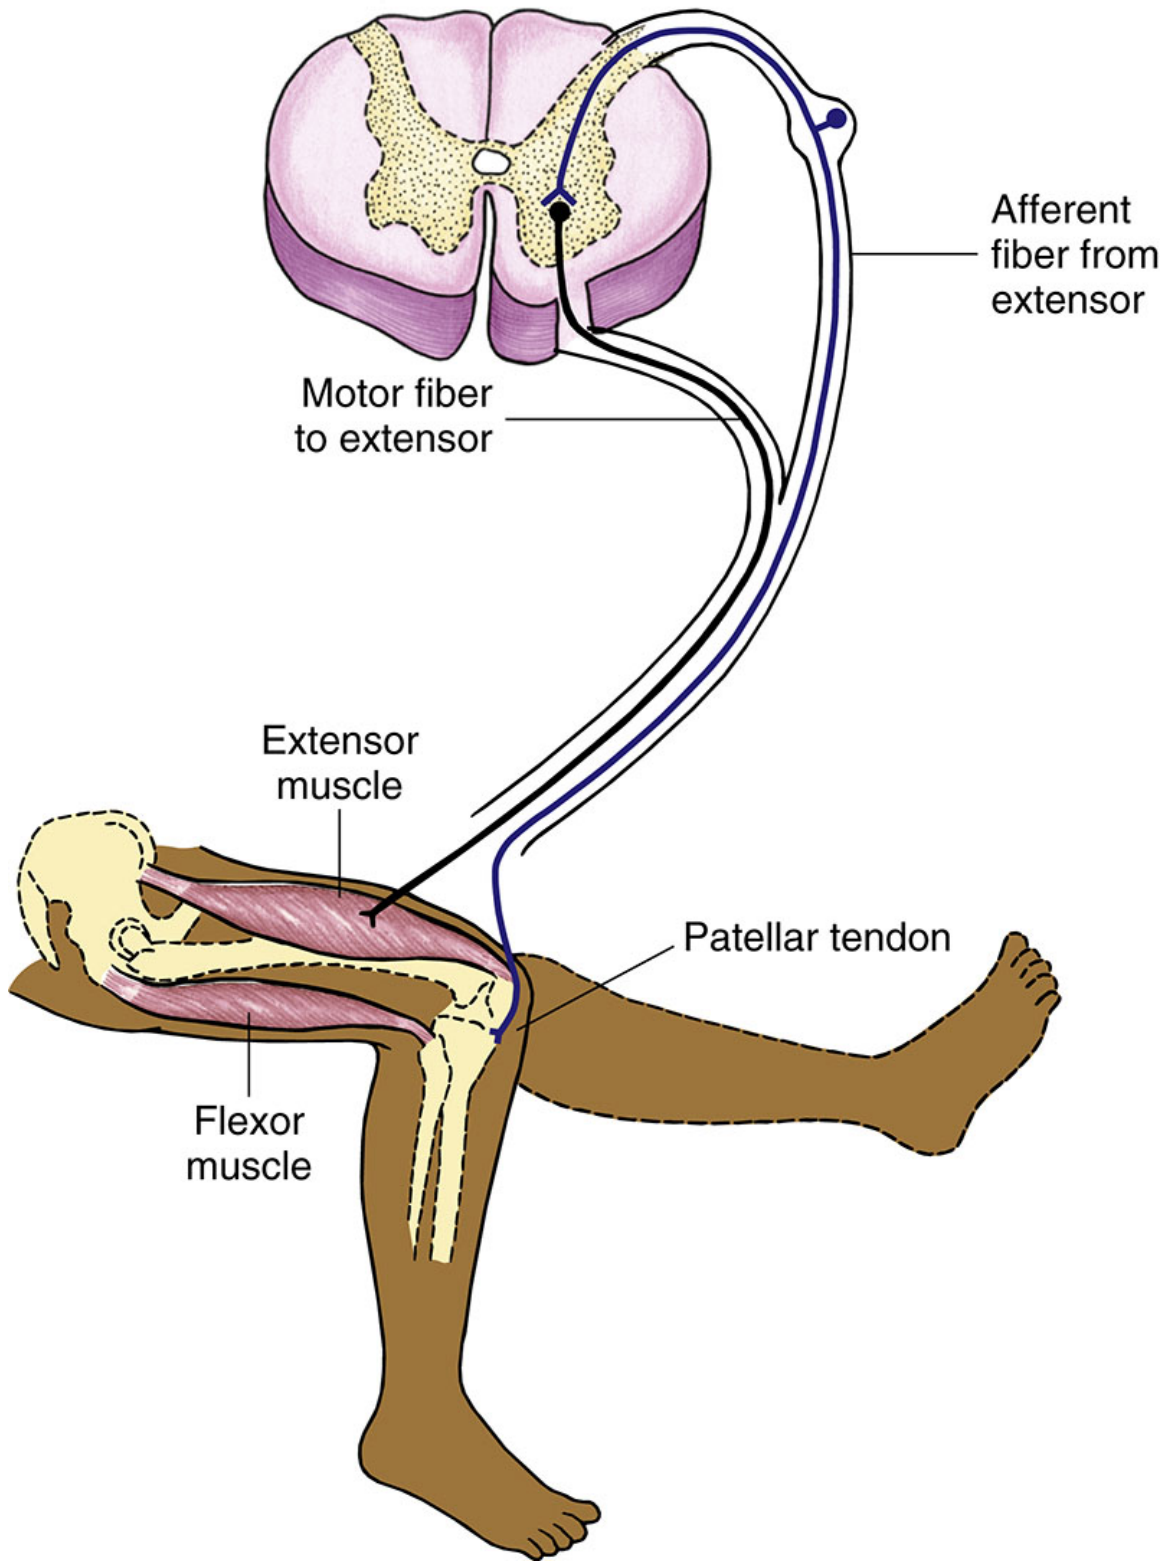

FIG. 30.67 Pathway of reflex arc.

The two categories of normal reflexes are deep tendon reflexes, elicited by mildly stretching a muscle and tapping a tendon, and cutaneous reflexes, elicited by stimulating the skin superficially. Grade reflexes as follows ([Ball et al., 2019](#)):

0: No response

1+: Sluggish or diminished

2+: Active or expected response

3+: More brisk than expected, slightly hyperactive

4+: Brisk and hyperactive with intermittent or transient clonus

When assessing reflexes, have the patient relax as much as possible to avoid voluntary movement or tensing of muscles. Position the limbs to slightly stretch the muscle being tested. Hold the reflex hammer loosely between the thumb and fingers so it can swing freely and tap the tendon briskly ([Fig. 30.68](#)). Compare the responses on corresponding sides. Normally the older adult presents with diminished reflexes. Reflexes are hyperactive in patients with alcohol, cocaine, or opioid intoxication. [Table 30.39](#) summarizes common deep tendon and cutaneous reflexes.

FIG. 30.68 Position for eliciting patellar tendon reflex. Lower leg normally extends.

TABLE 30.39**Assessment of Common Reflexes**

Type	Procedure	Normal Reflex
Deep Tendon Reflexes		
Biceps	Flex patient's arm up to 45 degrees at elbow with palms down. Place your thumb in antecubital fossa at base of biceps tendon and your fingers over biceps muscle. Strike biceps tendon with reflex hammer.	Flexion of arm at elbow
Triceps	Flex patient's arm at elbow, holding arm across chest, or hold upper arm horizontally and allow lower arm to go limp. Strike triceps tendon just above elbow.	Extension at elbow
Patellar	Have patient sit with legs hanging freely over side of table or chair or have him or her lie supine and support knee in a flexed 90-degree position. Briskly tap patellar tendon just below patella.	Extension of lower leg
Achilles	Have patient assume same position as for patellar reflex. Slightly dorsiflex patient's ankle by grasping toes in palm of your hand. Strike Achilles tendon just above heel at ankle malleolus.	Plantar flexion of foot
Cutaneous Reflexes		
Plantar	Have patient lie supine with legs straight and feet relaxed. Take handle end of reflex hammer and stroke lateral aspect of sole from heel to ball of foot, curving across ball of foot toward big toe.	Plantar flexion of all toes
Abdominal	Have patient stand or lie supine. Stroke abdominal skin with base of cotton applicator over lateral borders of rectus abdominis muscle toward midline. Repeat test in each abdominal quadrant.	Contraction of rectus abdominis muscle with pulling of umbilicus toward stimulated side

After the Examination

Record findings from the physical assessment either during the examination or after it has been completed. Special forms are available to record data both electronically and on printed forms. Review all findings before helping patients dress in case it is necessary to recheck any information or gather additional data. Integrate physical assessment findings into the plan of care.

After completing an assessment, give the patient time to dress. A patient in a hospital sometimes needs help with hygiene and returning to bed. When the patient is comfortable, it helps to share a summary of the assessment findings. If the findings have revealed serious abnormalities such as a mass or highly irregular heart rate, consult the patient's health care provider before revealing them. It is the health care provider's responsibility to make definitive medical diagnoses. Explain the type of abnormality found and the need for the health care provider to conduct an additional examination.

Delegate the cleanup of the examination area to support staff if needed. Use infection control practice to remove materials or instruments soiled with potentially infectious wastes. If the patient's bedside was the examination site, clear away soiled items from the bedside table and make sure that the bed linen is dry and clean. A patient appreciates a clean gown and the opportunity to wash the face and hands. Afterward be sure to perform hand hygiene.

Be sure to record a complete assessment. Review the documents for accuracy and thoroughness. Communicate significant findings to appropriate personnel, either verbally or in the patient's written care plan.

Building Competency in Safety

A 38-year-old female patient presents to the examination room via a wheelchair. You notice that she is frail, her feet are curled up into the chair, and both of her arms are across her stomach and pressing into her stomach in a firm manner. The patient is sitting in the fetal position within the wheelchair. When you ask her whether she

needs help getting on the table in the exam room, she answers in Spanish and you see tears in her eyes. She is accompanied by a younger woman who explains that the patient said, "My stomach hurts, and I don't think I can get to the table." Which aspects of the QSEN competency of safety would be used to best care for this patient throughout the entire physical examination related to culture and physical assessment of the abdomen? How does the competency of patient-centered care play a role in the patient's safety?

Key Points

- Knowing the purpose of the overall assessment is important so that you can focus and organize the history and physical.
- Your patient's cultural background will impact how you conduct your health assessment and physical examination, ensuring that you show cultural respect.
- Having an organized approach plan for the entire assessment helps ensure the mental and physical comfort of the patient.
- Using open-ended, focused questions helps you gather current information and history to complete a full assessment.
- Before the exam, set up the room and make sure it is a comfortable temperature for the patient.
- Review the nursing history to assist in the knowledge you will need to best complete the physical exam.
- Each assessment area has different techniques and normal and abnormal findings that you will use to interpret data.
- Recognize that the normal aging process impacts physical and assessment findings in older adults.
- During each part of the examination converse with the patient. Teaching health promotion activities related to the area being assessed is a good way to build a relationship of trust and to help the patient.

- Physical assessment can be incorporated into routine care. For example, skin assessment can be completed while helping the patient transfer or prepare for bathing.
- Physical measurements (i.e., height, weight, vital signs, evaluation scales) are used to assess the overall patient condition and within specific areas.

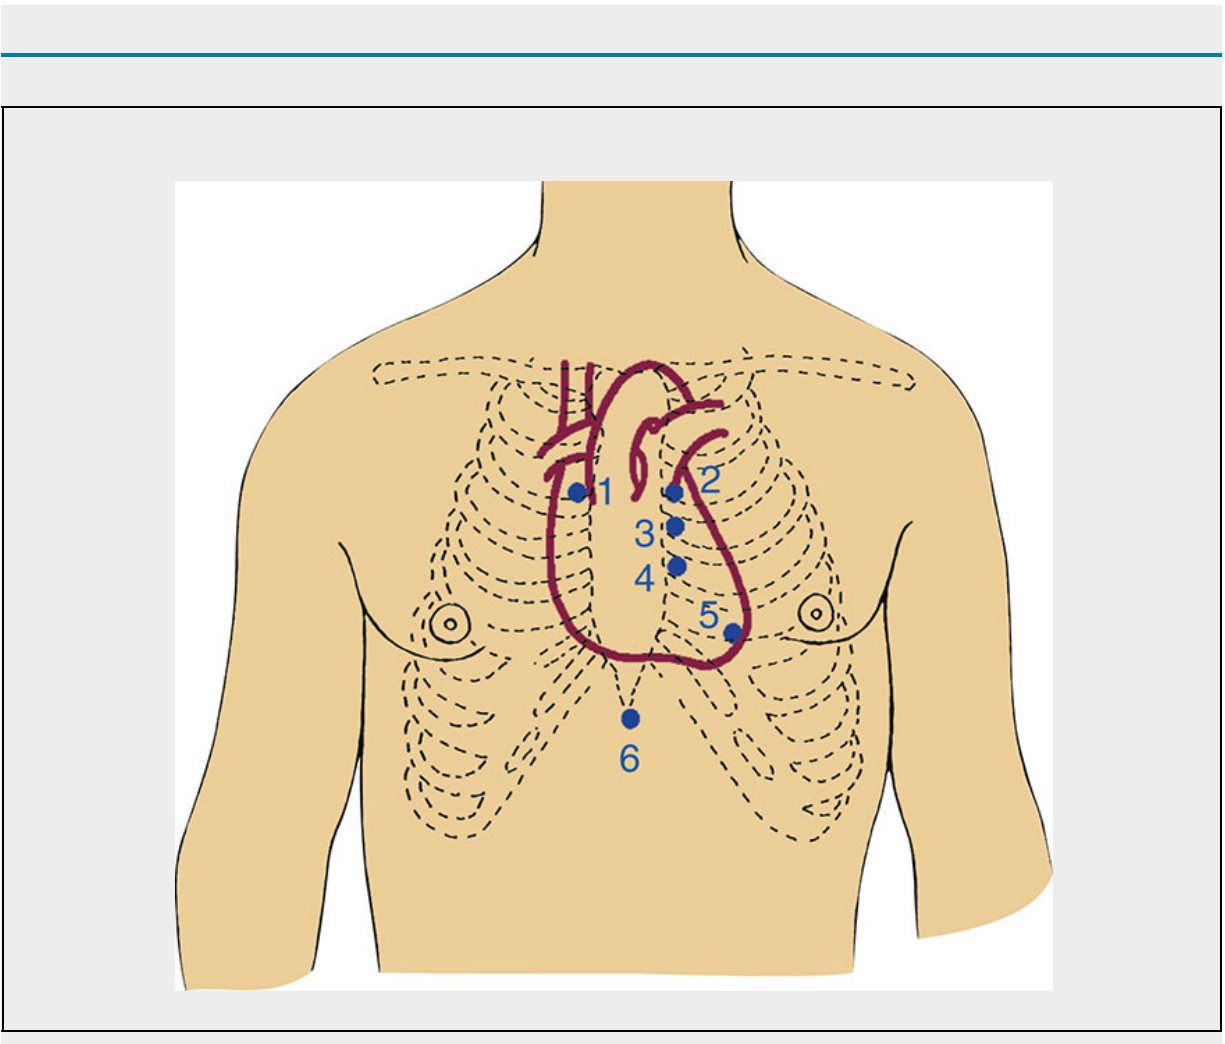

Reflective Learning

- Describe the order in which you completed the assessment on a patient that you cared for during your last clinical rotation. Explain the rationale for completing the assessment in this manner.
- Describe any abnormal assessment findings you obtained when assessing your patient during your clinical experience. What might these findings indicate? Describe the steps you took after obtaining the abnormal findings.
- Consider a patient that you cared for on the clinical unit. Describe how this patient's assessment findings varied based on his or her age.

Review Questions

1. The nurse prepares to conduct a general survey on an adult patient. Which assessment is performed first while the nurse initiates the nurse-patient relationship?
 1. Appearance and behavior
 2. Measurement of vital signs
 3. Observing specific body systems

4. Conducting a detailed health history
2. Which number corresponds to the area of the chest where you would auscultate for the tricuspid valve?

3. The nurse is assessing a patient who returned 1 hour ago from surgery for an abdominal hysterectomy. Which assessment finding would require immediate follow-up?
 1. Auscultation of an apical heart rate of 76
 2. Absence of bowel sounds on abdominal assessment

3. Respiratory rate of 8 breaths/min
4. Palpation of dorsalis pedis pulses with strength of +2
4. Which statement made by a patient who is at average risk for colorectal cancer indicates an understanding about teaching related to early detection of colorectal cancer?
 1. "I'll make sure to schedule my colonoscopy annually after the age of 60."
 2. "I'll make sure to have a colonoscopy every 2 years."
 3. "I'll make sure to have a flexible sigmoidoscopy every year once I turn 55."
 4. "I'll make sure to have a fecal occult blood test annually once I turn 45."
5. The nurse is teaching a patient to prevent heart disease. Which information should the nurse include? (Select all that apply.)
 1. Add salt to every meal.
 2. Talk with your health care provider about taking a daily low dose of aspirin.
 3. Work with your health care provider to develop a regular exercise program.
 4. Limit daily intake of fats to less than 25% to 35% of total calories.
 5. Review strategies to encourage the patient to quit smoking.
6. The nurse is assessing the cranial nerves. Match the cranial nerve with its related function.

Cranial Nerves	Cranial Nerve Function
1. XII Hypoglossal	a. Motor innervation to the muscles of the jaw
2. V Trigeminal	b. Lateral movement of the eyeballs
3. VI Abducens	c. Sensation of the pharynx
4. IV Trochlear	d. Downward, inward eye movements
5. X Vagus	e. Position of the tongue

7. The nurse is teaching a patient how to perform a testicular self-examination. Which statement made by the patient indicates a need for further teaching?
1. "I'll recognize abnormal lumps because they are very painful."
 2. "I'll start performing testicular self-examination monthly after I turn 15."
 3. "I'll perform the self-examination in front of a mirror."
 4. "I'll gently roll the testicle between my fingers."
8. The nurse is observing as the student nurse performs a respiratory assessment on a patient. Which action by the student nurse requires the nurse to intervene?
1. The student stands at a midline position behind the patient, observing for position of the spine and scapula.
 2. The student palpates the thoracic muscles for masses, pulsations, or abnormal movements.
 3. The student places the bell of the stethoscope on the anterior chest wall to auscultate breath sounds.
 4. The student places the palm of the hand over the intercostal spaces and asks the patient to say "ninety-nine."
9. A patient has undergone surgery for a femoral artery bypass. The surgeon's orders include assessment of dorsalis pedis pulses. The nurse will use which of the

following techniques to assess the pulses? (Select all that apply.)

1. Place the fingers behind and below the medial malleolus.
2. Have the patient slightly flex the knee with the foot resting on the bed.
3. Have the patient relax the foot while lying supine.
4. Palpate the groove lateral to the flexor tendon of the wrist.
5. Palpate along the top of the foot in a line with the groove between the extensor tendons of the great and first toes.

10. The faith community nurse is teaching the community center women's group about breast cancer risk factors. Which factors does the nurse include? (Select all that apply.)

1. First child at the age of 26 years
2. Menopause onset at the age of 49 years
3. Family history with *BRCA1* inherited gene mutation
4. Age over 40 years
5. Onset of menses before the age of 12
6. Recent use of oral contraceptives

Answers: 1.1; 2.4; 3.3; 4.4; 5.2, 3, 4, 5; 6.1e, 2a, 3b, 4d, 5c; 7.1; 8.3; 9.3, 5; 10.3, 4, 5, 6.

Medication Administration

OBJECTIVES

- Discuss nursing roles and responsibilities in medication administration.
- Discuss legal responsibilities in medication administration.
- Describe the physiological mechanisms of medication action.
- Differentiate among different types of medication actions.
- Discuss developmental factors that influence pharmacokinetics.
- Identify the characteristics of adverse medication events.
- Discuss factors that influence medication actions.
- Discuss methods used to educate patients about prescribed medications.
- Compare and contrast the roles of the health care provider, pharmacist, and nurse in medication administration.
- Implement nursing actions to prevent medication errors.
- Describe factors to consider when choosing routes of medication administration.
- Calculate prescribed medication doses correctly.
- Discuss factors to include in assessing a patient's needs for and response to medication therapy.
- Identify the seven rights of medication administration and apply them in clinical settings.
- Correctly and safely prepare and administer medications.

Patients with health problems use a variety of strategies to restore or maintain their health. One strategy they often use is medication, a substance used in the diagnosis, treatment, cure, relief, or prevention of health problems. No matter where patients receive health care (i.e., hospitals, clinics, or home), nurses play an essential role in preparing, administering, and evaluating the effects of medications. Family caregivers, friends, or home care personnel often administer medications when patients cannot administer them themselves at home. In all settings nurses are responsible for evaluating the effects of medications on the patient's ongoing health status, providing education about medications and side effects, encouraging adherence to the medication regimen, and evaluating the patient's and family caregiver's ability to administer medications.

Scientific Knowledge Base

Because medication administration and evaluation are a critical part of nursing practice, nurses need to understand the actions and effects of all medications taken by their patients. Administering medications safely requires an understanding of legal aspects of health care, pharmacology, pharmacokinetics (the movement of drugs in the human body), the life sciences, pathophysiology, human anatomy, and mathematics.

Medication Legislation and Standards

Federal Regulations

The US government protects the health of the people by ensuring that medications are safe and effective. The first American law to regulate medications was the Pure Food and Drug Act. This law simply requires all medications to be free of impure products. Subsequent legislation created standards related to safety, potency, and efficacy. Currently the Food and Drug Administration (FDA) enforces medication laws that ensure that all medications on the market undergo vigorous testing before they are sold to the public. Federal medication laws also control medication sales and distribution; testing, naming, and labeling; and the use of controlled substances. Official publications such as the *United States Pharmacopeia* (USP) and the *National Formulary* set standards for medication strength, quality, purity, packaging, safety, labeling, and dose form. In 1993 the FDA instituted the MedWatch program. This voluntary program encourages nurses and other health care professionals to report when a medication, product, or medical event causes serious harm to a patient by completing the MedWatch form. The form is available on the MedWatch website ([USFDA, 2018a](#)).

State and Local Regulation of Medication

State and local medication laws must conform to federal legislation. States often have additional controls, including control of substances not regulated by the federal government. Local governmental bodies regulate the use of alcohol and tobacco.

Health Care Institutions and Medication Laws

Health care agencies establish individual policies to meet federal, state, and local regulations. The size of the agency, the services it provides, and

the professional personnel it employs influence these policies. Agency policies are often more restrictive than governmental controls. For example, a common agency policy is the automatic discontinuation of narcotics after a set number of days. Although a health care provider can reorder the narcotic, this policy helps to control unnecessarily prolonged medication therapy because it requires the health care provider to regularly review the need for the medication.

Medication Regulations and Nursing Practice

State Nurse Practice Acts (NPAs) define the scope of nurses' professional functions and responsibilities. Most NPAs are purposefully broad so that nurses' professional responsibilities are not limited. Health care agencies can interpret specific actions allowed under NPAs, but they cannot modify, expand, or restrict the intent of the act. The primary intent of NPAs is to protect the public from unskilled, undereducated, and unlicensed personnel.

A nurse is responsible for following legal provisions when administering controlled substances such as opioids, which are carefully controlled through federal and state guidelines. Violations of the Controlled Substances Act are punishable by fines, imprisonment, and loss of nurse licensure. Hospitals and other health care agencies have policies for the proper storage and distribution of narcotics ([Box 31.1](#)).

Box 31.1 Guidelines for Safe Opioid (Narcotic)

Administration and Control

- Store all narcotics in a locked, secure cabinet or container (e.g., computerized, locked cabinets are preferred).
- Maintain a running count of opioids by counting them whenever dispensing them. If you find a discrepancy, correct and report it immediately.
- Use a special inventory record each time an opioid is dispensed. Records are often kept electronically and provide an accurate ongoing count of narcotics used, wasted, and remaining.
- Use the record to document the patient's name, date, time of medication administration, name of medication, and dosage. If the agency keeps a paper record, the nurse dispensing the medication

signs the record. If the agency uses a computerized system, the computer records the nurse's name.

- If a nurse gives only part of a dose of a controlled substance, a second nurse witnesses the disposal of the unused part. Computerized systems record the nurses' names electronically. If paper records are kept, both nurses sign their names on the form.
- Follow agency policy for appropriate waste of opioids. Do not place wasted parts of medications in sharps containers.

Pharmacological Concepts

Medication Names

Some medications have as many as three different names. The chemical name of a medication provides an exact description of its composition and molecular structure. Nurses rarely use chemical names in clinical practice. An example of a chemical name is *N*-acetyl-para-aminophenol, which is commonly known as Tylenol. The manufacturer who first develops the medication gives the generic or nonproprietary name, with United States Adopted Names (USAN) Council approval ([AMA, 2018](#)). Acetaminophen is an example of the generic name for Tylenol. The generic name becomes the official name listed in official publications such as the United States Pharmacopeia (USP). The trade name, brand name, or proprietary name is the name under which a manufacturer markets a medication. The trade name has the symbol (™) at the upper right of the name, indicating that the manufacturer has trademarked the name of the medication (e.g., Panadol™ and Tempra™).

Manufacturers choose trade names that are easy to pronounce, spell, and remember. Many companies produce the same medication, and similarities in trade names are often confusing. Therefore, be careful to obtain the exact name and spelling for each medication you administer to your patients. Because similarities in medication names are a common cause of medical errors, the Institute for Safe Medication Practices ([ISMP](#)) ([2015a](#); [2018a](#)) publishes a list of medications that are frequently confused with one another. The ISMP recommends the use of Food and Drug Administration (FDA)-approved tall-man or mixed-case letters when possible (e.g., aMILoride versus amLODIPine) to help health care providers easily recognize the difference between these commonly confused medications.

Classification

Medication classification indicates the effect of a medication on a body system, the symptoms a medication relieves, or its desired effect. Usually each class contains more than one medication that is used for the same type of health problem. For example, patients who have asthma often take a variety of medications, such as beta₂-adrenergic agonists, to control their illness. The *beta₂-adrenergic* classification contains more than 15 different medications (Burchum and Rosenthal, 2019). Some medications are in more than one class. For example, aspirin is an analgesic, an antipyretic, and an antiinflammatory medication.

Medication Forms

Medications are available in a variety of forms, or preparations. The form of the medication determines its route of administration. The composition of a medication enhances its absorption and metabolism. Many medications come in several forms, such as tablets, capsules, elixirs, and suppositories. When administering a medication, be certain to use the proper form (Table 31.1).

TABLE 31.1

Forms of Medication

Form	Description
Medication Forms Commonly Prepared for Administration by Oral Route	
Solid Forms	
Caplet	Shaped like capsule and coated for ease of swallowing
Capsule	Medication encased in gelatin shell
Tablet	Powdered medication compressed into hard disk or cylinder; in addition to primary medication, contains binders (adhesive to allow powder to stick together), disintegrators (to promote tablet dissolution), lubricants (for ease of manufacturing), and fillers (for convenient tablet size)
Enteric-coated tablet	Coated tablet that does not dissolve in stomach; coatings dissolve in intestine, where medication is absorbed
Liquid Forms	
Elixir	Clear fluid containing water and/or alcohol; often sweetened
Extract	Syrup or dried form of pharmacologically active medication, usually made by evaporating solution
Aqueous solution	Substance dissolved in water and syrups
Aqueous suspension	Finely dissolved medication particles dispersed in liquid medium; when suspension is left standing, particles settle to bottom of container
Syrup	Medication dissolved in a concentrated sugar solution
Tincture	Alcohol extract from plant or vegetable
Other Oral Forms and Terms Associated with Oral Preparations	
Troche (lozenge)	Flat, round tablets that dissolve in mouth to release medication; not meant for ingestion
Aerosol	Aqueous medication sprayed and absorbed in mouth and upper airway; not meant for ingestion
Sustained release	Tablet or capsule that contains small particles of a medication coated with material that requires a varying amount of time to dissolve
Medication Forms Commonly Prepared for Administration by Topical Route	
Ointment (salve or cream)	Semisolid, externally applied preparation, usually containing one or more medications
Liniment	Usually contains alcohol, oil, or soapy emollient applied to skin
Lotion	Semiliquid suspension that usually protects, cools, or cleanses skin
Paste	Medication preparation that is thicker than ointment; absorbed through skin more slowly than ointment; often used for skin protection
Transdermal disk or patch	Medicated disk or patch absorbed through skin slowly over long period of time (e.g., 24 hours)
Medication Forms Commonly Prepared for Administration by Parenteral Route	
Solution	Sterile preparation that contains water with one or more dissolved compounds
Powder	Sterile particles of medication that are dissolved in a sterile liquid (e.g., water, normal saline) before administration
Medication Forms Commonly Prepared for Instillation Into Body Cavities	
Intraocular disk	Small, flexible oval (similar to contact lens) consisting of two soft, outer layers and a middle layer containing medication; slowly releases medication when moistened by ocular fluid
Suppository	Solid dosage form mixed with gelatin and shaped in form of pellet for insertion into body cavity (rectum or vagina); melts when it reaches body temperature, releasing medication for absorption

Pharmacokinetics as the Basis of Medication Actions

For a medication to be useful therapeutically, it must be taken into a patient's body; be absorbed and distributed to cells, tissues, or a specific organ; and alter physiological functions. **Pharmacokinetics** is the study of how medications enter the body, reach their site of action, metabolize, and exit the body. You use knowledge of pharmacokinetics when timing medication administration, selecting the route of administration, and evaluating a patient's response.

Absorption

Absorption occurs when medication molecules pass into the blood from the site of medication administration. Factors that influence absorption are the route of administration, ability of the medication to dissolve, blood flow to the site of administration, body surface area (BSA), and lipid solubility of medication.

Route of Administration

Each route of medication administration has a different rate of absorption. When applying medications on the skin, absorption is slow because of the physical makeup of the skin. Because orally administered medications pass through the gastrointestinal (GI) tract, the overall rate of absorption is usually slow. Medications placed on the mucous membranes and respiratory airways are absorbed quickly because these tissues contain many blood vessels. Intramuscular (IM) and subcutaneous medications absorb more quickly than oral medications, with IM injections entering the bloodstream more quickly than medications in subcutaneous injections. Intravenous (IV) **injection** produces the most rapid absorption because medications are available immediately when they enter the systemic circulation.

Ability of a Medication To Dissolve

The ability of an oral medication to dissolve depends largely on its form or preparation. The body absorbs solutions and suspensions already in a liquid state more readily than tablets or capsules. Acidic medications pass through the gastric mucosa rapidly. Medications that are basic are not absorbed before reaching the small intestine.

Blood Flow to the Site of Administration

The blood supply to the site of administration will determine how quickly the body can absorb a medication. Medications are absorbed as blood

comes in contact with the site of administration. The richer the blood supply to the site of administration, the faster a medication is absorbed.

Body Surface Area

When a medication comes in contact with a large surface area, it is absorbed at a faster rate. This helps explain why most of medications are absorbed in the small intestine rather than the stomach ([Burchum and Rosenthal, 2019](#)).

Lipid Solubility

Because the cell membrane has a lipid layer, highly lipid-soluble medications cross cell membranes easily and are absorbed quickly. Another factor that often affects medication absorption is whether food is in the stomach. Some oral medications are absorbed more easily when administered between meals because food changes the structure of a medication and sometimes impairs its absorption. When some medications are administered together, they interfere with one another, impairing the absorption of both medications.

Safe medication administration requires knowledge of factors that alter or impair absorption of prescribed medications. You need to understand medication pharmacokinetics, a patient's health history, physical examination data, and knowledge gained through daily patient interactions. Use your knowledge and agency policy to plan medication administration times that will promote optimal absorption. For example, plan medication administration times around meals (e.g., before or after meals) when medications interact with food. When they interact with one another, make sure that you do not give them at the same time. Consult and collaborate with your patient's health care provider or a pharmacist when setting medication times to ensure that the patient achieves the therapeutic effect of all medications. Before administering any medication, check pharmacology books, medication references, or package inserts or consult with pharmacists to identify medication-medication or medication-food interactions.

Distribution

After a medication is absorbed, it is distributed within the body to tissues and organs and ultimately to its specific site of action. The rate and extent of distribution depend on the physical and chemical properties of the medication and the physiology of the person taking it.

Circulation

Once a medication enters the bloodstream, it is carried throughout the tissues and organs. How fast it reaches a site depends on the vascularity of the various tissues and organs. Conditions that limit blood flow or blood perfusion inhibit the distribution of a medication. For example, patients with heart failure have impaired circulation, which slows medication delivery to the intended site of action. Therefore, the effectiveness of medications in these patients is often delayed or altered.

Membrane Permeability

Membrane permeability refers to the ability of a medication to pass through tissues and membranes to enter target cells. To be distributed to an organ, a medication must pass through all of the tissues and biological membranes of the organ. Some membranes serve as barriers to the passage of medications. For example, the blood-brain barrier allows only fat-soluble medications to pass into the brain and cerebral spinal fluid. Therefore, central nervous system infections often require treatment with antibiotics injected directly into the subarachnoid space in the spinal cord. Some older adults experience adverse effects (e.g., confusion) because of the change in the permeability of the blood-brain barrier, with easier passage of fat-soluble medications.

Protein Binding

The degree to which medications bind to serum proteins such as albumin affects their distribution. Most medications partially bind to albumin, reducing the ability of a drug to exert pharmacological activity. The unbound or “free” medication is its active form. Older adults and patients with liver disease or malnutrition have decreased albumin in the bloodstream. Because more medication is unbound in these patients, they are at risk for an increase in medication activity, toxicity, or both.

Metabolism

After a medication reaches its site of action, it becomes metabolized into a less active or an inactive form that is easier to excrete. **Biotransformation** occurs under the influence of enzymes that **detoxify**, break down, and remove biologically active chemicals. Most biotransformation occurs within the liver, although the lungs, kidneys, blood, and intestines also metabolize medications. The liver is especially important because its specialized structure oxidizes and transforms many toxic substances. The

liver degrades many harmful chemicals before they become distributed to the tissues. If a decrease in liver function occurs such as with aging or liver disease, a medication is usually eliminated more slowly, resulting in its accumulation. Patients are at risk for medication toxicity if organs that metabolize medications are not functioning correctly. For example, a small sedative dose of a barbiturate sometimes causes a patient with liver disease to lapse into a coma.

Excretion

After medications are metabolized, they exit the body through the kidneys, liver, bowel, lungs, and exocrine glands. The chemical makeup of a medication determines the organ of excretion. Gaseous and volatile compounds such as nitrous oxide and alcohol exit through the lungs. Deep breathing and coughing (see [Chapter 41](#)) help patients eliminate anesthetic gases more rapidly after surgery. The exocrine glands excrete lipid-soluble medications. When medications exit through sweat glands, the skin often becomes irritated, requiring you to teach patients good hygiene practices (see [Chapter 40](#)). If a medication is excreted through the mammary glands, there is a risk that a nursing infant will ingest the chemicals. Check the safety of any medication used in breastfeeding women.

The GI tract is another route for medication excretion. Medications that enter the hepatic circulation are broken down by the liver and excreted into the bile. After chemicals enter the intestines through the biliary tract, the intestines resorb them. Factors that increase peristalsis (e.g., laxatives and enemas) accelerate medication excretion through the feces, whereas factors that slow peristalsis (e.g., inactivity and improper diet) often prolong the effects of a medication.

The kidneys are the main organs for medication excretion. Some medications escape extensive metabolism and exit unchanged in the urine. Others undergo biotransformation in the liver before the kidneys excrete them. Maintenance of an adequate fluid intake (50 mL/kg/hr) promotes proper elimination of medications for the average adult. If a patient's renal function declines, the kidneys cannot adequately excrete medications. Thus, the risk for medication toxicity increases. Health care providers usually reduce medication doses when this happens.

Types of Medication Action

Medications vary considerably in the way they act and their types of action. Patients do not always respond in the same way to each successive

dose of a medication. Sometimes the same medication causes very different responses in different patients. Therefore, you need to understand all the effects that medications you administer have on patients.

Therapeutic Effects

The **therapeutic effect** is the expected or predicted physiological response caused by a medication. For example, nitroglycerin reduces cardiac workload and increases myocardial oxygen supply. Some medications have more than one therapeutic effect. For example, prednisone, a steroid, decreases swelling, inhibits inflammation, reduces allergic responses, and prevents rejection of transplanted organs. Knowing the desired therapeutic effect for each medication allows you to provide patient education and accurately evaluate the desired effect of a medication.

Adverse Effects

Every medication can harm a patient. Undesired, unintended, and often unpredictable responses to medication are referred to as **adverse effects**. Adverse medication effects range from mild to severe. Some happen immediately, whereas others develop over time. Be alert and assess for unusual individual responses to medications, especially with newly prescribed medications. Patients most at risk for adverse medication reactions include the very young and older adults, pregnant women, patients taking multiple medications, patients who are extremely underweight or overweight, and patients with renal or liver disease. If adverse effects are mild and tolerable, patients often remain on the medications. However, if they are not tolerated and are potentially harmful, stop giving the medication immediately. When adverse responses to medications occur, the health care provider discontinues the medication immediately. Health care providers report adverse effects to the FDA using the MedWatch program ([USFDA, 2018a](#)).

Side Effects

A **side effect** is a predictable and often unavoidable adverse effect produced at a usual therapeutic dose. For example, some antihypertensive medications cause impotence in men. Side effects range from being harmless to causing serious symptoms or injury. If the side effects are serious enough to negate the beneficial effects of the therapeutic action of the medication, the health care provider discontinues the medication.

Patients often stop taking medications because of side effects, the most common of which are anorexia, nausea, vomiting, constipation, drowsiness, and diarrhea.

Toxic Effects

Toxic effects often develop after prolonged intake of a medication or when a medication accumulates in the blood because of impaired metabolism or excretion. Excess amounts of a medication within the body sometimes have lethal effects, depending on its action. For example, toxic levels of morphine, an opioid, cause severe respiratory depression and death. Antidotes are available to treat specific types of medication toxicity. For example, naloxone, an opioid antagonist, reverses the effects of opioid toxicity.

Idiosyncratic Reactions

Medications sometimes cause unpredictable effects such as an **idiosyncratic reaction**, in which a patient overreacts or underreacts to a medication or has a reaction different from normal. For example, a child who receives diphenhydramine, an antihistamine, becomes extremely agitated or excited instead of drowsy. At present, it is not possible to predict whether a patient will have an idiosyncratic response to a medication.

Allergic Reactions

Allergic reactions are unpredictable responses to a medication. Some patients become immunologically sensitized to the initial dose of a medication. With repeated administration the patient develops an allergic response to it, its chemical preservatives, or a metabolite. The medication or chemical acts as an antigen, triggering the release of the antibodies in the body. A patient's **medication allergy** symptoms vary, depending on the individual and the medication (Table 31.2). Among the different classes of medications, antibiotics cause a high incidence of allergic reactions. Severe or **anaphylactic reactions**, which are life threatening, are characterized by sudden constriction of bronchiolar muscles, edema of the pharynx and larynx, and severe wheezing and shortness of breath. Immediate medical attention is required to treat anaphylactic reactions. A patient with a known history of an allergy to a medication needs to avoid taking that medication in the future and wear an identification bracelet or medal (Fig. 31.1), which alerts nurses and other health care providers to

the allergy if a patient is unable to communicate when receiving medical care.

TABLE 31.2

Mild Allergic Reactions

Symptom	Description
Urticaria (hives)	Raised, irregularly shaped skin eruptions with varying sizes and shapes; eruptions have reddened margins and pale centers
Rash	Small, raised vesicles that are usually reddened; often distributed over entire body
Pruritus	Itching of skin; accompanies most rashes
Rhinitis	Inflammation of mucous membranes lining nose; causes swelling and clear, watery discharge

FIG. 31.1 Allergy identification bracelet and medal.

Medication Interactions

When one medication modifies the action of another, a **medication interaction** occurs. Medication interactions are common when individuals take several medications. Some medications increase or diminish the action of others or alter the way another medication is absorbed, metabolized, or eliminated from the body. When two medications have a **synergistic effect**, their combined effect is greater than the effect of the medications when given separately. For example, alcohol is a central nervous system depressant that has a synergistic effect on antihistamines, antidepressants, barbiturates, and narcotic analgesics. Sometimes a medication interaction is desired. Health care providers often combine medications to create an interaction that has a beneficial effect. For example, a patient with high blood pressure takes several medications such as diuretics and vasodilators that act together to control blood pressure when one medication is not effective on its own.

Medication Tolerance and Dependence

Medication tolerance occurs over time. It is usually noted clinically when patients receive more and more medication (higher doses) to achieve the same therapeutic effect. Medications that produce tolerance include opium alkaloids (e.g., morphine), nitrates, and ethyl alcohol. Patients hospitalized for acute illnesses usually do not develop medication tolerance. It may take a month or longer for tolerance to occur.

Medication tolerance is not the same as medication dependence. Two types of medication dependence (addiction) exist: physical and psychological. In psychological dependence a patient desires the medication for benefit other than the intended effect. Physical dependence is a physiological adaptation to a medication that manifests by intense physical disturbance when the medication is withdrawn. If a patient is dependent on alcohol, a higher-than-usual medication dose is necessary for the desired effect of the medication.

Nurses and other health care professionals play an important role in the care of patients with drug addiction. Patients need to be approached with positive attitudes, so the patient may be more open to learning about treatment options. Using the newest evidence-based treatment options can help patients with addictions receive the care and treatment they need.

Timing of Medication Dose Responses

Medications administered intravenously enter the bloodstream and act immediately, whereas those given in other routes take time to enter the bloodstream and have an effect. The quantity and distribution of a medication in different body compartments change constantly. Medications are ordered at various times, depending on when their response begins, becomes most intense, and ceases.

The **minimum effective concentration (MEC)** is the plasma level of a medication below which the effect of the medication does not occur. The toxic concentration is the level at which toxic effects occur. When a medication is prescribed, the goal is to achieve a constant blood level within a safe **therapeutic range**, which falls between the MEC and the toxic concentration (Fig. 31.2). When a medication is administered repeatedly, its serum level fluctuates between doses. The highest level is called the **peak** concentration, and the lowest level is called the **trough** concentration. After reaching its peak, the serum concentration of the medication falls progressively. With IV **infusions** the peak concentration occurs quickly, but the serum level also begins to fall immediately. Some medication doses (e.g., vancomycin) are based on peak and trough serum levels. The trough level is generally drawn 30 minutes before administering the medication, and the peak level is drawn whenever the medication is expected to reach its peak concentration. The time it takes for a medication to reach its peak concentration varies, depending on the pharmacokinetics of the medication.

FIG. 31.2 The therapeutic range of a medication occurs between the minimum effective concentration and the toxic concentration.
 From Burchum JR, Rosenthal LD: *Pharmacology for nursing care*, ed 10, St Louis, 2019, Elsevier.

All medications have a **biological half-life**, which is the time it takes for excretion processes to lower the serum medication concentration by half. To maintain a therapeutic plateau, a patient needs to receive regular fixed doses. For example, pain medications are most effective for some cancer patients when they are given around-the-clock (ATC) rather than when a patient intermittently complains of pain because the body maintains an almost constant level of pain medication (Burchum and Rosenthal, 2019). After an initial medication dose, the patient receives each successive dose when the previous dose reaches its half-life. The patient and nurse need to follow regular dosage schedules and administer prescribed doses at correct intervals. Know the following time intervals of medication action to anticipate the effect of a medication:

1. *Onset of medication action*: Period of time it takes after you administer a medication for it to produce a therapeutic effect

2. *Peak action*: Time it takes for a medication to reach its highest effective peak concentration
3. *Trough*: Minimum blood serum concentration of medication reached just before the next scheduled dose
4. *Duration of action*: Length of time during which a medication is present in a concentration great enough to produce a therapeutic effect
5. *Plateau*: Blood serum concentration reached and maintained after repeated, fixed doses

You and your patient follow prescribed doses and dosage intervals (Table 31.3). Health care agencies usually set schedules for medication administration. However, you can change this schedule based on your knowledge about a medication. For example, you work at an agency where medications ordered once a day are given at 0800. Your patient has a medication ordered once a day that works better when given before bedtime; therefore, you adjust the time to give the medication accordingly, based on agency policy. Acute care agencies also follow guidelines from the ISMP to determine safe, effective, and timely administration of medications (CMS, 2014; ISMP, 2011a). According to the guidelines, hospitals determine whether medications are time critical. Medications that are time critical most likely cause harm or have subtherapeutic effects if they are not administered on time (usually 30 minutes before or after the scheduled dose). Non-time-critical medications most likely do not cause harm if they are given within 1 to 2 hours before or after the scheduled time. Thus, you need to administer time-critical medications at a precise time, within 30 minutes before or after their scheduled time. You administer non-time-critical medications within 1 to 2 hours of their scheduled time. Ensure that you follow your agency medication policies about the timing of medications to ensure that your patients receive their medications at the right time (CMS 2014; ISMP, 2011a).

TABLE 31.3**Common Dosage Administration Schedules**

Dosage Schedule (Meaning)	Abbreviation
Before meals	AC, ac
As desired	ad lib
Twice each day	BID, bid
After meals	PC, pc
Whenever there is a need	prn
Every morning, every AM	q am
Every hour	qh
Every day	Daily
Every 4 hours	q4h
4 times per day	QID, qid
Give immediately	STAT, stat
3 times per day	TID, tid

When you teach patients about dosage schedules, use familiar language. For example, when teaching a patient about twice-daily medication dosing, instruct him or her to take the medication in the morning and again in the evening. Knowledge of the time intervals of medication action help you anticipate the effect of the medication (Table 31.4). With this knowledge, instruct the patient when to expect a response.

TABLE 31.4**Terms Associated with Medication Actions**

Term	Meaning
Onset	Time it takes after a medication is administered for it to produce a response
Peak	Time it takes for a medication to reach its highest effective concentration
Trough	Minimum blood serum concentration of medication reached just before the next scheduled dose
Duration	Time during which medication is present in concentration great enough to produce a response
Plateau	Blood serum concentration of medication reached and maintained after repeated fixed doses

Routes of Administration

The route prescribed for administering a medication depends on the properties and desired effect of the medication and the patient's physical and mental condition (Table 31.5). Work with the health care provider to determine the best route for a patient's medication.

TABLE 31.5

Factors Influencing Choice of Administration Routes

Advantages By Route	Disadvantages/Contraindications
Oral, Buccal, Sublingual Routes	
<p>Convenient and comfortable Economical Easy to administer Often produce local or systemic effects Rarely cause anxiety for patient</p>	<p>Oral route is avoided when patient has alterations in gastrointestinal (GI) function (e.g., nausea, vomiting), reduced GI motility (after general anesthesia or bowel inflammation), and surgical resection of the GI tract.</p> <p>Oral administration is contraindicated in patients unable to swallow (e.g., patients with neuromuscular disorders, esophageal strictures, mouth lesions).</p> <p>Oral administration is contraindicated in patients who are unconscious, confused, or unable or unwilling to swallow or hold medication under tongue.</p> <p>Oral medications cannot be administered when patients have gastric suction; are contraindicated before some tests or surgery.</p> <p>Oral medications sometimes irritate lining of GI tract, discolor teeth, or have unpleasant taste.</p> <p>Gastric secretions destroy some medications.</p>
Parenteral Routes (Subcutaneous, Intramuscular, Intravenous, Intradermal)	
<p>Can be used when oral medications are contraindicated More rapid absorption than with topical or oral routes Intravenous (IV) infusion provides medication delivery when patient is critically ill or long-term therapy is necessary; if peripheral perfusion is poor, IV route preferred over injections</p>	<p>There is risk of introducing infection.</p> <p>Some medications are expensive.</p> <p>Some patients experience pain from repeated needlesticks.</p> <p>Subcutaneous, intramuscular (IM), and intradermal (ID) routes are avoided in patients with bleeding tendencies.</p> <p>There is risk of tissue damage.</p> <p>IM and IV routes have higher absorption rates, thus placing patient at higher risk for reactions.</p> <p>They often cause considerable anxiety in many patients, especially children.</p>
Topical Routes	
Skin	
<p>Primarily provides local effect Painless Limited side effects</p>	<p>Patients with skin abrasions are at risk for rapid medication absorption and systemic effects.</p> <p>Medications are absorbed through skin slowly.</p>
Transdermal	
<p>Prolonged systemic effects with limited side effects</p>	<p>Medication leaves oily or pasty substance on skin and sometimes soils clothing.</p>
Mucous Membranes ^a	
<p>Therapeutic effects provided by local application to involved sites Aqueous solutions readily absorbed and capable of causing systemic effects Potential route of administration when oral medications are contraindicated</p>	<p>Mucous membranes are highly sensitive to some medication concentrations.</p> <p>Patients with ruptured eardrum cannot receive ear irrigations.</p> <p>Insertion of rectal and vaginal medication often causes embarrassment.</p> <p>Rectal suppositories contraindicated if patient has had rectal surgery or if active rectal bleeding is present.</p>
Other Routes	
Inhalation	
<p>Provides rapid relief for local respiratory problems Used for introduction of general anesthetic gases</p>	<p>Some local agents cause serious systemic effects.</p>
Intraocular Disk	
<p>Route advantageous because it does not require frequent administration as eyedrops do</p>	<p>Local reactions possible; expensive</p> <p>Patients must be taught to insert and remove disk</p> <p>Contraindicated in eye infections</p>

^a Includes eyes, ears, nose, vagina, rectum, and ostomy.

Building Competency in Evidence-Based Practice

A nursing student is caring for a patient being treated for multiple fractures after a recent fall. The health care provider writes a new

medication order for morphine sulfate liquid suspension 20 mg orally STAT and then q4h as needed for pain. The patient is having difficulty swallowing pills as a result of the trauma; thus, the medications are ordered in liquid suspension.

1. What does the student need to know about morphine sulfate before administering it?
2. Four unit-dose containers of liquid morphine sulfate arrive on the patient care unit. The labels on the medication say: "40 mg morphine sulfate/5 mL." You will need to waste some of the liquid morphine before administering it to the patient. What are the procedures for wasting a narcotic?
3. You collect the appropriate equipment to administer the medication, perform hand hygiene, prepare the medication, take it to the patient at the correct time, and use two unique patient identifiers to ensure that this is the right patient. Which step do you need to take next in administering the medication?

Oral Routes

The oral route is the easiest and the most commonly used route of medication administration. Medications are given by mouth and swallowed with fluid. Oral medications have a slower onset of action and a more prolonged effect than parenteral medications. Patients generally prefer the oral route.

Sublingual Administration

Some medications (e.g., nitroglycerin) are readily absorbed after being placed under the tongue to dissolve (Fig. 31.3). Instruct patients not to swallow a medication given by the **sublingual** route or drink anything until the medication is completely dissolved to ensure that the medication will have the desired effect.

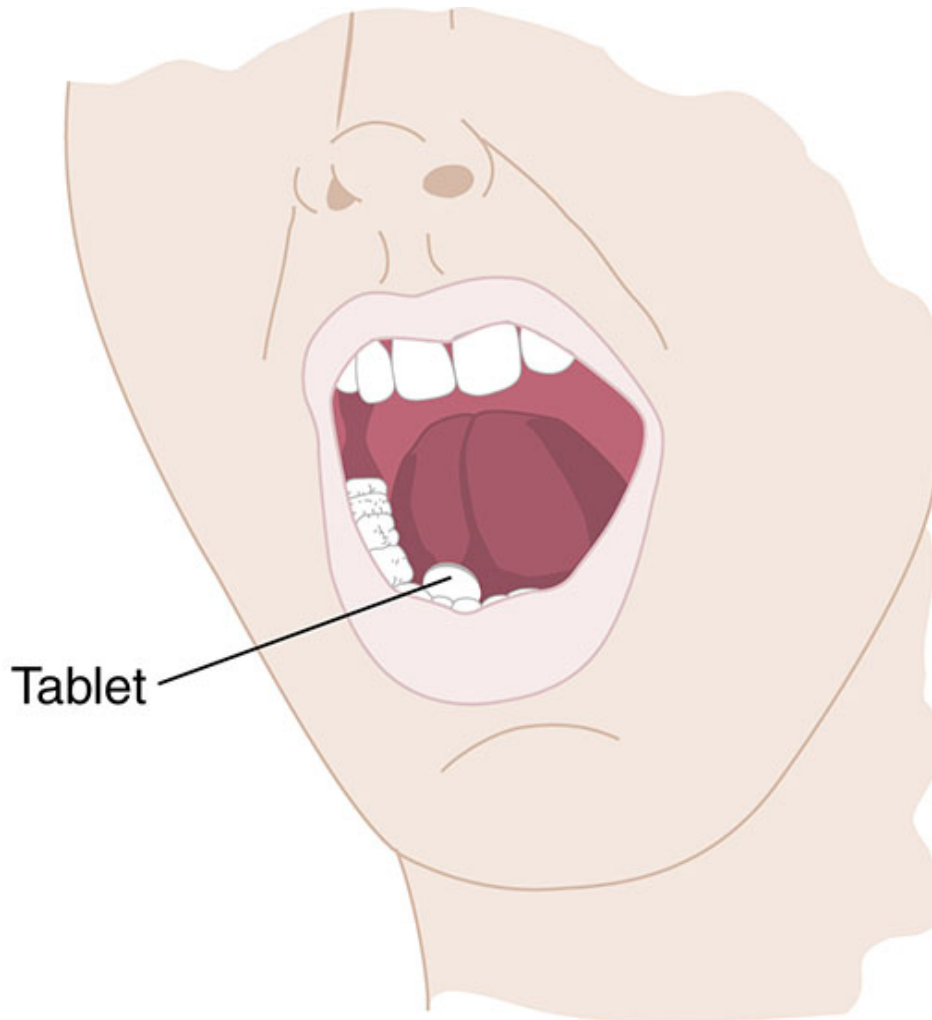

FIG. 31.3 Sublingual administration of a tablet.

Buccal Administration

Administration of a medication by the **buccal** route involves placing the solid medication in the mouth against the mucous membranes of the cheek until it dissolves (Fig. 31.4). Teach patients to alternate cheeks with each subsequent dose to avoid mucosal irritation. Warn patients not to chew or swallow the medication or to take any liquids with it. A buccal medication acts locally on the mucosa or systemically as it is swallowed in a person's saliva.

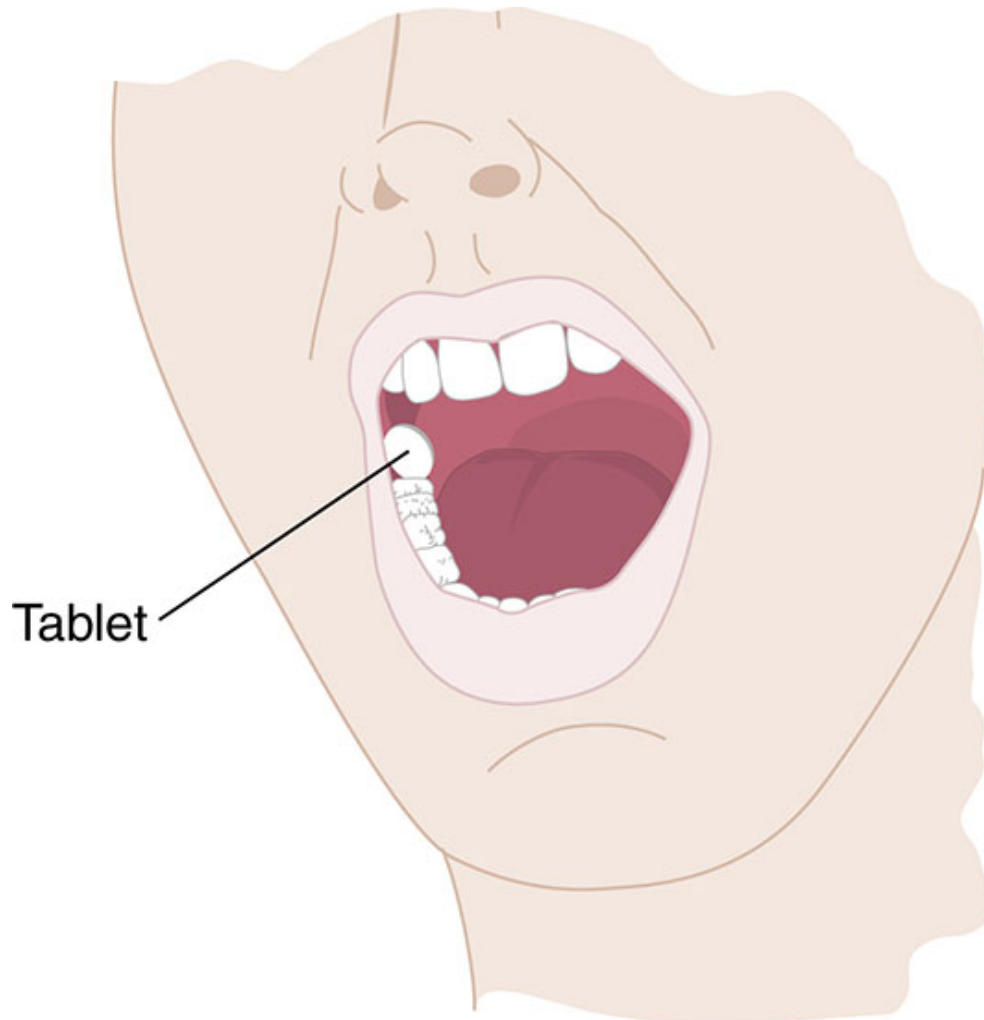

FIG. 31.4 Buccal administration of a tablet.

Parenteral Routes

Parenteral administration involves injecting a medication into body tissues. The following are the four major sites of injection:

1. **Intradermal (ID):** Injection into the dermis just under the epidermis
2. **Subcutaneous:** Injection into tissues just below the dermis of the skin
3. **Intramuscular (IM):** Injection into a muscle
4. **Intravenous (IV):** Injection into a vein

Some medications are administered into body cavities through other routes, including epidural, intrathecal, intraosseous, intraperitoneal,

intrapleural, and intraarterial. Nurses usually are not responsible for the administration of medications through these advanced techniques. Whether or not you actually administer a medication, you remain responsible for monitoring the integrity of the medication delivery system, understanding the therapeutic value of the medication, and evaluating a patient's response to the therapy.

Epidural

Epidural medications are administered in the epidural space via a catheter, which is placed by a nurse anesthetist or an anesthesiologist. This route is used for the administration of regional analgesia for surgical procedures (see [Chapters 44](#) and [50](#)). Nurses who have advanced education in the epidural route can administer medications by continuous infusion or a bolus dose.

Intrathecal

Physicians and specially educated nurses administer intrathecal medications through a catheter surgically placed in the subarachnoid space or one of the ventricles of the brain. Intrathecal medication administration often is a long-term treatment.

Intraosseous

This method of medication administration involves the infusion of medication directly into the bone marrow. It is used most commonly in infants and toddlers who have poor access to their intravascular space or when an emergency arises, and IV access is impossible.

Intraperitoneal

Medications administered into the peritoneal cavity are absorbed into the circulation. Chemotherapeutic agents, insulin, and antibiotics are administered in this fashion.

Intrapleural

A syringe and needle or a chest tube is used to administer intrapleural medications directly into the pleural space. Chemotherapeutic agents are the most common medications administered via this method. Physicians also instill medications that help resolve persistent pleural effusion to

promote adhesion between the visceral and parietal pleura. This is called *pleurodesis*.

Intraarterial

Intraarterial medications are administered directly into the arteries. Intraarterial infusions are common in patients who have arterial clots and receive clot-dissolving agents. A nurse manages a continuous infusion of the clot-dissolving agent and carefully monitors the integrity of the infusion to prevent inadvertent disconnection of the system and subsequent bleeding.

Other methods of medication administration that are usually limited to physician administration are **intracardiac**, an injection of a medication directly into cardiac tissue, and **intraarticular**, an injection of a medication into a joint.

Topical Administration

Medications applied to the skin and mucous membranes generally have local effects. You apply topical medications to the skin by painting or spreading the medication over an area, applying moist dressings, soaking body parts in a solution, or giving medicated baths. Systemic effects often occur if a patient's skin is thin or broken down, the medication concentration is high, or contact with the skin is prolonged. A **transdermal disk** or patch (e.g., nitroglycerin, scopolamine, and estrogens) has systemic effects. The disk secures the medicated ointment to the skin. These topical applications are left in place for as little as 12 hours or up to 7 days.

You apply topical medications to mucous membranes in the following ways:

1. Direct application of a liquid or ointment (e.g., eyedrops, gargling, or swabbing the throat)
2. Insertion of a medication into a body cavity (e.g., placing a suppository in rectum or vagina or inserting medicated packing into vagina)
3. Instillation of fluid into a body cavity (e.g., eardrops, nose drops, or bladder and rectal **instillation** [fluid is retained])
4. Irrigation of a body cavity (e.g., flushing eye, ear, vagina, bladder, or rectum with medicated fluid [fluid is not retained])
5. Spraying a medication into a body cavity (e.g., instillation into nose and throat)

Inhalation Route

The deeper passages of the respiratory tract provide a large surface area for medication absorption. Nurses administer inhaled medications through the nasal and oral passages or endotracheal or tracheostomy tubes. Endotracheal tubes enter the patient's mouth and end in the trachea, whereas tracheostomy tubes enter the trachea directly through an incision made in the neck. Inhaled medications are readily absorbed and work rapidly because of the rich vascular alveolar capillary network present in the pulmonary tissue. Many inhaled medications have local or systemic effects.

Intraocular Route

Intraocular medication delivery involves inserting a medication similar to a contact lens into a patient's eye. The eye medication disk has two soft outer layers that have medication enclosed in them. The nurse inserts the disk into the patient's eye, much like a contact lens. The medication remains in the eye for up to 1 week.

Systems of Medication Measurement

Safely administering medications requires the ability to compute medication doses accurately and measure medications correctly. A careless mistake in placing a decimal point or adding a zero to a dose can lead to a fatal error. Check every dose carefully before giving a medication.

The health care industry in the United States uses primarily the metric system of measurement for medication therapy. Globally most nations use the metric system as their standard of measurement. However, the household system may still be used in medication orders when health care providers write prescriptions, or orders for medications, that are to be administered at home by patients in household measures. The [ISMP \(2011b\)](#) recommends that a household measure can be listed in parentheses in an order immediately following the metric measure, such as 5 mL (1 teaspoonful). Health care providers rarely use the apothecary system, a measurement system that includes ounces, pounds, and pints.

Metric System

As a decimal system, the metric system is the most logically organized. You convert and compute metric units using simple multiplication and division. Each basic unit of measurement is organized into units of 10.

Multiplying or dividing by 10 forms secondary units. In multiplication the decimal point moves to the right; in division the decimal moves to the left. For example:

$$10 \text{ mg} \times 10 = 100 \text{ mg}$$

$$10 \text{ mg} \div 10 = 1 \text{ mg}$$

The basic units of measurement in the metric system are the meter (length), the liter (volume), and the gram (weight). For medication calculations only use the volume and weight units. The metric system uses lowercase or capital letters or a combination of lowercase and capital letters to designate basic units:

Gram = g or GM

Liter = l or L

Milligram = mg

Milliliter = mL

A system of Latin prefixes designates subdivision of the basic units: *deci-* (1/10 or 0.1), *centi-* (1/100 or 0.01), and *milli-* (1/1000 or 0.001). Greek prefixes designate multiples of the basic units: *deka-* (10), *hecto-* (100), and *kilo-* (1000). When writing medication doses in metric units, health care providers and nurses use fractions or multiples of a unit. Convert fractions to decimals.

500 mg or 0.5 g, *not* ½ g

10 mL or 0.01 L, *not* 1/100 L

Many actual and potential medication errors happen with the use of fractions and decimal points. Follow practice standards when medications are ordered in fractions to prevent these errors. For example, to make the decimal point more visible, a leading zero is *always* placed in front of a decimal (e.g., use 0.25, *not* .25). *Never* use a trailing zero (i.e., a zero after a decimal point) because if a health care worker does not see the decimal point, the patient may receive 10 times more medication than that prescribed (e.g., use 5, *not* 5.0) (ISMP, 2017a).

Household Measurements

Most people are familiar with household measures, which include liquid measures such as drops, teaspoons, tablespoons, cups, pints, and quarts. Even though household measurements are convenient and familiar, they are inaccurate. Dose errors have occurred when household measures are used (ISMP, 2018a, Consumer Med Safety, 2018a). As a result, the ISMP recommends a best practice for all oral liquids that are not commercially available as unit-dose products. The liquids should be dispensed by the pharmacy in an oral syringe using metric measurement (ISMP, 2018a). The ISMP also recommends that patients or family caregivers purchase oral liquid dosing devices (oral syringes/cups/droppers) that display only the metric scale. Encourage patients to never use household measuring devices with liquid medications (Table 31.6). Today's over-the-counter (OTC) liquid medications almost always have their own measuring devices (Consumer Med Safety, 2018a).

TABLE 31.6**Equivalents of Measurement**

Metric	Household
1 mL	15 drops (gtt)
5 mL	1 teaspoon (tsp)
15 mL	1 tablespoon (tbsp)
30 mL	2 tablespoons (tbsp)
240 mL	1 cup (c)
480 mL (approximately 500 mL)	1 pint (pt)
960 mL (approximately 1 L)	1 quart (qt)
3785 mL (approximately 4 L)	1 gallon (gal)

Solutions

Nurses use solutions of various concentrations for injections, **irrigations**, and infusions. A **solution** is a given mass of solid substance dissolved in a known volume of fluid or a given volume of liquid dissolved in a known volume of another fluid. When a solid is dissolved in a fluid, the concentration is in units of mass per units of volume (e.g., g/L, mg/mL). You can also express a concentration of a solution as a percentage. For example, a 10% solution is 10 g of solid dissolved in 100 mL of solution. A proportion also expresses concentrations. A $\frac{1}{1000}$ solution represents a solution containing 1 g of solid in 1000 mL of liquid or 1 mL of liquid mixed with 1000 mL of another liquid.

REFLECT NOW

You are teaching a family caregiver of a 5-year-old about administering an oral antibiotic after discharge. What are some important concepts to teach the family caregiver about administering oral medications to children in the home?

Nursing Knowledge Base

In 1999 the Institute of Medicine (IOM) published the book *To Err Is Human: Building a Safer Health System*. This book created national awareness about the effect of medical errors within the health care system. Recently, researchers from Johns Hopkins estimated that more than 250,000 Americans die each year from medical errors (Makary and Daniel, 2016). According to the CDC (2016) more people die from medical errors (e.g., surgical complications, health care–acquired infections, and medication errors) than from chronic lower respiratory diseases, accidents, stroke, Alzheimer’s disease, and diabetes mellitus.

Nurses play an important role in patient safety, especially in the area of medication administration. The safe administration of medications is also an important topic for current nursing researchers (Box 31.2). As a nurse you need to know how to calculate medication doses accurately and understand the different roles that members of the health care team play in prescribing and administering medications. Apply your knowledge and think critically to ensure safe medication administration.

Box 31.2 Evidence-Based Practice Reducing Errors

During Medication Administration

PICOT Question: In health care agencies does the use of computerized prescription order entry (CPOE), automated medication dispensers (AMDs), and bar-code medication administration (BCMA) during medication administration decrease the incidence of medication errors made by nurses when compared with nurses who do not use these health technologies?

Evidence Summary

Adverse medication effects account for about 19% of adverse effects patients experience in health care agencies. They can occur before admission, during the stay, or after discharge. A multisystem approach, including the provider, nurse, and health care system, should be used to prevent medication errors (Zhu and Weingart, 2018).

Application to Nursing Practice

- Everyone administering medications should review the medication list at each patient encounter.

- Be vigilant when handling and administering high-risk medications.
- Consider medications as the cause of any new symptoms.
- Use computerized physician order entry (CPOE) when possible to
 - Standardize practice.
 - Improve legibility of orders.
 - Alert and update health care providers on side effects, drug-drug interactions, and new orders (Rochon, 2019; Zhu and Weingart, 2018).
- Use an electronic medical record when possible and interface this with CPOE if available to improve communication and alert all providers to administration times (Rochon, 2019; Zhu and Weingart, 2018).
- Bar-coding medications linked to patient identification bracelets improves safety and provides one last opportunity to identify a medication error (Fanning et al, 2016; Zhu and Weingart, 2018).
- Use smart pumps to administer intravenous medications.
- Medication reconciliation identifies medication discrepancies and prevents errors.
- Patient, family caregiver, and provider education can be used to prevent medication errors.

Clinical Calculations

To administer medications safely, you need to understand basic mathematics skills to calculate medication doses, mix solutions, and perform a variety of other activities. This is important because medications are not always dispensed in the unit of measure in which they are ordered. Medication companies package and bottle medications in standard dosages. For example, a patient's health care provider orders 20 mg of a medication that is available only in 40-mg vials. Nurses frequently convert available units of volume and weight to desired doses. You use equivalents when performing other nursing actions such as when calculating patients' intake and output and IV flow rates. You are responsible for converting available units of volume and weight to the desired doses. Know the approximate equivalents in all major measurement systems.

Conversions Within One System

Converting measurements within one system is relatively easy; simply divide or multiply in the metric system. To change milligrams to grams, divide by 1000, moving the decimal 3 points to the left.

$$1000 \text{ mg} = 1 \text{ g}$$

$$350 \text{ mg} = 0.35 \text{ g}$$

To convert liters to milliliters, multiply by 1000 or move the decimal 3 points to the right.

$$1 \text{ L} = 1000 \text{ mL}$$

$$0.25 \text{ L} = 250 \text{ mL}$$

To convert units of measurement within the household system, consult an equivalence table. For example, when converting fluid ounces to quarts, you first need to know that 32 ounces is the equivalent of 1 quart. To convert 8 ounces to a quart measurement, divide 8 by 32 to get the equivalent, $\frac{1}{4}$ or 0.25 quart.

Conversion Between Systems

The conversion between systems is becoming less common because of the [ISMP \(2018a\)](#) recommendations for use of the metric system for liquid medication dosing. Even though health care providers are encouraged to

order using the metric system, you may encounter a situation when you calculate the correct dose of a medication by converting weights or volumes from one system of measurement to another. For example, metric units are sometimes converted to equivalent household measures for medication administration at home. To convert from one measurement system to another, always use equivalent measurements. Tables of equivalent measurements are available in all health care agencies. The pharmacist is also a good resource.

The liquids should be dispensed by the pharmacy in an oral syringe using metric measurement (ISMP, 2018a). The ISMP (2018a) also recommends that patients or family caregivers purchase oral liquid dosing devices (oral syringes/cups/droppers) that display only the metric scale. Encourage patients to never use household measuring devices with liquid medications (Table 31.6). Today's over-the-counter (OTC) liquid medications almost always have their own measuring devices (Consumer Med Safety, 2018a).

Dose Calculations

Dosage calculation methods include the ratio and proportion method, the formula method, and dimensional analysis. Use the method that is the most logical and comfortable for you. Use this same method consistently. Before you begin any calculation, make a mental estimate of the approximate and reasonable dosage. If your estimate does not closely match the answer you calculate, you need to recheck your math before preparing and administering the medication. Many nursing students feel uncomfortable or anxious when they have to do medication calculations. To enhance accuracy and decrease your anxiety, think critically about the steps you go through in calculating medications, and practice doing calculations to feel more confident about your math skills.

Most health care agencies require a nurse to double-check calculations with another nurse before giving medications, especially when the risk for giving the wrong medication dose is high (e.g., heparin or insulin). Always have another nurse or health care professional double-check your work if the answer to a medication calculation seems unreasonable or inappropriate.

The Ratio and Proportion Method

A ratio indicates the relationship between two numbers separated by a colon (:). The colon in the ratio indicates the need to use division. Think of

a ratio as a fraction; the number to the left is the numerator, and the number to the right is the denominator. For example, the ratio 1:2 is the same as $1/2$. A proportion is an equation that has two ratios of equal value. Write a proportion in one of three ways:

Example 1: $1:2 = 4:8$

Example 2: $1:2::4:8$

Example 3: $1/2 = 4/8$

In a proportion the first and last numbers are called the *extremes*, and the second and third numbers are called the *means*. When multiplying the extremes, the answer is the same as when multiplying the means. For example, in the previous proportions, multiplying the extremes ($1 \times 8 = 8$) yields the same result as multiplying the means ($2 \times 4 = 8$). Because of this relationship, if you know three of the numbers in the proportion, calculating the unknown fourth number is easy. The numbers need to all be in the same unit and system of measurement. To solve a calculation using the ratio and proportion method, first estimate the answer in your mind. Then set up the proportion, labeling all the terms. Put the terms of the ratio in the same sequence (e.g., $\text{mg} : \text{mL} = \text{mg} : \text{mL}$). Cross-multiply the means and the extremes and divide both sides by the number before the x to obtain the dosage. *Always* label the answer; if the answer is not close to the estimate, recheck the calculation.

Example: The health care provider orders 500 mg of amoxicillin to be administered in a gastric tube every 8 hours. The bottle of amoxicillin is labeled 400 mg/5 mL. Use the following steps to calculate how much amoxicillin to give:

1. **Estimate the answer:** The amount to be given is a little more than the labeled dose per 5 mL (unit dose) that is provided in the solution; therefore, the answer is a little more than 5 mL.
2. **Set up the proportion:**

$$\frac{400 \text{ mg}}{5 \text{ mL}} = \frac{500 \text{ mg}}{x \text{ mL}}$$

3. Cross-multiply the means and the extremes:

$$400x = 500 \times 5$$
$$400x = 2500$$

4. Divide both sides by the number before x:

$$\frac{400x}{400} = \frac{2500}{400}$$
$$x = \frac{2500}{400}$$
$$x = 6.25 \text{ mL}$$

- 5. Compare the estimate in Step 1 with the answer in Step 4:** The answer (6.25 mL) is close to the estimated amount (a little more than 5 mL). Therefore, the answer is correct; prepare and administer 6.25 mL in the patient's gastric tube.

The Formula Method

Using this method requires you to first memorize the formula. Estimate the answer and then place all the information from the medication order into the formula. Label all the parts of the formula and ensure that all measures in the formula are in the same units and system of measurement before calculating the dosage. If the measures are not in the same measurement system, convert the numbers to the same system before calculating the dose. Calculate and label the answer and compare the answer with the estimated answer. If the estimate is not similar to the answer, recheck the calculation. Use the following basic formula when using the formula method:

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$

The dose ordered is the amount of medication prescribed. The dose on hand is the dose (e.g., mg, units) of medication supplied by the pharmacy. The amount on hand is the basic unit or quantity of the medication that contains the dose on hand. For solid medications the amount on hand is often one capsule; the amount of liquid on hand is sometimes 1 mL or 1 L, depending on the container. For example, a liquid medication comes in the strength of 125 mg per 5 mL. In this case 125 mg is the dose on hand, and 5 mL is the amount on hand. The amount to administer is the actual amount of medication the nurse administers. Always express the amount to administer in the same unit as the amount on hand.

Example: The health care provider orders morphine sulfate 2 mg IV. The medication is available in a vial containing 10 mg/mL. The formula is applied as follows:

1. **Estimate the answer:** The medication is a liquid; thus, the answer will be in milliliters (mL). The amount to be given is less than $\frac{1}{2}$ of the dose; thus, the answer will be less than $\frac{1}{2}$ mL.
2. **Set up the formula:**

$$\frac{\text{Dose ordered}}{\text{Dose on hand}} \times \text{Amount on hand} = \text{Amount to administer}$$

$$\frac{2 \text{ mg}}{10 \text{ mg}} \times 1 \text{ mL} = \text{Amount to administer}$$

3. **Calculate the answer:**

$$\frac{2 \text{ mg}}{10 \text{ mg}} \times 1 \text{ mL} = 0.2 \text{ mL}$$

4. **Compare the estimate in Step 1 with the answer in Step 3:** The answer is less than $\frac{1}{2}$ mL; thus, it is close to the estimated answer. Prepare 0.2 mL of the medication in a syringe and administer it to the patient.

Dimensional Analysis

Dimensional analysis is the factor-label or the unit-factor method. There is no need to memorize a formula since only one equation is needed and the same steps are used in solving every medication calculation. Nursing students who use dimensional analysis to calculate medication dosages often find it easier to calculate medications than when they use the formula method. Use the following steps to calculate medication doses by dimensional analysis:

1. Identify the unit of measure that you need to administer. For example, if you are giving a pill, you usually give a tablet or a capsule; for parenteral or liquid oral medications, the unit is milliliters.
2. Estimate the answer.
3. Place the name or appropriate abbreviation for x on the left side of the equation (e.g., x tab, x mL).
4. Place available information from the problem in a fraction format on the right side of the equation. Place the abbreviation or unit that matches what you are going to administer (determined in Step 1) in the numerator.
5. Look at the medication order and add other factors into the problem. Set up the numerator so it matches the unit in the previous denominator.
6. Cancel out like units of measurement on the right side of the equation. You should end up with only one unit left in the equation, and it should match the unit on the left side of the equation.
7. Reduce to the lowest terms if possible and solve the problem or solve for x . Label your answer.
8. Compare your estimate from Step 1 with your answer in Step 2.

Example: The health care provider orders 0.45 g penicillin V potassium through a gastric tube. The vial label reads: penicillin V potassium 125 mg/5 mL.

1. **Identify the unit of measure that you need to administer.** This medication is given in a gastric tube, which is a liquid medication; therefore, the answer will be in milliliters (mL).
2. **Estimate the answer.** The medication order is more than 3 times but less than 4 times the unit dose in the vial; thus, the answer is more than 15 mL but less than 20 mL.
3. **Place the name or appropriate abbreviation for x on the left side of the equation.**

$$x \text{ mL} =$$

4. **Place available information from the problem in a fraction format on the right side of the equation.** Since the medication will be administered in milliliters, place mL in the numerator.

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ mg}}$$

5. **Look at the medication order and add other factors into the problem.** Set up the numerator so it matches the unit in the previous denominator. The order is for 0.45 g, and the medication is available in 125-mg bottles. Knowing that 1 g = 1000 mg, add this conversion to the calculation.

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ mg}} \times \frac{1000 \text{ mg}}{1 \text{ g}} \times \frac{0.45 \text{ g}}{1}$$

6. **Cancel out like units of measurement on the right side of the equation.**

$$x \text{ mL} = \frac{5 \text{ mL}}{125 \text{ mg}} \times \frac{1000 \text{ mg}}{1 \text{ g}} \times \frac{0.45 \text{ g}}{1}$$

7. **Reduce to the lowest terms if possible and solve the problem or solve for x .** Label your answer.

$$\begin{aligned} x \text{ mL} &= \frac{5 \times 1000 \times 0.45}{125} \\ x &= \frac{2250}{125} \\ x &= 18 \text{ mL} \end{aligned}$$

8. **Compare the estimate from Step 2 with the answer in Step 7.** The calculated answer is 18 mL, which is between 15 mL and 20 mL. This matches the estimate made in Step 2. Prepare and administer 18 mL of medication as ordered.

Pediatric Doses

Current evidence shows that children are at a much higher risk for experiencing a medication error than adults, and medication errors in children have a much greater chance of causing serious and even fatal consequences. To prevent medication errors in children ([Beal, 2017](#)):

- Use only the metric system on prescriptions, medication labels, and dosing instruments.
- Never administer medications using household spoons.
- Round all dosing instructions to the nearest 0.1, 0.5, or 1 mL.
- Provide education using hands-on demonstration and return demonstration.

- Consider using picture-based education if low health literacy is a possibility.

Calculating children's medication doses requires caution ([Hockenberry et al., 2019](#)). Even small errors or discrepancies in medication amounts can affect a child's health negatively. A child's age, weight, and maturity of body systems affect the ability to metabolize and excrete medications. Nurses sometimes have difficulty in evaluating a child's response to a medication, especially when he or she cannot communicate verbally. For example, a side effect of vancomycin is ototoxicity. If a child cannot talk yet, it is challenging to assess for ototoxicity. Use the following guidelines when calculating pediatric doses:

1. Most pediatric medications are ordered in milligrams per kilogram (mg/kg). Therefore, weigh the patient in kilograms before administering medications. Avoid converting the patient's weight from pounds to kilograms to prevent errors.
2. Pediatric doses are usually a lot smaller than adult doses for the same medication. You frequently use micrograms and small syringes (e.g., tuberculin or 1 mL).
3. IM doses are very small and usually do not exceed 1 mL in small children or 0.5 mL in infants.
4. Subcutaneous dosages are also very small and do not usually exceed 0.5 mL.
5. Most medications are not rounded off to the nearest tenth. Instead they are rounded to the nearest thousandth.
6. Measure dosages that are less than 1 mL in syringes that are marked in tenths of a milliliter if the dosage calculation comes out even and does not need to be rounded. Use a tuberculin syringe for medication preparation when the medication needs to be rounded to the nearest thousandth.
7. Estimate the patient's dose before beginning the calculation; label and compare the answer with the estimate before preparing the medication.
8. To determine if a dose is safe before giving the medication, compare and evaluate the amount of medication ordered over 24 hours with the recommended dosage.

Different formulas and methods are used to calculate medication dosages in children. The two most common methods of calculating

pediatric dosages are based on a child's weight or BSA. BSA is used in rare situations (e.g., determining chemotherapy doses). Refer to a pediatric or pharmacology resource and consult with the patient's health care provider or the pharmacist if you must calculate a medication based on BSA.

Most of the time you calculate medications based on a child's weight. You can use the ratio and proportion method, the formula method, or dimensional analysis to calculate a pediatric dose using body weight. Refer to the previous sections on ratio and proportion, formula method, and dimensional analysis to select the method easiest for you to use.

Health Care Provider's Role

A physician, nurse practitioner, or physician's assistant prescribes medications by writing an order on a form in a patient's medical record, in an order book, or on a legal prescription pad. Some health care providers use a desktop, laptop, or handheld electronic device to enter medication orders. Many health care agencies implement computerized physician order entry (CPOE) to handle medication orders to decrease medication errors (Zhu and Weingart, 2018). In these systems the health care provider completes all computerized fields before the order for the medication is filled, thus avoiding incomplete or illegible orders.

Sometimes a health care provider orders a medication by telephone or by talking to a nurse in person. An order for a medication or medical treatment made over the telephone is called a *telephone order*. If the order is given verbally to the nurse, it is called a **verbal order**. When a verbal or telephone order is received, the nurse who took the order writes the complete order or enters it into a computer, reads it back, and receives confirmation from the health care provider to confirm accuracy. The nurse indicates the time and the name of the health care provider who gave the order, signs it, and follows agency policy to indicate that it was read back. The health care provider countersigns the order later, usually within 24 hours after giving it. Follow guidelines for taking telephone or verbal orders for medications safely (Box 31.3). Agency policies vary regarding personnel who can take telephone or verbal orders. Nursing students cannot take medication orders of any kind. They give newly ordered medications only after a registered nurse has written and verified the order.

Box 31.3 Guidelines for Telephone and Verbal Orders

- Only authorized staff receive and record telephone or verbal orders. The health care agency identifies in writing the staff who are authorized.
- Clearly identify patient's name, room number, and diagnosis.
- Read back all orders to health care provider (TJC, 2020).
- Use clarification questions to avoid misunderstandings.
- Write "TO" (telephone order) or "VO" (verbal order), including date and time, name of patient, and complete order; sign the name of the health care provider and nurse.
- Follow agency policies; some agencies require documentation of the "read-back" or require two nurses to review and sign telephone or verbal orders.
- The health care provider co-signs the order within the time frame required by the agency (usually 24 hours; verify agency policy).

Common abbreviations are often used when writing orders. Abbreviations indicate dosage frequencies or times, routes of administration, and special information for giving the medication (see [Table 31.3](#)). Medication errors frequently involve the use of abbreviations. [Table 31.7](#) lists abbreviations that are associated with a high incidence of medication errors. Do *not* use these abbreviations when documenting medication orders or other information about medications ([ISMP, 2017a](#); [TJC, 2017](#)). Sometimes abbreviations used by different agencies vary. Check agency policy to determine which abbreviations are acceptable to use and their meaning.

TABLE 31.7**Prohibited and Error-Prone Abbreviations^a**

The abbreviations, symbols, and dose designations found in this table have been reported to ISMP through the USP-ISMP Medication Error Reporting Program as being frequently misinterpreted and involved in harmful medication errors. They should NEVER be used when communicating medical information. This includes internal communications, telephone/verbal prescriptions, computer-generated labels, labels for medication storage bins, medication administration records, and pharmacy and prescriber computer order entry screens. The Joint Commission (TJC) has established a National Patient Safety Goal that specifies that certain abbreviations must appear on the do-not-use list of the accredited organization; they are highlighted with a superscript "b" (^b). However, we hope that you will consider others beyond the minimum TJC requirements. By using and promoting safe practices and educating one another about hazards, we can better protect our patients.

Abbreviations	Intended Meaning	Misinterpretation	Correction
µg	Microgram	Mistaken as "mg"	Use "mcg"
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use "right ear," "left ear," or "each ear"
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use "right eye," "left eye," or "each eye"
BT	Bedtime	Mistaken as "BID" (twice daily)	Use "bedtime"
HS	Half-strength	Mistaken as bedtime	Use "half-strength" or "bedtime"
hs	At bedtime, hours of sleep	Mistaken as half-strength	Use "bedtime" or "half-strength"
IU ^b	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use "units"
o.d. or OD	Once daily	Mistaken as "right eye" (OD—oculus dexter), leading to oral liquid medications administered in the eye	Use "daily"
Per os	By mouth, orally	The "os" can be mistaken as "left eye" (OS—oculus sinister)	Use "PO," "by mouth," or "orally"
q.d. or QD ^b	Every day	Mistaken as q.i.d., especially if the period after the "q" or the tail of the "q" is misunderstood as an "l"	Use "daily"
qhs	Nightly at bedtime	Mistaken as "qhr" or every hour	Use "nightly"
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as "5 every"; the "q" in "sub q" has been mistaken as "every" (e.g., a heparin dose ordered "sub q 2 hours before surgery" misunderstood as every 2 hours before surgery)	Use "subcut" or "subcutaneously"
TIW or tiw	3 times a week	Mistaken as "3 times a day" or "twice in a week"	Use "3 times weekly"
U or u ^b	Unit	Mistaken as the number 0 or 4, causing a 10-fold overdose or greater (e.g., 4 U seen as "40" or 4 u seen as "44"); mistaken as "cc" so dose given in volume instead of units (e.g., 4 u seen as 4 cc)	Use "unit"

Dose Designations and Other Information	Intended Meaning	Misinterpretation	Correction
Trailing zero after decimal point (e.g., 1.0 mg) ^c	1 mg	Mistaken as 10 mg if the decimal point is not seen	Do not use trailing zeros for doses expressed in whole numbers
"Naked" decimal point (e.g., .5 mg) ^b	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Abbreviations such as mg. or mL. with a period following the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period

Drug Name Abbreviations	Intended Meaning	Misinterpretation	Correction
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (The "H" is misinterpreted as "K")	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT250 mg)	Use complete drug name
MgSO ₄ ^b	magnesium sulfate	Mistaken as morphine sulphate	Use complete drug name
MS, MSO ₄ ^b	morphine sulfate	Mistaken as magnesium sulphate	Use complete drug name
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name

Stemmed Drug Names	Intended Meaning	Misinterpretation	Correction
"Nitro" drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name

Symbols	Intended Meaning	Misinterpretation	Correction
3	Dram	Symbol for dram mistaken as "3"	Use metric system
× 3d	For three days	Mistaken as "3 doses"	Use "for three days"
> and <	Greater than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; "<10" mistaken as "40"	Use "greater than" or "less than"
@	At	Mistaken as "2"	Use "at"
&	And	Mistaken as "2"	Use "and"
+	Plus or and	Mistaken as "4"	Use "and"
°	Hour	Mistaken as a zero (e.g., q2° seen as q20)	Use "hr," "h," or "hour"

^a Applies to all orders and medication-related documentation that is handwritten (including free-text computer entry or on preprinted forms).

^b These abbreviations are included on The Joint Commission "minimum list" of dangerous abbreviations, acronyms, and symbols that must be included on the "Do Not Use" list of an organization.

^c Exception: A "trailing zero" may be used only where required to show precision of a reported value (e.g., laboratory test results), in studies that report the size of lesions, or for catheter and tube sizes. A "trailing zero" cannot be used in medication orders or medication-related documentation (ISMP, 2017a).

From The Joint Commission (TJC): *Facts about the Official "Do Not Use" List of Abbreviations*, 2017,

Building Competency in Safety

The health care provider has written the following orders for a 4-year-old patient with otitis media of the right ear. Which orders do you need to clarify before administering the medication? Provide a rationale for your answers, and rewrite the order so that it follows the ISMP current medication order safety guidelines.

Floxin otic solution AS twice a day
Amoxicillin 25 mg/kg/day in divided doses
Acetaminophen 1 teaspoon for fever greater than 38.3° C (101° F)

Types of Orders in Acute Care Agencies

A medication cannot be given to a patient without a health care provider order. The frequency and urgency of medication administration forms the basis for medication orders. Some conditions change the status of a patient's medication orders. For example, in some agencies a patient's preoperative medications are discontinued automatically, and the health care provider writes new medication orders after surgery (see [Chapter 50](#)). Agency policies that surround medication orders vary. Nurses need to be aware of and follow these policies.

Standing Orders or Routine Medication Orders

A standing order is carried out until the health care provider cancels it by another order or a prescribed number of days elapse. Some standing orders indicate a final date or number of treatments or doses. Know your agency policies surrounding the discontinuation of standing orders. The following are examples of standing orders:

Tetracycline 500 mg PO q6h
Decadron 10 mg daily × 5 days

prn Orders

Sometimes the health care provider orders a medication to be given only when a patient requires it. This is a prn order. Use objective and subjective assessment (e.g., severity of pain, body temperature) and discretion in determining whether the patient needs the medication. An example of a prn order is:

Morphine sulfate 2 mg IV q2h prn for incisional pain

This order indicates that the patient needs to wait at least 2 hours between doses and can take the medication if experiencing pain at the incision. When administering prn medications, document assessment findings to show why the patient needs the medication and the time of administration. Frequently evaluate the effectiveness of the medication and record evaluation data appropriately. Unclear orders for prn medications that include a range (e.g., morphine sulfate IM 5-10 mg every

4-6 hours) are a source of medication errors. If a range order is written, ensure that the order follows agency policy for these types of orders. An example of a safer range order is to increase morphine dosage 50% to 100% if pain is moderate to severe based on use of the agency pain scale.

When multiple prn medications with the same action are ordered, the orders need to identify when to use each medication and how to use the medications in relationship to each other. The order below provides an example of a safe prn order for two medications used for treatment of constipation:

Docusate 100 mg PO TID prn constipation for two days and if no results then administer magnesium hydroxide 30 mL PO prn constipation

Single (One-Time) Orders

Sometimes a health care provider orders a medication to be given once at a specified time. This is common for preoperative medications or medications given before diagnostic examinations. The following is an example of a single order:

Ativan 1 mg IV on call to MRI

STAT Orders

A STAT order signifies that a single dose of a medication is to be given immediately and only once. STAT orders are often written for emergencies when a patient's condition changes suddenly. For example:

Apresoline 10 mg IV STAT

Now Orders

A now order is more specific than a 1-time order and is used when a patient needs a medication quickly but not right away, as in a STAT order.

When receiving a now order, the nurse has up to 90 minutes to administer the medication. Only administer now medications 1 time. For example:

Vancomycin 1 g IV piggyback now

Prescriptions

The health care provider writes **prescriptions** for patients who are to take medications outside the hospital. The prescription includes more detailed information than a medication order because the patient needs to understand how to take the medication and when to refill the prescription if necessary. Some agencies require health care providers to write prescriptions for controlled substances on a special prescription pad that is different (e.g., a different color) than the prescription pad used for other medications. Fig. 31.5 illustrates the parts of a prescription.

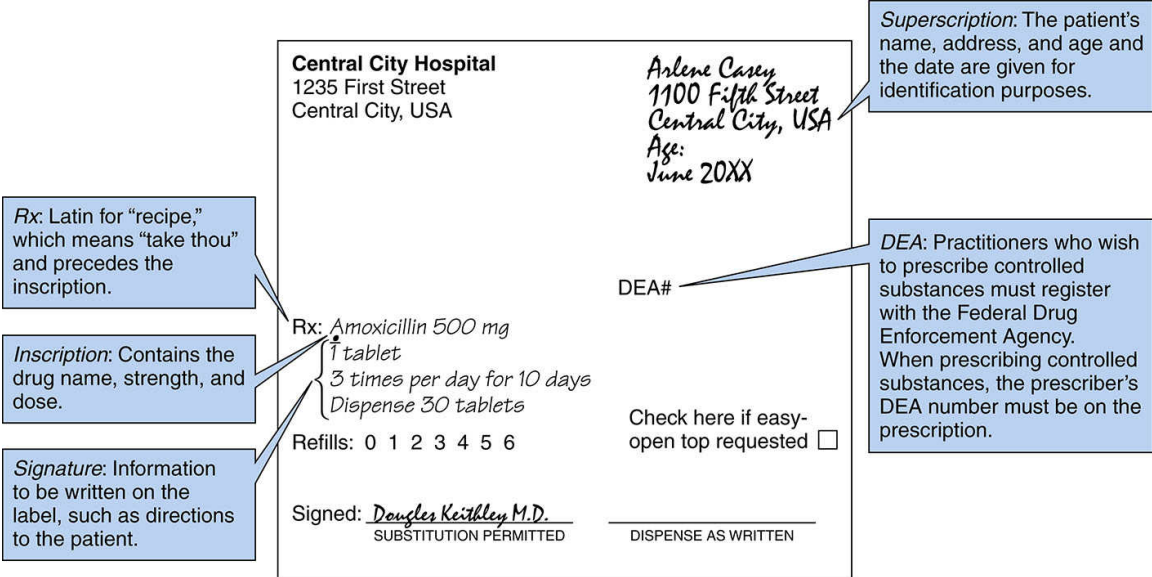

FIG. 31.5 Example of a medication prescription.

Pharmacist's Role

The pharmacist prepares and distributes prescribed medications. Pharmacists work with nurses, physicians, and other health care providers to evaluate the effectiveness of patients' medications. They are responsible for filling prescriptions accurately and being sure that prescriptions are valid. Pharmacists in health care agencies rarely mix compounds or solutions, except in the case of IV solutions. Most medication companies deliver medications in a form ready for use. Dispensing the correct medication, in the proper dosage and amount, with an accurate label is the pharmacist's main task. Pharmacists also provide information about medication side effects, toxicity, interactions, and incompatibilities.

Distribution Systems

Systems for storing and distributing medications vary. Health care agencies have a special area for stocking and dispensing medications. Examples of storage areas include special medication rooms, portable locked carts, computerized medication cabinets, and individual storage units next to patients' rooms. Medication storage areas need to be locked when unattended.

Unit Dose

A unit-dose system is a storage system that varies by health care agency. Pharmacists provide the medications in single-unit packages that contain the ordered dose of medication that a patient receives at one time. Nurses distribute the medications to patients. Each tablet or capsule is wrapped separately. Usually no more than a 24-hour supply of medication is available at any given time. Some unit-dose systems use carts containing a drawer with a 24-hour supply of medications for each patient. Each drawer is labeled with the name of the patient in his or her designated room. At a designated time, each day the pharmacist or a pharmacy technician refills the drawers in the cart with a fresh medication supply. The cart also contains limited amounts of prn and stock medications for special situations. Controlled substances are not kept in an individual patient drawer. Instead they are kept in a larger locked drawer to keep them secure. The unit-dose system reduces medication errors, decreases the amount of medication that is stocked in patient care areas, and saves time for nurses and pharmacists.

Automated Medication Dispensing Systems

Automated medication dispensing systems (AMDSs) are used throughout the country (Fig. 31.6). The systems within an agency are networked with one another and with other agency computer systems (e.g., computerized medical record). AMDSs control the dispensing of all medications, including narcotics. Each nurse accesses the system by entering a security code. Some systems require bio-identification as well. In these systems you place your finger on a screen to access the computer. You select the patient's name and his or her medication profile before the AMDS dispenses a medication. In these systems you can select the desired medication, dosage, and route from a list displayed on the computer screen. The system causes the drawer containing medication to open, records it, and charges it to the patient. Systems that are connected to the patient's computerized medical record then record information about the medication (e.g., medication name, dose, time) and the nurse's name in the patient's medical record. The bar-code medication administration (BCMA) system is often used with AMDSs. BCMA requires nurses to scan bar codes to identify the patient, the medication, and an identification tag of the nurse administering the medication before recording this information in the patient's computerized medical record. Agencies that implement AMDS with BCMA often reduce the incidence of medication errors (see Box 31.2).

FIG. 31.6 Automated medication dispensing system (AMDS).

Nurse's Role

Administering medications requires unique nursing knowledge and skills. You first determine that the medication ordered is the correct medication. As a nurse you need to assess the patient's ability to self-administer medications, determine whether a patient should receive a medication at a given time, administer medications correctly, and then closely monitor their effects. Do not delegate any part of the medication administration process to assistive personnel (AP), and use the nursing process to integrate medication therapy into care.

Patient and family caregiver education about proper medication administration and monitoring is an integral part of your role. Begin instruction about medications that the patient will be taking home as soon as possible. This often does not occur until the day of discharge, but if you can obtain this information sooner, the patient will benefit.

Medication Errors

The [National Coordinating Council for Medication Error Reporting and Prevention \(2018\)](#) defines a **medication error** as any preventable event that may cause inappropriate medication use or jeopardize patient safety. Medication errors include inaccurate prescribing, administering the wrong medication, giving the medication using the wrong route or time interval, administering extra doses, and/or failing to administer a medication. Preventing medication errors is essential. The process of administering medications has many steps and involves many members of the health care team. Because nurses play an essential role in preparing and administering medications, they need to be vigilant in preventing errors ([Box 31.4](#)). Advances in health care informatics have helped to decrease the occurrence of medication errors ([Box 31.5](#)).

Box 31.4 Steps to Take to Prevent Medication Errors

AMDS, Automated medication dispensing system;
MAR, medication administration record.

- Follow the seven rights of medication administration.
- Prepare medications for only one patient at a time.

- Be sure to read labels at least 3 times (comparing MAR with label): (1) when removing medication from storage, (2) before taking to patient's room, and (3) before giving medication.
- Use at least two patient identifiers every time you administer medications (e.g., patient name, birthday, hospital number) whenever administering a medication (TJC, 2020).
- Do not allow any other activity to interrupt administration of medication to a patient (e.g., phone call, pager, discussion with other staff).
- Double check all calculations and other high-risk medication administration processes (e.g., patient-controlled analgesia) and verify with another nurse.
- Do not interpret illegible handwriting; clarify with the health care provider.
- Question unusually large or small doses.
- Document all medications as soon as they are given.
- When you have made or discovered an error, reflect on what went wrong and ask how you could have prevented it. Complete an occurrence report per agency policy.
- Evaluate the context or situation in which a medication error occurred. This helps to determine whether nurses have the necessary resources for safe medication administration.
- When repeated medication errors occur within a work area, identify and analyze the factors that may have caused the errors and take corrective action.
- Attend in-service programs on the medications you commonly administer.
- Ensure that you are well rested when caring for patients. Nurses make more errors when they are tired.
- Involve and educate patients when administering medications. Address patients' concerns about medications before administering them (e.g., concerns about their appearance or side effects).
- Follow established agency policies and procedures when using technology to administer medications (e.g., automated medication dispensing system [AMDS] and bar-code scanning). Medication errors occur when nurses "work around" the technology (e.g., override alerts without thinking about them) (Zhu and Weingart, 2018).

Box 31.5 Informatics and Medication Safety

Many medication errors occur when a nurse incorrectly administers medications at the patient's bedside. The following innovations and advances in technology have helped reduce the number of medication errors in nursing practice.

- Networked computers allow all the patient's health care providers to see a current list of ordered and discontinued medications.
- Internet and intranet access allows nurses and other health care providers to access current information about medications (e.g., indications, desired effects, adverse effects) and specific agency policies that address medication administration (e.g., how fast to administer an intravenous [IV] push medication, how to administer medications through a nasogastric tube).
- In some agencies health care providers use computerized prescription order entry (CPOE), allowing them to enter medication orders directly into a networked computer system or a personal handheld computer (Zhu and Weingart, 2018).
- Automated medication dispensers (AMDs) and electronic medication administration records (eMARs) help with medication reconciliation, administration, and documentation (Fanning et al, 2016; Zhu and Weingart, 2018).
- Bar-coding technology requires nurses to scan the medication, the patient's identification bracelet, and the nurse's identification badge before administering the medication, which helps ensure the seven rights of medication administration.

Application to Nursing Practice

- Actively participate in selecting and evaluating advanced technologies and creating nursing policies and protocols used for medication administration.
- Always follow agency policies when administering medications.
- Implement agency policies when the technology cannot be used (e.g., during down time or power outages).

- Follow manufacturer guidelines for care of electronic equipment, and report problems with technology immediately.

Medication errors can be caused by many factors, such as technology work-arounds, the design of medication labels, and medication distribution systems. When an error occurs, the patient's safety and well-being are the top priorities. You first assess and examine the patient's condition and notify the health care provider of the incident as soon as possible. Once the patient is stable, report the incident to the appropriate person in the agency (e.g., manager or supervisor). You are responsible for preparing and filing an occurrence or incident report as soon as possible after the error occurs. The report includes patient identification information; the location and time of the incident; an accurate, factual description of what occurred and the actions taken; and your signature. The occurrence report is not a permanent part of the medical record and is not referred to anywhere in a patient's medical record to legally protect the nurse and health care agency (see [Chapters 23](#) and [26](#)). Occurrence reports track incident patterns and indicate the need to implement quality improvement actions.

Report all medication errors that reach the patient, including those that do not cause harm. You also need to report near misses. For example, you are caring for a patient who has a urinary tract infection and is allergic to sulfa medications. The patient's health care provider orders trimethoprim/sulfamethoxazole (TMP/SMZ). You know TMP/SMZ contains sulfa. You contact the health care provider before you administer the medication to obtain an order for a different medication. This type of medication error is a near miss because it did not actually reach the patient. All health care workers, including nurses, need to feel comfortable in reporting an error and not fear repercussions from managers or administrators. Even when a patient suffers no harm from a medication error, the agency can still learn why the mistake occurred and what can be done to avoid similar errors in the future.

Some medication errors happen when patients experience a transition in care such as when a patient is admitted or discharged from a hospital, is transferred from an intensive care unit to a general patient care unit, or sees a new health care provider. During these times the risk of unintended changes in medication orders increases. Thus, reconciling medication information is a key Hospital National Patient Safety Goal ([TJC, 2020](#)). During **medication reconciliation** nurses, pharmacists, and other health care providers compare the medication that a patient is taking currently

with what the patient should be taking and any newly ordered medications (Box 31.6). Throughout this process you identify and resolve orders that are duplicated and omitted. You also evaluate the risk for unintended medication interactions. Creating and maintaining an accurate list of all patient medications helps to ensure safe and effective patient care. For example, when you admit a patient who is having a hip replacement to an orthopedic unit, you compare the medications that the patient took at home with those ordered in the hospital. When the patient is discharged to a rehabilitation unit, you communicate the patient's current medications with the nurse who is accepting the patient. The nurse on the rehabilitation unit reconciles the patient's medications when the patient is discharged with the home health nurse. Many agencies have computerized or written forms to facilitate the process of medication reconciliation. The process is challenging and takes a lot of time and concentration. Eliminate distractions and go slowly when reconciling patients' medications. Always clarify information when needed and question for accuracy. Accurate medication reconciliation requires consulting with the patient, family caregivers, other clinicians, pharmacists, and other members of the health care team.

Box 31.6 Process for Medication Reconciliation

1. **Obtain, Verify, Document:** Obtain a comprehensive and current list of a patient's medications whenever he or she experiences a change in health care setting (e.g., during admission, transfer, discharge). Include all current prescriptions, over-the-counter (OTC) medications, and homeopathic products.
2. **Consider and Compare:** Review what the patient was taking at home or preadmission, and make sure that the list of medications, dosages, and frequencies is accurate. Compare this list to the current ordered medications and treatment plan to ensure accuracy. Include family caregiver in this discussion when appropriate.
3. **Reconcile:** Compare new medication orders with the current list; investigate any discrepancies with the patient's health care provider. Document any changes.
4. **Communicate:** Ensure that all the patient's health care providers have the most updated list of medications. Communicate and verify changes in medications as with the patient.

Data from Zhu J, Weingart S: Prevention of adverse drug events in hospitals, *UpToDate*, 2018,

Critical Thinking

Knowledge

You use knowledge from many disciplines when administering medications. Your knowledge helps you understand why a medication is prescribed for a patient and how it will alter the patient's physiology to have a therapeutic effect. For example, in physiology you learn that potassium is a major intracellular ion. When patients do not have enough potassium in their body (hypokalemia), they experience signs and symptoms such as muscle fatigue or weakness. In some cases, severe hypokalemia is fatal because of associated cardiac dysrhythmias. Prescribed medications help to restore the patient's potassium level to normal, which relieves the signs and symptoms of hypokalemia. In another example knowledge about child development indicates that children often associate medication administration with a negative experience. Use principles from child development to ensure that the child cooperates with the medication experience.

Patients take a variety of medications, and new medications are constantly approved. As a result, you will not always understand all the medications ordered for a patient. Critical thinkers admit what they do not know and acquire the knowledge needed to safely administer unfamiliar medications. This means that, when you do not know all the medications you need to administer, you will consult a reliable source (e.g., a more expert nurse, pharmacist, the health care provider, or a reference book) *before* administering the medication.

Experience

Nursing students have limited experience with medication administration as it applies to professional practice. Clinical experiences give you opportunities to use the nursing process as it applies to medication administration. As you gain experience, your psychomotor skills ("the how-to") become more refined. However, psychomotor skills represent a small part of medication administration. Patient attitudes, knowledge, physical and mental status, and responses make medication administration a complex responsibility.

Attitudes

Use your critical thinking skills to administer medications safely. Be disciplined and take adequate time to prepare and administer medications. Take the time to read your patient's medical record before administering medications, and carefully review the patient's history, physical examination, and orders. Look up medications that you do not know in a medication reference, and determine why each patient is taking each of the prescribed medications. Every step of safe medication administration requires a disciplined attitude and a comprehensive, systematic approach. Following the same procedure each time medications are administered ensures safe administration.

Responsibility and accountability are other critical thinking attitudes essential to safe medication administration. Accept full accountability and responsibility for all actions surrounding the administration of medications. Do not assume that a medication that is ordered for a patient is the correct medication or the correct dose. Be responsible for knowing that the medications and doses ordered are correct and appropriate. You are accountable if you give an ordered medication that is not appropriate for a patient. Therefore, be familiar with each medication, including its therapeutic effect, usual dosage, anticipated changes in laboratory data, and side effects. You are also responsible for ensuring that patients or caregivers who administer medications have been properly informed about all aspects of self-administration (TJC, 2020). If you determine that a patient cannot self-administer medications safely, design interventions such as involving family caregivers to ensure safe administration.

Standards

Standards are actions that ensure safe nursing practice. Standards for medication administration are set by health care agencies and the nursing profession. Agency policy sets limits on a nurse's ability to administer medications in certain units of the acute care setting. Sometimes nurses are limited by certain medication routes or dosages. Most agencies have nursing procedure manuals and formularies that contain policies that define the types of medications nurses can and cannot administer. The types and dosages of some medications that nurses deliver vary from unit to unit within the same agency. For example, phenytoin, a medication for treating seizures, may be administered by mouth or IV push. In large dosages phenytoin affects heart rhythm. Therefore, some agencies place limits on how much nurses can administer to a patient on a nursing unit that does not have the ability to monitor a patient's heart rate and rhythm.

Not all health care providers are aware of the limitations and sometimes prescribe medications that nurses cannot give in a particular health care setting. Recognize these limitations and inform the health care provider accordingly. Take appropriate actions to ensure that patients receive medications as prescribed and within the time prescribed in the appropriate environment.

Professional standards such as *Nursing: Scope and Standards of Practice* (ANA, 2015) (see [Chapters 1](#) and [23](#)) apply to the activity of medication administration. To prevent medication errors, follow the seven rights of medication administration consistently every time you administer medications. Many medication errors can be linked in some way to an inconsistency in adhering to these seven rights:

1. The right medication
2. The right dose
3. The right patient
4. The right route
5. The right time
6. The right documentation
7. The right indication

Right Medication

A medication order is required for every medication that you administer to a patient. Sometimes health care providers write orders by hand in the patient's medical record. Alternatively, some agencies use CPOE. CPOE allows a health care provider to order medications electronically, eliminating the need for written orders and enhancing medication safety ([Zhu and Weingart, 2018](#)). Regardless of how a nurse receives a medication order, he or she compares the health care provider's written orders with the medication administration record (MAR) or electronic MAR (eMAR) when it is ordered initially. Nurses verify medication information whenever new MARs are created or distributed or when patients transfer from one nursing unit or health care setting to another.

Once you determine that information on a patient's MAR is accurate, use it to prepare and administer medications. When preparing medications from bottles or containers, compare the label of the medication container with the MAR 3 times: (1) before removing the container from the drawer or shelf, (2) as the amount of medication ordered is removed from the container, and (3) at the patient's bedside

before administering the medication to the patient. Never prepare medications from unmarked containers or containers with illegible labels (TJC, 2020). With unit-dose prepackaged medications, check the label with the MAR when taking medications out of the medication dispensing system. Finally verify all medications at the patient's bedside with the patient's MAR and use at least two identifiers before giving the patient any medications (TJC, 2020).

Patients who self-administer medications need to keep them in their original labeled containers, separate from other medications, to avoid confusion. Many health care agencies require that nurses administer all medications rather than letting patients self-administer to enhance accuracy and patient safety. Because the nurse who administers the medication is responsible for any errors related to it, nurses administer only the medications they prepare. You cannot delegate preparation of medication to another person and then administer the medication to the patient. If a patient questions the medication, do not ignore these concerns. A patient or a family caregiver familiar with a patient's medications often knows whether a medication is different from those received before. In most cases a patient's medication order has changed; however, sometimes patient questions reveal an error. When this occurs, withhold the medication and recheck it against the health care provider's orders. If a patient refuses a medication, discard it rather than returning it to the original container. Unit-dose medications can be saved if they are not opened. If a patient refuses opioids or any controlled substance, follow proper agency procedure by having someone else witness the "wasted" medication.

Right Dose

The unit-dose system is designed to minimize errors. When preparing a medication from a larger volume or strength than needed or when the health care provider orders a system of measurement different from that which the pharmacy supplies, the chance of error increases. You need to have another qualified nurse check the calculated doses when performing medication calculations or conversions. Prepare medications using standard measurement devices such as graduated cups, syringes, and scaled droppers to measure medications accurately. Educate patients to use similar measurement devices at home, such as measuring spoons with metric calibrations rather than household teaspoons and tablespoons, which are inaccurate.

Medication errors occur when pills need to be split. Studies show that the accuracy of split tablets is questionable, even if a tablet is scored (ISMP, 2017c). In addition, in the home setting patients may assume that tablets in containers have already been split when they have not or split them again when they have been split already (ISMP, 2017c). The US FDA (USFDA, 2018b) developed suggestions to help patients split pills. They include ensuring that the tablet is designed to be split, using a tablet splitter and not splitting the entire prescription at one time, and determining whether the patient has the motor dexterity or visual acuity to split tablets. If possible, health care providers need to avoid ordering medications that require splitting.

Tablets are sometimes crushed and mixed with food. Be sure to completely clean a crushing device before crushing the tablet. Remnants of previously crushed medications increase the concentration of a medication or result in the patient receiving part of a medication that was not prescribed. Mix crushed medications with very small amounts of food or liquid (e.g., a single tablespoon). Do not use a patient's favorite foods or liquids because medications alter their taste and decrease the patient's desire for them. This is especially a concern for pediatric patients.

Not all medications are suitable for crushing. Some medications (e.g., extended-release capsules) have special coatings to prevent them from being absorbed too quickly. These medications should not be crushed. Refer to the "Do Not Crush List" (ISMP, 2016a) to ensure that a medication is safe to crush.

Right Patient

Medication errors often occur because a patient gets a medication intended for another patient. Therefore, an important step in safe medication administration is being sure that you give the right medication to the right patient. It is difficult to remember every patient's name and face. Before administering a medication, use at least two patient identifiers (TJC, 2020). Acceptable patient identifiers include the patient's name, his or her medical record number assigned by a health care agency, or a telephone number. Do not use the patient's room number or physical complaint as an identifier. To identify a patient correctly, you usually compare the patient identifiers on the MAR with the patient's identification bracelet while at the patient's bedside. If an identification bracelet becomes smudged or illegible or is missing, obtain a new one. All agencies in all health care settings need to use a system that verifies the patient's

identification with at least two identifiers before administering medications and other treatments.

Patients do not need to state their names and other identifiers when you administer medications. Collect patient identifiers reliably when he or she is admitted to a health care setting. Once the identifiers are assigned to the patient (e.g., putting identifiers on an armband and placing the armband on the patient), you use the identifiers to match the patient with the MAR, which lists the correct medications. Asking patients to state their full names and identification information provides a third way to verify that the nurse is giving medications to the right patient.

In addition to using two identifiers, some agencies use BCMA to help identify the right patient (Fig. 31.7). This system requires nurses to scan a personal bar code that is commonly placed on their name tag first. Then the nurse scans a bar code on the single-dose medication package. Finally, the nurse scans the patient's armband. All this information is then stored in a computer for documentation purposes. This system helps eliminate medication errors because it provides another step to ensure that the right patient receives the right medication (Hutton et al, 2017).

FIG. 31.7 Nurse using bar-code scanner to identify patient during medication administration.

Right Route

Always consult the health care provider if an order does not include a route of administration. Likewise alert the health care provider immediately if the specified route is not the recommended route. Recent evidence shows that medication errors involving the wrong route are common. For example, when nurses need to prepare an oral medication in a syringe, the risk to administer the medication via the wrong route (e.g., intravenously) is very high and often results in fatal consequences. Thus, the [ISMP \(2018a\)](#) recommends that pharmacists, *not nurses*, prepare all oral medications that are not prepared commercially as a unit product to enhance patient safety.

The accidental IV injection of a liquid designed for oral use produces local complications, such as sterile skin abscess, or systemic effects, such as a fatality. If you work in a setting that requires you to prepare oral medications, use only enteral syringes (e.g., ENFit) when you prepare oral medications ([ISMP, 2015c](#)). Enteral syringes often use a color different from the parenteral syringes and are clearly labeled for oral or enteral use. The syringe tips of enteral syringes will not connect with parenteral medication administration systems. Needles do not attach to enteral syringes, and the syringes cannot be inserted into any type of IV line. Label the syringe after preparing the medication and be sure to remove any caps from the tip of an oral syringe before administering the medication.

Right Time

To administer medications safely, you need to know why a medication is ordered for certain times of the day and whether you can alter the time schedule. For example, two medications are ordered, one q8h (every 8 hours) and the other 3 times a day. Both medications are scheduled for 3 times within a 24-hour period. You need to give the q8h medication every 8 hours ATC to maintain therapeutic blood levels of the medication. In contrast, you need to give the 3-times-a-day medication at 3 different times while the patient is awake. Each agency has a recommended time schedule for medications ordered at frequent intervals. You can alter these recommended times if necessary or appropriate.

The health care provider often gives specific instructions about when to administer a medication. A preoperative medication to be given “on call” means that you give the medication when the operating room staff members notify you that they are coming to get a patient for surgery. Give

a medication ordered PC (after meals) within half an hour after a meal, when a patient has a full stomach. Give a STAT medication immediately.

Give priority to time-critical medications that must act and therefore be given at certain times. Hospitals designate which medications are time critical and which are non-time critical (CMS, 2014; ISMP, 2011a). You administer time-critical medications within 30 minutes before or after their scheduled time. For example, give insulin (a time-critical medication) at a precise interval before a meal. Give antibiotics 30 minutes before or after they are scheduled ATC to maintain therapeutic blood levels. Give all routinely ordered non-time-critical medications within 1 to 2 hours before or after the scheduled time or per agency policy (CMS, 2014; ISMP, 2011a).

Some medications require a nurse's clinical judgment in deciding the proper time for administration. Administer a prn sleeping medication when a patient is prepared for bed. In addition, use judgment when administering prn analgesics. For example, you may need to obtain a STAT order from the health care provider if a patient requires a medication before the prn interval has elapsed. Always document when you call a patient's health care provider to obtain a change in a medication order.

Before discharge from the hospital setting, evaluate a patient's need for home care, especially if he or she was admitted to the hospital because of a problem with medication self-administration. Patients often leave the hospital with a basic knowledge of their medications but are unable to remember or implement this knowledge once back home. Before patients are discharged from the hospital, evaluate whether the medications are adequate or prescribed at therapeutic levels for them.

At home some patients take several medications throughout the day. Help to plan schedules based on preferred medication intervals, the pharmacokinetics of the medications, and the patient's daily schedule. For patients who have difficulty remembering when to take medications, make a chart that lists the times to take each one, or prepare a special container to hold each timed dose.

Right Documentation

Nurses and other health care providers use documentation to communicate with one another. Many medication errors result from inaccurate documentation. Therefore, always document medications accurately at the time of administration and identify any inaccurate documentation before you give medications.

Before you administer a medication, ensure that the MAR clearly shows:

- *The patient's full name*
- *The full name of the ordered medication (without abbreviations of medication names)*
- *The time the medication is to be administered*
- *The dosage, route, and frequency of administration*

Common problems with medication orders include incomplete information; inaccurate dosage form or strength; illegible order or signature; incorrect placement of decimals, leading to the wrong dosage; and nonstandard terminology. If there is any question about a medication order because it is incomplete, illegible, vague, or not understood, contact the health care provider before administering the medication. The health care provider is responsible to provide accurate, complete, and understandable medication orders. If he or she is unable to do this, nurses implement agency policy (usually a "chain of command" policy) to determine whom to contact until they resolve issues related to patients' medications. You are responsible to begin this chain of command to ensure that patients receive the correct medication. You are also responsible for documenting any preassessment data required of certain medications such as a blood pressure measurement for antihypertensive medications or laboratory values, as in the case of warfarin, before giving the medication.

After administering a medication, immediately document which medication was given on a patient's MAR per agency policy to verify that it was given as ordered. Inaccurate documentation, such as failing to document giving a medication or documenting an incorrect dose, leads to errors in subsequent decisions about patient care. For example, errors in documentation about insulin often result in negative patient outcomes. Consider the following situation: a patient receives insulin before breakfast, but the nurse who gave the insulin forgot to document it. The nurse caring for the patient goes home, and you are the patient's new nurse for the day. You notice that the insulin is not documented, you assume that the previous nurse did not give the insulin, and you give the patient another dose of insulin. Approximately 2 hours later, the patient experiences a low blood glucose level, which results in seizure activity. Accurate documentation and following up with the nurse from the previous shift to verify that the insulin was given as ordered would have prevented this situation from happening.

Never document that you have given a medication until you have actually given it. Document the name of the medication, the dose, the time of administration, and the route on the MAR. Also document the site of

any injections and the patient's responses to medications, either positive or negative. Notify a patient's health care provider of any negative responses to medications, and document the time, date, and name of the health care provider who was notified in the patient's medical record. The efforts you make to ensure proper documentation help provide safe care.

Maintaining Patients' Rights

In accordance with *The Patient Care Partnership* ([American Hospital Association, n.d.](#)) and because of the potential risks related to medication administration, a patient has the following rights:

- To be informed of the name, purpose, and action of a medication and its potential for undesired effects
- To refuse a medication regardless of the consequences
- To have qualified nurses or physicians assess a medication history, including allergies and use of herbals
- To be properly advised of the experimental nature of medication therapy and give written consent for its use
- To receive labeled medications safely and without discomfort in accordance with the seven rights of medication administration
- To receive appropriate supportive therapy in relation to medication therapy
- To receive no unnecessary medications
- To be informed if medications are a part of a research study

Know these rights and handle all patient and family caregiver questions courteously and professionally. Do not become defensive if a patient refuses medication therapy, recognizing that every person of consenting age has a right to refusal.

Right Indication

ISMP (2016b) is considering a seventh right of medication administration that would enhance the safety of every medication order, the *right indication*. Indication-based prescribing would narrow medication choices, dosage forms, and dosing regimens, which reduces the risk of a wrong medication being chosen ([Schiff et al., 2016](#)). In addition, indication-based prescribing would empower and educate patients, which can improve medication adherence. Communication would be improved between the interprofessional team and the patients and family caregivers. Medication

reconciliation would improve as indication-based prescribing would aid in preventing re-prescribing.

REFLECT NOW

You have three patients in need of 0800 medication administration. One needs a STAT medication on call for the operating room, the second needs routine 0800 medications, and the third needs pain medication, complaining of pain of a 4 on a scale of 0 to 10. Considering the seven rights of medication administration, how do you decide in what order to administer these medications?

◆ **Nursing Process**

Apply the nursing process and use a critical thinking approach in your care of patients. The nursing process provides a clinical decision-making approach for you to develop and implement an individualized plan of care.

◆ **Assessment**

Thoroughly assess each patient and critically analyze findings to ensure that you make patient-centered clinical decisions required for safe nursing care.

Through the Patient's Eyes

Use professional knowledge, skills, and attitudes to provide compassionate and coordinated care. Consider patients' preferences and values while determining their need for and possible responses to medication therapy. Assess their experiences and encourage them to express their beliefs, feelings, and concerns about their medications. For example, ask them how their religious or family backgrounds influence their beliefs about taking medications. Putting patients in the center of their care helps you to see the situation through their eyes and contributes to safe medication administration. Begin your assessment by asking a variety of questions to help you better understand your patients' current medication management routine, their ability to afford medications, and their beliefs and expectations about medications.

History

Before you administer medications, review a patient's medical history to help you understand the indications or contraindications for medication therapy. Some illnesses place patients at risk for adverse medication effects. For example, if a patient has a gastric ulcer, medications containing aspirin increase the likelihood of bleeding. Long-term health problems (e.g., diabetes or arthritis) require specific medications. This knowledge helps you anticipate the type of medications that a patient requires. A patient's surgical history also sometimes indicates the need for medications. For example, after a thyroidectomy a patient requires thyroid hormone replacement.

Allergies

Inform the other members of the health care team if a patient has a history of allergies to medications and foods. Many medications have ingredients also found in food sources. For example, propofol, which is used for anesthesia and sedation, includes egg lecithin and soybean oil as inactive ingredients. Therefore, patients who have an egg or soy allergy should not receive propofol (Skidmore-Roth, 2018). In most health care settings patients wear identification bands listing medication and food allergies. Ensure that all your patient's allergies and their allergic reactions are documented appropriately in the patient's medical record (e.g., history and physical, MAR) to facilitate communication of this essential information to members of the health care team.

Medications

Ask your patients questions to find out about each medication they take (Box 31.7). Possible questions include: How long have you been taking these medications? What is the current dosage of each medication? Do you experience side effects or adverse effects from your medications? In addition, review the action, purpose, normal dosage, routes, side effects, and nursing implications for administering and monitoring each medication. You often need to consult several resources such as pharmacology textbooks; medication manuals available on a computer, electronic tablet, or AMDS; nursing journals; the *Physicians' Desk Reference* (PDR); medication package inserts; and pharmacists to gather necessary information. As a nurse you are responsible for knowing as much as possible about each medication your patients take.

Box 31.7 Nursing Assessment Questions

- Which prescription and nonprescription medications and herbal and nutritional supplements do you take? When do you take them? How do you take them? Do you have a list of medications from your pharmacy or health care provider's office?
- Why do you take these medications?
- Which side effects do you experience? Which of the side effects bother you or affect you negatively?

- What have you been told to do if a side effect develops?
- Have you ever stopped taking your medications? If so, why?
- What do you do to help remember to take your medications?
- Do you have any allergies to medications or foods? If so, which ones? Describe what happens when you take the medication or eat the food.
- Describe your normal eating patterns. Which foods and at what times do you normally eat?
- How do you pay for your medications? Do you sometimes have to stretch your budget to afford them or space them out to save money?
- What questions do you have about your medications?

Diet History

A diet history reveals a patient's normal eating patterns and food preferences. Use your patient's diet history to plan an effective and individualized medication dosage schedule. Teach your patient to avoid foods that interact with medications. In addition, provide education when your patients take medications that need to be taken before, with, or after meals.

Patient's Perceptual or Coordination Problems

Patients with perceptual, fine-motor, or coordination limitations often have difficulty self-administering medications. For example, a patient who takes insulin to manage blood glucose and has arthritis has difficulty manipulating a syringe. Assess the patient's ability to prepare doses and take medications correctly. If a patient is unable to self-administer medications, assess whether a family caregiver or friends are available to help, or make a home care referral.

Patient's Current Condition

The ongoing physical or mental status of a patient affects whether a medication is given and how it is administered. *Assess a patient carefully before giving any medication.* For example, check a patient's blood pressure before giving an antihypertensive. A patient who is vomiting is unable to take medications by mouth. Notify the patient's health care provider when this happens. Assessment findings serve as a baseline in evaluating the effects of medication therapy.

Patient's Attitude About Medication Use

A patient's attitudes about medications (e.g., benefit, risk, likelihood to cure) sometimes reveal a level of medication dependence or medication avoidance. Some patients do not express their feelings about taking a medication, particularly if dependence is a problem. Listen carefully when a patient describes how he or she uses medications to identify evidence of dependence or avoidance. Also, be aware that cultural beliefs about Western medicine sometimes interfere with medication adherence ([Box 31.8](#); see [Chapter 9](#)).

Box 31.8 Cultural Aspects of Care

Influences in Medication Administration

Health beliefs vary by culture and often influence how patients manage and respond to medication therapy. Significant differences in attitudes, regional differences, and socioeconomic status affect a patient's adherence to or preference for medication therapy (Ball et al., 2019). Some cultures attach different symbolic meanings to medications and medication therapy. Herbal remedies and alternative therapies are common in various cultures and ethnic groups and sometimes interfere with prescribed medications (Saper, 2018). Some people stop taking medications when their symptoms are resolved, even if the medications are still needed for management of a chronic illness. In addition, health beliefs often differ markedly between health providers and patients, further affecting a patient's adherence to medical therapy (Ball et al., 2019). In addition to the psychosocial aspect of medication therapy, pharmacological research has shown that differences in medication response, metabolism, and side effects may be affected by patients' ethnicity, genetics, gender, and age (Ball et al., 2019).

Implications for Patient-Centered Care

- Assess cultural beliefs, attitudes, and values when administering medications and teaching patients about self-administration.
- Establish trust with patients and resolve conflicts between medications and cultural beliefs to achieve optimal patient outcomes (Ball et al., 2019).
- Investigate whether the patient practices any alternative therapies or is taking any herbal preparations (Saper, 2018).

- Consider cultural influences on medication response, metabolism, and side effects if a patient is not responding to medication therapy as expected. Confer with health care provider because a change in the patient's medication is sometimes necessary.
- Assess food preferences that may interfere with patients' medication therapy (Betancourt et al., 2018; Saper, 2018).

Factors Affecting Adherence To Medication Therapy

Many complex factors affect a patient's ability to adhere to prescribed medication therapy. For example, a patient's knowledge and understanding of medication therapy influence the willingness or ability to follow a medication regimen. If a patient has a history of poor adherence (e.g., frequently missed doses or failure to fill prescriptions), investigate whether he or she can afford prescribed medications, and review resources available for the purchase of medications if indicated. Also determine whether the patient understands the purpose of the medication, the importance of regular dosage schedules, proper administration methods, and the possible side effects. Without adequate funding, knowledge, and motivation, adherence to medication schedules is unlikely (Ball et al., 2019).

Patient's Learning Needs

Health-related information is difficult to understand because of the use of technical terminology. Serious errors can occur when patients do not understand information about their medications. Assess patients' health literacy regarding medication administration to determine their need for instruction (Betancourt et al., 2018) (see Chapter 25). Have the patient explain the medication schedule of a typical day. Have him or her read a medication label and explain what it includes. Health literacy also includes numeracy. Have a patient show how to give a medication dose if it is necessary to split a pill or give more than one in a container. Consider patient responses to your medication assessment questions such as those listed in Box 31.7. When a patient is unable to answer questions about medications appropriately, assess his or her health literacy.

REFLECT NOW

Using Box 31.8, how would you begin to assess the learning needs of a patient who has his or her own unique cultural, spiritual, or religious beliefs about medication administration?

• Nursing Diagnosis

Assessment provides data about the patient's condition, ability to self-administer medications, and medication adherence. Use these data to determine a patient's actual or potential problems with medication therapy. Certain data are assessment findings that, when clustered together, reveal actual nursing diagnoses. For example, *Complex Medication Regimen related to complexity of medication schedule* is indicated when patients have a complex medication schedule and admit to having difficulty integrating their medications into their daily routine. This list of nursing diagnoses may apply during medication administration in a variety of settings:

- *Impaired Health Maintenance*
- *Lack of Knowledge (Medication)*
- *Nonadherence (Medication Regimen)*
- *Adverse Medication Interaction*
- *Complex Medication Regimen (Polypharmacy)*

After selecting the diagnosis, identify the related factor (if applicable) that drives the selection of nursing interventions. In the example of *Nonadherence*, the related factors of *financial barriers* versus *lack of knowledge about the regimen* require different interventions. If a patient's nursing diagnosis is related to inadequate finances, you collaborate with family caregivers, social workers, case managers, or community agencies to connect the patient with necessary financial resources and develop a medication regimen the patient can afford. If the related factor is *lack of knowledge*, you implement a teaching plan with appropriate follow-up.

• Planning

Always organize your care activities to ensure the safe administration of medications. Rushing to give patients medications leads to errors (Westbrook et al., 2017). It is important to minimize distractions or interruptions when preparing and administering medications (Bravo and Cochran, 2016; Yoder et al., 2015). No-interruption zones (NIZs) have been recommended to reduce distractions and interruptions during medication administration (Yoder et al., 2015). NIZs are created by placing signs, red tape, or some type of border on the floor around medication carts or areas. Nurses standing in these areas are not to be interrupted.

Goals and Outcomes

Setting goals and related outcomes contributes to patient safety and allows for effective use of time during medication administration. For example, a nurse establishes the following goal and related outcomes for a patient with newly diagnosed type 2 diabetes who has the diagnosis of *Lack of Knowledge related to insufficient medication information*:

Goal: The patient will safely self-administer all ordered medications before discharge.

Outcomes:

- The patient verbalizes understanding of desired and adverse effects of medications.
- The patient states signs, symptoms, and treatment of hypoglycemia.
- The patient can monitor blood glucose levels to determine whether it is safe to take medication or an alteration in dose is needed.
- The patient prepares a dose of ordered medication.
- The patient describes a daily routine that will integrate timing of medication with daily activities.

Setting Priorities

Prioritize care when administering medications. Use patient assessment data to determine which medications to give first, whether it is time to evaluate a patient's response to a medication, or whether it is appropriate to administer prn medications. For example, if a patient is in pain, it is important to provide pain medication as soon as possible. If the patient's blood pressure is elevated, administer the blood pressure medication

before other medications. Nurses also prioritize when providing patient education about medications. Provide the most important information about the medications first. For example, hypoglycemia is a serious side effect of insulin. A patient taking insulin needs to be able to identify and treat hypoglycemia immediately; thus, first teach how to recognize and treat hypoglycemia before teaching how to administer an injection.

Teamwork and Collaboration

Collaboration during medication administration is essential. You need to collaborate with a patient's family caregivers whenever possible. Family caregivers and significant others often reinforce the importance of medication schedules when a patient is at home. Nurses often collaborate with patients' health care providers, pharmacists, and case managers to ensure that patients can afford their medications. On discharge ensure that patients know where and how to obtain medications. Be sure that patients can read medication labels and medication teaching information. Some patients also need to understand how to calculate dosages and prepare complex medication regimens. Collaborate with community resources (e.g., agency on aging, public health department, medical interpreters) when patients have significant literacy issues or difficulty in understanding medication instructions (see [Chapter 25](#)).

Implementation

Health Promotion

In promoting or maintaining a patient's health, nurses identify factors that improve or diminish well-being. Health beliefs, personal motivation, socioeconomic factors, and habits influence a patient's adherence with medications. Several nursing interventions promote adherence to the medication regimen and foster independence. Teach a patient and family caregiver about the benefit of a medication and the knowledge needed to take it correctly. Integrate a patient's health beliefs and cultural practices into the treatment plan. Help a patient and family caregiver establish a medication routine that fits into the patient's normal schedule. Make referrals to community resources if a patient is unable to afford or cannot arrange transportation to obtain necessary medications.

Patient and Family Caregiver Teaching

Some patients take medications incorrectly or not at all because they do not understand their medications. When this happens, you need to provide patient education using language your patient understands (see [Chapter 25](#)). Include information about the purpose, actions, timing, dosages, and side effects of medications. Many health care agencies offer easy-to-read teaching sheets written at the sixth-grade level about specific types of medications. Patients need to know how to take medications properly and the risks associated when they fail to do so. For example, after receiving a prescription for an antibiotic, a patient needs to understand the importance of taking the full prescription. Failure to do this can lead to a worsening of the condition and the development of bacteria resistant to the medication. Current recommendations suggest the use of teach-back as a method to confirm patient learning and improve health care provider education ([Betancourt et al., 2018](#)). Have the patient explain the topic about which you instructed him or her, so you can confirm understanding.

Nurses teach patients how to administer their medications correctly. For example, teach a patient how to measure a liquid medication accurately. Provide special education to patients who depend on daily injections ([Box 31.9](#)). The patient learns to prepare and administer an injection correctly using aseptic technique. Teach family caregivers how to give injections in case the patient becomes ill or physically unable to handle a syringe. Provide specially designed equipment such as syringes with enlarged calibrated scales or medications with labels in braille when patients have visual alterations.

Box 31.9 Patient Teaching Safe Insulin

Administration

Objective

- Patient will correctly self-administer subcutaneous insulin.

Teaching Strategies

- Teach patient how to determine whether insulin is expired.

- Instruct patient to keep medication in its original labeled container and refrigerated if needed.
- Demonstrate how to prepare insulin in a syringe, assessing visual acuity to ensure that patient can draw up the correct amount of insulin.
- Coach patient through the steps of administering subcutaneous insulin injection.
- Demonstrate how to rotate insulin injection sites.
- Help patient determine the amount of insulin required based on the results of home capillary glucose monitoring as ordered by the health care provider.
- Show patient how to keep a daily log for insulin injections, including results of home capillary glucose monitoring, type and amount of insulin given, expiration date on insulin vial, time of insulin injection, and injection site used.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Describe for me the procedure you use at home for determining the correct dose of insulin you need and how you select your injection site.
- Please show me how you draw up your insulin based on the results of your capillary glucose monitoring result. Show me how you select your injection site and administer your insulin.
- Review your log with me so I can evaluate it for completeness.

Patients need to know the symptoms of medication side effects or toxicity. For example, patients taking anticoagulants learn to notify their health care providers immediately when signs of bleeding or bruising develop. Inform family caregivers or friends of medication side effects such as changes in behavior because they are often the first to recognize these effects. Patients cope better with problems caused by medications if they understand how and when to act. All patients need to learn the basic guidelines for medication safety, which ensure the proper use and storage of medications in the home.

Acute Care

Patients are often hospitalized to receive expert nursing assessment and documentation of responses to medications. When a nurse receives a medication order, several nursing interventions are essential for safe and effective medication administration.

Receiving, Transcribing, and Communicating Medication Orders

A medication order is required to administer any medication to a patient. In the absence of CPOE, health care providers handwrite orders onto order sheets in a patient's chart. If orders are handwritten, be sure that medication names, dosages, and symbols are legible. Clarify and then rewrite any unclear or illegible transcribed orders.

The process of verifying medical orders varies among health care agencies. Nurses follow agency policy and current national patient safety standards when receiving, transcribing, and communicating medication orders. *Nursing students are prohibited from transcribing or receiving verbal and telephone orders.*

Medication orders need to contain all the elements in [Box 31.10](#). If a medication order is incomplete, inform the health care provider and ensure completeness before carrying it out. Nurses read back verbal or telephone orders to health care providers to ensure that the correct order is obtained. The registered nurse follows agency policy regarding receiving, recording, and transcribing verbal and telephone orders. Generally, the health care provider must sign them within 24 hours.

Box 31.10 Components of Medication Orders

A medication order needs to have all the following parts:

Patient's full name: A patient's full name distinguishes the patient from other people with the same last name. In the acute care setting patients are sometimes assigned special identification numbers (e.g., medical record number) to help distinguish patients with the same names. This number is often included on the order form.

Date and time that the order is written: The day, month, year, and time need to be included. Designating the time that an order is written clarifies when certain orders are to start and stop. If an

incident occurs involving a medication error, it is easier to document what happened when this information is available.

Medication name: A health care provider orders a medication by its generic or trade name. Correct spelling is essential to prevent confusion with medications with similar spelling.

Dosage: The amount or strength of the medication is included.

Route of administration: A health care provider uses only accepted abbreviations for medication routes. Accuracy is important to ensure that patients receive medications by the intended route.

Time and frequency of administration: A nurse needs to know what time and how frequently to administer medications. Orders for multiple doses establish a routine schedule for medication administration.

Signature of health care provider: The signature makes an order a legal request.

Nurses and pharmacists check all medication orders for accuracy and thoroughness several times during the transcription process. They also take patients' current problems, treatments, laboratory values, and other prescribed medications into consideration. Once the nurse and pharmacist determine that a medication order is safe and appropriate, it is placed on the appropriate medication form, usually called the *MAR*. The *MAR* is either printed on paper or available electronically. An electronic version of the *MAR* is called an *eMAR*. Whether it is handwritten, printed from a computer, or in an electronic version, it includes the patient's name, room, and bed number; medical record number; medical and food allergies; other patient identifiers (e.g., birthday); and medication name, dose, frequency, and route and time of administration. Each time a medication dose is prepared, the nurse refers to the *MAR*.

It is essential to verify the accuracy of every medication you give to your patients with the patients' orders. If the medication order is incomplete, incorrect, or inappropriate or if there is a discrepancy between the original order and the information on the *MAR*, consult with the health care provider. Do not give a medication until you are certain that you can follow the seven rights of medication administration. When you give the wrong medication or an incorrect dose, *you* are legally responsible for the error.

Accurate Dose Calculation and Measurement

You calculate each dose when preparing medications. To avoid calculation errors, pay close attention to the process of calculation and avoid interruptions from other people or nursing activities. Ask another nurse to double-check your calculations against the health care provider's order if you are in doubt about the accuracy of your calculation or if you are calculating a new or unusual dose.

Avoidance of Distractions

Research reveals that nurses are frequently distracted during three phases of medication administration—the acquisition of the medication, transportation to the bedside, and during actual administration ([Bravo and Cochran, 2016](#)). Distraction comes from a variety of sources such as a page, a phone call, or a request from a colleague that draws away, disturbs, or diverts attention from a current desired task or forces attention on a new task at least temporarily. Follow these tips:

- Reduce distractions (e.g., turn off pager) and interruptions around automated medication dispensing machines ([Bravo and Cochran, 2016](#)).
- In areas where medications are being prepared, use a brightly colored sign or tape to alert staff to avoid interruptions (e.g., discussions) ([Connor et al., 2016](#)).
- Establish a no-interruption zone (NIZ).
- Provide staff education about the risks of interruptions.
- Create checklists for critical procedures requiring medication administration
- Turn off or manage mobile devices.
- Gather supplies before prescribing, preparing, or administering medication.

REFLECT NOW

Observe two RNs administering medications on the clinical unit to which you are assigned. What types of distractions occurred while the RNs were setting up morning medications? What can you take away from this experience to help you safely set up and administer medications in the future?

Correct Administration

For safe administration follow the seven rights of medication administration. Verify the patient's identity by using at least two patient identifiers (TJC, 2020). In the acute care setting identifiers are usually on a patient's armband. Carefully compare patient identifiers with the MAR to ensure that you are giving the medication to the right patient. Use aseptic technique and proper procedures when handling and giving medications, and perform necessary assessments (e.g., heart rate for antidysrhythmic medications) before administering a medication to a patient. Carefully monitor a patient's response to a medication, especially when the first dose of a new medication is administered.

Recording Medication Administration

Follow all agency policies when documenting medication administration. After administering a medication, appropriately document the name of the medication, dose, route, and exact time of administration immediately. Include the site of any injections per agency policy.

If a patient refuses a medication or is undergoing tests or procedures that result in a missed dose, explain the reason that a medication was not given in the nurses' notes. Some agencies require the nurse to circle the prescribed administration time on the medication record or to notify the health care provider when a patient misses a dose. Be aware of the effects that missing doses may have on a patient (e.g., with hypertension or diabetes). Coordinating care with health care providers and other services when testing or diagnostic procedures are being completed helps ensure patient safety and therapeutic control of the disease.

Restorative Care

Because of the numerous types of restorative care settings, medication administration activities vary. Patients with functional limitations often require a nurse to fully administer all medications. In the home care setting patients usually administer their own medications or receive assistance from family caregivers. Regardless of the type of medication activity, the nurse is responsible for instructing patients and family caregivers in medication action, administration, and side effects. He or she is also responsible for monitoring adherence with medication and determining the effectiveness of medications that have been prescribed.

Special Considerations for Administering Medications To Specific Age-Groups

A patient's developmental level is a factor to consider when administering medications. Knowledge of developmental needs helps you anticipate responses to medication therapy.

Infants and Children

In many pediatric settings the standard of practice is to have another nurse verify all pediatric dose calculations before administration. All children require special psychological preparation before receiving medications. A child's parents are often valuable resources for determining the best way to give a child medication. Sometimes it is less traumatic for a child if a parent gives the medication and the nurse supervises. Supportive care is necessary if a child is expected to cooperate. Explain the procedure to a child, using words appropriate to his or her level of comprehension. Long explanations increase a child's anxiety, especially for painful procedures such as an injection. Providing a child with choices when possible can result in greater success. For example, saying "It's time to take your pill now. Do you want it with water or juice?" allows a child to make a choice. Do not give the child the option of not taking a medication. After the medication has been administered, praise the child and offer a simple reward such as a star or token. Tips for administering medication to children are in [Box 31.11](#).

Box 31.11 Tips for Administering Medications to Children

Oral Medications

- Liquids are safer to swallow than pills to avoid aspiration.
- Use calibrated droppers for administering liquids to infants; the use of straws often helps older children or patients who have difficulty swallowing pills.
- Offer juice, a soft drink, or frozen juice bar, if allowed, after the child swallows a medication.
- When mixing medications in other foods or liquids, use only a small amount. The child may refuse to take all of a larger mixture.
- Avoid mixing a medication in a child's favorite foods or liquids because the child may later refuse them.
- A plastic disposable oral syringe is the most accurate device for preparing liquid doses, especially those less than 10 mL. (Cups, teaspoons, and droppers are inaccurate.)

Injections

- Use caution when selecting intramuscular (IM) injection sites. Infants and small children have underdeveloped muscles. Follow agency policy.
- Children are sometimes unpredictable and uncooperative. Make sure that someone (preferably another nurse) is available to restrain a child if needed. Have the parent act as a comforter, not restrainer, if restraint is necessary.
- Always awaken a sleeping child before giving an injection.
- Distracting a child with conversation, bubbles, or a toy reduces pain perception.
- If time allows, apply a lidocaine ointment (e.g., EMLA cream) to an injection site before the injection to reduce pain perception during the injection.

Older Adults

Adverse medication events occur in 22% or more of older adult patients presenting to health care agencies (Rochon, 2019). The most common serious manifestations include falls, orthostatic hypotension, heart failure, and delirium. Older adults require special nursing considerations during medication administration (Box 31.12). Be vigilant when administering medications and know the physiological changes of aging (Fig. 31.8) so that you can anticipate adverse reactions. Nurses can collaborate with health care providers to minimize adverse medication events in older adults by discontinuing medications, prescribing new medications sparingly, reducing the number of prescribers, and frequently reconciling medications (Rochon, 2019).

Box 31.12 Focus on Older Adults Safety in Medication Administration

- Frequently review a patient's medication history, including use of over-the-counter medications, and consult with health care provider to simplify the medication therapy plan whenever possible (Rochon et al., 2018).
- Keep instructions clear and simple, provide memory aids (e.g., calendar, medication schedule), and ensure that written information about medications is in print large enough for a patient to see (Rochon, 2019; Touhy and Jett, 2017).
- Assess functional status (including vision, hand grasp, fine-motor skills) to determine whether patient will require assistance in taking medications (Touhy and Jett, 2017).
- Some older adults have a greater sensitivity to medications, especially those that act on the central nervous system. Therefore, carefully monitor patients' responses to medications and anticipate dosage adjustments as needed (Touhy and Jett, 2017).
- If patient has difficulty swallowing a capsule or tablet, ask the health care provider to substitute a liquid medication or instruct patient to place medication on the front of the tongue and then swallow fluid to help wash it to the back of the throat. If the patient continues to have problems, have him or her try taking medication with a very small amount of semisolid food (e.g., applesauce) (Touhy and Jett, 2017).

- Teach alternatives to medications such as a proper diet instead of vitamins and exercise instead of laxatives (Rochon, 2019; Touhy and Jett, 2017).

FIG. 31.8 Effects of aging on medication metabolism.
From Lewis SM, et al: *Medical-surgical nursing*, ed 9, St Louis, 2014, Mosby.

Polypharmacy

Polypharmacy is the use of multiple medications, the use of potentially inappropriate or unnecessary medications, or the use of a medication that does not match a diagnosis (Touhy and Jett, 2017). For example, polypharmacy exists when a patient takes two medications from the same chemical class to treat the same illness. Suspect polypharmacy if your patient uses two or more medications with the same or similar actions to

treat several illnesses simultaneously and mixes nutritional supplements or herbal products with medications. Older adults also often experience polypharmacy when they seek relief from a variety of symptoms (e.g., pain, constipation, insomnia, and indigestion) by using OTC preparations. Sometimes polypharmacy is unavoidable. For example, some patients need to take more than one medication to control their high blood pressure. When a patient experiences polypharmacy, the risk of adverse reactions and medication interactions with other medications and food is increased.

Because many older adults suffer chronic health problems, polypharmacy is common. However, it is also becoming more common in children and patients with mental illnesses. Taking OTC medications frequently, lack of knowledge about medications, incorrect beliefs about medications, and visiting several health care providers to treat different illnesses increase the risk for polypharmacy. To minimize risks associated with polypharmacy, frequent communication among health care providers is essential to make sure that the patients' medication regimen is as simple as possible (Rochon, 2019).

• Evaluation

Evaluation of medication administration is an essential role of professional nursing that requires assessment skills; critical thinking; analysis; and knowledge of medications, physiology, and pathophysiology. You need to thoroughly and accurately gather data to complete a holistic evaluation. The goal of safe and effective medication administration is met when a patient responds appropriately to medication therapy and assumes responsibility for self-care. When patients do not experience expected outcomes of medication therapy, investigate possible reasons and determine appropriate revisions to the plan of care.

Through the Patient's Eyes

Evaluation is more effective when you value your patients' participation. Therefore, partner with your patients and include them in the evaluation process. Ensure that they understand and can safely administer their medications. For example, if you are caring for a child who needs an inhaler, be sure to watch the patient use the inhaler. To determine whether patients understand their medication schedules, ask them to explain when they take their medications and whether they can take them as prescribed. When patients struggle with their medication schedule, determine barriers

to adherence (e.g., cost, lack of knowledge) and remove these barriers if possible. Also remember that patients have different values and define health differently. These values and beliefs influence their perception of the effectiveness of their medications. Therefore, ask patients to describe this effectiveness. Ask whether they are satisfied with their medications and how they make them feel. Use patients' statements and responses to questions (e.g., "I feel less anxious now") when determining the effectiveness of medications. Including patients in the evaluation process empowers them and helps them become more actively involved in their care.

Patient Outcomes

A patient's clinical condition can change minute by minute. Use knowledge of the desired effect and common side effects of each medication to compare expected outcomes with actual findings. A change in a patient's condition is often physiologically related to changes in health status or results from medications or both. Be alert for reactions in a patient taking several medications. To evaluate patient responses to medications nurses use a variety of measures, such as direct observation of physiological measures (e.g., blood pressure or laboratory values), behavioral responses (e.g., agitation), and rating scales (e.g., rating on a pain or nausea scale). The type of measurement used varies with the medication action being evaluated, the reading skill and knowledge level of the patient, and the patient's cognitive and psychomotor ability. The most common type of measurement is physiological. Examples of physiological measures are blood pressure, heart rate, and visual acuity. Nurses also use patient statements as evaluative measures. [Table 31.8](#) contains examples of goals, expected outcomes, and corresponding evaluative measures.

TABLE 31.8

Example Evaluation for Patient Goals

Goal	Expected Outcomes	Evaluative Measure with Example
Patient and family caregiver will understand medication therapy.	Patient and family caregiver describe information about medication, dosage, schedule, purpose, and adverse effects.	Written measurement: Have patient write out medication schedule for a 24-hour period. Oral questioning: Use teach-back and ask patient to describe purpose, dosage, and adverse effects of each prescribed medication.
	Patient and family caregiver identify situations that require medical intervention.	Oral questioning: Use teach-back and have family caregiver describe what to do when a patient has adverse effects from a medication.
	Patient and family caregiver demonstrate appropriate administration technique.	Direct observation: Have patient complete return demonstration by filling insulin syringe and administering injection.
Patient will safely self-administer medications.	Patient follows prescribed treatment regimen.	Anecdotal notes: Have family caregiver keep log of patient's adherence to therapy for 1 week.
	Patient performs administration techniques correctly.	Direct observation: Observe patient instill eyedrops.
	Patient identifies available resources for obtaining necessary medication.	Oral questioning: Use teach-back and ask family caregiver to identify how to contact local pharmacy or community clinic for necessary medications.

Medication Administration

A sound knowledge base is required for medications to be administered safely. Nurses need to be prepared to administer medications using a variety of routes.

Oral Administration

The easiest and most desirable route for administering medications is by mouth (see Skill 31.1). Patients usually can self-administer oral medications. Food sometimes affects the absorption, so give oral medications on an empty stomach if absorption is decreased. Likewise, give medications with meals if absorption is enhanced by food (Burchum and Rosenthal, 2019). Most tablets and capsules need to be swallowed and administered with approximately 60 to 240 mL of fluid (as allowed).

Oral medication administration is contraindicated in some situations (see Table 31.5). Many medications interact with nutritional and herbal supplements. You need to be knowledgeable about these interactions to determine the best time to give oral medications.

An important precaution to take when administering any oral preparation is to protect patients from aspiration. Aspiration occurs when food, fluid, or medication intended for GI administration inadvertently enters the respiratory tract. Protect a patient from aspiration by assessing his or her ability to swallow. Box 31.13 provides techniques that protect patients from aspiration. Proper positioning is essential. Position a patient in a seated position at a 90-degree angle when administering oral medications if not contraindicated by his or her condition. Usually having the patient slightly flex the head in a chin-down position reduces aspiration. Use a multidisciplinary approach (e.g., speech therapist, registered dietitian, and occupational therapist) to determine the best techniques for patients who have difficulty swallowing.

Box 31.13 Protecting a Patient From Aspiration

- Allow patient to self-administer medications if possible.
- Know signs of dysphagia (difficulty swallowing): cough, change in voice tone or quality after swallowing, delayed swallowing, incomplete oral clearance or pocketing of food, regurgitation.

- Assess patient's ability to swallow and cough by checking for presence of gag reflex and then offering 50 mL of water in 5-mL allotments. Stop if patient begins to cough.
- Prepare oral medication in form that is easiest to swallow.
- Position the patient in an upright seated position at a 90-degree angle with feet on the floor, hips and knees at 90 degrees, head midline, and back erect if possible and if not contraindicated by his or her condition.
- Suggest that the patient slightly flex the head in a chin-down position before swallowing.
- Prepare oral medications in the form that is easiest to swallow.
- If patient has unilateral (one-sided) weakness, place medication in stronger side of mouth.
- Administer pills one at a time, ensuring that each medication is properly swallowed before next one is introduced.
- Thicken regular liquids or offer fruit nectars if patient cannot tolerate thin liquids.
- Some medications can be crushed and mixed with pureed foods if necessary. Refer to a medication reference to identify medications that are safe to crush.
- Avoid straws because they decrease the control the patient has over volume intake, which increases risk of aspiration.
- Have patient hold and drink from a cup if possible.
- Time medications, if possible, to coincide with mealtimes or when patient is well rested and awake.
- Administer medications using another route if risk of aspiration is severe (see agency policy).

Special consideration is needed when administering medications to patients with enteral or small-bore feeding tubes ([Box 31.14](#)). Failing to follow current evidence-based recommendations from the American Society for Parenteral and Enteral Nutrition (ASPEN) can result in tube obstruction, reduced medication effectiveness, and increased risk of medication toxicity ([Boullata et al., 2017](#)). Tubing misconnections continue to cause patient injury because tubes with different functions can be connected with Luer connectors ([TJC, 2014](#)). In response to this issue the International Organization for Standardization (ISO) ([ISMP, 2015c](#)) has developed tubing connector standards in which the enteral connector will

no longer be Luer compatible. A new enteral-only connector (ENFit) is available, and health care agencies have changed enteral nutrition practices, policies, procedures, and processes per the new guidelines (TJC, 2014). Before giving a medication by this route, verify that the location of the tube (e.g., stomach or jejunum) is compatible with medication absorption. For example, iron dissolves in the stomach and is mostly absorbed in the duodenum. If it is administered through a jejunal tube, it has poor bioavailability.

Box 31.14 Procedural Guidelines Administering Medications Through an Enteral Tube (Nasogastric Tube, G-Tube, J-Tube, or Small-Bore Feeding Tube) Delegation and Collaboration

The skill of administering medications by enteral feeding tubes cannot be delegated to assistive personnel (AP). The nurse instructs the AP to:

- Keep the head of the bed elevated a minimum of 30 degrees (preferably 45 degrees) for 1 hour after medication administration; follow agency policy.
- Report immediately to the nurse coughing, choking, gagging, or drooling of liquid or dissolved pills.
- Report to the nurse any occurrence of possible medication side effects (specific to medication).

Equipment

Medication administration record (MAR) (electronic or printed), appropriate medication syringe or 60-mL Asepto syringe for large-bore tubes only, enteral-only connector (ENFit) designed to fit the specific enteral tube (TJC, 2014) (see illustration), gastric pH test strip (scale of 0 to 11.0), graduated container, medication to be administered, pill crusher if medication in tablet form, water or sterile water for immunocompromised patients, tongue blade or straw to stir dissolved medication, clean gloves, and pulse oximeter (for evaluation).

Enteral-only connector (ENFit).

Steps

1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indication and nursing implications.
3. Assess for any contraindications to receiving enteral medications, including presence of bowel inflammation, reduced peristalsis, recent gastrointestinal (GI) surgery, and gastric suction that cannot be turned off.
4. Avoid complicated medication schedules that often interrupt enteral feedings. Use alternative routes of medication administration if possible (e.g., transdermal, rectal, IV).
 - a. Determine where medication is absorbed and ensure that point of absorption is not bypassed by feeding tube. For example, some medications such as antacids are absorbed in stomach, not jejunum.

- b. Determine whether medication interacts with enteral feeding. If so, hold the feeding for at least 30 minutes before giving the medication (see agency policy or consult pharmacist).
5. Assess patient's medical, medication, and diet history and history of allergies. List patient's food and medication allergies on each page of the MAR, and prominently display it on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet. If you identify contraindications, withhold medication and inform health care provider.
6. For a postoperative patient, review the postoperative orders for type of enteral tube care.
7. Perform hand hygiene. Gather and review physical assessment data (e.g., bowel sounds, abdominal distention) and laboratory data (e.g., renal and liver function) that may influence medication administration.
8. Check with pharmacy for availability of liquid preparation for patient's medications. The health care provider may need to change dosage form.
9. Before administration of enteral medications, verify placement of feeding tube according to agency policy and determine that tube is placed in the stomach or small intestine correctly.
10. Assess patient's or family caregiver's knowledge, experience, and health literacy.
11. Perform hand hygiene. Collect equipment and MAR.
12. Prepare medications for instillation into feeding tube. Attend to procedure and avoid distractions. Check medication label against MAR two times—when removing medication from unit dose or automated medication dispensing system (AMDS) and before leaving medication preparation area. *These are the first and second checks for accuracy.* Fill graduated container with 50 to 100 mL of tepid water. Use sterile water for immunocompromised or critically ill patients (Boullata et al., 2017).

CLINICAL DECISION: Whenever possible, use liquid medications instead of crushed tablets. If you must crush tablets, flush the tubing before and after the medication administration to prevent the medication from adhering to the inside of the tube. In addition, make sure that concentrated medications are thoroughly diluted. Never add crushed medications directly to a tube feeding (Boullata et al., 2017).

- a. *Tablets*: Crush each tablet into a fine powder, using pill-crushing device or two medication cups. Dissolve each tablet in separate cup of 30 mL of warm water.
 - b. *Capsules*: Apply clean gloves. Ensure that contents of capsule (granules or gelatin) can be expressed from covering (consult with pharmacist). Open capsule or pierce gel cap with sterile needle and empty contents into 30 mL of warm water (or solution designated by drug company). Gel caps dissolve in warm water, but this may take 15 to 20 minutes. Remove and dispose of gloves.
 - c. Prepare liquid medication (prepared by pharmacy in appropriate syringe).
 - d. Perform hand hygiene.
13. Take medication(s) to patient at correct time (see agency policy). Consider if medication is time critical. During administration apply seven rights of medication administration.
 14. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
 15. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies. *This is the third check for accuracy.*
 16. Explain procedure to patient and discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about medications.
 17. Assist patient to sitting position. Elevate head of bed to minimum of 30 degrees and preferably 45 degrees (unless contraindicated) or sit patient up in a chair (Boullata et al., 2017).
 18. If continuous enteral tube feeding is infusing, adjust infusion pump setting to hold tube feeding.
 19. Perform hand hygiene. Apply clean gloves. Check placement of feeding tube by observing gastric contents and checking pH of aspirate contents. *Gastric pH less than 5.0 is a good indicator that tip of tube is correctly placed in stomach* (Boullata et al., 2017; Clifford et al., 2015).
 20. Check for gastric residual volume (GRV). Draw up 10 to 30 mL of air into a 60-mL syringe and connect syringe to feeding tube. Flush tube with air and pull back slowly to aspirate gastric contents.

Determine GRV using either scale on syringe or a graduated container. If GRV exceeds 500 mL, hold feeding for 2 hours and recheck (Boullata et al., 2017) (check agency policy). When GRV is excessive, hold medication and contact health care provider.

21. Irrigate the tubing.
 - a. Pinch or clamp enteral tube and remove syringe. Draw up 30 mL of water into syringe. Reinsert tip of syringe into tube, release clamp, and flush tubing. Clamp tube again and remove syringe.
 - b. Using the appropriate enteral connector, attach to enteral tube.
22. Remove bulb or plunger of syringe and reinsert syringe into tip of feeding tube.
23. Administer dose of first liquid or dissolved medication by pouring into syringe. Allow to flow by gravity.

CLINICAL DECISION: Verify that the connector meets the ISO tubing connector standards (Boullata et al., 2017; TJC, 2014). Do not attach the enteral tubing to a standardized Luer syringe or needleless device (Guenther, 2015; TJC, 2014). **CLINICAL DECISION:** Sometimes it is necessary to transfer oral medications into a medication cup for enteral administration. If medication does not flow freely, raise the height of the syringe to increase the rate of flow or try having the patient change position slightly because the end of the feeding tube may be against the gastric mucosa. If these measures do not improve the flow, a gentle push with bulb of Asepto syringe or plunger of the syringe may facilitate flow of fluid.

- a. If giving only one dose of medication, flush tubing with 30 to 60 mL of water after administration.
 - b. To administer more than one medication, give each separately and flush between medications with 15 to 30 mL of water.
 - c. Follow last dose of medication with 30 to 60 mL of water.
24. Clamp proximal end of feeding tube if tube feeding is not being administered, and cap end of tube.
 25. When continuous tube feeding is being administered by infusion pump, follow medication administration policy for turning off feedings prior to administering medications. If medications are not

compatible with feeding solution, hold feeding for additional 30 to 60 minutes (Boullata et al., 2017).

26. Help patient to comfortable position and keep head of bed elevated, if not contraindicated, for 1 hour (see agency policy).
27. Be sure nurse call system is in an accessible location within patient's reach.
28. Raise side rails (as appropriate) and lower bed to lowest position.
29. Dispose of soiled supplies, rinse graduated container and syringe with tap water, remove and dispose of gloves, and perform hand hygiene.
30. Document name of medication, dose, route, and time administered on MAR. Document patient's response in nurses' notes of MAR in the electronic health record (EHR) or chart.
31. Record patient teaching and validation of patient's understanding on flow sheet or nurses' notes in electronic health record (EHR) or chart.
32. Observe patient for signs of aspiration such as choking, gurgling, gurgling speech, breath sounds, and difficulty breathing.
33. Return within 30 minutes to evaluate patient's response to medications.
34. **Use Teach-Back:** "I want to be sure I explained clearly why your father must take his medications through his feeding tube. Tell me why he is receiving his medications through his feeding tube." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly. Determines patient's/family caregiver's level of understanding of instructional topic.

Use liquid medications when possible. When liquid medications are unavailable, crush simple tablets or open capsules and dilute them in water. Pierce a gel cap with a sterile needle and empty the contents into 30 mL of warm water or other solution as designated by the manufacturer of the medication. You can dissolve gel caps in warm water, but this often takes 15 to 20 minutes. Only use oral syringes when preparing medications for this route to prevent accidental parenteral administration. Flush tubes with at least 30 mL of water before and after giving medications. When administering more than one medication at a time, give each separately and flush between medications with 15 to 30 mL of water. Determine whether medications need to be given on an empty stomach or if they are compatible with the patient's enteral feeding. If a

medication needs to be given on an empty stomach or is incompatible with the feeding (e.g., phenytoin, carbamazepine, warfarin, fluoroquinolones, proton pump inhibitors), hold the feeding for at least 30 minutes before or 30 minutes after medication administration. Verify the time with a medication reference or consult with a pharmacist. Monitor the patient closely for adverse reactions. The risk for drug-drug interactions is high when two or more medications are given in this route because they can interact together as soon as they are administered.

Topical Medication Applications

Topical medications are medications that are applied locally, most often to intact skin. They come in many forms (see [Table 31.1](#)). They are also applied to mucous membranes.

Skin Applications

Because many locally applied medications such as lotions, pastes, and ointments create systemic and local effects, apply these medications with gloves and applicators. Use sterile technique if a patient has an open wound. Skin encrustation and dead tissues harbor microorganisms and block contact of medications with the tissues to be treated. Before applying medications, clean the skin thoroughly by washing the area gently with soap and water, soaking an involved site, or locally debriding tissue.

Apply each type of medication according to directions to ensure proper penetration and absorption. When applying ointments or pastes, spread the medication evenly over the involved surface and cover the area well without applying an overly thick layer. Health care providers sometimes order a gauze dressing to be applied over the medication to prevent soiling clothes and wiping away the medication. Lightly spread lotions and creams onto the surface of the skin; rubbing often causes irritation. Apply a liniment by rubbing it gently but firmly into the skin. Dust a powder lightly to cover the affected area with a thin layer.

Some topical medications are applied in the form of a transdermal patch that remains in place for an extended amount of time (e.g., 12 hours or 7 days). Before applying a new patch, don disposable gloves and remove the old one. Medication remains on the patch even after its recommended duration of use. Nurses and patients have inadvertently left old transdermal patches in place, resulting in the patient receiving an overdose of the medication. For example, patients who use fentanyl transdermal patches for pain management can experience respiratory

depression, coma, and death when the patches are not removed. In addition, some people, especially children, have experienced life-threatening harm from accidental exposure to fentanyl patches that were not disposed of properly. Many patches are clear, which makes them difficult to see. Therefore, carefully assess the patient's skin and be sure to remove the existing patch before applying a new one. Follow these guidelines to ensure safe administration of transdermal or topical medications:

- When taking a medication history or reconciling medications, specifically ask patients if they take any medications in the forms of patches, topical creams, or any route other than the oral route.
- When applying a transdermal patch, ask the patient whether he or she has an existing patch.
- Wear disposable clean gloves when removing and applying transdermal patches.
- If the dressing or patch is difficult to see (e.g., clear), apply a noticeable label to the patch.
- Document on the MAR the location on the patient's body where the medication was placed.
- Document removal of the patch or medication on the MAR. Fold sticky sides of the patch together and dispose of the patch in a childproof container. There are exceptions; a fentanyl patch, an adhesive patch that delivers a potent pain medication through the skin, comes with instructions to flush used or leftover patches ([USFDA, 2018a](#)). Always read package directions.

Nasal Instillation

Patients with nasal sinus alterations sometimes receive medications by spray, drops, or tampons ([Box 31.15](#)). The most common form of nasal instillation is via decongestant spray or drops, used to relieve symptoms of sinus congestion and colds. Caution patients to avoid abuse of medications because overuse leads to a rebound effect in which the nasal congestion worsens. When excess decongestant solution is swallowed, serious systemic effects also develop, especially in children. Saline drops are safer than nasal preparations that contain sympathomimetics (e.g., oxymetazoline or phenylephrine) as a decongestant for children.

Box 31.15 Procedural Guidelines Administering Nasal Medications

Delegation and Collaboration

The skill of administering nasal medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting any bloody nasal drainage to the nurse.

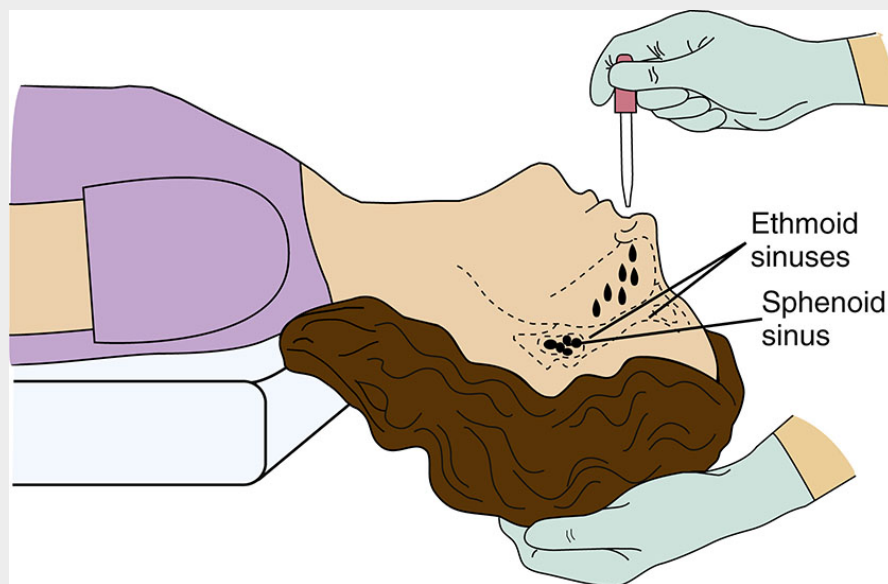

Equipment

Medication administration record (MAR) (electronic or printed), prepared medication with clean dropper or spray container, facial tissue, small pillow (*optional*), washcloth (*optional*), clean gloves

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name and medication name, dosage, route (which sinus), and time of administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
3. Assess patient's medical history (e.g., hypertension, heart disease, diabetes, and hyperthyroidism), medication history, and history of allergies. List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.
4. Perform hand hygiene. Using a penlight, inspect condition of nose and sinuses. Palpate sinuses for pain or tenderness (see Chapter 30). Note type of drainage if present.
5. Assess patient's knowledge regarding use of nasal instillation, technique for instillation, and willingness to learn self-administration.
6. Perform hand hygiene. Collect appropriate equipment and MAR.

7. Prepare medications for instillation. Attend to procedure to avoid distractions. Check label of medication against MAR two times (see Skill 31.1). Preparation usually involves checking label when removing nasal drops or sprays out of storage and before leaving preparation area. Check expiration date on container. *These are the first and second checks for accuracy.* Perform hand hygiene.
8. Take medication(s) to patient at correct time (see agency policy). Consider whether medication is time critical. During administration, apply seven rights of medication administration.
9. Identify patient using two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.

STEP 14a(2) Position for instilling nose drops into ethmoid or sphenoid sinus.

10. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies. *This is the third accuracy check.*
11. Explain procedure to patient and sensations to expect. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about medications. Patients who self-instill medications may be allowed to give drops under nurse's

supervision (check agency policy). Tell patients receiving nasal instillation that they may experience burning or stinging of mucosa or choking sensation as medication trickles into throat.

12. Arrange supplies and medications at bedside. Perform hand hygiene and apply clean gloves (if nasal drainage is present).
13. Gently roll or shake container. Instruct patient to clear or blow nose gently unless contraindicated (e.g., risk of increased intracranial pressure or nosebleeds).

14. *Administer nasal drops:*

a. Help patient to supine position and position head properly.

(1) For access to posterior pharynx, tilt patient's head backward.

(2) For access to ethmoid or sphenoid sinus, tilt head back over edge of bed or place small pillow under patient's shoulder and tilt head back (see illustration).

(3) For access to frontal and maxillary sinus, tilt head back over edge of bed or pillow with head turned toward side to be treated (see illustration).

b. Support patient's head with nondominant hand.

c. Instruct patient to breathe through mouth.

d. Hold dropper 1 cm ($\frac{1}{2}$ inch) above nares and instill prescribed number of drops toward midline of ethmoid bone.

e. Have patient remain in supine position 5 minutes.

f. Offer facial tissue to blot runny nose, but caution patient against blowing nose for several minutes.

15. *Administer nasal spray:*

a. Help patient into upright position with head tilted slightly forward.

b. Instruct or assist patient to insert tip of nasal spray into appropriate nares and occlude other nostril with finger. Point spray tip toward side and away from center of nose.

c. Have patient spray medication into nose while inhaling. Help patient remove nozzle from nose and instruct to breathe out through the mouth.

d. Offer facial tissue to blot runny nose, but caution patient against blowing nose for several minutes.

CLINICAL DECISION: Some medications are designed for one spray per dose. Examples include calcitonin, desmopressin, and sumatriptan. It

is essential to ensure that the patient understands the correct number of sprays to use per dose to prevent overdosing.

STEP 14a(3) Position for instilling nose drops into frontal and maxillary sinus.

16. Help patient to a comfortable position after medication is absorbed.
17. Dispose of soiled supplies, remove and dispose of gloves, and perform hand hygiene.
18. Document name of medication, dose, route, and time of administration on MAR.
19. Observe patient for onset of side effects 15 to 30 minutes after administration.
20. Ask whether patient can breathe through nose after decongestant administration. It may be necessary to have patient occlude one nostril at a time and breathe deeply.
21. Reinspect condition of nasal passages between instillations.
22. Ask patient to describe risks of overuse of decongestants and methods for administration.
23. Feedback ensures that patient can self-administer medications properly.
24. Have patient demonstrate self-administration of nasal medication.

25. Record patient response to medication, patient teaching, and validation of patient understanding and self-administration on flow sheet or nurses' notes in electronic health record (EHR) or chart.
26. **Use Teach-Back:** "I want to be sure I explained your nasal spray correctly. Can you tell me the best time for you to use this spray? What side effects may you get from using the spray?" If patient self-administers medications at home, state, "Show me how you're going to take this medication at home." Revise your instruction now or develop plan for revised teaching if patient/family caregiver is not able to teach back correctly. Determines patient's/family caregiver's level of understanding of instructional topic.

It is easier to have patients self-administer sprays because they can control the spray and inhale as the medication enters the nasal passages. For patients who use nasal sprays repeatedly, check the nares for irritation. When used to treat a sinus infection, position patients to permit the nasal medication to reach the affected sinus. Severe nosebleeds are usually treated with packing or nasal tampons, which are treated with epinephrine, to reduce blood flow. Usually a health care provider places nasal tampons.

Eye Instillation

Some patients use OTC eyedrops and ointments such as artificial tears and vasoconstrictors (e.g., Visine and Murine). Other patients, especially older adults, receive prescribed **ophthalmic** medications for eye conditions such as glaucoma or after cataract extraction. Age-related problems, including poor vision, hand tremors, and difficulty grasping or manipulating containers, affect an older adult's ability to self-administer eye medications. Educate your patients and family caregivers about the proper techniques for administering them (see Skill 31.2). Evaluate a patient's and family caregiver's ability to self-administer through a return demonstration of the procedure. Show patients each step for instilling eyedrops to help them understand the procedure. Follow these principles when administering eye medications:

- Avoid instilling any form of eye medications directly onto the cornea. The cornea of the eye has many pain fibers and thus is very sensitive to anything applied to it.

- Avoid touching the eyelids or other eye structures with eyedroppers or ointment tubes. The risk of transmitting infection from one eye to the other is high.
- Use eye medication only for the patient's affected eye.
- Never allow a patient to use another patient's eye medications.

Intraocular Administration

One less common way to administer eye medications is by the intraocular route (see Skill 31.2). These medications resemble a contact lens. You place the medication into the conjunctival sac, where it remains for up to 1 week. You need to teach patients how to insert and remove the disk and to monitor for adverse medication reactions.

Ear Instillation

Because internal ear structures are very sensitive to temperature extremes, you need to instill eardrops at room temperature to prevent vertigo, dizziness, or nausea. Although the structures of the outer ear are not sterile, sterile solutions are used in case the eardrum is ruptured. The entrance of nonsterile solutions into middle ear structures often results in infection.

If a patient has ear drainage, check with the health care provider to be sure that the patient does not have a ruptured eardrum before instilling the drops. Never occlude or block the ear canal with the dropper or irrigating syringe. Forcing medication into an occluded ear canal creates pressure that injures the eardrum. [Box 31.16](#) provides guidelines for administering eardrops.

Box 31.16 Procedural Guidelines Administering Ear Medications

Delegation and Collaboration

The skill of administering ear medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential side effects of medications and to report their occurrence.
- The potential for dizziness or irritation after administration of ear medications.

Equipment

Medication administration record (MAR) (electronic or printed)

Drops: Medication bottle with dropper, cotton-tipped applicator, cotton balls, clean gloves if drainage is present

Irrigation: Irrigating solution and syringe, kidney basin, towel

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, route, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review pertinent information related to medication, including action, purpose, normal dose and route (one or both ears), side effects, time of onset and peak action, and nursing implications.
3. Assess patient's medical history, medication history, and history of allergies (including latex). List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.
4. Perform hand hygiene. Assess condition of external ear structures (see Chapter 30). This may be done just before medication instillation (apply clean gloves if drainage is present).
5. Determine whether patient has any symptoms of ear discomfort or hearing impairment.
6. Assess patient's level of consciousness (LOC) and ability to follow directions.
7. Assess patient's knowledge regarding medication therapy and desire to self-administer medication.
8. Assess patient's ability to manipulate and hold ear dropper.
9. Perform hand hygiene. Collect appropriate equipment and MAR.
10. Prepare medications for instillation. Attend to procedure and avoid distractions. Check label of medication against MAR two times (see Skill 31.1). Take eardrops out of refrigerator and rewarm to room temperature before administering to patient. Preparation usually involves checking label when removing eardrops out of storage and

- before leaving preparation area. Check expiration date on container. *These are the first and second checks for accuracy.* Perform hand hygiene.
11. Take medication(s) to patient at correct time (see agency policy). Consider whether medication is time critical. During administration apply seven rights of medication administration.
 12. Arrange supplies at bedside.
 13. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
 14. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.

This is the third check for accuracy

15. Explain procedure to patient and sensations to expect. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the medications. Patients who self-instill medications may be allowed to give drops under nurse's supervision (check agency policy).
16. Perform hand hygiene.
17. *Administer eardrops*
 - a. Position patient on side (if not contraindicated) with ear to be treated facing up, or patient may sit in chair or at bedside. *Option:* Apply clean gloves if ear drainage is present.
 - b. If cerumen or drainage occludes outermost part of ear canal, wipe out gently with cotton-tipped applicator (see illustration) or washcloth. Take care not to force cerumen into canal.

STEP 17b Always clean only outer canal. Do not push cerumen or secretions into ear.

- c. Hold the container in the palm of your hands for a few minutes to warm the contents to body temperature. Then, if the eardrops are in a cloudy suspension, shake bottle for about 10 seconds.
- d. Straighten ear canal by pulling pinna up and back to 10 o'clock position (adult or child older than age 3) or down and back to 6 to 9 o'clock position (child under age 3).
- e. Instill prescribed drops holding dropper 1 cm ($\frac{1}{2}$ inch) above ear canal. Avoid contact of dropper tip against external ear canal (see illustration).
- f. Ask patient to remain in side-lying position for a few minutes. Apply gentle massage or pressure to tragus of ear with finger (see illustration).

STEP 17e Pull pinna up and back for adults and children older than 3 years.

STEP 17f Nurse applies gentle pressure to tragus of ear after instilling drops.

- g. If ordered, gently insert part of cotton ball into outermost part of canal. Do not press cotton into canal.
- h. Remove cotton after 15 minutes. Help patient to comfortable position after drops are absorbed.

18. Administer Ear Irrigations

- a. Assess the tympanic membrane or review medication record for history of eardrum perforation, which contraindicates ear irrigation.
 - b. Help patient into sitting position or lying position with head tilted or turned toward affected ear. Place towel under patient's head and shoulder and have patient hold basin under affected ear.
 - c. Fill irrigating syringe with solution (approximately 50 mL) at room temperature.
 - d. Gently grasp auricle and straighten ear by pulling pinna down and back for children younger than 3 years or upward and outward for patients 3 years of age and older.
 - e. Slowly instill irrigating solution by holding tip of syringe 1 cm ($\frac{1}{2}$ inch) above opening of ear canal. Allow fluid to drain out during instillation. Continue until you use all solution.
19. Clean area and put supplies away.

20. Remove and dispose of gloves and perform hand hygiene.
21. Record medication, concentration, dose or strength, number of drops, site of application (left, right, or both ears), and time of administration on MAR immediately after administration.
22. Observe response to medication by assessing hearing changes, asking whether symptoms are relieved, and noting any side effects or discomfort felt.
23. Ask patient to discuss purpose of medication, action, side effects, and technique of administration.
24. Record patient response to medication, patient teaching, and validation of patient understanding and self-administration on flow sheet or nurses' notes in electronic health record (EHR) or chart.
25. **Use Teach-Back:** "I want to be sure I clearly showed you how to administer eardrops. Let's take this time we have for you to show me how to place eardrops in your right ear." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly. Determines patient's/family caregiver's level of understanding of instructional topic.

Ear irrigations are performed when the external ear canal becomes occluded with cerumen that cannot be removed by more conservative measures such as wax softeners. Typically, an irrigation is performed only when the patient has a hearing deficit, ear discomfort, or if it is necessary to visualize the tympanic membrane. You should not perform an ear irrigation if there is a history of middle ear infection in the last 6 weeks, if the patient has undergone *any* form of ear surgery, if the patient has a perforation, or if there is a history of a mucous discharge in the last year.

Vaginal Instillation

Vaginal medications are available as suppositories, foam, jellies, or creams. Solid, oval-shaped suppositories (Fig. 31.9) are packaged individually in foil wrappers and are sometimes stored in the refrigerator to prevent them from melting. After a suppository is inserted into the vaginal cavity, body temperature causes it to melt and be distributed and absorbed. Foam, jellies, and creams are administered with an applicator inserter (Box 31.17)

FIG. 31.9 Vaginal suppositories (right) are larger and more oval than rectal suppositories (left).

From Lilley LL, et al: *Pharmacology and the nursing process*, ed 9, St Louis, 2020, Elsevier.

Box 31.17 Procedural Guidelines Administering Vaginal Medications

Delegation and Collaboration

The skill of administering vaginal medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting any change in comfort level or new or increased vaginal discharge or bleeding to the nurse.

Equipment

Medication administration record (MAR) (electronic or printed); vaginal cream, foam, jelly, tablet, suppository, or irrigating solution; applicators (Fig. 31.10) (if needed); clean gloves; tissues; towels and/or washcloths; perineal pad; drape or sheet; water-soluble lubricants; bedpan; irrigation or douche container (if needed); gooseneck lamp (*optional*)

Steps

1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication

- name and dosage, route, and time for administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review pertinent information related to medication, including action, indication, purpose, normal dose and route, side effects, time of onset and peak action, and nursing implications.
 3. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.
 4. Perform hand hygiene and apply clean gloves. During perineal care inspect condition of vaginal tissues; note if drainage is present. Remove and dispose of gloves and perform hand hygiene.
 5. Ask whether patient is experiencing any symptoms of pruritus, burning, or discomfort.
 6. Review patient's knowledge of medication and readiness to learn (e.g., asks questions about medication, requests education in use of suppository).
 7. Assess patient's ability to manipulate applicator, suppository, or irrigation equipment and to properly position self to insert medication (may be done just before insertion).
 8. Perform hand hygiene. Collect appropriate equipment and MAR.
 9. Prepare suppository for administration. Attend to the procedure and avoid distraction. Preparation usually involves checking the label when removing suppository from refrigerator and before leaving preparation area. Check expiration date on container. *These are the first and second checks for accuracy.* Perform hand hygiene.
 10. Take medication(s) to patient at correct time (see agency policy). Consider whether medication is time critical. During administration apply seven rights of medication administration.
 11. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
 12. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies. *This is the third check for accuracy.*

13. Explain procedure to patient. Be specific if patient plans to self-administer medication. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about medication.
14. Close door or pull curtain. Perform hand hygiene and apply clean gloves. Have patient void (using bathroom agencies or bedpan). Help her lie in dorsal recumbent position. Patients with restricted mobility in knees or hips may lie supine with legs abducted.
15. Keep abdomen and lower extremities draped.
16. Be sure that vaginal orifice is well illuminated by room light. Otherwise position portable gooseneck lamp.
17. Insert vaginal suppository.
 - a. Remove suppository from wrapper and apply liberal amount of water-soluble lubricant to smooth or rounded end (see illustration). Be sure that suppository is at room temperature. Lubricate gloved index finger of dominant hand.
 - b. With nondominant gloved hand gently separate labial folds in front-to-back direction.

STEP 17a Lubricate tip of suppository.

- c. With dominant gloved hand insert rounded end of suppository along posterior wall of vaginal canal the entire length of finger (7.5 to 10 cm [3 to 4 inches]) (see illustration).

STEP 17c Angle of vaginal suppository insertion.

- d. Withdraw finger and wipe away remaining lubricant from around orifice and labia with tissue or cloth.
- e. Remove and dispose of gloves and perform hand hygiene
18. Apply cream or foam.
- a. Perform hand hygiene and apply clean gloves. Fill cream or foam applicator following package directions.
- b. With nondominant gloved hand gently separate labial folds.
- c. With dominant gloved hand gently insert applicator approximately 5 to 7.5 cm (2 to 3 inches). Push applicator plunger to deposit medication into vagina (see illustration).

STEP 18c Applicator inserted into vaginal canal. Plunger pushed to instill medication.

- d. Withdraw applicator and place on paper towel. Wipe off residual cream from labia or vaginal orifice with tissue or cloth.
 - e. Remove and dispose of gloves and perform hand hygiene.
19. Administer irrigation or douche.
- a. Place patient on bedpan with absorbent pad underneath.
 - b. Be sure that irrigation or douche fluid is at body temperature. Run fluid through container nozzle (priming the tubing).
 - c. Perform hand hygiene and apply gloves
 - d. Gently separate labial folds and direct nozzle toward sacrum, following floor of vagina.
 - e. Raise container approximately 30 to 50 cm (12 to 20 inches) above level of vagina. Insert nozzle 7 to 10 cm (3 to 4 inches). Allow solution to flow while rotating nozzle. Administer all irrigating solution.
 - f. Withdraw nozzle and help patient to comfortable sitting position.

- g. Allow patient to remain on bedpan for a few minutes. Clean perineum with soap and water.
 - h. Help patient off bedpan. Dry perineal area.
 - i. Remove and dispose of gloves and perform hand hygiene
20. Instruct patient who received suppository, cream, or tablet to remain on her back for at least 10 minutes.
 21. If using an applicator, wash with soap and warm water, rinse, air dry, and then store for future use.
 22. Offer perineal pad when patient resumes ambulation.
 23. Dispose of supplies, remove and dispose of gloves, perform hand hygiene. Help patient to comfortable position.
 24. Record the medication, dosage, route, and actual time and date of administration on MAR immediately after administration, not before. Include initials or signature
 25. Thirty minutes after administration perform hand hygiene and apply clean gloves. Then inspect condition of vaginal canal and external genitalia. Assess vaginal discharge if present. Remove and dispose of gloves and perform hand hygiene.
 26. Question patient regarding continued pruritus, burning, discomfort, or discharge.
 27. Ask patient to discuss purpose, action, and side effects of medication.
 28. Record patient response to medication, patient teaching and validation of patient understanding and self-administration of suppository on flow sheet or nurses' notes in electronic health record (EHR) or chart.
 29. **Use Teach-Back:** "I want to be sure I explained how to use the vaginal cream applicator. Tell me how you will draw the correct amount of cream into the applicator." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly. Determines patient's/family caregiver's level of understanding of instructional topic.

Insert the suppository with a gloved hand in accordance with Standard Precautions (see [Chapter 28](#)). Patients often prefer administering their own vaginal medications and need privacy. Because vaginal medications are often given to treat infection, discharge is usually foul smelling. Follow aseptic technique and offer the patient frequent opportunities to maintain perineal hygiene (see [Chapter 40](#)).

Rectal Instillation

Rectal suppositories are thinner and more bullet-shaped than vaginal suppositories. The rounded end prevents anal trauma during insertion. Rectal suppositories contain medications that exert local effects such as promoting defecation or systemic effects such as reducing nausea. They are stored in a refrigerator until administered. Sometimes it is necessary to clear the rectum with a small cleansing enema before inserting a suppository (Box 31.18).

Box 31.18 Procedural Guidelines **Administering**

Rectal Suppositories

Delegation and Collaboration

The skill of rectal medication administration cannot be delegated to assistive personnel (AP). The nurse instructs the AP to:

- Report expected fecal discharge or bowel movement to the nurse.
- Report the occurrence of any potential side effects of medications to the nurse.
- Inform the nurse of any rectal pain or bleeding.

Equipment

Medication administration record (MAR) (electronic or printed); rectal suppository; water-soluble lubricating jelly; clean gloves; tissue; drape

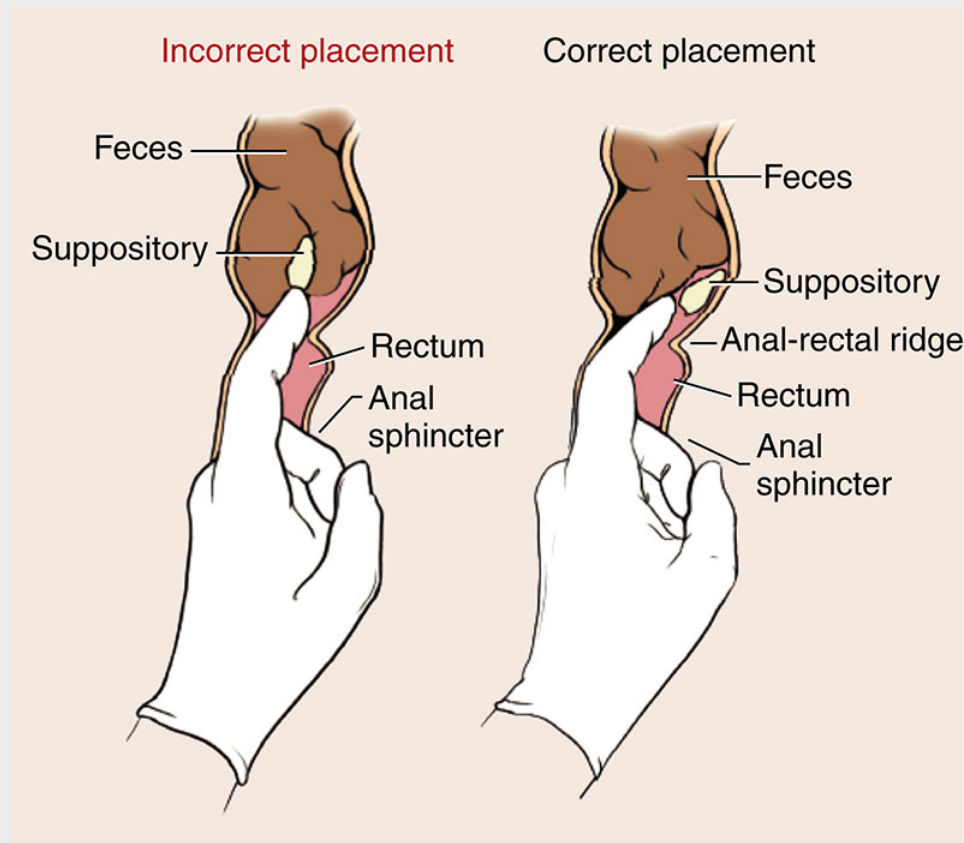

Steps

1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indication, and nursing implications.
3. Review patient's medical history (e.g., history of rectal surgery or bleeding, cardiac problems), medication history, and history of

allergies. List medication allergies on each page of the MAR and prominently display the list of allergies on the patient's medical record per agency policy. When patient has allergy, provide allergy bracelet.

4. Review any presenting signs and symptoms of GI alterations (e.g., constipation or diarrhea).
5. Assess patient's ability to hold suppository and position self to insert medication.
6. Review patient's knowledge of purpose of medication therapy and interest in self-administering suppository.
7. Perform hand hygiene. Collect appropriate equipment and MAR.
8. Prepare suppository for administration. Attend to procedure and avoid distraction. Check label of medication against MAR two times (see Skill 31.1). Preparation usually involves checking label when taking suppository out of refrigerator and before leaving preparation area. Check expiration date on container. *These are the first and second checks for accuracy.*
9. Take medication(s) to patient at correct time (see agency policy). Consider whether medication is time critical. During administration apply seven rights of medication administration.
10. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.
11. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies. *This is the third check for accuracy.*
12. Explain procedure to patient. Be specific if patient wishes to self-administer medication. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the medications. Explain procedure if patient plans to self-administer medication.
13. Perform hand hygiene. Arrange supplies at bedside and apply clean gloves. Close door or pull curtain.
14. Help patient assume left side-lying Sims' position with upper leg flexed upward.
15. If patient has mobility impairment, help into lateral position. Obtain help to turn patient and use pillows under upper arm and leg.
16. Keep patient draped with only anal area exposed.

17. Examine condition of anus externally. *Option:* Palpate rectal walls as needed (e.g., if impaction is suspected) (see Chapter 30). If you palpate rectal walls, dispose of gloves by turning them inside out and placing them in proper receptacle if they become soiled. Otherwise keep gloves on your hands and proceed to Step 19.
18. Perform hand hygiene and apply new pair of clean gloves (if previous gloves were soiled and discarded).
CLINICAL DECISION: Do not palpate patient's rectum if there is a recent history of rectal surgery. A suppository is contraindicated in the presence of active bleeding and diarrhea (Burchum and Rosenthal, 2019).
19. Remove suppository from foil wrapper and lubricate rounded end with water-soluble lubricant. Lubricate gloved index finger of dominant hand. If patient has hemorrhoids, use liberal amount of lubricant and touch area gently.
20. Ask patient to take slow, deep breaths through mouth and relax anal sphincter.
21. Retract patient's buttocks with nondominant hand. With gloved index finger of dominant hand, insert suppository gently through anus, past internal sphincter, and against rectal wall, 10 cm (4 inches) in adults (see illustration) or 5 cm (2 inches) in infants and children. You should feel rectal sphincter close around your finger.

STEP 21 Inserting rectal suppository past sphincter and against rectal wall.

From DeWit S, O'Neill P: *Fundamental concepts and skills for nursing*, ed 4, Philadelphia, 2014, Saunders.

CLINICAL DECISION: Do not insert suppository into a mass of fecal material; this will reduce effectiveness of medication.

22. *Option:* A suppository may be given through a colostomy (not ileostomy) if ordered. Patient should lie supine. Use small amount of water-soluble lubricant for insertion.
23. Withdraw finger and wipe patient's anal area.
24. Ask patient to remain flat or on side for 5 minutes.
25. Discard gloves by turning them inside out and dispose of them and used supplies in appropriate receptacle. Perform hand hygiene.
26. If suppository contains laxative or fecal softener, place nurse call system within reach so that patient can obtain help to reach bedpan or toilet.
27. If suppository was given for constipation, remind patient *not* to flush commode after bowel movement, so you can observe

- characteristics of stool.
28. Record the medication, dosage, route, and actual time and date of administration on MAR immediately after administration, not before. Include initials or signature.
 29. Return to bedside within 5 minutes to determine whether suppository was expelled.
 30. Ask whether patient experienced localized anal or rectal discomfort during insertion.
 31. Evaluate patient at time of peak medication effect for relief of symptoms for which medication was prescribed.
 32. Record patient response to medication, patient teaching, and validation of patient understanding of self-administration of suppository on flow sheet or nurses' notes in electronic health record (EHR) or chart.
 33. **Use Teach-Back:** "I want to be sure I explained clearly to you how to insert a rectal suppository. Describe the steps you will follow to insert the suppository." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly. Determines patient's/family caregiver's level of understanding of instructional topic.

Administering Medications By Inhalation

Medications administered with handheld inhalers are dispersed through an aerosol spray, mist, or powder that penetrates lung airways. The alveolar-capillary network absorbs medications rapidly.

Pressurized metered-dose inhalers (pMDIs), breath-actuated metered-dose inhalers (BAIs), and dry powder inhalers (DPIs) deliver medications that produce local effects such as bronchodilation. Some medications create serious systemic side effects. pMDIs use a chemical propellant to push the medication out of the inhaler and require the patient to apply approximately 5 to 10 pounds of pressure to the top of the canister to administer the medication. Children or older adults with chronic respiratory diseases often use pMDIs. These two populations have diminished hand strength; therefore, it is essential to assess whether they have enough strength to use the pMDI.

Sometimes patients use a spacer with the pMDI. A spacer is a tube that is 10.16 to 20.32 cm (4 to 8 inches) in length that attaches to the pMDI and allows the particles of medication to slow down and break into smaller

pieces. This helps the medication get deeper into the lungs and enhances absorption. Spacers are helpful when a patient has difficulty coordinating the steps involved in self-administering medications. However, patients who do not use their spacers correctly do not receive the full effect of the medication. BAIs and DPIs do not use spacers.

BAIs release medication when a patient raises a lever and inhales. Release of the medication depends on the strength of the patient's breath on inspiration, and a BAI is a good choice for patients who have difficulty in using pMDIs because it eliminates the need for hand-breath coordination ([Ari, 2015](#)).

DPIs hold dry powder medication and create an aerosol when the patient inhales through a reservoir that contains a dose of the medication. The reservoir holds a dose of the medication. Compared with MDIs, DPIs deliver more medication to the lungs ([Burchum and Rosenthal, 2019](#)). Some DPIs are unit dosed. These inhalers require patients to load a single dose of medication into the inhaler with each use. Other DPIs hold enough medication for 1 month. DPIs require less manual dexterity. Because the device is activated with the patient's breath, there is no need to coordinate puffs with inhalation. However, the medication inside the DPI can clump if the patient is in a humid climate, and some patients cannot inspire fast enough to administer the entire dose of the medication.

Patients who receive medications by inhalation frequently suffer from chronic respiratory disease such as chronic asthma, emphysema, or bronchitis. Different respiratory problems require different inhaled medication. For example, patients with asthma usually receive antiinflammatory medications because asthma is primarily an inflammatory disease, whereas patients with chronic obstructive pulmonary disease (COPD) receive bronchodilators because they usually have problems with bronchoconstriction. Inhaled medications are also often described as "rescue" or "maintenance" medications. Rescue medications are short acting and taken for immediate relief of acute respiratory distress. Maintenance medications are used on a daily schedule to prevent acute respiratory distress. The effects of maintenance medications start within hours of administration and last for a longer period of time than rescue medications. Some inhalers contain combinations of rescue and maintenance medications. Because patients depend on inhaled medications for disease control and current evidence shows that many patients do not use their inhalers correctly, nurses need to teach and reteach their patients about their safe and effective use ([Ari, 2015](#)) (see [Skill 31.3](#)).

One important aspect of patient teaching is to help the patient determine when the MDI, BAI, or DPI is empty and needs to be replaced. Floating an MDI in water to determine how much medication is left is not recommended because extra propellant causes the container to float even if no medication remains in the inhaler. Devices that count down the number of remaining doses are available for MDIs. Some DPIs have mechanisms that indicate how many doses are left. However, these mechanisms are not always accurate. Therefore, to calculate how long medication in an inhaler will last, divide the number of doses in the container by the number of doses the patient takes per day. For example, a patient is to take albuterol 2 puffs 4 times a day. The canister has a total of 200 puffs. Complete the following calculation to determine how long the MDI will last:

$$\begin{aligned} 2 \text{ puffs} \times 4 \text{ times a day} &= 8 \text{ puffs per day} \\ 200 \text{ puffs} \div 8 \text{ puffs per day} &= 25 \text{ days} \end{aligned}$$

The canister in this example will last 25 days. To ensure that the patient does not run out of medication, teach him or her to refill it at least 7 to 10 days before it runs out.

Administering Medications By Irrigations

Some medications irrigate or wash out a body cavity and are delivered through a stream of solution. Irrigations most commonly use sterile water, saline, or antiseptic solutions on the eye, ear, throat, vagina, or urinary tract. Use aseptic technique if there is a break in the skin or mucosa. Use clean technique when the cavity to be irrigated is not sterile, as in the case of the ear canal or vagina. Irrigations cleanse an area, instill a medication, or apply hot or cold to injured tissue (see [Chapter 48](#)).

Parenteral Administration of Medications

Parenteral administration of medications is the administration of medications by injection into body tissues. This is an invasive procedure that is performed using aseptic techniques ([Box 31.19](#)). A risk of infection

occurs after a needle pierces the skin. This is an invasive procedure that is performed with the following aseptic techniques:

Box 31.19 Preventing Infection During an Injection

- To prevent contaminating the solution, draw up medication quickly. Do not allow ampules to stand open.
- To prevent needle contamination, avoid letting a needle touch contaminated surfaces (e.g., outer edges of ampule or vial, outer surface of needle cap, nurse's hands, countertop, table surface).
- To prevent syringe contamination, avoid touching length of plunger or inner part of barrel. Keep tip of syringe covered with cap or needle.
- To prepare skin, wash with soap and water if soiled with dirt, drainage, or feces, and dry. Use friction and a circular motion while cleaning with an antiseptic swab. Swab from center of site and move outward in a 5-cm (2-inch) radius.

- Draw up medication quickly to avoid contaminating solutions. Do not allow ampules to stand open.
- Avoid letting a needle touch contaminated surfaces (e.g., outer edges of ampule or vial, outer surface of needle cap).
- Avoid touching length of plunger or inner part of barrel. Keep tip of syringe covered with cap or needle.
- Prepare skin by washing with soap and water if soiled. Use friction and a circular motion when cleaning with an antiseptic swab. Swab from center of site and move outward in a 5-cm (2-inch) radius.

Each type of injection requires certain skills to ensure that the medication reaches the proper location. The effects of a parenteral medication develop rapidly, depending on the rate of medication absorption. You must closely observe a patient's response to parenteral medications.

Equipment

You will administer parenteral medications by using a needle and a syringe, available in a variety of sizes. Each is designed to deliver a certain volume of a medication to a specific type of tissue. Determine the appropriate size of syringe, length and gauge of needle, volume of solution, and medication route based on the quantity and type of medication prescribed and the body size of a patient. Most syringes come with needleless systems or safety needles that help prevent needlestick injuries.

Syringes

Syringes consist of a cylindrical barrel with a tip designed to fit the hub of a hypodermic needle and a close-fitting plunger. Syringes are single use, disposable, and classified as being Luer-Lok or non-Luer-Lok. This terminology is based on the design of the tip of the syringe. Luer-Lok syringes have needles that are twisted onto the tip and lock themselves in place (Fig. 31.11, A and B). This design prevents the inadvertent removal of the needle. Non-Luer-Lok syringes (Fig. 31.11, C and D) have needles that slip onto the tip. Syringes come with or without a sterile needle and with a needleless sharp with engineered sharps injury protection (SESIP) device.

FIG. 31.10 From top: Vaginal cream with applicator, applicator, and vaginal suppository.

From Lilley LL, et al: *Pharmacology and the nursing process*, ed 9, St Louis, 2020, Elsevier.

FIG. 31.11 Types of syringes. **A**, 5-mL syringe. **B**, 3-mL syringe. **C**, Tuberculin syringe marked in 0.01 (hundredths) for doses less than 1 mL. **D**, Insulin syringe marked in units (50).

Syringes come in a variety of sizes, from 0.5 to 60 mL. It is unusual to use a syringe larger than 5 mL for an injection. A 1- to 3-mL syringe is usually adequate for a subcutaneous or IM injection. A larger volume creates discomfort. Use larger syringes to administer certain IV medications and to irrigate wounds or drainage tubes. Syringes often come prepackaged with a needle attached. However, you sometimes change a needle based on the route of administration and size of a patient.

The tuberculin syringe (see [Fig. 31.11, C](#)) is calibrated in sixteenths of a minim and hundredths of a milliliter and has a capacity of 1 mL. Use a tuberculin syringe to prepare small amounts of medications (e.g., ID or subcutaneous injections). A tuberculin syringe is also useful when preparing small, precise doses for infants or young children.

Insulin syringes (see [Fig. 31.11, D](#)) hold 0.3 mL to 1 mL, and low-dose insulin syringes (30 units per 0.3 mL or 50 units per 0.5 mL) hold 0.3 mL to 1 mL. Both come with preattached needles and are calibrated in units. Most insulin syringes are U-100s, designed for use with U-100–strength insulin. Each milliliter of solution contains 100 units of insulin.

Fill a syringe by pulling the plunger outward while the needle tip remains immersed in the prepared solution. Touch only the outside of the syringe barrel and the handle of the plunger to maintain sterility. Avoid letting any unsterile object touch the tip or inside of the barrel, the hub, the shaft of the plunger, or the needle (Fig. 31.12).

FIG. 31.12 Parts of a syringe.

Needles

Some needles come packaged in individual sheaths to allow flexibility in choosing the right needle for a patient, whereas others are preattached to standard-size syringes. Most needles are made of stainless steel, and all are disposable. A needle has three parts: the hub, which fits onto the tip of a syringe; the shaft, which connects to the hub; and the bevel, or slanted tip (Fig. 31.13). The tip of a needle, or the bevel, is always slanted. The bevel creates a narrow slit when injected into tissue that quickly closes when the needle is removed to prevent leakage of medication, blood, or serum. Long, beveled tips are sharper and narrower, minimizing discomfort when entering tissue used for subcutaneous or IM injections.

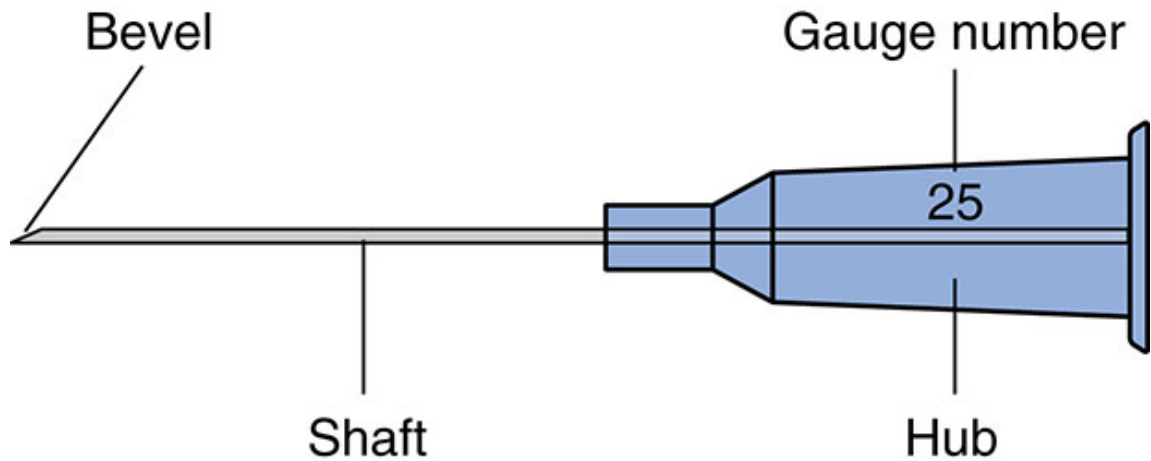

FIG. 31.13 Parts of the needle.

Most needles vary in length from $\frac{1}{4}$ to 3 inches (Fig. 31.14). Choose the needle length according to a patient's size and weight and the type of tissue into which the medication is to be injected. Current evidence suggests that needle length should be based on a patient's weight (Holliday et al., 2019). There should be a 5-mm depth of muscle penetration for an IM injection (Hibbard et al., 2017). A child or slender adult generally requires a shorter needle. Use longer needles (1 to $1\frac{1}{2}$ inches) for IM injections and a shorter needle ($\frac{3}{8}$ to $\frac{5}{8}$ inch) for subcutaneous injections. As the needle gauge becomes smaller, the diameter becomes larger. The selection of a gauge depends on the viscosity of fluid to be injected or infused.

FIG. 31.14 Hypodermic needles (*top to bottom*): 18 gauge, 1½-inch length; 21 gauge, 1½-inch length; 22 gauge, 1½-inch length; 23 gauge, 1-inch length; and 25 gauge, 5/8-inch length.

Disposable Injection Units

Single-dose, prefilled, disposable syringes are available for some medications. You do not need to prepare medication doses except perhaps to expel unneeded portions of medication or air. However, it is important to check the medication and concentration carefully because prefilled syringes appear very similar. Prefilled unit-dose systems such as Tubex and Carpuject include reusable plastic syringe holders and disposable, prefilled, sterile, glass cartridge units (Fig. 31.15). To assemble a prefilled system, place the cartridge barrel first into the plastic syringe holder. Following manufacturer's instructions, turn the plunger rod to the left (counterclockwise) and the lock to the right (clockwise) until it "clicks." Finally, remove the needle guard and advance the plunger to expel air and excess medication, as with a regular syringe. The cartridge may be used with SESIP needles. After administering a medication, dispose of the glass cartridge safely in a puncture-proof and leak-proof container. This design reduces the risk for needlestick injury.

FIG. 31.15 **A**, Carpuject syringe and prefilled sterile cartridge with needle. **B**, Assembling the Carpuject. **C**, Cartridge slides into syringe barrel. Turn and

lock syringe into cartridge. **D**, Screw plunger into end of cartridge. Expel excess medication to obtain accurate dose (not pictured).

Preparing an Injection From an Ampule

Ampules contain single doses of medication in a liquid. They are available in several sizes, from 1 mL to 10 mL or more (Fig. 31.16, A). An ampule is made of glass with a constricted neck that must be snapped off to allow access to the medication. A colored ring around the neck indicates where the ampule is prescored so that you can break it easily. Carefully aspirate the medication into a syringe (see Skill 31.4) with a filter needle. Filter needles must be used when preparing medication from a glass ampule to prevent glass particles from being drawn into the syringe (Joo et al., 2016). *Do not* use a filter needle to administer a medication. Place an appropriate-size needle on the syringe after withdrawing the medication.

FIG. 31.16 A, Medication in ampules. B, Medication in vials.

Preparing an Injection From a Vial

A vial is a single-dose or multidose container with a rubber seal at the top (see Fig. 31.16, B). A metal cap protects the seal until it is ready for use. Vials contain liquid or dry forms of medications. Medications that are

unstable in solution are packaged dry. The vial label specifies the solvent or diluent used to dissolve the medication and the amount of diluent needed to prepare a desired medication concentration. Normal saline and sterile distilled water are commonly used to dissolve medications.

Unlike the ampule, the vial is a closed system, and air needs to be injected into it to permit easy withdrawal of the solution. Failure to inject air when withdrawing creates a vacuum within the vial that makes withdrawal difficult. If concerned about drawing up parts of the rubber stopper or other particles into the syringe, use a filter needle when preparing medications from vials (ISMP, 2015d). Some vials contain powder, which is mixed with a diluent during preparation and before injection (see Skill 31.4). After mixing multidose vials, make a label that includes the date and time of mixing and the concentration of medication per milliliter. Some multidose vials require refrigeration after the contents are reconstituted.

Mixing Medications

If two medications are compatible, it is possible to mix them in one injection if the total dose is within accepted limits. This prevents a patient from having to receive more than one injection at a time. Most nursing units have charts that list common compatible medications. If there is any uncertainty about medication compatibilities, consult a pharmacist or a medication reference.

Mixing Medications From a Vial and an Ampule

When mixing medication from both a vial and ampule, prepare medication from the vial first. Using the same syringe and filter needle, next withdraw medication from the ampule. Nurses prepare the combination in this order because it is not necessary to add air to withdraw medication from an ampule.

Mixing Medications From Two Vials

Apply these principles when mixing medications from two vials:

1. Do not contaminate one medication with another.
2. Ensure that the final dose is accurate.
3. Maintain aseptic technique.

Use only one syringe with a needle or needleless access device attached to mix medications from two vials (Fig. 31.17). Aspirate the volume of air equivalent to the dose of the first medication (vial A) (see Fig. 31.17, A). Inject the air into vial A, making sure that the needle does not touch the solution. Withdraw the needle and aspirate air equivalent to the dose of the second medication (vial B). Inject the volume of air into vial B (see Fig. 31.17, B). Immediately withdraw the medication from vial B into the syringe and insert the needle back into vial A, being careful not to push the plunger and expel the medication within the syringe into the vial. Withdraw the desired amount of medication from vial A into the syringe (see Fig. 31.17, C). After withdrawing the necessary amount, withdraw the needle and apply a new safety needle or needleless access device suitable for injection.

FIG. 31.17 A, Injecting air into vial A. B, Injecting air into vial B and withdrawing dose. C, Withdrawing medication from vial A; medications are now mixed.

Insulin Preparation

Insulin is the hormone used to treat diabetes mellitus. It is administered by injection because the GI tract breaks down and destroys an oral form of

insulin. Most patients with diabetes mellitus who take insulin injections learn to administer their own injections. In the United States and Canada, health care providers usually prescribe insulin in concentrations of 100 units per milliliter of solution. This is called *U-100 insulin*. Insulin is also commercially available in concentrations of 500 units per milliliter of solution; it is called *U-500 insulin*. U-500 insulin is 5 times as strong as U-100 insulin and is used only in rare cases when patients are very resistant to insulin. Insulin injection guidelines have been developed and modified over the past several years in response to increasing evidence and research about best practices for patient assessment and site selection ([McCulloch et al., 2018](#)). Based on this evidence:

- Use the same technique for both insulin syringes and insulin pens.
- Use a body area where 2.5 cm (1 inch) of subcutaneous fat can be pinched.
- Use a 27-gauge needle, perpendicular to the pinched skin.
- Do not aspirate the injection and hold needle in place for several seconds. This is especially important with insulin pens to prevent leakage of medication.
- Insulin is absorbed rapidly through the abdominal wall, so the abdomen should be the first choice for sites when using rapid-acting insulin.

Use the correct syringe when preparing insulin. Use a 100-unit insulin syringe or an insulin pen to prepare U-100 insulin. Until recently there was no syringe designed to prepare U-500 insulin, and many medication errors resulted with this kind of insulin. To prevent errors, ensure that the health care provider order for U-500 specifies units and that the patient is taught the difference between U-500 and U-100 syringes ([Consumer Med Safety, 2018b](#); [ISMP, 2017b](#)). Verify every injection you prepare with another nurse before administering it. Additional safety measures common with U-500 insulin include listing the insulin as being concentrated in computerized medication dispensing systems, making health care providers and pharmacists verify that a patient is to receive U-500 insulin when it is ordered, and stocking U-500 insulin on patient care units only when it is ordered for a specific patient ([ISMP, 2017b](#); [ISMP, 2018c](#)).

Insulin is classified by rate of action, including rapid-acting, short-acting, intermediate-acting, and long-acting. To provide safe and effective care, you need to know the onset, peak, and duration for each of your patients' ordered insulin doses. Refer to a medication reference or consult

with a pharmacist if you are unsure of this information. Regular insulin is the only type of insulin that can be given intravenously.

A patient with diabetes mellitus sometimes requires more than one type of insulin. For example, by receiving a short-acting (regular) and intermediate-acting (NPH) insulin, a patient receives more sustained control of blood glucose levels over 24 hours. The timing of insulin injections attempts to imitate the normal pattern of insulin release from the pancreas. Some insulins come in a stable premixed solution (e.g., 70/30 insulin is 70% NPH [intermediate] and 30% regular), eliminating the need to mix the insulins in a syringe. Other patients use an insulin pen. The insulin pen provides multiple doses and allows a patient to dial in the dose, avoiding the need to use a syringe for insulin preparation. Research shows that different types of a patient's blood cells can enter into the insulin pen after an injection. Several US health care agencies recently reported that the same insulin pen was inadvertently used on multiple patients, exposing the patients to bloodborne illnesses (e.g., human immunodeficiency virus [HIV], hepatitis B, and hepatitis C). Thus, the [ISMP \(2017b\)](#) recommends that insulin pens be used only at home and that inpatient settings provide an insulin pen for a single patient use.

Insulin is ordered by a specific dose at select times. Correction or correctional insulin, also known as sliding-scale insulin, provides a dose of insulin based on the patient's blood glucose level ([Box 31.20](#)). The term *correctional insulin* is preferred because it indicates that small doses of rapid- or short-acting insulin are needed to correct a patient's elevated blood sugar. Reliance on correctional insulin is unlikely to achieve long-term glucose control; therefore, it should be ordered only on a temporary basis ([ISMP, 2017b](#)).

Box 31.20 Example of Correction Insulin Order

Give regular U-100 insulin subcutaneously:

- 2 units for glucose 150 to 200 mg/dL
- 4 units for glucose 201 to 275 mg/dL
- Call for glucose greater than 275 mg/dL

Clinical scenario: Before lunch patient's blood glucose level is 201 mg/dL. After referring to patient's correction insulin order, the nurse administers 4 units of insulin to patient.

Before drawing up insulin doses, gently roll all cloudy insulin preparations between the palms of the hands to resuspend the insulin. Do not shake insulin vials; shaking causes bubbles to form. Bubbles take up space in the syringe and alter the dose.

If more than one type of insulin is required to manage the patient's diabetes, you mix two different types of insulin into one syringe *if* they are compatible (Box 31.21). If regular and intermediate-acting insulins are ordered, prepare the regular insulin first to prevent it from becoming contaminated with the intermediate-acting insulin (ISMP, 2017b). Use the following principles when mixing insulins (ISMP, 2017b; McCulloch et al., 2018):

Box 31.21 Procedural Guidelines **Mixing Two Types of Insulin in One Syringe**

Delegation and Collaboration

The skill of mixing two types of insulin in one syringe cannot be delegated to assistive personnel (AP). The nurse directs the AP about:

- Potential side effects of medications and the need to immediately report their occurrence to the nurse.

Equipment

Medication administration record (MAR) (printed or electronic); insulin vials, insulin syringe, antiseptic swab

Steps

1. Check accuracy and completeness of MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.
2. Review medication and medical history (e.g., type of diabetes, reason for elevated blood sugar) and allergies to medications, food, and latex.
3. Verify insulin labels carefully against MAR before preparing the dose to ensure that you give the correct type of insulin. *This is the*

first check for accuracy.

4. Perform hand hygiene.
5. If patient takes insulin that is cloudy, roll the bottle of insulin between the hands to resuspend the insulin preparation.
6. Wipe off tops of both insulin vials with alcohol swabs and allow to dry.
7. Verify insulin dosages against MAR a second time. *This is the second accuracy check.*
8. If mixing rapid- or short-acting insulin with intermediate-acting insulin, take insulin syringe and aspirate volume of air equivalent to dose to be withdrawn from intermediate-acting insulin first. If two intermediate-acting insulins are mixed, it makes no difference which vial you prepare first.
9. Insert needle and inject air into vial of intermediate-acting insulin. Do not let the tip of the needle touch the insulin.
10. Remove the syringe from the vial of intermediate-acting insulin without aspirating medication.
11. With the same syringe, inject air equal to the dose of rapid- or short-acting insulin into the vial and withdraw the correct dose into the syringe.
12. Remove the syringe from the rapid- or short-acting insulin and get rid of air bubbles to ensure accurate dosing.
13. After verifying insulin dosages with MAR a third time, show insulin prepared in syringe to another nurse to verify that you prepared correct dosage of insulin. *This is the third accuracy check.* Determine which point on syringe scale combined units of insulin measure by adding the number of units of both insulins together (e.g., 5 units regular + 10 units NPH = 15 units total).
14. Place the needle of the syringe back into the vial of intermediate-acting insulin. Be careful not to push plunger and inject insulin in syringe into the vial.
15. Invert the vial and carefully withdraw the desired amount of insulin into syringe.
16. Withdraw needle and check fluid level in syringe. Keep needle of prepared syringe sheathed or capped until ready to administer medication. Show another nurse the syringe to verify that you prepared the correct dose.
17. Dispose of soiled supplies in proper receptacle. Place empty vials in puncture-proof and leak-proof container and perform hand hygiene.

18. Because rapid- or short-acting insulin binds with intermediate-acting insulin, which reduces the action of the faster-acting insulin, administer mixture within 5 minutes of preparing it.

Modified from McCulloch D, et al: *General principles of insulin therapy in diabetes mellitus*, UpToDate, 2018.

<http://www.uptodate.com/contents/general-principles-of-insulin-therapy-in-diabetes-mellitus>. Accessed May 16, 2018.

- Patients whose blood glucose levels are well controlled on a mixed-insulin dose need to maintain their individual routine when preparing and administering their insulin.
- Do not mix insulin with any other medications or diluents unless approved by the health care provider.
- Never mix insulin glargine or insulin detemir with other types of insulin.
- Inject rapid-acting insulins mixed with NPH insulin within 15 minutes before a meal.
- Verify insulin doses with another nurse while you are preparing the injection.

Administering Injections

Each injection route differs based on the type of tissues the medication enters. The characteristics of the tissues influence the rate of medication absorption, affecting the onset of medication action. Before injecting a medication, know the volume of the medication to administer, the characteristics and viscosity of the medication, and the location of anatomical structures underlying injection sites (see Skill 31.5).

If you do not administer injections correctly, negative patient outcomes result. Failure to select an injection site in relation to anatomical landmarks results in nerve or bone damage during needle insertion. Inability to maintain stability of the needle and syringe unit can result in pain and tissue damage. If you fail to aspirate the syringe before injecting an IM medication, the medication may be injected accidentally directly into an artery or vein. Injecting too large a volume of medication for the site selected causes extreme pain and results in local tissue damage.

Many patients, particularly children, fear injections. Patients with serious or chronic illness often are given several injections daily. Minimize discomfort in the following ways:

- Use a sharp-beveled needle in the smallest suitable length and gauge.
- Position a patient as comfortably as possible to reduce muscular tension.
- Select the proper injection site, using anatomical landmarks.
- Apply a vapocoolant spray (e.g., Fluori-Methane spray or ethyl chloride) or topical anesthetic (e.g., EMLA cream) to the injection site before giving the medication when possible (see agency policy).
- Divert the patient's attention from the injection through conversation using open-ended questioning.
- Insert the needle quickly and smoothly to minimize tissue pulling.
- Hold the syringe steady while the needle remains in tissues.
- Inject the medication slowly and steadily.

Subcutaneous Injections

Subcutaneous injections involve placing medications into the loose connective tissue under the dermis (see Skill 31.5). Because subcutaneous tissue is not as richly supplied with blood as the muscles, medication absorption is somewhat slower than with IM injections. Physical exercise or application of hot or cold compresses influences the rate of drug absorption by altering local blood flow to tissues. Any condition that impairs blood flow is a contraindication for subcutaneous injections. Because subcutaneous tissue contains pain receptors, a patient often experiences slight discomfort.

The best subcutaneous injection sites include the outer posterior aspect of the upper arms, the abdomen from below the costal margins to the iliac crests, and the anterior aspects of the thighs (Fig. 31.18). The site most frequently recommended for heparin injections is the abdomen (Fig. 31.19). Alternative subcutaneous sites for other medications include the scapular areas of the upper back and the upper ventral or dorsal gluteal areas. The injection site you choose needs to be free of skin lesions, bony prominences, and large underlying muscles or nerves.

FIG. 31.18 Sites recommended for subcutaneous injections.

FIG. 31.19 Giving subcutaneous heparin in abdomen.

The administration of low-molecular-weight heparin (LMWH) (e.g., enoxaparin) requires special considerations. When injecting the medication, use the right or left side of the abdomen at least 5 cm (2 inches) from the umbilicus (the patient's "love handles") and pinch the injection site as you insert the needle. Administer LMWH in its prefilled syringe with the attached needle, and do not expel the air bubble in the syringe before giving the medication.

Use U-100 insulin syringes with preattached 31- to 25-gauge needles when giving U-100 insulin and U-500 insulin syringes when giving U-500 insulin. [ISMP \(2017b; 2018c\)](#) recommends the use of individual patient insulin pens for all insulin administration. Recommended sites for insulin injections include the upper arm and the anterior and lateral parts of the thigh, buttocks, and abdomen. Rotating injections within the same body part (intrasite rotation) provides more consistency in the absorption of the insulin. For example, if a patient receives morning insulin in the right arm, give the next injection in a different place in the same arm. The injections are to be given at least 2.5 cm (1 inch) away from the previous site. Injection sites should not be used again for at least 1 month ([McCulloch et al., 2018](#)). The rate of insulin absorption varies based on the site; the abdomen has the quickest absorption, followed by the arms, thighs, and buttocks ([McCulloch et al., 2018](#)).

Subcutaneous tissue is sensitive to irritating solutions and large volumes of medications. Thus, you administer only small volumes (0.5 to 1.5 mL) of water-soluble medications subcutaneously to adults. You give smaller volumes up to 0.5 mL to children ([Hockenberry et al., 2019](#)). Hardened, painful lumps called *sterile abscesses* occur under the skin if medication collects within the tissues.

A patient's body weight indicates the depth of the subcutaneous layer. Therefore, choose the needle length and angle of insertion based on a patient's weight and an estimation of the amount of subcutaneous tissue ([Larkin et al., 2018](#)). Nurses typically use a 25-gauge, $\frac{5}{8}$ -inch (16-mm) needle inserted at a 45-degree angle ([Fig. 31.20](#)) or a $\frac{1}{2}$ -inch (12-mm) needle inserted at a 90-degree angle to administer subcutaneous medications to a normal-size adult patient. Some children require only a $\frac{1}{2}$ -inch needle. If the patient is obese, pinch the tissue and use a needle long enough to insert through fatty tissue at the base of the skinfold. Thin patients often do not have sufficient tissue for subcutaneous injections; the upper abdomen is usually the best site in this case. To ensure that a subcutaneous medication reaches the subcutaneous tissue, follow this rule: If you can grasp 2 inches (5 cm) of tissue, insert the needle at a 90-degree

angle; if you can grasp 2.5 cm (1 inch) of tissue, insert the needle at a 45-degree angle.

FIG. 31.20 Comparison of angles of insertion for intramuscular (90 degrees), subcutaneous (45 to 90 degrees), and intradermal (15 degrees) injections.

Newer research in insulin administration shows that insulin needles that are $\frac{5}{16}$ (8 mm) or longer often enter the muscles of men and people with a body mass index (BMI) of 25 or less. Shorter ($\frac{3}{16}$ -inch or 4- to 5-mm) needles were associated with less pain, adequate control of blood sugars, and minimal leakage of medication (ISMP, 2017b). Thus, when administering insulin, you should use needles of $\frac{3}{16}$ inch (4 to 5 mm) administered at a 90-degree angle to reduce pain and achieve adequate control of blood sugars with minimal adverse effects for people of all BMIs, including children (Levitsky et al., 2017).

Several new technologies are available for administration of subcutaneous injections. *Injection pens* are a technology that patients can use to self-administer medications (e.g., epinephrine, insulin, or interferon) subcutaneously (Fig. 31.21). They offer a convenient delivery method using prefilled, disposable cartridges. The patient pinches the skin, inserts the needle, and injects a predetermined medication dose. Teaching is essential to ensure that patients use the correct injection technique and deliver the correct dose of medication. Patients need to be taught the importance of purging the pen before a dose is given. The disadvantages to this technology include increased risk for needlestick injury and user's lack of knowledge and skill in administration technique (ISMP, 2017b). One new technology is a *needleless jet injection system* that administers subcutaneous medications without the use of needles. Needle-free injections use high pressure to penetrate the skin with the medication into

the subcutaneous tissue (Fig. 31.22). Another new advance in subcutaneous injection is the *subcutaneous injection device* (e.g., insuflon) (Fig. 31.23), which is inserted into the subcutaneous tissue; the needle is then removed, leaving the cannula in the tissue to provide an avenue for administering medications for up to 3 days without having to puncture the skin with each injection.

Intramuscular Injections

The intramuscular (IM) injection route deposits medication into deep muscle tissue, which has a rich blood supply, allowing medication to absorb faster than by the subcutaneous route. However, there is a risk for injecting medications directly into blood vessels. Any factor that interferes with local tissue blood flow affects the rate and extent of medication absorption. In addition, if a medication is not injected correctly into a muscle, complications can arise such as abscess, hematoma, ecchymosis, pain, and vascular and nerve injury ([Kaya et al., 2015](#)).

The viscosity of the medication, injection site, patient's weight, and amount of adipose tissue influence needle size selection. Determine needle gauge by the medication to be administered. Therefore, whenever administering a medication by the IM route, first verify that the injection is justified ([CDC, 2017](#); [WHO, 2016](#)). Some medications, such as hepatitis B and tetanus, diphtheria, and pertussis (Tdap) immunizations, are given only intramuscularly.

Use a longer and heavier-gauge needle to pass through subcutaneous tissue and penetrate deep muscle tissue (see Skill 31.5). A patient's BMI and the amount of adipose tissue influence needle size selection. The choice of needle length and site of injection must be made based on the size of the muscle, the thickness of adipose tissue at the injection site, the volume to be administered, injection technique, and the depth below the muscle surface to be injected (CDC, 2017). Investigate other medication routes, especially when IM injections are ordered for obese patients (Larkin et al., 2018). Note that the most common intramuscular injections are immunizations.

The angle of insertion for an IM injection is 90 degrees (see Fig. 31.20). Muscle is less sensitive to irritating and viscous medications. A normal, well-developed adult patient tolerates 2 to 5 mL of medication into a larger muscle without severe muscle discomfort (Hopkins and Arias, 2013). However, larger volumes of medication (4 to 5 mL) are unlikely to be absorbed properly. Children, older adults, and thin patients tolerate only 2 mL of an IM injection. Do not give more than 1 mL to small children and older infants, and do not give more than 0.5 mL to smaller infants (Hockenberry et al., 2019).

Assess a muscle before giving an injection. Properly identify the site for the IM injection by palpating bony landmarks, and be aware of the potential complications associated with each site. The site needs to be free of tenderness because repeated injections in the same muscle cause severe discomfort. With the patient relaxed, palpate the muscle to rule out any hardened lesions. Minimize discomfort during an injection by helping a patient assume a position that helps to reduce muscle strain. Other interventions such as distraction and applying pressure to an IM site decrease pain during an injection.

Rotate IM injection sites to decrease the risk for tissue hypertrophy. Emaciated or atrophied muscles absorb medication poorly; thus, avoid their use when possible. The **Z-track method**, a technique for pulling the skin during an injection, is recommended for IM injections (Ogston-Tuck, 2014b; Yilmaz, et al., 2016). It prevents leakage of medication into subcutaneous tissues, seals medication in the muscle, and minimizes irritation. To use the Z-track method, apply the appropriate-size needle to the syringe and select an IM site, preferably in a large, deep muscle such as the ventrogluteal. Pull the overlying skin and subcutaneous tissues approximately 2.5 to 3.5 cm (1 to 1 ½ inches) laterally to the side with the ulnar side of the nondominant hand. Hold the skin in this position until you have administered the injection (Fig. 31.24A). After cleaning a site,

inject the needle deeply into the muscle. To reduce injection site discomfort, there is no longer any need to aspirate after the needle is injected when *administering vaccines* (CDC, 2017). It is the nurse's responsibility to follow agency policy for aspirating vaccines after injecting the needle. Keep the needle inserted for 10 seconds to allow the medication to disperse evenly. Release the skin after withdrawing the needle. This leaves a zigzag path that seals the needle track wherever tissue planes slide across one another see (Fig. 31.24B). The medication is sealed in the muscle tissue.

A During injection

B After release

FIG. 31.24 **A**, Pulling on overlying skin during intramuscular injection moves tissue to prevent later tracking. **B**, Z-track method of injection prevents deposit of medication into sensitive tissue.

Sites

When selecting an IM site, consider the following: Is the area free of infection or necrosis? Are there local areas of bruising or abrasions? What

is the location of underlying bones, nerves, and major blood vessels? What volume of medication is to be administered? Each site has different advantages and disadvantages.

Ventrogluteal

The ventrogluteal muscle is the preferred and safest injection site for all adults, children, and infants, especially for large-volume, viscous, and irritating medications (CDC, 2017; Hockenberry et al., 2019; Hopkins and Arias, 2013; Kara et al., 2015). The site involves the gluteus medius where the thickness of subcutaneous tissue is less than other injection sites and there are relatively fewer nerves and blood vessels (Kara et al., 2015). Furthermore, in this site, the muscles are large, well established, and the muscle limit points are easy to find (Kara et al., 2015). Locate the ventrogluteal muscle by positioning the patient in a supine or lateral position. One way to locate the ventrogluteal muscle site to use is by the "V" method (Kara et al., 2015). You position a patient in a supine or lateral position with the knee and hip flexed to relax the muscle. Use your right hand for the left hip and your left hand for the right hip. For example, if you are administering the injection into the patient's left hip, place the palm of your right hand over the greater trochanter of the patient's hip with your wrist perpendicular to the femur. Then move your thumb toward the patient's groin and your index finger toward the anterior superior iliac spine. Extend or open your middle finger back along the iliac crest toward the patient's buttock. The index finger, middle finger and the iliac crest form a V-shaped triangle, with the injection site in the center of the triangle (Fig. 31.25A-C) (Kara et al., 2015; Larkin et al., 2018).

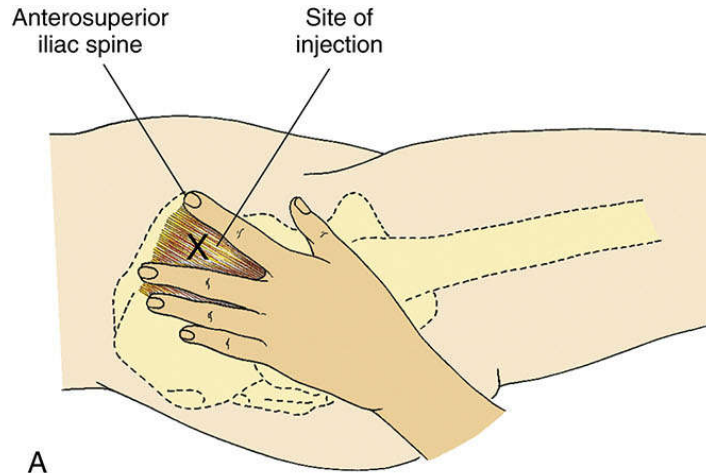

FIG. 31.25 **A**, Landmarks for ventrogluteal site. **B**, Locating ventrogluteal site in patient. **C**, Giving intramuscular injection in ventrogluteal muscle using Z-track method.

There has been some evidence to suggest that the “V” technique is not always reliable because of differences in nurses’ hand structure and patients’ body structure, especially when a patient is obese (Kara et al., 2015; Larkin et al., 2017). Thus, the “G” method, or geometric method, is another option for identifying the correct ventrogluteal site (Fig. 31.26). With a patient in the sidelying position you reference three bone prominences and draw imaginary lines between the ends of the bones (Kara et al., 2015). You imagine lines drawn from the patient’s greater trochanter to the iliac crest, and then to the anterosuperior iliac spine, and from the greater trochanter to the anterosuperior iliac spine. Thus, a triangle is created by the imaginary lines. After that, draw median lines from every single corner of triangle to the opposite side. The convergence point of the three median lines is the center for the triangle, the needle entry point for intramuscular injections (Kaya et al., 2015).

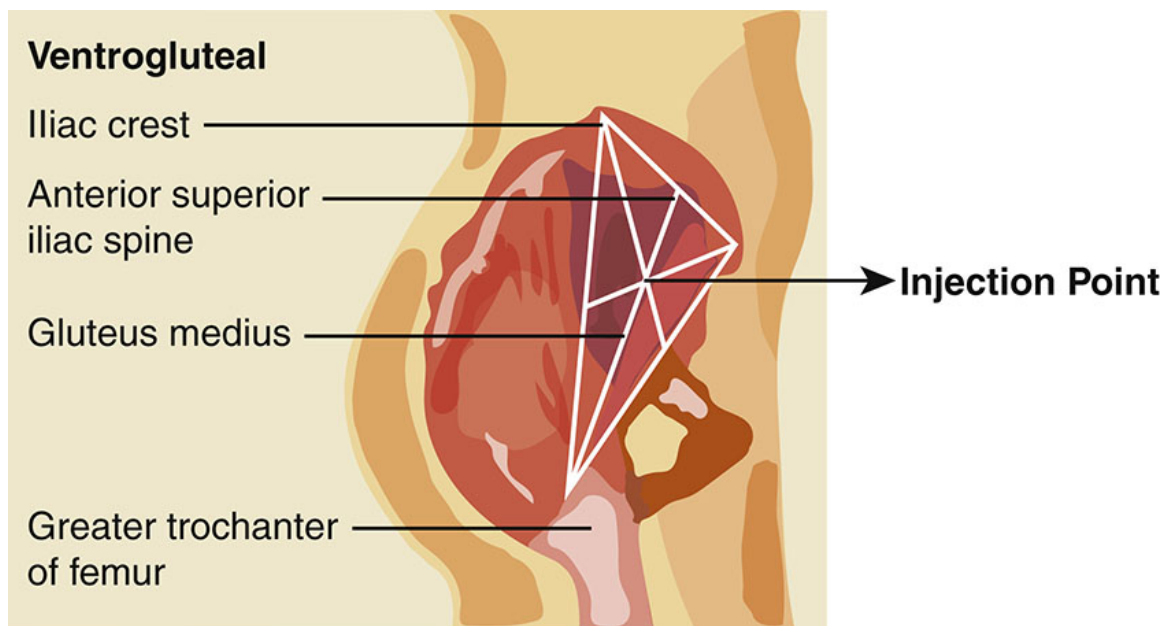

FIG. 31.26 Determination of intramuscular injection site using the G method.

From Kaya N, et al: The reliability of site determination methods in ventrogluteal area injection: a cross-sectional study, *Int J Nurs Stud* 52:355, 2015.

Vastus Lateralis

The vastus lateralis muscle is another injection site used in adults and is the preferred site for administration of biologicals (e.g., immunizations) to

infants, toddlers, and children (CDC, 2017; Hockenberry et al., 2019). The muscle is thick and well developed; it is located on the anterolateral aspect of the thigh. It extends in an adult from a hand breadth above the knee to a hand breadth below the greater trochanter of the femur (Fig. 31.27). Use the middle third of the muscle for injection. The width of the muscle usually extends from the midline of the thigh to the midline of the outer side of the thigh. With young children or cachectic patients, it helps to grasp the body of the muscle during injection to ensure that the medication is deposited in muscle tissue. To help relax the muscle, ask the patient to lie flat with the knee slightly flexed and foot externally rotated or to assume a sitting position.

FIG. 31.27 A, Landmarks for vastus lateralis site. B, Giving intramuscular injection in vastus lateralis muscle.

Deltoid

Although the deltoid site is easily accessible, the muscle is not well developed in many adults. There is potential for injury because the axillary, radial, brachial, and ulnar nerves and the brachial artery lie within the upper arm under the triceps and along the humerus (Fig. 31.28). *Carefully assess the condition of the deltoid muscle, consult medication references for suitability of medication, and carefully locate the injection site using anatomical landmarks.* Use this site for small medication volumes (less than 2 mL); administration of routine immunizations in toddlers, older children, and adults; or when other sites are inaccessible because of dressings or casts (CDC, 2017; Hopkins and Arias, 2013).

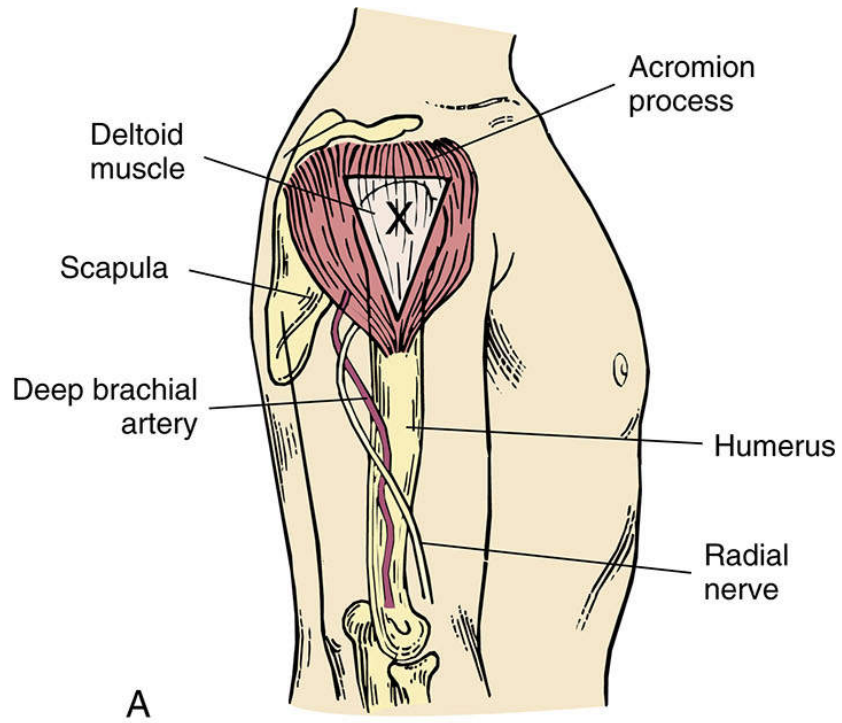

FIG. 31.28 A, Landmarks for deltoid site. B, Giving intramuscular injection in deltoid muscle.

Locate the deltoid muscle by fully exposing the patient's upper arm and shoulder and asking him or her to relax the arm at the side or by supporting the patient's arm and flexing the elbow. Do not roll up any tight-fitting sleeve. Allow the patient to sit or lie down. Palpate the lower edge of the acromion process, which forms the base of a triangle in line with the midpoint of the lateral aspect of the upper arm. The injection site is in the center of the triangle, about 3 to 5 cm (1 to 2 inches) below the acromion process (see [Fig. 31.28B](#)). You locate the apex of the triangle by placing four fingers across the deltoid muscle, with the top finger along the acromion process. The injection site is three finger widths below the acromion process.

Intradermal Injections

ID injections typically are used for skin testing (e.g., tuberculin screening and allergy tests). Because these medications are potent, they are injected into the dermis, where blood supply is reduced and medication absorption occurs slowly. Some patients have a severe anaphylactic reaction if medications enter the circulation too rapidly. You need to choose skin-testing sites that allow you to easily assess for changes in color and tissue integrity. Thus, ID sites need to be lightly pigmented, free of lesions, and relatively hairless. The inner forearm and upper back are ideal locations.

Use a tuberculin or small hypodermic syringe for skin testing. The angle of insertion for an ID injection is 5 to 15 degrees (see [Fig. 31.20](#)), and the bevel of the needle is pointed up. As you inject the medication, a small bleb resembling a mosquito bite appears on the surface of the skin. If a bleb does not appear or if the site bleeds after needle withdrawal, there is a good chance that the medication entered subcutaneous tissues. In this case test results will not be valid.

Safety in Administering Medications by Injection

Needleless Devices

Approximately 5.6 million health care workers in the United States are at risk of occupational exposure to bloodborne pathogens such as HIV and the hepatitis B virus ([Occupational Safety and Health Administration \[OSHA\], n.d.](#)). Occupational exposure often occurs through accidental needlesticks and sharps injuries. Needlestick injuries commonly occur when health care workers recap needles, mishandle IV lines and needles, or leave needles at a patient's bedside. Exposure to bloodborne pathogens

is one of the deadliest hazards to which nurses are exposed daily. Most needlestick injuries are preventable with the implementation of safe needle devices. The Needlestick Safety and Prevention Act mandates the use of special needle safety devices to reduce the frequency of needlestick injuries.

Safety syringes have a sheath or guard that covers a needle immediately after it is withdrawn from the skin (Fig. 31.29A-B). This eliminates the chance for a needlestick injury. The syringe and sheath are disposed of together in a receptacle. Use needleless devices whenever possible to reduce the risk of needlestick and sharps injuries (OSHA, n.d.). Always dispose of needles and other instruments considered sharps into clearly marked, appropriate containers (Fig. 31.30). Containers need to be puncture proof and leak proof. Never force a needle into a full needle disposal receptacle. Never place used needles and syringes in a wastebasket, in your pocket, on a patient's meal tray, or at the patient's bedside. Box 31.22 summarizes the recommendations for the prevention of needlestick injuries.

FIG. 31.29 Needle with plastic guard to prevent needlesticks. **A**, Position of guard before injection. **B**, After injection guard locks in place, covering needle.

FIG. 31.30 Sharps disposal using only one hand.

Box 31.22 Recommendations for Prevention of Needlestick Injuries

- Avoid using needles when effective needleless systems or SESIP devices are available.
- Do not recap needles after medication administration.
- Plan safe handling and disposal of needles before beginning a procedure that requires the use of a needle.
- Immediately dispose of used needles, needleless systems, and SESIP into puncture- and leak-proof sharps disposal containers.
- Maintain a sharps injury log that reports the following: type and brand of device involved in the incident; location of the incident (e.g., department or work area); description of the incident; privacy of the employees who have had sharps injuries (see agency policy).

- Attend educational offerings regarding bloodborne pathogens, and follow recommendations for infection prevention, including receiving the hepatitis B vaccine.
- Report all needlestick and sharps-related injuries immediately, according to agency policies.
- Participate in the selection and evaluation of SESIP devices with safety features within your agency whenever possible.

Data from Occupational Safety and Health Administration (OSHA): Bloodborne pathogens and needlestick injuries, *Fed Regist* 77(64):19934, 2012. https://www.osha.gov/FedReg_oshapdf/FED20120403.pdf. Accessed May 17, 2018.

Intravenous Administration

Nurses administer medications intravenously by the following methods:

1. Infusion of large volumes of IV fluid containers that contain medications mixed, labeled, and dispensed by pharmacy
2. Injection of a bolus or small volume of medication through an existing IV infusion line or intermittent venous access (heparin or saline lock)
3. “Piggyback” infusion of a solution containing the prescribed medication and a small volume of IV fluid through an existing IV line

In all three methods a patient has either an existing IV infusion running continuously or an IV access site for intermittent infusions. Most policies and procedures list who can administer IV medications and in which patient care units they can be given. These policies are made based on the medication, capability, and availability of staff and the type of monitoring equipment available.

[Chapter 42](#) describes the technique for performing venipuncture and establishing continuous IV fluid infusions. Medication administration is only one reason for supplying IV fluids. IV fluid therapy is used primarily for fluid replacement in patients unable to take oral fluids and as a means of supplying electrolytes and nutrients.

When using any method of IV medication administration, observe patients closely for symptoms of adverse reactions. After a medication

enters the bloodstream, it begins to act immediately, and there is no way to stop its action. Thus, take special care to avoid errors in dose calculation and preparation. Carefully follow the seven rights of safe medication administration, double-check medication calculations with another nurse, and know the desired action and side effects of every medication you give. If the medication has an antidote, make sure that it is available during administration. When administering potent medications, assess vital signs before, during, and after infusion. There are situations where it is recommended to do an independent double check of a medication dosage, especially high-risk medications given IV. The [ISMP \(2018a\)](#) describes how to do an independent double check:

- A double check must be conducted independently by a second person. A single person preparing and checking a medication is likely to see what he or she expects to see, even if an error has occurred.
- Two people must *separately* check each component of the work process. For example, a pharmacist calculates a dose, prepares a syringe of medication, and compares the product to the order; then a nurse *independently* checks the order, calculates the dose, and compares the results with the dispensed product for verification.
- Two people are unlikely to make the same mistake if they work independently. Holding up a syringe and a vial while saying “This is 5 units of insulin; can you check it?” is ineffective. The person asking for the double check must not influence the individual checking the product in any way.
- Use a double check only for very selective high-risk tasks or high-alert medications (not all) that most warrant their use (see agency policy).
- Fewer double checks performed strategically at the most vulnerable points of the medication use process are more effective than too many.

Administering medications by the IV route has advantages. Nurses often use this route in emergencies when a fast-acting medication needs to be delivered quickly. The IV route is also best when it is necessary to give medications to establish constant therapeutic blood levels. Some medications are highly alkaline and irritating to muscle and subcutaneous tissue. These medications cause less discomfort when given intravenously. Because IV medications are immediately available to the bloodstream once

they are administered, verify the rate of administration with a medication reference or a pharmacist before giving them to ensure that you give them safely over the appropriate amount of time. Patients experience severe adverse reactions if IV medications are administered too quickly.

Large-Volume Infusions

In the past nurses often, mixed medications into large volumes of intravenous (IV) fluids (500 to 1000 mL). However, today's safety standards and scientific evidence no longer support this practice ([Infusion Nurses Society \[INS\], 2016](#); [TJC, 2020](#)). Many patient safety risks such as incorrect calculation, poor aseptic technique, incorrect labeling, pump programming errors, lack of medication knowledge, and mix-up with another medication occur when nurses must prepare medications in IV containers on patient care units. [Box 31.23](#) summarizes current best practices for preparation and administration of IV medication.

Box 31.23 Best Practices for Administration of Intravenous Solutions and Medications

- Review medication orders for standardized concentrations and dosages of medication.
- Use standardized procedures for ordering, preparing, and administering intravenous (IV) medications.
- Administer solutions and medications prepared and dispensed from the pharmacy or as commercially prepared when possible.
- Never prepare high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or magnesium) on a patient care unit.
- Review medication order for use of standardized infusion concentrations of “high-alert” medications.
- Standardize the storage of IV medications.
- Use the mnemonic CATS PRRR to help remember safety checks for administering IV medications: *C*, compatibilities; *A*, allergies; *T*, tubing correct; *S*, site checked; *P*, pump safety checked; *R*, right rate; *R*, release clamps; *R*, return and reassess the patient.

- Use standardized label practices. Bold patient name, generic medication name, and patient-specific dose.
- Correctly use technology such as intelligent-infusion devices, bar code–assisted medication administration, and electronic medication administration record.

Adapted from Infusion Nurses Society: Infusion nursing standards of practice, *J Intraven Nurs* 39(1S), 2016; Gorski L: *Phillips's manual of I.V. therapeutics: evidence-based practice for infusion therapy*, ed 7, Philadelphia, 2019, FA Davis; and The Joint Commission (TJC): *2020 National Patient Safety Goals*, Oakbrook Terrace, IL, 2020, The Joint Commission.
http://www.jointcommission.org/standards_information/npsgs.aspx.

Pharmacies prepare medications in large volumes (500 or 1000 mL) of compatible IV fluids such as normal saline or lactated Ringer's solution. Vitamins and potassium chloride are two types of medications often added to IV fluids. Continuous infusion carries a risk: if the IV fluid is infused too rapidly, the patient is at risk for medication overdose and circulatory fluid overload.

Nurses mix medications into IV fluids only in emergency situations. The nurse *never* prepares high-alert medications (e.g., heparin, dopamine, dobutamine, nitroglycerin, potassium, antibiotics, or magnesium) on a patient care unit. Check with a pharmacist before mixing a medication in an IV container. If a pharmacist confirms that you need to prepare the medication, ask another nurse to verify your medication calculations and have that nurse watch you during the entire procedure to ensure that you prepare the medication safely. First ensure that the IV fluid and medication are compatible. Then prepare the medication in a syringe (see Skill 31.4) using strict aseptic technique. *Do not* add medications to IV bags that are already hanging because there is no way to tell the exact concentration of the medication. Add medications *only* to new IV bags.

When administering medications in large IV infusions, regulate the IV rate according to the health care provider's order. Monitor patients closely for adverse reactions to the medication and fluid volume overload. Also check the site frequently for infiltration and phlebitis (see [Chapter 42](#)).

Intravenous Bolus

An IV bolus involves introducing a concentrated dose of a medication directly into the systemic circulation (see Skill 31.6). Because a bolus

requires only a small amount of fluid to deliver the medication, it is an advantage when the amount of fluid that the patient can take is restricted. The IV bolus, or “push,” is the most dangerous method for administering medications because there is no time to correct errors. In addition, a bolus may cause direct irritation to the lining of blood vessels. Before administering a bolus confirm placement of the IV line. Never give a medication intravenously if the insertion site appears swollen or edematous or the IV fluid cannot flow at the proper rate. Accidental injection of a medication into the tissue around a vein causes pain, sloughing of tissue, and abscesses, depending on the composition of the medication. Medications that carry a risk of adverse effects if administered too quickly should be diluted and administered as a piggyback or via an infusion pump.

Determine the rate of administration of an IV bolus medication by the amount of medication that can be given each minute. For example, if a patient is to receive 4 mL of a medication over 2 minutes, give 2 mL of the IV bolus medication every minute. Look up each medication to determine the recommended concentration and rate of administration. The [ISMP \(2015d\)](#) recommends avoiding the use of terms such as “IV push,” “IVP,” or “bolus” in orders with medications that require administration over 1 minute or longer. Use more descriptive terms such as “IV over 5 minutes.” Remember, consider the purpose for which an IV medication is prescribed and any potential adverse effects related to the rate or route of administration.

Volume-Controlled Infusions

Another way of administering IV medications is through small amounts (50 to 100 mL) of compatible IV fluids. The fluid is within a secondary fluid container separate from the primary fluid bag. The container connects directly to the primary IV line or to separate tubing that inserts into the primary line (see Skill 31.7). Three types of containers are volume-control administration sets (e.g., Volutrol or Pediatrol), piggyback sets, and syringe pumps. Using volume-controlled infusions has several advantages:

- It reduces risk of rapid-dose infusion by IV push. Medications are diluted and infused over longer time intervals (e.g., 30 to 60 minutes).
- It allows for administration of medications (e.g., antibiotics) that are stable for a limited time in solution.

- It allows for control of IV fluid intake.

Piggyback

A piggyback is a small (25 to 250 mL) IV bag or bottle connected to a short tubing line that connects to the *upper* Y-port of a primary infusion line or to an intermittent venous access (Fig. 31.31). The label on the medication follows the ISMP IV piggyback medication label format (ISMP, 2018d) (Fig. 31.32). The piggyback tubing is a microdrip or macrodrip system (see Chapter 42). The set is called a *piggyback* because the small bag or bottle is higher than the primary infusion bag or bottle. In the piggyback setup the main line does not infuse when the piggybacked medication is infusing. The port of the primary IV line contains a back-check valve that automatically stops flow of the primary infusion once the piggyback infusion flows. After the piggyback solution infuses and the solution within the tubing falls below the level of the primary infusion drip chamber, the back-check valve opens, and the primary infusion again flows.

FIG. 31.31 Piggyback setup.

FIG. 31.32 IV piggyback medication with label following ISMP safe-labeling guidelines.

Volume-Control Administration

Volume-control administration (e.g., Buretrol) sets are small (150-mL) containers that attach just below the primary infusion bag or bottle. The set is attached and filled in a manner similar to that used with a regular IV infusion. Follow package directions for priming sets (see [Chapter 42](#)).

Syringe Pump

The syringe pump is battery operated and allows medications to be given in very small amounts of fluid (5 to 60 mL) within controlled infusion times using standard syringes.

Intermittent Venous Access

An intermittent venous access (commonly called a *saline lock*) is an IV catheter capped off on the end with a small chamber covered by a rubber diaphragm or a specially designed cap. Special rubber-seal injection caps usually accept needle safety devices (see [Chapter 42](#)). Advantages to intermittent venous access include the following:

- Cost savings resulting from the omission of continuous IV therapy
- Effectiveness of nurse's time enhanced by eliminating constant monitoring of flow rates
- Increased mobility, safety, and comfort for the patient

Before administering an IV bolus or piggyback medication, assess the patency and placement of the IV site. After the medication has been administered through an intermittent venous access, the access must be flushed with a solution to keep it patent. Generally normal saline is an effective flush solution for peripheral catheters. Some agencies require the use of heparin. Nurses need to verify and follow agency policies regarding the care and maintenance of the IV site.

Administration of Intravenous Therapy in the Home

Sometimes patients need IV therapy at home. Common infusions that patients receive include antimicrobials, chemotherapy, total parenteral nutrition, biological therapy, and other medications (Gorski, 2019). Most patients typically receive their home IV therapy through a long-term central venous catheter (CVC) (see Chapter 42). Home health nurses assess patients' responses to the medication, monitor the CVC site, and teach patients and their family caregivers how to administer infusions and maintain the CVC.

Carefully assess patients and their family caregivers to determine their ability to manage IV therapy at home. Begin instruction on IV care management as soon as you know that a patient will have IV therapy at home. Your instruction often begins while a patient is hospitalized. Patients and family caregivers need to learn how to check their catheter for signs of complications and to flush, lock, and ensure the patency of the IV catheter (Gorski, 2019). If the patient has a tunneled catheter (see Chapter 42), site care including dressing changes may be taught as well. Patients also need to know when to notify the home care nurse or health care provider. Plan to teach patients and their family caregivers how to maintain IV administration equipment, including the infusion pump.

Safety Guidelines for Nursing Skills

Ensuring patient safety is an essential role of a professional nurse. To ensure patient safety, communicate clearly with members of the interprofessional team, assess and incorporate the patient's priorities of care and preferences, and use the best evidence when making decisions about your patient's care. When performing the skills in this chapter, remember the following points to ensure safe, individualized patient care.

Follow these guidelines to ensure safe medication administration:

- Be vigilant during medication administration. Avoid distractions while preparing all medications. No-interruption zones (NIZs) have been recommended to reduce distractions during medication preparation and administration (Bravo and Cochran, 2016; Yoder et al., 2015). NIZs are created by placing signs, red tape, or tile borders on the floor around medication carts or areas. Nurses standing in these zones are not to be interrupted.
- Be sure that your patients receive the appropriate medications.
- Know why your patient is receiving each medication; know what you need to do before, during, and after medication administration; and evaluate the effectiveness of medications and any adverse effects.
- Verify that medications have not expired by checking labels.
- Use at least two identifiers before administering medications, and check against the medication administration record (MAR). Follow agency policy for patient identification.
- Before administering medication, it is critical to ensure that all information is correct. You should check for accuracy three times:
 1. The first check is when the medications are pulled or retrieved from the automated dispensing machine, the medication drawer, or whatever system is in place at the agency.
 2. The second check is when preparation of the medications for administration takes place.
 3. The final check occurs at the patient's bedside just before medications are given.
- Clarify unclear medication orders and ask for help whenever you are uncertain about an order or calculation. Consult with your peers, pharmacists, and other health care providers, and be sure that you have resolved all concerns related to medication administration before preparing and giving medications.
- Use the technology (e.g., bar scanning, electronic MARs) available in your agency when preparing and giving

medications. Follow all policies related to use of the technology, and do not use “work-arounds.” A *work-around* bypasses a procedure, policy, or problem in a system. Nurses who use “work-arounds” fail to follow agency protocols, policies, or procedures during medication administration in an attempt to get medications administered to patients in a timelier fashion.

- Use strict aseptic technique during parenteral medication preparation and administration.
- Educate patients about each medication they take while you are administering medications. It is important for a patient to know each medication with respect to purpose, daily dose and when to take the medications, most common side effects, and the problems to report to the health care provider. Make sure that you answer all their questions before administering medications. Educate family caregivers if appropriate.
- Most of the time you cannot delegate medication administration. Ensure that you follow standards set by the Nurse Practice Act in your state and guidelines established by your health care agency. Licensed practical nurses or licensed vocational nurses usually can administer medications via the oral (po), subcutaneous, IM, and ID routes. Sometimes they can give medications intravenously if they have had special training and if the medications are not high-alert medications. Some states also allow certified medical assistants to administer some types of medications (e.g., oral medications) in long-term care agencies.
- Follow safety guidelines to prevent needlestick injuries. Use engineered devices and dispose of all sharps in safety containers.

Skill 31.1. Administering Oral Medications ◦

Delegation and Collaboration

The skill of administering oral medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential side effects of medications and to report their occurrence.
- Informing nurse if patient condition changes or worsens (e.g., pain, itching, or rash) after medication administration.

Equipment

- Automated, computer-controlled medication dispensing system or medication cart
- Disposable medication cups (mL only cup)
- Glass of water, juice, or preferred liquid and drinking straw
- Pill-crushing device (*optional*)
- Paper towels
- Medication administration record (MAR) (electronic or printed)
- Clean gloves (if handling an oral medication)

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indications, and nursing implications.	Allows you to anticipate effects of medication and observe patient's response.
3. Assess for any contraindications to patient receiving oral medication, including being on NPO status, inability to swallow, nausea/vomiting, bowel inflammation, reduced peristalsis, recent gastrointestinal (GI) surgery, gastric suction, and decreased level of consciousness (LOC). Notify health care provider if any contraindications are present.	Alterations in GI function can interfere with medication absorption, distribution, and excretion. Patients with GI suction do not receive actions of oral medications because the medications are suctioned from the GI tract before they are absorbed.
4. Assess patient's medical, medication, and diet history, and history of allergies. List any medication allergies on each page of MAR and prominently display on patient's medical record. When allergies are present, patient should wear an allergy bracelet.	These factors influence how certain medications act. Information reveals previous problems with medication administration. Allergy alert helps prevent adverse events.
5. Perform hand hygiene. Gather and review physical assessment findings, including patient's weight (in metric units), vital signs, and laboratory data that influence medication administration such as results of renal and liver function studies.	Many medication doses are based on patient's weight. Physical examination findings or laboratory data may contraindicate medication administration. Renal and liver function status affects metabolism and excretion of medications (Burchum and Rosenthal, 2019).
6. Assess risk for aspiration using a dysphagia screening tool if available (see Chapter 45). Protect patient from aspiration by assessing swallowing ability.	Aspiration occurs when food, fluid, or medication intended for GI administration is inadvertently administered into the respiratory tract. Patients with altered ability to swallow are at higher risk for aspiration (Forough et al.,2018).
7. Assess patient's symptoms before initiating medication therapy.	Provides information to evaluate desired effect of medication.
8. Assess patient's preference for fluids and determine whether medications can be given with these fluids. Maintain fluid restrictions as prescribed.	Some fluids interfere with medication absorption (e.g., dairy products affect tetracycline). Offering fluids during medication administration is an excellent way to increase patient's fluid intake. Fluids ease swallowing and facilitate absorption from the GI tract. However, if fluid restriction exists, skillful planning of fluid intake must coordinate with medication times and types of medications.
9. Assess patient's and family caregiver's knowledge regarding health and medication use, medication schedule, and ability to prepare medications.	Determines patient's and family caregiver's need for medication education and guidance to achieve medication adherence.
Table Continued	

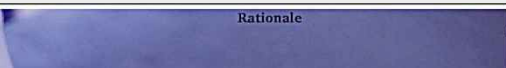

Step	Rationale
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR.	Promotes time management and efficiency when preparing medications for all patients.
2. Plan preparation to avoid interruptions. Create a quiet environment. Do not take phone calls or talk with others. Follow agency "No-interruption zone" (NIZ) policy.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications.	
a. Perform hand hygiene. Arrange medication tray and cups in medication preparation area or move medication cart to position outside patient's room.	Reduces transfer of microorganisms. Organization of equipment saves time and reduces error.
b. Log on to automated medication dispensing system (AMDS) or unlock medicine drawer or cart.	Medications are safeguarded when locked in cabinet, cart, or AMDS.
c. Perform hand hygiene and prepare medications for <i>one patient at a time</i> using aseptic technique. Follow the seven rights of medication administration. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR screen.	Ensures that medications remain sterile. Prevents preparation errors.
d. Select correct medication from AMDS, unit-dose drawer, or stock supply. Compare name of medication on label with MAR or computer printout (see illustration). Exit AMDS after removing medication.	Reading label and comparing it against transcribed order reduces errors. Exiting AMDS ensures no one else can remove medications using your identify. <i>This is the first check for accuracy.</i>
e. Check or calculate medication dose as necessary. Double-check any calculation. Check expiration date on all medications and return outdated medication to pharmacy.	Double-checking pharmacy calculations reduces risk for error. Agency policy may require you to check calculations of certain medications such as insulin with another nurse. Expired medications may be inactive or harmful to patient.
f. If preparing a controlled substance, check record for previous medication count and compare current count with available supply. Controlled medications may be stored in computerized locked cart.	Controlled substance laws require nurses to carefully monitor and count dispensed controlled medications (e.g., opioids).
g. Prepare solid forms of oral medications.	
(1) To prepare unit-dose tablets or capsules, place packaged tablet or capsule directly into medication cup without removing wrapper. Administer medications only from containers with labels that are clearly marked.	Wrappers maintain cleanliness and identify medication name and dose, which can facilitate teaching.
(2) When using a blister pack, "pop" medications through foil or paper backing into a medication cup (see illustration).	Packs provide a 1-month supply, with each "blister" usually containing a single dose.
(3) If it is necessary to give half the dose of medication, pharmacy should split, label, package, and send medication to unit. If you must split medication, use clean, gloved hand to cut with clean pill-cutting device. Only cut tablets that are prescored by the manufacturer (line traverses the center of the tablet).	Reduces contamination of the tablet. In health care agencies, only pharmacy should split tablets to ensure patient safety (USDHHS, 2015). If a tablet is FDA-approved to be split, this information will be printed in the "HOW SUPPLIED" section of the manufacturer's label insert.
 <p data-bbox="354 1444 740 1478">Step 1d Nurse compares label of medication with transcribed medication order on computerized MAR.</p>	 <p data-bbox="977 1402 1276 1436">STEP 1g(2) Place tablet from blister pack into medicine cup without removing wrapper.</p>

Table Continued

Step	Rationale
<p>(4) Place all tablets or capsules that patient will receive in one medicine cup, except for those requiring pre-administration assessments (e.g., pulse rate or blood pressure). Place those medications in separate additional cup with wrapper intact.</p>	<p>Keeping medications that require pre-administration assessments separate from others serves as a reminder and makes it easier to withhold medications as necessary.</p>
<p>(5) If patient has difficulty swallowing and liquid medications are not an option, use a pill-crushing device (see illustration A). Clean device before using. If device is unavailable, place medication between two cups, and grind and crush (see illustration B). Mix ground tablet in small amount (teaspoon) of soft food (custard or applesauce).</p>	<p>Large tablets are often difficult to swallow. A ground tablet mixed with palatable soft food is usually easier to swallow.</p>
<p>CLINICAL DECISION:Not all medications can be crushed safely. Consult with a pharmacist or the ISMP Do Not Crush List (ISMP, 2018a).</p>	
<p>h. Prepare liquids.</p>	
<p>(1) Use unit-dose container with correct amount of medication. Gently shake container. Administer medication packaged in a single-dose cup directly from the single-dose cup. Do not pour medicine into another cup.</p>	<p>Using unit-dose container with correct dosage of medication provides most accurate dose of medication (ISMP, 2018a). Shaking container ensures that medication is mixed before administration.</p>
<p>(2) Unit-dose oral syringe (see illustration): Be sure to use only oral syringes marked "Oral Use Only" dispensed by pharmacy.</p>	<p>Ensures that all oral medications that are not commercially available as unit-dose products are dispensed by the pharmacy in an oral syringe (ISMP, 2018a).</p>
<p>CLINICAL DECISION:Based on current best practice (ISMP, 2018a), liquid medications that are not available or are not in correct dose in a unit-dose container should be dispensed by the pharmacy in special oral syringes marked "Oral Use Only." These syringes do not connect to any type of parenteral (e.g., intravenous [IV] tubing). Additionally, current evidence shows that liquid measuring devices on patient care units result in inaccurate dosing. Having oral medications prepared in the pharmacy ensures that you give the most accurate dose of a medication possible and prevents parenteral administration of oral medications. Ensure that the small plastic ring on the syringe (especially 1-mL syringes) has been removed (ISMP, 2018b).</p>	
Step	Rationale
	

A

B

Step 1g(5) A, Pill crushing device. B, Crushing tablet with pill-crushing device.

Step

Rationale

Step 1h(2) Use special oral medication syringes to prepare small amounts of liquid medications.

Table Continued

Step	Rationale
i. Return stock containers or unused unit-dose medications to shelf or drawer. Label medication cups and poured medications with patient's name before leaving medication preparation area. Do not leave medications unattended.	Ensures that correct medications are prepared for correct patient.
j. Before going to patient's room, compare patient's name and name of medication on label of prepared medications with MAR.	Comparing labels a second time reduces errors. <i>This is the second check for accuracy.</i>
2. Administer medications.	
a. Take medication to patient at correct time (see agency policy). Medications that require exact timing include STAT doses, first-time or loading doses, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (no more than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011a). During administration apply seven rights of medication administration.	Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011a). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacological effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacological effect (DHHS, 2011; ISMP, 2011a).
b. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
c. At patient's bedside, again compare MAR or computer printout with name of medication on medication labels and patient name. Ask patient whether he or she has allergies.	<i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.
d. Explain the purpose of each medication, action, and most common adverse effects. Allow sufficient time for patient to ask questions. Include family caregiver if appropriate.	Patient has the right to be informed, and patient and family caregiver understanding of each medication improves adherence with medication therapy.
e. Perform hand hygiene. Perform necessary pre-administration assessment (e.g., blood pressure, pulse) for specific medications. Ask patient again whether he or she has allergies.	Reduces transmission of microorganisms. Determines whether specific medications should be withheld at that time. Confirms patient's allergy history.
CLINICAL DECISION: <i>If patient expresses concern regarding accuracy of a medication, do not give the medication. Explore patient's concern and verify health care provider's order before administering. Listening to patient's concerns may prevent a medication error.</i>	
f. Help patient to sitting or Fowler's position. Use side-lying position if he or she is unable to sit. Have patient stay in this position for 30 minutes after administration.	Decreases risk for aspiration during swallowing.
g. <i>For tablets:</i> Patient may wish to hold solid medications in hand or cup before placing in mouth. Offer water or preferred liquid to help patient swallow medications.	Patient can become familiar with medications by seeing each medication. Choice of fluid can improve fluid intake.
h. <i>For orally disintegrating formulations (tablets or strips):</i> Remove medication from packet just before use. Do not push tablet through foil. Place medication on top of patient's tongue. Caution against chewing it.	Orally disintegrating formulations begin to dissolve when placed on tongue. Water is not needed. Careful removal from packaging is necessary because tablets and strips are thin and fragile.
i. <i>For sublingually administered medications:</i> Have patient place medication under tongue and allow it to dissolve completely (see Fig. 31.3). Caution patient against swallowing tablet.	Medication is absorbed through blood vessels of undersurface of tongue. If swallowed, it is destroyed by gastric juices or rapidly detoxified by liver, preventing therapeutic blood level.
j. <i>For buccal administered medications:</i> Have patient place medication in mouth against mucous membranes of cheek and gums until it dissolves (see Fig. 31.4).	Buccal medications act locally or systemically as they are swallowed in saliva.
CLINICAL DECISION: <i>Avoid administering anything by mouth, including other oral medications, until orally disintegrating buccal or sublingual medication is completely dissolved.</i>	

Table Continued

Step	Rationale
k. For powdered medications: Mix with liquids at bedside and give to patient to drink.	When prepared in advance, powdered medications thicken; some even harden, making swallowing difficult.
l. For crushed medications mixed with food: Give each medication separately in teaspoon of food.	Ensures that patient swallows all of medicine. <i>Never mix medication in a meal serving of food.</i>
m. For lozenges: Caution patient against chewing or swallowing lozenges.	Lozenges act through slow absorption through oral mucosa, not gastric mucosa.
n. For effervescent medication: Add tablet or powder to glass of water. Administer immediately after dissolving.	Effervescence improves unpleasant taste and often relieves GI problems.
o. If patient is unable to hold medications, place medication cup or oral syringe to lips and gently introduce each medication into mouth one at a time. Administer each tablet or capsule one at a time. Inject liquid from oral syringe slowly. A spoon can also be used to place pill in patient's mouth. Do not rush or force medications.	Administering a single-dose tablet, capsule, or oral syringe dose eases swallowing and decreases risk for aspiration.
p. Stay until patient swallows each medication completely or takes it by the prescribed route. Ask patient to open mouth if uncertain whether medication has been swallowed.	Ensures that patient receives ordered dose. If left unattended, patient may not take dose or may save medications, causing health risks.
q. For highly acidic medications (e.g., aspirin), offer patient a nonfat snack (e.g., crackers) if not contraindicated by his or her condition.	Reduces gastric irritation. Fat content of foods may delay medication absorption.
r. Help patient return to position of comfort.	Maintains patient's comfort.
s. Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.
3. Dispose of soiled supplies and perform hand hygiene. Return cart to medication room and clean work area.	Reduces transmission of microorganisms.
Evaluation	
1. Return within an appropriate time to evaluate patient's response to medications, including therapeutic effects, side effects or allergic reactions, and adverse effects.	Evaluates therapeutic benefit of medication and helps to detect onset of side effects or allergic reactions. Sublingual medications act in 15 minutes; most oral medications act in 30 to 60 minutes.
2. Ask patient or family caregiver to identify medication name and explain purpose, indication, action, dose schedule, and potential side effects.	Determines level of knowledge gained by patient and family caregiver.
3. Use Teach-Back: "I want to be sure I showed you how to use your sublingual nitroglycerin. Show me where you will place the tablet in your mouth." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
1. Patient exhibits adverse effects (e.g., side effect, toxic effect, allergic reaction). <ul style="list-style-type: none"> • Notify health care provider and pharmacy. • Withhold further doses. • Assess vital signs. • Symptoms such as urticaria, rash, pruritus, rhinitis, and wheezing may indicate an allergic reaction and need for emergency medications. • Add allergy information to patient's medical record. 	
2. Patient refuses medication. <ul style="list-style-type: none"> • Assess reason for patient refusing medication. • Provide further instruction • Do not force patient to take medications. • Document and notify health care provider. 	
3. Patient or family caregiver is unable to explain medication information. <ul style="list-style-type: none"> • Further assess patient's or family caregiver's knowledge of medications and guidelines for medication safety. • Further instruction or different approach to instruction is necessary. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record medication, dose, route, and time administered on patient's MAR immediately after administration, not before. Include initials or signature. • If you do not administer the medication, record reason on flow sheet or nurses' notes in electronic health record (EHR) or chart, and follow agency policy for noting withheld medication. • Record patient response to medication, instructions (including teach-back), and validation of understanding on flow sheet or nurses' notes in electronic health record (EHR) or chart. 	
• 1	

Administering Eye (Ophthalmic) Medications Delegation and Collaboration

The skill of administering eye medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- The specific potential side effects of medications and to report their occurrence.
- The potential for temporary burning or blurring of vision after administration of eye medications.

Equipment

- Appropriate medication (eyedrops with sterile dropper, ointment tube, or medicated intraocular disk)
- Clean gloves (for eyedrops)
- Medication administration record (MAR) (electronic or printed)
- Eyedrops or Ointment
- Cotton balls or facial tissue
- Warm water and washcloth
- Eye patch and tape (*optional*)

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indication, and nursing implications.	Allows you to anticipate effects of medication and observe patient's response.
3. Assess patient's medical and medication history and history of allergies. List any medication allergies on each page of the MAR and prominently display it on the patient's medical record per agency policy. When allergies are present, patient should wear allergy bracelet.	Factors influence how certain medications act. Reveals patient's need for medication. Allergy alert prevents adverse effects.
4. Perform hand hygiene. Assess condition of external eye and structures (see Chapter 30). This may be done just before medication instillation (if drainage is present, apply clean gloves).	Provides baseline to determine whether local response to medications occurs. Also indicates need to clean eye before medication application.
5. Determine whether patient has any symptoms of eye discomfort or visual impairment.	Certain eye medications act to either lessen or increase these symptoms.
6. Assess patient's level of consciousness (LOC) and ability to follow directions.	If patient becomes restless or combative during procedure, greater risk for accidental eye injury exists.
7. Assess patient's and family caregiver's knowledge regarding medication therapy and patient's desire to self-administer medication.	Indicates need for health teaching. Motivation influences teaching approach.
8. Assess patient's ability to manipulate and hold dropper or ocular disk.	Reflects patient's ability to learn to self-administer medication.
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR	Promotes time management and efficiency when preparing medications for all patients.
2. Plan preparation to avoid interruptions. Create a quiet environment. Do not take phone calls or talk with others. Follow agency "No-interruption zone" policy.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications for one patient at a time. Attend to procedure and avoid distraction. Check label of medication against MAR two times, when removing medication from unit dose or AMDS and before leaving preparation area (see Skill 31.1). Prepare eyedrops by taking container out of refrigerator and rewarming to room temperature before administering to patient. Check expiration date on container. Perform hand hygiene.	Warming eyedrops reduces eye irritation. These are the first and second checks for accuracy. Process ensures that right patient receives right medication.
2. Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include STAT doses, first-time or loading doses, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (no more than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011a). During administration apply seven rights of medication administration.	Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011a). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacological effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacological effect (DHHS, 2011; ISMP, 2011a).
3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2019).
4. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.	This is the third check for accuracy and ensures that patient receives correct medication. Confirms patient's allergy history.
5. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the medications. Patients who self-instill medications may be allowed to give drops under nurse's supervision (check agency policy).	Patient has right to be informed, and patient's understanding of each medication improves adherence to medication therapy.
6. Tell patients receiving eyedrops (e.g., mydriatics) that vision will be blurred temporarily and that sensitivity to light may occur.	May relieve patient's anxiety.

Step	Rationale
CLINICAL DECISION: Instruct and reinforce that patient should not drive or operate machinery or perform any activity that requires clear vision until vision and sensitivity to light return to normal.	

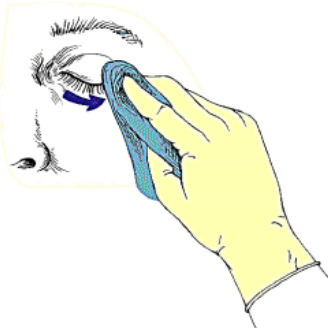

7. Instill eye medications.	
a. Apply clean gloves. Ask patient to lie supine or sit back in chair with head slightly hyperextended, looking up.	Position provides easy access to eye for medication instillation and minimizes drainage of medication into tear duct.
CLINICAL DECISION: Do not hyperextend the neck of a patient with cervical spine injury.	
b. If drainage or crusting is present along eyelid margins or inner canthus, gently wash away. Soak any dried crusts with warm, damp washcloth or cotton ball over eye for several minutes. Always wipe clean from inner to outer canthus (see illustration). Remove gloves and perform hand hygiene.	Soaking allows easy removal of crusts without applying pressure to eye. Cleaning from inner to outer canthus avoids entrance of microorganisms into lacrimal duct (Burchum and Rosenthal, 2019).
c. Explain that there might be temporary burning sensation from drops.	Corneas are highly sensitive.
d. Instill eyedrops.	
(1) Hold clean cotton ball or tissue in nondominant hand on patient's cheekbone just below lower eyelid.	Cotton or tissue absorbs medication that escapes eye.
(2) With tissue or cotton ball resting below lower lid, gently press downward with thumb or forefinger against bony orbit, exposing conjunctival sac. Never press directly against patient's eyeball.	Prevents pressure and trauma to eyeball and prevents fingers from touching eye.
(3) Ask patient to look at ceiling. Rest dominant hand on patient's forehead; hold filled medication eyedropper approximately 1 to 2 cm (0.5 to 1.0 inch) above conjunctival sac.	Action moves cornea up and away from conjunctival sac and reduces blink reflex. Prevents accidental contact of eyedropper with eye and reduces risk of injury and transfer of microorganisms to dropper (ophthalmic medications are sterile).
(4) Drop prescribed number of drops into conjunctival sac (see illustration).	Conjunctival sac normally holds 1 or 2 drops. Provides even distribution of medication across eye.
 <p>STEP 7b Clean eye, washing from inner to outer canthus before administering drops or ointment.</p>	 <p>STEP 7d(4) Hold eyedropper over lower conjunctival sac.</p>

Table Continued

Step	Rationale
(5) If patient blinks or closes eye, causing drops to land on outer lid margins, repeat procedure.	Drops must enter conjunctival sac to achieve therapeutic effect.
(6) When administering drops that have systemic effects, apply gentle pressure to patient's nasolacrimal duct with clean tissue for 30 to 60 seconds over each eye, one at a time (see illustration). Avoid pressure directly against patient's eyeball.	Prevents overflow of medication into nasal and pharyngeal passages. Prevents absorption into systemic circulation (Lilley et al., 2020).
(7) After instilling drops, ask patient to close eyes gently.	Helps distribute medication. Squinting or squeezing eyelids forces medication from conjunctival sac (Lilley et al., 2020).
e. Instill ophthalmic ointment.	
(1) Holding applicator above lower lid margin, apply thin ribbon of ointment evenly along inner edge of lower eyelid on conjunctiva (see illustration) from inner to outer canthus.	Reduces transmission of infection. Distributes medication evenly across eye and lid margin.
(2) Have patient close eye and rub lid lightly in circular motion with cotton ball if not contraindicated. Avoid placing pressure directly against patient's eyeball.	Further distributes medication without traumatizing eye.
(3) If excess medication is on eyelid, gently wipe it from inner to outer canthus.	Promotes comfort and prevents trauma to eye.
(4) If patient needs an eye patch, apply clean one by placing it over affected eye so that entire eye is covered. Tape securely without applying pressure to eye.	Clean eye patch reduces risk of infection.
f. Insert intraocular disk.	
(1) Open package containing disk. Gently press your fingertip against disk so that it adheres to your finger. It may be necessary to moisten gloved finger with sterile saline. Position convex side of disk on your fingertip.	Allows you to inspect disk for damage or deformity.
(2) With your other hand gently pull patient's lower eyelid away from eye. Ask patient to look up.	Prepares conjunctival sac for receiving medicated disk and moves sensitive cornea away.
(3) Place disk in conjunctival sac so that it floats on sclera between iris and lower eyelid (see illustration).	Ensures delivery of medication.
(4) Pull patient's lower eyelid out and over disk (see illustration). You should not be able to see disk at this time. Repeat if you can see disk.	Ensures accurate medication delivery.
8. Remove intraocular disk.	
a. Perform hand hygiene and apply clean gloves. Gently pull downward on lower eyelid using your nondominant hand.	Exposes disk.
b. Using forefinger and thumb of your dominant hand, pinch disk and lift it out of patient's eye (see illustration).	
9. After administering eye medications, remove and dispose of gloves and soiled supplies; perform hand hygiene.	Reduces transmission of microorganisms.
 <p data-bbox="358 1514 776 1535">STEP 7d(4) Apply gentle pressure against nasolacrimal duct after giving eye medications.</p>	 <p data-bbox="1101 1257 1268 1304">STEP 7e(1) Nurse applies ointment along inner edge of lower eyelid from inner to outer canthus.</p>

Table Continued

Step	Rationale
Evaluation	
1. Observe response to medication by assessing visual changes, asking whether symptoms are relieved, and noting any side effects or discomfort felt.	Evaluates effects of medication.
2. Ask patient to discuss purpose of medication, indication, action, side effects, and technique of administration.	Determines patient's level of understanding.
3. Use Teach-Back: "I want to be sure I showed you how to insert the intraocular disk. Show me how to insert it into your left eye." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient complains of burning or pain or experiences local side effects (e.g., headache, bloodshot eyes, local eye irritation). Medication concentration and patient's sensitivity both influence chances of side effects developing.</p> <ul style="list-style-type: none"> • Eyedrops may have been instilled onto cornea, or dropper touched surface of eye. • Notify health care provider for possible adjustment in medication type and dosage. 	
<p>2. Patient experiences systemic effects from drops (e.g., increased heart rate and blood pressure from epinephrine, decreased heart rate and blood pressure from timolol).</p> <ul style="list-style-type: none"> • Notify health care provider immediately. • Remain with patient. Assess vital signs. • Withhold further doses. 	
<p>3. Patient or family caregiver is unable to explain medication information or steps for administering eyedrops or has trouble manipulating dropper.</p> <ul style="list-style-type: none"> • Repeat instructions as appropriate. Include return demonstration. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Record medication, concentration, dose or strength, number of drops, site of application (e.g., right eye, left eye, or both eyes), and time administered on MAR immediately after administration, not before. Include initials or signature. • Record patient teaching (including teach-back) and validation of understanding on flow sheet or nurses' notes in electronic health record (EHR) or chart. • Record objective data related to tissues involved (e.g., redness, drainage, irritation), any subjective data (e.g., pain, itching, altered vision), and patient's response to medications. Note evidence of any side effects experienced on flow sheet or nurses' notes in electronic health record (EHR) or chart. • Report adverse effects and patient response and/or withheld medications to nurse in charge or health care provider. 	
Step	Rationale

STEP 7(3) Place intraocular disk in conjunctival sac between iris and lower eyelid.

Step

Rationale

STEP 7(4) Gently pull patient's lower eyelid over disk.

Using Metered-Dose or Dry Powder Inhalers

Delegation and Collaboration

The skill of administering inhaled medications cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential side effects of medications and to report their occurrence to the nurse.
- Reporting breathing difficulty (e.g., paroxysmal or sustained coughing, audible wheezing) to the nurse.

Equipment

- Inhaler device with medication canister (metered-dose inhaler [MDI], breath-actuated inhaler [BAI], or dry powder inhaler

[DPI]) (Fig. 31.33)

FIG. 31.33 Types of inhalers. **A**, Metered-dose inhaler (MDI). **B**, Breath-actuated inhaler (BAI). **C**, Dry powder inhaler (DPI).

- Spacer device such as AeroChamber or InspirEase (optional for MDI)
- Facial tissues (*optional*)
- Medication administration record (MAR) (electronic or printed)
- Stethoscope
- Pulse oximeter (*optional*)

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).
2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indication, and nursing implications.	Allows you to anticipate effects of medication while observing patient's response.
3. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display it on the patient's medical record. When allergies are present, patient should wear an allergy bracelet.	Factors influence how certain medications act. Reveals patient's need for medication. Allergy alert helps prevent adverse effects.
4. Perform hand hygiene. Assess respiratory status and auscultate breath sounds (see Chapter 30). Also assess exercise tolerance; does patient develop shortness of breath easily?	Reduces transmission of microorganisms. Establishes baseline of airway status for comparison during and after treatment.
5. Measure the patient's peak expiratory flow rate using a peak flow meter. Have patient measure if done so at home. Use patient's peak flow meter if available (see Chapter 41).	A peak flow meter is used to measure air flow or peak expiratory flow rate and aids in monitoring airway status of patients with chronic asthma (AAAAI, 2016).
6. Assess patient's symptoms before initiating medication therapy.	Provides information to evaluate desired effect of medication.
7. Assess patient's ability to hold, manipulate, and depress canister and inhaler.	Any impairment of grasp or presence of hand tremors interferes with patient's ability to depress canister within inhaler. Spacer device is often necessary with an MDI.
8. If patient was previously instructed in self-administration, have patient demonstrate how to use the device.	Patients who have adequate understanding of how to use an inhaler may forget the procedure. Ongoing assessment of inhaler technique identifies areas for further education and reinforcement (Ari, 2015).
Table Continued	

Step	Rationale
9. Assess patient's readiness and ability to learn and use inhaler. Determine type of device patient may prefer, considering portability, access to obtain, and cost. Ask questions about medication and its availability. Determine whether patient is alert, able to participate in own care, and is not fatigued, in pain, or in respiratory distress.	When selecting an aerosol delivery device, consider several factors, such as medication availability and administration time, patient age and ability to use the device correctly, portability of device, convenience in both outpatient and inpatient settings, and costs, as well as health care provider and patient preference (Barrons et al., 2015; Bonini and Usmani, 2015). In some situations, mental or physical limitations affect patient's ability to learn and methods used for instruction.
10. Assess patient's knowledge and understanding of disease and purpose and action of prescribed medications.	Knowledge of disease is essential for patient to realistically understand when to use inhaler.
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR.	Promotes time management and efficiency when preparing medications for all patients.
2. Plan preparation to avoid interruptions. Create a quiet environment. Do not take phone calls or talk with others. Follow agency "No-interruption zone" policy.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications for inhalation. Attend to procedure and avoid distraction. Check label of medication against MAR two times, when removing inhaler from unit dose or AMDS and before leaving medication preparation area (see Skill 31.1). Preparation usually involves taking inhaler device out of storage and into patient room. Check expiration date on container. Perform hand hygiene.	<i>These are the first and second checks for accuracy.</i> Process ensures that right patient receives right medication.
2. Take medication to patient at correct time (see agency policy). Medications that require exact timing include STAT dose, first-time or loading doses, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (no more than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011a). During administration apply seven rights of medication administration.	Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011a). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacological effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacological effect (DHHS, 2011; ISMP, 2011a).
Table Continued	

Step	Rationale
3. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
4. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.	<i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.
5. Help patient to sit up into high-Fowler's position or up in chair.	This position makes it easier to use inhaler.
6. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions about the medications. Warn about overuse of inhaler and side effects.	Patient has right to be informed, and patient's understanding of each medication improves adherence to medication therapy.
7. Explain procedure to patient. Be specific if patient wishes to self-administer medication. Allow adequate time for patient to manipulate inhaler, canister, and/or spacer device (if provided). Explain where and how to set up at home.	Patient must be familiar with how to use equipment.
8. Explain and demonstrate steps for administering MDI without spacer.	Simple one-on-one instruction and demonstration of step-by-step administration allow patient to ask questions at any point during procedure and increase patient adherence to inhaler use (Ari, 2015).
a. Insert MDI canister into holder. Then remove mouthpiece cover from inhaler.	
CLINICAL DECISION: <i>If using an MDI that is new or has not been used for several days, push a "test spray" into the air to prime the device before using. This ensures that the MDI is patent and that the metal canister is positioned properly.</i>	
b. Shake inhaler well for 2 to 5 seconds (five or six shakes).	Aerosolizes fine particles of medication.
c. Have patient hold inhaler in dominant hand.	Easier position to activate device.
Table Continued	

Step	Rationale
d. Instruct patient to position inhaler in one of two ways:	
(1) Have patient place close mouth around mouthpiece with opening toward back of throat, closing lips tightly around it (see illustration). Do not block the mouthpiece with the teeth or tongue	Proper positioning of inhaler is essential to administering medication correctly.
(2) Position mouthpiece 2 to 4 cm (1 to 2 inches) in front of widely opened mouth (see illustration), with opening of inhaler toward back of throat. Lips should not touch inhaler.	Directs aerosol spray toward airway. This is best way to deliver medication without a spacer.
e. While holding the mouthpiece away from the mouth, have patient take deep breath and exhale completely.	Empties lung volume and prepares airway to receive medication.
f. With inhaler positioned correctly, be sure patient holds inhaler with thumb at mouthpiece and index and middle fingers at top. <i>This is a three-point or lateral hand position.</i>	MDIs are easier to activate when patients use a three-point or lateral hand position to activate canister (Burchum and Rosenthal, 2019).
g. Instruct patient to tilt head back slightly and inhale slowly and deeply through mouth for 3 to 5 seconds while depressing canister fully.	Medication is distributed to airways during inhalation.
h. Have patient hold breath for as long as comfortable, up to 10 seconds.	Allows aerosol spray droplets to reach deeper branches of airways.
i. Have patient remove MDI from mouth before exhaling and exhale slowly through nose or pursed lips.	Keeps small airways open during exhalation.
9. Explain and demonstrate steps to administer MDI using spacer device.	Simple one-on-one instruction and demonstration of step-by-step administration allows patient to ask questions at any point during procedure and increases patient adherence to inhaler use (Ari, 2015).
a. Remove mouthpiece cover from MDI and mouthpiece of spacer device.	Inhaler fits into end of spacer device.
b. Shake inhaler well for 2 to 5 seconds (five or six shakes).	Aerosolizes fine particles of medication.
c. Insert MDI into end of spacer device.	Spacer device traps medication released from MDI; patient then inhales medication from device. These devices resolve hand-breath coordination difficulty to improve delivery of correct dose of inhaled medication (Barrons et al., 2015).
d. Instruct patient to place spacer device mouthpiece in mouth and close lips. Do not insert beyond raised lip on mouthpiece. Avoid covering small exhalation slots with lips.	Medication should not escape through mouth.
e. Have patient take a deep breath, exhale, and then breathe normally through spacer device mouthpiece (see illustration).	Allows patient to empty lungs and relax before delivering medication.
f. Instruct patient to depress medication canister 1 time, spraying one puff into spacer device.	Spacer contains fine spray and allows patient to inhale more medication. The spacer increases medication delivery and deposition of the medication on the oropharyngeal mucosa (Burchum and Rosenthal, 2019).
g. Have patient breathe slowly and fully through mouth for 5 seconds.	Ensures that particles of medication are distributed to deeper airways.
h. Instruct patient to hold full breath for 10 seconds.	Ensures full medication distribution through airways.
i. Have patient remove MDI and spacer and then exhale.	
10. Explain steps to administer a DPI or breath-actuated (BAI) inhaler	
a. If DPI has an external counter, note number indicated.	Determines doses remaining.
	 <p>Step 6d(2) Patient positions inhaler mouthpiece 2 to 4 cm (1 to 2 inches) from widely open mouth. This is considered the best way to deliver medication without a spacer.</p>

Step	Rationale
b. Remove mouthpiece cover. <i>Do not shake</i> inhaler	

• Step 8d(1) Patient opens lips and places inhaler mouthpiece in mouth with opening toward back of throat.

Table Continued

Step	Rationale
c. Prepare medication. Some DPIs require loading medication before administration; some require rotation of a lever to load medication or insertion of a capsule; and some require insertion of a disk into inhaler device. Follow manufacturer specific instructions.	Primes inhaler, ensuring that medication is delivered to patient effectively.
d. Have patient take a breath and exhale away from the inhaler.	Prevents loss of powder.
e. Have patient position mouthpiece of DPI between lips and inhale quickly and deeply through mouth (see illustration).	Keeps medication from escaping through mouth. Forceful inhalation creates an aerosol.
f. Have patient hold breath for 5 to 10 seconds.	Distributes medication.
11. Instruct patient to wait 20 to 30 seconds between inhalations (if same medication) or 2 to 5 minutes between inhalations (if different medications). Be sure patient inhales correct number of prescribed puffs.	Medications must be inhaled sequentially. Always administer bronchodilators before steroids so that dilators can open airway passages (Burchum and Rosenthal, 2019).
12. Instruct patient to not repeat inhalations before next scheduled dose.	Medications are prescribed at intervals during day to provide constant medication levels and minimize side effects. Beta-adrenergic MDIs are used either on an "as needed" basis or regularly every 4 to 6 hours.
13. Warn patients that they may feel gagging sensation in throat caused by droplets of medication on pharynx or tongue.	This occurs when medication is sprayed and inhaled incorrectly.
14. About 2 minutes after last dose, instruct patient to rinse mouth with warm water and spit water out.	Steroids may alter normal flora of oral mucosa and lead to development of fungal infection. Rinsing out patient's mouth reduces risk of fungal infection (Art, 2015).
15. Instruct patient how to clean the inhaler.	Removes residual medication and reduces transmission of microorganisms.
a. Once a day remove MDI canister and cap from the mouthpiece. Do not wash the canister or immerse it in water. Run warm tap water through the top and bottom of the plastic mouthpiece for 30 to 60 seconds. Make sure that inhaler is completely dry before reusing. Do not get valve mechanism of canister wet.	Water damages valve mechanism of canister. Accumulation of medication around mouthpiece interferes with proper medication distribution during use.
b. Instruct patient to clean mouthpiece of MDI and spacer twice a week with a mild dishwashing soap, rinse thoroughly, and dry completely before storage.	Provides better antimicrobial removal. Pressurized metered-dose inhalers are potential reservoirs for bacteria.
16. Help patient to comfortable position and perform hand hygiene.	Reduces transmission of microorganisms and promotes patient comfort.
Evaluation	
1. Auscultate patient lungs, listen for abnormal breath sounds, and obtain peak flow measures if ordered.	Determines patient response to medication.
2. Have patient explain and demonstrate steps in use and cleaning of inhaler.	Return demonstration provides feedback for measuring patient's learning.
3. Ask patient to explain medication schedule and dose of medication.	Improves likelihood of adherence to therapy.
4. Ask patient to describe side effects of medication and criteria for calling health care provider.	Allows patient to recognize signs of overuse and need to seek medical support when medications are ineffective.
5. Use Teach-Back: "I want to be sure I clearly showed you how to use your inhaler. Let's take this time; show me how you will use the inhaler to take your medicine." Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
 <p data-bbox="365 1682 553 1703">Step 10c Using spacer device with an MDI.</p>	 <p data-bbox="1036 1549 1295 1591">Step 10e Have patient place mouthpiece of dry powder inhaler (DPI) between lips.</p>

Table Continued

Step	Rationale
Unexpected Outcomes and Related Interventions	
1. Patient's respirations are rapid and shallow; breath sounds indicate wheezing.	<ul style="list-style-type: none"> • Evaluate vital signs and respiratory status. • Notify health care provider. • Reassess type of medication and/or delivery method.
2. Patient needs bronchodilator more than every 4 hours (may indicate respiratory problem).	<ul style="list-style-type: none"> • Reassess type of medication and delivery methods needed. • Notify health care provider.
3. Patient experiences cardiac dysrhythmias (e.g., light-headedness, syncope), especially if receiving beta-adrenergic medications.	<ul style="list-style-type: none"> • Withhold all further doses of medication. • Evaluate cardiac and pulmonary status (see Chapter 30). • Notify health care provider for reassessment of type of medication and delivery method.
Recording and Reporting	
	<ul style="list-style-type: none"> • Record medication administered, dose or strength, number of inhalations, and actual time administered immediately after administration, not before. Include initials or signature. • Record patient and family caregiver teaching (use of teach-back) and validation of understanding on flow sheet or nurses' notes in electronic health record (EHR) or chart. • Record on flow sheet or nurses' notes in electronic health record (EHR) or chart the patient's response to inhaled medication (e.g., respiratory rate and pattern, breath sounds), evidence of side effects (e.g., arrhythmia, patient's feelings of anxiety), and patient's ability to use inhaler. • Report adverse effects and patient response and/or withheld medications to nurse in charge or health care provider.

Preparing Injections From Vials and Ampules

Delegation and Collaboration

The skill of preparing injections from ampules and vials cannot be delegated to assistive personnel (AP).

Equipment

Medication in an Ampule

- Syringe, needle, and filter needle
- Small sterile gauze pad or alcohol swab

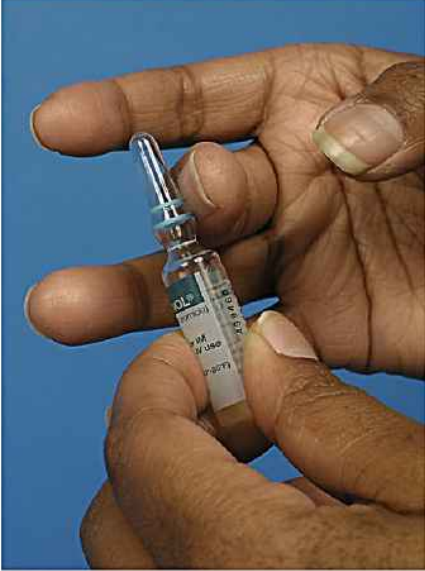

Medication in a Vial

- Syringe and two needles
- Needles:
 - Needleless blunt-tip vial-access cannula or needle (with safety sheath) for drawing up medication (if needed)
 - Filter needle if indicated
- Small sterile gauze pad or alcohol swab
- Diluent (e.g., 0.9% sodium chloride or sterile water if indicated)

Both

- Sharps with engineered sharps injury protection (SESIP) safety needle for injection
- Medication administration record (MAR) or computer printout
- Medication in vial or ampule
- Puncture-proof container for disposal of syringes, needles, and glass

Step	Rationale
Assessment	
<p>1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.</p>	<p>The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).</p>
<p>2. Review pertinent information related to medication, including action, purpose, normal dose and route, side effects, time of onset and peak action, indication and nursing implications.</p>	<p>Allows you to anticipate effects of medication while observing patient's response.</p>
<p>3. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display it on the patient's medical record. When allergies are present, patient should wear an allergy bracelet.</p>	<p>Factors influence how certain medications act. Reveals patient's need for medication. Allergy alert helps prevent adverse effects.</p>
<p>4. Review medication reference information for action, purpose, side effects, and nursing implications.</p>	<p>Allows you to administer medication properly and monitor patient's response.</p>
<p>5. Assess patient's body build, muscle size, weight, and viscosity of medication if giving subcutaneous or intramuscular (IM) medication.</p>	<p>Determines type and size of syringe and needle for injection.</p>
Planning	
<p>1. Perform hand hygiene. Collect appropriate equipment and MAR.</p>	<p>Promotes time management and efficiency when preparing medications for all patients.</p>
<p>2. Plan preparation to avoid interruptions. Create a quiet environment. Do not take phone calls or talk with others. Follow agency "No-interruption zone" policy. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR at a time.</p>	<p>Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).</p>
Table Continued	

Step	Rationale
Implementation	
1. Perform hand hygiene and prepare medications.	
a. If using a medication cart, move it outside patient's room.	Organization of equipment saves time and reduces error.
b. Unlock medication drawer or cart or log onto AMDS.	Medications are safeguarded when locked in cabinet, cart, or AMDS.
c. Select correct medication from stock supply or unit-dose drawer. Compare label of medication with MAR computer printout or computer screen.	Reading label and comparing it with transcribed order reduce errors. <i>This is the first check for accuracy.</i>
d. Check expiration date on each medication, one at a time.	Medications used past their expiration date are sometimes inactive, less effective, or harmful to patients.
e. Calculate medication dose as necessary. Double-check your calculation. In the case of high-risk medications ask another nurse to perform an independent double check of dosage (see agency policy).	Double-checking may help reduce error. Independent double checks should be used only for very selective high-alert medications (not all) that most warrant their use (ISMP, 2018a).
f. If preparing a controlled substance, check record for previous medication count and compare with supply available.	Controlled substance laws require careful monitoring of dispensed narcotics.
g. Do not leave medications unattended.	Nurse is responsible for safekeeping of medications.
2. Prepare ampule.	
a. Tap top of ampule lightly and quickly with finger until fluid moves from its neck (see illustration).	Dislodges any fluid that collects above neck of ampule. All solution moves into lower chamber.
b. Place small gauze pad around neck of ampule (see illustration).	Protects fingers from trauma as glass tip is broken off. Do not use opened alcohol swab to wrap around top of ampule because alcohol may leak into ampule.
c. Snap neck of ampule quickly and firmly away from hands (see illustration).	Protects your fingers and face from shattering glass.
d. Draw up medication quickly, using filter needle long enough to reach bottom of ampule to access medication.	System is open to airborne contaminants. Filter needles filter out any fragments of glass (Joo et al., 2016).
e. Hold ampule upside down or set it on flat surface. Insert filter needle into center of ampule opening. Do not allow needle tip or shaft to touch rim of ampule.	Broken rim of ampule is considered contaminated. When ampule is inverted, solution dribbles out if needle tip or shaft touches rim of ampule.
f. Aspirate medication into syringe by gently pulling back on plunger (see illustrations).	Withdrawal of plunger creates negative pressure within syringe barrel, which pulls fluid into syringe.
 <p data-bbox="357 1575 592 1606">Step 2a Tapping ampule moves fluid down neck. A and B Courtesy and © Becton, Dickinson and Company.</p>	
Step	Rationale

Step 2b Gauze pad placed around neck of ampule.

Step 2c Neck snapped away from hands.

Step 2f A, Medication aspirated with ampule inverted. B, Medication aspirated with ampule on flat surface

Step	Rationale
	Table Continued

Step	Rationale
g. Keep needle tip under surface of liquid. Tip ampule to bring all fluid within reach of needle.	Prevents aspiration of air bubbles.
h. If you aspirate air bubbles, do not expel air into ampule.	Air pressure forces fluid out of ampule, and medication will be lost.
i. To expel excess air bubbles, remove needle from ampule. Hold syringe vertically with needle pointing up. Tap side of syringe to cause bubbles to rise toward needle. Draw back slightly on plunger and push plunger upward to eject air. Do not eject fluid.	Withdrawing plunger too far removes it from barrel. Holding syringe vertically allows fluid to settle in bottom of barrel. Pulling back on plunger allows fluid within needle to enter barrel so that fluid is not expelled. Then expel air at top of barrel and within needle.
j. If syringe contains excess fluid, use sink for disposal. Hold syringe vertically with needle tip up and slanted slightly toward sink. Slowly eject excess fluid into sink. Recheck fluid level in syringe by holding it vertically.	Safely disperses excess medication into sink. Position of needle allows you to expel medication without having it flow down needle shaft. Rechecking fluid level ensures proper dose.
k. Cover needle with its safety sheath or cap. Replace filter needle with regular SESIP needle.	Minimizes needlesticks. Filter needles cannot be used for injection.
3. Prepare vial containing a solution.	
a. Remove cap covering top of unused vial to expose sterile rubber seal. If a multi-dose vial has been used before, cap is already removed. Firmly and briskly wipe surface of rubber seal with alcohol swab and allow it to dry.	Vial comes packaged with cap that cannot be replaced after seal removal. Not all medication manufacturers guarantee that rubber seals of unused vials are sterile. Swabbing with alcohol reduces transmission of microorganisms. Allowing alcohol to dry prevents alcohol from coating needle and mixing with medication.
b. Pick up syringe and remove needle cap or cap covering needleless access device (see illustration). Pull back on plunger to draw amount of air into syringe equivalent to volume of medication to be aspirated from vial.	Injecting air into vial prevents buildup of negative pressure in vial when aspirating medication.
c. With vial on flat surface, insert tip of needle or needleless device through center of rubber seal (see illustration). Apply pressure to tip of needle during insertion.	Center of seal is thinner and easier to penetrate. Using firm pressure prevents dislodging rubber particles that could enter vial or needle.
d. Inject air into air space of vial, holding on to plunger. Hold plunger firmly; plunger is sometimes forced backward by air pressure within vial.	Injection of air creates vacuum needed to get medication to flow into syringe. Injecting into air space of vial prevents formation of bubbles and an inaccurate dose.
 <p data-bbox="358 1087 703 1119">Step 3b: A, Needleless system. B, Safety needle system. C, Detail of safety needle system.</p>	
 <p data-bbox="358 1619 703 1650">Step 3c: Insert safety needle through center of vial diaphragm (with vial flat on table).</p>	
	Rationale

Step 3a Withdraw fluid with vial inverted.

Step 3b Hold syringe upright; tap barrel to dislodge air bubbles.

Table Continued

Step	Rationale
e. Invert vial while keeping firm hold on syringe and plunger. Hold vial between thumb and middle fingers of nondominant hand (see illustration). Grasp end of syringe barrel and plunger with thumb and forefinger of dominant hand to counteract pressure in vial.	Inverting vial allows fluid to settle in lower half of container. Position of hands prevents forceful movement of plunger and permits easy manipulation of syringe.
f. Keep tip of needle or needleless device below fluid level.	Prevents aspiration of air.
g. Allow air pressure from vial to fill syringe gradually with medication. If necessary, pull back slightly on plunger to obtain correct amount of medication.	Positive pressure within vial forces fluid into syringe.
h. When you obtain desired volume, position needle or needleless device into air space of vial; tap side of syringe barrel gently to dislodge any air bubbles (see illustration). Eject any air remaining at top of syringe into vial.	Forcefully striking barrel while needle is inserted in vial may bend needle. Accumulation of air displaces medication and causes dose errors.
i. Remove needle or needleless access device from vial by pulling back on barrel of syringe.	Pulling plunger rather than barrel causes plunger to separate from barrel, resulting in loss of medication.
j. Hold syringe at eye level at 90-degree angle to ensure correct volume and absence of air bubbles. Remove any remaining air by tapping barrel to dislodge any air bubbles. Draw back slightly on plunger; then push it upward to eject air. Do not eject fluid. Recheck volume of medication.	Holding syringe vertically allows fluid to settle in bottom of barrel. Tapping dislodges air to top of barrel. Pulling back on plunger allows fluid within needle to enter barrel so that you do not expel fluid. You then expel air at top of barrel and within needle.
CLINICAL DECISION: When preparing medication from single-dose vial, do not assume that volume listed on label is total volume in vial. Some manufacturers provide small amount of extra liquid, expecting loss during preparation. Be sure to draw up only desired volume.	
k. Before you inject medication into patient's tissue, change needle with regular SESIP to appropriate gauge and length according to route of medication administration.	Inserting needle through rubber stopper dulls beveled tip. New needle is sharper and, because no fluid is along shaft, does not track medication through tissues. Filter needles cannot be used for injection.
l. Cover needle with its safety sheath or cap.	Minimizes needlesticks.
m. For multi-dose vial, make label that includes date of opening, concentration of medication per milliliter, and your initials.	Ensures that nurses will prepare future doses correctly. You discard some medications within a certain time frame after mixing.
4. Prepare vial containing powder (reconstituting medications).	
a. Remove cap covering vial of powdered medication and cap covering vial of proper diluent. Firmly swab both rubber seals with alcohol swab and allow alcohol to dry.	Allowing alcohol to dry prevents it from coating needle and mixing with medication.
b. Draw up manufacturer suggestion for volume and type of diluent into syringe following Steps 3b through 3j.	Prepares diluent for injection into vial containing powdered medication.
c. Insert tip of needle or needleless device through center of rubber seal of vial of powdered medication. Inject diluent into vial. Remove needle.	Diluent begins to dissolve and reconstitute medication.
d. Mix medication thoroughly. Roll in palms. Do not shake.	Ensures proper dispersal of medication throughout solution and prevents formation of air bubbles.
e. Reconstituted medication in vial is ready to be drawn into new syringe. Read label carefully to determine dose after reconstitution.	Once you add diluent, concentration of medication (mg/mL) determines dose you give. Reading medication label carefully decreases medication errors.
f. Draw up reconstituted medication into syringe. Insert needleless device/needle into vial. Do not add air. Then follow Steps 3e through 3l.	Prepares medication for administration.
CLINICAL DECISION: Some agencies require that doses of certain medications (e.g., insulin and heparin) be checked using an independent double check by another nurse (ISMP, 2018a). Check policies and procedures before administering medication.	
5. Compare label of medication with MAR, computer screen, or computer printout.	<i>This is the second check for accuracy.</i>
6. Dispose of soiled supplies. Place broken ampule and/or used vials and used needle or needleless device in puncture- and leak-proof container. Clean work area and perform hand hygiene.	Proper disposal of glass and needle prevents accidental injury to staff. Controls transmission of infection.
Evaluation	
1. Just before administering medication to patient, compare MAR with label of prepared medication and compare dose in syringe with desired dose.	Ensures that dose is accurate. <i>This is the third check for accuracy.</i>
Unexpected Outcomes and Related Interventions	
<ol style="list-style-type: none"> Air bubbles remain in syringe. <ul style="list-style-type: none"> Expel air from syringe and add medication to it until you prepare correct dose. Incorrect dose of medication is prepared. <ul style="list-style-type: none"> Discard prepared dose. Prepare correct new dose. 	

Administering Injections

Delegation and Collaboration

The skill of administering injections cannot be delegated to assistive personnel (AP). The nurse instructs the AP about:

- Potential medication side effects and allergic responses and the need to report their occurrence along with any changes in patient's vital signs or level of consciousness (e.g., sedation).

Equipment

- Proper size syringe and (SESIP) needle:
 - *Subcutaneous*: syringe (1- to 3-mL) and needle (25- to 27-gauge, $\frac{3}{8}$ - to $\frac{5}{8}$ -inch)
 - *Immunizations*: $\frac{5}{8}$ -inch, 23- to 25-gauge needle (CDC, 2017)
 - *Subcutaneous U-100 insulin*: insulin syringe (1 mL) with preattached needle (28- to 31-gauge, $\frac{3}{8}$ - to $\frac{5}{8}$ -inch)
 - *Subcutaneous U-500 insulin*: insulin syringe (1 mL) with preattached needle (28- to 31-gauge, $\frac{3}{8}$ - to $\frac{5}{8}$ -inch) (Consumer Med Safety, 2018b).
 - *Intramuscular (IM)*: Syringe 2 to 3 mL for adult, 0.5 to 1 mL for infants and small children
 - Needle length typically corresponds to site of injection, age, gender, and size of patient. Refer to following guidelines for vaccine administration; length needed may vary outside of these guidelines for patients who are smaller or larger than average.

Needle Length for Immunizations*

Site	Child	Adult
Ventrogluteal	Not recommended	1½ inches
Vastus lateralis	⅝-1.25 inch	⅝-1 inch
Deltoid	⅝-1 inch	1-1½ inches

Needle Length for Immunizations*

Gender-Male	Gender-Female	Needle Length
Less than 130 pounds	Less than 130 pounds	⅝-1 inch
130-152 pounds	130-152 pounds	1 inch
153-260 pounds	153-200 pounds	1-1½ inches
260+ pounds	200+ pounds	1½ inches

Needle Length for Immunizations*

Age-Group	Needle Length	Site
Neonates ^a	⅝ inch (16 mm) ^b	Vastus lateralis
Infants, 1-12 months	1 inch (25 mm)	Vastus lateralis
Toddlers, 1-2 years	1-1.25 inch (25-32 mm)	Vastus lateralis ^c
	⅝ ^b -1 inch (16-25 mm)	Deltoid muscle of arm
Children, 3-10 years	⅝ ^b -1 inch (16-25 mm)	Deltoid muscle of arm ^c
	1-1.25 inches (25-32 mm)	Vastus lateralis
Children, 11-18 years	⅝ ^b -1 inch (16-25 mm)	Deltoid muscle of arm ^c
	1-1.5 inches (25-38 mm)	Vastus lateralis
Men and women, <60 kg (130 lb)	1 inch (25 mm)	Deltoid muscle of arm
Men and women, 60-70 kg (130-152 lb)	1 inch (25 mm)	Deltoid muscle of arm
Men, 70-118 kg (152-260 lb)	1-1.5 inches (25-38 mm)	Deltoid muscle of arm
Women, 70-90 kg (152-200 lb)	1-1.5 inches (25-38 mm)	Deltoid muscle of arm
Men, >118 kg (260 lb)	1.5 inches (38 mm)	Deltoid muscle of arm
Women, >90 kg (200 lb)	1.5 inches (38 mm)	Deltoid muscle of arm

* Centers for Disease Control and Prevention (CDC): *Vaccine administration*, 2017, <https://www.cdc.gov/vaccines/hcp/acip-recs/general-recs/administration.html>.

^a First 28 days of life.

^b If skin is stretched tightly and subcutaneous tissues are not bunched.

^c Preferred site.

Based on CDC, 2017 Guidelines

- Needle gauge often depends on length of needle; administer biologic and medication in aqueous solution with a 20- to 25-gauge needle. Use 18- to 21-gauge needles for medications in oil-based solutions
- *Intradermal (ID)*: 1-mL tuberculin syringe with needle (25- to 27-gauge, 1/2- to 5/8-inch)

All Injections

- Small gauze pad
- Alcohol swab
- Vial or ampule of medication or skin test solution
- Clean gloves
- Medication administration record (MAR) (electronic or printed)
- Puncture-proof container for sharps

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR with health care provider's medication order. Check patient's name, medication name and dosage, and route and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Tritt et al., 2016).
2. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record. When allergies are present, patient should wear an allergy bracelet.	Factors influence how certain medications act. Reveals patient's need for medication. Allergy alert helps prevent adverse effects.
3. Review medication reference information for medication action, purpose, normal dose, side effects, time and peak of onset, and nursing implications. In the case of an intradermal injection, review expected reaction and/or anticipated effects when testing skin with specific allergen and appropriate time to read site.	Allows you to administer medication safely and monitor patient's response to therapy. Type of reaction to an immunization depends on patient's ability to mount a cell-mediated immune response. Knowledge of expected and adverse reactions to skin testing helps you determine for which symptoms to monitor, how frequently, and when to reassess patient.
4. Assess for contraindications to injections.	
a. For ID injections	
(1) Reduced local tissue perfusion. Assess for history of severe adverse reactions that occurred after previous ID injection.	Decreased tissue perfusion reduces absorption of ID medications. Prior history of severe reactions increases the risk for future severe reactions.
b. For subcutaneous injections	
(1) Assess for factors such as circulatory shock or reduced local tissue perfusion. Assess adequacy of patient's adipose tissue.	Reduced tissue perfusion interferes with medication absorption and distribution. Physiological changes of aging or patient illness often influence amount of subcutaneous tissue that patient possesses.
c. For IM injections	
(1) Assess for factors such as muscle atrophy, reduced blood flow, or circulatory shock.	Atrophied muscle absorbs medication poorly. Factors interfering with blood flow to muscles impair medication absorption.
5. Assess patient's knowledge of purpose and expected response to medication or skin testing.	Patients need to know when to return for follow-up reading of skin test and when and how to report any reaction. Poses implications for patient education.
6. Assess patient's symptoms before initiating medication therapy.	Provides information to evaluate desired effect of medication.
7. Assess patient's knowledge about medication.	Determines whether there is a need for patient education.
8. For subcutaneous insulin or heparin, assess relevant laboratory results (e.g., blood glucose, partial thromboplastin).	Provides baseline for measuring medication response.
9. Observe patient's previous verbal and nonverbal responses toward injection.	Anticipating patient's anxiety allows you to use distraction to reduce pain awareness.
10. Check expiration date on medication.	Dose potency increases or decreases when expired.
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR	Promotes time management and efficiency when preparing medications for all patients.
2. Plan preparation to avoid interruptions. Create a quiet environment. Do not take phone calls or talk with others. Follow agency "No-interruption zone" policy. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR at a time.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications for injection. Attend to procedure and avoid distraction. Check label of medication against MAR two times, when removing medication from unit dose or AMDS and before leaving medication preparation area (see Skill 31.1). Perform hand hygiene.	Ensures that medication is sterile. Preventing distractions reduces medication preparation errors. These are the first and second checks for accuracy and ensure that correct medication is administered. Reduces transmission of microorganisms. Hand hygiene decreases transfer of microorganisms.
2. Take medications to patient at correct time (see agency policy). Medications that require exact timing include STAT doses, first-time, loading, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (within 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of either 1 or 2 hours of scheduled doses (ISMP, 2011a). Apply the seven rights of medication administration throughout medication administration.	Ensures intended therapeutic effect and complies with professional standards. Hospitals need to adopt a medication administration policy and procedure for the timing of medication administration that considers patient needs, prescribed medication, and specific clinical indications (CMS, 2014; ISMP, 2011a). Time-critical scheduled medications are medications in which early or delayed administration of maintenance doses of more than 30 minutes before or after the scheduled dose may cause harm or result in suboptimal therapy or pharmacological effect. Non-time-critical medications are medications in which early or delayed administration of 1 to 2 hours should not cause harm or result in suboptimal therapy or pharmacological effects (CMS, 2014; ISMP, 2011a).

Table Continued

Step	Rationale
3. Close room curtain or door.	Provides privacy.
4. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.	Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).
5. At patient's bedside, compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.	This is the third accuracy check and ensures that patient receives correct medication. Confirms patient's allergy history.
6. Discuss purpose of each medication and/or skin test, action, and possible adverse effects. Allow patient to ask any questions. Tell patient that injection will cause slight burning or sting. An intradermal injection will create a small bleb on the skin.	Patient has right to be informed, and patient's understanding of each medication improves adherence to medication therapy. Helps minimize patient's anxiety.
7. Perform hand hygiene and apply clean gloves. Keep sheet or gown draped over body parts not requiring exposure.	Reduces transmission of microorganisms. Draping the patient provides privacy.
8. Select appropriate injection site. Inspect skin surface over sites for bruises, inflammation, or edema.	Injection sites need to be free of abnormalities that interfere with medication absorption. Sites used repeatedly become hardened from lipohypertrophy (increased growth in fatty tissue). Do not use an area that is bruised or has signs associated with infection.
a. Intradermal (ID):	
(1) Note lesions or discolorations of skin. If possible, select site three to four finger widths below antecubital space and a hand width above wrist. If you cannot use forearm, inspect upper back. If necessary, use sites for subcutaneous injections.	An ID site needs to be clear, so you can see results of skin test and interpret them correctly (WHO, 2016).
b. Subcutaneous:	
(1) Do not use an area that is bruised or has signs associated with infection. Palpate sites and avoid those with masses or tenderness. Be sure that needle is correct size by grasping skinfold at site with thumb and forefinger. Measure fold from top to bottom. Make sure that needle is one-half length of fold.	You can mistakenly give subcutaneous injections in muscle, especially in abdomen and thigh sites. Appropriate size of needle ensures that you inject medication into subcutaneous tissue (Ogston-Tuck, 2014a).
(2) When administering insulin or heparin, use abdominal injection sites first, followed by thigh injection site. Choose site on right or left side of abdomen at least 5 cm (2 inches) away from umbilicus.	Injecting LMWH on side of abdomen helps decrease pain and bruising at injection site (RCN, 2016).
c. IM:	
(1) Note integrity and size of muscle and palpate for tenderness or hardness. Avoid these areas. If injections are given frequently, rotate sites. Use ventrogluteal site if possible.	Ventrogluteal is the preferred injection site for adults (CDC, 2017). The anterolateral thigh can be used for children of all ages but the ventrogluteal site is the preferred choice as it causes fewer reactions (Hockenberry et al, 2019; Ogston-Tuck, 2014b).
9. Help patient to comfortable position:	
a. ID: Have patient extend elbow and support it and forearm on flat surface.	Stabilizes injection site for easiest accessibility.
b. Subcutaneous: Have patient relax arm, leg, or abdomen, depending on site selection.	Relaxation of site minimizes discomfort.
c. IM: Position patient depending on site chosen (e.g., sit or lie flat, on side, or prone).	Reduces strain on muscle and minimizes discomfort of injections.
CLINICAL DECISION: Ensure that medical condition (e.g., circulatory shock, orthopedic surgery) does not contraindicate patient's position for injection.	
10. Relocate site using anatomical landmarks. For subcutaneous insulin, rotate site within anatomical area (e.g., abdomen) and systematically rotate sites within area.	Injection into correct anatomical site prevents injury to nerves, bones, and blood vessels.
11. Clean site with an antiseptic swab. Apply swab at center of site and rotate outward in circular direction for approximately 5 cm (2 inches) (see illustration).	Mechanical action of swab removes secretions containing microorganisms.
<i>Option for IM injection:</i> Apply eutectic mixture of local anesthetic (EMLA) cream on injection site at least 1 hour before IM injection or use vapocoolant spray (e.g., ethyl chloride) just before injection (see agency policy).	Decreases pain at injection site.
12. Hold swab or gauze between third and fourth fingers of nondominant hand.	Gauze or swab remains readily accessible when withdrawing needle after injection.
13. Remove needle cap or sheath from needle by pulling it straight off.	Preventing needle from touching sides of cap prevents contamination.
14. Hold syringe between thumb and forefinger of dominant hand:	
a. ID: Hold syringe with bevel of needle pointing up.	With bevel up, medication is less likely to be deposited into tissues below dermis.
b. Subcutaneous and IM: Hold as dart, palm up (see illustration).	Quick, smooth injection requires proper manipulation of syringe parts.

Table Continued

Step	Rationale
15. Administer injection:	
a. Intradermal	
(1) With nondominant hand stretch skin over site with forefinger or thumb.	Needle pierces tight skin more easily.
(2) With needle almost against patient's skin, insert it slowly with bevel up at 5- to 15-degree angle until resistance is felt. Advance needle through epidermis to approximately 3 mm (¼ inch) below skin surface. You will see needle tip through skin.	Ensures that needle tip is in dermis. You obtain inaccurate results if you do not inject needle at correct angle and depth (WHO, 2016).
(3) Inject medication slowly. Normally you feel resistance. If not, needle is too deep; remove and begin again.	Slow injection minimizes discomfort at site. Dermal layer is tight and does not expand easily when solution is injected.
(4) While injecting medication, notice that small bleb approximately 6 mm (¼ inch) in diameter (resembling mosquito bite) appears on surface of skin (see illustration). Instruct patient that this is normal finding.	Bleb indicates that medication is deposited in dermis.
b. Subcutaneous	
(1) For average-size patient, pinch skin with nondominant hand.	Needle penetrates taut skin more easily than loose skin. Pinching skin elevates subcutaneous tissue and desensitizes area.
(2) Inject needle quickly and firmly at 45- to 90-degree angle (see Fig. 31.19). Release skin. <i>Option:</i> If using injection pen or administering heparin, continue to pinch skin while injecting medication.	Quick, firm insertion minimizes discomfort. (Injecting medication into compressed tissue irritates nerve fibers.) Correct angle prevents accidental injection into muscle.
(3) For obese patient pinch skin at site and inject needle at 90-degree angle below tissue fold.	Obese patients have fatty layer of tissue above subcutaneous layer.
(4) After needle enters site, grasp lower end of syringe barrel with nondominant hand to stabilize it. Move dominant hand to end of plunger and slowly inject medication over several seconds (see illustration). When giving heparin, inject over 30 seconds (Mohammady et al., 2017; RCN, 2016). Avoid moving syringe.	Movement of syringe may displace needle and cause discomfort. Slow injection of medication minimizes discomfort.
 <p data-bbox="370 1661 545 1675">Step 11 Clean site with circular motion.</p>	

Step	Rationale
	

Step 15a(4) Injection creates small bleb.

Step 14b Hold syringe as if grasping a dart.

Step	Rationale
 <p data-bbox="370 976 922 1018">Step 15b(4) Inject medication slowly.</p>	

Table Continued

Step	Rationale
CLINICAL DECISION: <i>Aspiration after injecting a subcutaneous medication is not necessary. Piercing a blood vessel in a subcutaneous injection is very rare. Aspiration after injecting heparin and insulin is not recommended (CDC, 2017; Sepah, 2017).</i>	
c. Intramuscular	
(1) Position ulnar aspect of your nondominant hand just below site and pull skin approximately 2.5 to 3.5 cm (1 to 1.5 inches) down or laterally to administer in a Z-track. Hold position until medication is injected (see Fig. 31.24). With dominant hand inject needle quickly at 90-degree angle into muscle (see Fig. 31.20).	Z-track creates zigzag path through tissues that seals needle track to avoid tracking of medication. Use Z-track for all IM injections (Ogston-Tuck, 2014; Yilmaz et al., 2016). A quick, dartlike injection reduces discomfort.
(2) <i>Option:</i> If patient's muscle mass is small, grasp body of muscle between thumb and fingers.	Ensures that medication reaches muscle mass (CDC, 2017; Hockenberry et al., 2019).
CLINICAL DECISION: <i>When giving immunizations to adults, to avoid injection into subcutaneous tissue, spread the skin of the selected vaccine administration site taut between the thumb and forefinger, isolating the muscle (CDC, 2017).</i>	
(3) After needle pierces skin, still pulling on skin with nondominant hand, grasp lower end of syringe barrel with fingers of nondominant hand to stabilize it. Move dominant hand to end of plunger. Avoid moving syringe.	Smooth manipulation of syringe reduces discomfort from needle movement. Skin remains pulled until after medication is injected to ensure Z-track administration.
(4) Pull back on plunger 5 to 10 seconds. If no blood appears, inject medicine slowly, at rate of 1 mL/10 seconds. <i>Note:</i> Do not aspirate if administering immunizations (CDC, 2017).	Aspiration of blood into syringe indicates possible placement of needle into a vein. Slow injection rate reduces pain and tissue trauma and reduces chance of leakage of medication back through needle track (Hockenberry et al., 2019). The CDC (2017) no longer recommends aspiration when administering an immunization.
CLINICAL DECISION: <i>If blood appears in syringe, remove needle and dispose of medication and syringe properly. Prepare another dose of medication for injection.</i>	
(5) Once medication is injected, wait 10 seconds; then smoothly and steadily withdraw needle, release skin, and apply gauze gently over site.	Allows time for medication to absorb into muscle before removing syringe. Dry gauze minimizes discomfort associated with alcohol on nonintact skin.
16. Apply gentle pressure to site. Do not massage site. Apply bandage if needed.	Massage causes underlying tissue damage. Massaging ID site disperses medication into underlying tissue layers and alters test results.
17. Help patient to comfortable position.	Gives patient sense of well-being.
18. Discard uncapped needle or needle enclosed in safety shield and attached syringe into puncture-proof, leak-proof receptacle.	Prevents injury to patient and health care personnel. Recapping needles increases risk of needlestick injury (OSHA, n.d.).
19. Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of microorganisms.
20. Stay with patient and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction, which is life-threatening emergency.
Evaluation	
1. Return to room in 15 to 30 minutes and ask whether patient feels any acute pain, burning, numbness, or tingling at injection site.	After an ID injection, continued discomfort could indicate injury to underlying tissue. After a subcutaneous or IM injection continued discomfort may indicate injury to underlying bones or nerves.
2. After an ID injection ask patient to discuss implications of skin testing and signs of hypersensitivity.	Patient's ability to recognize signs of skin testing helps to ensure timely reporting of results.

Table Continued

Step	Rationale
<p>3. Inspect ID bleb. <i>Option:</i> Use skin pencil and draw circle around perimeter of injection site. Read TB test site at 48 to 72 hours; look for induration (hard, dense, raised area) of skin around injection site of:</p> <ul style="list-style-type: none"> • 15 mm or more in patients with no known risk factors for tuberculosis. • 10 mm or more in patients who are recent immigrants; injection medication users; residents and employees of high-risk settings; patients with certain chronic illnesses; children younger than 4 years of age; and infants, children, and adolescents exposed to high-risk adults. • 10 mm or more in patients who are recent immigrants; injection medication users; residents and employees of high-risk settings; patients with certain chronic illnesses; children younger than 4 years of age; and infants, children, and adolescents exposed to high-risk adults. • 5 mm or more in patients who are human immunodeficiency virus (HIV) positive, have fibrotic changes on chest x-ray film consistent with previous tuberculosis infection, have had organ transplants, or are immunosuppressed. 	<p>Determines whether reaction to antigen occurs; indication positive for tuberculosis or tested allergens. Site must be read at various intervals to determine test results. Pencil marks make site easy to find. You determine results of skin testing at various times, based on type of medication used or type of skin testing completed. Manufacturer directions determine when to read test results. Degree of reaction varies based on patient condition.</p>
<p>4. Inspect subcutaneous or IM site, noting any bruising or induration. Document bruising or induration if present. Notify health care provider and provide warm compress to site.</p>	<p>Bruising or induration indicates complication associated with injection. Document findings and notify health care provider.</p>
<p>5. Observe patient's response to medication at times that correlate with onset, peak, and duration of medication. Review laboratory results as appropriate (e.g., blood glucose, partial thromboplastin).</p>	<p>Adverse effects of parenteral medications develop rapidly. Evaluate effect of medication on basis of onset, peak, and duration of action.</p>
<p>6. Use Teach-Back: "I want to be sure I explained about your injection. Can you explain why you need this injection and the side effects to watch for and report to me if they occur?" Revise your instruction now or develop plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.</p>	<p>Determines patient's/family caregiver's level of understanding of instructional topic.</p>
<p>Unexpected Outcomes and Related Interventions</p> <ol style="list-style-type: none"> 1. Raised, reddened, or hard zone (induration) forms around an ID test site. <ul style="list-style-type: none"> • Notify patient's health care provider. • Document sensitivity to injected allergen or positive test if tuberculin skin testing was completed. 2. Patient has adverse reaction with signs of urticaria, pruritus, wheezing, and dyspnea. <ul style="list-style-type: none"> • Notify patient's health care provider immediately. • Follow agency policy for appropriate response to medication reactions (e.g., administration of antihistamine such as diphenhydramine or epinephrine). • Add allergy information to patient's record. 3. Patient complains of localized pain, numbness, tingling, or burning at injection site, indicating possible injury to nerve or tissues. <ul style="list-style-type: none"> • Assess injection site. • Document findings. • Notify patient's health care provider. <p>Recording and Reporting</p> <ul style="list-style-type: none"> • Record medication, dose, route, site, time, and date on MAR in the electronic health record (EHR) or chart immediately after administration, not before. Correctly sign MAR according to agency policy. • Record patient teaching, validation of understanding, and patient's response to medication in the electronic health record (EHR) or chart. • Record area of ID injection and appearance of skin in the electronic health record (EHR) or chart. • Report any undesirable effects from injection to patient's health care provider and document adverse effects in record. • Document immunizations in patient's permanent record, including date of administration, vaccine manufacturer and lot number, expiration date, name and title of the person who administered the vaccine and the address of the agency where the permanent record will reside, vaccine information statement (VIS) and date printed on the VIS, and date VIS given to patient or parent/guardian (CDC, 2018). 	

Administering Medications by Intravenous Bolus

Delegation and Collaboration

The skill of administering medications by IV bolus cannot be delegated to assistive personnel (AP). The nurse directs the AP about:

- Potential medication actions and side effects and to immediately report their occurrence to the nurse.
- Reporting any patient complaints of moisture or discomfort around IV insertion site.
- Obtaining any required vital signs and reporting them to the nurse.

Equipment

- Watch with second hand
- Clean gloves
- Antiseptic gloves
- Medication in vial or ampule
- Proper-size syringes for medication and saline flush with needleless device or SESIP needle (21- to 25- gauge)
- Intravenous lock: Vial of normal saline flush solution (saline recommended [Gorski, 2019]); if agency continues to use heparin flush, the most common concentration is 10 units/mL; check agency policy.
- Medication administration record (MAR) or computer printout
- Puncture-proof container

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).
CLINICAL DECISION: Some IV medications can be pushed safely only when a patient is monitored continuously for dysrhythmias, blood pressure changes, or other adverse effects. Therefore, some medications can be pushed only in specific patient care units. Confirm agency guidelines.	
2. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record. When allergies are present, patient should wear an allergy bracelet.	Determines need for medication or possible contraindications for medication administration. IV bolus delivers medication rapidly. Allergic response is immediate.
3. Review medication reference information for medication action, purpose, side effects, normal dose, time of peak onset, how slowly to give medication, and nursing implications such as need to dilute medication or administer it through a filter.	Knowledge of medication allows you to give it safely and monitor patient's response to therapy.
4. If you give medication through an existing IV line, determine compatibility of medication with IV fluids and any additives within IV solution.	IV medication is not always compatible with IV solution and/or additives, and a new site may need to be initiated.
5. Assess patient's symptoms before initiating medication therapy.	Provides information to evaluate desired effects of medication.
6. Perform hand hygiene. (Apply clean gloves if risk of contact with body fluids). Assess condition of IV needle insertion site for signs of infiltration or phlebitis.	Reduces transmission of microorganisms. Do not administer medication if site is edematous or inflamed.
7. Assess patency of patient's existing IV infusion line or saline lock (see Chapter 42).	For medication to reach venous circulation effectively, IV line must be patent, and fluids must infuse easily.
8. Assess patient's understanding of purpose of medication therapy.	Poses implication for education.
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR.	Reduces transmission of microorganisms. Ensures organized procedure.
2. Follow agency's "No-interruption zone" policy. Prepare medications for one patient at a time. Keep all pages of MARs or computer printouts for one patient together, or look at only one patient's electronic MAR at a time.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications for intravenous bolus administration. Attend to procedure and avoid distraction. Check label of medication against MAR two times, when removing medication from unit dose or AMDS and before leaving medication preparation area. Perform hand hygiene.	Ensures that medication is sterile. These are the first and second checks for accuracy and ensure that correct medication is administered. Reduces transmission of microorganisms.
CLINICAL DECISION: Some IV medications require dilution before administration. Verify with agency policy or pharmacy if dilution is permitted. If a small amount of medication is given (e.g., less than 1 mL), dilute medication in small amount (e.g., 5 mL) of normal saline or sterile water so that it does not collect in the "dead spaces" (e.g., Y-site injection port, IV cap) of the IV delivery system.	

Table Continued

Step	Rationale
<p>2. Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include STAT doses, first-time or loading doses, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (no more than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011a). During administration apply seven rights of medication administration.</p>	<p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011a). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacological effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacological effect (DHHS, 2011; ISMP, 2011a).</p>
<p>3. Close room curtain or door.</p>	<p>Provides privacy.</p>
<p>4. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).</p>
<p>5. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.</p>	<p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p>
<p>6. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask questions. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at IV site.</p>	<p>Keep patient informed of planned therapies, minimizing anxiety. Patients who verbalize pain at IV site help detect IV infiltrations early, lessening damage to surrounding tissue.</p>
<p>7. Perform hand hygiene and apply clean gloves.</p>	<p>Reduces transmission of microorganisms.</p>
<p>8. IV push (existing IV line):</p>	
<p>a. Select injection port of IV tubing closest to patient. Use needleless injection port.</p>	<p>Follows provisions of Needle Safety and Prevention Act of 2001 (OSHA, n.d.).</p>
<p>CLINICAL DECISION: <i>Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.</i></p>	
<p>b. Clean injection port with antiseptic swab. Allow to dry.</p>	<p>Prevents transfer of microorganisms during blunt cannula insertion.</p>
<p>c. Connect syringe to IV line: Insert needleless tip of syringe containing medication through center of port (see illustration).</p>	<p>Prevents introduction of microorganisms. Prevents damage to port diaphragm and possible leakage from site.</p>
<p>d. Occlude IV line by pinching tubing just above injection port (see illustration). Pull back gently on plunger of syringe to aspirate for blood return.</p>	<p>Final check ensures that medication is being delivered into bloodstream.</p>
<p>CLINICAL DECISION: <i>In the case of smaller-gauge IV needles, blood return sometimes is not aspirated even if IV line is patent. If IV site does not show signs of infiltration and IV fluid is infusing without difficulty, give IV push.</i></p>	
<p>Step</p>	<p>Rationale</p>

Step Bc Connect syringe to IV line with needleless blunt cannula tip.

Step

Rationale

Step Bd Occlude IV tubing above injection port.

Table Continued

Step	Rationale
<p>e. Release tubing and inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administrations (see illustration). You can pinch IV line while pushing medication and release it when not pushing medication. Allow IV fluids to infuse when not pushing medication.</p>	<p>Ensures safe medication infusion. Rapid injection of IV medication can be fatal. Allowing IV fluids to infuse while pushing IV medication enables medication to be delivered to patient at prescribed rate.</p>
<p>f. After injecting medication, withdraw syringe and recheck IV fluid infusion rate.</p>	<p>Injection of bolus may alter rate of fluid infusion. Rapid fluid infusion can cause circulatory fluid overload.</p>
<p>g. If IV medication is incompatible with IV fluids, stop IV fluids, clamp IV line, and flush with 10 mL of normal saline or sterile water (see agency policy). Then give IV bolus over appropriate amount of time and flush with another 10 mL of normal saline or sterile water at same rate as medication was administered.</p>	<p>Allows IV bolus to be administered without risks associated with IV incompatibilities. Ensure that agency guidelines permit flushing lines with incompatible medications. A new site may need to be initiated.</p>
<p>h. If IV line that currently is hanging is a medication, disconnect it and administer IV push medication as outlined in Step 9. Verify agency policy for stopping IV fluids or continuous IV medications. If unable to stop IV infusion, start new IV site (see Chapter 42) and administer medication using IV push (IV lock) method.</p>	<p>Avoids giving patient sudden bolus of medication in existing IV line.</p>
<p>9. IV push (IV lock):</p>	
<p>a. Prepare flush solutions according to agency policy.</p>	
<p>(1) <i>Saline flush method (preferred method):</i> Prepare two syringes filled with 2 to 3 mL of normal saline (0.9%). Many agencies do not provide prefilled normal saline syringes for flushing IV lines.</p>	<p>Normal saline is effective in keeping IV locks patent and is compatible with wide range of medications (Gorski, 2019).</p>
<p>(2) Heparin flush method (prepare heparin flush and saline syringe according to agency policy).</p>	
<p>b. Administer medication:</p>	
<p>(1) Clean injection port with antiseptic swab.</p>	<p>Prevents transfer of microorganisms during needle insertion.</p>
<p>(2) Insert needleless tip of syringe with normal saline 0.9% through center of injection port of IV lock (see illustrations).</p>	
<div data-bbox="367 892 889 1234" data-label="Image"> </div> <p data-bbox="357 1239 581 1255">Step 9a Use watch to time IV push medication.</p>	
<div data-bbox="367 1306 889 1465" data-label="Image"> </div> <p data-bbox="357 1470 776 1486">Step 9b(2) A, IV catheter with saline lock adapter. B, Syringe inserted into injection port.</p>	

Table Continued

Step	Rationale
(3) Pull back gently on syringe plunger and check for blood return.	Indicates if needle or catheter is in vein.
(4) Flush IV site with normal saline by pushing slowly on plunger.	Clears needle and reservoir of blood. Flushing without difficulty indicates patent IV line.
CLINICAL DECISION: Carefully observe the area of skin above the IV catheter. Note any puffiness or swelling as the IV site is flushed, which could indicate infiltration into the vein, requiring removal of catheter.	
(5) Remove saline-filled syringe.	
(6) Clean injection port with antiseptic swab.	Prevents transmission of microorganisms.
(7) Insert needleless tip of syringe containing prepared medication through injection port of IV lock.	Allows administration of medication.
(8) Inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration.	Many medication errors are associated with IV pushes being administered too quickly. Following guidelines for IV push rates promotes patient safety.
(9) After administering bolus, withdraw syringe.	
(10) Clean injection port with antiseptic swab.	Prevents transmission of microorganisms.
(11) Flush injection port.	
(a) Attach syringe with normal saline and inject flush at same rate that medication was delivered.	Flushing IV line with saline prevents occlusion of IV access device and ensures that all medication is delivered. Flushing IV site at same rate as medication ensures that any medication remaining within IV needle is delivered at the correct rate.
10. Help patient to comfortable position.	Gives patient sense of well-being.
11. Discard uncapped needle or needle enclosed in safety shield and attached syringe into puncture- and leak-proof receptacle.	Prevents injury to patients and health care personnel. Recapping needles increases risk for needlestick injury (OSHA, n.d.).
12. Remove and dispose of gloves and perform hand hygiene.	Reduces transmission of microorganisms.
13. Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.
Evaluation	
1. Observe patient closely for adverse reactions during administration and for several minutes thereafter.	IV medications act rapidly.
2. Observe IV site during injection for sudden swelling and for 48 hours after IV push.	Swelling indicates infiltration into tissue surrounding vein. Signs of infiltration may not occur for 48 hours.
3. Assess patient's status after giving medication to evaluate effectiveness of the medication.	Some IV bolus medications can cause rapid changes in patient's physiological status, thus requiring careful monitoring and assessment and possibly future laboratory testing (e.g., vasopressors and antiarrhythmics require blood pressure and heart rate monitoring, and heparin requires laboratory studies after administration to determine therapeutic levels).
4. Use Teach-Back: "I want to be sure I explained to you why you are receiving this IV medication. Can you explain to me what the medication is for and when to call the nurse?" Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient develops adverse reaction to medication.</p> <ul style="list-style-type: none"> • Stop delivering medication immediately and follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine or epinephrine) and reporting of adverse medication reactions. • Notify patient's health care provider of adverse effects immediately. • Add allergy information to patient's record. <p>2. IV site shows symptoms of infiltration or phlebitis (see Chapter 42).</p> <ul style="list-style-type: none"> • Stop IV infusion immediately or discontinue access device and restart in another site. • Determine how much damage IV medication can produce in subcutaneous tissue. • Provide IV extravasation care as indicated by agency policy; use a medication reference and consult pharmacist to determine appropriate follow-up care. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Immediately record medication administration, including medication, dose, route, time instilled, and date and time administered on MAR in the electronic health record (EHR) or chart. Include initials or signature. • Record patient's medication response in nurses' notes. • Record patient teaching and validation of understanding on the flow sheet or nurses' notes in the electronic health record (EHR) or chart. • Report any adverse reactions to patient's health care provider. Patient's response sometimes indicates need for additional medical therapy. 	

Administering Intravenous Medications by Piggyback, Intermittent Intravenous Infusion

Sets, and Mini-infusion (Syringe) Pumps

Delegation and Collaboration

The skill of administering IV medications by piggyback, intermittent infusion sets, and mini-infusion (syringe) pumps cannot be delegated to assistive personnel (AP). The nurse directs the AP about:

- Potential medication actions and side effects and to immediately report their occurrence to the nurse.
- Reporting any patient complaints of moisture or discomfort around IV insertion site.
- Reporting any change in patient's condition or vital signs to the nurse.

Equipment

- Adhesive tape (*optional*)
- Antiseptic swab
- Clean gloves
- IV pole
- MAR or computer printout
- Puncture-proof container

Piggyback or Mini-Infusion (Syringe) Pump

- Medication prepared in 5- to 250-mL labeled infusion bag or syringe
- Prefilled syringe containing normal saline flush solution (for saline lock only)
- Short microdrip, macrodrip, or syringe IV tubing set, with blunt-end needleless cannula attachment
- Needleless device
- Syringe pump if indicated

Volume-Control Administration Set

- Volutrol or Buretrol
- Infusion tubing with needleless system attachment
- Syringe (1 to 20 mL)
- Vial or ampule of ordered medication

Step	Rationale
Assessment	
1. Check accuracy and completeness of each MAR or computer printout with health care provider's written medication order. Check patient's name, medication name and dosage, route of administration, and time of administration. Clarify incomplete or unclear orders with health care provider before administration.	The order sheet is the most reliable source and only legal record of medications that patient is to receive. Ensures that patient receives the correct medications (Westbrook et al., 2017). Transcription errors are a source of medication errors (Truitt et al., 2016).
2. Assess patient's medical and medication history and history of allergies. List medication allergies on each page of the MAR and prominently display any allergies on the patient's medical record. When allergies are present, patient should wear an allergy bracelet.	Determines need for medication or possible contraindications for medication administration. IV bolus delivers medication rapidly. Allergic response is immediate.
3. Review medication reference information for medication action, purpose, side effects, normal dose, time of peak onset, how slowly to give medication, and nursing implications such as need to dilute medication or administer it through a filter.	Allows you to administer medication safely and monitor patient's response to therapy.
4. If you give medication through existing IV line, determine compatibility of medication with IV fluids and any additional additives within IV solution.	IV medication is sometimes not compatible with IV solution and/or additives.
CLINICAL DECISION: <i>Never administer IV medications through tubing that is infusing blood, blood products, or parenteral nutrition solutions.</i>	
5. Perform hand hygiene. Assess patency and placement of patient's existing IV infusion line or saline lock (see Chapter 42).	Do not administer medication if site is edematous or inflamed. For medication to reach circulation effectively, IV line must be patent, and fluids must infuse easily.
CLINICAL DECISION: <i>If patient's IV site is saline locked, clean the port with alcohol and assess the patency of the IV line by flushing it with 2 to 3 mL of sterile sodium chloride.</i>	
6. Assess patient's symptoms before initiating medication therapy.	Provides information to evaluate desired effects of medication.
7. Assess patient's knowledge of medication.	Poses implications for education.
Planning	
1. Perform hand hygiene. Collect appropriate equipment and MAR.	Reduces transmission of microorganisms. Ensures organized procedure.
2. Follow agency's "No-interruption zone" policy. Prepare medications for one patient at a time. Keep all pages of MARs or computer printouts for one patient together or look at only one patient's electronic MAR at a time.	Interruptions contribute to medication errors (Westbrook et al., 2017; Yoder et al., 2015) (see Box 31.4).
Implementation	
1. Prepare medications for intravenous administration. Attend to procedure and avoid distraction. Check label of medication against MAR two times, when removing medication from unit dose or AMDS and before leaving medication preparation area. Pharmacy prepares piggyback and prefilled syringes. You will prepare medication for a volume administration set. Perform hand hygiene.	Ensures that medication is sterile. <i>These are the first and second checks for accuracy</i> and ensure that correct medication is administered. Reduces transmission of microorganisms.

Table Continued

Step	Rationale
<p>2. Take medication(s) to patient at correct time (see agency policy). Medications that require exact timing include STAT doses, first-time or loading doses, and one-time doses. Give time-critical scheduled medications (e.g., antibiotics, anticoagulants, insulin, anticonvulsants, or immunosuppressive agents) at exact time ordered (no more than 30 minutes before or after scheduled dose). Give non-time-critical scheduled medications within a range of 1 or 2 hours of scheduled dose (ISMP, 2011a). During administration apply seven rights of medication administration.</p>	<p>Hospitals must adopt medication administration policy and procedure for timing of medication administration that considers nature of the prescribed medication, specific clinical application, and patient needs (DHHS, 2011; ISMP, 2011a). Time-critical scheduled medications are those for which early or delayed administration of maintenance doses of greater than 30 minutes before or after the scheduled dose may cause harm or result in substantial suboptimal therapy or pharmacological effect. Non-time-critical medications are those for which early or delayed administration within a specified range of either 1 or 2 hours should not cause harm or result in substantial suboptimal therapy or pharmacological effect (DHHS, 2011; ISMP, 2011a).</p>
<p>3. Close room curtain or door.</p>	<p>Provides privacy.</p>
<p>4. Identify patient using at least two identifiers (e.g., name and birthday or name and medical record number) according to agency policy. Compare identifiers with information on patient's MAR or medical record.</p>	<p>Ensures correct patient. Complies with The Joint Commission standards and improves patient safety (TJC, 2020).</p>
<p>5. At patient's bedside again compare MAR or computer printout with names of medications on medication labels and patient name. Ask patient whether he or she has allergies.</p>	<p><i>This is the third check for accuracy</i> and ensures that patient receives correct medication. Confirms patient's allergy history.</p>
<p>6. Discuss purpose of each medication, action, and possible adverse effects. Allow patient to ask any questions. Explain that you will give medication through existing IV line. Encourage patient to report symptoms of discomfort at site.</p>	<p>Keep patient informed of planned therapies, minimizing anxiety. Patients who verbalize pain at IV site help detect IV infiltrations early, lessening damage to surrounding tissues.</p>
<p>7. Perform hand hygiene and apply clean gloves. Administer infusion:</p>	<p>Reduces transmission of microorganisms.</p>
<p>a. Piggyback infusion:</p>	
<p>(1) Connect infusion tubing to medication bag (see Chapter 42). Fill tubing by opening regulator flow clamp. Once tubing is full, close clamp and cap end of tubing.</p>	<p>Filling infusion tubing with solution and freeing air bubbles prevent air embolus. Capping reduces transmission of microorganisms.</p>
<p>(2) Hang piggyback (see illustration) medication bag above level of primary fluid bag. (Use hook to lower main bag.) Primary line continues to infuse.</p>	<p>Height of fluid bag affects rate of flow to patient.</p>
<div data-bbox="358 1016 688 1507" data-label="Image"> </div> <p data-bbox="358 1514 625 1528">Step 7a(2) Small-volume minibag for piggyback infusion.</p>	

Table Continued

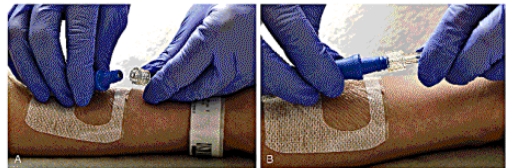

Step	Rationale
(3) Connect tubing of piggyback infusion to appropriate connector on upper Y-port of primary infusion line:	Connection allows IV medication to enter main IV line.
(a) <i>Needleless system</i> : Wipe off needleless port of main IV line with alcohol swab, allow to dry, and insert cannula tip of piggyback infusion tubing.	Use needleless connections to prevent accidental needlestick injuries (INS, 2016; OSHA, n.d.).
(b) <i>Normal saline lock</i> : Follow steps to flush and prepare lock (see Skill 31.6). Wipe off port with alcohol swab, let dry, and insert tip of piggyback infusion tubing via needleless access (see illustrations).	Flushing of lock ensures patency.
(4) Regulate flow rate of medication solution by adjusting regulator clamp or IV pump infusion rate. Infusion times vary. Refer to medication reference or agency policy for safe flow rate.	Provides slow, safe, intermittent infusion of medication and maintains therapeutic blood levels.
(5) Once medication has infused:	
(a) <i>Continuous infusion</i> : Check flow rate of primary infusion. Primary infusion automatically begins after piggyback solution is empty.	Back-check valve on piggyback prevents flow of primary infusion until medication infuses. Checking flow rate ensures proper administration of IV fluids.
(b) <i>Normal saline lock</i> : Disconnect tubing, clean port with alcohol, and flush IV line with 2 to 3 mL of sterile 0.9% sodium chloride. Maintain sterility of IV tubing between intermittent infusions.	
(6) Regulate continuous main infusion line to ordered rate.	Infusion of piggyback sometimes interferes with main line infusion rate.
(7) Leave IV piggyback and tubing in place for future medication administration (see agency policy) or discard it and the uncapped needle/needle enclosed safety shield of flushing syringe in puncture- and leak-proof container.	Establishing secondary line produces route for microorganisms to enter main line. Repeated changes in tubing increase risk for infection transmission.
 <p data-bbox="370 999 873 1014">Step 7a(3)(b) A, Needleless lock cannula system. B, Blunt-ended cannula inserts into port and locks.</p>	

Table Continued

Step	Rationale
b. Volume-control administration set (e.g., Volutrol):	
(1) Fill Volutrol with desired amount of IV fluid (50 to 100 mL) by opening clamp between Volutrol and main IV bag (see illustration).	Small volume of fluid dilutes IV medication and reduces risk of fluid infusing too rapidly.
(2) Close clamp and check to be sure that clamp on air vent Volutrol chamber is open.	Prevents additional leakage of fluid into Volutrol. Air vent allows fluid in Volutrol to exit at regulated rate.
(3) Clean injection port on top of Volutrol with antiseptic swab.	Prevents introduction of microorganisms during needle insertion.
(4) Remove needle cap or sheath and insert needleless syringe or syringe needle through port and inject medication (see illustration). Gently rotate Volutrol between hands.	Rotating mixes medication with solution to ensure equal distribution in Volutrol.
(5) Regulate IV infusion rate to allow medication to infuse in time recommended by agency policy, pharmacist, or medication reference manual.	For optimal therapeutic effect, medication should infuse in prescribed time interval.
(6) Label Volutrol with name of medication; dosage; total volume, including diluent; and time of administration following ISMP (2018d) safe-medication label format.	Alerts nurses to medication being infused. Prevents other medications from being added to Volutrol.
(7) If patient is receiving continuous IV infusion, check infusion rate after Volutrol infusion is complete.	Ensures appropriate rate of administration.
(8) Dispose of uncapped needle or needle enclosed in safety shield and syringe in puncture- and leak-proof container. Discard supplies in appropriate container. Perform hand hygiene.	Prevents accidental needlesticks (OSHA, n.d.). Reduces transmission of microorganisms.
c. Mini-infusion administration:	
(1) Connect prefilled syringe to mini-infusion tubing; remove end cap of tubing.	Special tubing designed to fit syringe delivers medication to main IV line.
(2) Carefully apply pressure to syringe plunger, allowing tubing to fill with medication.	Ensures that tubing is free of air bubbles to prevent air embolus.
(3) Place syringe into mini-infusion pump (follow product directions) and hang on IV pole. Be sure that syringe is secured.	<p>Secure placement is needed for proper infusion.</p>  <p>Step 7b(1) Fill volume-control administration device.</p>  <p>Step 7b(4) Medication injected into device.</p>

Table Continued

Step	Rationale
(4) Connect end of mini-infusion tubing to main IV line or saline lock:	Establishes route for IV medication to enter main IV line.
(a) <i>Existing IV line:</i> Wipe off needleless port on main IV line with alcohol swab, allow to dry, and insert tip of mini-infusion tubing through center of port.	Needleless connections reduce risk for accidental needlestick injuries (OSHA, n.d.).
(b) <i>Normal saline lock:</i> Follow steps to flush and prepare lock (see Skill 31.6). Wipe off port with alcohol swab, allow to dry, and insert tip of mini-infusion tubing.	Flushing of lock ensures patency.
(5) Set pump to deliver medication within time recommended by agency policy, pharmacist, or medication reference manual. Press button on pump to begin infusion.	Pump automatically delivers medication at safe, constant rate based on volume in syringe.
(6) Once medication has infused:	
(a) <i>Main IV infusion:</i> Check flow rate. Infusion automatically begins to flow once pump stops. Regulate infusion to desired rate as needed.	Maintains patent primary IV fluids.
(b) <i>Normal saline lock:</i> Disconnect tubing, clean port with alcohol, and flush IV line with 2 to 3 mL of sterile 0.9% sodium chloride. Maintain sterility of IV tubing between intermittent infusions.	
(c) Dispose of uncapped needle or needle enclosed in safety shield of flushing syringe in puncture- and leak-proof container. Discard supplies in appropriate container. Perform hand hygiene.	
8. Help patient to comfortable position.	Gives patient sense of well-being.
9. Stay with patient for several minutes and observe for any allergic reactions.	Dyspnea, wheezing, and circulatory collapse are signs of severe anaphylactic reaction.
Evaluation	
1. Observe patient for signs or symptoms of adverse reaction.	IV medications act rapidly.
2. During infusion periodically check infusion rate and condition of IV site.	IV must remain patent for proper medication administration. Infiltration of IV site requires discontinuing infusion.
3. Ask patient to explain purpose and side effects of medication.	Evaluates patient's understanding of instruction.
4. Use Teach-Back: "I want to be sure I explained to you the reason for this IV medication. Can you explain to me why you are receiving the medication and what to report to the nurse?" Revise your instruction now or develop a plan for revised patient/family caregiver teaching if patient/family caregiver is not able to teach back correctly.	Determines patient's/family caregiver's level of understanding of instructional topic.
Unexpected Outcomes and Related Interventions	
<p>1. Patient develops adverse or allergic reaction to medication.</p> <ul style="list-style-type: none"> • Stop medication infusion immediately. • Follow agency policy or guidelines for appropriate response to allergic reaction (e.g., administration of antihistamine such as diphenhydramine or epinephrine) and reporting of adverse medication reactions. • Notify patient's health care provider of adverse effects immediately. • Add allergy information to patient record per agency policy. <p>2. Medication does not infuse over established time frame.</p> <ul style="list-style-type: none"> • Determine reason (e.g., improper calculation of flow rate, poor positioning of IV needle at insertion site, infiltration). • Take corrective action as indicated by agency policy or health care provider. <p>3. IV site shows signs of infiltration or phlebitis (see Chapter 42).</p> <ul style="list-style-type: none"> • Stop IV infusion and discontinue access device. • Treat IV site as indicated by agency policy. • Insert new IV catheter if therapy continues. • For infiltration determine how harmful IV medication is to subcutaneous tissue. Provide IV extravasation care (e.g., injecting phentolamine around IV infiltration site) as indicated by agency policy, or consult pharmacist to determine appropriate follow-up care. 	
Recording and Reporting	
<ul style="list-style-type: none"> • Immediately record medication administration, including medication, dose, route, time instilled, and date and time administered on MAR in the electronic health record (EHR) or chart. Include initials or signature. • Record volume of fluid in medication bag or syringe pump as fluid intake. • Record patient teaching and validation of understanding on the flow sheet or nurses' notes in the electronic health record (EHR) or chart • Report any adverse reactions to patient's health care provider. Patient's response sometimes indicates need for additional medical therapy. 	

Key Points

- Apply knowledge of the four major pharmacokinetic processes—medication absorption, distribution, metabolism, and excretion—to time medication administration, select the route of administration, and evaluate a patient's response.
- Prompt recognition and reporting of adverse medication events prevents serious patient injury.
- In health care agencies, patients with known medication allergies have their allergy information recorded in a clearly identifiable place.
- A health care provider prescribes a patient's medications while the pharmacist prepares and distributes prescribed medications. Nurses, physicians, and other health care providers work together to evaluate the effectiveness of medication therapy.
- When a medication is prescribed, the goal is a constant blood level within a safe therapeutic range.
- Medications that are time critical most likely cause harm or have subtherapeutic effects if they are not administered on time (usually 30 minutes before or after the scheduled dose).
- The route prescribed for administering a medication depends on the medication's properties and desired effect and on a patient's physical and mental condition.

- Metric units are easy to convert and calculate using simple multiplication and division, with each basic unit of measurement organized into units of 10.
- Responsibilities of medication administration include knowing medication therapeutics, assessing a patient before administration, calculating doses, administering medications using the seven rights, monitoring and evaluating medication effects, and assessing a patient's ability to self-administer medications.
- The seven rights of medication administration include the right medication, right dose, right patient, right route, right time, right documentation, and right indication.
- Before administering medications, perform a physical assessment, which will reveal physical findings for any indications or contraindications for medication therapy.
- Factors contributing to medication nonadherence in older adults include depression, problems with cognitive or functional abilities, dislike for medication side effects, a busy and active lifestyle, and inability to afford medications.
- Distractions may cause a medication error. Distractions include a page, phone call, or request from a colleague or patient that draws away, disturbs, or diverts attention from a current desired task, or forces attention on a new task at least temporarily.
- Collaboration with patients and their family caregivers is essential, particularly if patients will require assistance with self-administration and if medication regimens are complicated.

- For patient safety it is essential that you refer to the MAR each time you prepare a medication and have it available at the patient's bedside when administering medications.
- Rotate IM injection sites to decrease the risk for tissue hypertrophy, and use the Z-track method for administration.

Reflective Learning

- You are a new nurse and have started a staff nurse position on a busy medical-surgical unit. You must administer many medications to four different patients throughout the shift and feel overwhelmed. How would you organize safe medication administration for these patients?
- Consider all the nonparenteral routes of medication your patients may be receiving during their admission to a health care agency. Consider the need for different approaches to administering these medications. When might it be acceptable to allow a patient to administer some of these routes of medications themselves?
- Consider a time when you were caring for patients who required a variety of routes for administering IV medication. How might you ensure you are correctly assessing for medication compatibility, rate of infusion, and route of administration?

Review Questions

1. It is important to take precautions to prevent medication errors. A nurse is administering an oral tablet to a patient.

Which of the following steps is the second check for accuracy in determining the patient is receiving the right medication?

1. Logging on to automated dispensing system (ADS) or unlocking medicine drawer or cart.
 2. Before going to patient's room, comparing patient's name and name of medication on label of prepared drugs with MAR.
 3. Selecting correct medication from ADS, unit-dose drawer, or stock supply and comparing name of medication on label with MAR or computer printout.
 4. Comparing MAR or computer printout with names of medications on medication labels and patient name at patient's bedside.
2. The health care provider has written the following orders. Which orders does the nurse need to clarify before administering the medication? Provide rationale for your answers, and rewrite the order so that it follows the ISMP current medication order safety guidelines.

Timoptic .25% solution 1 drop OD BID

Metoprolol 12.50 mg QD

Insulin Glargine 6 u SC twice a day

Enalapril 2.5 mg. PO three times a day, hold for systolic blood pressure <100

3. An older adult states that she cannot see her medication bottles clearly to determine when to take her prescription. What should the nurse do? (Select all that apply.)
1. Provide a dispensing system for each day of the week.
 2. Provide larger, easier-to-read labels.

3. Tell the patient what is in each container.
 4. Have a family caregiver administer the medication.
 5. Use teach-back to ensure that the patient knows what medication to take and when.
4. The nurse must take a verbal order during an emergency on the unit. Which of the following guidelines can be used for taking verbal or telephone orders? (Select all that apply).
1. Only authorized staff may receive and record verbal or telephone orders. The health care agency identifies in writing the staff who are authorized.
 2. Clearly identify patient's name, room number, and diagnosis.
 3. Read back all orders to health care provider.
 4. Use clarification questions to avoid misunderstandings.
 5. Write "VO" (verbal order) or "TO" (telephone order), including date and time, name of patient, and complete order; sign the name of the health care provider and nurse.
5. A nurse is administering ophthalmic ointment to a patient. Place the following steps in correct order for the administration of the ointment.
1. Clean eye, washing from inner to outer canthus.
 2. Assess patient's level of consciousness and ability to follow instructions.
 3. Apply thin ribbon of ointment evenly along inner edge of lower eyelid on conjunctiva.

4. Have patient close eye and rub lightly in a circular motion with a cotton ball.
5. Ask patient to look at ceiling, and explain the steps to patient.
6. The nurse is administering an IV push medication to a patient who has a compatible IV fluid running through intravenous tubing. Place the following steps in the appropriate order.
 1. Release tubing and inject medication within amount of time recommended by agency policy, pharmacist, or medication reference manual. Use watch to time administration.
 2. Select injection port of IV tubing closest to patient. Whenever possible, injection port should accept a needleless syringe. Use IV filter if required by medication reference or agency policy.
 3. After injecting medication, release tubing, withdraw syringe, and recheck fluid infusion rate.
 4. Connect syringe to port of IV line. Insert needleless tip or small-gauge needle of syringe containing prepared drug through center of injection port
 5. Clean injection port with antiseptic swab. Allow to dry.
 6. Occlude IV line by pinching tubing just above injection port. Pull back gently on syringe plunger to aspirate blood return.
7. A nurse is administering a metered-dose inhaler (MDI) with a spacer to a patient with chronic obstructive pulmonary disease. Place the steps of the procedure in the correct order.

1. Insert MDI into end of spacer.
 2. Perform a respiratory assessment.
 3. Remove mouthpiece from MDI and spacer device.
 4. Place the spacer mouthpiece into patient's mouth, and instruct patient to close lips around the mouthpiece.
 5. Depress medication canister, spraying 1 puff into spacer device.
 6. Shake inhaler for 2-5 seconds.
 7. Instruct patient to hold breath for 10 seconds.
 8. Instruct patient to breathe in slowly through mouth for 3 to 5 seconds.
8. A patient is to receive medications through a small-bore nasogastric feeding. Which nursing actions are appropriate? (Select all that apply.)
1. Verifying tube placement after medications are given
 2. Mixing all medications together to give all at once
 3. Using an enteral tube syringe to administer medications
 4. Flushing tube with 30 to 60 mL of water after the last dose of medication
 5. Checking for gastric residual before giving the medications
 6. Keeping the head of the bed elevated 30 to 60 minutes after the medications are given
9. Place the steps of administering an intradermal injection in the correct order.
1. Inject medication slowly.
 2. Note the presence of a bleb.

3. Advance needle through epidermis to 3 mm.
 4. Using nondominant hand, stretch skin over site with forefinger.
 5. Insert needle at a 5- to 15-degree angle into the skin until resistance is felt.
 6. Cleanse site with antiseptic swab.
10. After receiving an intramuscular (IM) injection in the deltoid, a patient states, "My arm really hurts. It's burning and tingling where I got my injection." What should the nurse do next? (Select all that apply.)
1. Assess the injection site.
 2. Administer an oral medication for pain.
 3. Notify the patient's health care provider of assessment findings.
 4. Document assessment findings and related interventions in the patient's medical record.
 5. This is a normal finding, so nothing needs to be done.
 6. Apply ice to the site for relief of burning pain.
