Preface to the Instructor

Acknowledgments

Unit 1. Nursing and the Health Care Environment

1. Nursing Today

Nursing as a Profession

Historical Influences

Contemporary Influences

Trends in Nursing

Professional Registered Nurse Education

Nursing Practice

Professional Nursing Organizations

2. The Health Care Delivery System

Traditional Level of Health Care

Integrated Health Care Delivery

Issues in Health Care Delivery for Nurses

The Future of Health Care

3. Community-Based Nursing Practice

Community-Based Health Care

Community-oriented nursing

Community-based nursing

Community Assessment

Changing patients' health

4. Theoretical Foundations of Nursing Practice

Theory

Shared Theories

Select Nursing Theories

Link between Theory and Knowledge Development in Nursing

5. Evidence-Based Practice

The Need for Evidence-Based Practice

Nursing Research

Research Process

Performance Improvement

The Relationship Between EBP, Research, and Performance Improvement

Unit 2. Caring Throughout the Life Span

6. Health and Wellness

Healthy People

Definition of Health

Models of Health and Illness

Variables Influencing Health and Health Beliefs and Practices

Health Promotion, Wellness, and Illness Prevention

Risk Factors

Risk-Factor Identification and Changing Health Behaviors

Illness

Caring for Yourself

7. Caring in Nursing Practice

Theoretical Views on Caring

Patients' Perceptions of Caring

Ethic of Care

Caring in Nursing Practice

The Challenge of Caring

8. Caring for Patients With Chronic Illness

The Prevalence and Costs of Chronic Disease

Multifactorial Nature of Chronic Disease

Physical Effects of Chronic Illness

Psychosocial Needs of Patients with Chronic Illness

Growth AND Development Considerations

Family Caregivers

The Chronic Care Model

Implications for Nursing

Health Promotion and Disease Prevention

Public Policy

9. Cultural Competence

World View

Health Disparities

Racial, Ethnic, and Cultural Identity

Disease and Illness

A Model of Cultural Competence

Cultural Awareness and Knowledge

Cultural Skill

Cultural Encounter

Cultural Desire

10. Family Dynamics

The Family

Family Forms and Current Trends

Family Nursing

Family-Centered Care and the Nursing Process

11. Developmental Theories

Developmental Theories

12. Conception Through Adolescence

Stages of Growth and Development

Selecting a Developmental Framework for Nursing

Intrauterine Life

Transition from Intrauterine to Extrauterine Life

Newborn

Infant

Toddler

Preschoolers

School-Age Children and Adolescents

School-Age Children

Adolescents

13. Young and Middle Adults

Young Adults

Middle Adults

14. Older Adults

Variability Among Older Adults

Myths and Stereotypes

Nurses' Attitudes Toward Older Adults

Developmental Tasks for Older Adults

Community-Based and Institutional Health Care Services

Assessing the Needs of Older Adults

Addressing the Health Concerns of Older Adults

Older Adults and the Acute Care Setting

Older Adults and Restorative Care

Unit 3. Critical Thinking in Nursing Practice

15. Critical Thinking in Nursing Practice

Clinical Judgment in Nursing Practice

Critical Thinking Defined

Levels of Critical Thinking in Nursing

Critical Thinking Competencies

Nursing Process Competency

A Critical Thinking Model for Clinical Decision Making

Developing Critical Thinking Skills

Managing Stress

Critical Thinking Synthesis

16. Nursing Assessment

Critical Thinking in Assessment

The Nurse-Patient Relationship in Assessment

The Patient-Centered Interview

Nursing Health History

The Assessment Process

17. Nursing Diagnosis

Types of Diagnoses

Terminologies for Nursing Diagnoses

Critical Thinking and the Nursing Diagnostic Process

Use of Nursing Diagnosis in Practice

Sources of Diagnostic Error

Documentation and Informatics

Nursing Diagnoses Application to Care Planning

18. Planning Nursing Care

Establishing Priorities

Critical Thinking in Setting Goals and Expected Outcomes

Critical Thinking in Planning Nursing Care

Systems for Planning Nursing Care

Consulting with Health Care Professionals

19. Implementing Nursing Care

Standard Nursing Interventions

Critical Thinking in Implementation

Implementation Process

Direct Care

Indirect Care

Achieving Patient Goals

20. Evaluation

Standards for Evaluation

Critical Thinking in Evaluation

Collaborate and Evaluate Effectiveness of Interventions

Document Outcomes

Evaluation of Health Care

21. Managing Patient Care

Building a Nursing Team

Leadership Skills for Nursing Students

Unit 4. Professional Standards in Nursing Practice

22. Ethics and Values

Basic Terms in Health Ethics

Professional Nursing Code of Ethics

Values

Approaches to Ethics

Nursing Point of View

Issues in Health Care Ethics

23. Legal Implications in Nursing Practice

Legal Limits of Nursing

Federal Statutes Impacting Nursing Practice

State Statutes Impacting Nursing Practice

Legal Implications and Issues Associated with Nursing Practice

24. Communication

Communication and Nursing Practice

Elements of the Communication Process

Forms of Communication

Professional Nursing Relationships

Elements of Professional Communication

Nursing Process

25. Patient Education

Standards for Patient Education

Purposes of Patient Education

Teaching and Learning

Domains of Learning

Basic Learning Principles

Nursing Process

26. Informatics and Documentation

Purposes of the Health Care Record

Interprofessional Communication Within the Health Record

Standards and Guidelines for Quality Nursing Documentation

Methods of Documentation

Common Record-Keeping Forms Within The Electronic Health Record

Documenting Communication With Providers and Unique Events

Acuity Rating Systems

Documentation in the Long-Term Health Care Setting

Documentation in the Home Health Care Setting

Case Management and use of Critical Pathways

Informatics and Information Management in Health Care

Unit 5. Foundations for Nursing Practice

27. Patient Safety and Quality

Scientific Knowledge Base

Nursing Knowledge Base

Critical Thinking

Nursing Process

28. Infection Prevention and Control

Scientific Knowledge Base

Nursing Knowledge Base

Nursing Process

29. Vital Signs

Guidelines for Measuring Vital Signs

Body Temperature

Nursing Process

Pulse

Nursing Process

Respiration

Nursing Process

Blood Pressure

Nursing Process

30. Health Assessment and Physical Examination

Purposes of the Physical Examination

Preparation for Examination

Organization of the Examination

Techniques of Physical Assessment

General Survey

Skin, Hair, and Nails

Head and Neck

Thorax and Lungs

Heart

Vascular System

Breasts

Abdomen

Female Genitalia and Reproductive Tract

Male Genitalia

Rectum and Anus

Musculoskeletal System

Neurological System

After the Examination

31. Medication Administration

Scientific Knowledge Base

Nursing Knowledge Base

Dedication

I wish to dedicate this book to the incredible circle of friends that I call family. Their support, presence, and encouragement are priceless.

You all know who you are. Love you all.

Patricia A. Potter

This book is dedicated to all students who are committed to studying this rewarding but challenging profession.

To all nursing faculty who work tirelessly to provide students with excellent, state-of-the art classroom and clinical experiences.

Finally, to all practicing nurses who welcome students to the clinical practice site and partner with nursing faculty to demonstrate excellence in clinical nursing.

Anne Griffin Perry

During my doctoral education, I was blessed to meet Pat and Anne, who gave me this wonderful opportunity to participate in authoring and editing nursing textbooks. It was an unexpected but wonderful part of my nursing career. Thank you, Pat and Anne, for letting me join your journey of

providing nursing students with the best fundamentals nursing textbook! Over the years, I have learned much from both of you and all the wonderful editorial staff at Elsevier. I look forward to continuing the journey with you in the future.

To the nursing students who read this textbook as you start your nursing career, I am glad that we are able to provide you a solid foundation and best evidence to build on as you progress through your nursing programs. You are developing the knowledge and skills necessary to provide safe, competent, patient-centered nursing care. I wish you all the best as you join the wonderful profession of nursing!

And finally, thank you to my husband, Drake, for your patience and support as I spend my time writing and editing. I couldn't have done this without you!

Patricia A. Stockert

To all nurses and nursing faculty, especially those at Franciscan Missionaries of Our Lady University. Your never-ending enthusiasm for nursing is so inspirational and demonstrates the importance of life-long learning to improve patient care every day.

To Patti, Anne, and Pat for your never-ending friendship and support. You push me to be a better person and nurse every day.

To Julia, Tina, Chris, Chuck, Mistie, Blaize, Donna, Jesse, Jenni, Jane, and the rest of the Varsity Sports Running Team

for accepting me into your family and showing me the importance of running hard and living easy.

And to Greg. Your love, patience, and support has allowed me to achieve personal and professional goals I never could have imagined.

Amy M. Hall

Preface to the Instructor

The nursing profession is always responding to dynamic change and continual challenges. Today, nurses need a broad knowledge base from which to provide care. More importantly, nurses require the ability to know how to apply best evidence in practice to assure the best outcomes for their patients. The role of the nurse includes assuming the lead in preserving nursing practice and demonstrating its contribution to the health care of our nation. Nurses of tomorrow, therefore, need to become competent clinicians, critical thinkers, patient advocates, clinical decision makers, and patient educators within a broad spectrum of care services.

The tenth edition of *Fundamentals of Nursing* was revised to prepare today's students for the challenges of tomorrow. This textbook is designed for beginning students in all types of professional nursing programs. The comprehensive coverage provides fundamental nursing concepts, skills, and techniques of nursing practice and a firm foundation for more advanced areas of study.

Fundamentals of Nursing provides a contemporary approach to nursing practice, discussing the entire scope of primary, acute, and restorative care. This new edition continues to address a number of key current practice issues, including an emphasis on patient-centered care and evidence-based practice. Evidence-based practice is one of the most important initiatives in health care today. The increased focus on applying current evidence in patient care helps students understand how the latest research findings should guide their clinical decision making. Current evidence is reflected in each chapter's references.

Key Features

We have carefully developed this tenth edition with the student in mind. We have designed this text to welcome the new student to nursing, communicate our own love for the profession, and promote learning and understanding. Key features of the text include the following:

- Students will appreciate the **clear, engaging writing style**. The narrative actually addresses the reader, making this textbook more of an active instructional tool than a passive reference. Students will find that even complex technical and theoretical concepts are presented in a language that is easy to understand.
- **Comprehensive** coverage and readability of all fundamental nursing content.
- The **attractive, functional design** will appeal to today's visual learner. The clear, readable type and bold headings make the content easy to read and follow. Each special element is consistently color-keyed so students can readily identify important information.
- Hundreds of **large, clear, full-color photographs and drawings** reinforce and clarify key concepts and techniques.
- A **critical thinking model** is incorporated within all clinical chapters, showing how elements of critical thinking, including knowledge, critical thinking attitudes, intellectual and professional standards, and experience, are applied in the nursing process for making clinical decisions.
- The **nursing process** format provides a consistent organizational framework for clinical chapters.
- **Learning aids** to help students identify, review, and apply important content in each chapter include Objectives, Key Terms, Key Points, Clinical Application Questions, and Review Questions.
- **Evolve Resources** lists at the beginning of every chapter detail the electronic resources available for the student.

- **Health promotion and acute and continuing care** are covered to address today's practice in various settings.
- A **health promotion/wellness** thread is used consistently throughout the text.
- **Cultural competence, care of the older adult, and patient teaching** are stressed throughout chapter narratives, as well as highlighted in special boxes.
- **Procedural Guidelines** boxes provide more streamlined, step-by-step instructions for performing very basic skills.
- **Concept Maps** included in clinical chapters show you the association between multiple nursing diagnoses for a patient with a selected medical diagnosis and the relationship between nursing interventions.
- **Nursing Care Plans** guide students on how to conduct an assessment and analyze the defining characteristics in order to select nursing diagnoses. The plans include NIC and NOC classifications to familiarize students with this important nomenclature. The evaluation sections of the plans show students how to evaluate and then determine the outcomes of care.
- Information related to the **Quality and Safety Education for Nurses (QSEN)** initiative is highlighted by headings that coordinate with the key competencies. Building Competency scenarios in each chapter incorporate one of the six key competencies in QSEN. Answers to these activities can be found online in the Evolve student resources.
- **More than 55 nursing skills** are presented in a clear two-column format, with steps and supporting rationales that are often supported with current evidenced-based research.
- **Delegation Considerations** guide when it is appropriate to delegate tasks to assistive personnel.
- **Unexpected Outcomes and Related Interventions** are highlighted within nursing skills to help students anticipate and appropriately respond to possible problems faced while performing skills.
- **Video Icons** indicate video clips associated with specific skills that are available on the Evolve Student Resources.

- **Printed endpapers** on the inside back cover provide information on locating specific assets in the book, including Skills, Procedure Guidelines, Nursing Care Plans, and Concept Maps.

New to this Edition

- **Reflect Now** boxes interspersed throughout the chapters prompt students to consider a recent clinical experience based on the topic being discussed in the text.
- **Review Questions** have been updated in each chapter, with a minimum of 4 alternate-item type questions. Answers are provided with questions and rationales on Evolve.
- **Evidence-Based Practice** boxes in each chapter have been updated to reflect current research topics and trends.
- A **Reflective Learning** section helps students better understand and think about their clinical and simulation experiences as they progress through their first nursing courses.
- **Teach-back** has been incorporated into the Evaluation section of the Patient Teaching boxes.
- **Chapter 8, Caring for Patients with Chronic Illness**, has been expanded to help prepare students to address the unique health care needs of patients and families who are living with the physical, emotional, social, and economic stressors of chronic illness.

Learning Supplements for Students

- The **Evolve Student Resources** are available online at <http://evolve.elsevier.com/Potter/fundamentals/> and include the following valuable learning aids organized by chapter:
 - Chapter Review Questions with Answers and Rationales
 - Answers and rationales to Building Competency scenario questions
 - Video clips to highlight common skills
 - Conceptual Care Map (included in each clinical chapter)
 - Case Study with questions
 - Audio Glossary
 - Fluids & Electrolytes Tutorial
 - Printable versions of Chapter Key Points
 - Printable Skills Performance Checklists (included for each skill in the text)
- A thorough *Study Guide* by GERALYN OCHS provides an ideal supplement to help students understand and apply the content of the text. Each chapter includes multiple sections:
 - Preliminary Reading includes a chapter assignment from the text.
 - Case Study with related questions
 - Comprehensive Understanding provides a variety of activities to reinforce the topics and main ideas from the text.
 - Review Questions include multiple-choice, matching, and fill-in-the-blank questions. Answers and rationales are provided in the answer key.
 - Clinical chapters include an Application of Critical Thinking Synthesis Model that expands the case study from the chapter's Care Plan and asks students to develop a step in the synthesis model based on the nurse and patient in the scenario. This

helps students learn to apply both content learned and the critical thinking synthesis model.

- The handy *Clinical Companion* complements, rather than abbreviates, the textbook. Content is presented in tabular, list, and outline format that equips your students with a concise, portable guide to all the facts and figures they'll need to know in their early clinical experiences.
- **Virtual Clinical Excursions** is an exciting workbook and video experience that brings learning to life in a virtual hospital setting. The workbook guides students as they care for patients, providing ongoing challenges and learning opportunities. Each lesson in *Virtual Clinical Excursions* complements the textbook content and provides an environment in which students can practice what they are learning. This CD/workbook is available separately or packaged at a special price with the textbook.

Teaching Supplements for Instructors

- The **Evolve Instructor Resources** (available online at <http://evolve.elsevier.com/Potter/fundamentals>) are a comprehensive collection of the most important tools instructors need, including the following:
 - **TEACH for Nurses** ties together every chapter resource you need for the most effective class presentations, with sections dedicated to objectives, teaching focus, nursing curriculum standards (including QSEN, BSN Essentials, and Concepts), instructor chapter resources, student chapter resources, answers to chapter questions, and an in-class case study discussion. Teaching Strategies help you create learning activities you can use to assess students' understanding of the content presented in the textbook. Examples of student activities, online activities, new health promotion-focused activities, and large group activities are provided for more "hands-on" learning.
 - The **Test Bank** contains 1100 questions, with answers coded for NCLEX Client Needs category, nursing process, and cognitive level. The ExamView software allows instructors to create new tests; edit, add, and delete test questions; sort questions by NCLEX category, cognitive level, nursing process step, and question type; and administer/grade online tests.
 - Updated **PowerPoint Presentations** include more than 1500 slides for use in lectures. Art is included within the slides, and progressive case studies include discussion questions and answers.
 - The **Image Collection** contains more than 1150 illustrations from the text for use in lectures.
 - **Simulation Learning System** is an online toolkit that helps instructors and facilitators effectively

incorporate medium- to high-fidelity simulation into their nursing curriculum. Detailed patient scenarios promote and enhance the clinical decision-making skills of students at all levels. The system provides detailed instructions for preparation and implementation of the simulation experience, debriefing questions that encourage critical thinking, and learning resources to reinforce student comprehension. Each scenario in *Simulation Learning System* complements the textbook content and helps bridge the gap between lectures and clinicals. This system provides the perfect environment for students to practice what they are learning in the text for a true-to-life, hands-on learning experience.

Multimedia Supplements for Instructors and Students

- **Nursing Skills Online 4.0** contains 19 modules rich with animations, videos, interactive activities, and exercises to help students prepare for their clinical lab experience. The instructionally designed lessons focus on topics that are difficult to master and pose a high risk to the patient if done incorrectly. Lesson quizzes allow students to check their learning curve and review as needed, and the module exams feed out to an instructor grade book. Modules cover Airway Management, Blood Therapy, Bowel Elimination/Ostomy Care, Cardiac Care, Closed Chest Drainage Systems, Enteral Nutrition, Infection Control, Maintenance of IV Fluid Therapy, IV Fluid Therapy, Administration of Parenteral Medications: Injections, Administration of Parenteral Medications: IV Medications, Administration of Nonparenteral Medications, Safe Medication Preparation, Safety, Specimen Collection, Urinary Catheterization, Caring for Central Vascular Access Devices (CVAD), Vital Signs, and Wound Care. Available alone or packaged with the text.
- **Mosby's Nursing Video Skills: Basic, Intermediate, Advanced, 4th edition** provides 126 skills with overview information covering skill purpose, safety, and delegation guides; equipment lists; preparation procedures; procedure videos with printable step-by-step guidelines; appropriate follow-up care; documentation guidelines; and interactive review questions. Available online, as a student DVD set, or as a networkable DVD set for the institution.

Acknowledgments

The tenth edition of *Fundamentals of Nursing* is one that we believe continues to prepare the student nurse to practice in the challenging health care environment. Collaboration on this project allows us to be creative, visionary, and thoughtful as to students' learning needs. Each edition is a new adventure for the author team as we try to create the very best textbook for beginning nurses. Each of us wishes to acknowledge the professionalism, support, and commitment to detail from the following individuals:

- The editorial and production professionals at Mosby/Elsevier, including:
 - Tamara Myers, Director, Traditional Education, for her vision, organization, professionalism, energy, and support in assisting us to develop a text that offers a state-of-the-art approach to the design, organization, and presentation of *Fundamentals of Nursing*. Her skill is in motivating and supporting a writing team so it can be creative and innovative while retaining the characteristics of a high-quality textbook.
 - Tina Kaemmerer, our Senior Content Development Specialist for *Fundamentals of Nursing*. As a dedicated professional, Tina keeps the writing team organized and focused and performs considerable behind-the-scenes work to ensure accuracy and consistency in how we present content within the textbook. She has limitless energy and is always willing to go the extra mile.
 - Jodi Willard, Senior Project Manager, consistently performs miracles. She is an amazing and accomplished production editor who applies

patience, humor, and attention to detail. It is an honor to work with Jodi because of her professionalism and ability to coordinate the multiple aspects of completing a well-designed finished product.

- KJ Filmworks, Hennessey, Oklahoma, for their excellent photography.
- Memorial Hospital East, in Shiloh, Illinois, for granting permission to use its facility for the new photographs.
- To our contributors and clinician and educator reviewers, who share their expertise and knowledge about nursing practice and the trends within health care today, helping us to create informative, accurate, and current information. Their contributions allow us to develop a text that embodies high standards for professional nursing practice through the printed word.
- And special recognition to our professional colleagues at Barnes-Jewish Hospital, Southern Illinois University Edwardsville, Saint Francis Medical Center College of Nursing, and Franciscan Missionaries of Our Lady University.

We believe that *Fundamentals of Nursing*, now in its tenth edition, is a textbook that informs and helps to shape the standards for excellence in nursing practice. Nursing excellence is a goal we all seek, and we are happy to have the opportunity to continue the work we love.

UNIT 1

Nursing and the Health Care Environment

OUTLINE

1. Nursing Today
2. The Health Care Delivery System
3. Community-Based Nursing Practice
4. Theoretical Foundations of Nursing Practice
5. Evidence-Based Practice

1

Nursing Today

OBJECTIVES

- Explore the development of professional nursing roles.
- Describe educational programs available for professional registered nurse (RN) education.
- Describe how nursing standards affect nursing care.
- Discuss the roles and career opportunities for professional nurses.
- Discuss the influence of social, historical, political, and economic changes on nursing practices.
- Discuss how advances in nursing science and evidence-based practice improve patient care.

KEY TERMS

Advanced practice registered nurse (APRN), p. 4

American Nurses Association (ANA), p. 2

Caregiver, p. 3

Certified nurse-midwife (CNM), p. 5

Certified registered nurse anesthetist (CRNA), p. 5

Clinical nurse specialist (CNS), p. 4

Code of ethics, p. 3

Continuing education, p. 10

Genomics, p. 9

In-service education, p. 10

International Council of Nurses (ICN), p. 2

Nurse administrator, p. 5

Nurse educator, p. 5

Nurse practitioner (NP), p. 4

Nurse researcher, p. 5

Nursing, p. 2

Patient advocate, p. 3

Professional organization, p. 11

Quality and Safety Education for Nurses (QSEN), p. 8

Registered nurse (RN), p. 10

Nursing is an art and a science. As an art, you learn to deliver care with compassion, caring, and respect for each patient's dignity and individuality. As a science, nursing practice is based on a body of knowledge and evidence-based practices that are continually changing with new discoveries and innovations. By integrating the art and science of nursing, the quality of care you provide is at the highest standards and benefits patients and their families. Your care reflects your patients' multidimensional needs as well as the needs and values of society and professional standards of care.

Nursing offers personal and professional rewards every day. This chapter presents a contemporary view of the evolution of nursing and nursing practice and the historical, practical, social, and political influences on the discipline of nursing.

Nursing as a Profession

The patient is the center of your practice. Your patient includes individuals, families, and/or communities. Patients have a wide variety of health care needs, knowledge, experiences, vulnerabilities, and expectations, but this is what makes nursing both challenging and rewarding. Making a difference in your patients' lives is fulfilling (e.g., helping a young mother learn parenting skills, finding ways for older adults to remain independent in their homes, assisting family caregivers with end-of-life care symptom management).

Nursing is not simply a collection of specific skills, and you are not simply a person trained to perform specific tasks. Nursing is a profession. No one factor absolutely differentiates a job from a profession, but the difference is important in terms of how you practice. To act professionally, use your critical thinking skills to administer quality evidenced-based, patient-centered care in a safe, prudent, and knowledgeable manner. You are responsible and accountable to yourself, your patients, and your peers.

A variety of career opportunities are available in nursing, including clinical practice, education, research, management, administration, and even entrepreneurship. As a student it is important for you to understand the scope of professional nursing practice and how nursing influences the lives of your patients, their families, and their communities.

Health care advocacy groups recognize the importance of the role quality professional nursing has on a nation's health care. One such program was the Robert Wood Johnson Foundation (RWJF) *Future of Nursing: Campaign for Action* (RWJF, 2014a). This program is a multifaceted campaign to transform health care through nursing, and it is a response to the Institute of Medicine (IOM) publication on *The Future of Nursing* (IOM, 2010). A new RWJF (2017) initiative, *Catalysts for Change: Harnessing the power of nurses to build population health in the 21st century*, reinforces the fact that nurses are educated to consider health care issues within a broader context; as a result, nurses identify factors outside health care that affect a person's level of health. These initiatives prepare a professional workforce to meet health promotion, illness prevention, and complex care needs of the population in a changing health care system.

Science and Art of Nursing Practice

Because nursing is both an art and a science, nursing practice requires a blend of current knowledge and practice standards with an insightful and

compassionate approach to your patients' health care needs. Your care must reflect the needs and values of society and professional standards of care and performance, meet the needs of each patient, and integrate evidence-based findings to provide the highest level of care.

Clinical expertise takes time and commitment. According to [Benner \(1984\)](#), an expert nurse passes through five levels of proficiency when acquiring and developing generalist or specialized nursing skills ([Box 1.1](#)). Expert clinical nursing practice is a commitment to the application of knowledge, ethics, aesthetics, and clinical experience. Your ability to interpret clinical situations and make complex decisions is the foundation for your nursing care and the basis for the advancement of nursing practice and the development of nursing science ([Benner et al., 1997, 2010](#)).

Box 1.1 Benner: From Novice to Expert

- **Novice:** Beginning nursing student or any nurse entering a situation in which there is no previous level of experience (e.g., an experienced operating room nurse chooses to now practice in home health). The learner learns via a specific set of rules or procedures, which are usually stepwise and linear.
- **Advanced Beginner:** A nurse who has had some level of experience with the situation. This experience may be only observational in nature, but the nurse is able to identify meaningful aspects or principles of nursing care.
- **Competent:** A nurse who has been in the same clinical position for 2 to 3 years. This nurse understands the organization and specific care required by the type of patients (e.g., surgical, oncology, or orthopedic patients). He or she is a competent practitioner who is able to anticipate nursing care and establish long-range goals. In this phase the nurse has usually had experience with all types of psychomotor skills required by this specific group of patients.
- **Proficient:** A nurse with more than 2 to 3 years of experience in the same clinical position. This nurse perceives a patient's clinical situation as a whole, is able to assess an entire situation, and can readily transfer knowledge gained from multiple previous experiences to a situation. This nurse focuses on managing care as opposed to managing and performing skills.

- **Expert:** A nurse with diverse experience who has an intuitive grasp of an existing or potential clinical problem. This nurse is able to zero in on the problem and focus on multiple dimensions of the situation. He or she is skilled at identifying both patient-centered problems and problems related to the health care system or perhaps the needs of the novice nurse.

Data from Benner P: *From novice to expert: excellence and power in clinical nursing practice*, Menlo Park, CA, 1984, Addison-Wesley.

Use critical thinking skills to help you gain and interpret scientific knowledge, integrate knowledge from clinical experiences, and become a lifelong learner ([Chapter 15](#)). Integrate the competencies of critical thinking in your practice. This includes incorporating knowledge from the basic sciences and nursing, applying knowledge from past and present experiences, applying critical thinking attitudes to a clinical situation, and implementing intellectual and professional standards. When you provide well-thought-out care with compassion and caring, you provide each patient the best of the science and art of nursing care (see [Chapter 7](#)).

Scope and Standards of Practice

When giving care, it is essential to provide a specified service according to standards of practice and to follow a code of ethics ([ANA, 2015](#)). Professional practice includes knowledge from social and behavioral sciences, biological and physiological sciences, and nursing theories. In addition, nursing practice incorporates ethical and social values, professional autonomy, and a sense of commitment and community ([ANA, 2015](#)). The following definition from the **American Nurses Association (ANA)** illustrates the consistent commitment of nurses to provide care that promotes the well-being of their patients and communities ([Fowler, 2015a](#)). **Nursing** is the protection, promotion, and optimization of health and abilities; prevention of illness and injury; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, communities, and populations ([ANA, 2015](#)). The **International Council of Nurses (ICN, 2018)** has another definition: *Nursing encompasses autonomous and collaborative care of individuals of all ages, families, groups, and communities, sick or well, and in all settings. Nursing includes the promotion of health; prevention of illness; and the care of ill, disabled, and dying people. Advocacy, promotion of a safe environment, research,*

participation in shaping health policy and in patient and health systems management, and education are also key nursing roles. Both of these definitions support the prominence and importance that nursing holds in providing safe, patient-centered health care to the global community.

Since 1960 the ANA has defined the scope of nursing and developed Standards of Practice and Standards of Professional Performance (ANA, 2015). It is important that you know and apply these standards in your practice (Box 1.2). Most schools of nursing and practice settings have published copies of the scope and standards of nursing practice. The scope and standards of practice guide nurses to make significant and visible contributions that improve the health and well-being of all individuals, communities, and populations (ANA, 2015).

Box 1.2 ANA Standards of Nursing Practice

1. **Assessment:** The registered nurse collects pertinent data and information relative to the healthcare consumer's health or the situation.
2. **Diagnosis:** The registered nurse analyzes the assessment data to determine the actual or potential diagnoses, problems, and issues.
3. **Outcomes Identification:** The registered nurse identifies expected outcomes for a plan individualized to the health care consumer or the situation.
4. **Planning:** The registered nurse develops a plan that prescribes strategies to attain expected, measurable outcomes.
5. **Implementation:** The registered nurse implements the identified plan.
 - 5a. **Coordination of Care:** The registered nurse coordinates care delivery.
 - 5b. **Health Teaching and Health Promotion:** The registered nurse employs strategies to promote health and a safe environment.
6. **Evaluation:** The registered nurse evaluates progress toward attainment of outcomes.

Standards of Professional Nursing Practice

The Standards of Professional Nursing Practice contain authoritative statements of the duties that all registered nurses, regardless of role, population, or specialty, are expected to perform competently (ANA, 2015). The duties are supported by a critical thinking model known as the nursing process: assessment, diagnosis, outcomes identification and planning, implementation, and evaluation (ANA, 2015). The nursing process is the model for clinical decision making and includes all significant actions taken by nurses in providing care to patients (see Unit III).

Standards of Professional Performance

The ANA Standards of Professional Performance (Box 1.3) describe a competent level of behavior in the professional role (ANA, 2015). The standards provide a method to assure patients that they are receiving high-quality care and to ensure that the nurses must know exactly what is necessary to provide nursing care. The standards also are in place to determine whether nursing care meets the standards.

Box 1.3 ANA Standards of Professional Performance

1. **Ethics:** The registered nurse practices ethically.
2. **Culturally Congruent Care:** The registered nurse practices in a manner that is congruent with cultural diversity and inclusion principles.
3. **Communication:** The registered nurse communicates effectively in all areas of practice.
4. **Collaboration:** The registered nurse collaborates with health care consumer and other key stakeholders in the conduct of nursing practice.
5. **Leadership:** The registered nurse demonstrates leadership in the professional practice setting and the profession.
6. **Education:** The registered nurse seeks knowledge and competency that reflects current nursing practice and promotes futuristic thinking.
7. **Evidence-Based Practice and Research:** The registered nurse integrates evidence and research findings into practice.

8. **Quality of Practice:** The registered nurse contributes to quality nursing practice.
9. **Professional Practice Evaluation:** The registered nurse evaluates one's own and others' nursing practice.
10. **Resources Utilization:** The registered nurse uses appropriate resources to plan and provide and sustain evidence-based nursing services that are safe, effective, and fiscally responsible.
11. **Environmental Health:** The registered nurse practices in an environmentally safe and healthy manner.

Code of Ethics

The nursing **code of ethics** is a statement of philosophical ideals of right and wrong that define the principles you will use to provide care to your patients. It is important for you to also incorporate your own values and ethics into your practice. As you incorporate these values, explore what type of nurse you will be and how you will function within the discipline (Fowler, 2015b). Ask yourself how your ethics, values, and practice compare with established standards. The ANA has a number of publications that address ethics and human rights in nursing. *The Code of Ethics for Nurses with Interpretive Statements* is a guide for carrying out nursing responsibilities and providing quality nursing care; it also outlines the ethical obligations of the profession (Fowler, 2015b). [Chapter 22](#) provides a review of the nursing code of ethics and ethical principles for everyday practice.

Professional Responsibilities and Roles

You are responsible for obtaining and maintaining specific knowledge and skills for a variety of professional roles and responsibilities. Nurses provide care and comfort for patients in all health care settings. Nurses' concern for meeting their patient's needs remains the same whether care focuses on health promotion and illness prevention, disease and symptom management, family support, or end-of-life care.

Autonomy and Accountability

Autonomy is an essential element of professional nursing that involves the initiation of independent nursing interventions without medical orders. Although the nursing profession regulates accountability through nursing audits and standards of practice, you also need to develop a commitment to personal professional accountability. For example, you independently implement coughing and deep-breathing exercises to clear the lungs and promote oxygenation for a patient who recently had major surgery. As you continue to care for this patient, a complication arises. You note that the patient has a fever, and the surgical wound has a yellow-green discharge. You collaborate with other health care professionals to develop the best treatment plan for this patient's surgical wound infection.

With increased autonomy comes greater responsibility and accountability. Accountability means that you are responsible professionally and legally for the type and quality of nursing care provided. You must remain current and competent in nursing and scientific knowledge and in technical skills.

Caregiver

As a **caregiver** you help patients maintain and regain health, manage disease and symptoms, and attain a maximal level of function and independence through the healing process. You provide evidence-based nursing care to promote healing through both physical and interpersonal skills. Healing involves more than achieving improved physical well-being. You need to support patients by providing measures that restore their emotional, spiritual, and social well-being. As a caregiver you help the patient and family set goals and assist them with meeting these goals with minimal financial cost, time, and energy.

Advocate

As a **patient advocate** you protect your patient's human and legal rights and provide assistance in asserting these rights if the need arises. As an advocate you act on behalf of your patient and secure your patient's health care rights (Kowalski, 2016). For example, you provide additional information to help a patient decide whether to accept a treatment, or you find an interpreter to help family members communicate their concerns. You sometimes need to defend patients' rights to make health care decisions in a general way by speaking out against policies or actions that put patients in danger or conflict with their rights. Furthermore, advocates ensure that patients' autonomy and self-determination are respected

(Gerber, 2018). Patient advocacy is hard and often provides unique emotional challenges to health care providers, especially when caring for patients with terminal or debilitating chronic illnesses (O'Mahoney et al, 2017). As an advocate it is important to be mindful of personal stressors and to identify ways to cope with these stressors (see Chapter 37).

Educator

As an educator you explain concepts and facts about health, describe the reason for routine care activities, demonstrate procedures such as self-care activities, reinforce learning or patient behavior, and evaluate the patient's progress in learning. Some of your patient teaching is unplanned and informal. For example, during a casual conversation you respond to questions about the reason for an intravenous infusion, a health issue such as smoking cessation, or necessary lifestyle changes. Other teaching activities are planned and more formal such as when you teach your patient how to self-administer insulin injections. Assess your patient's and family caregiver's learning styles and needs and develop a teaching plan that includes teaching methods that match your patient's and family's needs (see Chapter 25).

Communicator

An effective communicator is central to the nurse-patient relationship. It allows you to know your patients, including their preferences, strengths, weaknesses, and needs. Quality communication is essential for all nursing roles and activities (see Chapter 24). You routinely communicate with patients and families, other nurses and health care professionals, resource people, and the community. Effective communication strategies are fundamental to providing quality care, coordinating and managing patient care, assisting patients in rehabilitation, advocating for patients, assisting patients and families in decision making, and providing patient education (Christian, 2017).

Manager

Today's health care environment is fast-paced and complex. Nurse managers need to establish an environment for collaborative patient-centered care to provide safe, quality care with positive patient outcomes. A manager coordinates the activities of members of the nursing staff in delivering nursing care and has personnel, policy, and budgetary responsibility for a specific nursing unit or agency. A manager uses

appropriate leadership styles to create a nursing environment for patients and staff that reflects the mission and values of the health care organization (see [Chapter 21](#)).

Career Development

Innovations in health care, expanding health care systems and practice settings, and the increasing needs of patients have created new nursing roles. Today the majority of nurses practice in hospital settings, followed by community-based care, ambulatory care, home care, and nursing homes/extended care settings.

Nursing provides an opportunity for you to commit to lifelong learning and career development. Because of increasing educational opportunities for nurses, the growth of nursing as a profession, and a greater concern for job enrichment, the nursing profession offers different career opportunities. Your career path is limitless. You will probably switch career roles more than once. Take advantage of the different clinical practice and professional opportunities. Examples of these career opportunities include advanced practice registered nurses (APRNs), nurse researchers, nurse risk managers, quality improvement nurses, consultants, and entrepreneurs.

Provider of Care

Most nurses provide direct patient care in an acute care setting. However, as changes in health care services and reimbursement continue, there will be an increase in direct care activities provided in the home care setting and an increased need for community-based health promotion activities, restorative care, and end-of-life care. Educate your patients and families on how to maintain their health and implement self-care activities. While collaborating with other health care team members, focus your care on returning a patient to his or her home at an optimal functional status.

In the hospital you may choose to practice in a medical-surgical setting or concentrate on a specific area of specialty practice such as pediatrics, critical care, or emergency care. Most specialty care areas require some experience as a medical-surgical nurse and additional continuing or in-service education. Many intensive care unit and emergency department nurses are required to have certification in advanced cardiac life support and critical care, emergency nursing, or trauma nursing.

Advanced Practice Registered Nurses

The **advanced practice registered nurse (APRN)** is the most independently functioning nurse. An APRN has a master's degree or Doctor of Nursing Practice (DNP) degree in nursing; advanced education in pathophysiology, pharmacology, and physical assessment; and certification and expertise in a specialized area of practice (AACN, 2011). In 2008, the APRN Consensus Work Group and the National Council of State Boards of Nursing APRN Advisory Committee developed the Consensus Model for APRN Regulation: Licensure, Accreditation, Certification and Education (APRN, 2008). The Model addresses inconsistent standards in APRN education, regulation, and practice, which had limited APRN mobility from one state to another (Doherty et al., 2018). The consensus model identified that the title of APRN is for nurses with advanced graduate-level knowledge prepared in one of four roles: clinical nurse specialist (CNS), nurse practitioner (NP), certified nurse-midwife (CNM), and certified registered nurse anesthetist (CRNA). The educational preparation for the four roles is in at least one of the following six populations: adult-gerontology, pediatrics, neonatology, women's health/gender related, family/individual across life span, and psychiatric mental health. The Consensus Model, which had an implementation goal of 2015, has not yet been adopted by all US states and territories, thus requiring nurses to carefully choose their education program (Doherty et al., 2018). APRNs function within their area of practice to plan or improve the quality of nursing care for patients and their families.

Clinical Nurse Specialist

A **clinical nurse specialist (CNS)** is an APRN who is an expert clinician in a specialized area of practice (Fig. 1.1). The specialty may be identified by a population (e.g., geriatrics), setting (e.g., critical care), disease specialty (e.g., diabetes), type of care (e.g., rehabilitation), or type of problem (e.g., pain) (NACNS, 2018). Clinical nurse specialists provide diagnosis, treatment, and ongoing management of patients in all health care settings. They also provide expertise and support to nurses caring for patients at the bedside, help drive practice changes throughout an organization, and ensure the use of best practices and evidence-based care to achieve the best possible patient outcomes (National Association of Clinical Nurse Specialists, 2019).

FIG. 1.1 Clinical nurse specialist consults on a complex patient case.
[iStock.com/Sturti](https://www.iStock.com/Sturti).

Nurse Practitioner

A **nurse practitioner (NP)** is an APRN who provides comprehensive health care to a group of patients in an inpatient, outpatient, ambulatory care, or community-based setting. This care includes assessment, diagnosis, planning, and treatment; monitoring ongoing health status; evaluation of therapies; and health education. Some NPs provide care to acutely ill patients in hospital settings, including critical care units. Other NPs provide comprehensive care, directly managing the nursing and medical care of patients who are healthy or who have chronic conditions. It is important to review state regulations for advanced practice. Some states require the NP to have a collaborative provider agreement with an agency or physician/physician group to treat a specific group of patients; other states do not.

Certified Nurse-Midwife

A **certified nurse-midwife (CNM)** is an APRN who is also educated in midwifery and is certified by the American College of Nurse-Midwives (ACNM). The scope of practice of nurse-midwifery has been defined by

the ACNM (2011) as encompassing a full range of primary health care services for women from adolescence beyond menopause. These services include primary care; gynecologic and family planning services; preconception care; care during pregnancy, childbirth, and the postpartum period; care of the normal newborn during the first 28 days of life; and treatment of male partners for sexually transmitted infections ([ACNM, 2011](#)). The nurse-midwife conducts physical examinations; prescribes medications, including controlled substances and contraceptive methods; admits, manages, and discharges patients; orders and interprets laboratory and diagnostic tests; and orders the use of medical devices.

Certified Registered Nurse Anesthetist

A **certified registered nurse anesthetist (CRNA)** is an APRN with advanced education from a nurse anesthesia–accredited program. Before applying to a nurse anesthesia program, a nurse must have at least 1 year of critical care or emergency experience. Nurse anesthetists practice both autonomously and in collaboration with a variety of health care providers on the interprofessional team to deliver high-quality, holistic, evidence-based anesthesia and pain care services ([American Association of Nurse Anesthetists, 2017](#)). CRNAs practice under the guidance and supervision of an anesthesiologist, a physician with advanced knowledge of surgical anesthesia.

Nurse Educator

A **nurse educator** works primarily in schools of nursing, staff development departments of health care agencies, and patient education departments. Nurse educators need experience in clinical practice to provide them with practical skills and theoretical knowledge. A faculty member in a nursing program educates students to become professional nurses. Nursing faculty members are responsible for teaching current nursing practice; trends; theory; and necessary skills in classroom, laboratories, and clinical settings. Nursing faculty have graduate degrees such as a master's degree in nursing or an earned doctorate in nursing or related field. Generally, they have a specific clinical, administrative, or research specialty and advanced clinical experience.

Nurse educators in staff development departments of health care institutions provide educational programs for nurses within their institution. These programs include orientation of new personnel, critical care nursing courses, assisting with clinical skill competency, safety

training, and instruction about new equipment or procedures. These nursing educators often participate in the development of nursing policies and procedures.

The primary focus of the nurse educator in a patient education department of an agency such as a wound treatment clinic is to teach and coach patients and their families how to self-manage their illness or disability and make positive choices or change their behaviors to promote their health. These nurse educators are usually specialized and hold a certification such as a certified diabetes educator (CDE) or an ostomy care nurse and see only a specific population of patients.

Nurse Administrator

A **nurse administrator** manages patient care and the delivery of specific nursing services within a health care agency. Nursing administration begins with positions such as clinical care coordinators. Experience and additional education sometimes lead to a middle-management position such as nurse manager of a specific patient care area or house supervisor or to an upper-management position such as an associate director or director of nursing services.

Nurse manager positions usually require at least a baccalaureate degree in nursing, and director and nurse executive positions generally require a master's degree. Chief nurse executive and vice president positions in large health care organizations often require preparation at the doctoral level. Nurse administrators often have advanced degrees such as a master's degree in nursing administration, hospital administration (MHA), public health (MPH), or an MBA.

In today's health care organizations directors have responsibility for more than one nursing unit. They often manage a particular service or product line such as medicine or cardiology. Vice presidents of nursing or chief nurse executives often have responsibilities for all clinical functions within the hospital (e.g., pharmacy, respiratory care, and rehabilitation). This may include all ancillary personnel who provide and support patient care services. The nurse administrator needs to be skilled in business and management and understand all aspects of nursing and patient care. Functions of administrators include budgeting, staffing, strategic planning of programs and services, employee evaluation, and employee development.

Nurse Researcher

The **nurse researcher** conducts evidence-based practice and research to improve nursing care and further define and expand the scope of nursing practice (see [Chapter 5](#)). She or he often works in an academic setting, hospital, or independent professional or community service agency. The preferred educational requirement is a doctoral degree, with at least a master's degree in nursing.

REFLECT NOW

In reviewing the roles and responsibilities of the professional nurse and career options, think about your personal academic and career goals. Design a plan that you can modify as you progress through your academic nursing program.

Nursing Shortage

There is an ongoing shortage of qualified RNs to fill vacant positions ([AACN, 2018](#)). This shortage affects all aspects of nursing, including patient care, administration, and nursing education, but it also represents challenges and opportunities for the profession. Many health care dollars are invested in strategies aimed at recruiting and retaining a well-educated, critically thinking, motivated, and dedicated nursing workforce. There is a positive correlation between direct patient care provided by an RN and positive patient outcomes, reduced complication rates, and a more rapid return of the patient to an optimal functional status ([Box 1.4](#)) ([Giuliano et al., 2016](#); [Aiken, 2013a,b](#)). Research also correlates poor staffing with missed nursing assessments and missed nursing care. In postoperative patients whose status changes rapidly, these missed assessments and care result in poor patient outcomes ([Ball et al., 2018](#)).

Box 1.4 Evidence-Based Practice Impact of Nurse Staffing and Patient Outcomes

PICOT Question: Are patient outcomes improved in hospitals with adequate nursing staffing versus hospitals with lower nursing staffing?

Evidence Summary

There is a growing body of research that shows that nurse staffing affects patient outcomes, patient survival, and the occurrence of adverse events. A secondary data analysis from 661 hospitals showed that there was a significantly lower 30-day readmission rate for patients with heart failure in hospitals that were categorized in the high nurse staffing group, thus reducing health care costs (Giuliano et al., 2016). Patients experiencing an in-hospital cardiac arrest were more likely to survive when there was a decreased patient-to-nurse ratio (McHugh et al., 2016).

Higher nurse staffing was also found to significantly correlate with nursing-sensitive outcomes, such as reduced falls and improved risk assessment for pressure injuries (Burnes Bolton et al., 2017). When there is poor nurse staffing, resulting in larger numbers of patients assigned to a nurse, there is an increase in the occurrence of medication errors, pressure injury formation, and falls with injuries (Cho et al., 2016). Studies demonstrating the positive impact that increased nurse-to-patient ratios have on outcomes provide nursing administrators with evidence to support the hiring of qualified professional nurses.

Application To Nursing Practice

- Consider the nurse-to-patient ratio when looking at a hospital or unit for employment.
- Adequate nursing levels help to improve the nursing work environment (Cho et al., 2016).
- Patient care units in which there is an increased risk for falls due to the patient population or diseases need increased nurse staffing (Burnes Bolton et al., 2017).
- While research supports the economic impact of nurse staffing and improved nursing-sensitive outcomes and other patient outcomes, there needs to be continued research on the impact of nurse staffing ratios (Burnes Bolton, 2017; Giuliano et al., 2016).

Professional nursing organizations predict that the number of nurses will continue to diminish ([AACN, 2018](#); [Aiken, 2013a](#)). With fewer

available nurses, it is important for you to learn to use your patient contact time efficiently and professionally. Time management, therapeutic communication, patient education, and compassionate implementation of bedside skills are just a few of the essential skills you need. It is important for your patients to leave the health care setting with a positive image of nursing and a feeling that they received quality care. Your patients should never feel that they received rushed or incomplete care. They need to feel that they are important and are involved in decisions and that their needs are met. If a certain aspect of patient care requires 15 minutes of contact, it takes you the same time to deliver organized and compassionate care as it does if you rush through your nursing care.

Historical Influences

Nurses have and will always respond to the needs of their patients. In times of war they responded by meeting the needs of the wounded in combat zones and military hospitals in the United States and abroad. When communities face health care crises such as natural disasters, disease outbreaks, or insufficient public health resources, nurses establish community-based immunization and screening programs, treatment clinics, and health promotion activities. Our patients are most vulnerable when they are injured, sick, or dying.

Today nurses are active in determining best practices in a variety of areas such as pressure injury prevention, wound care management, pain control, nutritional management, and care of individuals across the life span. Nurse researchers are leaders in expanding knowledge in nursing and other health care disciplines. Their work ensures that nurses have the best available evidence to support their practices (see [Chapter 5](#)).

Knowledge of the history of the nursing profession increases your ability to understand the social and intellectual origins of the discipline. Although it is not practical to describe all of the historical aspects of professional nursing, some of the more significant nursing leaders and milestones are described in the following paragraphs.

Florence Nightingale

In *Notes on Nursing: What It Is and What It Is Not*, Florence Nightingale established the first nursing philosophy based on health maintenance and restoration ([Nightingale, 1860](#)). She saw the role of nursing as having “charge of somebody’s health” based on the knowledge of “how to put the body in such a state to be free of disease or to recover from disease” ([Nightingale, 1860](#)). During the same year she developed the first organized program for training nurses, the Nightingale Training School for Nurses at St. Thomas’ Hospital in London.

Nightingale was the first practicing nurse epidemiologist. Her statistical analyses connected poor sanitation with cholera and dysentery. She volunteered during the Crimean War in 1853 and traveled the battlefield hospitals at night, carrying her lamp; thus, she was known as the “lady with the lamp.” The sanitary, nutritional, and basic conditions in the battlefield hospitals were poor, and she was asked to ensure the quality of sanitation facilities. As a result of her actions, the mortality rate at the

Barracks Hospital in Scutari, Turkey, reduced from 42.7% to 2.2% in 6 months ([Donahue, 2011](#)).

The Civil War To the Beginning of the Twentieth Century

The Civil War (1860–1865) stimulated the growth of nursing in the United States. Clara Barton, founder of the American Red Cross, cared for soldiers on the battlefields, cleansing their wounds, meeting their basic needs, and comforting them at end of life. Dorothea Lynde Dix, Mary Ann Ball (Mother Bickerdyke), and Harriet Tubman also influenced nursing during the Civil War ([Donahue, 2011](#)). Dix and Bickerdyke organized hospitals and ambulances, appointed nurses, cared for the wounded soldiers, and oversaw and regulated supplies to the troops. Tubman was active in the Underground Railroad movement and assisted in leading more than 300 slaves to freedom ([Donahue, 2011](#)).

The first professionally educated African-American nurse was Mary Mahoney. She was concerned with relationships between cultures and races. As a noted nursing leader, she brought forth an awareness of cultural diversity and respect for the individual, regardless of background, race, color, or religion.

Isabel Hampton Robb helped found the Nurses' Associated Alumnae of the United States and Canada in 1896. This organization became the ANA in 1911. She authored many nursing textbooks and was one of the original founders of the *American Journal of Nursing* (*Am J Nurs*).

Nursing in hospitals expanded in the late nineteenth century. However, nursing in the community did not increase significantly until 1893, when Lillian Wald and Mary Brewster opened the Henry Street Settlement, which focused on the health needs of poor people who lived in tenements in New York City ([Donahue, 2011](#)).

Twentieth Century

In the early twentieth century a movement toward developing a scientific, research-based defined body of nursing knowledge and practice evolved. Nurses began to assume expanded roles. Mary Adelaide Nutting, who became the first nursing professor at Columbia Teachers College in 1906, was instrumental in moving nursing education into universities ([Donahue, 2011](#)).

As nursing education developed, nursing practice also expanded, and the Army and Navy Nurse Corps were established. By the 1920s nursing specialization started to develop. The last half of the century saw specialty-nursing organizations such as the American Association of Critical Care Nurses, Association of Operating Room Nurses (AORN), Infusion Nurses Society (INS), and Emergency Nurses Association (ENA) created. In 1990 the ANA established the Center for Ethics and Human Rights, which provides a forum to address the complex ethical and human rights issues confronting nurses and designs activities and programs to increase ethical competence in nurses ([Fowler, 2015b](#)).

Twenty-First Century

Today the profession faces multiple challenges. Nurses are revising nursing practice and school curricula to meet the ever-changing needs of society, including an aging population, bioterrorism, emerging infections, and disaster management. Advances in technology and informatics (see [Chapter 26](#)), the high-acuity level of care of hospitalized patients, and early discharge from health care institutions require nurses in all settings to have a strong and current knowledge base from which to practice. In addition, nursing and the Robert Wood Johnson Foundation are taking a leadership role in developing standards and policies for end-of-life care through the *Last Acts Campaign* (see [Chapter 36](#)). The End-of-Life Nursing Education Consortium (ELNEC), offered collaboratively by the American Association of Colleges of Nursing (AACN) and the City of Hope Medical Center, has brought end-of-life care and practices into nursing curricula and professional continuing education programs for practicing nurses ([AACN, 2017](#)).

Contemporary Influences

Multiple external forces affect nursing, including the need for nurses' self-care, health care reform and rising health care costs, demographic changes of the population, human rights, and increasing numbers of the medically underserved.

Importance of Nurses' Self-Care

Nursing is a dynamic gratifying career. However, it also has both physical and emotional demands and challenges. You cannot give fully engaged, compassionate care to others when you feel depleted or do not feel cared for yourself. You and your colleagues will have many self-care needs that must be met to function as healthy professionals.

In your educational experience and in your career, you will experience grief and loss. Many times, even before you have a chance to recover from an emotionally draining situation, you will encounter another difficult human story. Nurses in acute care settings frequently witness prolonged, concentrated suffering, leading to feelings of frustration, anger, guilt, sadness, or anxiety (Kelly et al., 2015). Nursing students report feeling initially hesitant and uncomfortable with their first encounters with a dying patient and identify feelings of sadness and anxiety.

Frequent, intense, or prolonged exposure to grief and loss places nurses at risk for developing compassion fatigue. *Compassion fatigue* is a term used to describe a state of burnout and secondary traumatic stress (Potter et al., 2013a). It occurs without warning and often results from giving high levels of energy and compassion over a prolonged period to those who are suffering, often without experiencing improved patient outcomes (Kelly et al., 2015). Secondary traumatic stress is the trauma that health care providers experience when witnessing and caring for others suffering trauma. Examples include an oncology nurse who cares for patients undergoing surgery and chemotherapy over the long term for their cancer or a spouse who witnesses his wife deteriorating over the years from Alzheimer's disease.

Burnout is the condition that occurs when perceived demands outweigh perceived resources (Potter et al., 2013a). It is a state of physical and mental exhaustion that often affects health care providers because of the nature of their work environment. Over time, giving of oneself in often intense caring environments sometimes results in emotional exhaustion, leaving a nurse feeling irritable, restless, and unable to focus and engage

with patients (Potter et al., 2013b). This often occurs in situations in which there is a lack of social support, organizational pressures influencing staffing, and the inability of the nurse to practice self-care. Compassion fatigue typically results in feelings of hopelessness, a decrease in the ability to take pleasure from previously enjoyable activities, a state of hypervigilance, and anxiety.

Compassion fatigue negatively impacts the health and wellness of nurses and the quality of care provided to patients. It also affects the organizations as nurses experience changes in job performance and in their personal lives; it can result in nurses' desire to leave the profession or their specialty. In addition, these factors affect patient satisfaction and an agency's ability to maintain a caring, competent staff (Ledoux, 2015).

There is a need for health care agencies to identify early signs of compassion fatigue and to develop interventions to help nurses manage it. Prompt interventions improve nurse retention and job satisfaction rates (Kelly et al., 2015.) Agency-based programs that provide opportunities for nurses to validate their experiences and an opportunity to talk about the challenges of the type of care they give help nurses cope with compassion fatigue and its implication for professional nursing care (Wentzel and Brysiewicz, 2017).

Compassion fatigue may contribute to what is described as *lateral violence* (see Chapter 24). Lateral violence sometimes occurs in nurse-nurse interactions and includes behaviors such as withholding information, making snide remarks, and demonstrating nonverbal expressions of disapproval, such as raising eyebrows or making faces. New graduates and nurses new to a unit are most likely to face problems with lateral or horizontal violence (Sanner-Stiehr and Ward-Smith, 2017).

All nurses require resiliency skills to better manage the stressors that contribute to compassion fatigue and lateral violence. Managing stress and conflict, building connections with colleagues to share difficult stories, and self-care are helpful stress-management techniques in dealing with difficult situations and contribute to safe and effective care (see Chapter 37) (Perez, 2015).

Health Care Reform and Costs

Health care reform affects not only how health care is paid for but also how it is delivered. There is greater emphasis on health promotion, disease prevention, and illness management in the future. More services will be in community-based care settings. However, hospitals will continue to

manage the care of very seriously ill patients. As a result, more nurses will be needed to practice in community care centers, patients' homes, schools, and senior centers. This will require nurses to be skilled at assessing for resources, service gaps, and how patients adapt to return to their communities. Nursing needs to respond to such changes by assessing for resources, improving staffing and management models in hospitals, changing nursing education, helping patients adapt to new health care delivery methods, and providing care to safely return patients to their homes.

Skyrocketing health care costs present challenges to the profession, the consumer, and the health care delivery system. As a nurse you are responsible for providing the patient with the best-quality care in an efficient and economically sound manner, including following established protocols, exercising timely well-planned patient discharge from a care setting, and judiciously using supplies and equipment. The challenge is to use health care and patient resources wisely. [Chapter 2](#) summarizes reasons for the rise in health care costs and its implications for nursing.

Demographic Changes

The US Census Bureau (2018) predicts that the 2030s will be a transformative decade, with the population expected to grow at a slower pace, age considerably, and become more racially and ethnically diverse. These changes will require expanded health care resources. The US Census Bureau's 2017 population projections predict that by 2030, all baby boomers will be older than 65 years of age. This will expand the size of the older population so that 1 in every 5 residents will be of retirement age ([US Census Bureau, 2018](#)). It is also predicted that by 2044 more than half of the US population will be part of a minority group ([Colby et al., 2014](#)). To effectively meet all the health care needs of the expanding minority and aging populations, changes need to occur as to how care is provided, especially in the area of public health. The population is still shifting from rural areas to urban centers, and more people are living with chronic and long-term illness. Not only are outpatient settings expanding, but more and more people want to receive outpatient and community-based care and remain in their homes or community (see [Chapters 2](#) and [3](#)).

Medically Underserved

Unemployment, underemployment and low-paying jobs, mental illness, homelessness, and rising health care costs all contribute to increases in the medically underserved population. Caring for this population is a global challenge; the social, political, economic, and health literacy factors affect both access to care and access to health care–related resources ([Kaphingst et al., 2016](#)). In addition, the number of underserved patients who require home-based palliative care services is increasing. This is a group of patients whose physical status does not improve and whose health care needs increase. People with low health literacy are less likely to participate in decision making regarding their care because they do not understand the medical information provided, nor do they understand the consequences of indecision ([Seo et al., 2016](#)).

Trends in Nursing

Nursing is a dynamic profession that grows and evolves as society and lifestyles change, as health care priorities and technologies change, and as nurses themselves change. The current philosophies and definitions of nursing have a holistic focus, which addresses the needs of the whole person in all dimensions, in health and illness, and in interaction with the family and community. In addition, there continues to be an increasing awareness for patient safety in all care settings.

Evidence-Based Practice

Today the general public is more informed about their health care needs, the cost of health care, best practices, and the incidence of medical errors within health care institutions. Your current and future practice needs to be based on current evidence, not just according to your education and experiences and the policies and procedures of health care agencies (see [Chapter 5](#)). The delivery of and reimbursement for evidence-based nursing care is essential ([Melnyk and Gallagher-Ford, 2018](#)). Health care organizations must show their commitment to each health care stakeholder (e.g., patients, insurance companies, and governmental agencies) to reduce health care errors and improve patient safety by implementing evidence-based practices ([National Quality Forum, 2010](#)). In addition, many hospitals are achieving Magnet Recognition®, which recognizes excellence in nursing practice (ANCC, n.d.). A component of excellence in practice is quality of care, represented by the implementation of evidence-based practices (see [Chapter 2](#)).

Quality and Safety Education for Nurses

The Robert Wood Johnson Foundation sponsored the **Quality and Safety Education for Nurses (QSEN)** initiative to respond to reports about safety and quality patient care by the Institute of Medicine (IOM) ([QSEN Institute, 2018](#)). QSEN addresses the challenge to prepare nurses with the competencies needed to continuously improve the quality of care in their work environments ([Table 1.1](#)). The QSEN initiative encompasses the competencies of patient-centered care, teamwork and collaboration, evidence-based practice, quality improvement, safety, and informatics ([QSEN Institute, 2018](#)). For each competency there are targeted knowledge, skills, and attitudes (KSAs). The KSAs are elements that were

initially developed for prelicensure programs (QSEN Institute, 2018). Now KSAs have been developed for graduate nursing programs (QSEN, 2018; Sherwood and Zomorodi, 2014).

TABLE 1.1

Quality and Safety Education for Nurses

Competency	Definition With Examples
Patient-centered care	Recognize the patient or designee as the source of control and full partner in providing compassionate and coordinated care based on respect for patient’s preferences, values, and needs. <i>Examples: Involve family and friends in care. Elicit patient’s values and preferences. Provide care with respect for diversity of the human experience.</i>
Teamwork and collaboration	Function effectively within nursing and interprofessional teams, fostering open communication, mutual respect, and shared decision making to achieve quality patient care. <i>Examples: Recognize the contributions of other health team members and patient’s family members. Discuss effective strategies for communicating and resolving conflict. Participate in designing methods to support effective teamwork.</i>
Evidence-based practice	Integrate best current evidence with clinical expertise and patient and/or family preferences and values for delivery of optimal health care. <i>Examples: Demonstrate knowledge of basic scientific methods. Appreciate strengths and weaknesses of scientific bases for practice. Appreciate the importance of regularly reading relevant journals.</i>
Quality improvement	Use data to monitor the outcomes of care processes and use improvement methods to design and test changes to continuously improve the quality and safety of health care systems. <i>Examples: Use tools such as flow charts and diagrams to make process of care explicit. Appreciate how unwanted variation in outcomes affects care. Identify gaps between local and best practices.</i>
Safety	Minimize risk of harm to patients and providers through both system effectiveness and individual performance. <i>Examples: Examine human factors, basic safety design principles, and commonly used unsafe practices. Value own role in preventing errors.</i>
Informatics	Use information and technology to communicate, manage knowledge, mitigate error, and support decision making. <i>Examples: Navigate an electronic health record. Protect confidentiality of protected health information in electronic health records.</i>

Adapted from QSEN Institute: *QSEN competencies: definitions and pre-licensure KSAs*, 2018, <http://qsen.org/competencies/pre-licensure-ksas/>. Accessed May 2018.

As you gain experience in clinical practice, you face situations in which your education helps you to make a difference in improving patient care. Whether that difference is to provide evidence for implementing care at the bedside, identify a safety issue, or study patient data to identify trends in outcomes, each of these situations requires competence in patient-centered care, safety, or informatics. Although it is not within the scope of this textbook to present the QSEN initiative in its entirety, subsequent clinical chapters will provide you an opportunity to address how to build competencies in one or more of these areas.

Building Competency in Patient-Centered Care

You are caring for Kitty, a 10-year-old with severe delayed development. Kitty, an only child, lives with her parents and goes to a school that is able to meet her needs. Her mom gives her seizure medicine each day, and her seizures are well controlled. Kitty has very little independent function. She needs assistance with all of her activities of daily living (e.g., bathing, toileting, eating, and hygiene). Up to now Kitty's parents have been able to provide all of her care and meet her needs. As a patient advocate, what do you need to know about Kitty's parents goals for her future care? Think about how you can use this information to advocate for Kitty and her parents to achieve these goals.

Impact of Emerging Technologies

Emerging technologies have the potential to change nursing practice. These technologies provide more accurate, noninvasive assessment tools; help you to implement evidence-based practices; collect and trend patient outcome data; and use clinical decision support systems. The electronic health record (EHR) is an efficient method for documenting and managing patient health care information (see [Chapter 26](#).) Computerized physician/provider order entry (CPOE) is a critical patient safety initiative ([Houston, 2014](#)).

Emerging technologies will assist you to communicate, provide care for, and build relationships with your patients. Telehealth, e-visits, and devices that allow your patient to phone in pertinent health information are examples of technology that open new venues for providing care. Learn how these electronic tools work so that you can teach patients how to use them. Evidence-based practice, clinical decision support systems, and case-based reasoning are all methods to increase information acquisition and distribution.

Technological innovations help family caregivers monitor and manage home environments of older adults, enable older adults to stay in their homes but stay connected to their support systems, and help with decision support and care coordination ([Andruszkiewicz and Fike, 2015–2016](#)). Additionally, the availability and use of telehealth and telemedicine functions to provide health care are increasing ([NCSBN, 2016](#)).

Genomics

As you use and understand genomics remember to use genomic information in a confidential, ethical, and culturally appropriate manner to help health care providers and patients make informed care decisions (Houston, 2014).

Genetics is the study of inheritance, or the way traits are passed down from one generation to another. Genes carry the instructions for making proteins, which in turn direct the activities of cells and functions of the body that influence traits such as hair and eye color. **Genomics** is a newer term that describes the study of all the genes in a person and interactions of these genes with one another and with that person's environment (CDC, 2018). Genomic information combined with technology can potentially improve health outcomes, quality, and safety and reduce health care costs (McCormick and Calzone, 2016). This information allows health care providers to determine how genomic changes contribute to patient conditions and influence treatment decisions (Sharoff, 2016; Miaskowski and Aouizerat, 2012). For example, when a family member has colon cancer before the age of 50, it is likely that other family members are at risk for developing this cancer. Genomics counseling and testing can determine family status. Knowing this information is important for family members who will need a colonoscopy before the age of 50 and repeat colonoscopies more often than the patient who is not at risk. Nurses identify the patients' risk factors through assessment and counsel patients about what this genomic finding means to them personally and to their families.

Public Perception of Nursing

Nursing is a pivotal health care profession. As frontline health care providers, nurses practice in all health care settings and constitute the largest number of health care professionals. They are essential to providing skilled, specialized, knowledgeable care; improving the health status of the public; and ensuring safe, effective quality care (ANA, 2015).

Consumers of health care are more informed than ever; with the Internet consumers have access to more health care and treatment information. For example, *Hospital Compare* is a consumer-oriented website that allows people to select multiple hospitals and directly compare performance measure information on specific diseases such as health attack, heart

failure, pneumonia, and surgery (CMS, 2016). This information can help consumers make informed decisions about health care.

Consumers can also access *Hospital Consumer Assessment of Healthcare Providers Systems* (HCAHPS) to obtain information about patients' perspectives on hospital care. Although many hospitals collect information on patient satisfaction, HCAHPS offers a survey that helps consumers obtain valid comparisons about patient perspectives across all hospitals. This information is intended to allow consumers to make "apples to apples" comparisons to support their choice (HCAHPS, 2018).

REFLECT NOW

A nurse is often the first health care professional a patient sees when in the emergency department or following admission to a hospital. Think about the type of impression you want to make in terms of compassion, competency, and professionalism.

Impact of Nursing On Politics and Health Policy

Political power or influence is known as the ability to influence or persuade an individual holding a governmental office to exert the power of that office to effect a desired outcome. Nurses' involvement in politics is receiving greater emphasis in nursing curricula, professional organizations, and health care settings. Professional nursing organizations and state nursing boards employ lobbyists to urge state legislatures and the US Congress to pass legislation that will improve the quality of health care (Mason et al., 2016).

The ANA works for the improvement of health standards and the availability of health care services for all people, fosters high standards of nursing, stimulates and promotes the professional development of nurses, and advances their economic and general welfare. The ANA's purposes are unrestricted by considerations of nationality, race, creed, lifestyle, color, gender, or age.

You can influence policy decisions at all governmental levels. One way to get involved is by participating in local and national efforts ([Mason et al., 2016](#)). This effort is critical to exerting nurses' influence early in the political process. Nurses can help make the future bright by becoming serious students of social needs, activists in influencing policy to meet those needs, and generous contributors of time and money to nursing organizations and to candidates working for universal good health care ([Mason et al., 2016](#)).

Professional Registered Nurse Education

Nursing requires a significant amount of formal education. The issues of standardization of nursing education and entry into practice remain a major controversy. Various prelicensure educational programs are available for individuals intending to be an RN. In addition, graduate nurse education and continuing and in-service education are available for practicing nurses.

Prelicensure

Currently in the United States the most frequent way to become a **registered nurse (RN)** is through completion of either an associate or baccalaureate degree program. Graduates of both programs are eligible to take the National Council Licensure Examination for Registered Nurses (NCLEX-RN®) to become RNs in the state in which they will practice.

The associate degree program in the United States is a 2-year program that is usually offered by a university or community college. This program focuses on the basic sciences and theoretical and clinical courses related to the practice of nursing.

The baccalaureate degree program usually includes 4 years of study in a college or university. It focuses on the basic sciences; theoretical and clinical courses; and courses in the social sciences, arts, and humanities to support nursing theory. In Canada the degree of Bachelor of Science in Nursing (BScN) or Bachelor in Nursing (BN) is equivalent to the degree of Bachelor of Science in Nursing (BSN) in the United States. The *Essentials of Baccalaureate Education for Professional Nursing* (AACN, 2008) delineates essential knowledge, practice and values, attitudes, personal qualities, and professional behavior for the baccalaureate-prepared nurse and guides faculty on the structure and evaluation of the curriculum. Standards published by nursing program accrediting organizations typically specify core competencies for the professional nurse that should be in the nursing curriculum. In addition, one of the IOM recommendations is that 80% of nurses be prepared with a baccalaureate in nursing by 2020 (IOM, 2010) (see [Chapter 2](#)).

Graduate Education

After obtaining a baccalaureate degree in nursing, you can pursue graduate education leading to a master's or doctoral degree in any number

of graduate fields, including nursing. A nurse completing a graduate program can receive a master's degree in nursing. The graduate degree provides the advanced clinician with strong skills in nursing science and theory. Graduate education emphasizes advanced knowledge in the basic sciences and research-based clinical practice. A master's degree in nursing is important for the roles of nurse educator and nurse administrator, and it is a minimum requirement for an APRN.

Doctoral Preparation

Professional doctoral programs in nursing (DSN or DNSc) prepare graduates to apply research findings to clinical nursing. Other doctoral programs prepare nurses for more rigorous research and theory development and award the research-oriented Doctor of Philosophy (PhD) in nursing. Recently the AACN recommended the Doctor of Nursing Practice (DNP) as the terminal practice degree and required preparation for all APRNs. The DNP is a practice-focused doctorate. It provides skills in obtaining expanded knowledge through the formulation and interpretations of evidence-based practice.

The need for nurses with doctoral degrees is increasing. Expanding clinical roles and continuing demand for well-educated nursing faculty, nurse administrators, and APRNs in the clinical settings and new areas of nursing specialties such as nursing informatics are just a few reasons for increasing the number of doctoral-prepared nurses.

Continuing and In-Service Education

Nursing is a knowledge-based profession, and clinical decision making and technological expertise are qualities that health care consumers demand and expect. Continuing education updates your knowledge about the latest research and practice developments, helps you to specialize in a particular area of practice, and teaches you new skills and techniques, all of which are crucial factors to improving patient care (Wellings et al., 2017). **Continuing education** involves educational programs offered by universities, hospitals, state nurses associations, professional nursing organizations, and educational and health care institutions. An example is a program on caring for older adults with dementia offered by a university or a program on safe medication practices offered by a hospital. While many of these programs are on-site as a lecture, seminar, or skills training, there is a growth in virtual learning, especially for those nursing subspecialties, such as oncology, that require continuing nursing

education. (das Gracas Silva Matsubara and De Domenico, 2016). Many states require a set number of continuing education hours as part of license renewal. In some cases there are continuing education requirements for specific topics such as bioterrorism and pain management.

In-service education programs are instruction or training provided by a health care agency or institution. An in-service program is held in the institution and is designed to increase the knowledge, skills, and competencies of nurses and other health care professionals employed by the institution. Often in-service programs are focused on new technologies such as how to correctly use the newest safety syringes. Many in-service programs are designed to fulfill required competencies of an organization. For example, a hospital might offer an in-service program on safe principles for administering chemotherapy or a program on cultural sensitivity.

Nursing Practice

You will have an opportunity to practice in a variety of settings, in many roles within those settings, and with caregivers in other related health professions. The ANA standards of practice, standards of performance, and code of ethics for nurses are part of the public recognition of the significance of nursing practice to health care and implications for nursing practice regarding trends in health care. State and provincial nurse practice acts (NPAs) establish specific legal regulations for practice, and professional organizations establish standards of practice as criteria for nursing care.

Nurse Practice Acts

In the United States each State Board of Nursing oversees its NPA. The NPA regulates the scope of nursing practice for the state and protects public health, safety, and welfare. This protection includes protecting the public from unqualified and unsafe nurses. Although each state has its own NPA that defines the scope of nursing practice, most NPAs are similar. The definition of nursing practice published by the ANA is representative of the scope of nursing practice as defined in most states. During the last decade, many states have revised their NPAs to reflect the growing autonomy of nursing, minimum education requirements, certification requirements, and the expanded roles and scope of practice of APRNs.

Licensure and Certification

Licensure

In the United States all boards of nursing require RN candidates to pass the NCLEX-RN®. Regardless of educational preparation, the examination for RN licensure is the same in every state in the United States. This provides a standardized minimum knowledge base for nurses. Other requirements for licensure such as criminal background checks vary from state to state.

Certification

After passing NCLEX-RN®, a nurse may choose to work toward certification in a specific area of nursing practice. Minimum practice

and/or educational requirements are set, based on specific certification. National nursing organizations such as the ANA have many types of certification to enhance your career, such as certification in medical-surgical or geriatric nursing. After passing the initial examination, you maintain your certification by ongoing continuing education and maintaining a set number of hours in clinical or administrative practice.

Professional Nursing Organizations

A **professional organization** deals with issues of concern to those practicing in the profession. In addition to the educational organizations previously discussed, a variety of specialty nursing organizations exist. For example, some organizations focus on specific areas such as critical care, advanced practice, maternal-child nursing, oncology, and nursing research. These organizations seek to improve the standards of practice, expand nursing roles, and foster the welfare of nurses within the specialty areas. In addition, professional organizations present educational programs and publish journals.

As a student you have the opportunity to take part in organizations such as the National Student Nurses Association (NSNA) in the United States and the Canadian Student Nurses Association (CSNA) in Canada. These organizations consider issues of importance to nursing students such as career development and preparation for licensing. The NSNA often cooperates in activities and programs with the professional organizations.

Key Points

- Nursing responds to the health care needs of society, which are influenced by economic, social, and cultural factors.
- Changes in society, such as health care reform, changing demographic patterns, increases in the medically underserved population, and increased consumerism, affect the practice of nursing.
- Nursing standards provide the guidelines for implementing and evaluating nursing care.
- Advances in nursing's scientific knowledge base and the application of evidence-based practice have improved nursing practice and patient outcomes.
- Nursing education programs must adhere to educational standards established by a nursing education accreditation body.

- A nurse may take multiple professional career paths, such as advanced practice, nurse educator, research, and administration, to advance within the discipline.
- Professional nursing organizations impact educational standards and certifications, specialty practice, consumerism, and patient advocacy.
- Nurses are increasingly aware of the role of politics and its influence on the health care system. As a result, nurses are more aware of the profession's influence on health care policy and practice.

Reflective Learning

- You are on the patient safety committee at your hospital. Your assignment is to identify two resources related to safety. One resource must relate to the individual nurse, and the second must relate to the practice and work environment.
- Thinking back on your recent clinical experiences, which QSEN competencies knowledge, skills, or attitudes did you use while providing care?
- What impact do evidence-based practice and emerging technologies have on quality patient-centered care?

Review Questions

1. You are preparing a presentation for your classmates regarding the clinical care coordination conference for a patient with terminal cancer. As part of the preparation you have your classmates read the Nursing Code of Ethics for Professional Registered Nurses. Your instructor asks the class why this document is important. Which statement best describes this code?

1. Improves self–health care
 2. Protects the patient’s confidentiality
 3. Ensures identical care to all patients
 4. Defines the principles of right and wrong to provide patient care
2. A nurse is caring for a patient with end-stage lung disease. The patient wants to go home on oxygen and be comfortable. The family wants the patient to have a new surgical procedure. The nurse explains the risk and benefits of the surgery to the family and discusses the patient’s wishes with them. The nurse is acting as the patient’s:
1. Educator.
 2. Advocate.
 3. Caregiver.
 4. Communicator.
3. The nurse spends time with a patient and family reviewing a dressing change procedure for the patient’s wound. The patient’s spouse demonstrates how to change the dressing. The nurse is acting in which professional role?
1. Educator
 2. Advocate
 3. Caregiver
 4. Communicator
4. The examination for registered nurse (RN) licensure is the same in every state in the United States. This examination:
1. Guarantees safe nursing care for all patients.
 2. Ensures standard nursing care for all patients.
 3. Provides a minimal standard of knowledge for an RN in practice.

4. Guarantees standardized education across all prelicensure programs.
5. Contemporary nursing requires that the nurse has knowledge and skills for a variety of professional roles and responsibilities. Which of the following are examples of these roles and responsibilities? (Select all that apply.)
 1. Caregiver
 2. Autonomy
 3. Patient advocate
 4. Health promotion
 5. Genetic counselor
6. Match the advanced practice nurse specialty with the statement about the role.

1. Clinical nurse specialist	a. Provides independent care, including pregnancy and gynecological services
2. Nurse anesthetist	b. Expert clinician in a specialized area of practice such as adult diabetes care
3. Nurse practitioner	c. Provides comprehensive care, usually in a primary care setting, directly managing the medical care of patients who are healthy or have chronic conditions
4. Nurse-midwife	d. Provides care and services under the supervision of an anesthesiologist

7. Health care reform will bring changes in the emphasis of care. Which of these models is expected from health care reform?
 1. Moving from an acute illness to a health promotion, illness prevention model
 2. Moving from an illness prevention to a health promotion model
 3. Moving from hospital-based to community-based care
 4. Moving from an acute illness to a disease management model
8. A nurse meets with the registered dietitian and physical therapist to develop a plan of care that focuses on improving nutrition and mobility for a patient. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?

1. Patient-centered care
 2. Safety
 3. Teamwork and collaboration
 4. Quality improvement
9. A critical care nurse is using a new research-based intervention to correctly position her ventilated patients to reduce pneumonia caused by accumulated respiratory secretions. This is an example of which Quality and Safety in the Education of Nurses (QSEN) competency?
1. Patient-centered care
 2. Evidence-based practice
 3. Teamwork and collaboration
 4. Quality improvement
10. The nurses on an acute care medical floor notice an increase in pressure injury formation in their patients. A nurse consultant decides to compare two types of treatment. The first is the procedure currently used to assess for pressure injury risk. The second uses a new assessment instrument to identify at-risk patients. Given this information, the nurse consultant exemplifies which career?
1. Clinical nurse specialist
 2. Nurse administrator
 3. Nurse educator
 4. Nurse researcher

The Health Care Delivery System

OBJECTIVES

- Describe the six levels of health care.
- Discuss the factors that affect a person's access to health care.
- Explain the concept of "pay for value," used to reward hospitals financially.
- Explain the relationship between levels of health care and levels of prevention.
- Discuss the features of an integrated health care system.
- Discuss the types of settings in which professionals provide various levels of health care.
- Discuss the role of nurses in various health care settings.
- Describe the elements of discharge planning.
- Explain approaches nurses can use to improve patient satisfaction.
- Discuss the nursing implications regarding issues facing the health care system.
- Describe the effects of health disparities on the health of a community.

The US health care system is complex and constantly changing. Over the past decade, efforts focused on reducing the costs of health care while improving access to the health care system and ensuring high-quality outcomes. In 2014, health care expenditures in the United States totaled 17.5% of the gross domestic product, which averaged \$9523 per person (Young and Kroth, 2018). A variety of services are available from different disciplines of health professionals, but gaining access to services is often very difficult for those with limited health care insurance. The US Census Bureau reports that 28.1 million people remain uninsured (Himmelstein et al., 2018). There are millions more who have health insurance but do not seek preventive or needed health care because of the high cost of shared expenses (Himmelstein et al., 2018). Patients who are uninsured present a challenge to health care and nursing because they are more likely to skip or delay treatment for acute and chronic illnesses and die prematurely (Young and Kroth, 2018).

You will better succeed in your career if you understand the functioning of the health care system and the roles nurses play. Nursing is a caring discipline. The profession's values are rooted in helping people to regain, maintain, or improve their health; prevent illness; and find comfort and dignity at a time of death.

The practice of nursing is changing. The American Nurses Association (ANA) states: "Nursing promotes the delivery of holistic consumer-centered care and optimal health outcomes throughout the life span and across the health-illness continuum within an environmental context that encompasses culture, ethics, law, politics, economics, access to health care resources and competing priorities" (ANA, 2015). It is critical for nurses to be prepared to face the challenges in the health care system today and to work toward improving access and maintaining quality and safety, while working to lessen health care costs that create a barrier to optimal wellness.

Traditional Level of Health Care

The US health care system has six levels of care for which health care providers offer services: preventive, primary, secondary, tertiary, restorative, and continuing health care. Levels of care describe the scope of services and settings delivered by health care providers to patients in all stages of health and illness. It is important for the nurse to understand how the health care industry organizes and delivers services within these levels of care. [Box 2.1](#) provides examples of the types of services available to patients and families at each level of care.

Box 2.1 Examples of Health Care Services

<p>Preventive Care</p> <ul style="list-style-type: none">• Adult screenings for blood pressure, cholesterol, tobacco use, and cancer• Pediatric screenings for hearing, vision, autism, and developmental disorders• HIV screening for adults at higher risk• Wellness visits• Immunizations• Diet counseling• Mental health counseling and crisis prevention• Community legislation (seat belts, car seats for children, bike helmets) <p>Primary Care (Health Promotion)</p> <ul style="list-style-type: none">• Diagnosis and treatment of common illnesses• Ongoing management of chronic health problems• Prenatal care• Well-baby care• Family planning• Patient-centered medical home	<p>Secondary (Acute Care)</p> <ul style="list-style-type: none">• Urgent care; hospital emergency care• Acute medical-surgical care: ambulatory care, outpatient surgery, hospital• Radiological procedures <p>Tertiary Care</p> <ul style="list-style-type: none">• Highly specialized: intensive care, inpatient psychiatric facilities• Specialty care (such as neurology, cardiology, rheumatology, dermatology, oncology) <p>Restorative Care</p> <ul style="list-style-type: none">• Rehabilitation programs (such as cardiovascular, pulmonary, orthopedic)• Sports medicine• Spinal cord injury programs• Home care <p>Continuing Care</p> <ul style="list-style-type: none">• Long-term care: assisted living, nursing centers• Psychiatric and older-adult day care
--	--

Each level of care presents different requirements and opportunities for a nurse. For example, in your role within a primary care setting, you will be involved in patient assessment. You will be expected to identify changes in chronic conditions or the development of new acute conditions. You will teach new mothers how to care for their babies or young adults how to use an inhaler. In a continuing care setting, you will apply gerontology nursing principles to help patients adapt to permanent health changes so that they can remain active and engaged.

Levels of care are not the same as levels of prevention (see [Chapter 6](#)). Levels of prevention describe the focus of health-related activities in a care setting. These include health promotion and disease prevention (primary prevention), curing of disease (secondary prevention), and reducing

complications (tertiary prevention). For example, in a tertiary level of care, such as an intensive care unit, a nurse practices primary prevention by preventing pneumonia through repositioning a patient frequently, secondary prevention by administering antibiotics on time to treat the pneumonia, and tertiary prevention by assessing the patient frequently for signs of antibiotic intolerance.

At every level of care, nurses and other health care providers offer a variety of prevention services. For example, a nurse working in a specialized acute care (secondary/tertiary) hospital setting monitors the recovery of a patient following open heart surgery while also providing health promotion information to the family caregiver concerning diet and exercise.

Health care reform has led to changes unique to each level of care. For example, the health care industry now places greater emphasis on wellness. Thus, the industry directs more resources toward primary and preventive care. Wellness care focuses on the health of populations and their communities rather than simply curing an individual's disease. In wellness care, nurses can help lead communities and health care systems in coordinating resources to better serve their populations. Finding strategies to better address patient needs at all levels of care is critical to improving the functioning of the health care delivery system.

Integrated Health Care Delivery

Integrated health care delivery (IHCD) came about as part of the US health care reform movement in response to the fragmented, costly, and varying quality of health care found in the United States at the time. An integrated health care delivery system is “a network of organizations that provides or arranges to provide a coordinated continuum of services to a defined population and is willing to be held clinically and fiscally accountable for the outcomes and health status of the population served” (Hwang et al., 2013, p.2). IHCDs were developed with a primary focus on improving health care quality and decreasing overall health care costs. The goal of focusing on population health is to decrease health care cost through effective management of patients with chronic health problems. An example of an IHCD is the Accountable Care Organizations that developed in response to health care reform.

There is no single model for an integrated health care system. Basically, two types of integrated health care systems are found: an organizational structure that follows economic imperatives (such as combining financing with all providers, from hospitals, clinics, and physicians to home care and long-term care facilities) and a structure that supports an organized care delivery approach (coordinating care activities and services into seamless functioning) (Hwang et al., 2013).

The Patient-Centered Medical Home model is an example of an integrated health care system. The Patient-Centered Medical Home strengthens the physician-patient relationship with coordinated, goal-oriented, individualized care. In this approach, a patient’s primary health care provider is the coordinator/manager who enlists the skills and knowledge of health care professionals from various services. These professionals can include nurses, medical assistants, nutritionists, social workers, pharmacists, hospice care providers, and other caregivers. Members of a Patient-Centered Medical Home care team are linked by information technology, electronic health records and system-best practices to ensure that patients receive care when and where they need it and how they want it. Patient-centeredness is a unifying principle. It describes an ongoing, active partnership with a personal primary care physician or nurse practitioner who leads a team of professionals dedicated to providing proactive, preventive, and chronic care management through all stages of a patient’s life (American Academy Family Physicians, 2018).

Primary and Preventive Health Care Services

Primary health care focuses on improved health outcomes for an entire population. It includes primary care and health education, proper nutrition, maternal/child health care, family planning, immunizations, and control of diseases. The [World Health Organization \(2018b\)](#) holds that 80% to 90% of a person's health care needs in their lifetime can be met with primary care services. Primary health care requires collaboration among health professionals, health care leaders, and community members. In settings in which patients receive preventive and primary care, such as schools, physicians' offices, occupational health clinics, community health centers, and nursing centers, health promotion is a major theme ([Table 2.1](#)). Health promotion programs are designed to lower the overall costs of health care by reducing the incidence of disease, minimizing complications, and thus reducing the need to use more expensive health care resources. In contrast, preventive care is more disease oriented and focused on reducing and controlling risk factors for disease through activities such as immunization and occupational health programs. [Chapter 3](#) provides a more comprehensive discussion of primary health care in the community.

TABLE 2.1

Preventive and Primary Care Services

Type of Service	Purpose	Available Programs/Services
School health	Comprehensive programs integrate health promotion principles into a school curriculum. Services emphasize program management, interprofessional collaboration, and community health principles. Research shows a link between the health outcomes of young people and their academic success (CDC, 2015b).	Health education Physical education and physical activity Nutrition environment and services Health services Physical environment Social and emotional climate Counseling, psychological services, and social services Employee wellness Family engagement Community involvement
Occupational health	The workplace is an important setting for delivering comprehensive health-protection, health-promotion and disease/accident-prevention programs. Americans working full time spend an average of more than one-third of their day, 5 days a week at the workplace (CDC, 2015a). The goal is to increase worker productivity, reduce absenteeism, reduce health risks, and reduce the use of expensive medical care.	Environmental surveillance Create company policies that promote healthy behaviors such as a tobacco-free campus policy Work environment: offer healthy foods through vending machines or cafeterias Physical assessment and health screening Health education classes Communicable disease control Counseling
Physicians' offices	Provide primary health care and diagnose and treat acute and chronic illnesses. Practitioners are beginning to focus more on health-promotion practices. Advanced nurse practitioners often partner with a physician in managing a patient population.	Routine physical examination Health screening and risk appraisal Diagnostics Disease management Prevention services: diabetes and osteoporosis screenings, smoking cessation programs, and immunizations Wellness counseling
Nurse-managed clinics	Nurse-managed clinics or centers deliver nursing services with a focus on health promotion and health education, chronic disease assessment and management, and support for self-care and caregivers. Clinics often are associated with a school, college, department of nursing, federally qualified health center, or independent nonprofit health care agency.	Day care Clinical education site for other health care providers in school Prevention services: diabetes screenings, smoking cessation programs, and immunizations Physical exams, cardiovascular checks Health risk appraisal Wellness counseling Employment readiness Acute and chronic care management
Type of Service	Purpose	Available Programs/Services
Block and parish nursing	Nurses deliver health care services to patients (e.g., older adults or those unable to leave their homes) within their own religious communities. Provides services that are unavailable in traditional health care system.	Running errands/transportation Respite care

		Counseling Spiritual health: balancing body and mind health to achieve overall wellness
Community centers	Provide comprehensive and cost-effective primary care and supportive services that promote access to health care. Often deliver services to a specific patient population (such as well-baby, mental health, diabetes patients) within underserved communities. Sometimes affiliated with a hospital, medical school, church, or other community organization. The care offered by community centers is culturally appropriate and delivered in languages that many in these communities speak (Center for American Progress, 2018).	Physical assessment and health screening Nutrition education Translation services Dental care Mental health services Care coordination and case management Specialty care (such as orthopedic, cardiac, or podiatric care) Disease management Health education

Secondary and Tertiary Care

The traditional reason people use health care services (such as a hospital) is to diagnose and treat illness. When the nature or severity of a condition makes primary care insufficient, secondary and tertiary care may become necessary. The difference between secondary and tertiary care arises from the complexity of a patient’s medical needs. **Secondary health care** is provided by a specialist or agency upon referral by a primary health care provider. It requires more specialized knowledge, skill, or equipment than the primary care physician or nurse practitioner can provide. For example, an individual sees a cardiologist because of increasing shortness of breath with activity.

Tertiary health care is specialized consultative care, usually provided on referral from secondary medical personnel. For example, the cardiac surgeon sees the patient referred from the cardiologist for possible cardiac bypass surgery. However, changes in medical cost reimbursement, improved technology, and less invasive treatments have often made secondary and tertiary care available at the primary care level. For example, more surgeons are performing simple surgeries in outpatient surgical centers or office suites. However, if a patient develops a problem that the surgeon or primary health care provider is not able to treat and/or if intensive nursing care is needed, the patient needs a medical specialist, often resulting in hospitalization. Secondary and tertiary care (also called **acute care**) typically are expensive, especially if the patient has waited to seek care until after symptoms have developed. Delays in treating or diagnosing chronic illness may cause disability, decreased quality of life, and increased health care costs (Young and Kroth, 2018).

Hospitals

Hospitals provide comprehensive secondary and tertiary health care to patients who are acutely ill. During 2016, over 35 million patients were admitted to American Hospital Association–registered hospitals (AHA, 2018). Even allowing for the fact that some patients are admitted multiple times during a year, a large percentage of the US population receives health care in a hospital each year.

Hospitals vary in the services they offer. Most small rural hospitals offer general inpatient services but have limited emergency and diagnostic services. The exception is critical access hospitals. In comparison, large urban medical centers offer comprehensive, state-of-the-art diagnostic services, trauma and emergency care, surgical intervention, intensive care units (ICUs), inpatient services, and rehabilitation centers. Larger hospitals hire professional staff from a variety of specialties, such as nursing, social service, respiratory therapy, physical and occupational therapy, and speech therapy. Most patients who require these services are having acute episodes of illness. As a nurse, you need to be able to think critically and identify patients' changing problems quickly and accurately. This is challenging when you are assigned multiple patients at one time, depending on your unit. You must be able to deliver an array of nursing interventions safely and effectively and recognize when the needs of your patients no longer match the level of health care where they are receiving treatment. You also must be able to plan and coordinate care with other health care providers quickly and competently.

Hospitals use evidence-based practice guidelines and clinical protocols (see Chapter 5) in the delivery of care to patients. As a nurse, you need to keep current on evidence-based practices to ensure safe, effective care. As a part of the nursing process, the nurse is expected to continually evaluate patient outcomes.

According to the American Hospital Association (2017), delivering the right care, at the right time, in the right setting is the core mission of hospitals across the country. To fulfill this mission, hospitals fully support quality and safety initiatives. An example of a quality initiative is patient satisfaction. Patient satisfaction is challenging to achieve in a stressful setting, such as an inpatient nursing unit. Patients expect to be treated courteously and respectfully. Patients want to be involved in daily care decisions. Hospitals are adopting models of patient-centered care that focus on care that is responsive to individual patient and family preferences, needs, and values and ensuring that patient values guide clinical decisions (IOM, 2001). In a patient-centered care model nurses

engage patients and families early in the decision-making process. As a nurse, you have a key role in learning patient needs and expectations early to form effective therapeutic partnerships. By treating the nurse-patient relationship with respect and dignity, nursing care delivery is improved, which enhances patient satisfaction.

Intensive Care

An ICU or critical care unit is a hospital unit in which patients receive close monitoring and intensive medical care. The status of a patient who is critically ill can change by the minute, so health care providers must have specialized knowledge and skills. ICUs have advanced technologies such as computerized cardiac monitors and high-tech mechanical ventilators. Although many of these devices are on regular nursing units, patients hospitalized within ICUs are monitored and maintained on multiple devices. An ICU is the most expensive health care delivery site because each nurse usually cares for only one or two patients at a time and because of all the treatments and procedures the patients in the ICU require.

Mental Health Facilities

According to the National Alliance on Mental Illness (NAMI) (2018) about 1 in 5 adults in the United States—43.8 million, or 18.5%—experience mental illness in a given year. Perhaps more concerning is the report that only 41% of adults in the United States with a mental health condition received mental health services in the past year (NAMI, 2018). Patients who have emotional and behavioral problems such as depression, mood disorders, violent behavior, and eating disorders require special counseling and treatment in psychiatric facilities. The massive cuts to non-Medicaid state mental health spending in 2011, totaling more than \$1.8 billion, resulted in states having to cut vital mental health services for tens of thousands of youth and adults living with the most serious mental illnesses. These services include community- and hospital-based psychiatric care, housing, and access to medications (NAMI, 2011). This reduction of mental health agencies and services continues to have consequences today, such as loss of income due to missed work, high suicide rates, and high education dropout rates (NAMI, 2018). Individuals with serious mental illness are more likely to suffer chronic disease and as a result die on average 25 years earlier than others, largely due to treatable medical conditions (NAMI, 2018).

The psychiatric facilities that do exist are located in hospitals, independent outpatient clinics, and private mental health hospitals. They offer inpatient and outpatient services, depending on the severity of a patient's problem. Patients enter mental health facilities voluntarily or involuntarily. Patients who are hospitalized usually have short stays intended to stabilize them before transfer to outpatient treatment centers. Patients with mental illness receive a comprehensive interprofessional treatment plan that engages patients and their families. Medical, nursing, social work, and activity therapy providers collaborate to develop a plan of care that enables patients to become more functional within their communities. Patients usually receive referrals for follow-up care at clinics or with counselors during discharge from inpatient settings.

Rural Hospitals

Lack of access to health care in rural areas is a serious public health problem. Only about 10% of physicians practice in rural America, while nearly one-fourth of the US population lives in these areas ([NRHA, 2018](#)). Rural Americans face a unique combination of factors that create health care disparities that are not found in urban areas, including (1) economic factors (rural Americans are more likely to live below the poverty level), (2) cultural and social differences, (3) lower levels of education, (4) lack of attention to rural problems by legislators, and (5) isolation of living in remote rural areas ([NRHA, 2018](#)).

Many rural hospitals have failed economically and closed. To address this problem, the Balanced Budget Act of 1997 changed the designation of some rural hospitals to Critical Access Hospital (CAH) when certain criteria were met ([CMS MLN, 2017](#)). A CAH is located in a rural area (35 miles from another hospital) and provides 24-hour emergency care with no more than 25 inpatient beds for temporary care for 96 hours or less to patients needing stabilization before transfer to a larger hospital. Physicians, advanced practice nurses, or physician assistants staff a CAH. The CAH provides inpatient care to acutely ill or injured people before they are transferred to better-equipped health care centers. Basic radiological and laboratory services are also available. To improve care for patients residing in rural areas, rural hospitals are expected to ([HealthIT.gov, 2017](#)):

- Improve access to services, including urgent care services, and to meet unmet health needs in isolated rural communities.
- Engage rural communities in developing rural health care systems.

- Develop collaborative delivery systems in rural communities as the hubs of rural health care.
- Create protocols for coordinating care transition by aligning urban health care systems.
- Be the subject matter experts and coordinators for the health care environment of providers, patients, and staff.

Health care reform has enabled urban health care systems to branch out and establish affiliations or mergers with rural hospitals. Rural hospitals and CAH provide a referral base to the larger tertiary care medical centers. Nurses who work in rural hospitals or clinics often function independently without a physician. These nurses must be competent in physical assessment, clinical decision making, and emergency care. Advanced practice nurses (such as nurse practitioners and clinical nurse specialists) use medical protocols and establish collaborative agreements with staff physicians.

Health care payers, such as CMS and private insurers, expect patients who are hospitalized to be treated and discharged within a reasonably predictable time period. Reimbursements are affected by the quality and timeliness of care. Nurses must use resources efficiently and effectively to help patients recover and return home. For example, you may collaborate with members of the interprofessional health care team, such as case managers, advanced practice providers such as nurse practitioners, physical therapists, physicians, and social workers, to plan a quick yet realistic transition to another level of health care. This process is known as *discharge planning*.

Discharge Planning

Discharge planning is a coordinated, interprofessional process that develops a plan for continuing care after a patient leaves a health care agency. Studies have shown that patients tend to be discharged “quicker and sicker” from hospitals. This can result in adverse events during the immediate post-discharge period ([Mabire et al., 2013](#)). Such problems include medication prescribing errors, poor communication between hospital and primary care providers, and lack of coordination with community health care services. The focus of discharge planning is to ensure that a patient transitions to the setting in which his or her health care needs can be appropriately met.

According to the [Department of Health and Human Services and Centers for Medicare and Medicaid Services \(DHHS-CMS\) \(2017\)](#), patients

within acute care hospitals have an average length of stay (LOS) of only 2 to 3 days. Thus, *discharge planning with coordination of services must begin the moment a patient is admitted to a hospital*. As a nurse you will play a large role in discharge planning by knowing a patient's plan of care (developed by the interprofessional team) as soon as possible, informing the patient and family of that plan, encouraging their participation, acting on the plan, and evaluating progress (Fig. 2.1). Discharge planning involves these elements (DHHS-CMS, 2017):

FIG. 2.1 Providing discharge teaching to decrease hospital readmission.

- Determining the appropriate post-hospital destination for a patient. A case manager or social worker usually selects this setting based on a patient's health care needs, self-care capacity, insurance, and place of residence.
- Identifying a patient's needs for a smooth and safe transition from the acute care hospital/post-acute care agency to his or her discharge destination. Nurses, therapists (physical, occupational,

speech), health care providers, and dietitians usually identify these needs.

- Beginning the process of meeting a patient's needs while the patient is still hospitalized, with approaches such as early mobility protocols, health education, and new medication regimens.

With a well-developed discharge plan, a patient is less likely to have unavoidable complications or unrelated illnesses or injuries and will be able to continue progressing toward the goals of his or her plan of care after discharge (DHHS-CMS, 2017). As a nurse, participate in discharge planning by anticipating and identifying each patient's continuing needs before the actual time of discharge and coordinating efforts to achieve an appropriate discharge plan.

The DHHS-CMS does not require discharge planning for outpatients, including those who present to an emergency department and are not admitted as hospital inpatients. At the same time, hospitals may help some outpatients (such as emergency department or same-day surgery patients) by providing some discharge planning services (DHHS-CMS, 2017). A nurse-driven discharge planning model that includes discharge teaching and follow-up after discharge can help reduce hospital readmission rates (Dizon and Reinking, 2017). Box 2.2 describes models of discharge planning that focus on the patient and his or her family caregiver.

Box 2.2 Discharge Planning Models

Coleman's "Care Transitions Program" (Coleman et al., 2006)

Emphasizes the role of a transition coach in managing/facilitating the discharge of a patient to home or to a rehabilitation center. Model is based on four pillars: (1) medication self-management, (2) patient-centered record, (3) follow-up, and (4) indicators of worsening medical condition. Each pillar has different interventions depending on the stage of the hospitalization.

Naylor's "Transitional Care Model" (Naylor et al., 2009)

Emphasizes comprehensive discharge planning and follow-up for older adults who are chronically ill. Model contains six key components: (1) in-

hospital assessment and development of the discharge care plan by a transitional care nurse/advanced practice nurse/gerontological nurse; (2) discharge preparation by an interprofessional care team; (3) patient participation (communication between nursing staff and the patient) regarding the process, the decision making, the discharge planning, and the discharge education; (4) continuity of care and communication among health care providers; (5) pre-discharge assessment; and (6) post-discharge follow-up.

High-intensity Care Team (GRACE Team Care Model, Indiana University)

The team is headed by *both* a nurse practitioner and a social worker. This team works in tandem to support the primary care physician and, following best practice protocols, to fully address a patient's health conditions. The focus is to help patients manage their health conditions, coordinate their health care, and achieve optimal health (Michigan Care Management Resource Center, 2018). This achieves a patient's goal from the convenience and security of his or her own home (Counsell, 2015).

Some patients are more in need of discharge planning because of their health-related risks. For example, some patients have poor health literacy, limited financial resources, or limited family support; others have long-term disabilities or chronic illness, and older adults sometimes have cognitive and/or hearing impairments affecting their attention to discharge instruction. There are also barriers to effective discharge planning, including ineffective communication (health care provider to provider; health care provider to patient), lack of role clarity among health care team members (responsibility and follow-up), and lack of resources (e.g., rehab and nursing home beds) (Okoniewska et al., 2015). You can reduce barriers to discharge planning by clearly communicating about the plan of care with patients, families, and members of the health care team. Change of shift hand-offs and hourly bedside rounds are ways to keep all health care providers and patients informed (Chapter 24). Communicate clearly both verbally and in the entries you make in the electronic health record (EHR) (see Chapter 26). Clarify any role confusion to be sure elements of the plan are completed.

Discharge instructions prepare patients for transition from a hospital to the next level of care (such as home, rehabilitation, or long-term care). Nurses can offer useful and relevant information that will prepare patients and their family caregivers for post-discharge care. To develop discharge

instructions, you must understand the proper timing for discharge, engage the patient and family caregiver in the process, and know the health care team's plan of care. Patients cannot learn when they are having pain, nausea, confusion, or other disabling symptoms. Family caregivers can be excellent resources when the patient desires their help. Always involve patients and family caregivers in the decisions about the patient's discharge destination ([Mabire et al., 2013](#)).

Provide discharge instruction as early as possible so that you and other health care team members can reinforce the information several times to improve learning. For example, when a patient is receiving care that follows a standard protocol, you can easily anticipate the treatment and the patient's estimated discharge date. When the patient has multiple complications, the plan of care and estimated discharge date might not be clear. Begin to explain discharge instruction as soon as you know the plan of care. The following are required discharge instruction topics ([The Joint Commission \[TJC\], 2016](#)): discharge medications, follow-up care (if needed), list of all medications changed and/or discontinued, dietary needs, and follow-up tests or procedures.

Some patients assume passive roles when they receive instructions. They might be satisfied when a nurse, physician, or therapist rushes through an explanation and finishes by simply inquiring, "Any questions?" This often leads the patient to automatically answer "no." This patient might never have been invited to actively participate in their health care plan. A patient-centered approach does more. The health care provider *invites* the patient to participate: "I want to make sure that I've helped you understand everything you need to know about your illness. Patients usually have questions because their situations can be complicated. Could you tell me what you understand, and then I can help clarify?" The teach-back approach (see [Chapter 25](#)) is an excellent way to ensure that a patient understands instructions. Comprehensive discharge instruction ensures that patients know what to do when they get home, how to perform care activities, and what to do when problems develop.

Discharge planning often leads to referrals to other health care providers, especially when specific therapies are planned (such as physical therapy) (see [Chapter 18](#)). Some tips for making a successful referral include the following:

- Engage the patient and family caregiver in the referral process, including selecting the care provider. Explain the reason for the

referral, the service to be provided, and how the service will be provided.

- Make the referral as soon as possible.
- Give the care provider receiving the referral as much information as possible about the patient. This can avoid unnecessary duplication of assessment (e.g., current vital signs or pain status) and omission of important information.
- The care provider, such as a physical therapist, social worker, dietitian, or radiologist, will make recommendations for the patient's care. Learn these recommendations and incorporate them into the treatment plan as soon as possible.

Restorative Care

Patients recovering from an acute or chronic illness or disability often require additional services to return to their previous level of function or to reach a new level of function limited by their illness or disability. The goals of **restorative care** are to help individuals regain maximal functional status and to enhance quality of life through promotion of independence and self-care. With the emphasis on early discharge from hospitals, patients usually require some level of restorative care. For example, some patients require ongoing wound care and activity and exercise management until they have recovered enough following surgery to independently resume normal activities of daily living.

The intensity of care has increased in restorative care settings because patients leave hospitals earlier. Patients in a home or rehabilitation setting often still receive IV fluids (see [Chapter 42](#)), aggressive pain control (see [Chapter 44](#)), or enteral nutrition (see [Chapter 45](#)). The restorative health care team is interprofessional and includes the patient and family or significant others. In restorative settings nurses recognize that success depends on effective and early collaboration with patients and their families. Patients and families require a clear understanding of goals for physical recovery, the rationale for any physical limitations, and the purpose and potential risks associated with therapies. Patients and families are more likely to follow treatment plans and achieve optimal functioning when they are engaged in their care.

Home Care

Home care is the provision of medically related professional and paraprofessional services and equipment to patients and families in their

homes for health maintenance, education, illness prevention, diagnosis and treatment of disease, palliation, and rehabilitation. This care consists of part-time, medically necessary skilled care (nursing, physical therapy, occupational therapy, and speech-language therapy) that is prescribed by a health care provider (CMS, 2016a). A home care service also coordinates the access to and delivery of home health equipment, or durable medical equipment, which is a medical product adapted for home use.

Home care nurses have their own patient caseloads and deliver highly individualized nursing care. They help patients adapt to many permanent or temporary physical limitations so that the patients can assume a daily home routine that is as normal as possible. Home care requires a strong knowledge base in many areas, such as family dynamics (see Chapter 10), cultural competency (see Chapter 9), spiritual values (see Chapter 35), and communication principles (see Chapter 24). Home health nurses must also have expertise in assessment. Nurses who work in Medicare-certified home care agencies conduct patient-specific comprehensive assessments at a patient's start of care, at 60-day follow-ups, at discharge, and before and after an inpatient stay (Research Data Assistance Center [ResDac], 2016). This comprehensive assessment, OASIS (the Outcome and Assessment Information Set), includes a group of standardized core assessment items for an adult home care patient. OASIS forms the basis for measuring patient outcomes for the purposes of outcome-based quality. Data items within OASIS include socio-demographic, environmental, support system, health status, functional status, and health service utilization characteristics of a patient (ResDac, 2016). The OASIS assessment tool was designed to gather the data items needed to measure both outcomes and patient risk factors in the home setting.

Home health care focuses on the goal of helping patients and their family members achieve independence. Home care addresses recovery from and stabilization of illness in the home. In addition, home care identifies problems related to lifestyle, safety, environment, family dynamics, and health care practices in the home. Home care agencies employ skilled and intermittent professional services, such as wound care, administering parenteral and enteral nutrition, administering medications and blood therapy, and home care aide services. These services usually are delivered once or twice a day as often as 7 days a week.

Approved home care agencies usually receive reimbursement for services from governmental programs (such as **Medicare** and **Medicaid** in the United States), private insurance, and private payers. The government strictly regulates reimbursement for home care services. An agency cannot

simply charge whatever it wants for a service and expect to receive that amount. Governmental programs set the amount of reimbursement for most professional services.

Rehabilitation

The World Health Organization (WHO) defines **rehabilitation** as the process aimed at enabling people with disabilities to reach and maintain their optimal physical, sensory, intellectual, psychological, and social functional levels. Rehabilitation gives people with disabilities the tools they need to attain independence and self-determination (WHO, 2018a). Patients require rehabilitation after a physical or mental illness, injury, or chemical addiction. Rehabilitation was once offered mostly to patients with illnesses or injury to the nervous or musculoskeletal system, but the expanded scope of services now includes cardiovascular, neurological, musculoskeletal, pulmonary, and mental health rehabilitation programs. The goal of these specialized rehabilitation services is to help patients and families adjust to necessary changes in lifestyle and learn to function with the limitations of their disease. An example is drug rehabilitation centers that help patients become free from drug dependence and return to the community.

Rehabilitation services after acute care include physical, occupational, and speech therapy and social services. Ideally rehabilitation begins the moment a patient enters a health care setting for treatment. For example, some orthopedic programs now have patients perform physical therapy exercises before major joint repair to enhance their recovery after surgery. Initially rehabilitation usually focuses on preventing complications related to an illness or injury, such as promoting early mobility in patients after surgery. As the patient stabilizes, it helps to maximize a patient's functioning and level of independence, often by examining the need for assist devices such as walkers or canes.

Rehabilitation settings include rehabilitation institutions within acute care centers, free-standing outpatient settings, and the home. Patients who have severe disabilities may not be able to carry out the activities of daily living independently. An example would be a patient who has had a stroke or spinal cord injury. These patients may benefit from long-term rehabilitation to reach their maximum potential.

Patients who use rehabilitation services in an outpatient setting receive treatment at appointments during the week but live in their home. Sometimes, specific rehabilitation services are also used in the home to help the patient.

Extended Care Facilities

An **extended care facility** provides intermediate medical, nursing, or custodial care for patients recovering from acute illness or those with chronic illnesses or disabilities. Extended care facilities include intermediate care and skilled nursing facilities. Some include long-term care and assisted-living facilities. At one point extended care facilities primarily cared for older adults. However, because hospitals discharge their patients sooner, there is a greater need for intermediate care settings for patients of all ages. For example, health care providers transfer a young patient who has experienced a traumatic brain injury resulting from a car accident to an extended care facility for rehabilitative or supportive care until discharge to the home becomes a safe option.

An intermediate care or **skilled nursing facility** offers skilled care from a licensed nursing staff. This often includes administration of IV fluids, wound care, long-term ventilator management, and physical rehabilitation. Patients receive extensive supportive care until they are able to move back into the community or into residential care. Extended care facilities provide around-the-clock nursing coverage. Nurses who work in a skilled nursing facility need nursing expertise similar to that of nurses working in acute care inpatient settings, along with a background in gerontological nursing principles (see [Chapter 14](#)).

Continuing Care

Continuing care describes a variety of health, personal, and social services provided over a prolonged period. These services are for people who are disabled, who were never functionally independent, or who suffer a terminal disease. The need for continuing health care services is growing in the United States. People are living longer, and many of those with continuing health care needs have no immediate family members to care for them. A decline in the number of children families choose to have, the aging of care providers, and the increasing rates of divorce and remarriage complicate this problem.

Continuing care is available within institutional settings (e.g., nursing centers or nursing homes, group homes, and retirement communities), communities (e.g., adult day care and senior centers), or the home (e.g., home care, home-delivered meals, and hospice) ([Meiner and Yeager, 2019](#)). Another alternative for the patient who does not need nursing care but needs some assistance to stay independent is elder care services. These

services offer companionship, assistance with activities of daily living, and food preparation.

Nursing Centers or Facilities

The language of long-term care is confusing and constantly changing. *Nursing home* was the dominant setting for long-term care (Meiner and Yeager, 2019). With the 1987 Omnibus Budget Reconciliation Act, *nursing facility* became the term for nursing homes and other facilities that provided long-term care. Now *nursing center* is the most appropriate term. A nursing center typically provides 24-hour intermediate and custodial care such as nursing, rehabilitation, dietary, recreational, social, and religious services for residents of any age with chronic or debilitating illnesses. Nursing center services provided by Medicaid-certified nursing homes, offer:

- Skilled nursing
- Rehabilitation
- Long-term care (Medicaid.gov, 2018).

These three services include 24-hour licensed nursing, rehabilitation, medically related social services, pharmaceutical services, dietary services individualized to the needs of each resident, a professionally directed program of activities to meet the interests and needs for the well-being of each resident, emergency dental services, room and bed maintenance services, and routine personal hygiene items and services. A skilled nursing facility must care for its residents in a manner and in an environment that will promote maintenance or enhancement of the quality of life of each resident (Legal Information Institute, 2010).

Most people living in nursing centers are older adults. A nursing center may be a resident's temporary or permanent home with surroundings made as homelike as possible. Residents receive a planned, systematic, and interprofessional approach to care to help them reach and maintain their highest level of function.

Nursing centers must comply with the Omnibus Budget Reconciliation Act of 1987 and its minimum requirements for nursing facilities to receive payment from Medicare and Medicaid. Government regulations require that staff members in nursing centers comprehensively assess each resident and that care planning decisions be made within a prescribed period. A resident's functional ability (such as the ability to perform

activities of daily living and instrumental activities of daily living) and long-term physical and psychosocial well-being are the focus.

A nursing facility must complete the Resident Assessment Instrument (RAI) for each resident. The RAI helps nursing facility staff gather definitive information on a resident's strengths and needs, which must then be addressed in an individualized care plan (CMS, 2015b). The RAI has three components: the **Minimum Data Set (MDS)** Version 3.0, the Care Area Assessment (CAA) process, and the RAI Utilization Guidelines (Box 2.3). The components of the RAI yield information about a resident's functional status, strengths, weaknesses, and preferences, as well as offering guidance on further assessment once problems have been identified (CMS, 2015b). The MDS Version 3.0 is an initial overview of a resident's health care needs. It is a preliminary assessment to identify the resident's potential problems, strengths, and preferences. The CAAs are triggered by individual MDS item responses that reveal the need for additional assessment. These item responses identify problems, known as "triggered care areas," which form a critical link between the MDS and decisions about care planning. CAAs enable facilities to identify and use tools that are grounded in current clinical standards of practice, such as evidence-based or expert-endorsed research, clinical practice guidelines, and resources.

Box 2.3 Components of the Resident Assessment Instrument (RAI)

Minimum Data Set (MDS)

A core set of screening, clinical, and functional status elements, including common definitions and coding categories, which forms the foundation of a comprehensive assessment for all residents of nursing homes that are Medicare- or Medicaid-certified. Elements include:

- Resident's background
- Cognitive, communication/hearing, and vision patterns
- Physical functioning and structural problems
- Mood, behavior, and activity pursuit patterns
- Psychosocial well-being
- Bowel and bladder continence

- Disease diagnoses and other health conditions
- Mood and behavior patterns
- Activity pursuit patterns
- Oral/nutritional and dental status
- Skin condition
- Medication use
- Treatments and procedures

Care Area Assessment (CAA) Process

This process is designed to assist the assessor to systematically interpret the information recorded on the MDS. Once a care area has been triggered, nursing home providers use current, evidence-based clinical resources to conduct an assessment of the potential problem and determine a plan of care for it. The CAA process helps the clinician to focus on key issues.

- Care Area Triggers (CATs) are specific resident responses for one or a combination of MDS elements. The triggers identify residents who have or are at risk for developing specific functional problems and require further assessment.
- Care Area Assessment is the further investigation of triggered areas, to determine if the care area triggers require interventions and care planning.
- CAA Summary provides a location for documentation of the care area(s) that have triggered from the MDS and the decisions made during the CAA process regarding whether to proceed to care planning.

Utilization Guidelines

The Utilization Guidelines provide instructions for when and how to use the RAI.

Adapted from Centers for Medicare and Medicaid Services (CMS): Long-Term Care Facility Resident Assessment Instrument 3.0 User's Manual Version 1.13, 2015b. <https://www.cms.gov/Medicare/Quality-Initiatives-Patient-Assessment-Instruments/NursingHomeQualityInits/Downloads/MDS-30-RAI-Manual-V113.pdf>. Accessed August 2018.

The information gathered using the RAI provides a national database for nursing facilities that enables policy makers to better understand the health care needs of the long-term-care population. The MDS and CAAs are a rich resource for nurses in selecting interventions that best meet the health care needs of this growing population.

Assisted Living

Assisted living is one of the fastest-growing industries within the United States. There are approximately 30,000 assisted-living facilities that house more than 835,000 people in the United States (NCAL, 2018). **Assisted living** offers an attractive long-term care setting with an environment more like home and greater resident autonomy. Residents require some assistance with activities of daily living but remain relatively independent within a partially protective setting. A group of residents live together, but each resident has his or her own room and shares dining and social activity areas. Usually people keep all of their personal possessions in their residences.

Assisted-living residences range from hotel-like buildings with hundreds of units to modest group homes that house a handful of seniors. Assisted living provides independence, security, and privacy all at the same time (Touhy and Jett, 2018). These settings promote physical and psychosocial health (Fig. 2.2). Services in an assisted-living center include laundry, assistance with meals and personal care, 24-hour oversight, and housekeeping (NCAL, 2018). Some centers provide assistance with medication administration. Nursing care services are not always directly available, although home care nurses can visit patients in assisted-living residences. Unfortunately, most residents of assisted-living residences pay privately. The national median monthly fee is \$3750 for a private unit (NCAL, 2018). With no government fee caps and little regulation, assisted living is not always an option for individuals with limited financial resources.

FIG. 2.2 Providing nursing services in assisted-living facilities promotes physical and psychosocial health.

Respite Care

Caring for family members within the home creates great physical and emotional burdens for adult caregivers. This is especially true when the family member who needs assistance is physically or cognitively limited. The caregiver is usually an adult who not only has the responsibility for providing care to a loved one (such as a spouse, parent, or sibling) but often maintains a full-time job, raises a family, and manages the routines of daily living as well.

Respite care is a service that offers short-term relief by providing a new environment or time to relax for family caregivers who support the ill, disabled, or frail older adult ([Alzheimer's Association, 2016](#)). Recommend respite services to the family caregivers of your patient whenever indicated. Respite care can be provided at home by a friend, another family member, a volunteer, by a paid service, or in a care setting such as adult day care or a residential center ([Alzheimer's Association, 2016](#)).

Research has shown that family caregivers must have great trust in the respite care service and that they perceive that the major benefits for the recipients of care are social interaction and meaningful activity, with a resulting improvement in well-being (Stirling, 2014).

Adult Day Care Centers

Adult day care centers provide a variety of health and social services to specific patient populations who live alone or with family in the community. Services offered during the day allow family members to maintain their lifestyles and employment and still provide home care for their relatives (Meiner and Yeager, 2019). Day care centers are associated with a hospital or nursing home or exist as independent centers. Frequently the patients need continuous health care services but not hospitalization (e.g., physical therapy, meals, recreational activities, or counseling) while their families or support people work. Patients who typically use adult day care are physically frail, cognitively impaired, or both and require some supervision but not continuous care (Meiner and Yeager, 2019).

The centers usually operate weekdays during typical business hours and usually charge on a daily basis. Adult day care centers allow patients to retain more independence by living at home, thus potentially reducing the costs of health care by avoiding or delaying an older adult's admission to a nursing center. Nurses working in day care centers provide continuity between care delivered in the home and the center. For example, nurses ensure that patients continue to take prescribed medication and administer specific treatments. Knowledge of community needs and resources is essential in providing adequate patient support (Touhy and Jett, 2018).

Palliative and Hospice Care

Palliative care is a holistic, patient- and family-centered care approach with a goal of improving the quality of life of patients and families who are experiencing problems related to life-threatening illnesses. Palliative care is delivered through the continuum of illness with a focus on early identification and treatment of physical, psychosocial, and spiritual problems; relief of pain and suffering; continuity of care; and helping patients and families make informed decisions (NHPCO, n.d.; Parola et al., 2018). Palliative care can be delivered in any health care setting. Some health care agencies have dedicated palliative care units to care for these

patients with complex health problems. Key to palliative care delivery is the nurse-patient and nurse-family relationship. With the patient, the nurse develops a singular relationship, and with the family, a partner, supportive relationship is formed (Parola et al., 2018).

A **hospice** is a system of family-centered care that allows patients to live with comfort, independence, and dignity while easing the pain of terminal illness. A patient entering into hospice care is in the terminal phase of illness, and the patient, family, and health care provider agree that no further treatment will reverse the disease process. Hospice care is provided in a setting that best meets the needs of each patient and family, such as in a patient's home, in nursing homes, assisted living facilities, freestanding hospices, and hospitals. The focus of hospice care is supportive care, not curative treatment (see Chapter 36). Hospice benefits patients in the terminal phase of any disease, such as cardiomyopathy, multiple sclerosis, acquired immunodeficiency syndrome (AIDS), and cancer. Hospice team members are available 24 hours a day, 7 days a week to answer questions or visit anytime the need for support arises. Team members collaborate to provide care that ensures death with dignity. Services continue without interruption even if a patient's care setting changes. Chapter 36 offers more detail on hospice care.

Palliative and hospice care are similar in that both focus on symptom management and ensuring the patient's comfort. Both care delivery methods are managed by an interprofessional team that works together with the patient's primary health care provider to develop and maintain a patient-directed, individualized plan of care (Pawlow et al., 2018). An essential member of the interprofessional team is the advanced practice registered nurse (APRN). To meet the increasing need for APRNs in palliative and hospice care, integration of core competencies into APRN education, development of clinical education opportunities in palliative and hospice care, and provision of continuing education in palliative and hospice care for practicing APRNs need to occur (Pawlow et al., 2018).

Issues in Health Care Delivery for Nurses

The climate in health care today influences both health care professionals and consumers. Because those who provide patient care are the most qualified to make changes in the health care delivery system, you need to participate fully and effectively within all aspects of health care. Health care agencies today are working hard to improve patient experience and engagement while delivering high quality care, improving outcomes, and controlling cost (Considine, 2018). In today's health care system, the outcomes of patient satisfaction and quality care indicators such as infection rates are tied to health care payments (McCay et al., 2018). As you face issues of how to maintain health care quality while reducing costs, you need to acquire the knowledge, skills, and values necessary to practice competently and effectively. It is also more important than ever to collaborate with other health care professionals to design new approaches for patient care delivery.

Health Care Costs and Quality

It is impossible today to separate two initiatives facing health care institutions: managing costs and achieving high-quality patient care. Health care payers (Table 2.2) (such as Medicare, Medicaid, and private insurers) have been trying to manage and address health care costs for many years. The Social Security Act establishes a system of payment for the operating costs of acute care hospital inpatient stays under Medicare Part A (hospital insurance) based on prospectively set rates (CMS, 2016d). This payment system is referred to as the **inpatient prospective payment system** (IPPS). Under the IPPS, each case is categorized into a **diagnosis-related group** (DRG). Each DRG has a payment weight assigned to it, based on the average resources used to treat Medicare patients in that DRG (CMS, 2016d). Regardless of the amount a hospital spends to care for a patient, the DRG-established payment is the amount the hospital receives. The DRG payment groups are still used, but many payers now demand that evidence-based standards of care be followed to further reduce the cost of health care.

Table 2.2**Common Health Care Payers in the United States**

Among the current health care payment models, quality is a key component. Most health care cost reimbursement arrangements tie the final payment to the achievement of key quality metrics.	
Fee-for-service	<ul style="list-style-type: none">• The most traditional health care payment model• Requires patients or payers to reimburse the health care provider for each service performed• No incentive to implement preventive care strategies, prevent hospitalization, or take any other cost-saving measures
Pay-for-coordination	<ul style="list-style-type: none">• Coordinates care between the primary care provider and specialists• Coordinating care among multiple providers can help patients and their families manage a unified care plan and can help reduce redundancy in expensive tests and procedures.
Pay for performance (P4P)	<ul style="list-style-type: none">• Same as value-based reimbursement• Health care providers are compensated only if they meet certain metrics for quality and efficiency.• Quality benchmark metrics tie physicians' reimbursement directly to quality of care they provide.
Bundled payment or episode-of-care payment	<ul style="list-style-type: none">• Reimburses health care providers for specific episodes of care, such as an inpatient hospital stay• Encourages efficiency and quality of care because only a set amount of money will pay for the entire episode of care
Upside shared savings programs (Centers for Medicare and Medicaid Services [CMS] or commercial)	<ul style="list-style-type: none">• Provide incentives for providers treating specific patient populations• A percentage of any net savings realized is given to the provider.• Upside-only shared savings is most common with Medicare Shared Savings Program (MSSP) Accountable Care Organizations, but all MSSP participants must move to a downside model after three years.
Downside shared savings programs (CMS or commercial)	<ul style="list-style-type: none">• Includes both the gain share potential of an upside model, but also the downside risk of sharing the excess costs of health care delivery between provider and payer• Because providers are taking on greater risk with this model, the upside opportunity potential is larger in most cases than in an all-upside program.
Partial or full capitation	<ul style="list-style-type: none">• Patients are assigned a per-member per-month (PMPM) payment based on their age, race, sex, lifestyle, medical history, and benefit design.• Payment rates are tied to expected usage regardless of whether the patient visits more or less.• As with bundled payment models, health care providers have an incentive to help patients avoid expensive procedures and tests in order to maximize their compensation.• Only certain types or categories of services are paid on a capitation basis.

CMS, Centers for Medicare and Medicaid Services; MSSP, Medicare Shared Savings Program

Data from American Academy of Pediatrics: Getting paid: alternative payment models, 2019, <https://www.aap.org/en-us/professional-resources/practice-transformation/getting-paid/Pages/Payment-Models.aspx>. Accessed August 2018; and Brookings: The beginner's guide to new healthcare payment models, 2014, <https://www.brookings.edu/blog/usc-brookings-schaeffer-on-health-policy/2014/07/23/the-beginners-guide-to-new-health-care-payment-models/>. Accessed August 2018.

The US Congress created the Centers for Medicare and Medicaid (CMS) Innovation Center to test “innovative payment and service delivery models to reduce program expenditures ... while preserving or enhancing the quality of care” for those who receive Medicare, Medicaid, or

Children's Health Insurance Program (CHIP) benefits (CMS, 2016b). The Innovation Center supports the following priorities: testing new payment and service delivery models, evaluating results and advancing best practices, and engaging a broad range of stakeholders to develop additional models for testing. One example of an initiative supported by the Innovation Center is the creation of Medicare Accountable Care Organizations (ACOs). The ACOs are groups of doctors, hospitals, and other health care providers who come together voluntarily to give coordinated high-quality care to their Medicare fee-for-service (FFS) beneficiaries and reduce unnecessary costs (CMS, 2016e). As of 2015, 424 ACOs participate in the CMS Shared Savings Program (CMS, 2015a).

The Affordable Care Act ties payment to organizations offering Medicare Advantage plans to the quality ratings of the coverage they offer. If hospitals perform poorly in quality scores, they receive lower payments for services. Quality outcome measures include patient satisfaction and more effective management of care by reducing complications and readmissions and improving care coordination. Examples of reforms that incent or "Pay for Value," designed to build a health care system that better serves the American population (CMS, 2015a), include the following:

- *Hospital Value-Based Purchasing*: This program links a portion of hospitals' Medicare payments (1.5% of base operating DRG payment) for inpatient acute care to their performance in important quality measures. The Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) is the standardized survey instrument and data collection methodology CMS requires for measuring patients' perceptions of hospital care. HCAHPS is a patient satisfaction measure that sets a national standard for collecting or publicly reporting patients' perceptions that enables users to make valid comparisons across all hospitals (HCAHPS, 2018). Research shows that hospitals that have a higher percentage of hospitalists providing care are linking services for improved coordination of care, resulting in higher performance scores (Spaulding et al., 2018).
- *Hospital Readmissions Reduction Program*: This CMS program reduces Medicare payments to hospitals with excess patient readmissions within 30 days of hospital discharge. It is designed to encourage patient safety and care quality. The maximum reduction in payments under the Hospital Readmissions

Reduction Program increased in 2015 to 3 percent of base DRG amounts. The conditions that are regulated under this program include heart attack, heart failure, pneumonia, chronic obstructive pulmonary disease, and knee and hip replacements ([National Quality Forum, 2018a](#)). Nurses are a vital part of interprofessional teams. These team members collaborate to design treatment and discharge instruction protocols to reduce unnecessary patient readmissions.

- *Bundled Payments for Care Improvements*: Certain health care organizations are testing whether bundled payments (single payment for all services performed to treat a patient) for a specific episode of care (inpatient stays in an acute care hospital) can better coordinate care for Medicare patients and reduce Medicare costs. A bundled payment includes payments for services such as medical, radiological, and therapeutic. This initiative focuses on improving care for specific conditions. Bundling payments for services, such as heart bypass surgery, is one way to encourage doctors and hospitals to better coordinate care during hospitalization and after discharge ([CMS, 2015a](#)). Health care institutions enter into payment arrangements that include financial and performance accountability for an episode of care ([CMS, 2016c](#)).
- *Hospital Acquired Condition (HAC) Reduction Program*. This program was developed by CMS to encourage hospitals to improve health care quality and patient safety. As a component of this program, hospitals that have a high incidence of HACs, such as pressure injury development, catheter-associated urinary tract infections, central line-associated bloodstream infections, surgical site infections, and *Clostridium difficile* in patients, received reduced or no funding from CMS for the treatment of these HACs ([CMS, 2018](#)). This program saves CMS approximately \$350 million annually ([CMS, 2018](#)). Because of this reduced funding, hospitals have focused quality improvement efforts on reducing and preventing these HACs.

Patient Satisfaction

Patient satisfaction is the responsibility of all health care providers. It is more important than ever because patient satisfaction measures are linked to hospital reimbursement. Patient perceptions of the quality of their health care have been incorporated into quality assessment. As a result,

health care organizations have made the patient experience and patient-centered care major components of their health care missions (Cody and Williams-Reed, 2018; Niederhauser and Wolf, 2018). Hospitals now report patient satisfaction scores for patient care units monthly. All health care staff members help identify satisfaction trends and determine ways to improve quality of care. Hospitals and other health care agencies use a variety of instruments to measure patient satisfaction (Al-Abri and Al-Balushi, 2014). Instruments are provided by private vendors. They usually are not published, and their reliability and validity are unclear:

- Public and standardized instruments such as patient satisfaction questionnaires: PSQ-18 and consumer assessment health plans (e.g., HCAHPS). Such instruments have the advantage of good reliability and validity; however, they have a limited scope of survey questions.
- Internally developed instruments that are derived mainly from questions extracted from other instruments

The HCAHPS, developed by the Centers for Medicare and Medicaid Services and the Agency for Healthcare Research and Quality (AHRQ), is a patient satisfaction tool many hospitals use to collect and publicly report data for comparison purposes (HCAHPS, 2018). The HCAHPS survey has 32 questions that ask patients to respond about communication with doctors, communication with nurses, responsiveness of hospital staff, pain management, communication about medicines, discharge information, cleanliness of the hospital environment, quietness of the hospital environment, transition of care, and willingness to recommend the hospital (HCAHPS, 2018). The survey also includes four screening questions and seven demographic items, which are used for adjusting the mix of patients across hospitals and for analytical purposes.

Much research has been conducted to identify the factors that patients perceive affect their satisfaction, including relational communication techniques, hourly rounding (Box 2.4), nurse staffing patterns, and bedside shift report (Cody et al., 2018; Persolja, 2018; Dilts Skaggs et al., 2017). One common factor among the studies is interpersonal skills, especially the courtesy and respect of health care providers. This is in addition to the communication skills of providing explanations and clear information, which are more influential in affecting patient perceptions than other technical skills (George et al., 2018; Pattison et al., 2017).

Box 2.4 Evidence-Based Practice Purposeful Nurse

Rounding and Patient Satisfaction

PICOT Question: Does the practice of intentional rounding on a nursing unit improve patient outcomes?

Evidence Summary

Intentional rounding (IR) is a practice that has been adopted by many health care agencies with the goal of improving the patient experience, improving patient satisfaction, ensuring patient safety, and proactively addressing patient concerns or problems (Daniels, 2016; Dilts Skaggs et al., 2018). Typically, IR has a member of the unit's health care team rounding hourly on each patient using an established protocol (Christiansen et al., 2018). Key components to making IR successful are engaging all staff on the unit, holding all workers accountable for the rounding, having an infrastructure and organized approach, and a stable management team monitoring the practice (Daniels, 2016; Flowers et al., 2016). Hourly IR has been found to improve patient satisfaction and patient perception of nurse responsiveness (Bragg et al., 2016; Dilts Skaggs et al., 2018). Studies have also shown that IR reduces the incidence of patient falls and use of the nurse call system because patient problems are addressed proactively (Christiansen et al., 2018). Family members in intensive care units found that IR helped make a connection with staff, provided consistency in communication, and helped prepare families for the future (Cody et al., 2018). Patients also felt that IR helped with the management of their pain (Bragg et al., 2016). Occasionally, patients found IR to be intrusive, but education given by staff on the purpose of the rounding helped patients understand the importance of the practice (Flowers et al., 2016).

Application to Nursing Practice

- Conduct IR on patients as a best practice for your nursing unit.
- Conduct ongoing staff education on the importance of IR to help hard-wire the practice and improve teamwork and compliance (Christiansen et al., 2018; Dilts Skaggs et al., 2018).
- Use a structured approach such as the "12 Step" or "Four Ps" (pain, "potty" (bathroom), positioning, placement of personal items) when rounding (Daniels, 2016).

- Provide education to patients on the practice of IR when orienting patients to the hospital environment and practices (Daniels, 2016; Flowers et al., 2016).
- Participate with the nursing manager to conduct unit audits to monitor compliance of staff with the practice of IR.
- Celebrate successes on your unit such as increased patient satisfaction, decreased incidence of falls, and decreased nurse call system usage.

Nursing Shortage

The American Association of Colleges of Nursing (AACN) warns of a shortage of registered nurses (RNs) that is expected to intensify as baby boomers age and the need for health care grows (AACN, 2017). The problem is complicated by the fact that nursing schools across the country are struggling to expand their capacity to meet the rising demand for RNs. In addition, aging nurses are retiring from the workforce. The AACN noted important shortage indicators:

- The Bureau of Labor Statistics' (BLS) Employment Projections for 2014-2024 shows RNs among the top occupations in terms of job growth through 2024 (BLS, 2015). The RN workforce is expected to grow 16% (increase of 439,300) by 2024. The Bureau also predicts the need for 649,100 replacement nurses in the workforce, bringing the total number of RN job openings to 1.09 million by 2024.
- The [Institute of Medicine's \(2010\)](#) report, *The Future of Nursing: Leading Change, Advancing Health*, called for an increase in the percentage of nurses who attain a bachelor's degree to 80% and a doubling in the number of nurses with doctoral degrees. The current nursing workforce falls far short of these recommendations, with only 55% of registered nurses prepared at the baccalaureate or graduate degree level.
- With the passage of the **Patient Protection and Affordable Care Act** in 2010, more than 32 million Americans are gaining access to health care services, including those provided by RNs and APRNs (AACN, 2017).

The nursing shortage opens great opportunities for every nurse. If you pursue further education and watch trends in health care, you will be able

to find employment in any professional position you choose.

Competency

Health care practitioner competencies are an excellent tool for measuring how well a nurse practices nursing and serve as a guide for the development of a professional nursing career. The Quality and Safety Education for Nurses (QSEN) project developed quality and safety competencies for nurses so that they would have the knowledge, skills, and attitudes to meet the challenges in today's health care settings (QSEN, 2018). The Massachusetts Nurse of the Future Nursing Core Competencies were developed by the Massachusetts Department of Higher Education (DHE) and the Massachusetts Organization of Nurse Executives (MONE) to identify knowledge, attitude, and skills for 10 competencies considered essential for the registered nurse for the future (MDH&H, 2016). Box 2.5 shows the QSEN and Massachusetts Nurse of the Future competencies. A consumer of health care expects that the standards of nursing care and practice in any health care setting are appropriate, safe, and effective. Health care organizations ensure quality care by establishing policies, procedures, and protocols that are evidence-based and follow national accrediting standards. Your responsibility is to follow policies and procedures and know the most current practice standards. Ongoing competency is your responsibility. You are also responsible for obtaining necessary continuing education, following an established code of ethics, and earning certifications in specialty areas.

Box 2.5 Registered Nurse Competencies

Patient-Centered Care

In a landmark report, *Crossing the Quality Chasm*, the Institute of Medicine (IOM) defines **patient-centered care** as “care that is respectful of and responsive to individual patient preferences, needs, and values and (ensures) that patient values guide all clinical decisions” (IOM, 2001). Hospitals across the country have been attempting to implement patient-centered care strategies, specifically delivery of care models (see [Chapter 21](#)). Patient-centered care is a component of the total patient experience, which includes all interactions that a patient has in a health care setting. The overall patient experience is influenced by the health care settings’ culture and patient perceptions ([Wolf, 2017](#)).

Patient-centered care is much more than simply “individualizing” patient care. A critical component of patient-centered care is the nurse, patient, and family caregiver partnering to identify the patient’s health

care needs within the context of the patient's lifestyle and to coordinate the entire health care team so that patient and family are engaged in the care process and associated decisions. This is a major shift in how care is delivered, empowering the patient and family to participate in the plan of care and engaging patients and families in a dialogue about the patient experience (Niederhauser and Wolf, 2018). The following are the Picker Institute's eight principles of patient-centered care (Oneview, 2015), based on input from patients, families, and health care experts:

1. Respect for patients' values, preferences, and expressed needs

Engage patients in decision making, recognizing that they are individuals with their own unique values and preferences. Treat patients with dignity, respect, and sensitivity to their cultural values and autonomy.

2. Coordination and integration of care

Coordinate care to reduce patients' feelings of vulnerability: coordinate clinical care, coordinate ancillary and support services, and coordinate frontline patient care.

3. Information and education

Improve communication with patients and families.

- Information on clinical status, progress, and prognosis
- Information on processes of care (e.g., discharge, surgery)
- Information to facilitate autonomy, self-care, and health promotion

4. Physical comfort

Provide physical comfort throughout the care experience, including pain management, assistance with activities of daily living needs, and comforting hospital surroundings and environment.

5. Emotional support and alleviation of fear and anxiety

Professional caregivers should pay attention to patients' fear and anxiety, especially:

- Anxiety over physical status, treatment, and prognosis
- Anxiety over the effect of the illness on themselves and family
- Anxiety over the financial impact of illness

6. Involvement of family and friends

Support family and friends in taking a role in the patient's experience. Family dimensions of patient-centered care include:

- Providing accommodations for family and friends
- Involving family and close friends in decision making
- Supporting family members as caregivers
- Recognizing the needs of family and friends

7. Continuity and transition

Offer support and resources so that patients can care for themselves after discharge or receive the assistance they need.

- Provide understandable, detailed information about topics such as medications, physical limitations, and dietary needs.
- Coordinate and plan treatment and services to continue after discharge.
- Provide information about access to clinical, social, physical, and financial support continually.

8. Access to care

Patients need to know they can access care when it is needed, especially ambulatory care.

- Access to hospitals, clinics, and physician offices
- Availability of transportation
- Ease in scheduling appointments
- Availability of appointments when needed
- Accessibility of specialists or specialty services when a referral is made

- Clear instructions provided on when and how to get referrals

REFLECT NOW

After completing your assigned clinical experience, complete a self-assessment evaluating your use of the principles of patient-centered care. Identify areas that you can improve on for your next clinical assignment.

Building Competency in Patient-Centered Care

Nathan, a new graduate nurse, is assigned to care for a patient who had surgery yesterday for cancer. The plan is for the patient to be discharged home in 2 days. Identify strategies that Nathan can use to meet his patient's expectations.

Magnet Recognition Program®

The American Nurses Credentialing Center (ANCC) established the Magnet Recognition Program® to recognize health care organizations that achieve excellence in nursing practice (ANCC, 2018). Health care organizations that apply for Magnet® status must demonstrate quality patient care, nursing excellence, and innovations in professional practice. The professional work environment needs to allow nurses to practice with a sense of empowerment and autonomy to deliver quality nursing care. The Magnet® Model has five components affected by global issues that are challenging nursing today (ANCC, 2018). The five components are (1) Transformational Leadership, (2) Structural Empowerment, (3) Exemplary Professional Practice, (4) New Knowledge, Innovation, and Improvements,

and (5) Empirical Quality Results (Box 2.6). In Magnet® hospitals, the organizational culture is focused on nurse engagement, commitment to quality improvement, clear strategic direction, shared governance, and trust in leadership (Moss et al., 2017; Underwood and Hayne, 2017). Peer review is often used as a mechanism to improve accountability and foster professional growth (Roberts and Cronin, 2017). Magnet® status requires nurses to collect data on specific nursing-sensitive quality indicators or outcomes and compare their outcomes against a national, state, or regional database to demonstrate quality of care.

Box 2.6 Model and Forces of Magnetism

Magnet® Model Components	Forces of Magnetism
Transformational leadership—A vision for the future and the systems and resources to achieve the vision are created by nursing leaders.	<ul style="list-style-type: none"> • Quality of nursing leadership • Management style
Structural empowerment—Structures and processes provide an innovative environment in which staff are developed and empowered and professional practice flourishes.	<ul style="list-style-type: none"> • Organizational structure • Personnel policies and programs • Community and the health organization • Image of nursing • Professional development
Exemplary professional practice—Strong professional practice is established, and accomplishments of the practice are demonstrated.	<ul style="list-style-type: none"> • Professional models of care • Consultation and resources • Autonomy • Nurses as teachers • Interprofessional relationships
New knowledge, innovations, and improvements—Contributions are made to the profession in the form of new models of care, use of existing knowledge, generation of new knowledge, and contributions to the science of nursing.	<ul style="list-style-type: none"> • Quality improvement
Empirical quality outcomes—Focus is on structure and processes and demonstration of positive clinical, workforce, and patient and organizational outcomes.	<ul style="list-style-type: none"> • Quality of care

Adapted from American Nurses Credentialing Center (ANCC): *Magnet Model*, 2018, <http://www.nursingworld.org/organizational-programs/magnet/magnet-model/>. Accessed August 2018.

Nursing-Sensitive Outcomes

Nursing-sensitive outcomes are patient outcomes and nursing workforce characteristics that are directly related to nursing care, such as changes in patients’ symptom experiences, functional status, safety, psychological distress, RN job satisfaction, total nursing hours per patient day, and costs.

As a nurse you assume accountability and responsibility for achieving and accepting the consequences of these outcomes. Measuring and monitoring nursing-sensitive outcomes reveal the interventions that improve patients' outcomes. Nurses and health care agencies use nursing-sensitive outcomes to improve nurses' workloads, enhance patient safety, and develop sound policies related to nursing practice and health care. The American Nurses Association developed the National Database of Nursing Quality Indicators (NDNQI) to measure and evaluate nursing-sensitive outcomes with the purpose of improving patient safety and quality care ([Press Ganey, 2018](#)). The NDNQI reports quarterly results on nursing outcomes at the nursing unit level. This provides a database for individual hospitals to compare their performance against nursing performance nationally. The evaluation of patient outcomes and nursing workforce characteristics remains important to nursing and the health care delivery system. [Chapter 5](#) describes approaches for measuring outcomes.

Technology in Health Care

Technological advances continually affect health care organizations and change the ways in which nurses deliver evidence-based care to patients. Emerging technologies that will change how nurses practice include genetics and genomics, less invasive and more accurate tools for diagnosis and treatment, 3-D printing, robotics, biometrics, electronic health records (see [Chapter 26](#)), and computerized physician/provider order entry and clinical decision support. Technology makes your work easier in many ways, but it does not replace your judgment. For example, when you manage an IV infusion smart pump, you must monitor the device to ensure that it infuses on schedule and without complications despite its numerous automatic settings. An infusion device infuses at a constant rate, but you must confirm that the rate is calculated correctly. An infusion device sets off an alarm if the infusion slows, making it important for you to respond to the alarm and fix the problem. Technology does not replace a nurse's astute, critical eye and clinical judgment.

Robotics is a form of emerging technology that will greatly impact how nursing is practiced in the future. It is estimated that robotic use will grow due to workforce shortages, a growing elderly population, and a call for higher quality care not subject to human limitations ([Huston, 2013](#); [Simshaw et al., 2016](#)). Most robotic applications are limited to food service, medication distribution, infection control, surgery, and even diagnosing patients ([Maleski, 2014](#)). However, one area with huge potential for

affecting nursing is the use of robots as direct care providers. [Maleski \(2014\)](#) reports that there are daily care robots designed to support older adults and people with disabilities in such activities as preparing and serving meals and in daily care tasks ([Simshaw et al., 2016](#)). In addition, exoskeleton-powered robots are used to help patients who are paralyzed stand, with the goal of reducing morbidity and augmenting physical therapy for patients with impaired extremities. The implications for nursing are significant. Nursing must be on the front line in deciding how robotics is utilized in order to advocate for patients and families and to ensure that professional standards of care are delivered.

Telemedicine is a technology that relies on interactive video; it uses medical information gathered and reviewed at one site (such as a hospital, home, clinic, or urgent care center) and transmits treatment recommendations to another site to improve a patient's clinical health status ([American Telemedicine Association, 2019](#)). There are a variety of applications and services using two-way video, smartphones, wireless tools, and other forms of telecommunications technology. The benefits of telemedicine include providing services that meet patient demand, increasing access to care, and decreasing cost ([American Telemedicine Association, 2019](#)). However, varying federal and state policies on telemedicine use and reimbursement pose an obstacle to wider adoption of this emerging practice ([Young and Kroth, 2018](#)).

Nurses need to play a role in evaluating and implementing new technological advances. You use technology to improve the effectiveness of nursing care, enhance safety, and improve patient outcomes. Most important, it is essential for you to remember that the focus of nursing care is not the machine or the technology; it is the patient. Therefore, you need to constantly attend to and connect with your patients and ensure that their dignity and rights are preserved at all levels of care.

Health Care Disparities

Health care disparities are differences in health care outcomes and dimensions of health care, including access, quality, and equity, among population groups ([Almgren, 2018](#); [Kneipp et al., 2018](#)). Disparities can be related to many variables, such as race, ethnicity, socioeconomic status, gender, location, or disability ([Orgera and Artiga, 2018](#)). Factors such as lack of health insurance, lack of access to care, and poor health outcomes contribute to the disparities for certain groups ([Orgera and Artiga, 2018](#)). Social determinants affect health disparities, the differences in the health

status of different groups of people. Differences in health status, particularly in a community where the majority have poor health, will affect the productivity and vulnerability of a population. The [National Quality Forum \(2018b\)](#) reports that health care disparities have been linked to the following social determinants: inadequate resources, poor patient-provider communication, a lack of culturally competent care (see [Chapter 9](#)), and inadequate access to patient language services, among other factors ([Box 2.7](#)). The health care system and the many professionals who serve patients must address these factors and reduce their effect so that all patients receive needed care. One strategy is to establish and support policies that positively influence social and economic conditions and support changes in individual behavior (such as pursuing healthful diets and adhering to medication regimens).

Box 2.7 Social Determinants of Health

- Availability of resources to meet daily needs (such as safe housing, local food markets, pharmacy)
- Access to educational, economic, and job opportunities
- Access to health care services
- Quality of education and job training
- Availability of community-based resources in support of community living and opportunities for recreational and leisure activities
- Transportation options
- Public safety
- Social support
- Social norms and attitudes (such as discrimination, racism, distrust of health care providers)
- Exposure to crime, violence, and social disorder
- Socioeconomic conditions (such as concentrated poverty and stressful conditions that accompany it)
- Residential segregation
- Language/literacy
- Access to mass media and emerging technologies
- Culture

Adapted from *Healthy People 2020: social determinants of health*, 2018, <https://www.healthypeople.gov/2020/topics-objectives/topic/social-determinants-of-health>. Accessed May 8, 2019.

Healthy People 2020 recognizes that health starts in our homes, schools, workplaces, and communities (2018a). One goal of *Healthy People 2020* is to “create social and physical environments that promote good health for all” ([Healthy People 2020, 2018a](#)). Another important goal is to achieve **health care equity**, or the highest level of health care for all individuals and populations ([Healthy People 2020, 2018b](#)). To achieve health equity, health care disparities and inequalities must be eliminated. Nurses practice in a wide variety of settings that require an awareness of the social determinants of health that contribute to creating health disparities (see [Chapter 9](#)). Social determinants of health impact a person’s health, overall functioning, and quality of life ([Kneipp et al., 2018](#)). Nursing plays a key role in promoting access to health care and in offering appropriate teaching resources to patients and families.

REFLECT NOW

Discuss with your clinical group the social determinants of health impacting the community where you are assigned to complete your clinical experiences. Have these created health disparities in the community?

The Future of Health Care

A discussion of the health care delivery system today is incomplete without discussing the issue of change. The current system is in a constant state of change and reform, making it challenging to try to predict the future (Young and Kroth, 2018). Change is often threatening, but it also opens up opportunities for improvement. The ultimate issue in designing and delivering health care is to ensure the health and welfare of the populations health care institutions serve. Young and Kroth (2018) report that the US health care system is a paradox—extreme successes and technologic advances offset by limited access, high costs, and quality issues. One example of this is the high cost of prescription medications in the United States. Sarnak et al. (2017) reported that the United States had higher prescription drug spending per capita in comparison with nine other high-income countries reviewed. Four factors typically contribute to the spending on prescription drugs for a country. The factors are (1) population numbers and volume of drugs consumed, (2) the amount of drugs used by an individual person, (3) type and mix of drugs prescribed and purchased (e.g., generic drugs versus brand-name drugs), and (4) prices the patient pays at time of purchase (Sarnak et al., 2017). Often patients are uninsured or underinsured and do not have access to necessary services. However, health care organizations are trying to become better prepared to deal with the challenges. Increasingly, they are changing how they provide their services, reducing unnecessary costs, improving access to care, and trying to provide high-quality patient care. Professional nursing is an important player in the future of health care delivery. The solutions necessary to improve the quality of health care depend largely on the active participation of nurses.

Key Points

- Levels of health care describe the scope of services and settings in which health care is delivered to patients in all stages of health and illness.
- The primary level of health care includes medical health care services, health education, nutritional care, maternal/child health care, family planning, and control of diseases.

- Rural Americans' access to health care is affected by economic factors (rural Americans are more likely to live below the poverty level), cultural and social differences, educational shortcomings, lack of recognition of the problem by legislators, and the isolation of living in remote rural areas.
- "Pay for value" ties reimbursement to quality; if hospitals perform poorly in quality scores, they receive lower payments for services. Levels of prevention describe the focus of health-related activities in a care setting. The holistic model of care is used within integrated health care systems and delivers a coordinated continuum of services that supports patients with chronic conditions and improves the health of specific populations.
- Hospitals deliver health care to patients who are acutely ill and need comprehensive specialized secondary and tertiary health care.
- In restorative care settings, nurses know that success depends on their effective and early partnering with patients and their families.
- Discharge planning begins at admission to a health care agency and helps in the transition of a patient's care from one environment to another.
- Barriers to effective discharge planning include ineffective communication, lack of role clarity among health care team members, and lack of resources.
- Nurses promote patient satisfaction through providing patient- and family-centered care and good interpersonal skills, including courtesy, respect, and good communication skills.
- The nursing shortage opens vast opportunities to nurses. Furthering education and following trends in health care open professional options for nurses.

- Social determinants affect health disparities, the differences in the health status of different groups of people in a community. Differences in health status, particularly in a community where the majority have poor health, will affect the productivity and vulnerability of a population.

Reflective Learning

- Investigate whether the clinical unit on which you are assigned displays its patient satisfaction data on the unit. If so, review the data and identify areas that as students you can work on to help improve patient satisfaction. Discuss with your clinical group.
- Select one of the registered nurse competencies identified in [Box 2.5](#). Develop a plan on improving your knowledge, skills, and attitudes for the competency during your upcoming clinical experience.
- Discuss with your clinical group changes in health care that have occurred in the last five years. How have these changes impacted how you practiced nursing today?

Review Questions

1. Which activity performed by a nurse is related to maintaining competency in nursing practice?
 1. Asking another nurse about how to change the settings on a medication pump
 2. Regularly attending unit staff meetings
 3. Participating as a member of the professional nursing council
 4. Attending a review course in preparation for a certification examination

2. Which of the following are examples of a nurse participating in primary care activities? (Select all that apply.)
 1. Providing prenatal teaching on nutrition to a pregnant woman during the first trimester
 2. Assessing the nutritional status of older adults who come to the community center for lunch
 3. Working with patients in a cardiac rehabilitation program
 4. Providing home wound care to a patient
 5. Teaching a class to parents at the local grade school about the importance of immunizations
3. Which of the following statements is true regarding Magnet® status recognition for a hospital?
 1. Nursing is run by a Magnet manager who makes decisions for the nursing units.
 2. Nurses in Magnet hospitals make all of the decisions on the clinical units.
 3. Magnet is a term that is used to describe hospitals that are able to hire the nurses they need.
 4. Magnet is a special designation for hospitals that achieve excellence in nursing practice.
4. Which of the following nursing activities is provided in a secondary health care environment?
 1. Conducting blood pressure screenings for older adults at the Senior Center
 2. Teaching a patient with chronic obstructive pulmonary disease purse-lipped breathing techniques at an outpatient clinic
 3. Changing the postoperative dressing for a patient on a medical-surgical unit
 4. Doing endotracheal suctioning for a patient on a ventilator in the medical intensive care unit

5. A nurse is providing restorative care to a patient following an extended hospitalization for an acute illness. Which of the following is an appropriate goal for restorative care?
 1. Patient will be able to walk 200 feet without shortness of breath.
 2. Wound will heal without signs of infection.
 3. Patient will express concerns related to return to home.
 4. Patient will identify strategies to improve sleep habits.
6. Which of the following describe characteristics of an integrated health care system? (Select all that apply.)
 1. The focus is holistic.
 2. Participating hospitals follow the same model of health care delivery.
 3. The system coordinates a continuum of services.
 4. The focus of health care providers is finding a cure for patients.
 5. Members of the health care team link electronically to use the EMR to share the patient's health care record.
7. The school nurse has been following a 9-year-old student who has shown behavioral problems in class. The student acts out and does not follow teacher instructions. The nurse plans to meet with the student's family to learn more about social determinants of health that might be affecting the student. Which of the following factors would be appropriate for this type of assessment? (Select all that apply.)
 1. The student's seating placement in the classroom
 2. The level of support parents offer when the student completes homework
 3. The level of violence in the family's neighborhood
 4. The age at which the child first began having behavioral problems

5. The cultural values about education held by family
8. A nurse is assigned to care for an 82-year-old patient who will be transferred from the hospital to a rehabilitation center. The patient and her husband have selected the rehabilitation center closest to their home. The nurse learns that the patient will be discharged in 3 days and decides to make the referral on the day of discharge. The nurse reviews the recommendations for physical therapy and applies the information to fall prevention strategies in the hospital. What discharge planning action by the nurse has not been addressed correctly?
 1. Patient and family involvement in referral
 2. Timing of referral
 3. Incorporation of referral discipline recommendations into plan of care
 4. Determination of discharge date
9. Which of the following are common barriers to effective discharge planning? (Select all that apply.)
 1. Ineffective communication among providers
 2. Lack of role clarity among health care team members
 3. Sufficient number of hospital beds to manage patient volume
 4. Patients' long-term disabilities
 5. The patient's cultural background
10. A nurse newly hired at a community hospital learns about intentional hourly rounding during orientation. Which of the following are known evidence-based outcomes from intentional rounding? (Select all that apply.)
 1. Reduction in nurse staffing requirements
 2. Improved patient satisfaction
 3. Reduction in patient falls
 4. Increased costs

5. Reduction in patient call light use

Answers:1.4; 2.1, 2, 5; 3.4; 4.3; 5.1; 6.1, 3, 5; 7.2, 3, 5; 8.2; 9.1, 2; 10.2, 3, 5.

Community-Based Nursing Practice

OBJECTIVES

- Explain the relationship between public health and community health nursing.
- Differentiate community-oriented nursing from community-based nursing.
- Discuss the role of the community health nurse.
- Discuss the role of the nurse in community-based practice.
- Identify characteristics of patients from vulnerable populations that influence the community-based nurse's approach to care.
- Describe the competencies important for success in community-based nursing practice.
- Describe elements of a community assessment.

KEY TERMS

Community-based nursing, p. 34

Community health nursing, p. 34

Community-oriented nursing, p. 34

Incident rates, p. 33

Population, p. 34

Public health nursing, p. 34

Social determinants of health, p. 33

Vulnerable populations, p. 35

Community-based care focuses on health promotion, disease prevention, and restorative care. Patients are often discharged quickly from acute care settings, requiring continued care outside traditional settings. These patients also require preventive care such as immunizations, screenings, lifestyle teaching, and counseling. Health care delivery has changed greatly over the past few decades, resulting in a growing need to provide health care services where people live, work, socialize, and learn. One way to achieve this goal is through a community-based health care model. Community-based health care is a collaborative, patient-centered approach to provide culturally appropriate health care within a community ([Centers for Medicare & Medicaid Services \[CMS\], 2017](#)). A healthy community includes elements that maintain a high quality of life and productivity such as access to health services, preventive care, nutrition, safety, physical activity, oral health, and environmental quality ([Office of Disease Prevention and Health Promotion \[ODPHP\], 2018d](#)). Including interventions that address both mental and physical health is essential for community health programs ([CDC, 2016](#)). Nurses directly influence the health and well-being of patients every day and can encourage lifestyle changes within communities ([American Nurses Association \[ANA\], n.d.](#)). As more community health care partnerships develop, nurses are in a strategic position to play an important role in health care delivery and to improve the health of the community.

The focus of health promotion and disease prevention continues to be essential for the holistic practice of professional nursing. Historically, nurses have established and met the public health needs of their patients. Within community health settings, nurses continue to be leaders in assessing, diagnosing, planning, implementing, and evaluating the types of public and community health services needed. Community health nursing and community-based nursing are components of a health care delivery system that improve the health of the general public.

Community-Based Health Care

Regardless of where you practice nursing, you need to understand the focus of community-based health care. Community-based health care is a model of care that reaches everyone in a community (including the poor and underinsured), focuses on primary rather than institutional or acute care, and provides knowledge about health and health promotion and models of care to the community. Community-based health care occurs outside traditional health care institutions such as hospitals. It provides services to individuals and families within the community for acute and chronic conditions (Stanhope and Lancaster, 2018). Providing care in nontraditional settings such as ambulatory care clinics, community hospice centers, senior centers, parishes, and schools allows those who would not be able to access care in other areas to receive the care they need. Providing necessary care to maintain and restore health decreases vulnerability in at-risk populations.

Today the challenges in community-based health care are numerous. Political policy, social determinants of health, increases in health disparities, and economics all influence public health problems and subsequent health care services. Some of these problems include a lack of adequate health insurance, chronic illnesses (e.g., heart disease and diabetes), substance abuse, an increase in sexually transmitted infections, and underimmunization of infants and children (ODPHP, 2018d). Today's leaders in the health care system must commit to reform and bring attention to health promotion and disease prevention and provide health care services to all communities. Many community health programs are trying to decrease disparity by addressing ways to improve quality of care, access to care, and cost (ODPHP, 2018d).

Achieving Healthy Populations and Communities

The USDHHS Public Health Service designed a program to improve the overall health status of people living in this country. The *Healthy People Initiative* was created to establish ongoing health care goals for the US population (see Chapter 6) to meet the diverse public health needs that exist and to seize opportunities to achieve its goals. Health of the nation is tracked and goals are updated every 10 years based on data gathered during program evaluation and national health trends. *Healthy People* has become a broad-based public engagement initiative, with thousands of citizens helping to shape it at every step along the way. The overall goals

of *Healthy People 2020* are to increase life expectancy and quality of life and eliminate health disparities through improved delivery of health care services (ODPHP, 2018a). Improved delivery of health care involves three key components: assessment, development and implementation of public health policies, and improved access to care.

Assessment of health care needs of individuals, families, and communities is the first component. Assessment includes systematic data collection on the population, monitoring the health status of the population, and accessing available information about the health of the community (Stanhope and Lancaster, 2018). Some examples of community assessment include gathering information on **incident rates**, such as identifying and reporting new infections or diseases, determining adolescent pregnancy rates, and reporting the number of motor vehicle accidents caused by teenage drivers. A comprehensive community assessment informs the development and maintenance of community health programs aimed at infection control, adolescent sex education, or ways to reduce distractions for teen drivers.

The second component of improved health care delivery is policy. Health professionals provide leadership in developing public policies to support the health of the population (Stanhope and Lancaster, 2018). Strong policies are driven by community assessment. For example, assessing the level of lead poisoning in young children often leads to a lead cleanup program to reduce the incidence of lead poisoning. This is the case in Flint, Michigan. Nurses were instrumental as case managers for children exposed to lead but also led public health efforts to lobby for and educate about water filtration and ways to prevent further exposure to lead (Kennedy et al., 2016). Nurses also play an important role in advocating and educating about the nation's opioid epidemic. Nurses can lobby for strict prescription monitoring programs, as well as make referrals and implement evidence-based substance abuse or pain relief treatments to reduce the abuse of opioids (Davis et al., 2015). Identifying evidence-based practices to help people manage chronic illnesses in the home and the community addresses the needs of nurses and their patients (Croft et al., 2018).

The last component of improved health care delivery is access to care. Improved access to care ensures that essential community-wide health services are available and accessible to the entire community (Stanhope and Lancaster, 2018). Insurance coverage, geographic availability of care, and developing relationships with health care providers are essential in establishing access to community-wide health promotion and health

maintenance activities ([ODPHP, 2018d](#)). Examples include prenatal care programs and programs focusing on disease prevention, health protection, and health promotion. The five-level health services pyramid is an example of how to provide community-based services within existing health care services in a community ([Fig. 3.1](#)). In this population-focused health care services model, the goals of disease prevention, health protection, and health promotion provide a foundation for primary, secondary, and tertiary health care services.

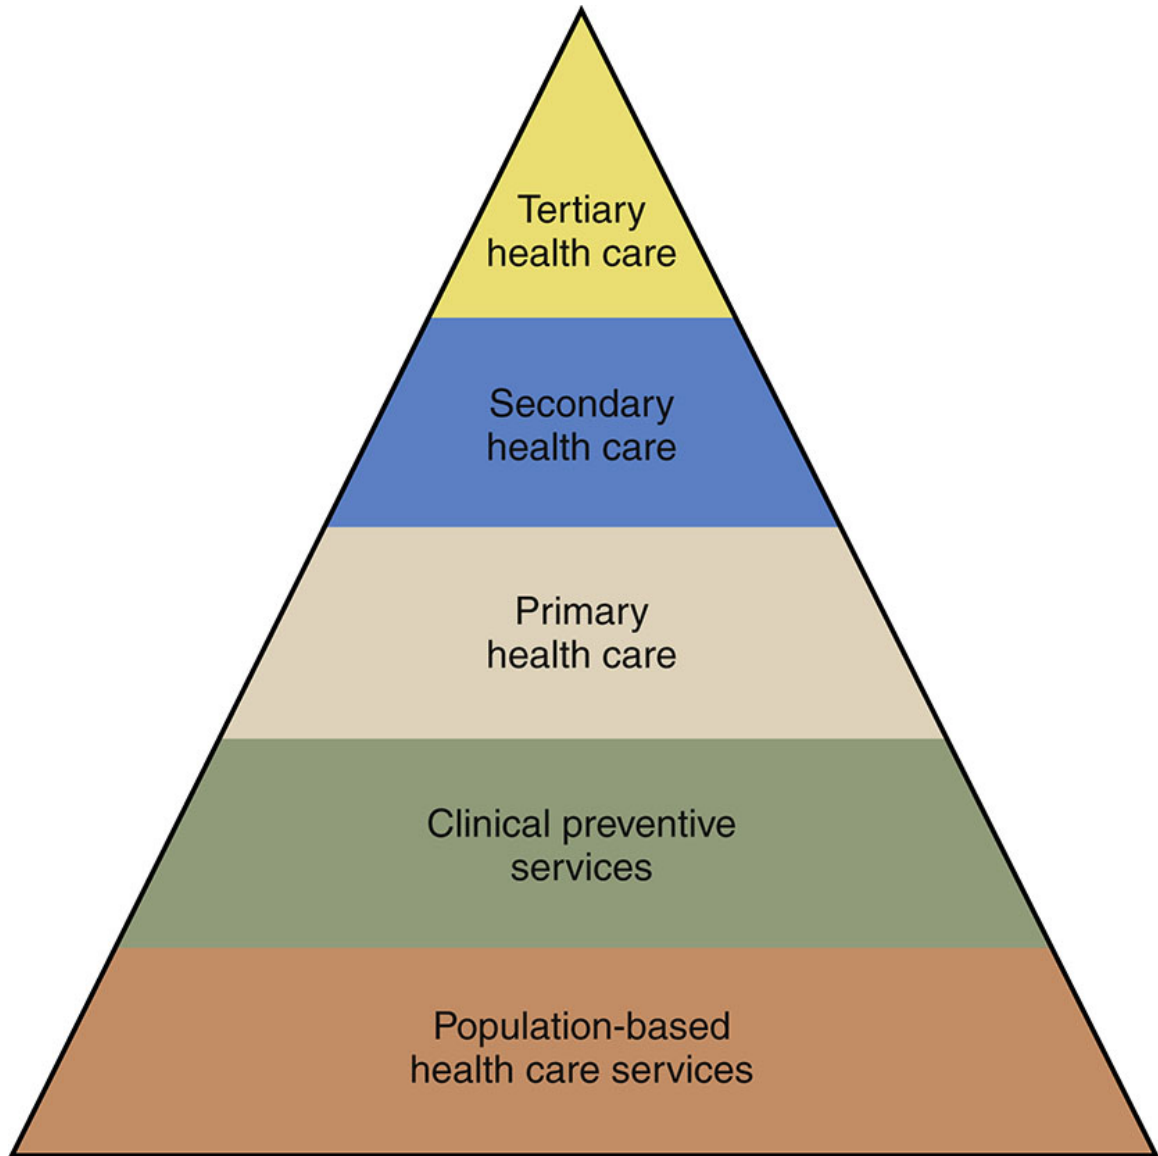

FIG. 3.1 Health services pyramid.
Courtesy US Public Health Service: For a healthy nation: return on investments in public health, Washington DC, 2008, USDHHS.

A rural community does not always have a hospital to meet the acute care needs of its citizens. However, the community may have the resources for providing childhood immunizations, flu vaccines, and primary preventive care services and is able to focus on child developmental problems and child safety. For example, a nurse completing a community assessment identifies services available to meet the needs of expectant mothers, reduce teenage smoking, and provide nutritional support for older adults. In addition, the nurse also identifies the health care gaps for the community. Community-based programs provide needed services and

are effective in improving the health of the community by ensuring that members of the community are aware of the resources that are available.

Public health services aim at achieving a healthy environment for all individuals. Health care providers apply these principles for individuals, families, and the communities in which they live. Nursing plays a role in all levels of the health services pyramid. By using public health principles, you are better able to understand the types of environments in which patients live and the interventions necessary to help keep them healthy.

Social Determinants of Health

Our health is determined in part by access to social and economic opportunities; the resources and support systems available in our homes, neighborhoods, and communities; the quality of our schooling; the safety of our workplaces; the cleanliness of our water, food, and air; and the nature of our social interactions and relationships.

Health starts in our homes, schools, workplaces, neighborhoods, and communities. We know that taking care of ourselves by eating well and staying active, not smoking, getting the recommended immunizations and screening tests, and seeing a doctor when we are sick all influence our health. However, there are also social determinants of health. **Social determinants of health** are biological, socioeconomic, psychosocial, behavioral, or social factors that contribute to a person's current state of health (CDC, 2018c). *Healthy People 2020* lists five determinants of health: biology and genetics (sex and age), individual behavior (such as alcohol, injection drug use, unprotected sex, and smoking), social environment (such as discrimination, income, and gender), physical environment (where a person lives or crowding conditions), and health services (such as access to quality health care and having health insurance) (ODPHP, 2018c). Whether these factors affect a single family or the community, they impact the overall health and wellness of that community (see Chapter 2).

Health Disparities

Health disparities negatively affect groups of people who have systematically experienced social or economic obstacles to health. These obstacles stem from characteristics historically linked to discrimination or exclusion such as race or ethnicity, religion, socioeconomic status, gender, mental health, sexual orientation, or geographic location. Other characteristics include cognitive, sensory, or physical disability.

Health disparities are preventable differences in a population's ability to achieve optimal health. Disparity exists if health outcomes vary by population. Populations can be disadvantaged by the burden of disease, injury, violence, or opportunities to achieve optimal health due to social, political, economic, or environmental resources ([ODPHP, 2018b](#)). Disparity is multifactorial, including poverty, environmental threats, inadequate access to health care, individual and behavioral factors, and educational inequalities ([ODPHP, 2018b](#)).

REFLECT NOW

Consider the community in which your nursing program is located. What are some health disparities that are present within your community?

Community-oriented nursing

Frequently the terms *community health nursing* and *public health nursing* are used interchangeably and fall under the umbrella term *community-oriented nursing*. **Community health nursing** is nursing practice in the community, with the primary focus on the health care of individuals, families, and groups within the community. The goal is to preserve, protect, promote, or maintain health (Stanhope and Lancaster, 2018). The emphasis of such nursing care is to improve the quality of health and life within a community. **Public health nursing** is a nursing specialty that requires understanding the needs of a **population** or a collection of individuals who have one or more personal or environmental characteristics in common (Stanhope and Lancaster, 2018). Examples of populations include high-risk infants, older adults, or an ethnic group such as Native Americans. A public health nurse understands factors that influence health promotion and health maintenance, the trends and patterns influencing the incidence of disease within populations, environmental factors contributing to health and illness, and the political processes that affect public policy. For example, a public health nurse uses data on increased incidence of playground injuries to lobby for a policy to use shock-absorbing material rather than concrete for new public playgrounds.

The community health nurse may also provide direct care services to subpopulations within a community. These subpopulations often have a clinical focus in which the nurse has expertise. For example, a case manager follows older adults recovering from stroke and sees the need for community rehabilitation services, or a nurse practitioner gives immunizations to patients with the objective of managing communicable disease within the community. By focusing on subpopulations, a community health nurse cares for the community and considers an individual or family as only one member of a group at risk. In summary, the focus of **community-oriented nursing** is on health promotion, disease prevention, and improving quality of life of the population (Stanhope and Lancaster, 2018).

Public health nurses are sometimes required to have a baccalaureate degree in nursing educational preparation and clinical practice in public health nursing. A specialist in public health has a graduate-level education with a focus in the public health sciences (ANA, 2014). Competence as a community health nurse requires the ability to use interventions that include the broad social and political context of the community (Stanhope and Lancaster, 2018). The educational requirements for entry-level nurses

practicing in community health nursing roles are not as clear as those for public health nurses. Not all hiring agencies require an advanced degree. However, nurses with a graduate degree in nursing who practice in community settings are considered community health nurse specialists, regardless of their public health experience ([Stanhope and Lancaster, 2018](#)).

Nursing Practice in Community Health

Community health nursing practice requires a unique set of skills and knowledge. In the health care delivery system, nurses who become experts in community health practice usually have advanced nursing degrees, yet the baccalaureate-prepared nurse generalist is also able to formulate and apply population-focused assessments and interventions. The expert community health nurse understands the needs of a population or community through experience with individual families or populations, which includes working through their social and health care issues. In this context, critical thinking involves applying knowledge of public health principles, community health nursing, family theory, and communication in finding the best approaches to partner with families.

Successful community health nursing practice involves building relationships with the community and being responsive to changes within the community. For example, when there is an increase in the incidence of grandparents assuming child care responsibilities, a community health nurse becomes an active part of a community by establishing an educational program in cooperation with local schools to assist and support grandparents in this caregiving role. The nurse knows the community members, along with their needs and resources, and works in collaboration with community leaders to establish effective health promotion and disease prevention programs. This requires working with highly resistant systems (e.g., welfare system) and trying to encourage them to be more responsive to the needs of a population. Skills of patient advocacy, communicating people's concerns, and designing new systems in cooperation with existing systems help to make community nursing practice effective.

Community-based nursing

Community-based nursing care takes place in community settings such as a home or clinic, where nurses focus on the needs of an individual or family. It involves the safety needs and acute and chronic care of individuals and families, enhances their capacity for self-care, and promotes autonomy in decision making (Stanhope and Lancaster, 2018). Community-based nurses tend to provide illness care within the community setting (Stanhope and Lancaster, 2018). It requires critical thinking and decision making for the individual patient and family—assessing health status, diagnosing health problems, planning care, implementing interventions, and evaluating outcomes of care. Because nurses provide direct care services where patients live, work, and play, it is important that they place the perspectives of the community members first and foremost when planning care (Stanhope and Lancaster, 2018). This is an example of population-focused care where community is the client.

Community-based nursing centers function as the first level of contact between members of a community and the health care delivery system (Fig. 3.2). Ideally health care services are provided near where patients live, work, and socialize. This approach helps to reduce the cost of health care for the patient and the stress associated with the financial burdens of care. In addition, these centers offer direct access to nurses and comprehensive patient-centered health services and readily incorporate the patient and the patient's family or friends into a plan of care. Community-based nursing centers often care for the most vulnerable of the population (Stanhope and Lancaster, 2018).

FIG. 3.2 Patient and family receiving care in a community-based care center.

Courtesy Mass Communication Specialist 2nd Class Daniel Viramontes.

With the individual and family as the patients, the context of community-based nursing is family-centered care within the community. This focus requires a strong knowledge base in family theory (see [Chapter 10](#)), principles of communication (see [Chapter 24](#)), group dynamics, and cultural diversity (see [Chapter 9](#)). Nurses partner with their patients and families to enable them to ultimately assume responsibility for their health care decisions.

Vulnerable Populations

Nurses care for patients from diverse cultures and backgrounds and with various health conditions. Changes in the health care delivery system have made high-risk groups the principal patients. For example, you are not likely to visit low-risk mothers and babies. Instead, you are more likely to visit adolescent mothers or mothers with drug addiction. **Vulnerable populations** are groups of patients who are more likely to develop health problems as a result of excess health risks, who are limited in access to health care services, or who depend on others for care. Vulnerable populations include those living in poverty, older adults, the disabled, people who are homeless, immigrants, individuals in abusive relationships, people living with substance abuse, and people with mental illnesses. These vulnerabilities are often associated with the

individual's/community's social determinants of health or individual health disparities.

Public and community health nursing and primary care providers share health care responsibility for health promotion, screening, and early detection and disease prevention for vulnerable populations. These patients have intense health care needs that are unmet or ignored or require more care than can be provided in outpatient or hospital settings. Individuals and their families who are vulnerable often belong to more than one of these groups. In addition, health care vulnerability affects all age-groups (Stanhope and Lancaster, 2018).

Patients who are vulnerable often come from various cultures, have different beliefs and values, face language and literacy barriers, or have few sources of social support. These diverse needs will be challenging as you care for patients with increasingly complex acute and chronic health conditions. To provide competent care for vulnerable populations, you need to assess these patients accurately (Box 3.1). In addition, you need to evaluate and understand a patient's and family's cultural beliefs, values, and practices to determine their specific needs and the interventions that will be most successful in improving their state of health (see Chapter 9). It is important not to judge or evaluate your patient's beliefs and values about health in terms of your own culture, beliefs, and values. Communication and caring practices are critical in learning a patient's perceptions of his or her problems and then planning health care strategies that will be meaningful, culturally appropriate, and successful.

Box 3.1 Guidelines for Assessing Members of Vulnerable Population Groups

Setting the Stage

- Create a comfortable, nonthreatening environment.
- Obtain information about a patient's culture so that you understand the practices, beliefs, and values that affect the patient's health care.
- If the patient speaks a different language, use a professional interpreter and observe nonverbal behavior to complete a culturally competent assessment (see Chapter 9).
- Be sensitive to the fact that patients often have priorities other than their health care (e.g., financial, legal, or social issues). Help them

with these concerns before beginning a health assessment. If a patient needs financial assistance, consult a social worker. If there are legal issues, provide the patient with a resource. Do not attempt to provide financial or legal advice yourself.

Nursing History of an Individual or Family

- Because you often have only one opportunity to conduct a nursing history, obtain an organized history of all essential information to help an individual or family during that visit.
- Collect data that focus on the specific needs of the vulnerable population with whom you work. However, be flexible so as not to overlook important health information. For example, when with a mother who is an adolescent, obtain a nutritional history on both the mother and baby. Be aware of the developmental needs of the young mother, and listen to her social needs as well.
- Identify both developmental and health care needs. Remember, the goal is to collect enough information to provide family-centered care.
- Identify any risks to the patient's immune system. This is especially important for vulnerable patients who are homeless and sleep in shelters.

Physical Examination and Home Assessment

- Complete a thorough physical and/or home assessment. Only collect data that are relevant to providing care to the patient and family.
- Be alert for signs of physical abuse, substance abuse, or neglect (e.g., inadequately clothed, underweight).
- When assessing a patient's home, observe: Is there adequate water and plumbing? What is the status of the utilities? Are foods and perishables stored properly? Are there signs of insects or vermin? Is the paint peeling? Are the windows and doors adequate? Are there water stains on the ceiling, evidence of a leaky roof? What is the temperature? Is it comfortable? What does the outside environment look like: Are there vacant houses/lots nearby? Is there a busy intersection? What is the crime level?

Modified from Stanhope M, Lancaster J: *Foundations for population health in community/public health nursing*, ed 5, St Louis, 2018, Mosby.

Barriers to access and use of services often lead to adverse health outcomes for vulnerable populations (ODPHP, 2018b). Because of these poorer outcomes, vulnerable populations have shorter life spans and higher morbidity rates. Members of vulnerable groups frequently have multiple risk factors, resulting in cumulative effects of individual risk factors. It is essential for community-based nurses to assess members of vulnerable populations by considering the multiple stressors that affect their patients' lives. It is also important to learn patients' strengths and resources for coping with stressors. Complete assessment of vulnerable populations enables a community-based nurse to design interventions within the context of the patient's community (Stanhope and Lancaster, 2018).

Immigrant Population

The CDC (2018b) predicts a continued increase in the immigrant population. This continued growth creates many social and health care needs. Social problems involved with immigration sometimes include poverty, acculturation, education, housing, and employment. Some immigrant populations face multiple diverse health issues that cities, counties, and states need to address. These health care needs pose significant legal and policy issues. For some immigrants, access to health care is limited because of language barriers and/or lack of benefits, resources, and transportation. Immigrant populations often have higher rates of hypertension, diabetes mellitus, and infectious diseases; decreased outcomes of care; and shorter life expectancies (Stanhope and Lancaster, 2018).

Frequently patients from immigrant populations practice nontraditional healing practices (see Chapter 9). Although many of these healing practices are effective and complement traditional therapies, it is important that you know how the therapies act physically and understand your patient's health beliefs about these healing practices.

Certain immigrant populations left their homes as a result of oppression, war, or natural disaster. You must be sensitive to these physical and psychological stressors and identify the appropriate resources to help your patients meet their health care needs (Stanhope and Lancaster, 2018).

Effects of Poverty and Homelessness

People who live in poverty are more likely to have more health disparities because they are at a higher risk of living in hazardous environments, working at high-risk jobs, eating less nutritious diets, having multiple stressors in their lives, lacking adequate transportation, and being homeless. Patients who are experiencing homelessness have even fewer resources than people who are poor. They are often jobless, do not have the advantage of a permanent shelter, and must continually cope with finding food and a place to sleep at night. Chronic health problems tend to worsen because of poor nutrition and the inability to store nutritional foods. In addition, people who are experiencing homelessness usually have barriers to accessing health care, causing them to seek health care in emergency departments ([American Public Health Association \[APHA\], 2017](#)).

REFLECT NOW

What health care resources are available to help the homeless and those living in poverty within your community? How can you participate in providing health care to these vulnerable groups?

Patients Who Are Abused

Physical, emotional, and sexual abuse and neglect are major public health problems that often affect older adults, women, and children. Risk factors for abusive relationships include mental health problems, substance abuse, socioeconomic stressors, lack of understanding of child development or parenting skills, and dysfunctional family relationships ([CDC, 2018a](#)). For some, risk factors may not be present. When dealing with patients at risk for or who have suffered abuse, it is important to provide protection. Interview a patient you suspect is abused at a time when the patient has privacy and the individual suspected of being the abuser is not present. Patients who are abused may fear retribution if they discuss their problems with a health care provider. Nurses must use therapeutic

communication techniques that reinforce that the abuse is not the victim's fault. Nurses are mandatory reporters for abuse involving elders over the age of 65, children under the age of 18, and disabled individuals.

Patients With Mental Illness

Patients with severe mental illness such as schizophrenia or bipolar disorder may experience multiple health and socioeconomic problems. Many patients with severe mental illnesses are homeless or live in poverty and lack the ability to remain employed or to care for themselves on a daily basis (APHA, 2015). Patients who have a mental illness often require medication therapy, counseling, housing, and vocational assistance. In addition, they are at a greater risk for abuse and assault. Patients with mental illnesses are no longer routinely hospitalized in long-term psychiatric institutions. Instead, resources are offered within the community. Although comprehensive service networks may be available in the community, many patients still go untreated or undertreated because of an inability to navigate the health care system (Stanhope and Lancaster, 2018).

Older Adults

The older adult population is increasing, resulting in simultaneous increases in the number of patients suffering from chronic diseases and a greater demand for health care services. Take time to understand what health means to an older adult and which assessment findings to expect; view health promotion in the older adult within a broad context (see Chapter 14). Help older adults and their families understand which steps they need to take to maintain their health and improve their level of function through physical activity (APHA, 2015). Design appropriate community-based interventions that provide an opportunity to improve the lifestyle and quality of life of older adults (Table 3.1).

TABLE 3.1**Major Health Problems in Older Adults and Community-Based Nursing Roles and Interventions**

Problem	Community-Based Nursing Roles and Interventions
Hypertension	Monitor blood pressure and weight; educate about nutrition and antihypertensive drugs; teach stress management techniques; promote a good balance between rest and activity; establish blood pressure screening programs; assess patient's current lifestyle and promote lifestyle changes; promote dietary modifications by using techniques such as a diet diary.
Cancer	Obtain health history; promote monthly breast self-examinations and recommended screening intervals for Papanicolaou (Pap) smears and mammograms for older women; promote colorectal screening; promote regular physical examinations; encourage smokers to stop smoking; correct misconceptions about processes of aging; provide emotional support and quality of care during diagnostic and treatment procedures.
Arthritis	Educate about management of activities, reducing stress on affected joints, availability of mechanical appliances, and adequate rest; promote stress management; counsel and assist the family to improve communication, role negotiation, and use of community resources.
Visual impairment (e.g., loss of visual acuity, eyelid disorders, opacity of the lens)	Provide support in a well-lighted, glare-free environment; use printed aids with large, well-spaced letters; help adult clean eyeglasses; help make arrangements for vision examinations and obtain necessary prostheses.
Hearing impairment (e.g., presbycusis)	Speak with clarity at a moderate volume and pace, and face audience when performing health teaching; help make arrangements for hearing examination and obtain necessary prostheses; teach how to care for hearing aids.
Cognitive impairment	Provide complete assessment; correct underlying causes of impairment (if possible); provide for a protective environment; promote activities that reinforce reality; help with personal hygiene, nutrition, and hydration; provide emotional support to the family; recommend applicable community resources such as adult day care, home care aides, and homemaker services.
Dementia	Maintain high-level functioning, protection, and safety; encourage human dignity; demonstrate to the primary family caregiver techniques to dress, feed, and toilet adult; provide frequent encouragement and emotional support to caregiver; act as an advocate for patient when dealing with respite care and support groups; protect the patient's rights; provide caregiver support to maintain family members' physical and mental health and to prevent caregiver role strain; maintain family stability; recommend financial services if needed.
Dental problems	Perform oral assessment and refer to dentist as necessary; emphasize regular brushing and flossing, proper nutrition, and dental examinations; encourage patients with dentures to wear and take care of them; calm fears about dentist; help provide access to financial services (if necessary) and dental care resources.
Substance and alcohol abuse	Get drug use history; educate about safe storage, risks for drug, drug-drug, drug-alcohol, and drug-food interactions; give general information about drug (e.g., drug name, purpose, side effects, dosage); instruct adult about presorting techniques (using small containers with one dose of drug that are labeled with specific times to take drug). Counsel adults about substance abuse; promote stress management to avoid need for drugs or alcohol and arrange for and monitor detoxification if appropriate. Provide community resources for substance abuse treatment.
Sexually transmitted infections	Perform a full sexual risk assessment and bring awareness regarding risk factors and susceptibility to human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS). Educate about safe sexual practices such as abstinence or use of condoms, and refer as necessary for HIV and other infection testing and HPV immunization.

Accessed May 20, 2019; Centers for Disease Control and Prevention (CDC): *Health information for older adults*, 2018, <https://www.cdc.gov/aging/aginginfo/index.htm>. Accessed May 20, 2019.

Competency in Community-Based Nursing

A nurse in community-based practice needs a variety of skills and talents to be successful. In addition to assisting patients with their health care needs and developing relationships within the community, the community-based nurse needs skills in health promotion and disease prevention. Nurses use the nursing process and critical thinking (see Unit III) to ensure individualized nursing care for specific patients and their families. Students' clinical practice in a community-based care setting will probably be in partnership with a community nurse.

Caregiver

First and foremost a nurse is a caregiver (see [Chapter 1](#)). In the community setting you manage and care for the health of patients and families in the community. Use a critical thinking approach to apply the nursing process (see Unit III) and ensure appropriate, individualized nursing care for your patients and their families.

Historically, well-baby and child care was integral to community nursing practices. Community child care services are increasing to address changes in the health care delivery system, changing economics, homelessness, and the increased number of people who are medically underinsured. Community nurses are undertaking more complex and expanded child health services for increasingly diverse client populations ([ODPHP, 2018e](#)).

In addition, the community nurse must individualize care within the context of a patient's community so that long-term success is more likely. Together with a patient and family you develop a caring partnership to recognize actual and potential health care needs and identify needed community resources. For example, if a patient is placed on an exercise program, you recommend a safe park or recreational area where the patient can exercise. Competent community-based practice builds healthy communities that are safe and include elements to enable people to achieve and maintain a high quality of life.

Building Competency in Safety

Maria Perez is a 74-year-old widow with heart failure (HF) who has been referred to the Home Care Agency for services. Maria has been admitted to the hospital three times in the past two months. Two admissions were

for HF exacerbation and the other was for a fractured wrist after falling in the bathroom. Maria lives alone in a senior housing apartment building that has an elevator. The hospitalist requests a home safety evaluation, along with assessment of medication management. What information does the nurse need to begin this assessment?

Case Manager

In community-based practice, case management is an important competency (see [Chapter 2](#)). Case managers establish an appropriate plan of care based on assessment of patients and families and coordinate needed resources and services for a patient's well-being across a continuum of care. Generally, a community-based case manager assumes responsibility for the case management of multiple patients. The greatest challenge is to coordinate the activities of multiple providers and payers in different settings throughout a patient's continuum of care. An effective case manager eventually learns the obstacles, limits, and even the opportunities that exist within the community that influence the ability to find solutions for patients' health care needs.

Change Agent

A community-based nurse is also a change agent. This involves identifying and implementing new and more effective approaches to problems. You act as a change agent within a family system or as a mediator for problems within a patient's community. You identify any number of problems (e.g., quality of community child care services, availability of older-adult day care services, or the status of neighborhood violence). As a change agent you empower individuals and their families to creatively solve problems or become instrumental in creating change within a health care agency. For example, if your patient has difficulty keeping regular health care visits, you determine why. Maybe the health clinic is too far and difficult to reach, or perhaps the hours of service are incompatible with a patient's transportation resources. You work with the patient to solve the problem and help identify an alternative site such as a nursing clinic that is closer and has more convenient hours.

To effect change, you gather and analyze facts before you implement programs to help people make changes to improve their health. This requires you to be very familiar with the community itself. Many communities resist change, preferring to provide services in the established manner. Before analyzing facts, it is often necessary to manage

conflict among the health care providers, clarify their roles, and clearly identify the needs of the patients. If the community has a history of poor problem solving, you will have to focus on developing problem-solving capabilities ([Stanhope and Lancaster, 2018](#)).

Patient Advocate

Patient advocacy is important in community-based practice mainly because of the confusion surrounding access to health care services. Patients often need someone to help them walk through the system and identify where to go for services, how to reach individuals with the appropriate authority, which services to request, and how to follow through with the information they receive. As a patient advocate, you ensure patients have the information necessary to make informed decisions in choosing and using services appropriately. In addition, it is important for you to support and at times defend your patients' decisions.

Collaborator

Community-based nursing practice requires you to be competent in communicating and working with patients, their families, and other members of the health care team. Collaboration, or working in a combined effort with all those involved in care delivery, is necessary to develop a mutually acceptable plan that will achieve common goals ([Stanhope and Lancaster, 2018](#)). For example, when your patient is discharged home with terminal cancer, you collaborate with hospice staff, social workers, and pastoral care to initiate a plan to support interprofessional end-of-life care for the patient in the home and support the family. For collaboration to be effective, you need mutual trust and respect for each professional's roles, abilities, and contributions.

Counselor

To be an effective counselor, you need to be aware of a patient's community resources (e.g., mental health clinics, day care services, respite care). A counselor helps patients identify and clarify health problems as well as choose appropriate courses of action to solve those problems. For example, if you are a nurse in an employee-assistance program or a women's shelter, you will often assume the role of counselor with your patients. As a counselor, you are responsible for providing information; listening objectively; and being supportive, caring, and trustworthy. You do not make decisions but rather help your patients reach decisions that

are best for them ([Stanhope and Lancaster, 2018](#)). Patients and families often require assistance in first identifying and clarifying health problems. For example, a patient who repeatedly reports a problem in following a prescribed diet is unable to afford nutritious foods or has family members who do not support healthy eating habits. You discuss with your patient factors that block or aid problem resolution, identify a range of solutions, and then discuss which solutions are most likely to be successful. You also encourage your patient to make decisions and express your confidence in the choice the patient makes.

Educator

Patient education is often a priority in community-based nursing. Become familiar with community service organizations that offer educational support to a wide range of individuals and patient groups. Prenatal classes, infant care, child safety, and cancer screening are just some of the health education programs provided in a community.

When the goal is to help your patients assume responsibility for their own health care, being an educator takes on greater importance ([Stanhope and Lancaster, 2018](#)). Patients and families need to gain skills and knowledge to care for themselves. Assess your patient's learning needs and readiness to learn within the context of the individual, the systems with which the individual interacts (e.g., family, business, and school), and the resources available for support. Adapt your teaching skills so you can instruct a patient within the home setting and make the learning process meaningful. Community-based nursing gives you the opportunity to follow patients over time. Planning for return demonstration of skills, using follow-up phone calls, and referring to community support and self-help groups give you an opportunity to provide continuity of instruction and reinforce important instructional topics and learned behaviors (see [Chapter 25](#)).

Epidemiologist

As a community-based nurse, you apply principles of epidemiology, the science dealing with the incidence, distribution, and possible control of diseases and other health problems. Your contacts with families, community groups such as schools and industries, and health care agencies place you in a unique position to initiate epidemiological activities, such as case finding, health teaching, and tracking incident rates of an illness. For example, a cafeteria worker in the local high school is

diagnosed with active tuberculosis (TB). As a community health nurse, you help find where the exposure to TB may have occurred, such as within the worker's home, place of employment, or community.

Nurse epidemiologists are responsible for community surveillance (e.g., tracking incidence of elevated lead levels in children and identifying increased fetal and infant mortality rates, increases in adolescent pregnancy, presence of infectious and communicable diseases, and outbreaks of head lice). Nurse epidemiologists protect the level of health of the community, develop sensitivity to changes in the health status of the community, and help identify the cause of these changes.

Community Assessment

When practicing in a community setting, you need to learn how to assess the community at large. Community assessment is the systematic data collection on the population, monitoring the health status of the population, and making information available about the health of the community (Stanhope and Lancaster, 2018). This is the environment in which patients live, work, play, and learn. Without an adequate understanding of that environment, any effort to promote a patient's health and bring about necessary change is unlikely to be successful. The community has three components: structure or locale, the people, and the social systems. To develop a complete community assessment, take a careful look at each of the three components to identify needs for health policy, health programs, and needed health services (Box 3.2).

Box 3.2 Community Assessment

Structure

- Name of community or neighborhood
- Geographical boundaries
- Emergency services
- Water and sanitation
- Housing
- Economic status (e.g., average household income, number of residents on public assistance)
- Transportation
- Safety

Population

- Age distribution
- Sex distribution
- Growth trends
- Density

- Education level
- Predominant ethnic groups
- Predominant religious groups

Social System

- Educational system
- Government
- Communication system
- Welfare system
- Volunteer programs
- Health system

When assessing the structure or locale, you travel around the neighborhood or community and observe its design, the location of services, and where residents meet. As you assess the physical environment, you look for possible environmental hazards in the air, water, or soil, as well as safety issues, such as abandoned buildings, a lack of sidewalks, or roads that are in poor repair. You obtain the demographics of the population by accessing statistics on the community from reliable websites, a local public health department or public library. You acquire information about existing social systems such as schools or health care agencies by visiting various sites and learning about their services.

Once you have a good understanding of the community, you can perform all individual patient assessments against that background. For example, when assessing a patient's home for safety, you consider the following: Does the patient have secure locks on doors? Are windows secure and intact? Is lighting along walkways and entryways operational? As you conduct a patient assessment, it is important to know the level of community violence and the resources available when help is necessary. Always assess an individual in the context of the community.

REFLECT NOW

Complete a community assessment in the area surrounding your nursing program. What are the demographics of the population? What social systems exist within the community?

Changing patients' health

In community-based practice, nurses care for patients from diverse backgrounds and in diverse settings. It is relatively easy over time to become familiar with the available resources within a community practice setting. Likewise, with practice you learn how to identify the unique needs of individual patients. Similarly, you bring together the resources necessary to improve a patient's continuity of care. When you collaborate with your patients and their health care providers, you provide patient-centered care and help reduce duplication of health care services. For example, when caring for a patient with a healing wound, you coordinate wound care services and help the patient and family locate cost-effective dressing materials.

You need to promote and protect a patient's health within the context of the community using an evidence-based practice approach when possible. For example, nurses can help reduce health disparities surrounding childhood obesity in racial/ethnic minority populations through community engagement (Frerichs et al., 2018; Luesse et al., 2018; Subica et al., 2016) (Box 3.3). Frerichs et al. (2018) investigated the effect of an evidence-based community approach to develop strategies to support reducing obesity risk factors among minority groups. Evidence showed that community involvement in collaborative initiatives has a high success rate in reducing obesity among racial/ethnic minority children.

Box 3.3 Evidence-Based Practice Promoting

Community Involvement in Reducing Childhood Obesity in Racial/Ethnic Minority Population

PICOT Question: Do community-based interventions decrease childhood obesity rates in diverse populations?

Evidence Summary

Obesity is more prevalent in children from ethnically diverse populations in the United States (Isong et al., 2018). Research has found that there are genetic, epigenetic, biological, social, and environmental risk factors associated with obesity in children (Isong et al., 2018). Current evidence shows links between childhood obesity and ethnicity, lack of physical activity, increased screen time from television and electronics, nutrition, sleep, and socioeconomic status, as well as maternal smoking and

breastfeeding (Alexander, 2017; Isong et al., 2018). Childhood obesity has lifelong physical, mental, and social health consequences (Alexander, 2017; Sato et al., 2016).

Evidence shows that early interventions are most successful in decreasing racial/ethnic disparities related to childhood obesity (Isong et al., 2018). Adult perceptions of obesity must align with interventions for success (Alexander, 2017). Evidence shows that when caregivers perceive interventions as useful, children have greater success in adhering to interventions to address obesity (Alexander, 2017). Asking children to adhere to lifestyle changes without adult support and role modeling will not result in positive outcomes (Stanhope and Lancaster, 2018; Trude et al., 2018).

Community involvement is a key element in reducing health disparities (Subica et al., 2018). Community engagement in childhood obesity programs can include community workshops and media resources to gain attendance and community buy-in (Luesse et al., 2018). Collaborative initiatives with community involvement have high success rates in reducing obesity among children, especially those from a variety of racial and ethnic groups (Frerichs et al., 2018). Public policy must ensure that people from underserved communities have access to healthful food choices as well as improved socioenvironmental areas (Stanhope and Lancaster, 2018; Subica et al., 2018). It is important to ensure that families have access to the recommended food to ensure that healthy choices can be followed through on (Frerichs et al., 2018; Luesse et al., 2018). Communities can also help address the socioenvironmental aspects associated with obesity such as underutilized parks (Frerichs et al., 2018). With collaborative community partnerships, childhood obesity in the racial/ethnic minority population can be reduced.

Application to Nursing Practice

- Understand the modifiable risk factors for obesity and design effective interventions targeted at reducing the risk factors (Isong et al., 2018). Interventions need to include both diet and physical activity recommendations (Alexander, 2017). Nutritional information must include information pertaining to both the school and home environments (Luesse et al., 2018). Include culturally and linguistically appropriate interventions and communication, especially when providing care to patients who are from ethnically diverse populations (Luesse et al., 2018).

- Community involvement is a key element in reducing health disparities (Subica et al., 2016). Community engagement in childhood obesity programs can include community workshops and media resources to gain attendance and community buy-in (Luesse et al., 2018).

While providing community-based nursing care, it is important to consider how well you understand your patients' lives. You begin by establishing strong, caring relationships with your patients and their families (see [Chapter 7](#)). As you gain experience and are accepted by a patient's family, you are able to advise, counsel, and teach effectively and understand what truly makes your patient unique. The day-to-day activities of family life are the variables that influence how you will adapt nursing interventions. The time of day a patient goes to work, the availability of the spouse and patient's parents to provide child care, and the family values that shape views about health are just a few examples of the many factors you will consider in community-based practice. Once you acquire a picture of a patient's life, you then design patient-centered interventions to promote health and prevent disease within the community-based practice setting.

Key Points

- The terms *community health nursing* and *public health nursing* are used interchangeably and fall under the umbrella term *community-oriented nursing*.
- The community-oriented nurse's focus is on health promotion, disease prevention, and improving quality of life of the population, while the focus of the community-based nurse is to provide direct illness care to individuals and families within the community setting.
- Vulnerable populations are groups of patients who are more likely to develop health problems as a result of excess health risks, who have limited access to health care services, or who depend on others for care. Individuals living in poverty, older adults, people who are homeless, immigrant populations,

individuals in abusive relationships, people with substance abuse disorders, and people with severe mental illnesses are examples of vulnerable populations.

- The community-based nurse needs skills in health promotion, disease prevention, and relationship building to fill the role of caregiver, case manager, change agent, patient advocate, collaborator, counselor, educator, and epidemiologist.
- Community assessment is the systematic collection of data on the population, monitoring of the health status of the population, and making information available about the health of the community. Community assessment includes structure, population, and social system.

Reflective Learning

- What population in the community do you see most frequently in your clinical setting? What are some nursing assessments, skills, or tasks you are able to perform with this population?
- In your clinical setting, what nursing education or community resources do you provide to patients? Do you think the method used to disseminate this information is adequate to meet the patients' needs? Explain your answer.
- Identify key information you learned in your clinical setting that you can take with you in your future nursing practice. How were you inspired to improve your nursing knowledge, practice, and skills by the people you worked with?

Review Questions

1. Using *Healthy People 2020* as a guide, which of the following would improve delivery of care to a community? (Select all that apply.)

1. Community assessment
 2. Implementation of public health policies
 3. Home safety assessment
 4. Increased access to care
 5. Determining rates of specific illnesses
2. A community health nurse is working in a clinic with a focus on asthma and allergies. What is the primary focus of the community health nurse in this clinic setting? (Select all that apply.)
1. Decrease the incidence of asthma attacks in the community
 2. Increase patients' ability to self-manage their asthma
 3. Treat acute asthma in the hospital
 4. Provide asthma education programs for the teachers in the local schools
 5. Provide scheduled immunizations to people who come to the clinic
3. The nurse caring for a refugee community identifies that the children are undervaccinated and the community is unaware of resources. The nurse assesses the community and determines that there is a health clinic within a 5-mile radius. The nurse meets with the community leaders and explains the need for immunizations, the location of the clinic, and the process of accessing health care resources. Which of the following practices is the nurse providing? (Select all that apply.)
1. Raising awareness about community resources for the children
 2. Teaching the community about health promotion and illness prevention
 3. Promoting autonomy in decision making about health practices
 4. Improving the health care of the community's children

5. Participating in professional development activities to maintain nursing competency
4. What factor results in vulnerable populations being more likely to develop health problems?
 1. The ability to use available resources to find housing
 2. Adequate transportation to the grocery store and community clinics
 3. Availability of others to help provide care
 4. Limited access to health care services
5. Many older homes in a neighborhood are undergoing a lot of restoration. Lead paint was used to paint the homes when they were built. The community clinic in the neighborhood is initiating a lead screening program. This activity is based on which social determinant of health?
6. A community health nurse conducts a community assessment focused on adolescent health behaviors. The nurse determines that a large number of adolescents smoke. Designing a smoking cessation program at the youth community center is an example of which nursing role?
 1. Educator
 2. Counselor
 3. Collaborator
 4. Case manager
7. A nurse in a community health clinic reviews screening results from students in a local high school during the most recent academic year. The nurse discovers a 10% increase in the number of positive tuberculosis (TB) skin tests when comparing these numbers to the previous year. The nurse contacts the school nurse and the director of the health department. Together they begin to expand their assessment to all students

and employees of the school district. The community nurse was acting in which nursing role(s)? (Select all that apply.)

1. Epidemiologist
 2. Counselor
 3. Collaborator
 4. Case manager
 5. Caregiver
8. A nursing student is giving a presentation to a group of other nursing students about the needs of patients with mental illnesses in the community. Which statement by the student indicates that the nursing professor needs to provide further teaching?
1. "Many patients with mental illness do not have a permanent home."
 2. "Unemployment is a common problem experienced by people with a mental illness."
 3. "The majority of patients with mental illnesses live in long-term care settings."
 4. "Patients with mental illnesses are often at a higher risk for abuse and assault."
9. The nurse in a new community-based clinic is requested to complete a community assessment. Order the steps for completing this assessment.
1. Structure or locale
 2. Social systems
 3. Population
10. The public health nurse is working with the county health department on a task force to fully integrate the goals of *Healthy People 2020*. Most of the immigrant population do not have a primary care provider, nor do they participate in health

promotion activities; the unemployment rate in the community is 25%. How does the nurse determine which goals need to be included or updated? (Select all that apply.)

1. Assess the health care resources within the community.
2. Assess the existing health care programs offered by the county health department.
3. Compare existing resources and programs with *Healthy People 2020* goals.
4. Initiate new programs to meet *Healthy People 2020* goals.
5. Implement educational sessions in the schools to focus on nutritional needs of the children.

Answers: 1.1, 2, 4, 5; 2.1, 2, 4; 3.1, 2, 4; 4.4; 5. Physical environment; 6.2; 7.1, 3; 8.3; 9.1, 3, 2; 10.1, 2, 3.

Theoretical Foundations of Nursing Practice

OBJECTIVES

- Analyze the components of a theory.
- Recognize the evolution of nursing theory.
- Describe types of nursing theories.
- Describe theory-based nursing practice.
- Review selected shared theories from other disciplines.
- Review selected nursing theories
- Understand the use of theories in nursing research.

Providing patient-centered nursing care is an expectation for all nurses. As you progress through your nursing classes, you will learn to apply knowledge from nursing; social, physical, and biobehavioral sciences; ethics; and health policy. Theory-based nursing practice helps you to design and implement nursing interventions that address individual and family responses to health problems. Some nurses find nursing theory difficult to understand or appreciate. However, as your knowledge about theories improves, you will find that nursing theories help to describe, explain, predict, and/or prescribe nursing care measures.

Common questions nurses have about theory include: What is theory? How are nursing theories created? Why is theory important to the nursing profession? This chapter answers these questions and will help you understand how to use theory in your nursing practice.

Imagine that you are building a house. You need to complete the foundation before you start building the walls. Without a strong foundation, the house will collapse. Such is the case with nursing practice. Theory serves as the foundation for nursing care. Nurses use theory every day but are not always aware of it. For example, when a nurse ensures that a patient's room is free of clutter, excess noise, and soiled linens, the nurse is using Florence Nightingale's environmental theory to promote healing and comfort. A nurse uses Imogene King's theory of goal attainment when encouraging patients to set goals for their recovery. A nurse uses Dorothea Orem's self-care deficit theory when feeding or bathing a patient until the patient is able to do this independently. Even though the term *theory* may

sound intimidating, you will find that it is a standard part of everyday nursing practice.

The scientific work used to develop theories expands the scientific knowledge of the profession. Theories offer well-grounded rationales for how and why nurses perform specific interventions and for predicting patient behaviors and outcomes. Expertise in nursing is a result of knowledge and clinical experience. Nursing knowledge improves nursing practice by connecting theory and research. Theory, research, and practice are bound together in a continuous interactive relationship (Fig. 4.1). Nurses develop theories to explain the relationship among variables. Theories may be tested through critical reasoning, description of personal experiences, and use in practice. Throughout this process new information often comes to light that indicates the need to revise a theory, and the cycle repeats (Meleis, 2018). Throughout your nursing career you need to reflect and learn from your experiences to grow professionally and use well-developed theories as a basis for your approach to patient care.

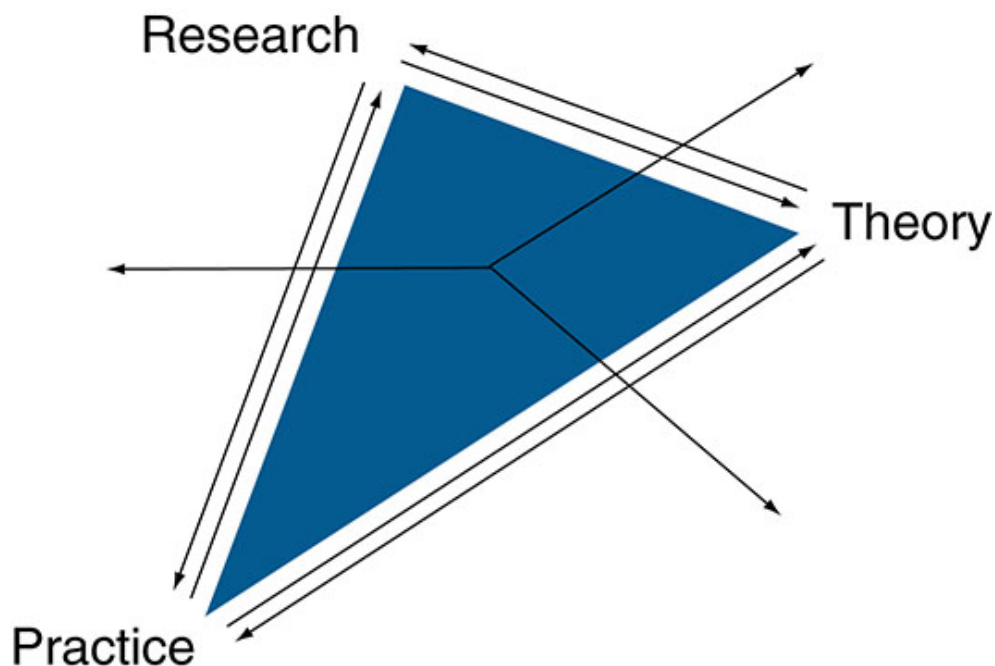

FIG. 4.1 Cyclical relationship among theory, research, and practice. From LoBiondo-Wood G, Haber J: *Nursing research: methods for critical appraisal for evidence-based practice*, ed 9, St Louis, 2018, Elsevier.

Theory

What is theory? A **theory** helps explain an event by defining ideas or concepts, explaining relationships among the concepts, and predicting outcomes (McEwen and Wills, 2019). In the case of nursing, theories are designed to explain a phenomenon such as self-care or caring.

A **metatheory** is an area of study that looks at the relationships of various components that make up the knowledge of a discipline. These include philosophical, theoretical, and empirical components and provide a broad overview of discipline. Metatheory is used to derive theories and theoretical concepts (Reed and Shearer, 2018).

A **nursing theory** conceptualizes an aspect of nursing to describe, explain, predict, or prescribe nursing care (Meleis, 2018). Theories offer a perspective for assessing your patients' situations. They also help you organize, analyze, and interpret data. For example, if you use Orem's theory in practice, you assess and interpret data to determine patients' self-care needs, deficits, and abilities in the management of their disease. Orem's theory then guides your development of patient-centered nursing interventions.

Nursing is both a science and an art. The *science* of nursing is based on data obtained from current research, whereas the *art* of nursing stems from a nurse's experience and the unique caring relationship that a nurse develops with a patient (Chinn and Kramer, 2018). A nursing theory helps to identify the focus, means, and goals of practice. Nursing theories enhance communication and accountability for patient care (Meleis, 2018).

Components of a Theory

A theory contains a set of concepts, definitions, and assumptions or propositions that explain a phenomenon. It explains how these elements are uniquely related to the phenomenon (Fig. 4.2). These components provide a foundation of knowledge for nurses to direct and deliver caring nursing practices. Researchers test theories, and as a result they gain a clearer perspective and understanding of all parts of a phenomenon.

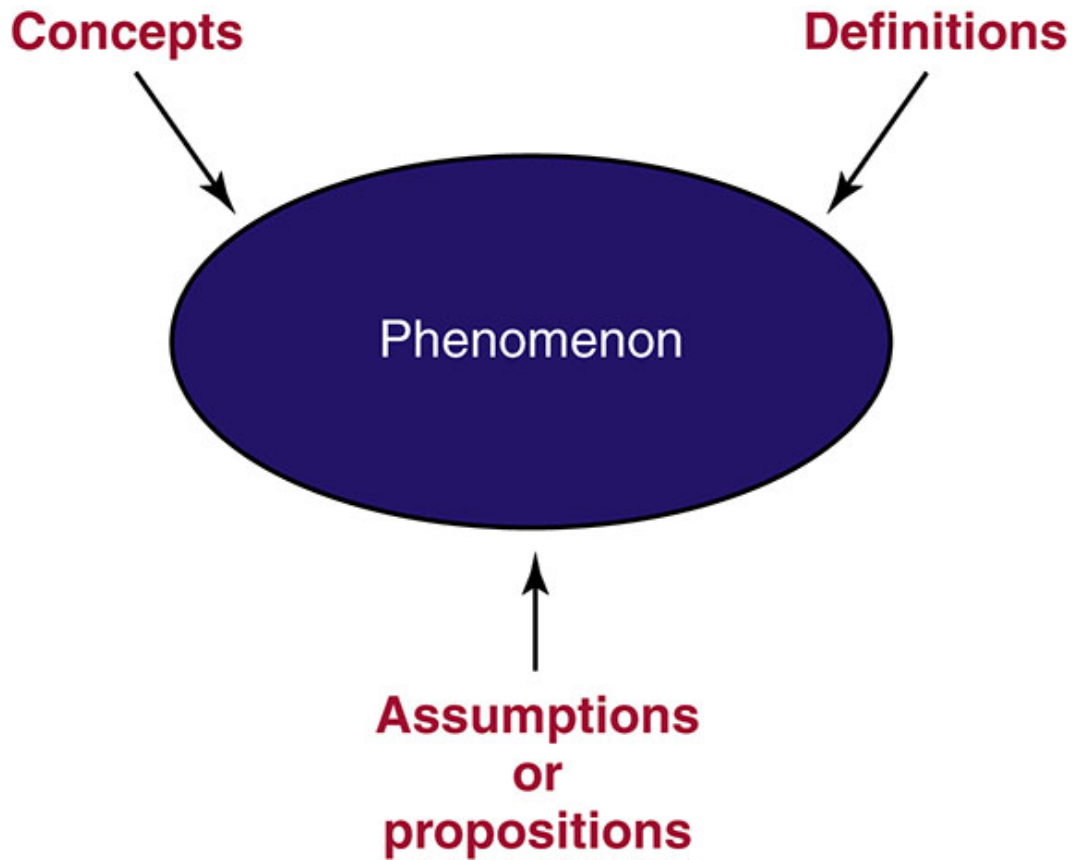

FIG. 4.2 Components of a nursing theory.

Phenomenon

Nursing theories focus on the phenomena of nursing and nursing care. A **phenomenon** is the term, description, or label given to describe an idea or responses about an event, a situation, a process, a group of events, or a group of situations (Meleis, 2018). Phenomena may be temporary or permanent. Examples of phenomena of nursing include caring, self-care, and patient responses to stress.

Concepts

A theory also consists of interrelated concepts that help describe or label phenomena. A concept is a thought or idea of reality that is put into words or phrases to help describe or explain a specific phenomenon (Smith and Liehr, 2018). **Concepts** can be abstract such as emotions or concrete such as physical objects (Chinn and Kramer, 2018). For example, in Meleis and colleagues' theory of transitions, abstract concepts include coping and adapting, while Nightingale described concrete concepts such as physical

conditions and health care environments (Meleis, 2018). Theories use concepts to communicate meaning.

Definitions

Theorists use definitions to communicate the general meaning of the concepts of a theory. Definitions may be *theoretical/conceptual* or *operational*. Theoretical or conceptual definitions simply define a particular concept, much like what can be found in a dictionary, based on the theorist's perspective (Meleis, 2018; McEwen and Wills, 2019). Operational definitions state how concepts are measured (Chinn and Kramer, 2018). For example, a nursing concept *conceptually* defines pain as physical discomfort and *operationally* as a patient reporting a score of three or above on a pain scale of zero to ten.

Assumptions

Assumptions are the "taken-for-granted" statements that explain the nature of the concepts, definitions, purpose, relationships, and structure of a theory. Assumptions are accepted as *truths* and are based on values and beliefs (Masters, 2015; Meleis, 2018). For example, Watson's transpersonal caring theory has the assumption that a conscious intention to care promotes healing and wholeness (Alligood, 2018).

The Domain of Nursing

The **domain** is the perspective or territory of a profession or discipline (Meleis, 2018). It provides the subject, central concepts, values and beliefs, phenomena of interest, and central problems of a discipline. The domain of nursing provides both a practical and theoretical aspect of the discipline. It is the knowledge of nursing practice and nursing history, nursing theory, education, and research. The domain of nursing gives nurses a comprehensive perspective that allows you to identify and treat patients' health care needs in all health care settings.

A **paradigm** is a pattern of beliefs used to describe the domain of a discipline. It links the concepts, theories, beliefs, values, and assumptions accepted and applied by the discipline (McEwen and Wills, 2019). The term **conceptual framework** is often used synonymously with paradigm. A conceptual framework provides a way to organize major concepts and visualize the relationship among phenomena. Different frameworks provide alternative ways to view the subject matter of a discipline and

represent the perspective of the author. For example, the grand theorists all address similar concepts in their respective theories, but each theorist defines and describes the concepts in a different way based on the theorist's own ideas and experiences (Schmidt and Brown, 2015).

The **nursing metaparadigm** allows nurses to understand and explain what nursing *is*, what nursing *does*, and *why* nurses do what they do (Peterson and Bredow, 2017). The nursing metaparadigm includes the four concepts of person (or human beings), health, environment/situation, and nursing. **Person** is the recipient of nursing care, including individual patients, groups, families, and communities. The person is central to the nursing care you provide. Because each person's needs are often complex, it is important to provide individualized patient-centered care. **Health** has different meanings for each patient, the clinical setting, and the health care profession (see Chapter 6). It is a state of being that people define in relation to their own values, personality, and lifestyle. It is dynamic and continuously changing. Your challenge as a nurse is to provide the best possible care based on a patient's level of health and health care needs at the time of care delivery.

Environment/situation includes all possible conditions affecting patients and the settings where they go for their health care. There is a continuous interaction between a patient and the environment. This interaction has positive and negative effects on a person's level of health and health care needs. Factors in the home, school, workplace, or community all influence the level of these needs. For example, an adolescent girl with type 1 diabetes needs to adapt her treatment plan to adjust for physical activities of school, the demands of a part-time job, and the timing of social events such as her prom.

Nursing includes "care of individuals of all ages, families, groups and communities, sick or well and in all settings. Nursing includes the promotion of health, prevention of illness, and the care of ill, disabled and dying people" (International Council of Nurses, 2018). The scope of nursing is broad. For example, a nurse does not medically diagnose a patient's health condition as heart failure. However, he or she assesses a patient's response to the decrease in activity tolerance as a result of the disease and develops *nursing diagnoses* of fatigue, activity intolerance, and difficulty coping (see Chapter 17). From these nursing diagnoses the nurse creates a patient-centered plan of care for each of the patient's health problems (see Chapter 18). Use critical thinking skills to integrate knowledge, experience, attitudes, and standards into the individualized plan of care for each of your patients (see Chapter 15).

Evolution of Nursing Theory

How are theories created? Nursing theories often build on prior theories. Florence Nightingale is generally regarded as the first nursing theorist; her theory was founded on her belief that nursing could improve a patient's environment to facilitate recovery and prevent complications. In the Nightingale era nurses were taught to observe each patient's condition and report changes to the doctor, thus beginning the status of nursing as subservient to the physician—a sign of the Victorian era in which Nightingale lived (Chinn and Kramer, 2018).

Nursing began to transition from a vocation to a profession in the twentieth century, which prompted American nurses to standardize nursing education in diploma programs and encouraged more nurses to seek academic degrees. The first national gathering of nurses occurred at the World's Fair in Chicago in 1893, and the first edition of the *American Journal of Nursing* (AJN) was published in 1900 (Alligood, 2014). The "curriculum era" of nursing spanned the 1900s to the 1940s. During this period nursing education expanded beyond basic anatomy and physiology courses to include courses in the social sciences, pharmacology, and "nursing arts" that addressed nursing actions, skills, and procedures (Alligood, 2014).

The "research era" encompassed the 1950s, 1960s, and 1970s, during which nurses became increasingly involved in conducting studies and sharing their findings. The earliest research studies had a psychosocial, anthropological, or educational focus. Nurses studied their own attitudes, their relationships with other disciplines, and their functions in work and political settings. In the early years, nursing research did not explore clinical questions based on the medical model of research because the discipline was attempting to show its uniqueness from medicine. At this same time the "graduate education era" began, and early versions of nursing theories were developed that offered more structure to nursing research. The renowned theorists of this time period included Johnson, King, Levine, Neuman, Orem, Rogers, and Roy (Alligood, 2014).

The *theory* era, which included the 1980s and 1990s, significantly contributed to knowledge development, and the nursing metaparadigm was proposed by Fawcett. This era resulted in the publication of several nursing journals, the development of nursing conferences, and the offering of more doctoral programs in nursing (Alligood, 2018).

The twenty-first century is considered the era of *theory utilization*. Today nurses strive to provide evidence-based practice (EBP), which stems from theory, research, and experience. The focus of EBP is safe, comprehensive,

individualized, quality health care (see [Chapter 5](#)). The original *grand* theories served as springboards for the development of the more modern *middle-range* theories, which, through testing in research studies, provided “evidence” for EBP and promoted the translation of research into practice. Theory use is congruent with current national goals for quality health care ([Alligood, 2018](#)).

Nursing theories have changed over time in response to changes in society and the world. The environment of war was a primary factor in developing Nightingale’s theory. At the other end of the nursing spectrum, Rogers’ introduction of “energy fields” was developed during the 1980s when the advent of the space shuttle program brought an allure of space ([Meleis, 2018](#)).

Theorists developed their theories from their own experiences in nursing education and nursing practice and from knowledge gained from the disciplines of philosophy, sociology, psychology, and anthropology. Many nursing theorists revise their theories over time to remain current with health care changes. Such evolution shows that theories are not stagnant; rather they are dynamic and responsive to the changing environment in which we live ([McEwen and Wills, 2019](#)).

Types of Theory

The unique theories of a discipline help to distinguish the discipline from other professions. Before the development of nursing theories, nursing was considered a task-oriented occupation that functioned under the direction of the medical profession ([McEwen and Wills, 2019](#)). “The primary uses of theory are to provide insights about nursing practice situations and to guide research” and to provide a guideline or explanation of why nurses do what they do ([Meleis, 2018](#), p. 35). Theories have different purposes and are sometimes classified by levels of abstraction (grand vs. middle-range vs. practice theories) or the goals of the theory (descriptive or prescriptive). For example, a descriptive theory describes a phenomenon such as grief or caring and also identifies conditions or factors that predict when a phenomenon may occur but does not guide nursing actions. Prescriptive theory details nursing interventions for a specific phenomenon and the expected outcome of the interventions. [Box 4.1](#) summarizes goals of theoretical nursing models.

Box 4.1 Goals of Theoretical Nursing Models

- Identify domain and goals of nursing.
- Provide knowledge to improve nursing administration, practice, education, and research.
- Guide research to expand the knowledge base of nursing.
- Identify research techniques and tools used to validate nursing interventions.
- Develop curriculum plans for nursing education.
- Establish criteria for measuring quality of nursing care, education, and research.
- Guide development of a nursing care delivery system.
- Provide systematic structure and rationale for nursing activities.

Grand theories are abstract, broad in scope, and complex; therefore they require further clarification through research so that they can be applied to nursing practice. A grand theory does not provide guidance for *specific* nursing interventions. Instead it provides the structural framework for general, global ideas about nursing. Grand theories intend to answer the question “What is nursing?” and focus on the *whole* of nursing rather than on a *specific* type of nursing. The grand theorists developed their works based on their own experiences and the time in which they were living, which helps to explain why there is so much variation among the theories. Grand theories address the nursing metaparadigm components of person, nursing, health, and environment. For example, in Imogene King’s theory of goal attainment, the focus of nursing is the interaction of human beings and the environment with an end goal of health (Meleis, 2018).

Middle-range theories are more limited in scope and less abstract. They address a specific phenomenon and reflect practice (administration, clinical, or teaching). While grand theories take a wide-angled lens perspective to nursing, middle-range theories expand on specific concepts or phenomena in a specific field of nursing such as uncertainty, incontinence, social support, quality of life, and caring (Peterson and Bredow, 2017; Smith and Liehr, 2018). For example, Kolcaba’s theory of comfort encourages nurses to meet patients’ needs for comfort in physical, psychospiritual, environmental, and sociocultural realms (Schmidt and Brown, 2015). Like many middle-range theories, Kolcaba’s theory was based on the works of a grand theorist—in this case, Nightingale. Middle-

range theories are also sometimes developed from research, nursing practice, or the theories of other disciplines (McEwen and Wills, 2019).

Practice theories, also known as situation-specific theories, bring theory to the bedside. Narrow in scope and focus, these theories guide the nursing care of a *specific* patient population at a *specific* time (Meleis, 2018). An example of a practice theory is a pain-management protocol for patients recovering from cardiac surgery. Practice theories are less abstract and are often easier to understand and apply than the grand and middle-range theories (Meleis, 2018). Fig. 4.3 demonstrates the level of abstraction for each of the grand, middle-range, and practice theory categories.

FIG. 4.3 Correlation of theory category with level of abstraction.
From McEwen M, Wills EM: *Theoretical basis for nursing*, ed 5, Philadelphia, 2019, Wolters Kluwer Health.

Descriptive theories are the first level of theory development. They describe phenomena and identify circumstances in which the phenomena occur (Meleis, 2018). For example, theories of growth and development describe the maturation processes of an individual at various ages (see Chapter 11). Descriptive theories do not direct specific nursing activities or attempt to produce change but rather help to explain patient assessments.

Prescriptive theories address nursing interventions for a phenomenon, guide practice change, and predict the consequences. Nurses use prescriptive theories to anticipate the outcomes of nursing interventions (McEwen and Wills, 2019). Prescriptive theories direct nursing actions toward an explicit goal. Wiedenbach's prescriptive theory of the helping art of nursing conveys the purpose of nursing through three components:

to motivate the patient, to facilitate efforts to overcome obstacles, and to develop nursing action based on the immediate situation (Meleis, 2018).

REFLECT NOW

Think about your most recent clinical day.
Consider what type(s) of nursing theories you used
when providing care to your patient.

Theory-Based Nursing Practice

Why is theory important to the nursing profession? Nursing knowledge is derived from basic and nursing sciences, experience, aesthetics, nurses' attitudes, and standards of practice. As nursing continues to grow as a practice-oriented profession, new knowledge is needed to prescribe specific interventions to improve patient outcomes. Nursing theories and related concepts continue to evolve. Florence Nightingale spoke with firm conviction about the "nature of nursing as a profession that requires knowledge distinct from medical knowledge" (Nightingale, 1860). The overall goal of nursing knowledge is to explain the practice of nursing as different and distinct from the practice of medicine, psychology, and other health care disciplines. Theory generates nursing knowledge for use in practice, thus supporting EBP (see Chapter 5). The integration of theory into practice leads to coordinated care delivery and therefore serves as the basis for nursing (McEwen and Wills, 2019).

The nursing process is used in clinical settings to determine individual patient needs (see Unit 3). Although the nursing process is central to nursing, it is not a theory. It provides a systematic process for the delivery of nursing care, not the knowledge component of the discipline. However, nurses use theory to provide direction in how to *use* the nursing process. For example, the theory of caring influences what nurses need to assess, how to determine patient needs, how to plan care, how to select

individualized nursing interventions, and how to evaluate patient outcomes.

Shared Theories

To practice in today's health care systems, nurses need a strong scientific knowledge base from nursing and other disciplines such as the biomedical, sociological, and behavioral sciences. **Shared theory**, also known as a *borrowed* or *interdisciplinary* theory, explains a phenomenon specific to the discipline that developed the theory (McEwen and Wills, 2019). For example, Piaget's theory of cognitive development helps to explain how children think, reason, and perceive the world (see Chapter 11). Knowledge and use of this theory help pediatric nurses design appropriate therapeutic play interventions for ill toddlers or school-age children. Knowles' adult learning theory helps a nurse plan and provide appropriate discharge teaching for a patient who is recovering from surgery.

Several nursing theories are based on systems theory. The nursing process is a system (Fig. 4.4). Like all systems, the nursing process has a specific purpose or goal (see Unit 3). The goal of the nursing process is to organize and deliver patient-centered care. As a system the nursing process has the following components: input, output, feedback, and content. **Input** for the nursing process is the data or information that comes from a patient's assessment. **Output** is the end product of a system; in the case of the nursing process it is whether the patient's health status improves, declines, or remains stable as a result of nursing care.

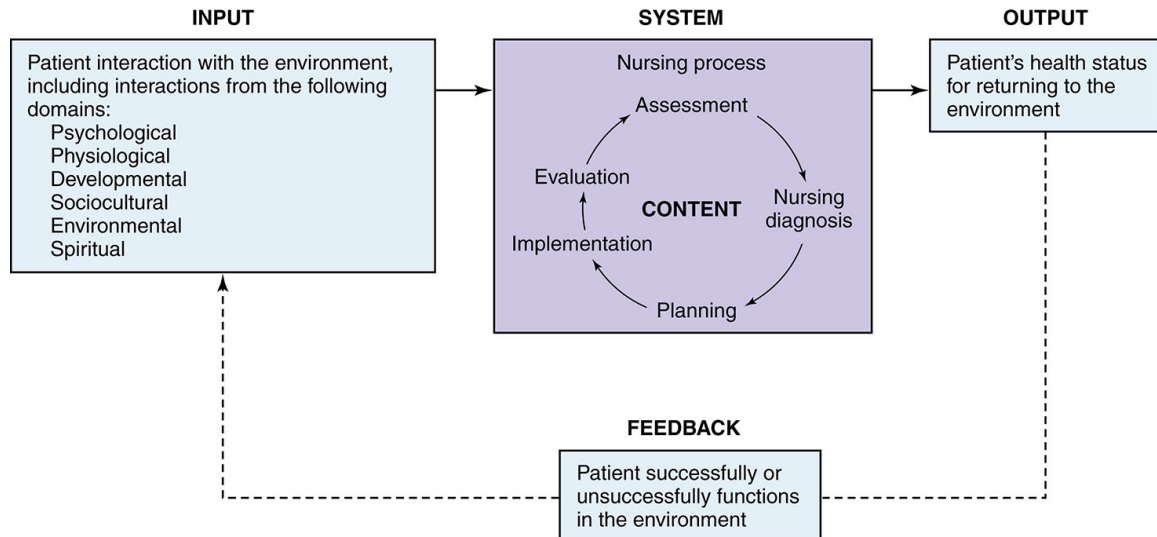

FIG. 4.4 Providing nursing services in assisted-living facilities promotes physical and psychosocial health.

Feedback serves to inform a system about how it functions. For example, in the nursing process the outcomes reflect the patient's responses to nursing interventions. The outcomes are part of the feedback system to refine the plan of care. Other forms of feedback in the nursing process include responses from family members and consultation from other health care professionals.

The **content** is the product and information obtained from the system. For example, patients with impaired bed mobility have common skin care needs and interventions (e.g., hygiene and scheduled positioning changes) that are very successful in reducing the risk for pressure injuries. [Table 4.1](#) provides an overview of additional select shared theories that are often used in nursing practice.

TABLE 4.1**Overview of Select Shared Theories**

Theory Categories	Focus	Application To Nursing
Human needs	Need motivates human behavior. Maslow's hierarchy of basic human needs includes five levels of priority (e.g., physiological, safety and security, love and belonging, self-esteem, and self-actualization) (see Fig. 6.3).	Basic physiological and safety needs are usually a patient's first priority, especially when he or she is dependent on others to meet these needs. When a patient has no emergent physical or safety needs, the nurse gives high priority to his or her psychological, sociocultural, developmental, or spiritual needs. Patients entering the health care system generally have unmet needs. A patient in pain after surgery (basic need) is not ready for discharge teaching (higher-level need) until the pain is relieved. The hierarchy of needs is a way to plan for individualized patient care (McEwen and Wills, 2019).
Stress/adaptation	Humans respond to actual or perceived threats by adapting to maintain function and life.	Patients demonstrate a similar pattern of reacting to stress through physiological and psychological responses. Failure to adapt to stress can lead to exhaustion and decline in health. Nurses need to understand the reaction of body and mind to stress and intervene to help patients develop methods of coping/adapting to prevent or manage illness and disease (Masters, 2015).
Developmental	Humans have a common pattern of growth and development.	Human growth and development are orderly, predictive processes that begin with conception and continue through death. Varieties of well-tested theories describe and predict behavior and development at various phases of the life continuum (McEwen and Wills, 2019).
Biomedical	Theory explains causes of disease; principles related to physiology.	Nurses must have knowledge of theories from the fields of biology, medicine, public health, physiology, and pharmacology to provide holistic patient care, promote health, and prevent illness (McEwen and Wills, 2019).
Psychosocial	Theory explains and/or predicts human responses within the physiological, psychological, sociocultural, developmental, and spiritual domains.	Nursing is a diverse discipline that strives to meet holistic needs of patients. Chapter 9 discusses models for understanding cultural diversity and implementing care to meet the diverse needs of the patient. Chapter 10 describes family theory and how to meet the needs of the family when the family is the patient or the caregiver. Chapter 36 discusses several models of grieving and demonstrates how to help patients through loss, death, and grief.
Educational	Theory explains the teaching-learning process by examining behavioral, cognitive, and adult learning principles.	Nurses provide education to patients, families, community groups, and members of the health care team. A basic understanding of various teaching-learning theories is critical for this aspect of the professional nursing role (Butts and Rich, 2015).
Leadership/management	Theory promotes organization, change, power/empowerment, motivation, conflict management, and decision making.	Nurses often assume leadership positions in the health care realm and as such are expected to effectively manage individuals and groups to promote change and improve quality care and outcomes (McEwen and Wills, 2019).

Select Nursing Theories

Definitions and theories of nursing can help you understand the practice of nursing. The following sections describe select theories and their concepts. See [Table 4.2](#) for a review of additional grand and middle-range nursing theories.

TABLE 4.2

Overview of Select Grand and Middle-Range Nursing Theories

Theory Category	Theorist	Focus	Application	
Grand theory	Henderson	Principles and practice of nursing	Nurses assist patients with 14 activities (breathing, eating/drinking, elimination, movement/positioning, sleep/rest, clothing, body temperature, hygiene, safety, communication/socialization/play, practice of faith, learning) until patients can meet these needs for themselves or they help patients have a peaceful death (Butts and Rich, 2015; McEwen and Wills, 2019).	
	Johnson	Behavioral system	Nurses perceive patients as being more important than their disease; a patient is viewed as a collection of subsystems that form an overall behavioral system focused on meeting basic drives of achievement, affiliation, aggression/protection, dependence, elimination, ingestion, sex, and restoration. The goal of nursing is to help the patient attain/maintain balance, function, and stability in each of the subsystems (Butts and Rich, 2015).	
	Neuman	Systems	Nurses view a patient (physical, psychological, sociocultural, developmental, and spiritual) as being an open system that is in constant energy exchange with both internal and external environments. Nurses help a patient (individual, group, family, or community) cope with intrapersonal, interpersonal, and extrapersonal stressors that can break through the patient’s line of defense and cause illness. The role of nursing is to stabilize a patient or situation, and the focus is on wellness and prevention of disease (McEwen and Wills, 2019).	
	Abdellah	Patient-centered care	Nurses address 21 “nursing problems” to meet patients’ physical, psychological, and social needs and should strive to know each patient. Nurses use knowledge constructed from previous experiences to determine a general plan of care and then personalize the plan to the patient to provide patient-centered care. A nurse also involves a patient’s family in the plan of care when appropriate (McEwen and Wills, 2019).	
	King	Goal attainment	Nurses view a patient as a unique personal system that is constantly interacting/transacting with other systems (e.g., nurse, family, friends); nurses help patients become active participants in their care by working with them to establish goals for attaining, restoring, or maintaining health (Johnson and Webber, 2014; McEwen and Wills, 2019).	
	Roy	Adaptation	Nurses help a patient cope with or adapt to changes in physiological, self-concept, role function, and interdependence domains (Masters, 2015).	
	Watson	Caring	Caring is a fundamental component of professional nursing practice and is based on 10 <i>carative factors</i> (see Chapter 7). The purpose of nursing is to understand the interrelationship among health, illness, and human behavior rather than focus on the disease-cure model. Caring occurs when a nurse and patient engage in a <i>transpersonal relationship</i> that facilitates the patient’s ability for self-healing (Johnson and Webber, 2014).	
	Rogers/Parse/Newman	Unitary beings/human becoming/expanding consciousness	Nurses view a patient as a unique, dynamic energy field in constant energy exchange with the environment; nursing care focuses on helping a patient use his or her own potential to identify and alter personal rhythms/patterns (e.g., eating, breathing, sleeping) to promote and maintain health. Nurses understand that patients are responsible for their own health and that health stems from how patients live their lives in accordance with their own values; the nurse’s role is to be truly present with the patient and accept his or her view of reality while providing guidance to the patient in making health-related choices in accordance with his or her belief system (Johnson and Webber, 2014; McEwen and Wills, 2019).	
	Middle-range theory	Benner	Skill acquisition	Nurses progress through five stages of skill acquisition: novice, advanced beginner, competent, proficient, and expert (Butts and Rich, 2015).
		Kolcaba	Comfort	Nurses facilitate health-seeking behaviors in patients by striving to relieve physical, emotional, social, environmental, and/or spiritual distress (McEwen and Wills, 2019).
Pender		Health promotion	Nurses understand that a patient’s personal characteristics, experiences, and beliefs affect his or her motivation for adopting healthy behaviors (see Chapter 6) (McEwen and Wills, 2019).	
American Association of Critical-Care Nurses		Synergy	Matching nurse competencies to patient needs in the critical care environment improves patient outcomes (McEwen and Wills, 2019).	
Meleis, Sawyer, Im, Messias, and Schumacher		Transitions	Patients are more vulnerable during changes in health and illness. Nurses can facilitate healthy transitions through the development of nursing interventions specific to each patient. For example, the transition from living at home to a nursing home due to declining health (Alligood, 2018).	

Nightingale’s Environmental Theory

Known as the founder of modern nursing, Florence Nightingale is credited with developing the first nursing theory. The focus of Nightingale's grand theory is a patient's environment, which Nightingale believed nurses should manipulate (e.g., ventilation, light, decreased noise, hygiene, nutrition) so that nature is able to restore a patient to health (McEwen and Wills, 2019). Through observation and data collection, she linked the patient's health status with environmental factors and initiated improved hygiene and sanitary conditions during the Crimean War. Nightingale taught and used the nursing process, noting that "vital observation [assessment] ... is not for the sake of piling up miscellaneous information or curious facts, but for the sake of saving life and increasing health and comfort" (Nightingale, 1860).

Peplau's Interpersonal Theory

Hildegard Peplau is considered the mother of psychiatric nursing; the focus of her middle-range theory includes interpersonal relations among a nurse, a patient, and a patient's family and developing the nurse-patient relationship (McEwen and Wills, 2019). According to Peplau, nurses help patients reduce anxiety by converting it into constructive actions (McEwen and Wills, 2019). They develop therapeutic relationships with patients that are respectful, empathetic, and nonjudgmental (Hagerty et al., 2017). The following phases characterize the nurse-patient interpersonal relationship: preorientation (data gathering), orientation (defining issue), working phase (therapeutic activity), and resolution (termination of relationship). In developing a nurse-patient relationship, the nurse serves as a resource person, counselor, and surrogate. For example, when a patient seeks help, the nurse and patient first discuss the nature of any problems, and the nurse explains the services available. As the nurse-patient relationship develops, the nurse and patient mutually define the problems and potential solutions. When the patient's original needs are resolved, new needs sometimes emerge. This middle-range theory is useful in establishing effective nurse-patient communication when obtaining a nursing history, providing patient education, or counseling patients and their families (see Chapter 24).

Orem's Self-Care Deficit Nursing Theory

Dorothea Orem's Self-Care Deficit Nursing Theory is commonly used in nursing practice (Alligood, 2014). When applying this grand theory, a

nurse continually assesses a patient's ability to perform self-care and intervenes as needed to ensure that patients meet physical, psychological, sociological, and developmental needs. According to Orem, people who participate in self-care activities are more likely to improve their health outcomes (Kurtz and Schmidt, 2016; Rustøen et al., 2014). Nursing care becomes necessary when patients are unable to fulfill biological, psychological, developmental, or social needs. Nurses continually assess and determine why patients are unable to meet these needs, identify goals to help them, intervene to help them perform self-care, and evaluate how much self-care they are able to perform. For example, a patient may need a nurse to bathe or feed him or her while acutely ill but, as his or her condition improves, the nurse encourages the patient to begin doing these activities independently.

REFLECT NOW

Consider Orem's Self-Care Deficit Nursing Theory. How can you apply this theory to promote recovery in your patient?

Leininger's Culture Care Theory

As early as the 1950s Madeleine Leininger recognized the need to focus on culture in nursing as she predicted that nursing and health care would become more global. She blended her background in anthropology with nursing to form her middle-range theory of cultural care diversity and universality (Alligood, 2014). Human caring varies among cultures in its expressions, processes, and patterns. Social structure factors such as a patient's politics, culture, and traditions are significant forces affecting care and influencing the patient's health and illness patterns. Think about the diversity of patients and their nursing care needs (see Chapter 9). The major concept of Leininger's theory is cultural diversity, and the goal of

nursing care is to provide a patient with culturally specific nursing care (Alligood, 2014). To provide care to patients of unique cultures, nurses safely integrate their cultural traditions, values, and beliefs into a plan of care. Leininger's theory recognizes the importance of culture and its influence on everything that involves a patient, including health beliefs, the role of family and community, and dietary practices (Alligood, 2014

Building Competency in Patient-Centered Care

You are caring for a high school student who was in a motor vehicle accident on the way to spring break. She is without her parents. She has not previously been hospitalized and has never been away from home this long. How could you use *Peplau's interpersonal theory* when caring for this patient?

). For example, some cultures believe that the leader of the community needs to be present during health care decisions. As a result, a health care team needs to reschedule when rounds occur to include the community leader. In addition, symptom expression also differs among cultures. A person with an Irish background might be stoic and not complain about pain, whereas a person from a Middle Eastern culture might be very vocal about pain. In both cases a nurse needs to skillfully incorporate the patient's cultural practices in assessing his or her level of pain (e.g., asking, "Is the pain getting worse or remaining the same?").

Link between Theory and Knowledge Development in Nursing

Nursing has its own body of knowledge that is both theoretical and experiential. You acquire theoretical knowledge through “reading, observing, or discussing” concepts (Alligood, 2014, p. 123). Theoretical knowledge stimulates thinking and creates a broad understanding of nursing science and practice. Experiential or clinical knowledge, often called the *art* of nursing, is formed from nurses’ clinical experience. Both types of knowledge are needed to provide safe, comprehensive nursing care.

Nursing theories guide nursing practice (McEwen and Wills, 2019). When using theory-based nursing practice, you apply the principles of a theory in delivering nursing interventions. Grand theories help shape and define your practice, middle-range theories continue to advance nursing knowledge through nursing research, and practice theories help you provide specific care for individuals and groups of diverse populations and situations (Peterson and Bredow, 2017).

Relationship Between Nursing Theory and Nursing Research

Research validates, refutes, supports, and/or modifies theory, while theory stimulates nurse scientists to explore significant issues in nursing practice (McEwen and Wills, 2019; Meleis, 2018). The relationship between nursing theory and nursing research builds the scientific knowledge base of nursing, which is then applied to practice. Nurses better understand the appropriate use of a theory to improve patient care as more research is conducted. The relationships between the components of a theory often help identify research questions and determine the overall design of a study. For example, nurse researchers used Peplau’s interpersonal theory as the framework for a project to improve communication of a health care team. The aim of the project was to increase health care staff teamwork and communication (Holtmann, 2018). Table 4.3 provides some examples of how theories are used in nursing research. Nurses consider findings from theory-based research to determine whether the theory can be used in practice.

TABLE 4.3**Theories Used in Nursing Practice and Research**

Theory	Main Concepts Utilized in Research Example	Example of Use in Research
Kolcaba's theory of comfort	Enhanced comfort	The intervention of "quiet time" was studied for possible use with patients experiencing cardiac symptoms (Krinsky et al., 2014).
AACN Synergy Model	Nurse competencies, environmental factors, patient characteristics	Clinical judgment and duration of transport were found to influence patient safety during critical care transport (Swickard et al., 2018).
Mishel's uncertainty in illness theory	Appraisal and management of uncertainty	Study results indicate that young adults with congenital heart disease are at risk for posttraumatic stress disorder (PTSD) and long-term stress due to chronic uncertainty (Moreland and Santacrocce, 2018).
Meleis et al.'s transitions theory	Nursing therapeutics (assessment of readiness, preparation for transition, role supplementation), mindfulness	A mindfulness-based transition program was applied to mothers with premature rupture of membranes to measure acceptance of pregnancy, readiness to give birth, maternal attachment, and competency in the role of motherhood (Korukcu and Kukulcu, 2017).

AACN, American Association of Critical-Care Nurses.

Sometimes research is used to develop new theories (Meleis, 2018). *Theory-generating* research uses logic to explore relationships among phenomena (McEwen and Wills, 2019). In theory-generating research an investigator makes observations (*without* any preconceived ideas) to view a phenomenon in a new way. Middle-range theories are often developed in this manner. For example, the middle-range theory of chronic sorrow stemmed from a researcher's initial observations of cyclic periods of sadness in parents of children with intellectual or developmental disabilities (Vitale and Falco, 2014).

Theory-testing research determines how accurately a theory describes a nursing phenomenon. Testing develops the evidence for describing or predicting patient outcomes. A researcher has *some* preconceived idea as to how patients describe or respond to a phenomenon and generates research questions or hypotheses to test the assumptions of the theory. No one study tests *all* components of a theory; researchers test the theory through a variety of research activities. For example, nurse researchers studied Kolcaba's middle-range nursing theory of comfort in relation to the pain and discomfort experienced by patients with heart disease. The researchers explored the specific intervention of "quiet time" as a comfort measure in this patient population (Krinsky et al., 2014).

Both theory-generating and theory-testing research refine the knowledge base of nursing. In turn, nurses incorporate research-based interventions into theory-based practice (Box 4.2). As research activities continue, not only does the knowledge and science of nursing increase, but

patients receive high-quality evidence-based nursing care (see [Chapter 5](#)). As an art, nursing relies on knowledge gained from practice and reflection on past experiences. The “expert nurse” translates both the art and science of nursing into the realm of *creative caring*, which takes the extra step of individualizing care to the specific needs of each patient. For example, a nurse provides creative caring when arranging for a patient who is in the hospital to visit with a beloved pet or in finding a way to honor a patient’s wish to die at home.

Box 4.2 Evidence-Based Practice Theory-Based

Practice in the Management of First-time Parents

PICOT Question: In patients experiencing their first pregnancy, how does application of Meleis’ theory of transitions compared to no specific theory application influence a healthy transition to parenthood?

Evidence Summary

The transition to parenthood is a life-changing and often challenging time. Successful transitioning to the role of a parent can be accomplished by gaining confidence, planning for the birth, and developing a strong support system (Barimani et al., 2017; Korukcu and Kukulu, 2017).

According to Meleis et al.’s theory of transitions, a transition is required when one’s reality is interrupted, causing the need for a change and a new reality to be formed (Vardaman and Mastel-Smith, 2016). Transitions theory can be applied to various types of transitions: developmental, health-illness, situational, and organizational. Nurses can assist expectant parents by providing professional support during the prenatal period. Expectant parents will require information regarding birth plans, feeding routines, maternal and child appointments, and routine testing before birth (Barimani et al., 2017). It is important for the patient to be engaged in all decisions and for the nurse to remain nonjudgmental (Korukcu and Kukulu, 2017). Nursing actions based on Meleis et al.’s theory can assist patients in managing life’s transitions (Barimani et al., 2017; Vardaman and Mastel-Smith, 2016).

Application to Nursing Practice

- Ensure that expectant parents are knowledgeable about health care access in the prenatal period (Barimani et al., 2017).

- Help patients identify support groups in the community, allowing expectant parents to share knowledge and emotions with others (Barimani et al., 2017).
- Provide new parent education that covers expectations, coping behaviors, and changes in relationships to facilitate successful transitions (Barimani et al., 2017; Vardaman and Mastel-Smith, 2016).
- Recognize that a first-time parent's level of self-confidence may change during the pregnancy (Barimani et al., 2017; Korukcu and Kukulcu, 2017).

Theory is the foundation of nursing; it defines our unique profession and sets it apart from other disciplines. Theory provides a basis for research and practice and serves as a guide in providing safe, comprehensive, individualized care, which is the hallmark of nursing. As you progress in your nursing education and practice, you will use theory in a variety of ways. Keep in mind that these theories apply not only to patient care but also are useful in communicating with other members of the health care team.

REFLECT NOW

Analyze the nursing program you are enrolled in to determine what theories are reflected in the nursing program and nursing curriculum.

Key Points

- The components of a theory provide a foundation for knowledge for nurses to direct and deliver nursing care.

- Theories are dynamic and responsive to the changing environment in which we live.
- The types of nursing theories include grand theories, middle-range theories, practice theories, descriptive and prescriptive theories.
- The integration of theory into practice leads to coordinated care delivery.
- Nurses need a strong scientific knowledge base from nursing and other disciplines, such as the biomedical, sociological, and behavioral sciences.
- Grand and middle-range nursing theories can help you understand the practice of nursing.
- The relationship between theory and research builds the scientific knowledge base of nursing, which is then applied to practice.

Reflective Learning

- Reflect back on a patient you recently were assigned to care for during a clinical or simulation experience. Describe how you did or could have applied Nightingale's environmental theory while you were caring for this patient.
- Reflect back on a patient with a chronic health condition you were recently assigned to care for during a clinical or simulation experience. Explain how you would apply Peplau's interpersonal theory to help this patient prevent complications and promote disease management.
- Reflect on a patient you were assigned to care for in a recent clinical or simulation experience who required total patient care. Describe how you would apply Orem's self-care deficit theory for this patient.

Review Questions

1. The components of the nursing metaparadigm include:
 1. Person, health, environment, and theory.
 2. Health, theory, concepts, and environment.
 3. Nurses, physicians, health, and patient needs.
 4. Person, health, environment, and nursing.
2. Theory is essential to nursing practice because it: (Select all that apply.)
 1. Contributes to nursing knowledge.
 2. Predicts patient behaviors in situations.
 3. Provides a means of assessing patient vital signs.
 4. Guides nursing practice.
 5. Formulates health care legislation.
 6. Explains relationships between concepts.
3. A nurse ensures that each patient's room is clean; well ventilated; and free from clutter, excessive noise, and extremes in temperature. Which theorist's work is the nurse practicing in this example?
 1. Henderson
 2. Orem
 3. King
 4. Nightingale
4. The nurse is caring for a patient admitted to the neurological unit with the diagnosis of a stroke and right-sided weakness. The nurse assumes responsibility for bathing and feeding the patient until the patient can begin performing these activities. The nurse in this situation is applying the theory developed by:
 1. Johnson.
 2. Orem.

3. Roy.

4. Peplau.

5. Match the following types of theory with the appropriate description.

1. Middle-range theory 2. Shared theory 3. Grand theory 4. Practice theory	a. Very abstract; attempts to describe nursing in a global context b. Specific to a particular situation; brings theory to the bedside c. Applies theory from other disciplines to nursing practice d. Addresses a specific phenomenon and reflects practice
---	---

6. Match the following descriptions to the appropriate grand theorist.

1. King 2. Henderson 3. Orem 4. Neuman	a. Based on the theory that focuses on <i>wellness</i> and <i>prevention</i> of disease b. Based on the belief that people who participate in self-care activities are more likely to improve their health outcomes c. Based on 14 activities, the belief that the nurse should assist patients with meeting needs until they are able to do so independently d. Based on the belief that nurses should work with patients to develop goals for care
---	---

7. Which of the following statements related to theory-based nursing practice are correct? (Select all that apply.)

1. Nursing theory differentiates nursing from other disciplines.

2. Nursing theories are standardized and do not change over time.

3. Integrating theory into practice promotes coordinated care delivery.

4. Nursing knowledge is generated by theory.

5. The theory of nursing process is used in planning patient care.

6. Evidence-based practice results from theory-testing research.

8. A nurse is caring for a patient who recently lost a leg in a motor vehicle accident. The nurse best assists the patient to cope with this situation by applying which of the following theories?

1. Roy

2. Watson

3. Johnson

4. Benner

9. Using Maslow's hierarchy of needs, identify the priority for a patient who is experiencing chest pain and difficulty breathing.

1. Self-actualization

2. Air, water, and nutrition

3. Safety

4. Esteem and self-esteem needs

10. Which of the following categories of shared theories would be most appropriate for a patient who is grieving the loss of a spouse?

1. Biomedical

2. Leadership

3. Psychosocial

4. Developmental

Answers: 1.4; 2. 1, 2, 4, 6; 3.4; 4.2; 5.1d, 2c, 3a, 4b; 6.1d, 2c, 3b, 4a; 7.1, 3, 4, 6; 8.1; 9.2; 10.3.

Evidence-Based Practice

OBJECTIVES

- Discuss the benefits of evidence-based practice.
- Describe the steps of evidence-based practice.
- Develop a PICOT question.
- Explain the levels of evidence available in the literature.
- Discuss how nurses apply evidence in practice.
- Explain how nursing research improves nursing practice.
- Discuss the steps of the research process.
- Explain the relationship among evidence-based practice, research, and performance improvement.

KEY TERMS

Active errors, p. 64

Bias, p. 60

Confidentiality, p. 63

Empirical data, p. 60

Evaluation research, p. 62

Evidence-based practice (EBP), p. 53

Validity, p. 60
Variables, p. 57

Many nurses practice nursing according to what they learn in nursing school, their experiences in practice, and the policies and procedures of their health care agency. These approaches to practice do not guarantee that nursing practice is always based on up-to-date scientific information. Sometimes it is based on tradition and not on current evidence. Nursing practice is in an “age of accountability,” in which nursing care impacts the quality, safety, and cost of health care (Jun et al., 2016; White and Spruce, 2015). People are more informed about their own health and the incidence of medical errors within health care institutions. Health care organizations are required to show their commitment to each health care stakeholder (e.g., patients, insurance companies, governmental agencies) to reduce health care errors and improve safety by putting into place evidence-based safe practices (National Quality Forum, 2018). Nurses and other health care providers can no longer accept and practice the status quo. Nurses need to better understand why certain health care approaches are used, which ones work, and which ones do not. Research priorities identified by nurse administrators include the economic value of nursing, the design of nursing practice and care delivery models, patient safety and outcomes, and creating a healthy practice environment (Scott et al., 2016). Evidence-based practice (EBP) guides nurses and other health care providers in making effective, timely, and appropriate clinical decisions.

Cathy and Tom are two nurses who work in the surgical intensive care unit (ICU). They are members of the interprofessional unit practice committee (UPC) that meets monthly to discuss practice issues on the unit and the quality indicators for their unit. Cathy notes that the monthly quality report shows an increased incidence of central line–associated bloodstream infections (CLABSIs) over each of the past 3 months. Patients with central venous catheters (CVCs) used to deliver fluids and medications are becoming infected, but why? Tom questions whether the problem is related to the type of dressing placed over catheters or the way sites are cleansed before insertion. The occurrence of CLABSIs is considered a “Never Event,” meaning that the hospital will not be reimbursed for the care of patients who have this hospital-acquired complication (Centers for Medicare and Medicaid Services, 2015). Thus, it is important for the UPC to find ways to prevent CLABSIs from occurring. The UPC decides to explore these questions as part of its evidence-based practice (EBP) process. The first step is to develop a clinical question to efficiently search the scientific literature. Tom volunteers to do the search with the aid of the hospital librarian. The aim is to determine what evidence is available so that the committee can make an informed decision about standards needed to reduce CLABSIs in their patients.

The Need for Evidence-Based Practice

Evidence-based practice (EBP) is a problem-solving approach to clinical practice that combines the deliberate and systematic use of best evidence in combination with a clinician's expertise, patient preferences and values, and available health care resources in making decisions about patient care (Fig. 5.1) (Melnyk and Fineout-Overholt, 2019). Put in simpler terms, EBP addresses a clinical problem by looking for the very best scientific and clinical evidence available for treating or managing the problem and implementing changes in practice. Research shows that EBP enhances the patient experience, decreases cost, empowers clinicians, and improves patient outcomes (Crabtree et al., 2016; Melnyk and Fineout-Overholt, 2019). Use of EBP competencies by nurses and advanced practice nurses further improves the quality and consistency of health care (Melnyk et al., 2017; McNeil, 2016).

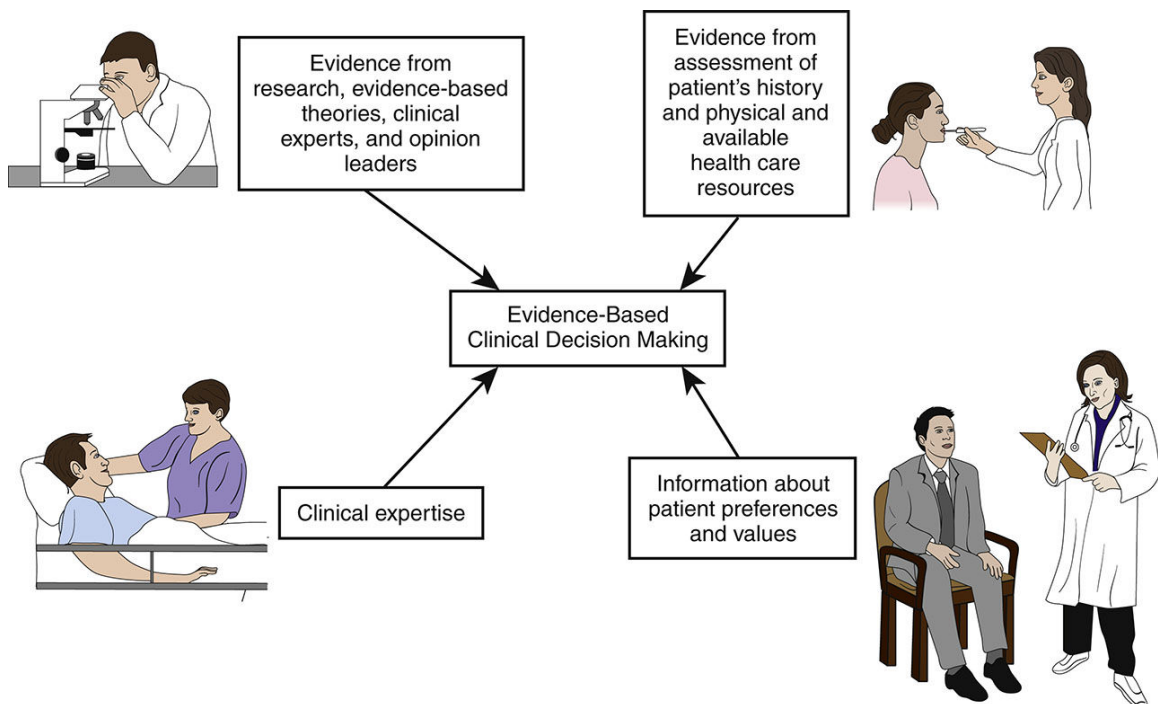

FIG. 5.1 Model for evidence-based clinical decision making.

Nurses regularly face important clinical decisions when caring for patients (e.g., Why do I use this approach in providing patient care? Is a change needed? Is there a way to improve patient outcomes?). Implementing health care processes or practices that are known to work

(evidence based) in a reliable way is a feature of “quality care” and effective timely and appropriate clinical decisions (Peterson et al., 2014). Implementing new knowledge into practice requires a systematic approach that applies evidence to improve clinical educational and administrative practice. EBP is one of the Quality and Safety Education for Nurses’ (QSEN) competencies. The overall goal for the QSEN initiative is to prepare nurses in prelicensure and graduate programs with the knowledge, skills, and attitudes (KSAs) necessary to continuously improve the quality and safety of the health care systems where they work (QSEN, 2018). Following this, Melnyk et al. (2017) developed and validated 12 EBP competencies considered essential for practicing RNs and an additional 11 competencies essential for practicing advanced practice nurses. These EBP competencies are foundational for delivering high-quality care.

There are many sources of evidence. A textbook incorporates evidence into the information, practice guidelines, and procedures it includes. Articles from nursing and health care literature are available on almost any topic involving nursing practice in either journals or on the Internet. Although the scientific basis of nursing practice has grown, some nursing care practices do not have adequate research to guide practice decisions. The challenge is to obtain the very best, most relevant, current, and accurate information when you need it for patient care.

The best scientific evidence comes from well-designed, systematically conducted research studies found in scientific, peer-reviewed journals. Researchers are usually able to conclude whether a new treatment or approach truly makes a difference at the completion of a research study. Unfortunately, much of that evidence never reaches the bedside. While more health care settings have adopted evidence-based practice, there are still nurses who may not have easy access to databases for scientific literature. Instead they often care for patients based on tradition or convenience.

Even when you use the best evidence available, application of the evidence and outcomes differ based on your patients’ values, state of health, preferences, concerns, and/or expectations. The correct application of EBP involves ethical and accountable professional nursing practice. As a nurse you use critical thinking skills to determine which evidence is appropriate and related to your patients’ clinical situations. For example, a single research article involving adults shows that the use of therapeutic touch is effective in reducing patients’ perceptions of abdominal pain after surgery. However, if your patients have cultural beliefs that discourage use of touch, you probably need to search for a different evidence-based

therapy that your patients will accept. Using your clinical expertise and considering patients' values and preferences ensure that you apply the evidence available in practice both safely and appropriately.

Steps of Evidence-Based Practice

EBP is a systematic, problem-solving process that facilitates achievement of best practices. Consistently following a step-by-step approach ensures that you obtain the strongest available evidence to apply in patient care. There are seven steps of EBP, which are numbered from zero to six (Melnyk and Fineout-Overholt, 2019):

0. Cultivate a spirit of inquiry within an EBP culture and environment.
1. Ask a clinical question in PICOT format.
2. Search for the most relevant and best evidence.
3. Critically appraise the evidence you gather.
4. Integrate the best evidence with your clinical expertise and patient preferences and values to make the best clinical decision.
5. Evaluate the outcomes of practice changes based on evidence.
6. Communicate the outcomes of EBP decision or changes.

Cultivate a Spirit of Inquiry

Changes in health care are often made slowly because of multiple barriers that often prevent the implementation of EBP. When your care is not evidence based, your patients will sometimes experience poor outcomes. To be an effective change agent and foster optimal patient care, you need to have a never-ending spirit of inquiry. Constantly questioning current practices and believing in the value of EBP lead to the consistent use of EBP in clinical nursing practice. For an institution to be successful at implementing and sustaining EBP changes, there must be a culture that promotes and supports a spirit of inquiry (Melnyk and Fineout-Overholt, 2019).

Health care institutions that promote and support EBP demonstrate a culture in which nurses are encouraged to question practice and identify EBP mentors to mentor other nurses in the process. These institutions have an infrastructure that supports inquiry and provides tools to support EBP, evidence-based policies and procedures, nursing leaders who value EBP, integration of EBP competencies in performance evaluations and clinical

ladders, and recognition programs for nurses for their work in EBP (Caramanica and Spiva, 2018; Melnyk et al., 2018a). You need to gain knowledge and skills associated with EBP and maintain a commitment to provide the best care possible to your patients and their families.

Ask a Clinical Question in PICOT Format

Always think about your practice when caring for patients. Question what does not make sense to you and what needs to be clarified. Think about a problem or area of interest that is time consuming, costly, or illogical. These thoughts are part of an ongoing spirit of inquiry into best practice. A problem-focused trigger is one you face while caring for patients or a trend you see on a nursing unit. *For example, Cathy and Tom identified from the quality indicator report that the trend in CLABSIs increased over each of the past 3 months.* Data gathered from a health care setting allows you to examine clinical trends and form questions. Most hospitals keep monthly records on key quality or performance indicators such as medication errors or infection rates. All Magnet®-designated hospitals maintain the National Database of Nursing Quality Improvement (NDNQI). The database has information on falls, pressure injury incidence, and nurse satisfaction. Quality- and risk-management data do not give you evidence for finding a solution to a problem. Rather the data inform you about the nature or severity of problems, which then allows you to form practice questions. Other examples of problem-focused triggers include a patient injury following a fall or a patient who develops a stage III pressure injury following surgery.

A knowledge-focused trigger is a question regarding new information available on a topic. For example, “What current evidence exists to improve pain management in patients with migraine headaches?” Important sources of this type of information are standards and practice guidelines available from national agencies such as the Agency for Healthcare Research and Quality (AHRQ), the American Pain Society (APS), or the American Association of Critical Care Nurses (AACN). Other sources of knowledge-focused triggers include recent research publications and nurse experts within an organization.

Sometimes you use data gathered from a health care setting to examine clinical trends when developing clinical questions. For example, most hospitals keep monthly records on key quality indicators such as medication errors or infection rates. You use quality and risk-management data to help you understand the nature or severity of problems that then

allow you to form practice questions. The questions you ask eventually lead you to the evidence for an answer.

After you identify an area of interest, there are two types of questions you may ask: a background question or foreground question. A background question asks general information about a clinical issue and needs to be answered before a searchable and answerable foreground question can be posed (Melnyk and Fineout-Overholt, 2019). For example: What is the best way to reduce wandering in patients with dementia? The question might lead you to a variety of references, some that are even irrelevant, describing approaches for reducing wandering. But background information is often important to help you form a more specific foreground question. A foreground question focuses on specific knowledge that comes from a background question (Melnyk and Fineout-Overholt, 2019). For example, a foreground question might be: In patients with dementia, does the use of stress reduction techniques reduce wandering? Forming a foreground question using a PICOT format is very specific and assists you in finding the right evidence to answer the question with some certainty. When you ask a question and then go to the scientific literature, you do not want to read 100 articles to find the handful that are most helpful. You want to be able to read the best six articles that specifically address your practice question. Melnyk et al. (2017) suggest using a PICOT format to state a foreground question. Box 5.1 summarizes the five elements of a **PICOT question**. The more focused your question is, the easier it becomes to search for evidence in the scientific literature. *For example, Cathy and Tom first went to the literature with a general background question: "Which factors cause CLABSI in CVCs?" They were quickly frustrated when they found numerous articles about different factors that influence CLABSIs in CVCs. They decide to write two focused PICOT questions: (1) "Does the use of 2% chlorhexidine (I) compared with alcohol (C) for cleansing central catheter insertion sites in hospitalized patients (P) reduce the incidence of CLABSI (O) within 6 months (T)?" (2) "Does the use of sterile barrier techniques during catheter insertion (I) compared with sterile gloving only (C) reduce the incidence of CLABSI (O) in patients who have had surgery (P) during their hospitalization (T)?"*

Box 5.1 Developing a PICOT Question

P = Patient population of interest

Identify patients by age, gender, ethnicity, and disease or health problem.

I = Intervention or area of interest

Which intervention is worthwhile to use in practice (e.g., a treatment, diagnostic test, prognostic factor)? What area of interest influences a desired outcome (e.g., complementary therapy, motivational interviewing)?

C = Comparison intervention or area of interest

What is the usual standard of care or current intervention used now in practice?

O = Outcome

What result do you wish to achieve or observe as a result of an intervention (e.g., change in patient behavior, physical finding, or patient perception)?

T = Time

What amount of time is needed for an intervention to achieve an outcome (e.g., the amount of time needed to change quality of life or patient behavior)?

Proper question formatting allows you to identify key words to use when conducting your literature search. Note that a well-designed EBP question does not have to follow the sequence of P, I, C, O, and T. For example, a specific intervention (I), comparison (C), and time (T) are not used in every question. The aim is to ask a question that contains as many of the PICOT elements as possible. For example, here is a meaningful qualitative question that contains only a P and O: How do patients with cystic fibrosis (P) perceive their quality of life (O)? The PICOT format allows you to ask questions that are intervention focused. For questions that are not intervention focused, the meaning of the letter I can be an area of interest instead of an intervention ([Melnyk and Fineout-Overholt, 2019](#)).

For example, does the use of complementary therapies (I) compared with analgesics (C) lessen pain (O) in patients with osteoarthritis (P)?

The questions you ask using as many elements as possible in a PICOT format help to identify knowledge gaps within a clinical situation. Asking well-thought-out questions allows you to identify evidence needed to guide clinical practice. Remember: Do not be satisfied with clinical routines. Always question and use critical thinking to consider better ways to provide patient care.

Search for the Best Evidence

Once you have a clear and concise PICOT question, you are ready to search for evidence. A variety of sources will provide the evidence needed to answer your question, such as agency policy and procedure manuals, quality improvement data, existing clinical practice guidelines, and journal articles. Do not hesitate to ask for help to find appropriate evidence. Key resources include nursing faculty, librarians, advanced practice nurses, staff educators, risk managers, and infection control nurses.

When using scientific literature for evidence, seek the assistance of a medical librarian who knows the various online databases available to you ([Table 5.1](#)). The databases contain large collections of published scientific studies, including peer-reviewed research. A **peer-reviewed** article is reviewed for accuracy, validity, and rigor and approved for publication by experts before it is published. MEDLINE and the Cumulative Index of Nursing and Allied Health Literature (CINAHL) are among the best-known online databases for scientific knowledge in health care ([Melnyk and Fineout-Overholt, 2019](#)). Some databases are available through vendors at a cost, some are free of charge, and some offer both options. Students typically have access provided by their schools. One of the more common vendors is OVID, which offers several different databases. Databases are also available on the Internet free of charge. The Cochrane Database of Systematic Reviews is a valuable source of high-quality evidence. It includes the full text of regularly updated systematic reviews and protocols for reviews currently under way. Collaborative review groups prepare and maintain the reviews. The protocols provide the background, objectives, and methods for reviews in progress ([Melnyk and Fineout-Overholt, 2019](#)).

TABLE 5.1**Searchable Scientific Literature Databases and Sources**

Databases	Sources
AHRQ	Agency for Healthcare Research and Quality; includes clinical guidelines and evidence summaries http://www.ahrq.gov
CINAHL	Cumulative Index of Nursing and Allied Health Literature; includes studies in nursing, allied health, and biomedicine https://www.ebscohost.com/nursing/products/cinahl-databases/cinahl-complete
MEDLINE	Includes studies in medicine, nursing, dentistry, psychiatry, veterinary medicine, and allied health https://www.nlm.nih.gov/bsd/medline.html
EMBASE	Biomedical and pharmaceutical studies http://www.embase.com
PsycINFO	Psychology and related health care disciplines http://www.apa.org/psycinfo/
Cochrane Database of Systematic Reviews	Full text of regularly updated systematic reviews prepared by the Cochrane Collaboration; includes completed reviews and protocols https://www.cochrane.org/search/site/systematic%20reviews
PubMed	Health science library at the National Library of Medicine; offers free access to journal articles https://www.ncbi.nlm.nih.gov/pubmed/
World Views on Evidence-Based Nursing	Electronic journal containing articles that provide a synthesis of research and an annotated bibliography for selected references

Seek the help of a librarian to identify the databases and key words that will provide the best evidence to answer your PICOT question. When conducting a search, you need to enter and manipulate different key words until you get the combination of terms that provides the best articles to help answer your question. It usually takes several searches to find the most appropriate articles. *For example, Cathy and Tom's first PICOT question includes the key words "catheter-associated bloodstream infection," "surgical patients," "chlorhexidine," and "alcohol."* The key words you select often have one meaning to one author and a very different meaning to another. Be patient and persistent and keep trying different words and combinations of words until you find the evidence you need.

Fig. 5.2 represents the hierarchy of evidence. The level of rigor or amount of confidence you can have in the findings of a study decreases as you move down the pyramid. As a nursing student, you cannot be an expert on all aspects of the types of studies conducted. But you can learn enough about the types of studies to help you know which ones have the best scientific evidence. At the top of the pyramid are systematic reviews or meta-analyses, which are state-of-the-art summaries from an individual researcher or panel of experts. Meta-analyses and systematic reviews are the perfect answers to PICOT questions because they rigorously summarize current evidence about a specific topic or intervention.

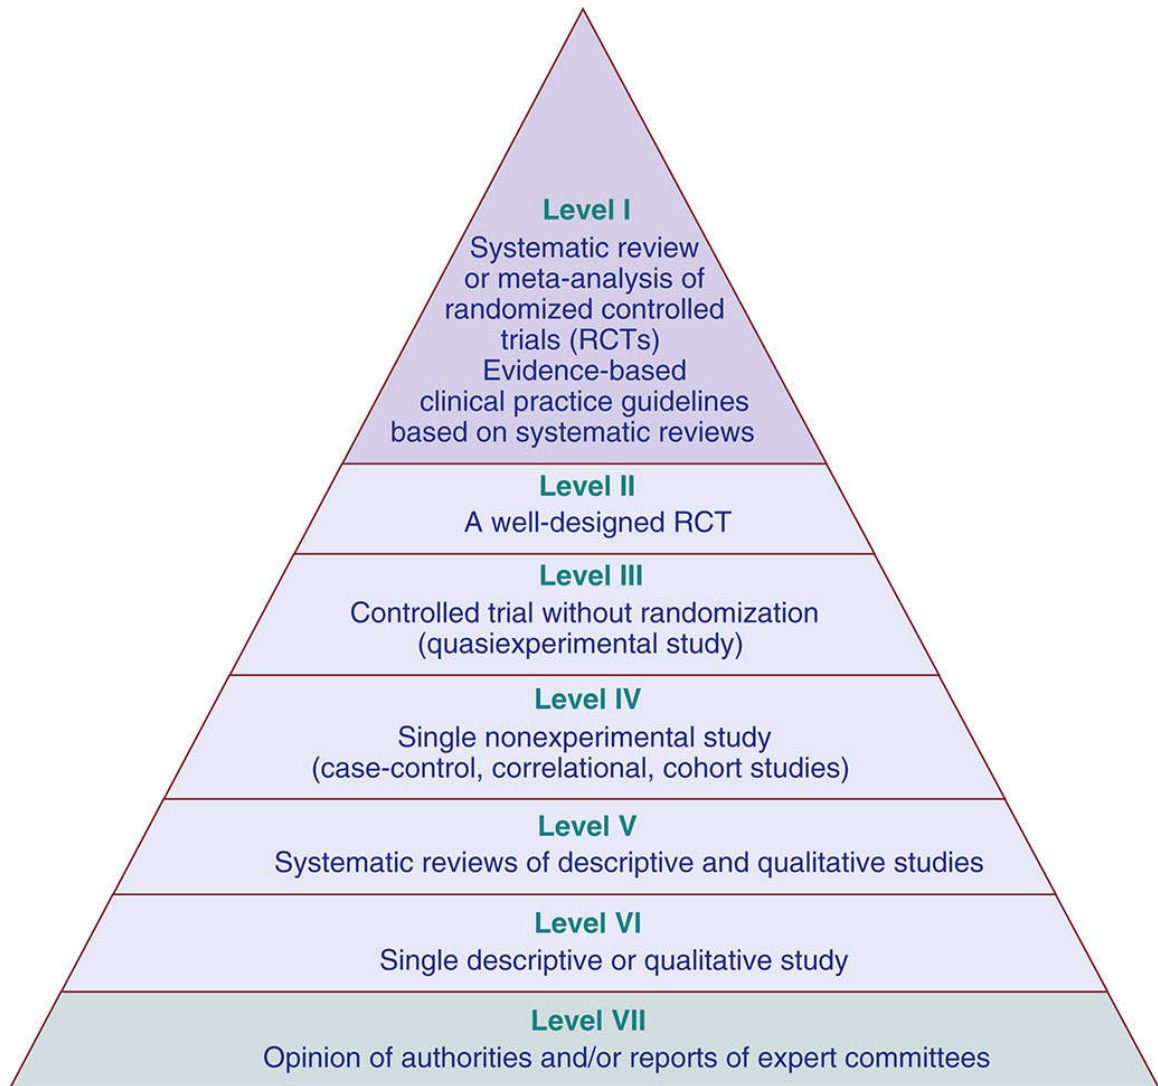

FIG. 5.2 Levels of evidence.
(From LoBiondo-Wood G, Haber J: *Nursing research*, ed 9, St Louis, 2018, Elsevier).

During either a meta-analysis or a systematic review, a researcher asks a PICOT question, reviews the highest level of evidence available (e.g., randomized controlled trials [RCTs]), summarizes what is currently known about the topic, and reports whether current evidence supports a change in practice or whether further study is needed. The main difference is that in a meta-analysis the researcher uses statistics to show the effect of an intervention on an outcome. In a systematic review, no statistics are used to draw conclusions about the evidence. In the Cochrane Library, all entries include information on meta-analyses and systematic reviews. If you use MEDLINE or CINAHL, enter a text word such as *meta-analysis*,

systematic reviews, or evidence-based medicine to obtain scientific reviews on your PICOT question.

A randomized controlled trial (RCT) is the highest level of experimental research. In an RCT a researcher tests an intervention (e.g., method for intravenous [IV] site care or patient education) against the usual standard of care. Researchers randomly assign subjects in an experiment to either a control or a treatment group. In other words, all of the subjects have an equal chance to be in either group. The treatment group receives the experimental intervention, and the control group receives the usual standard of care. The researchers measure both groups for the same outcomes and then perform statistical tests to see whether the experimental intervention made a significant difference. When an RCT is completed, the researcher has evidence if the intervention leads to better outcomes than the standard of care.

A single RCT is not as conclusive as a review of several RCTs on the same question. However, a single RCT that tests the intervention included in your question yields useful evidence. If an RCT is not available on your question, use results from other research studies such as descriptive or qualitative studies to answer your PICOT question. The use of clinical experts may be at the bottom of the evidence pyramid but does not consider clinical experts to be poor sources of evidence. Expert clinicians use evidence frequently as they build their own practice, and they are rich sources of information for clinical problems.

REFLECT NOW

Write a PICOT question related to a situation you encountered during a recent clinical experience. Identify the key words that you would use to search the databases and literature for evidence.

Critically Appraise the Evidence

With the help of the hospital librarian, *Tom searched three databases: PubMed, CINAHL, and the Cochrane Database of Systematic Reviews. He found a*

systematic review summary on central line dressings from the Cochrane Database. An article from the highly regarded New England Journal of Medicine reported on a research study that showed a reduction in CLABSIs after use of a bundling of several interventions (including use of chlorhexidine and barrier precautions). Cathy helped by searching the Centers for Disease Control and Prevention (CDC) website for clinical guidelines on central line catheters. Once they obtained the full text of all articles (not just the abstracts), Cathy and Tom distributed them to members of their UPC for critical review and evaluation.

Critically reviewing and analyzing the available evidence requires a systematic approach. When evaluating the available evidence, you determine the value, feasibility, and usefulness of evidence for making a practice change (Mitchell and Freise, 2016). There are numerous critical appraisal tools available for nurses to use to evaluate the evidence using a structured format (Buccheri and Sharifi, 2017). Review each source of evidence (article, clinical guideline, expert summary) to determine its value, feasibility, and utility of evidence for making a practice change. This requires you to review each source of evidence carefully to determine its scientific worth and the strength of any study methods (when appropriate), to identify the level of evidence from each source, to summarize your findings, and to determine whether the evidence is conclusive regarding your practice question (Buccheri and Sharifi, 2017). *The ICU UPC committee reviews the articles and clinical guidelines on CLABSIs and decides whether there is convincing evidence for the use of chlorhexidine instead of alcohol in cleansing catheter sites. The team also determines whether the use of barrier precautions during catheter insertion makes a difference in infection rates.*

It takes time to develop skills needed to critique the evidence like an expert. When you read an article, do not put it down and walk away because of the statistics and technical language. To determine its worth to practice, consider:

- What is the level of evidence?
- How well was the study (if research) conducted?
- How useful are the findings to practice?

Know the elements of an article when reviewing each one. Read each article carefully to decide how well the study was conducted. When reading through a scientific study, summarize key elements. Many EBP committees use critical appraisal guides or useful checklists for evaluating studies (Spruce et al., 2016). A guide lists questions about essential

elements of research (e.g., purpose, sample size, setting, method of study). It is important to know the elements of scientific articles to decide the value and relevance to your PICOT question (Buccheri and Sharifi, 2017). Evidence-based articles include the following elements:

- *Abstract.* An abstract is a brief summary that quickly tells you if the article is research or clinically based. An abstract summarizes the purpose of the article. It also includes the major themes or findings and the implications for nursing practice.
- *Introduction.* The introduction contains more information about the purpose of the article. There is usually brief supporting evidence as to why the topic is important. Together the abstract and introduction help you decide if you want to continue to read the entire article. You will know if the topic of the article is similar to your PICOT question or related closely enough to provide useful information. If you decide that an article will most likely help answer your question, continue to read the next elements of the article.
- *Literature review or background.* A good author offers a detailed background of the level of science or clinical information about the topic. The literature review offers an argument about what led the author to conduct a study or report on a clinical topic. This section of an article is very valuable. Even if the article itself does not address your PICOT question the way you desire, the literature review may lead you to more useful articles and build your knowledge base in nursing. After reading a literature review, you should have a good idea of how past research led to the researcher's question. *For example, one article Tom found described a study designed to test the effects of aseptic practices on CLABSI. This study reviewed literature that describes the nature of CLABSI and the patients most at risk, the type of factors shown previously in the literature to contribute to CLABSI, and previous interventions used to prevent CLABSI.*
- *Manuscript narrative.* The "middle section," or narrative, of an article differs according to the type of evidence-based article it is (Melnyk and Fineout-Overholt, 2019). A clinical article describes a clinical topic, which often includes a description of a patient population, the nature of a certain disease or health alteration, how patients are affected, and the appropriate nursing therapies. An author sometimes writes a clinical article to explain how to use

a therapy or new technology. A research article contains several subsections within the narrative, including the following:

- *Purpose statement*: Explains the focus or intent of a study. It includes research questions or **hypotheses**—predictions made about the relationship or differences among study **variables** (concepts, characteristics, or traits that vary within or among subjects). *An example of a research question is: Does the use of chlorhexidine 2% compared with povidone-iodine reduce CLABSI in patients with CVCs? Within this question the author is studying the variables (independent) of chlorhexidine and povidone-iodine solutions as they affect the outcome (dependent variable) of CLABSI in patients. In contrast, a hypothesis might state: Chlorhexidine 2% for site care reduces the incidence of CLABSI in patients with CVCs.*
- *Methods or design*: Explains how a research study was organized and conducted to answer the research question or test the hypothesis. This section explains the type of study that was conducted (e.g., RCT, case control study, or qualitative study) and the number of subjects or people who participated in the study. In health care research, subjects often include patients, family members, or health care staff. The methods section is sometimes confusing because it explains details about how the researcher designed the study to obtain the most accurate results possible. Use your faculty member as a resource to help interpret this section.
- *Analysis*: This section explains how the data collected in a study are analyzed. If quantitative data such as physical measurements and scores on surveys are collected, statistical results from the study are explained. Statistics can be confusing. Focus on learning whether the researcher found differences between groups or if an association was found between different variables. For example, if a researcher tests a new fall-prevention strategy, did the strategy reduce falls more so than the standard approach to care? The researcher statistically reports a “p value.” The p value (usually set at 0.05) is a probability level that tells you whether the difference between two groups was likely related to the intervention or if it was simply a difference by chance ([Lobiondo-Wood and Haber, 2018](#)). When the statistic shows that the value was less than the p value (<0.05), the result was likely the result of the intervention (less than 5% probability caused by chance). If a study involved collection of qualitative information such as audiotaped interviews

or open-ended surveys, the analysis describes the major themes from the data. This section helps to determine whether a study was conducted in a way that allows you to trust the results and use them to inform practice ([Lobiondo-Wood and Haber, 2018](#)).

- *Results or conclusions:* Clinical and research articles have a summary section. In a clinical article the author explains the clinical implications for the topic presented. In a research article the author details the results of the study and explains whether a hypothesis is supported or how a research question is answered. This section includes a statistical analysis if it is a quantitative research study. A qualitative study summarizes the descriptive themes and ideas that arise from the researcher's analysis of data. Do not let the statistical analysis in an article overwhelm you. Read carefully and ask these questions: Does the researcher describe the results? Were the results significant? An effective author also discusses limitations to a study in this section. The information on limitations is valuable in helping you decide if you want to use the evidence with your patients. Have a faculty member or an expert nurse help you interpret statistical results.
- *Clinical implications:* A research article includes a section that explains whether the findings from the study have clinical implications. The researcher explains the generalizability or how to apply findings in a practice setting for the type of subjects studied.

After you have critically reviewed each article for your PICOT question, combine the findings from all of the articles to determine the state of the evidence. If you used a critical appraisal guide for each article, summarize information in all of the forms into a final evaluation table. As you complete the evaluation table, use critical thinking to consider the scientific rigor or strength of the combined evidence and how well it answers your area of interest. Consider the evidence in light of your patients' concerns, values, preferences, and available health care resources. Your review of articles offers a snapshot conclusion of the combined evidence on your PICOT question. As a new nurse you learn to judge whether to use the evidence for a particular patient or group of patients who usually have complex health care situations ([Melnik and Fineout-Overholt, 2019](#)). Ethically it is important to consider evidence that benefits patients and does no harm.

After appraising all articles, the UPC in the case study focuses on the systematic review, the *research study*, and *CDC clinical guidelines* as offering the most information about the use of chlorhexidine and other interventions for preventing CLABSI. The committee collaborates by discussing their conclusions, reviews the results of the final evaluation table, and applies their clinical expertise. They consider the types of patients they see in the ICU and determine whether the evidence is strong enough for use in practice. The systematic review article (evidence level 1) did not address chlorhexidine use but concluded that there was no definitive advantage of transparent IV dressings over gauze for preventing CLABSI. Although Level VII evidence, the clinical guidelines from the CDC contained recommendations categorized on the basis of strength of existing scientific data and applicability. The CDC guidelines reported that research has shown no difference between transparent and gauze dressings in causing bloodstream infection (BSI) and highly recommends use of chlorhexidine for IV site care and the use of sterile barriers during catheter insertion. The cohort study (evidence level IV) showed a significant reduction in CLABSI in ICUs that used a bundle of interventions, including rigorous hand hygiene, chlorhexidine site care, and sterile barriers. The data from all studies were applicable to adult critically ill patients. The committee recommended adopting practice changes to include chlorhexidine site care, sterile barrier precautions for catheter insertion, and reinforcement of strict hand hygiene during all forms of central line site care.

Integrate the Evidence

If you decide that the evidence is strong and applicable to your patients and clinical situation, you begin to identify how to incorporate it into practice. Your first step is simply to apply the research in your plan of care for a patient (see [Chapter 18](#)). Use the evidence you find as a rationale for an intervention you plan to try. For instance, you learned about an approach to bathe older adults who are confused and decide to use the technique during your next clinical assignment. If you find that the bathing technique is successful with your own assigned patients, you may begin to work with a group of other students or nurses to revise the policy and procedure for bathing patients or develop a new clinical protocol.

When you work as a part of a hospital committee or task force, sometimes EBP change occurs on a larger scale. Engagement involves bringing all stakeholders (individuals who have an interest or concern in the practice change) together to explain why the evidence-based interventions are important. For example, administrators want to know if the practice change improves patient outcomes and lowers costs. Staff nurses want to know if the practice change improves patient outcomes and

how it will affect the way they provide care. Health care providers also want to know how the practice change affects the way they provide care. It is important to consider the setting in which you want to apply the evidence and ask if stakeholders support the change. To integrate evidence into practice, education of all those involved in the practice change must occur. This requires approaches such as teaching seminars, informational newsletters, and ongoing discussions during staff and UPC meetings.

The actual execution of a practice change requires planning, especially if it occurs on a large scale, involving more than one nursing unit or work area. The staff who are implementing a practice change must work closely with those who will be adopting the new practice to anticipate what will be needed to make a change successful. For example, new documentation forms, different types of supplies, or a change in the way information is communicated among disciplines may be needed. It is often best to test a new practice change by conducting a 3-month pilot before implementing on a large scale. A pilot study is a small-scale research study or one that includes a quality or performance improvement (PI) project. The results of the pilot tell you whether the practice change can be implemented easily and whether it results in desired outcomes. Nursing staff buy-in is important to the success of the pilot project and to sustaining the change. Nurses are more likely to use evidence-based practices if they perceive the practices to be useful and relevant and if their work environment is supportive and promotes communication (Jun et al., 2016).

A common approach used for integrating evidence into practice is to incorporate new evidence into policies and procedures (P&Ps). A key feature of a practice environment that supports the use of best evidence is to require clinical practice policies and procedures to be evidence based (Hanrahan et al., 2015; Jun et al., 2016). Many organizations involve staff nurses and research-prepared advanced practice nurses to review scientific articles relevant to P&Ps and make appropriate revisions. P&Ps are important tools for supporting hospital-based nurses in using evidence in their everyday practice and promoting positive patient outcomes (Jun et al., 2016).

After reviewing the evidence on CLABSI, the UPC committee decides to revise the P&P for central catheter insertion and maintenance. Cathy and Tom recommend that the committee conduct in-service sessions to educate all staff about the new P&P. A brief explanation about the change is also placed in the monthly newsletter of the unit. The bundle of interventions (hand hygiene, chlorhexidine use, and full barrier precautions) is implemented after the staff have the opportunity to ask questions about the new protocol in staff meetings. The

ICU implements the new P&P with the UPC committee monitoring the monthly reports on CLABSI to determine whether infection rates change. In addition, the UPC audits staff practices to be sure that the new interventions are being followed consistently and that the change in practice is sustained.

Evaluate the Outcomes of the Practice Decision or Change

After applying evidence in your practice, your next step is to evaluate the outcome. How does the intervention work? How effective was the clinical decision for your patient or practice setting? Sometimes your evaluation is as simple as determining whether the expected outcomes you set for an intervention are met (see [Chapters 18](#) and [20](#)). For example, after the use of a transparent IV dressing, does the IV dislodge, or does the patient develop the complication of phlebitis? When using a new approach to preoperative teaching, do patients learn what to expect after surgery?

When an EBP change occurs on a larger scale, an evaluation is more formal. *For example, evidence of factors that reduce the incidence of CLABSI leads the ICU to adopt the new P&P for central line catheter care. To evaluate the procedure, the members of the EBP committee track the outcome of incidence of CLABSI over a course of time before and after the practice change (e.g., 3 to 6 months). Measures from preintervention and postintervention are needed to determine change. In this case the CLABSI measure is collected by the hospital monthly. In addition, the staff collect data to describe both the patients who develop CLABSI and those who do not. This comparative information is valuable in determining the effects of the protocol and whether modifications are necessary.*

When evaluating an EBP change, determine whether the change was effective, whether modifications in the change are needed, or whether the change needs to be discontinued. Events or results that you do not expect may occur. *For example, the changes made in the protocol developed by Cathy and Tom might lead to an increase in CLABSIs. If this is not determined during evaluation, the practice would continue, and patients would suffer. Never implement a practice change without evaluating its effects.*

Communicate the Outcomes of the Evidence-Based Practice Decision

After implementing an EBP change, it is important to communicate the results. If you implement an evidence-based intervention with one patient, you and the patient determine the effectiveness of that intervention. When a practice change occurs on a nursing unit level, the first group to discuss the outcomes of the change is often the clinical staff on that unit. Unit

huddles and visual management tools, such as a Gemba board to collect process issues, are effective strategies for communicating EBP changes and practices (Bourgault et al., 2018). To enhance professional development and promote positive patient outcomes beyond the unit level, share the results with various groups of nurses or other care providers such as the nursing practice council, EBP council, or the research council (Carter and Rivera, 2018). Clinicians enjoy and appreciate seeing the results of a practice change. In addition, the practice change will more likely be sustainable and remain in place when staff are able to see the benefits of an EBP change. A good way to share this information on the nursing unit is through a poster presentation to the unit staff.

As a professional nurse it is critical to contribute to the growing knowledge of nursing practice. Nurses often communicate the outcomes of EBP changes during clinical grand rounds and at professional conferences and meetings. Being involved in professional organizations allows them to present EBP changes in scientific abstracts, poster presentations, or even podium presentations.

REFLECT NOW

On your assigned patient care clinical unit, discuss with two nurses the most effective strategies they use to communicate EBP changes to the nursing staff.

Sustain Knowledge Use

Sustaining change in practice as a result of the EBP process is a challenge. Health care institutions are bombarded by change from governmental and accrediting agencies, internal administrative initiatives, and the ongoing demands of delivering safe and effective patient care. When a new practice change is introduced, it is important that it be incorporated into the culture and practice environment of an organization. It is important for health care institutions to use targeted strategies to sustain use of EBP decisions and changes (Box 5.2). Often larger hospitals or health care systems will hire

nurse researchers or nurse scientists to manage and further develop the EBP and nursing research programs within the agency (Carter and Rivera, 2018). Mentorship and modeling of EBP by advanced practice nurses facilitate implementation of EBP in clinical settings (Melnyk et al., 2018b). *After the ICU adopts the new P&P for central line catheter care, the committee posts the monthly CLABSI outcome measure on the conference room bulletin board for all staff to see. Members of the UPC conduct occasional audits to be sure that the processes of using chlorhexidine and sterile barriers are being followed by staff members. When the incidence of CLABSI starts to go back up, the UPC committee discusses the results and reviews the causes for each patient situation.* Translating new knowledge into practice requires transformational nursing leadership (see Chapter 21) that provides the resources to develop EBP education for nurses to increase EBP knowledge, such as a toolkit to standardize nursing practices, participation on interprofessional EBP teams, and role modeling of EBP behaviors (Warren et al., 2016a; Warren et al., 2016b)

Box 5.2 Evidence-Based Practice Strategies to Sustain Nurses' Use of Evidence-Based Practice

PICOT Question: Does the use of targeted strategies improve nurses' implementation and sustained use of evidence-based practice (EBP)?

Evidence Summary

Nurses' implementation and sustained use of EBP continues to be a challenge. To be successful in sustaining EBP, health care institutions need to have an implementation plan with targeted strategies (Hanrahan et al., 2015). It is essential that leaders in the institution actively engage in and role model EBP behaviors and provide mentorship to other nurses (Warren et al., 2016b). Nurses who work on units where the leaders have clear vision and use integrated strategies and EBP activities have higher levels of continued use of EBP practices (Caramanica and Spiva, 2018; Fleiszer et al., 2016). Forming a health care agency or unit committee such as a Nursing Clinical Effectiveness Committee or EBP committee within the Shared Governance Councils was found to be an effective targeted strategy to engage nurses in EBP at the unit level (Gallagher-Ford, 2014; McKeever et al., 2016). Nurses are more interested in and willing to adopt innovative practices when they have nursing leaders who provide ongoing communication related to research and EBP (Morteniuss et al.,

2016). Scholarly mentorships from nursing faculty through academic partnerships or from advanced practice nurses and participation in journal clubs helped nurses develop EBP skills (Carter and Rivera, 2018; Fritz, 2017). EBP fellowship programs increased nurses' EBP knowledge as well as EBP implementation (Friesen et al., 2017; Kim et al., 2017). Visual management tools, such as gemba boards (visual board that includes a method for collecting process issues identified by nurses), and huddles foster an EBP culture (Bourgault et al., 2018). Targeted approaches help nurses engage in EBP in their practices.

Application to Nursing Practice

- Be familiar with the nursing leader's vision as it relates to strategies and activities for EBP in the health care agency (Fleiszer et al., 2016; Melnyk et al., 2018a).
- Form an EBP team or journal club with other nurses to help create a culture of inquiry in your agency (Kitson and Harvey, 2016; Fritz, 2017).
- Watch for strategic communication from leadership about research and EBP educational opportunities and improvements within your agency (Mortenijs et al., 2016; Melnyk et al., 2018a).
- Partner with a nursing professor or an advanced practice nurse who can mentor you as you develop your skills in EBP (Carter and Rivera, 2018; Melnyk et al., 2018b).
- As a student, partner with a nurse on the unit to search the literature to answer a practice improvement question and share your findings with the other nurses (Raines, 2016).

Nursing Research

After completing a thorough review and critique of the scientific literature, you might not have enough strong evidence to make a practice change. Instead you may find a gap in knowledge that makes your PICOT question go unanswered. When this happens, the best way to answer your PICOT question is to conduct a research study. At this time in your career you will not be conducting research. However, you may observe nurses performing research within the hospital. It is important for you to understand the process of nursing research and how it generates new knowledge.

Nursing research improves the health and welfare of people who are underserved (NINR, n.d.). **Nursing research** is a way to identify new knowledge, improve professional education and practice, and use nursing and health care resources effectively. Research means to search again or to examine carefully. It is a systematic process that asks and answers questions to generate knowledge. The knowledge provides a scientific basis for nursing practice and validates the effectiveness of nursing interventions. Nursing research improves professional education and practice and helps nurses use resources effectively (e.g., how to best use human resources by determining the best practice mix of nurses and assistive personnel on a nursing unit). The scientific knowledge base of nursing continues to grow, providing evidence that nurses can use to provide safe and effective patient care. Many professional and specialty nursing organizations have agendas for research among their members to advance nursing science.

Translation Research

Translation research focuses on “testing implementation interventions to improve uptake and use of evidence to improve patient outcomes and population health” (Titler, 2018, p. 1). It is also called implementation science. The purpose of studies in translation research is to test implementation strategies to determine which strategies work best to promote use of EBP (Titler, 2018). In testing strategies, translation research helps to uncover which strategies work for whom, in what settings, and why. In conducting translation research, nurses can improve and sustain use of best evidence in practice with the goal of improving patient care, population health, and health outcomes (Titler, 2018). Translation research occurs along a dynamic continuum that moves through five phases—from

basic research to application of research findings in a variety of settings. The five phases include:

- Preclinical and animal studies—basic science research
- Phase 1 clinical trials—testing safety and efficacy in a small group of human subjects
- Phase 2 and 3 clinical trials—testing safety and efficacy in a larger group of human subjects and testing for comparison to standard treatment
- Phase 4 clinical trials and outcomes research—translation to practice
- Phase 5 population-level outcomes research—translation to community (Titler, 2018)

Translation research differs from EBP. In translation research, a research study tests the strategies that were used to implement and sustain EBP, whereas EBP focuses on the use of best evidence in practice. Translation research poses a research question and hypothesis. Then a variety of research designs and methods can be used to answer the research question and test the hypothesis (Titler, 2014). Doctorally prepared nurses play a key role in conducting translation research to improve health outcomes (Trautman et al., 2018).

Outcomes Research

In today's health care delivery system, it is more important than ever to understand the results of health care practices. Outcomes research helps patients, health care providers, and those in health care policy make informed decisions based on current evidence (PCORI, 2018). Outcomes research typically focuses on the benefits, risks, costs, and holistic effects of a treatment on patients. For example, researchers are conducting outcomes research when they study the effects of managing Parkinson disease in patients using videoconferencing and telemedicine to increase access to health care.

Care delivery outcomes are the observable or measurable effects of health care interventions (Melnyk and Fineout-Overholt, 2019). Like the expected outcomes you develop in a plan of care (see Chapter 18), a care delivery outcome focuses on the recipients of service (e.g., patient, family, or community) and not the providers (e.g., nurse or physician). For example, an outcome of a diabetes education program is that patients are

able to self-administer insulin, not the nurses' success in teaching patients who have diabetes to administer insulin.

Nurses sometimes experience difficulty in clearly defining or selecting measurable outcomes. Components of an outcome include the outcome itself, how it is observed (the indicator), its critical characteristics (how it is measured), and its range of parameters (Melnyk and Fineout-Overholt, 2019). For example, health care facilities commonly identify patient satisfaction as an outcome when introducing new services (e.g., new care delivery model or outpatient clinic). Patient satisfaction is often measured by patients' responses to a satisfaction instrument, which asks patients to rank their satisfaction with different aspects of their experience, such as nursing care, physician care, support services, and the environment. Patients complete the instrument, responding to a scale (parameter) designed to measure their degree of satisfaction (e.g., scale of 1 to 5). The combined score on the instrument yields a measure of patient satisfaction, an outcome that the agency and health care team can track over time.

Nurse-sensitive indicators are outcomes that are directly influenced by nursing practice (Grove and Gray, 2019). Although it is important to research the effects of nursing care on nurse-sensitive indicators, some researchers choose outcomes that do not measure a direct effect of nursing care, such as length of stay, mortality, quality of life, and patient satisfaction. Researchers need to select appropriate outcomes when designing their studies. For example, if a nurse researcher intends to measure the success of a nurse-initiated protocol to manage blood glucose levels in patients who are critically ill, the researcher will not likely measure mortality because it is too broad and susceptible to many factors outside the control of the nurse-initiated protocol (e.g., the selection of medical therapies, the patients' acuity of illness). Instead the nurse researcher will have a better idea of the effects of the protocol by measuring the outcome of patients' blood glucose ranges. The researcher obtains the blood glucose level of patients placed on the protocol and compares them to a desired range that represents good blood glucose control.

Scientific Method

The **scientific method** is the foundation of research and the most reliable and objective of all methods of gaining knowledge. This method is an objective way to gain and test knowledge. The method guides you in applying research-based evidence in practice and conducting future

research. When using research findings to change practice, you need to understand the process used to guide a study. The scientific method is a systematic, step-by-step process. When completed correctly, you know that the study supports the **validity, reliability, and generalizability** of the data. Thus, you can safely apply the findings of such a study to similar subjects in a different study.

Researchers use the scientific method to understand, explain, predict, or control a nursing phenomenon ([Lobiondo-Wood and Haber, 2018](#)).

Systematic, orderly procedures reduce the possibility for error. Although this possibility always exists, the scientific method minimizes the chance that a researcher's **bias** or opinion will influence the results of the study and thus the knowledge gained. Scientific research includes the following characteristics:

- The research identifies the problem area or area of interest to study.
- The steps of planning and conducting a research study are systematic and orderly.
- Researchers try to control external factors that are not being studied but can influence a relationship between the phenomena they are studying. For example, if a nurse is studying the relationship between diet and heart disease, he or she controls other characteristics among subjects, such as stress or smoking history, because they are risk factors for heart disease. Patients on an experimental diet and those on a regular diet would both need to have similar levels of stress and smoking histories to test the true effect of the diet.
- Researchers gather **empirical data** through the use of observations and assessments and use the data to discover new knowledge.
- The goal is to apply the knowledge gained from a study to a broader group of patients.

Nursing and the Scientific Approach

In the past much of the information used in nursing practice was borrowed from other disciplines, such as biology, physiology, and psychology. Often nurses applied this information to their practice without testing it. For example, nurses use several methods to help patients sleep. Interventions such as giving a patient a back rub, making sure that the bed is clean and comfortable, and preparing the environment

by dimming the lights are nursing measures that are used frequently and in general are logical, commonsense approaches. However, when these measures are considered in greater depth, questions arise about their applications. For example, are they the best methods to promote sleep? Do different patients in different situations require other interventions to promote sleep?

Research allows you to study nursing questions and problems in greater depth within the context of nursing. Nurses who do not use an evidence-based approach to practice often rely solely on personal experience or the advice of nursing experts. These nurses do not question whether there is an intervention that produces better outcomes. When an intervention is unsuccessful, nurses who do not use EBP will usually use an approach practiced by a colleague or try a different sequence of accepted measures. Even if an intervention discovered with this trial-and-error approach is effective for one or more patients, it is not always appropriate for patients in other settings. Nursing interventions must be tested through research to determine the measures that work best with specific patients.

Nursing research addresses issues important to the discipline of nursing. Some of these issues relate to the profession itself, education of nurses, identification of patient and family needs in specific situations, and issues within the health care delivery system. Once research is completed, it is important to disseminate or communicate the findings. One method of dissemination is through publication of the findings in professional journals. Nursing research uses many methods to study clinical problems (Box 5.3). There are two broad approaches to research: quantitative and qualitative methods.

Box 5.3 Types of Research

- **Historical research:** Studies designed to establish facts and relationships concerning past events. Example: Study examining the societal factors that led to the acceptance of advanced practice nurses by patients.
- **Exploratory research:** Initial study designed to develop or refine the dimensions of phenomena (facts or events) or to develop or refine a hypothesis about the relationships among phenomena. Example: Pilot study testing the benefits of a new exercise program for older adults with dementia.

- **Evaluation research:** Study that tests how well a program, practice, or policy is working. Example: Study measuring the outcomes of an informational campaign designed to improve parents' ability to follow immunization schedules for their children.
- **Descriptive research:** Study that measures characteristics of people, situations, or groups and the frequency with which certain events or characteristics occur. Example: Study to examine RNs' biases toward caring for obese patients.
- **Experimental research:** Study in which the investigator controls the study variable and randomly assigns subjects to different conditions to test the variable. Example: RCT comparing chlorhexidine with Betadine in reducing the incidence of IV-site phlebitis.
- **Correlational research:** Study that explores the interrelationships among variables of interest without any active intervention by the researcher. Example: Study examining the relationship between RNs' educational levels and their satisfaction in the nursing role.

RNs, Registered nurses; *RCT*, randomized controlled trial; *IV*, intravenous.

Quantitative Research

Quantitative nursing research precisely measures and quantifies a study's variables. Two examples of quantitative research are (1) a study dealing with a new pain therapy that quantitatively measures participants' pain severity and (2) a study testing different forms of surgical dressings to measure the extent of wound healing. Quantitative research is the precise, systematic, objective examination of specific concepts. It focuses on numerical data, statistical analysis, and controls to eliminate bias in findings ([Lobiondo-Wood and Haber, 2018](#)). There are many quantitative methods. Some of the more commonly used quantitative methods include experimental, nonexperimental, survey, and evaluation research.

Experimental Research

An RCT is a true **experimental study** that tightly controls conditions to eliminate bias with the goal of generalizing the results of the study to similar groups of subjects. Researchers test an intervention (e.g., a new drug, therapy, or educational method) against the usual standard of care. They randomly assign subjects to either a control or a treatment group.

When an RCT is completed, the researcher hopes to know whether the intervention leads to better outcomes than the standard of care.

Controlled trials without randomization test interventions, but researchers have not randomized the subjects into control (group with no intervention) or treatment groups (group receiving experimental intervention). Thus, there is bias in how the study is conducted. Some findings are distorted because of how the study was designed. A researcher wants to be as certain as possible when testing an intervention that the intervention is the reason for the desired outcomes. In a nonrandomized controlled trial, the way in which subjects fall into the control or treatment group sometimes influences the results. This suggests that the intervention tested was not the only factor affecting the results of the study. Careful critique allows you to determine whether bias was present in a study and what effect, if any, the bias had on the results of the study.

Although RCTs investigate cause and effect and are excellent for testing drug therapies or medical treatments, this approach is not always the best for testing nursing interventions. The nature of nursing care causes nurse researchers to ask questions that are not always answered best by an RCT. For example, nurses help patients with problems such as knowledge deficits and symptom management. When researchers attempt to plan an RCT, ethical issues will often develop if the control group does not receive the new therapeutic intervention. Also, learning to understand how patients experience health problems cannot always be addressed through an RCT. Therefore, nonexperimental descriptive studies are often used in nursing research.

Nonexperimental Research

Nonexperimental descriptive studies describe, explain, or predict phenomena (an observable fact, event, or occurrence). Two examples include (1) a study examining factors that lead to an adolescent's decision to smoke cigarettes, and (2) a study determining factors that lead patients with dementia to fall in a hospital setting.

In a case-control study researchers study one group of subjects with a certain condition (e.g., asthma) at the same time as another group of subjects who do not have the condition. A case-control study determines whether there is an association between one or more predictor variables and the condition ([Melnyk and Fineout-Overholt, 2019](#)). For example, is there an association between predictor variables such as family history or environmental exposure to dust and the incidence of asthma? Often a case

control study is conducted retrospectively, or after the fact. Researchers look back in time and review available data about the two groups of subjects to understand which variables explain the condition. These studies involve a small number of subjects, creating a risk of bias. Sometimes the subjects in the two groups differ on certain other variables (e.g., amount of stress or history of contact allergies) that also influence the incidence of the condition, more so than the variables being studied, which can make it difficult to interpret the results of the study.

Correlational studies describe the relationship between two variables (e.g., the age of the adolescents and whether the adolescents smoke). The researcher determines whether the two variables are correlated or associated with one another and to what extent.

Many times researchers use findings from descriptive studies to develop studies that test interventions. For example, if a researcher determines that adolescents 15 years of age and older tend to smoke, he or she might later test whether participation in a program about smoking for older adolescents is effective in helping adolescents stop smoking.

Surveys

Quantitative research often uses surveys to obtain information regarding the frequency, distribution, and interrelation of variables among subjects in the study (Lobiondo-Wood and Haber, 2018). An example is a survey designed to measure nurses' perceptions of physicians' willingness to collaborate in practice. Surveys obtain information about practices, perceptions, education, experience, opinions, and other characteristics of people. The most basic function of a survey is description. Surveys gather a large amount of data to describe the population and the topic of study. It is important in survey research that the population sampled is large enough to keep **sampling error** at a minimum.

Evaluation Research

Evaluation research is a form of quantitative research that determines how well a program, practice, procedure, or policy is working (Lobiondo-Wood and Haber, 2018). Evaluation research determines why a program (or some components of the program) is successful or unsuccessful. When programs are unsuccessful, evaluation research identifies problems with the program and opportunities for change or barriers to program implementation.

Qualitative Research

Qualitative nursing research studies phenomena that are difficult to quantify or categorize, such as patients' perceptions of illness or quality of life. This research method describes information obtained in a nonnumeric form (e.g., data in the form of transcribed written transcripts from a series of interviews). Qualitative researchers aim to understand patients' experiences with health problems and the contexts in which the experiences occur. Patients tell their stories and share their experiences in these studies. The findings have depth because patients are usually descriptive in what they choose to share. Examples of qualitative studies include (1) patients' perceptions of nurses' caring in a palliative care unit, and (2) the perceptions of stress by family members of critically ill patients.

Qualitative research involves **inductive reasoning** to develop generalizations or theories from specific observations or interviews ([Lobiondo-Wood and Haber, 2018](#)). For example, a nurse extensively interviews cancer survivors and then summarizes the common themes from the interviews to inductively determine the characteristics of cancer survivors' quality of life. Qualitative research involves the discovery and understanding of important behavioral characteristics or phenomena.

There are several different qualitative research methods, including ethnography, phenomenology, and grounded theory. Each is based on a different philosophical or methodological view of how to collect, summarize, and analyze qualitative data.

Research Process

The **research process** is an orderly series of steps that allow a researcher to move from asking the research question to finding the answer. Usually the answer to the initial research question leads to new questions and other areas of study. The research process builds knowledge for use in similar situations. For example, a nurse researcher wants to know the best way to provide psychosocial support for patients with breast cancer. The research process ultimately provides knowledge that nurses from a variety of settings will use to provide evidence-based nursing care. [Table 5.2](#) summarizes steps of the research process in comparison to the nursing process (see Unit 3). Initially the researcher identifies an area of inquiry (identifying a problem), which often results from clinical practice. For example, a nurse notices that many surgical patients experience nausea after colon surgery. While speaking with a researcher at a professional nursing conference, the nurse decides to conduct a pilot study on the nursing unit to determine whether chewing peppermint gum following colon surgery prevents patients from having nausea and reduces the incidence of postoperative ileus. The nurse reviews the relevant literature to determine what is known about chewing peppermint gum and its effect on bowel mobility and nausea after abdominal surgery. The nurse notes that although many patients report problems with nausea and return of bowel function, there is limited research on the effects of chewing gum on these two outcomes.

TABLE 5.2**Comparison of Steps of the Nursing Process With the Research Process**

Nursing Process	Research Process
Assessment	Identify area of interest or clinical problem. <ul style="list-style-type: none">• Review literature.• Formulate theoretical framework.• Reflect on personal practice and/or discuss clinical issues with experts to better define the problem.
Diagnosis	Develop research question(s)/hypotheses.
Planning	Determine how study will be conducted: <ul style="list-style-type: none">• Select research design/methodology.• Identify plan to recruit sample, taking into consideration population, number, and assignment to groups.• Identify study variables: specific interventions (independent variable) and outcomes (dependent variables).• Select data collection methods.• Select approach for measuring outcomes: questionnaires, surveys, physiological measures, interviews, observations.• Formulate plan to analyze data: statistical methods to answer research questions/hypotheses.
Implementation	Conduct the study: <ul style="list-style-type: none">• Obtain necessary approvals.• Recruit and enroll subjects.• Implement the study protocol/collect data.
Evaluation	Analyze results of the study: <ul style="list-style-type: none">• Continually analyze study methodology. Is study consistently carried out? Are all investigators following study protocol?• Interpret demographics of study population.• Analyze data to answer each research question/hypothesis.• Interpret results, including conclusions, limitations. Use of the findings: <ul style="list-style-type: none">• Formulate recommendations for further research.• Determine implications for nursing.• Disseminate the findings: presentations, publications, need for further study, how to apply findings in practice.

Following identification of the problem and review of the literature, the nurse forms a research team who designs a study with the help of a nurse researcher. The research team includes nurses, gastrointestinal surgeons, and a statistician. The study sample includes all patients who are having elective colon resections. Subjects are excluded if they need to have surgery because of an emergency situation. After obtaining approval from the hospital institutional review board, the research team randomly assigns each subject into one of the two groups (experimental or control), which means subjects have a 50-50 chance of being in each group. The control group receives standard postoperative care. Subjects in the experimental or treatment group get standard postoperative care, and they chew gum for 5 minutes 3 times a day. The research team selects appropriate instruments to measure postoperative nausea and patient assessment data to determine when nurses first hear bowel sounds and when patients first pass flatus and have their first bowel movement after surgery.

Before conducting any study with human subjects, a researcher obtains approvals from the human subjects committee or institutional review board (IRB) of an agency. An IRB includes scientists and laypeople who

review all studies conducted in the institution to ensure that ethical principles, including the rights of human subjects, are followed. **Informed consent** means that research subjects (1) are given full and complete information about the purpose of a study, procedures, data collection, potential harm and benefits, and alternative methods of treatment; (2) are capable of fully understanding the research and the implications of participation; (3) have the power of free choice to voluntarily consent or decline participation in the research; and (4) understand how the researcher maintains confidentiality or anonymity. **Confidentiality** guarantees that any information a subject provides will not be reported in any manner that identifies the subject and will not be accessible to people outside the research team.

Once the study begins, the nurses on the unit collect data as indicated in the study protocol. Once all data are collected from every patient in the study, the team analyzes the data from the nausea instrument and the chart review about bowel function from the two groups studied. With the help of the statistician, analysis of the results determines whether patients who chewed peppermint gum experienced less nausea and a quicker return of bowel function than the patients who had standard nursing care. The results from this study may advance postoperative nursing care.

Researchers always need to consider study limitations. Limitations are factors that affect study findings, such as a small sample of subjects, a unique setting where the study was conducted, or the failure of the study to include representative cultural groups or age-groups. The research team conducted a pilot study because little data were available about the benefits of chewing gum following abdominal surgery. The sample size included only 20 patients in each group, and it was challenging to collect all the data from the patient charts because of inconsistencies in documentation. Therefore, the results of the study have limited generalizability to other patients who are experiencing abdominal surgery. These limitations help the team decide how to refine or adapt the study for further investigation in the future.

A researcher also addresses the implications for nursing practice. This ultimately helps fellow researchers, clinicians, educators, and administrators apply findings from a study in practice. At the end of the chewing gum study, the research team recommends that patients who have elective colon resections be offered the opportunity to chew peppermint gum following surgery. The surgeons on the unit agreed to the change in practice. The team decides to conduct another study to investigate this intervention with patients who have other types of

abdominal surgeries to enhance the generalizability of the results. In addition, the team suggests ways to effectively introduce the use of chewing gum into other surgical units following surgery.

Performance Improvement

Performance improvement (PI) is a formal approach for the analysis of health care–related processes. It does not involve introduction of new practices, as is the case of EBP, but it can involve review of how interventions within a process function effectively. Health care organizations routinely promote efforts for improving patient care processes and outcomes, particularly with respect to reducing medical errors and enhancing patient safety. PI is the continuous and ongoing effort to achieve measurable improvements in the efficiency, effectiveness, performance, accountability, outcomes, and other indicators of quality services or processes ([Green et al., 2018](#)).

Every health care organization gathers and reports data on multiple health outcome measures to determine its quality of care. When findings suggest potential problems, an organization institutes a formal PI initiative. Also, in many cases the trending from PI data reveals problems that lead to EBP projects. PI projects usually occur more quickly than an EBP or research project. An organization analyzes and evaluates current performance data to solve system problems (e.g., supply delivery, appointment scheduling), people problems (e.g., staffing ratios, communication protocols), or clinical problems (e.g., surgical incision infection rates, patient injuries from falls). When interprofessional teams participate in PI activities, they may or may not use research findings to develop strategies; however, an evidenced-based approach is advised when dealing with clinical problems.

Performance Improvement Programs

A well-organized PI program focuses on processes or systems that significantly contribute to outcomes of a specific organization as well as plan on how to sustain measurable improvements over time. Facilities need an organization-wide, systematic approach to ensure that everyone supports a continuous PI philosophy. This begins with the organizational culture, in which all staff members understand their responsibility toward maintaining and improving quality ([Connelly, 2018](#)). Typically, in health care many people are involved in single processes of care. For example, medication delivery involves the health care provider who prescribes medications, the secretary who communicates new orders being written, the pharmacist who prepares the dosage, the transporter who delivers medications, and the nurse who prepares and administers the drugs.

When an organization identifies a need to improve the medication administration process, all professions involved in medication administration need to be engaged in the PI process. Because most health care processes are interprofessional, all members of the health care team collaborate in PI activities. As a member of the nursing team, you participate in recognizing trends in practice, identifying recurrent problems, and initiating opportunities to improve care.

The PI process begins at the staff level, where all disciplines become involved in identifying quality problems. This requires staff members to know the outcomes measured by the organization and the practice standards or guidelines that define quality. Unit PI committees review quality data and the activities or services considered to be most important in providing quality care to patients. One way to identify the greatest opportunity for improving quality is to consider activities that are high volume (greater than 50% of the activity of a unit); high risk (potential for trauma or death); and problem areas for patients, staff, or the institution. For example, on an orthopedic nursing unit hip surgery volume is high, adults over 80 years of age have more postoperative complications, and family members are dissatisfied with patients' pain control. Any one of these factors could become the focus of a PI project.

Another approach to PI is to use The Joint Commission's annual patient safety goals (TJC, 2020), which provide an excellent focus for PI initiatives (see Chapter 27). Sometimes a problem is presented to a committee in the form of a **sentinel event**, an unexpected occurrence involving death or serious physical or psychological injury of a patient. After a sentinel event, the unit conducts a root cause analysis (RCA). The goal of the RCA is to review all information and identify how the event occurred through identification of **active errors** (i.e., the acts that personnel perform) and why it occurred through identification and analysis of **latent errors** (i.e., the organization or steps of the process). Once a committee defines the problem, it applies a formal PI model for exploring and resolving quality concerns. There are several models for PI (Table 5.3). Health care organizations today are changing current organizational culture toward the concept of a "just culture." In a "just culture" the organization values the reporting of errors and is focused on the processes that lead to the error. "Just culture" also values nurses' critical thinking and problem-solving skills and the nurses' work on improving patient care processes (Kennedy, 2016).

TABLE 5.3**Examples of Performance Improvement Models**

Performance Improvement Model	Summary Description
1. Balanced scorecard	A multidimensional framework for managing strategy by linking objectives, initiatives, targets, and performance measures across key organization perspectives
2. Root cause analysis (RCA)	A structured method used to analyze serious adverse events. A central tenet of RCA is to identify underlying problems that increase the likelihood of errors while avoiding the trap of focusing on mistakes by individuals.
3. Six Sigma	A disciplined methodology for process improvement that deploys a wide set of tools based on rigorous data analysis to identify sources of variation in performance and ways of reducing them
4. Plan-Do-Study-Act (PDSA)	An experiential learning method that involves analyzing a quality problem and testing a change by developing a plan to test the change (Plan), carrying out the test (Do), observing and learning from the consequences (Study), and determining which modifications should be made to the test (Act).

PI combined with EBP is the foundation for excellent patient care and outcomes. Once a PI committee makes an evidence-based practice change, it is important to monitor the results and then communicate the results to staff from all appropriate departments. Practice changes are unlikely to last when PI committees fail to report findings and the results of interventions (Nilsen et al., 2017). Regular discussions of PI activities through staff meetings, newsletters, and memos are good communication strategies. Often a PI study reveals information that prompts organization-wide change. An organization must be responsible for responding to the problem with the appropriate resources. Revision of policies and procedures, modification of standards of care, and implementation of new support services are examples of ways an organization responds.

Building Competency in Evidence-Based Practice

The Nursing Practice Council notes that the incidence of falls with injuries has increased on all units in the agency over the past year. When checking its fall prevention protocol, the council notes it was last reviewed 4 years ago. The council knows that falls with injuries are a nursing-sensitive outcome (NDNQI) and established a goal to reduce the incidence of falls in the upcoming year. How should the Nursing Practice Council proceed?

The Relationship Between EBP, Research, and Performance Improvement

EBP, research, and performance improvement (PI) are closely interrelated (Fig. 5.3) and exist along a continuum of clinical scholarship (Carter et al., 2017). All three processes require you to use the best evidence to provide the highest quality of patient care. As a nurse you are professionally accountable to know the differences and which process to select when facing clinical problems or when you desire to improve patient care. Although you will use all of these in nursing practice, it is important to know the similarities and differences among them (Carter et al., 2017) (Table 5.4). When implementing an EBP project, it is important to first review evidence from appropriate research and PI data. This information helps you better understand the extent of a problem in practice and within your organization. PI data inform you about how processes work within an organization and thus offer information about how to make EBP changes. EBP and PI sometimes reveal problems that create opportunities for research.

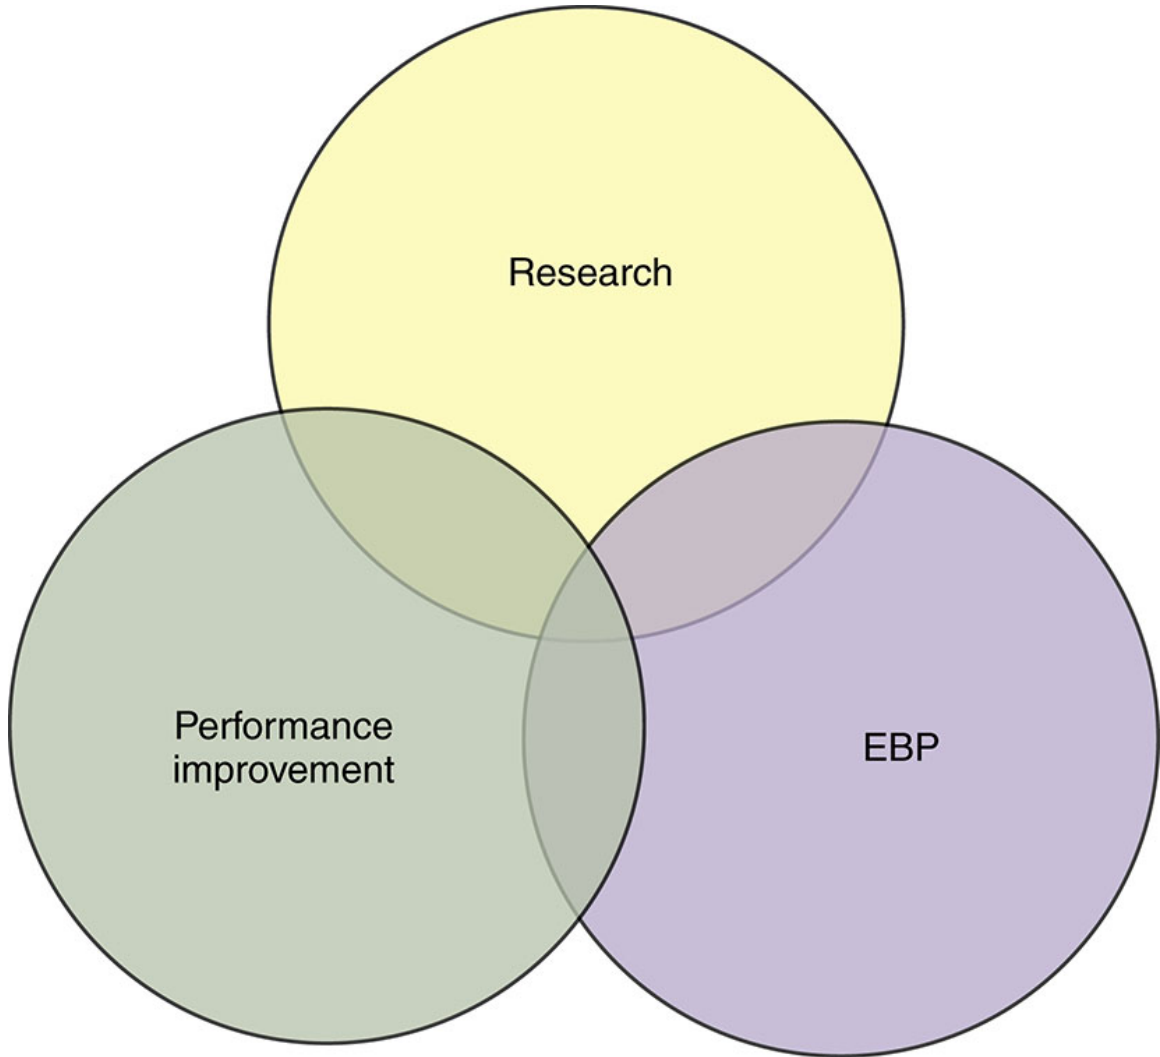

FIG. 5.3 The overlapping relationship among research, evidence-based practice (EBP), and performance improvement.

TABLE 5.4**Similarities and Differences Among Evidence-Based Practice, Research, and Performance Improvement**

	Evidence-Based Practice	Research	Performance Improvement
Purpose	Use of information from research, professional experts, personal experience, and patient preferences to determine safe and effective nursing interventions with the goal of improving patient outcomes	Systematic inquiry answers questions, solves problems, and contributes to the generalizable knowledge base of nursing; it may or may not improve patient care.	Improves local work processes to improve patient outcomes and efficiency of health systems; results usually not generalizable
Focus	Implementation of evidence already known into practice	New knowledge is generated to find answers for questions that are not known about nursing practice.	Measures effects of practice and/or practice change on specific patient population
Data sources	Multiple research studies, expert opinion, personal experience, patients	Subjects or participants have predefined characteristics that include or exclude them from a study; researcher collects and analyzes data from subjects.	Data from patient records or patients who are in a specific area such as on a patient care unit or admitted to a particular hospital
Who conducts the activity?	Practicing nurses and possibly other members of the health care team	Researchers who may or may not be employed by the health care agency and usually are not a part of the clinical health care team.	Employees of a health care agency such as nurses, physicians, pharmacists
Is activity part of regular clinical practice?	Yes	No	Yes
Is IRB approval needed?	Sometimes	Yes	Sometimes
Funding sources	Internal, from health care agency	Funding is usually external, such as a government grant. However, larger health care organizations often have internal grants available from their foundations.	Internal, from health care agency

IRB, Institutional review board.

The following is an example of how the three processes merge to improve nursing practice:

A nursing unit is experiencing a decrease in patient satisfaction with pain management over the last several months. PI data identify factors associated with pain management (e.g., the types of pain medications typically ordered, patient reports of pain relief following administration of pain medications). A thorough analysis of PI data leads a unit-based quality council team of nurses to conduct a literature review and implement the best evidence available to improve their pain-management protocol for the type of patients on the unit. The staff implement a revised pain management protocol and evaluate its results. Despite the implementation of the revised pain-management protocol, patient satisfaction data continue to be lower than desired. Thus, staff decide to conduct a research study to further investigate this clinical problem and improve patient care.

Key Points

- EBP guides nurses and other health care providers in making effective, timely, and appropriate clinical decisions.
- The steps of EBP include cultivate a spirit of inquiry, ask a clinical question in PICOT format, search for the most relevant and best evidence, critically appraise the evidence, integrate the best evidence, evaluate the outcomes of the practice change, and communicate results of the change.
- Using problem- and knowledge-focused triggers to think critically about clinical and operational nursing-unit issues helps you define a PICOT question.
- A focused PICOT question allows you to search for evidence in the scientific literature.
- After appraising the evidence for a PICOT question, if the question is unanswered and there is a gap in knowledge, the research process is the next option for gaining new evidence.
- The research process is an orderly series of six steps that allow the researcher to move from problem identification to finding an answer to the research question.
- The hierarchy of evidence offers a guide to evaluate literature or information and determine whether a source is relevant, valid, and appropriate for use in practice.
- An RCT is the highest level of experimental research.
- Use your clinical expertise and consider patients' values and preference to ensure that you will apply the evidence in practice both safely and appropriately.
- Research is a systematic process that asks and answers questions to generate knowledge and provide a scientific basis for nursing practice.

- The best scientific evidence comes from well-designed, systematically conducted research studies.
- Although EBP, research, and PI are closely related, they are separate processes in nursing practice that all require the use of the best evidence to provide high-quality patient care.

Reflective Learning

- While on the clinical unit, talk to a staff nurse about the PI activities on the nursing unit. Report on the focus of the unit's PI activities to improve patient outcomes.
- Think about the nursing care that you provided to your patients on the clinical unit today. What questions came to your mind about the practices that you were doing? Formulate one of the questions in PICOT format.
- After asking the PICOT question, search the literature and find two or three research studies on the topic. What is the current state of the evidence related to your question?

Review Questions

1. Match the components of PICO using the question "Does the use of guided imagery compared with standard care decrease the postoperative pain in hospitalized adolescents?"

___ (P) Patient/population	A. Adolescents receiving standard care
___ (I) Intervention	B. Decreased postoperative pain
___ (C) Comparison	C. Hospitalized adolescents
___ (O) Outcome	D. Guided imagery

2. Place the steps of the EBP process in the appropriate order.
 1. Critically appraise the evidence you gather.

2. Ask the clinical question in PICOT format.
 3. Evaluate the outcomes of the practice decision or change.
 4. Search for the most relevant and best evidence.
 5. Cultivate a spirit of inquiry.
 6. Integrate the evidence.
 7. Communicate the outcomes of the EBP change.
3. A nurse is reading a research article discussing a new practice to decrease the incidence of catheter-associated urinary tract infections. One section of the article describes who was studied and how the data were collected to answer the research questions and hypotheses. What section of the research article is currently being read?
 1. The literature review
 2. The data analysis
 3. The methods
 4. The implications for practice
 4. A nurse implements an EBP change that teaches patients the importance of taking their diabetes medications correctly and regularly on time using videos streamed on the Internet. The nurse measures the patients' behavioral outcome from the practice change using which type of measurement?
 1. Measuring the patient's weight
 2. Chart auditing teaching sessions
 3. Observing patients viewing the videos
 4. Checking patients' blood sugars
 5. A patient in the intensive care unit experiences a sentinel event related to central-line catheter care that resulted in serious injury. What performance improvement model should the unit use to identify errors that led to the sentinel event?
 1. Six Sigma

2. Root cause analysis
 3. PDSA
 4. Balanced scorecard
6. Which of the following are outcomes measurements? (Select all that apply.)
1. A nurse teaches a patient how to administer an injection and then observes the patient do a return demonstration.
 2. A nurse implements a new pain-management protocol and checks patients' charts to confirm whether interventions are being provided.
 3. A nursing unit adopts a set of strategies for reducing pressure injuries, and the UPC members use direct observation of the skin to measure incidence of pressure injuries.
 4. A nursing unit implements a new fall-prevention protocol and checks the monthly performance data for incidence of falls on the unit.
 5. A nursing unit implements a patient rounding program, and the charge nurse watches the assistive personnel to see whether hourly rounding is being done on patients.
7. The nurses on a medical unit have seen an increase in the number of pressure injuries developing in their patients. The nurses decide to initiate a performance improvement project using the PDSA model. Which of the following is an example of "Plan" from that model?
1. Orienting patients to the unit's practice of hourly rounding on patients
 2. Reviewing the incidence of pressure injuries on patients cared for using the protocol
 3. Based on findings from patients who developed injuries, implementing an evidence-based skin care protocol on all units

4. Meeting with all disciplines to develop a multidisciplinary approach for reducing pressure injuries
8. The nurse is using the QSEN competency of EBP when working with the unit council to initiate a change related to pain management. Which behaviors demonstrate the nurse practicing behaviors associated with EBP? (Select all that apply.)
 1. Initiating plan for self-development as a team member
 2. Reading original research related to pain management
 3. Demonstrating effective use of strategies to reduce risk of harm to self or others
 4. Valuing EBP as critical to the development of pain management guidelines for the unit
 5. Describing to the unit council reliable sources for locating clinical guidelines
 6. Applying technology and information management tools to support safe processes of care
9. Nurses in a community clinic are conducting an EBP project focused on improving the outcomes of children with asthma. The PICO question asked by the nurses is “In school-aged children, does the use of an electronic gaming education module versus educational book improve the usage of inhalers?” In the question, what is the “O”?
 1. School-aged children
 2. Educational book
 3. Use of inhalers
 4. Electronic gaming education
10. During an EBP committee meeting, a nurse discussed two systematic integrative reviews related to the use of prepackaged bath kits versus the standard use of bath basins. What level of evidence is the nurse presenting?
 1. Level I

2. Level II

3. Level IV

4. Level VI

Answers: **1.** C, D, A, B; **2.** 5, 2, 4, 1, 6, 3, 7; **3.** 3; **4.** 4; **5.** 2; **6.** 1, 3, 4; **7.** 4; **8.** 2, 4, 5; **9.** 3; **10.** 1

14. Older Adults

Health and Wellness

OBJECTIVES

- Explain how *Healthy People* guides public health goals for Americans.
- Discuss how individuals define health.
- Discuss the health belief, health promotion, basic human needs, and holistic health models to understand the relationship between patients' attitudes toward health and health practices.
- Describe variables influencing health, health beliefs, and health practices.
- Describe health promotion, health education, and illness prevention activities.
- Discuss the three levels of prevention.
- Compare and contrast nonmodifiable and modifiable risk factors that threaten health.
- Discuss nursing's role in risk-factor modification and changing health behaviors.
- Describe variables influencing illness behavior.
- Describe the effect of illness on patients and families.

Illness behavior, p. 77

Illness prevention, p. 73

Primary prevention, p. 73

Risk factor, p. 74

Secondary prevention, p. 74

Tertiary prevention, p. 74

Nurses are in a unique position to help individuals, families, communities, and populations become or remain healthy. Because nurses are caregivers, advocates, and educators, they promote health and wellness in all health care settings. Through their knowledge and assessment, nurses identify actual and potential risk factors that predispose an individual or a group to illness. In addition, nurses use strategies to help patients modify those risk factors to prevent illness.

People react in different ways to their own illness or the illness of a family member. Nurses who understand how patients react to illness can help patients and their families maintain or return to the highest level of functioning, which reduces health care costs. Thus, it is important that you help patients make changes to improve their health and wellness.

Healthy People

The *Healthy People* initiative provides evidence-based, 10-year national objectives for promoting health and preventing disease. *Healthy People* provides a framework to help the United States increase its focus on health promotion and disease prevention (instead of illness care) and encourages cooperation among individuals, communities, and other public, private, and nonprofit organizations to improve health ([USDHHS, 2018](#)). Widely cited by the media, in professional journals, and at health conferences, *Healthy People* emphasizes how the health of communities affects the overall health status of the nation. Because of its interprofessional approach, it has inspired health promotion programs throughout the country since its first publication in 1979.

The current publication, *Healthy People 2020*, was approved in December 2010; it promotes a society in which all people live long, healthy lives. *Healthy People 2020* identifies leading health indicators (LHIs) (e.g., access to health services; injury and violence prevention; maternal, infant, and child health), which are high-priority health issues in the United States. Although the United States has made great progress on the LHIs, it falls behind other developed countries on key measures of health and well-being, including life expectancy, infant mortality, and obesity ([USDHHS, 2018](#)). Each month, the [HealthyPeople.gov](#) website reports on one or more of the LHIs to explain existing health disparities ([USDHHS, 2018](#)).

The Secretary's Advisory Committee on National Health Promotion and Disease Prevention Objectives for 2030 is guiding the development and implementation of *Healthy People 2030*. The framework proposed by *Healthy People 2030* will build on the previous editions of *Healthy People*, promote a holistic approach to health promotion and disease prevention, and help to engage community leaders to act and design policies to improve the health and well-being of all Americans ([USDHHS, 2018](#)).

Definition of Health

The World Health Organization (WHO) defines **health** as a “state of complete physical, mental, and social well-being, not merely the absence of disease or infirmity” (WHO, 1947, 2018a). Health is a state of being that people define in relation to their own values, personality, and lifestyle. Each person has a personal concept of health. Health is the actualization of inherent and acquired human potential through goal-directed behavior, competent self-care, and satisfying relationships with others (Pender et al., 2015; Murdaugh et al., 2019). People adjust as needed to maintain structural integrity and harmony with the environment.

Individuals’ views of health vary among different cultural orientations (Murdaugh et al., 2019). People who are free from disease are not necessarily healthy (Pender, 1996). Health is influenced by a person’s values, personality, and lifestyle. People often define their health by the circumstances surrounding their lives rather than by their physical condition. Life conditions can have positive or negative effects on health long before an illness is evident (Murdaugh et al., 2019). Life conditions include socioeconomic variables such as environment, diet, lifestyle practices or choices, and many other physiological and psychological variables.

Individual perceptions and definitions of health are affected by a person’s health beliefs and change as a person ages. For example, the definition of health for older people is often influenced by the absence of disease and disability, the maintenance of physical and cognitive functioning, having connections with others, and health practices a person uses regularly (Griffith et al., 2018). Thus, you consider the total person and his or her environment to individualize nursing care and enhance a patient’s health.

Models of Health and Illness

Models help explain complex concepts or ideas, such as health and illness. Models help you understand the relationships between these concepts and a patient's attitudes toward health and health behaviors.

Health beliefs are a person's ideas, convictions, and attitudes about health and illness. They are sometimes based on facts or misinformation, common sense or myths, good or bad experiences, or reality or false expectations. Because health beliefs influence health behavior, they can positively or negatively affect a patient's level of health. Positive health behaviors maintain, attain, or regain health and prevent illness. Common positive health behaviors include immunizations, proper sleep patterns, adequate exercise, stress management, and nutrition. Negative health behaviors include practices that are harmful to health, such as smoking, drug or alcohol abuse, poor diet, and refusing to take necessary medications.

Nurses use several health models to understand patients' unique attitudes and values about health and illness and to provide effective health care. These models allow you to understand and predict patients' health behaviors, including how they use health services and adhere to recommended therapy. Positive health models focus on the individual's strengths, resiliencies, resources, potential, and capabilities rather than on disease or pathology (Murdaugh et al., 2019).

Use these models to individualize plans of care that will be effective in restoring or promoting a patient's health. Remember that each patient has a unique view of health and wellness. A person's individual belief system influences the ability to make lasting changes in health status. Do not make judgments when your patients have views and beliefs that differ from your own.

Health Belief Model

The **Health Belief Model** (Fig. 6.1) addresses the relationship between a person's beliefs and behaviors (Rosenstoch, 1974; Becker and Maiman, 1975). The first component of this model involves an individual's perception of susceptibility to an illness. For example, a patient whose family history includes one parent and two siblings who have died from a myocardial infarction recognizes the familial link for coronary artery disease and perceives a personal risk of heart disease.

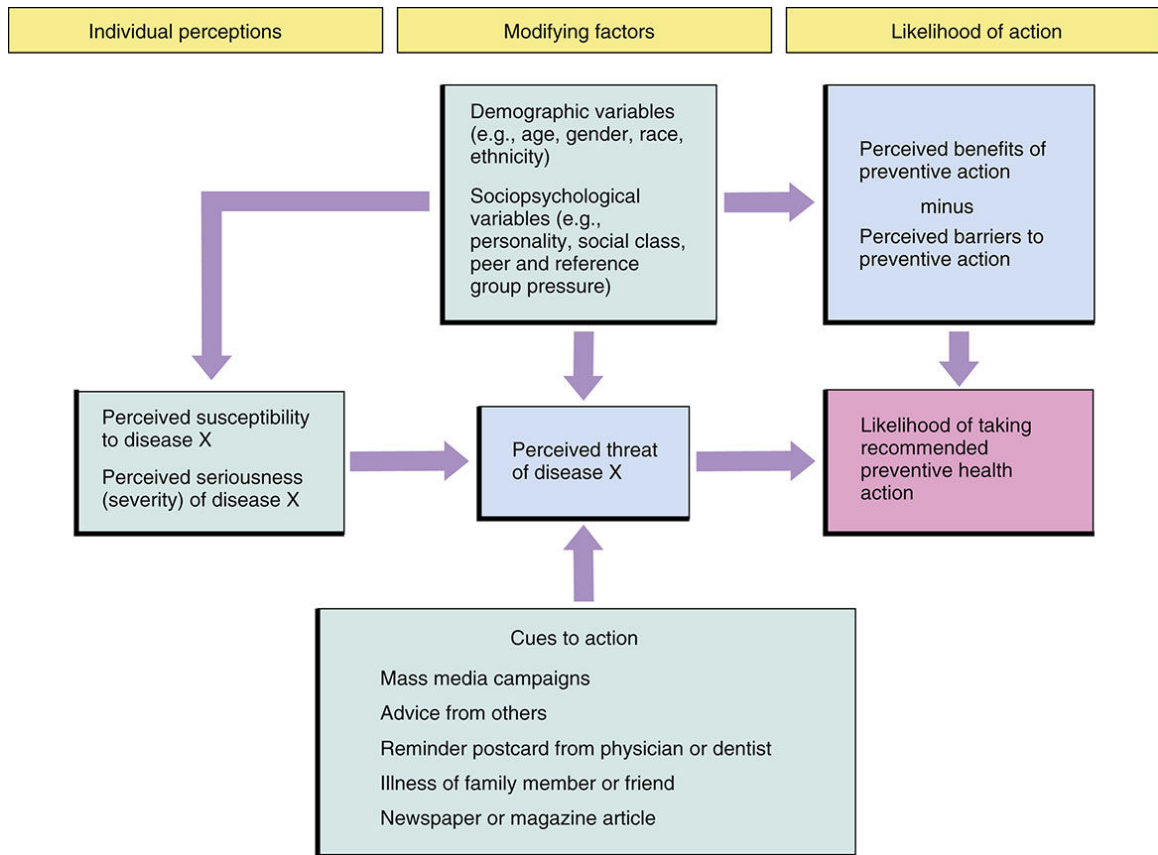

FIG. 6.1 Health Belief Model.

Data from Becker M, Maiman L: Sociobehavioral determinants of compliance with health and medical care recommendations, *Med Care* 13[1]:10, 1975.

The second component is an individual's perception of the seriousness of the illness. This perception is influenced and modified by demographic and sociopsychological variables, perceived threats of the illness, and cues to action (e.g., mass media campaigns and advice from family, friends, and medical professionals). For example, a patient may not perceive his heart disease to be serious, which may affect the way he takes care of himself.

The third component is the likelihood that a person will take preventive action. This component results from a person's perception of the benefits of and barriers to taking action. Preventive actions include lifestyle changes, increased adherence to medical therapies, or a search for medical advice or treatment. A patient's perception of susceptibility to disease and his or her perception of the seriousness of an illness help to determine the likelihood that the patient will adopt healthy behaviors. This model helps you understand factors influencing patients' perceptions, beliefs, and behaviors to plan care so that you can more effectively help patients maintain or restore health and prevent illness.

Health Promotion Model

The Health Promotion Model (HPM) (Pender, 1982, 1996; Pender et al., 2015; Murdaugh et al., 2019) defines health as a positive, dynamic state, not merely the absence of disease (Fig. 6.2). Health promotion increases a patient's level of well-being. The HPM describes the multidimensional nature of people as they interact within their environment to pursue health (Pender, 1996; Murdaugh et al., 2019). The model focuses on the following three areas: (1) individual characteristics and experiences; (2) behavior-specific knowledge and affect; and (3) behavioral outcomes, in which the patient commits to or changes a behavior. Each person has unique personal characteristics and experiences that affect subsequent actions. The set of variables for behavior-specific knowledge and affect influence a patient's motivation to change or adopt healthy behaviors. When applying this model, you modify these variables through nursing actions. Health-promoting behaviors result in improved health, enhanced functional ability, and better quality of life at all stages of development (Murdaugh et al., 2019).

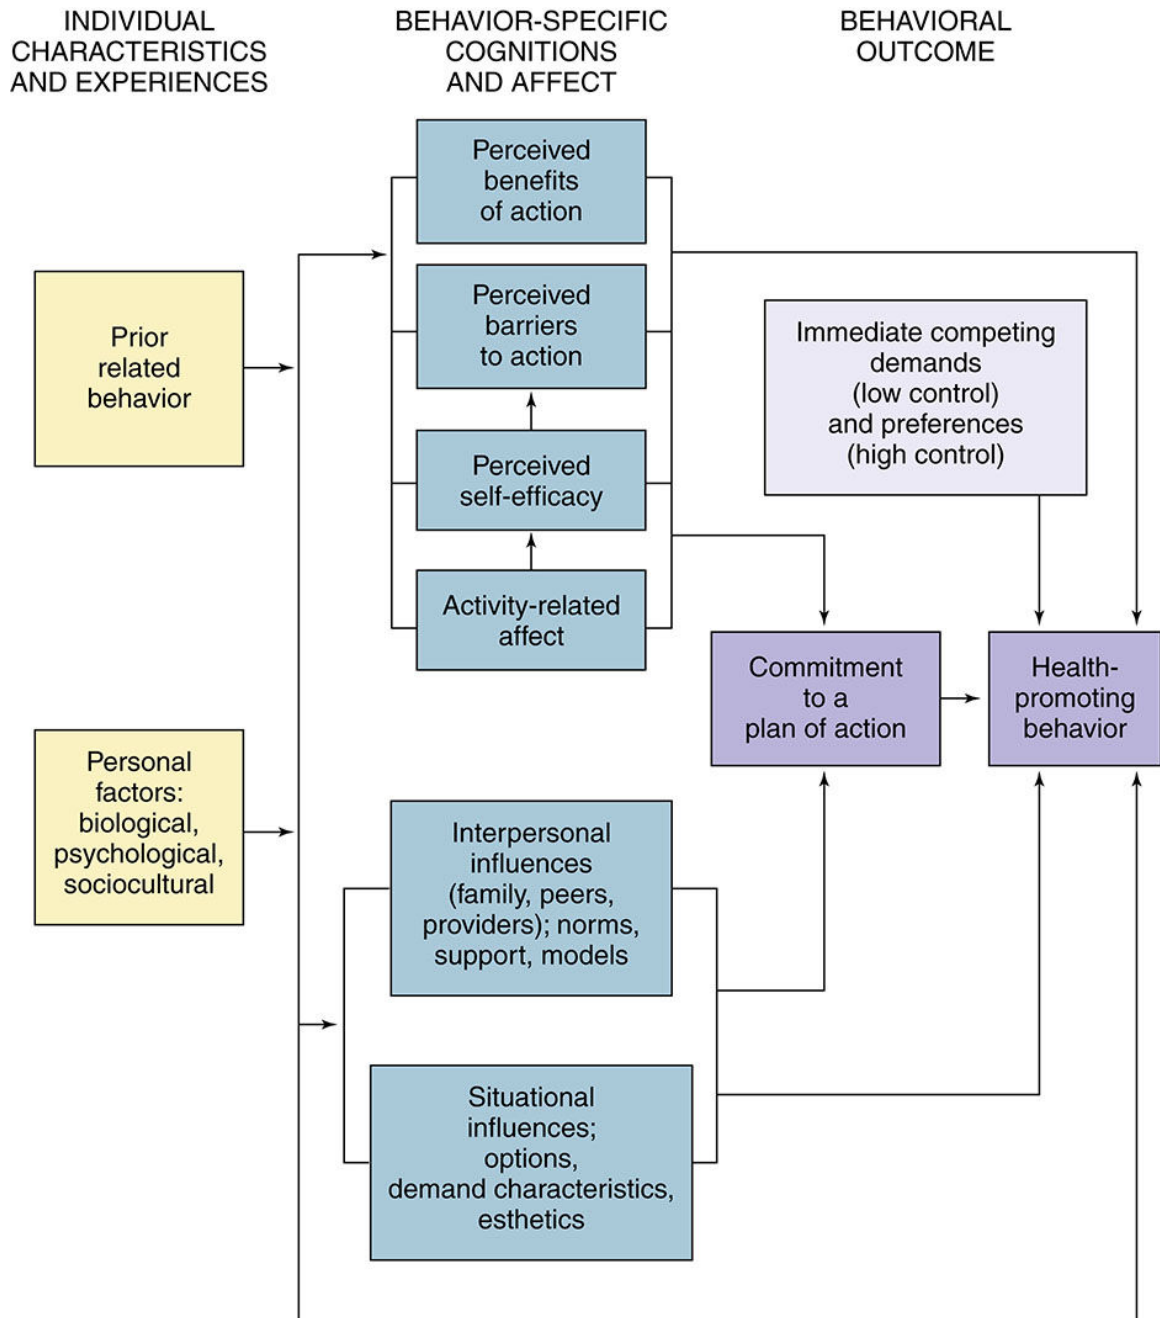

FIG. 6.2 Health Promotion Model (revised).

Redrawn from Maslow AH, Frager RD (Editor), Fadiman J (Editor): *Motivation and personality*, ed 3. ©1987. Reprinted with permission of Ann Kaplan.

Maslow's Hierarchy of Needs

Nurses use Maslow's hierarchy of needs to understand the interrelationships of basic human needs (Fig. 6.3). Basic human needs are

necessary for human survival and health (e.g., food, water, safety, and love). Although each person has unique needs, all people share basic human needs, and the extent to which people meet their basic needs is a major factor in determining their level of health.

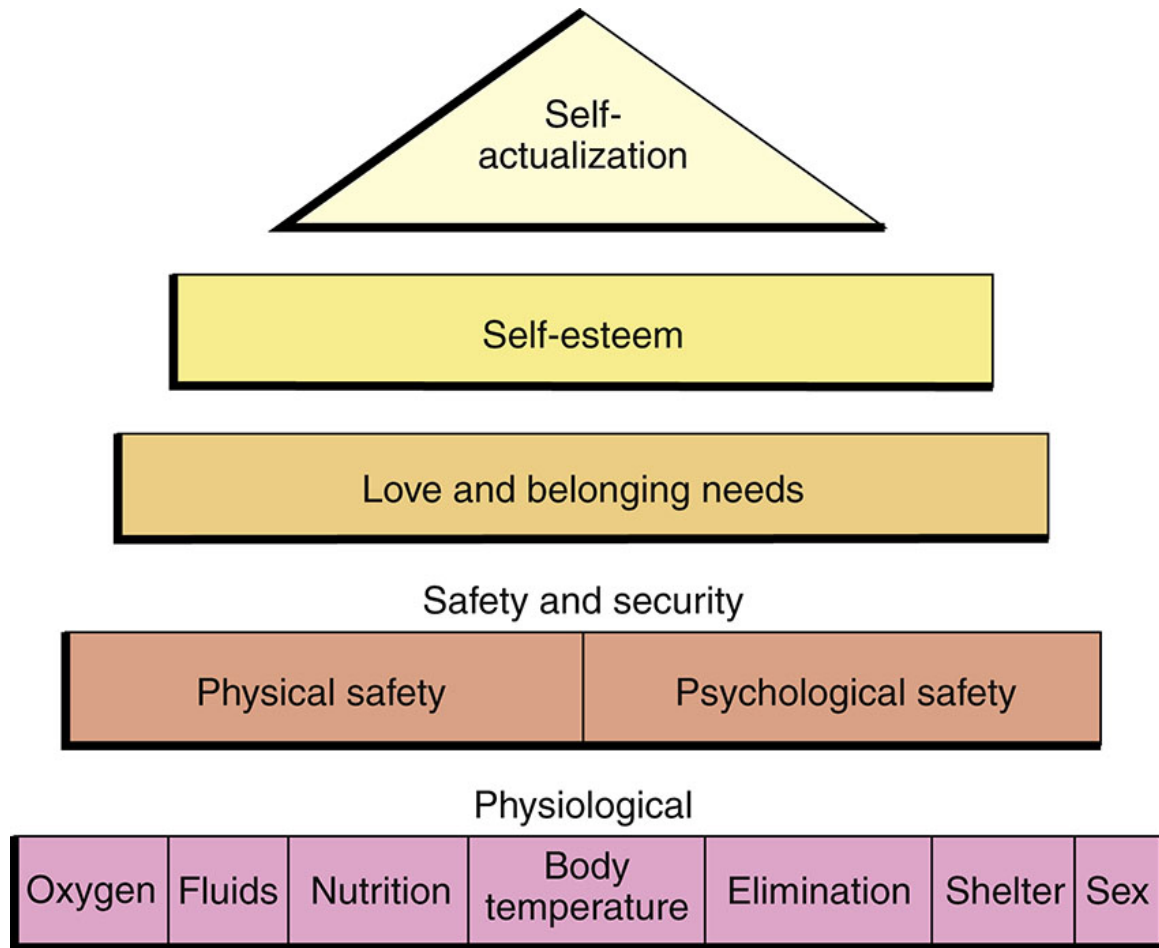

FIG. 6.3 Maslow's hierarchy of needs.
Redrawn from Maslow AH: *Motivation and personality*, ed 3, Upper Saddle River, NJ, 1970, Prentice Hall.

According to this model, certain human needs are more basic than others, and some needs must be met before other needs (e.g., fulfilling physiological needs before the needs of love and belonging). Self-actualization is the highest expression of one's individual potential and allows for continual self-discovery. Maslow's model considers individual experiences, which are always unique to that individual (Touhy and Jett, 2016).

Maslow's hierarchy provides a basis for nurses to care for patients of all ages in all health settings. However, when applying the model, the focus of care is on a patient's needs rather than on strict adherence to the hierarchy. It is unrealistic to always expect a patient's basic needs to occur in the fixed hierarchical order. In all cases an emergent physiological need takes precedence over a higher-level need. In other situations, a psychological or physical safety need takes priority. For example, in a house fire, fear of injury and death takes priority over self-esteem issues. Although you might anticipate a patient who has just had surgery has the strongest need for pain control in the physiological area, if the patient just had a mastectomy, her main need may be in the areas of love, belonging, and self-esteem. It is important not to assume the patient's needs just because other patients reacted in a certain way. Apply Maslow's hierarchy to each patient individually. To provide the most effective care, you need to understand the relationships of different needs and the factors that determine the priorities for each patient.

Holistic Health Model

The relationship between body, mind, and spirit affects a person's health. The **Holistic Health Model** of nursing promotes a patient's optimal level of health by considering the dynamic interactions among the emotional, spiritual, social, cultural, and physical aspects of an individual's wellness (LaVela et al., 2017). You put your patients at the center of their care and recognize your patients as the ultimate experts concerning their own health. A patient's subjective experience is relevant in maintaining health or assisting in healing. The Holistic Health Model empowers patients to engage in their own recovery and assume some responsibility for health maintenance (Edelman and Kudzma, 2018).

The Holistic Health Model recognizes a person's choices powerfully affect an individual's health. Some of the most widely used holistic interventions include meditation, music therapy, reminiscence, relaxation therapy, therapeutic touch, and guided imagery (see Chapter 32). These holistic strategies, which can be used in all stages of health and illness, are integral in the expanding role of nursing.

Nurses use holistic therapies either alone or in conjunction with conventional medicine. For example, using reminiscence sometimes helps relieve anxiety for older patients dealing with memory loss. Meditation sometimes helps patients cope with the difficult side effects of

chemotherapy. Helping your patients understand different holistic therapies allows them to make choices that enhance their health.

Variables Influencing Health and Health Beliefs and Practices

Many variables influence a patient's health beliefs and practices. Internal and external variables influence how a person thinks and acts. Health beliefs usually influence health behaviors or health practices, which positively or negatively affect a patient's level of health. Understanding the effects of these variables allows you to plan and deliver individualized care.

Internal Variables

Internal variables include a person's developmental stage, intellectual background, perception of functioning, and emotional and spiritual factors.

Developmental Stage

A person's perceptions of health, illness, and health behaviors change over time (see [Chapter 11](#)). Considering a patient's growth and development stage helps you predict a patient's response to an actual illness or the threat of a future illness. Fear and anxiety are common among ill children, especially if thoughts about illness, hospitalization, or procedures are based on lack of information or lack of clarity of information. Emotional development may also influence personal beliefs about health-related matters. For example, you use different techniques for teaching about the need to be physically active to an adolescent than you use for an adult. A person's developmental stage sometimes differs from his or her chronological age. Adapt your nursing care based on a patient's developmental stage and the ability to participate in self-care.

Intellectual Background

A person's beliefs about health are shaped in part by knowledge or misinformation about body functions and illnesses, educational background, traditions, and past experiences. These variables influence how a patient thinks about health. In addition, cognitive abilities shape the *way* a person thinks, including the ability to understand factors involved in illness and apply knowledge of health and illness to personal health practices. Cognitive abilities also relate to a person's developmental stage.

Consider your patient's intellectual background while providing patient teaching ([Edelman and Kudzma, 2018](#)).

Perception of Functioning

Perceptions of physical functioning affect people's health beliefs and practices. When you assess a patient's level of health, gather subjective data about the way a patient perceives physical functioning, such as level of fatigue, shortness of breath, or pain. Then obtain objective data about actual functioning such as blood pressure, height measurements, and lung sounds. This information allows you to more successfully plan and implement individualized approaches to improve a person's ability to function (e.g., self-care, mobility).

Emotional Factors

A patient's degree of stress, depression, or fear influences health beliefs and practices. How people handle stress throughout each phase of life influences their reaction to illness. A person who generally is very calm may have little emotional response during illness, whereas another individual may be unable to cope emotionally with the threat of illness and may overreact or deny the presence of symptoms and not take therapeutic action (see [Chapter 37](#)).

Spiritual Factors

Spirituality is reflected in how a person lives his or her life, including the values and beliefs exercised, the relationships established with family and friends, and the ability to find hope and meaning in life. Spirituality serves as an integrating theme in people's lives and often provides motivation to participate in health promoting activities ([Janssen-Neimeijer et al., 2017](#); [Pilger et al., 2016](#)). Religious practices are one way that people exercise spirituality. Some religions restrict the use of certain forms of medical treatment. For example, persons of the Jehovah Witness faith do not receive blood transfusions. You need to understand patients' spiritual beliefs to incorporate them effectively in nursing care (see [Chapter 35](#)).

External Variables

External variables influencing a person's health beliefs and practices include family practices, psychosocial and socioeconomic factors, and cultural background.

Family Role and Practices

The roles and organization of a family influence how each family member defines health and illness and values health practices. Their perceptions of the seriousness of diseases and their history of preventive care behaviors (or lack of them) influence how patients think about health. For example, a child whose parents believe in the importance of eating healthy foods and physical activity may continue to practice these health beliefs, whereas parents who have misconceptions and unhealthy perceptions about diet quality often contribute to eating habits that lead to obesity in their children ([Adamo and Brett, 2014](#); [Rausch et al., 2015](#)).

Social Determinants of Health

Health is determined by a person's circumstances and environment. External factors such as where a person lives, the quality of the environment, income, educational level, and relationships with others have a considerable impact on a patient's health. Social determinants of health (SDOH) include a variety of social, commercial, cultural, economic, environmental, and political factors that affect health inequalities. They refer to the conditions in which people are born, grow, live, work, and age ([WHO, 2018b](#)). There are five categories of SDOH: economic stability, education, health and health care, social and community context, and neighborhood and built environment ([USDHHS, 2018](#)). Examples of SDOH include poverty, food insecurity, access to primary health care, culture, exposure to violence, and access to green spaces ([Schroeder et al., 2018](#)).

REFLECT NOW

What is food insecurity, and how does it affect the health of your community?

SDOH, especially those related to economic stability, often affect a patient's level of health by increasing the risk for disease, affecting the ability to find affordable and safe housing, and influencing how or at what point the patient enters the health care system ([Schroeder et al., 2018](#)). A

person's adherence to a treatment designed to maintain or improve health is also affected by economic status. For example, a patient may give higher priority to food and shelter than to medications, treatments, and food for special diets if the patient has high utility bills, cares for a large family, and has a low income.

Culture, a social and community context, influences a patient's beliefs, values, and customs. It influences the approach to the health care systems, personal health practices, and the nurse-patient relationship. Cultural background also influences an individual's beliefs about causes of illness and remedies or practices to restore health (Box 6.1). If you are not aware of your own cultural patterns of behavior and language, you will have difficulty interacting with your patients and recognizing and understanding your patient's behaviors and beliefs. Effective nursing interventions incorporate cultural factors into a patient's, family's, or community's plan of care (Harris et al., 2016; Schroeder et al., 2018) (see Chapter 9).

Box 6.1 Cultural Aspects of Care **Cultural Health Beliefs**

Cultural beliefs shape patients' views of health, how they treat and prevent illness, and preferences for care. Health beliefs often vary within a cultural group; therefore, it is important to assess the health beliefs of each patient and not stereotype a patient based on cultural background (Abboud et al., 2017; Xu et al., 2016). Cultural health beliefs influence individuals' responses to health and illness such as eye contact, response to pain and pain management, use of touch, perception and treatment of mental illness, and sick role behaviors (Giger, 2017). Recognizing a patient's health beliefs helps you provide culturally competent nursing care that considers the physical, psychological, social, emotional, and spiritual needs of each patient.

Implications for Patient-Centered Care

- Be aware of the effect of culture on a patient's view and understanding of illness (Giger, 2017).
- Understand a patient's traditions, values, and beliefs and how these dimensions may affect a patient's perceptions about illness prevention and treatment (Abboud et al., 2017; Xu et al., 2016).

- Do not stereotype patients based on their culture and do not assume that they will adopt all cultural beliefs and practices (Giger, 2017).
- Recognize your patient's unique cultural perceptions regarding the cause of an illness and attitudes and beliefs about disease prevention when providing patient education about illness and treatment options (Abboud et al., 2017).
- Be aware of your own cultural background and recognize prejudices that lead to stereotyping and discrimination (Geiger, 2017; Smigelski-Theiss et al., 2017).

Health Promotion, Wellness, and Illness Prevention

Public health focuses on health promotion, wellness, and illness prevention. Health education, legislation, and policy help individuals, groups, and communities improve their health, decrease the incidence of disease and disability, and improve their quality of life.

Health policies and laws affect all people in a community, state, or country, even if the people affected by the policies or laws are not aware of them. For example, because of the current opioid crisis, all 50 states have passed legislation that facilitates the availability and dispensation of naloxone, especially to certain people, such as first responders and caregivers of people who are addicted to opioids. Most states allow prescribers to order naloxone without examining the patient who needs it to allow qualified individuals the ability to administer naloxone in an emergency ([The Network for Public Health Law, n.d.](#)). Other health promotion programs provide guidance in pain management and improve access to substance abuse treatment.

The concepts of health promotion, health education, and illness prevention are closely related and sometimes overlap. All are focused on the future; the differences among them involve motivations and goals. **Health promotion** helps individuals maintain or enhance their present health. It motivates people to engage in healthy activities such as routine exercise and good nutrition to reach more stable levels of health. **Health education** includes topics such as physical awareness, stress management, and self-responsibility. Health education helps people develop a greater understanding of their health and how to better manage their health risks. **Illness prevention** activities such as immunization programs and blood pressure screenings protect people from actual or potential threats to health. They also help people avoid declines in their health or ability to function.

Illnesses, especially chronic illnesses, increase health care costs. Improving self-management and providing preventive services help to reduce health care needs and costs and improve overall health. Taking a holistic approach recognizes that many factors affect a person's health and helps improve well-being in all dimensions ([Box 6.2](#)).

Box 6.2 Evidence-Based Practice Health Promotion Strategies

PICOT Question: Do holistic approaches effectively promote adult health and assist individuals with lifestyle changes?

Evidence Summary

Nurses use a variety of holistic strategies to improve health promotion in individuals. Holistic strategies focus on a person's body, mind, and spirit and take a person's culture, spirituality, and faith into consideration. Research shows that using culturally appropriate approaches that include a person's faith or provide social support are effective when helping individuals make lifestyle changes (D'Alonzo et al., 2018; Sattin et al., 2016; Schwingel and Gálvez, 2016).

For example, a health promotion program that included spiritual and social support within an African-American faith community was effective in helping people lose weight and maintain weight loss over a 12-month period, thus reducing the risk of developing type 2 diabetes (Sattin et al., 2016). Health promotion programs that use *promotoras*, trained Latino community leaders, to provide evidence-based health promotion interventions and education that is culturally appropriate and includes social support also improve health outcomes. One study found that using *promotoras* who were selected from a church was very effective in improving physical activity, nutrition, and stress management (Schwingel and Gálvez, 2016). Another program trained *promotoras* who were community health workers to improve participants' level of physical activity, aerobic fitness, muscle strength, and flexibility (D'Alonzo et al., 2018)

Application to Nursing Practice

- Use role models from similar cultures when possible to encourage individuals to make health promotion and lifestyle changes (D'Alonzo et al., 2018; Sattin et al., 2016; Schwingel and Gálvez, 2016).
- Provide evidence-based interventions that include a person's faith and provide social support when helping individuals make lifestyle changes (Sattin et al., 2016; Schwingel and Gálvez, 2016).
- Work with churches and other faith-based organizations when implementing community-based health promotion strategies (Sattin et al., 2016; Schwingel and Gálvez, 2016).

Examples of the health topics and objectives as defined by *Healthy People 2020* include physical activity; adolescent health; tobacco use; substance abuse; sexually transmitted diseases; mental health and mental disorders; injury and violence prevention; environmental health, immunization and infectious disease; access to health services; and lesbian, gay, bisexual, and transgender health (USDHHS, 2018). A complete list of topics and objectives is available on the *Healthy People* website (www.healthypeople.gov). These objectives and topics show the importance of health promotion, wellness, and illness prevention and encourage all to participate in the improvement of health.

Some health promotion programs help individuals change their lifestyles by developing more health-oriented habits that affect their overall health. Other programs are aimed at preventing specific health care problems. For example, support groups help people with human immunodeficiency virus (HIV) infection. Exercise programs encourage participants to exercise regularly to reduce their risk of cardiac disease. Stress-reduction programs teach participants to cope with stressors and reduce their risks for multiple illnesses such as infections, gastrointestinal disease, and cardiac disease.

Some health promotion, wellness education, and illness prevention programs are operated by health care agencies; others are operated independently. Many businesses have on-site health promotion activities for employees. Likewise, colleges and community centers offer health promotion and illness prevention programs. These programs often include nurses who provide direct care, act as consultants, or refer patients to them. The goal of these activities is to improve a patient's level of health through preventive health services, environmental protection, and health education.

Health promotion activities are often classified as either passive or active. With passive strategies of health promotion, individuals gain from the activities of others without acting themselves. The fluoridation of municipal drinking water and the fortification of homogenized milk with vitamin D are examples of passive health promotion strategies. With active strategies of health promotion, individuals become personally involved. For example, weight-reduction and smoking-cessation programs require patients to be actively involved in measures to improve their present and future levels of wellness while decreasing the risk of disease.

Health promotion is a process of helping people gain control of and improve their health and focuses on a wide range of socioeconomic and environmental interventions (WHO, 2018c). An individual takes

responsibility for health and wellness by making appropriate lifestyle choices. Lifestyle choices are important because they affect a person’s quality of life and well-being. Making positive lifestyle choices and avoiding negative lifestyle choices also play a role in preventing illness. In addition to improving quality of life, preventing illness has an economic impact because it decreases health care costs.

Three Levels of Prevention

Nursing care oriented to health promotion, wellness, and illness prevention is described in terms of health activities on primary, secondary, and tertiary levels (Table 6.1). As a nurse, you will care for patients in all three levels.

TABLE 6.1

Three Levels of Prevention

Primary Prevention		Secondary Prevention		Tertiary Prevention
Health Promotion	Specific Protection	Early Diagnosis and Prompt Treatment	Disability Limitations	Restoration and Rehabilitation
<p>Health education</p> <p>Good nutrition based on developmental stage</p> <p>Provision of adequate housing, recreation, and working conditions</p> <p>Marriage counseling, sex education, and genetic screening</p>	<p>Providing immunizations</p> <p>Attention to personal hygiene</p> <p>Use of environmental sanitation</p> <p>Protection from occupational hazards</p> <p>Protection from accidents and carcinogens</p>	<p>Individual and mass screening surveys</p> <p>Focused examinations to cure and prevent diseases, prevent spread of communicable diseases, prevent complications, limit disability, and prevent death</p>	<p>Adequate treatment to stop disease process and prevent further complications</p> <p>Provision of facilities to limit disability and prevent death</p>	<p>Providing retraining and education to return to highest level of functioning</p> <p>Helping people with disabilities find work and accommodating them in the workplace</p>

Modified from Edelman C, Kudzma E: *Health promotion throughout the life span*, ed 9, St Louis, 2018, Mosby.

Primary Prevention

Primary prevention is true prevention. Its goal is to reduce the incidence of disease. Many primary prevention programs are supported by the government (e.g., federally funded immunization programs). Primary prevention includes health education programs, nutritional programs, and physical fitness activities. It includes all health promotion efforts and

wellness education activities that focus on maintaining or improving the general health of individuals, families, and communities (Edelman and Kudzma, 2018). Examples of primary prevention include promoting hearing protection in occupational settings and providing education to reduce cardiac disease risk factors.

Secondary Prevention

Secondary prevention focuses on preventing the spread of disease, illness, or infection once it occurs. Activities are directed at diagnosis and prompt intervention, thereby reducing severity and enabling the patient to return to a normal level of health as early as possible (Edelman and Kudzma, 2018). Examples include identifying people who have a new case of a disease or following people who have been exposed to a disease but do not have it yet. It includes screening techniques and treating early stages of disease to limit disability by averting or delaying the consequences of advanced disease. Screening activities may lead to primary prevention intervention. For example, a nurse screens a patient who is obese for diabetes. After gathering more information from the patient, the nurse provides health education about physical activity and preventing hypertension.

Tertiary Prevention

Tertiary prevention occurs when a defect or disability is permanent and irreversible. It involves minimizing the effects of long-term disease or disability by interventions directed at preventing complications and deterioration (Edelman and Kudzma, 2018). Activities are directed at rehabilitation rather than diagnosis and treatment. For example, a patient with a spinal cord injury undergoes rehabilitation to learn how to use a wheelchair and perform activities of daily living independently. Care at this level helps patients achieve as high a level of functioning as possible, despite the limitations caused by illness or impairment.

Risk Factors

A **risk factor** is any attribute, quality, environmental situation, or trait that increases the vulnerability of an individual or group to an illness or accident. An example is risk factors for falls, such as impaired gait, reduced vision, and lower extremity weakness. Risk factors and behaviors, risk factor modification, and behavioral modification are integral components of health promotion, wellness, and illness prevention. Nurses in all areas of practice have opportunities to reduce patients' risk factors to promote health and decrease risks of illness or injury.

Risk factors do not cause diseases or accidents. Instead, they increase the chances that the individual, community, or population will experience a disease or dysfunction. Risk factors play a major role in how you identify a patient's health status. They also often influence health beliefs and practices if a person is aware of their presence. People can modify some of their risk factors, while other risk factors are unmodifiable.

Nonmodifiable Risk Factors

Nonmodifiable risk factors such as age, gender, genetics, and family history cannot be changed. You use your understanding of nonmodifiable risk factors to select appropriate secondary prevention strategies. For example, a person's age increases the susceptibility to certain illnesses and accidents. Premature infants and neonates are more susceptible to infections. Children are at risk for accidental deaths due to drowning and aspiration. As a person ages, the risk of heart disease and many types of cancers increases. Age risk factors are often closely associated with other risk factors such as family history and personal habits. Educate your patients about the importance of regularly scheduled screenings based on their age. Various professional organizations and federal agencies develop and update recommendations for health screenings, immunizations, and counseling. [Box 6.3](#) discusses ways to support health promotion in older adults.

Box 6.3 Focus on Older Adults Health Promotion

- Base health promotion for older adults on their common risk factors, chronic health conditions, and health promotion needs, including

heart disease, cancer, chronic bronchitis, stroke, diabetes mellitus, dementia, caregiving, and injury prevention (<https://www.healthypeople.gov/2020/topics-objectives/topic/older-adults>, USDHHS, 2018).

- Consider an older adult's social environment, and strengthen social support to promote health and provide access to resources (Touhy and Jett, 2016).
- Injury prevention is a key strategy to promote and improve health (Touhy and Jett, 2016).
- Promote holistic health promotion programs such as community-based exercise programs and programs that encourage creativity, such as making art or improvisation to improve well-being, decrease social isolation, and increase independence (Cantu and Fleuret, 2018; Morse et al., 2018; Seo and Chao, 2018).
- Carefully assess each older adult you care for to determine various factors that affect health. Every individual is unique. Current evidence shows factors such as an older adult's social networks, access to transportation, knowledge of local services, mobility, perceptions of age, personal motivation, and perceived confidence in the ability to make effective changes can influence health-promoting behaviors and quality of life (Bardach et al., 2016; Frost et al., 2018; Hong et al., 2018).

Sometimes gender affects a person's risk factors. For example, the risk for asthma is higher in boys than girls. However, after puberty, the number of women with asthma becomes more prevalent and severe ([Zein and Erzurum, 2015](#)). Men have a higher risk for cardiovascular disease (CVD) than premenopausal women. However, after menopause, the risk for CVD is similar between men and women.

Family history and genetics are other risk factors for some illnesses. Cancers such as breast, ovarian, and colon appear to have a genetic link. These patients can benefit from genetic counseling. A person with a family history of diabetes or CVD is at higher risk for developing these diseases. Sometimes it is difficult to determine if the family link to illness is related to genetics, lifestyle choices, environmental exposure, or a combination of these factors. For example, you are caring for a patient who is obese and develops hypertension. Her parents have hypertension, and her husband smokes. It is difficult for you to determine which risk factor—lifestyle, genetics, or environmental toxins—contributed to her hypertension or

whether it was a combination of all of these. In this example, you introduce health promotion strategies targeted at modifiable risk factors for the woman's obesity, such as nutrition counseling and exercise.

Modifiable Risk Factors

Some risk factors such as lifestyle practices and behaviors can be modified. Modifiable risk factors include poor nutrition, overeating, and insufficient rest and sleep. Some risk factors put a person at risk for developing specific diseases. For example, excessive sunbathing increases the risk of skin cancer; smoking increases the risk of lung diseases, including cancer; and a poor diet and being overweight increase the risk of cardiovascular disease.

Examples of modifiable behavioral risk factors that contribute to chronic illnesses include unhealthy diet, physical inactivity, tobacco use, alcohol abuse, poor control of hypertension, and elevated lipid and glucose levels (CDC, 2018). Modifiable risk factors for people who are 10 to 24 years of age include behaviors that lead to unintentional injuries (e.g., texting while driving, driving under the influence of drugs or alcohol, bullying); carrying a weapon; use of tobacco, smokeless tobacco products, alcohol, and other drugs; sexual behaviors leading to unintended pregnancy and sexually transmitted infections; unhealthy diet choices; and physical inactivity (Kann et al., 2018).

Lifestyle behavioral choices are also modifiable. Lifestyle choices can lead to health problems that cause a huge impact on our health care system, our economy, and our communities. Therefore, it is important to understand the effect of lifestyle behaviors on health status. For example, a teenager who makes nutritional choices that lead to obesity will most likely make similar nutritional choices as an adult. Lifestyle choices affect patients throughout the life span. Thus, it is important to understand the relationship between growth and development, lifestyle behaviors, and your patient's health status.

Stress is a lifestyle risk factor if it is severe or prolonged or if the person is unable to cope with life events adequately. Stress threatens both mental health (emotional stress) and physical well-being (physiological stress). Stress also interferes with health promotion activities and the ability to implement needed lifestyle modifications. Some emotional stressors result from life events such as divorce, pregnancy, death of a spouse or family member, and financial instabilities. For example, job-related stressors overtax a person's cognitive skills and decision-making ability, leading to

“mental overload” or “burnout” (see [Chapters 1](#) and [37](#)). Stress also threatens physical well-being and is associated with illnesses such as heart disease, cancer, and gastrointestinal disorders ([Chiang et al., 2018](#)). Always review life stressors as part of a patient’s comprehensive risk factor analysis.

Environment

Where we live and the condition of that area (its air, water, and soil) determine how we live, what we eat, the disease agents to which we are exposed, our state of health, and our ability to adapt. The physical environment in which a person works or lives can increase the likelihood that certain illnesses will occur. For example, some kinds of cancer and other diseases are more likely to develop when industrial workers are exposed to certain chemicals or when people live near toxic waste disposal sites. Environmental exposure rarely occurs at one time, in one location, and from one source because we are constantly interacting with our environment ([Edelman and Kudzma, 2018](#)).

Risk-Factor Identification and Changing Health Behaviors

You identify your patients' modifiable and unmodifiable risk factors to help them understand what they can modify, control, or even eliminate to promote wellness and prevent illness. Health risk appraisal forms help identify health threats based on the presence of various risk factors (Edelman and Kudzma, 2018). Use data from a health risk appraisal tool to develop educational programs and other community resources if a patient needs to make lifestyle changes and reduce health risks (Murdaugh et al., 2019).

Once you identify a patient's risk factors, you implement appropriate and relevant health education and counseling to help a person change or implement behaviors to maintain or improve health status (Edelman and Kudzma, 2018). Risk-factor modification, health promotion, illness prevention activities, or any program that attempts to change unhealthy lifestyle behaviors is a wellness strategy. Ask patients which changes they perceive they need to make or are willing to make. Patients typically will not change their behaviors unless they see a need and are motivated to change.

Sometimes patients need to stop health-damaging behaviors (e.g., tobacco use or alcohol misuse), while other times patients need to adopt healthy behaviors (e.g., healthy diet or exercise) (Murdaugh et al., 2019). Changing health behavior, especially long-term lifestyle habits, is difficult. Using a health promotion model to identify risky behaviors and implement the change process will help you motivate patients and facilitate health behavior changes (Edelman and Kudzma, 2018). Use evidence-based guidelines and recommendations when helping patients make health behavior changes.

You will be able to help your patients make difficult changes more effectively if you understand the process of change. Current evidence supports that many people go through a series of five stages when they make a change, described by the Transtheoretical Model of Change (Table 6.2) (pro-change Behavior Systems, Inc., 2018; Yusufov et al., 2016). These stages range from no intention to change (precontemplation) to maintaining a changed behavior (maintenance stage) (DiClemente and Prochaska, 1998). Change is not a linear process. People often relapse and cycle through the stages (pro-change Behavior Systems, Inc., 2018). When relapse occurs, a person will return to the contemplation or

precontemplation stage before attempting the change again. Help your patients understand that relapse is a learning process; they can apply the lessons learned from relapse to their next attempt to change. It is important to understand what happens at the various stages of the change process to time the implementation of interventions (wellness strategies) adequately and provide appropriate assistance at each stage.

TABLE 6.2

Stages of Health Behavior Change

Stage	Definition	Assessment Findings
Precontemplation	No intent to make changes within the next 6 months	Patient is unaware of, not interested in, or underestimates the problem. May be defensive. “There is nothing I really need to change.”
Contemplation	Considering a change within the next 6 months	May be ambivalent about the change or is thinking about making a change. “I have a problem that I think I need to work on.”
Preparation	Making small changes in preparation for a change in the next month	May have tried to make changes in the past but was unsuccessful. Patient believes that advantages outweigh disadvantages of behavior change. “I started running once, but I didn’t keep it up. I think I might try again in a few weeks.”
Action	Actively engaged in strategies to change behavior; lasts up to 6 months	Committed to change. Previous habits may become barriers to change. “I am really working hard to stop smoking.”
Maintenance stage	Sustained change over time; begins 6 months after action has started and continues indefinitely	Changes integrated into the patient’s lifestyle and behaviors adopted to prevent relapse. “I need to avoid people who smoke so I won’t be tempted to start smoking again.”

Once an individual identifies a stage of change, the change process facilitates movement through the stages. To be most effective, you choose nursing interventions that match the stage of change. Most behavior-change programs are designed for (and have a chance of success with) people ready to take action regarding their health behavior problems. Changes are maintained over time only if they are integrated into an individual’s overall lifestyle (Box 6.4). Maintaining healthy lifestyles can prevent hospitalizations and potentially lower the cost of health care.

Box 6.4 PATIENT TEACHING Lifestyle Changes

Objective

- Patient will reduce health risks related to poor lifestyle habits (e.g., high-fat diet, sedentary lifestyle) through behavior change.

Teaching Strategies

- Practice active listening and establish rapport with the patient.
- Begin with determining information that the patient knows regarding health risks related to poor lifestyle.
- Ask which barriers the patient perceives with the planned lifestyle change.
- Help the patient establish goals for change.
- Collaborate with the patient to establish timelines for modification of eating and exercise lifestyle habits.
- Reinforce the process of change.
- Have patient maintain a log of key behavioral changes (Schneider and Stone, 2016).
- Ensure that educational materials are culturally appropriate (Abboud et al., 2017; Sattin et al., 2016).
- Include family members and significant others to support the lifestyle change (Sattin et al., 2016).

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Ask the patient to repeat back the teaching on reducing risks and lifestyle changes (Dinh et al., 2016).
- Review patient's log to track adherence; ask patient to explain importance of tracking and provide positive reinforcement.
- Ask the patient to discuss success with lifestyle changes (e.g., "How many days did you exercise last week?").

Building Competency in Safety

A nurse who works at a health center on a university campus notices that there are many students who smoke. The nurse partners with the local health department to implement a smoking-cessation program on

campus. The program is based on the Transtheoretical Model of Change. In applying this model, which strategies does the nurse need to consider?

Illness

Illness and disease are different concepts. **Illness** is a state in which a person's physical, emotional, intellectual, social, developmental, or spiritual functioning is diminished or impaired. A person can feel ill in the presence or absence of disease. For example, cancer is a disease. A patient with leukemia continues to function as usual, whereas another patient with breast cancer feels well physically but experiences great spiritual distress. Many patients who have an illness feel healthy. Sometimes illness motivates people to adopt healthy behaviors. Although you need to be knowledgeable about different diseases, you also need to understand illness, which includes the holistic effects of diseases and treatments on your patient's functioning and well-being.

Acute and Chronic Illness

Both acute and chronic illnesses have the potential to affect many dimensions of functioning. An **acute illness** is usually reversible and has a short duration. The symptoms appear abruptly, are intense, and subside after a relatively short period. A **chronic illness** usually lasts more than 6 months, is irreversible, and affects functioning in one or more systems. Patients often fluctuate between maximal functioning and serious health relapses that may be life threatening. A person with a chronic illness is like a person with a disability in that both have varying degrees of functional limitations (Larsen, 2019).

Chronic illnesses and disabilities remain a leading health problem in the United States. Coping and living with a chronic illness is usually complex and overwhelming. Half of the adults in the United States have one chronic illness, and one in four adults has two or more chronic health problems (CDC, 2018). Many chronic illnesses are related to four modifiable health behaviors: physical inactivity, poor nutrition, tobacco use and secondhand smoke exposure, and excessive alcohol use (CDC, 2018). A major role for nursing is to provide patient education aimed at helping patients manage their illness or disability and to help patients reduce the occurrence or improve the severity of symptoms.

Patients with chronic diseases and their families continually adjust and adapt to their illnesses. How an individual perceives an illness influences the type of coping responses. In response to a chronic illness, an individual develops an illness career. The illness career is flexible and changes in response to changes in health, interactions with health professionals,

psychological changes related to grief, and stress related to the illness (Larsen, 2019).

The nature of the illness, either acute or chronic, also affects a patient's illness behavior. Patients with acute illnesses are likely to seek health care and adhere to therapy. On the other hand, a patient with a chronic illness in which symptoms are not cured but only partially relieved may not be motivated to adhere to the therapy plan. Some patients who are chronically ill become less actively involved in their care, experience greater frustration, and adhere less readily to care. Because nurses often spend more time than other health care professionals with chronically ill patients, they are in the unique position of being able to help these patients overcome problems related to illness behavior. A patient's coping skills and his or her locus of control (the degree to which people believe they control what happens to them) are other internal variables that affect the way the patient behaves when ill (see Chapter 37).

Illness Behavior

People who are ill generally act in a way that medical sociologists call **illness behavior**. People who are ill often adopt cognitive, affective, and behavioral reactions that are influenced by sociocultural and psychological factors. Illness behaviors affect how people monitor their bodies, define and interpret their symptoms, take remedial actions, and use health care resources (Mechanic, 1995). Personal history, social situations, social norms, and past experiences affect illness behaviors (Larsen, 2019). How people react to illness varies widely; illness behavior displayed in sickness is often used to manage life adversities (Mechanic, 1995). In other words, if people perceive themselves to be ill, illness behaviors become coping mechanisms. For example, illness behavior can result in a patient being released from roles, social expectations, or responsibilities.

The nature of the illness also affects a patient's illness behavior. Patients with acute illnesses are likely to seek health care. On the other hand, patients with a chronic illness in which symptoms are only partly relieved may become less actively involved in their care, experience greater frustration, and have difficulty adhering to their treatment plan.

Variables Influencing Illness and Illness Behavior

Many variables influence illness and illness behaviors. Physical stressors such as a poor living environment, work stress, exposure to air pollution, and living in an unsafe environment affect health. Heredity and individual practices such as poor eating habits and not exercising regularly also influence health and health behaviors and illness and illness behaviors. The influences of emotional, intellectual, social, developmental, and spiritual factors often affect the likelihood of seeking health care, adherence to therapy, and health outcomes. Plan individualized care based on an understanding of these variables and behaviors to help patients cope with their illness at various stages. The goal is to promote optimal functioning in all dimensions throughout an illness.

Internal Variables

Internal variables are a patient's perceptions of symptoms and the nature of an illness. A patient's coping skills and his or her locus of control (the degree to which people believe they control what happens to them) are other internal variables that affect the way the patient behaves when ill (see [Chapter 37](#)). If patients believe that the symptoms of their illnesses disrupt their normal routine, they are more likely to seek health care assistance than if they do not perceive the symptoms to be disruptive. Patients are also more likely to seek assistance if they believe the symptoms are serious or life threatening. A patient awakened by crushing chest pain in the middle of the night who sees this symptom as serious and life threatening is motivated to seek assistance. However, such a perception can have the opposite effect. Another patient with the same symptoms fears serious illness, reacts by denying it, and does not seek medical assistance.

External Variables

External variables influencing a patient's illness behavior include the visibility of symptoms, social group, cultural background, economic variables, accessibility of the health care system, and social support. The visibility of the symptoms of an illness affects body image and illness behavior. A patient with a visible symptom (e.g., a high fever) is often more likely to seek assistance than a patient with no visible symptoms (e.g., symptoms associated with ovarian cancer such as fatigue and bloating).

Patients' social groups help them accept or deny the threat of illness. Families, friends, and co-workers all influence patients' illness behaviors.

Patients often react positively to social support while practicing positive health behaviors. A person's family and cultural background teach the person how to be healthy, how to recognize illness, and how to be ill. For example, dietary practices, influenced by family and spiritual, religious and cultural beliefs, contribute to illness and disease maintenance (Giger, 2017).

Economic variables are SDOH that influence the way a patient reacts to illness. Financial difficulties often lead to delayed treatment and affect an individual's ability to carry out prescribed treatments and therapies. Patients' access to the health care system is closely related to economic factors. The health care system is a socioeconomic system that patients enter, interact within, and exit. For many patients, entry into the system is complex or confusing. Some patients seek nonemergency medical care in an emergency department because they do not know how to obtain health services in other ways or do not have access to care. The physical proximity of patients to a health care agency often influences how soon they enter the system after deciding to seek care.

Impact of Illness on the Patient and Family

Illness is never an isolated life event. A patient and family deal with changes resulting from illness and treatment. Each patient responds uniquely to illness, requiring you to individualize nursing interventions. The patient and family commonly experience behavioral and emotional changes and changes in roles, body image and self-concept, and family dynamics.

Behavioral and Emotional Changes

People react differently to illness or the threat of illness. Individual behavioral and emotional reactions depend on the nature of an illness, a patient's attitude toward it, the reaction of others to it, and the variables of illness behavior.

Short-term, non-life-threatening illnesses usually require few changes in the functioning of a patient or family. For example, a father who has a cold lacks the energy and patience to spend time in family activities. He becomes irritable and prefers not to interact with his family. This is a behavioral change, but the change is subtle and does not last long. Some may even consider such a change a normal response to illness.

Severe illness, particularly one that is life threatening, leads to more extensive emotional and behavioral changes such as anxiety, shock, denial,

anger, and withdrawal. These are common responses to the stress of illness. You develop interventions to help a patient and family cope with and adapt to this stress because the stressor cannot be changed.

Impact on Body Image

Body image is the subjective concept of physical appearance (see [Chapter 33](#)). Some illnesses result in changes in physical appearance. Patient and family reactions differ and usually depend on the type of changes (e.g., loss of a limb or an organ), their adaptive capacity, the rate at which changes take place, and the support services available.

When a profound change in body image occurs, such as after a leg amputation or mastectomy, the patient generally adjusts by experiencing phases of the grief process (see [Chapter 36](#)). Initially the patient is in shock because of the change or impending change. As the patient and family recognize the reality of the change, they become anxious and often withdraw, refusing to discuss it. Withdrawal is an adaptive coping mechanism that helps the patient adjust. As a patient and family acknowledge the change, they gradually accept the loss. During rehabilitation the patient becomes ready to learn how to adapt to the changed body image.

Impact on Self-Concept

Self-concept is a mental self-image of all aspects of your personality. Self-concept depends in part on body image and roles but also includes other aspects of psychology and spirituality (see [Chapters 33](#) and [35](#)). The effect of illness on the self-concepts of patients and family members is usually more complex and less readily observed than role changes.

Self-concept is important in relationships with other family members. For example, a patient whose self-concept changes (e.g., feeling like a failure) because of illness may no longer meet family expectations, leading to tension or conflict. As a result, family members change their interactions with the patient. While providing care, you observe changes in a patient's self-concept (or in the self-concepts of family members) and develop a care plan to facilitate adjustment to the changes resulting from the illness.

Impact on Family Roles

People have many roles in life, such as wage earner, decision maker, professional, child, sibling, or parent. When an illness occurs, parents and children try to adapt to the major changes that result. Role reversal is

common (see [Chapter 10](#)). If a parent becomes ill and cannot carry out usual activities, an adult child often assumes many of the parent's responsibilities and in essence becomes a parent to the parent. Such a reversal of the usual situation sometimes leads to stress, conflicting responsibilities for the adult child, or direct conflict over decision making.

An individual and family generally adjust more easily to subtle, short-term changes. In most cases they know that the role change is temporary and will not require a prolonged adjustment. However, long-term changes require an adjustment process similar to the grief process (see [Chapter 36](#)). A patient and family often require specific counseling and guidance to help them cope with role changes.

REFLECT NOW

Think about a patient or family member who recently experienced a change in health status. How did this change affect the individual's family?

Impact on Family Dynamics

Family dynamics is the process by which the family functions, makes decisions, gives support to individual members, and copes with everyday changes and challenges. Family dynamics often change because of the effects of illness. For example, a single parent experiences severe injury from a car accident. Her brother assumes some of her roles and responsibilities, such as getting the children to and from school. Although the patient and her brother are very close, the family experiences some tension as roles and responsibilities change. Include the whole family when appropriate to help patients and their families attain the maximal level of functioning and well-being (see [Chapter 10](#)).

Caring for Yourself

To be able to provide competent, quality, and safe care, nurses need to take care of themselves to ensure they remain healthy. Nurses are particularly susceptible to the development of compassion fatigue, which is a combination of secondary traumatic stress (STS) and burnout (BO) (see [Chapter 1](#)). Secondary traumatic stress develops because of the relationships that nurses develop with their patients and families, whereas BO stems from conflicts or nurse job dissatisfaction within the work setting ([Kelly and Lefton, 2017](#)). Compassion fatigue frequently affects a nurse's health, often leading to a decline in health, changes in sleep and eating patterns, emotional exhaustion, irritability, restlessness, impaired ability to focus and engage with patients, feelings of hopelessness, inability to take pleasure from activities, and anxiety ([Kelly and Lefton, 2017](#); [Henson, 2017](#)). In the workplace the effects of compassion fatigue are often manifested by diminished performance, reduced ability to feel empathy, depersonalization of the patient, poor judgment, chronic absenteeism, high turnover rates, and conflict between nurses ([Henson, 2017](#)). It is important for nurses to engage in personal and professional strategies to help combat compassion fatigue and promote resiliency.

Personal strategies focus on health-promoting behaviors and healthy lifestyle choices. To combat STS and BO, you need to eat a nutritious diet, get adequate sleep regularly, engage in regular exercise and relaxation activities, establish a good work-family balance, and engage in regular nonwork activities ([Kelly and Lefton, 2017](#); [Mendes, 2017](#)). Other strategies that can help you prevent or deal with STS and BO include developing coping skills, allowing personal time for grieving the loss of patients, and focusing on your spiritual health ([Kim and Yeom, 2018](#)). Another strategy is to find a mentor or experienced nurse who understands the stress of the job and can help you identify coping strategies ([Doré et al., 2017](#)).

An increasing number of health care institutions and organizations offer educational programs and resources for nurses that are designed to help decrease compassion fatigue and increase resiliency ([Kelly and Lefton, 2017](#)). These programs educate nurses about compassion fatigue and its negative effects and provide resources and tools for nurses to use to prevent or cope with STS and BO. For example, participating in debriefing sessions or a compassion fatigue support group allows nurses to identify stressors and work as a group to develop healthy coping strategies ([Schmidt and Haglund, 2017](#); [Doré et al., 2017](#)). Health care organizations

need to also provide resources for nurses, such as a mental health professional to provide assistance in managing STS and BO.

Key Points

- *Healthy People* identifies leading health indicators that are high-priority health issues in the United States.
- Definitions of health vary among individuals based on a person's health beliefs, developmental age, and level of functioning.
- Multiple models of health in which persons are active participants explain relationships among health beliefs, health behaviors, health promotion, and individual well-being.
- Internal variables, such as a person's developmental stage and spirituality, and external factors, such as family roles and SDOH, influence a person's health, health beliefs, and health practices.
- Health promotion activities help maintain or enhance health, health education helps people better understand their health and health risks, and illness prevention activities protect against health threats.
- Primary prevention reduces the incidence of disease, secondary prevention prevents the spread of disease when it occurs, and tertiary prevention minimizes the effects of disease or disability.
- You use your understanding of different types of risk factors to select appropriate secondary prevention strategies for your patients. Nonmodifiable risk factors, such as age and family history, cannot be changed, while modifiable risk factors, such as smoking and activity levels, can be changed.
- Reducing risk factors and improving health usually require a change in health behaviors.

- Illness behaviors are different reactions people have when they become ill. Variables such as perceptions of the illness, the type of illness, and the visibility of symptoms affect a person's illness behaviors.
- Illness has many effects on a patient and family, including changes in behavior and emotions, family roles and dynamics, body image, and self-concept.
- Using personal and professional strategies that focus on caring for self can help to decrease or prevent compassion fatigue.

Reflective Learning

- Understanding a person's risk factors helps you determine appropriate health education and health promotion interventions. Reflect on a patient you recently cared for or someone you know such as a friend or family member. What actual and/or potential health problems does this person have? What risk factors contribute to these health problems? Are the risk factors nonmodifiable or modifiable? What health education or health promotion interventions could you implement to limit the effect of these risk factors?
- Interview a patient or someone you know who is trying to make a health behavior change. What behavior change is the person trying to make? What stage of change is this person currently in based on the Transtheoretical Model of Change (see [Table 6.2](#))? Once this person moves into the maintenance stage, what can you do to help this person prepare for potential relapses?
- Reflect on your own health as well as your beliefs and values. How do you define health? Do you consider yourself healthy? What health behaviors would you like to change or implement right now to improve your health? Develop a plan to make a change in your behavior to improve your health. What barriers

might prevent you from implementing your plan? If you implemented this plan, how might your health improve? Remember to consider your health holistically as you reflect on your answers.

Review Questions

1. A patient discharged a week ago following a stroke is currently participating in rehabilitation sessions provided by nurses, physical therapists, and registered dietitians in an outpatient setting. In what level of prevention is the patient participating?
 1. Primary prevention
 2. Secondary prevention
 3. Tertiary prevention
 4. Transtheoretical prevention
2. Based on the Transtheoretical Model of Change, what is the most appropriate response to a patient who states: "Me, stop smoking? I've been smoking since I was 16!"
 1. "That's fine. Some people who smoke live a long life."
 2. "OK. I want you to decrease the number of cigarettes you smoke by one each day, and I'll see you in 1 month."
 3. "What do you think is the greatest reason why stopping smoking would be challenging for you?"
 4. "I'd like you to attend a smoking-cessation class this week and use nicotine replacement patches as directed."
3. A nurse working on a medical patient care unit states, "I am having trouble sleeping, and I eat nonstop when I get home. All I can think of when I get to work is how I can't wait for my shift to be over. I wish I felt happy again." What are the best responses from the nurse manager? (Select all that apply.)

1. "I'm sure this is just a phase you are going through. Hang in there. You'll feel better soon."
 2. "I know several nurses who feel this way every now and then. Tell me about the patients you have cared for recently. Did you find it difficult to care for them?"
 3. "You can take diphenhydramine over the counter to help you sleep at night."
 4. "Describe for me what you do with your time when you are not working."
 5. "The hospital just started a group where nurses get together to talk about their feelings. Would you like for me to e-mail the schedule to you?"
4. A patient has been laid off from his construction job and has many unpaid bills. He is going through a divorce from his marriage of 15 years and has been praying daily to help him through this difficult time. He does not have a primary health care provider because he has never really been sick, and his parents never took him to a physician when he was a child. Which external variables influence the patient's health practices? (Select all that apply.)
1. Difficulty paying his bills
 2. Praying daily
 3. Age of patient (46 years)
 4. Stress from the divorce and the loss of a job
 5. Family practice of not routinely seeing a health care provider
5. A nurse is conducting a home visit with a new mom and her three children. While in the home the nurse weighs each family member and reviews their 3-day food diary. She checks the mom's blood pressure and encourages the mom to take the children for a 15- to 30-minute walk every day. The nurse is addressing which level of need, according to Maslow?

1. Physiological
 2. Safety and security
 3. Love and belonging
 4. Self-actualization
6. When taking care of patients, a nurse routinely asks whether they take any vitamins or herbal medications, encourages family members to bring in music that the patient likes to help the patient relax, and frequently prays with her patients if that is important to them. The nurse is practicing which model?
1. Holistic
 2. Health belief
 3. Transtheoretical
 4. Health promotion
7. Using the Transtheoretical Model of Change, order the steps that a patient goes through to make a lifestyle change related to physical activity.
1. The individual recognizes that he is out of shape when his daughter asks him to walk with her after school.
 2. Eight months after beginning walking, the individual participates with his wife in a local 5K race.
 3. The individual becomes angry when the physician tells him that he needs to increase his activity to lose 30 lb.
 4. The individual walks 2 to 3 miles, 5 nights a week, with his wife.
 5. The individual visits the local running store to purchase walking shoes and obtain advice on a walking plan.
8. Which of the following are symptoms of secondary traumatic stress and burnout that commonly affect nurses? (Select all that apply.)
1. Regular participation in a book club

2. Lack of interest in exercise
 3. Difficulty falling asleep
 4. Lack of desire to go to work
 5. Anxiety while working
9. As part of a faith community nursing program in her church, a nurse is developing a health promotion program on breast self-examination for the women's group. Which statement made by one of the participants is related to the individual's accurate perception of susceptibility to an illness?
1. "I have a door hanging tag in my bathroom to remind me to do my breast self-examination monthly."
 2. "Since my mother had breast cancer, I know that I am at increased risk for developing breast cancer."
 3. "Since I am only 25 years of age, the risk of breast cancer for me is very low."
 4. "I participate every year in our local walk/run to raise money for breast cancer research."
10. The nurse assesses the risk factors for coronary artery disease (CAD) in a female patient. Which of these factors are classified as genetic and physiological? (Select all that apply.)
1. Sedentary lifestyle
 2. Mother died from CAD at age 48
 3. History of hypertension
 4. Eats diet high in sodium
 5. Elevated cholesterol level

Caring in Nursing Practice

OBJECTIVES

- Discuss the role that caring plays in the nurse-patient relationship.
- Compare and contrast theories on caring.
- Discuss the evidence about patients' perceptions of caring.
- Explain how an ethic of care influences nurses' decision making.
- Describe ways to express caring through presence and touch.
- Describe the therapeutic benefit of listening to patients.
- Explain the relationship between knowing a patient and clinical decision making.
- Discuss the relationship of compassion to caring.

KEY TERMS

Caring, p. 82

Comforting, p. 87

Compassion, p. 83

Ethic of care, p. 86

Presence, p. 87

Transcultural, p. 83

Transformative, p. 84

Nursing is closely related to the core of caring for patients in both illness and health ([Theofanidis and Sapountzi-Krepia, 2015](#)). Caring is central to nursing practice, but it is even more important in today's hectic, high-tech health care environment, where productivity and efficiency can interfere with nurses' capacity to be caring, compassionate professionals ([Letourneau et al., 2017](#)). The demands, pressure, and time constraints in

the health care environment threaten nurses' opportunities to establish therapeutic relationships and interpersonal connections with patients and family caregivers (Percy and Richardson, 2018; Adams, 2016).

It is important to maintain a relationship-centered approach to patient care for all aspects of nursing, whether the care focuses on pain management, teaching self-care, or providing basic hygiene measures. Caring relationships require sincerity, presence, availability, and engagement (Martin, 2015). Despite the challenges in health care, more professional organizations stress the importance of caring in health care and keeping the nurse engaged at a patient's bedside (RWJF, 2014). The American Organization of Nurse Executives (AONE, 2010) describes caring and knowledge as the core of nursing, with caring being a key component of what a nurse brings to a patient experience (Fig. 7.1).

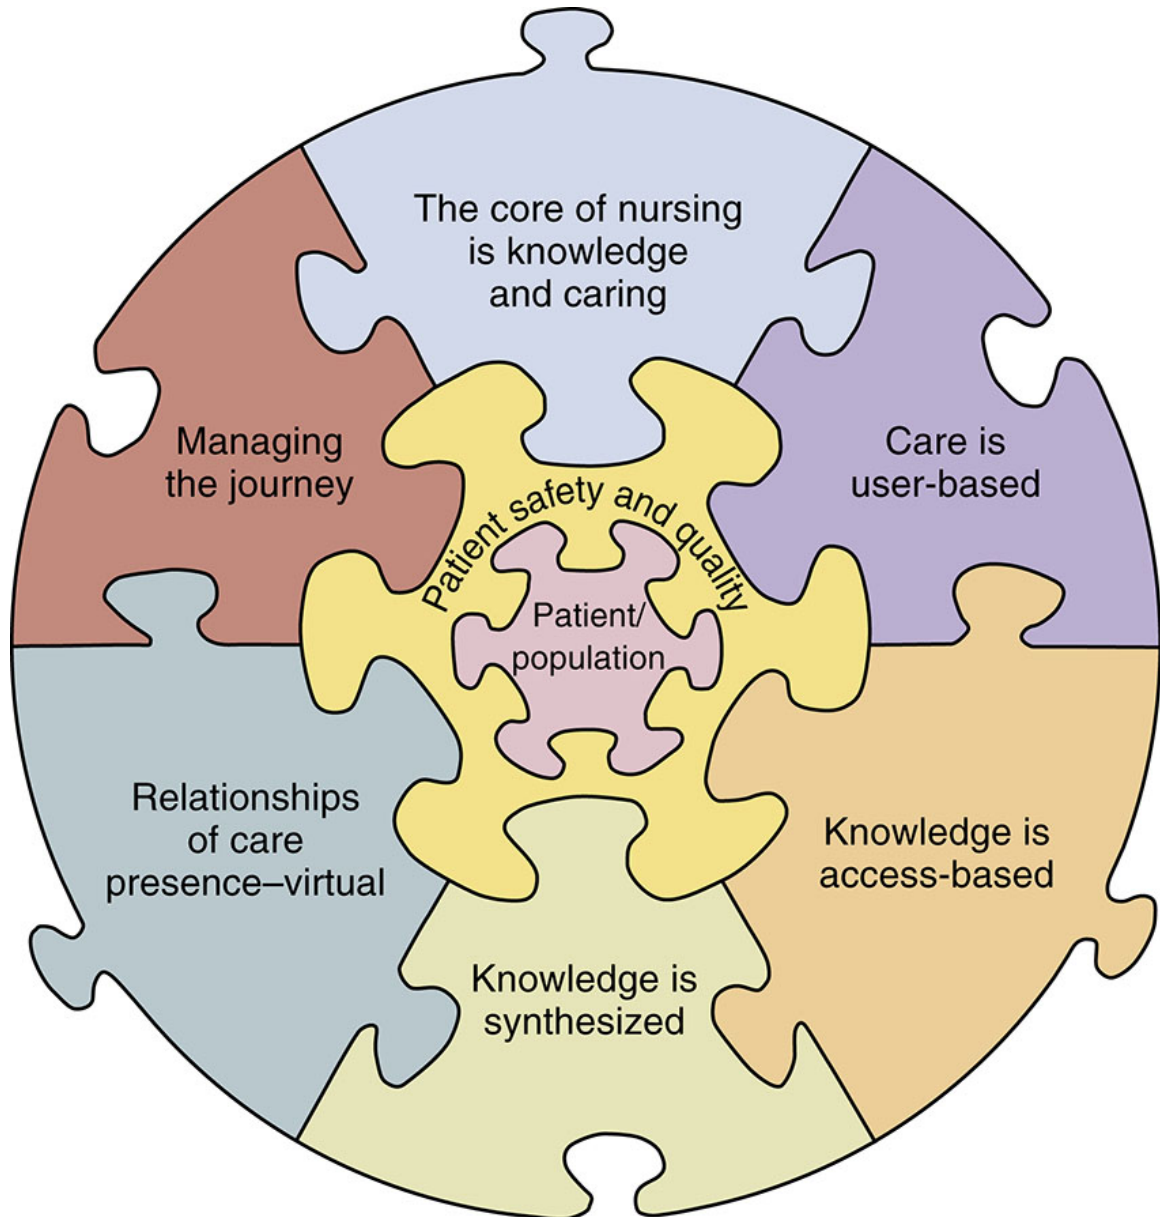

FIG. 7.1 AONE guiding principles for the role of the nurse in future patient care delivery.

Competent nursing practice values and embraces caring practices and expert knowledge (Benner et al., 2010). Your expertise in caring will come with clinical practice. When you engage patients in a caring and compassionate manner, the therapeutic gain in caring contributes greatly to the health and well-being of your patients. Think about a time when you were ill or experienced a problem requiring health care intervention.

Then consider the following two scenarios and select the situation that you believe most successfully demonstrates a sense of caring:

- A nurse enters a patient's room, greets the patient warmly while touching him or her lightly on the shoulder, makes eye contact, sits down for a few minutes and asks about the patient's thoughts and concerns, listens to the patient's story, looks at the intravenous (IV) solution hanging in the room, briefly examines the patient, and then checks the vital sign summary on the bedside computer screen before leaving the room.
- A second nurse enters the patient's room, looks at the IV solution hanging in the room, checks the vital sign summary sheet on the bedside computer screen, and acknowledges the patient but never sits down or touches him or her. The nurse makes eye contact from above while the patient is lying in bed, asks a few brief questions about the patient's symptoms, and leaves.

Both of these scenarios take about the same amount of time but are very different. In times of illness or when a person seeks the professional guidance of a nurse, caring is essential in helping an individual reach positive outcomes.

Theoretical Views on Caring

Caring is a universal phenomenon influencing the ways in which people think, feel, and behave in relation to one another. Since Florence Nightingale, nurses have studied caring from a variety of philosophical and ethical perspectives. Some nursing scholars developed theories on caring because of its importance to nursing practice. This chapter does not detail all of the theories, but it is designed to help you understand how caring enables a nurse to work with all patients in a respectful, therapeutic way.

Caring Is Primary

Dr. Patricia Benner offers nurses a rich, holistic understanding of nursing practice and caring through her research involving the interpretation of expert nurses' stories. After listening to nurses' stories and analyzing their meaning, she described caring as the essence of excellent nursing practice. The stories revealed the nurses' behaviors and decisions that expressed caring. Caring means that people, events, projects, and things matter to people (Benner and Wrubel, 1989; Benner et al., 2010). It is a word for being connected.

Caring underlies a wide range of interactions, from parental love to friendship, from caring for one's work to caring for one's pet, to caring for and about one's patients, and caring for one's self (Hines and Gaughan, 2017). "Caring creates possibility." Personal concern for another person, an event, or a thing provides motivation and direction for people to care. Through caring, nurses help patients recover in the face of illness, give meaning to their illness, and maintain or reestablish connection. Caring and **compassion** interventions need to be taught and practiced early in nursing education and emphasized in all clinical practice settings (Labraque et al., 2017).

Patients are not all the same. Each person brings a unique background of experiences, values, and cultural perspectives to a health care encounter. Caring is specific and relational for each nurse-patient encounter. As nurses acquire more experience, they typically learn that caring helps them focus on the patients for whom they care (Porter et al., 2014). Caring improves a nurse's ability to know a patient, recognize a patient's problems, and find and implement individualized solutions.

Because illness is the human experience of loss or dysfunction, any treatment or intervention given without consideration of its meaning to an

individual is unlikely to be effective. Develop a caring relationship with your patients and listen to their stories to fully understand the meaning and impact of their condition and to provide patient-centered care.

Leininger's Transcultural Caring

Madeleine [Leininger \(1991\)](#) offers a **transcultural** view of caring. She describes the concept of care as the domain that sets nursing apart from other health care disciplines (see [Chapter 4](#)). Care is an essential human need. Care, unlike cure, helps an individual or group improve a human condition. Acts of caring are nurturing and skillful activities, processes, and decisions that help people in empathetic, compassionate, and supportive ways. A caring act depends on the needs, problems, and values of a patient.

Nurses need to understand cultural caring behaviors ([Leininger, 1991](#)). Even though human caring is a universal phenomenon, the expressions, processes, and patterns of caring vary among people of different cultures ([Box 7.1](#)). Caring is very personal; thus its expression differs for each patient. For caring to be effective, nurses need to learn culturally specific behaviors and words that reflect human caring in different cultures to identify and meet the needs of all patients (see [Chapter 9](#)). As nurses we care for patients from certain “subcultures” that have unique needs (e.g., people who are chronically ill, physically disabled, developmentally challenged, or homeless).

Box 7.1 Cultural Aspects Of Care Nurse Caring

Behaviors

Caring includes knowing your patient's cultural values and beliefs; respecting privacy, diversity, and individual needs; and interacting and listening to the patient and his or her family (Darnell and Hickson, 2015). To provide culturally sensitive patient-centered care, you must understand and respect the impact of a patient's cultural beliefs and values on his or her health condition and treatments.

Implications for Patient-Centered Care

- Know and clarify a patient's beliefs and attitudes regarding health care, caring practices, and end-of-life-care (Zolnierek, 2014; Darnell

and Hickson, 2015).

- Determine whether a member of the patient's family or cultural group is the best resource to guide the use of caring practices, such as providing presence or touching (Marion et al., 2017; Lusk and Fater, 2013).
- Encourage the patient and the family caregiver, if appropriate, to share the perspective of the personal impact of the patient's illness/trauma (Mohammadipour et al., 2017; Palos, 2014).
- Know the patient's cultural practices (such as touching, family involvement) regarding the impact of uncertainty related to diagnoses, treatments, and outcomes of care (Markey et al., 2018).

Watson's Transpersonal Caring

According to Jean Watson, caring is a central focus of nursing, and it is integral to maintain the ethical and philosophical roots of the profession (Porter et al., 2014; Dey, 2016). Patients and their families expect a high quality of human interaction from nurses; they need conversations with their nurses and caregivers that are meaningful and address their needs (Sitzman, 2017). Unfortunately, many conversations between patients and nurses are brief and disconnected. Many are not really "conversations" but rather simply the nurse reporting information to a patient and family. Watson's theory of caring is a holistic model that supports a nurse's conscious intention to care to promote healing and wholeness (Watson, 2008, 2010). It integrates the human caring processes with healing environments, incorporating the life-generating and life-receiving processes of human caring and healing for nurses and their patients (WCSI, 2018). The theory describes a consciousness that allows nurses to raise new questions about what it means to be a nurse, to be ill, and to be caring and healing. The transpersonal caring theory rejects the disease orientation to health care and *places care before cure* (Watson, 2008). A nurse who focuses on transpersonal caring looks for deeper sources of inner healing to protect, enhance, and preserve a person's dignity, humanity, wholeness, and inner harmony.

Creating caring-healing environments in the current high-tech health care system is crucial to establishing and maintaining the nurse-patient relationship (Sitzman, 2017). Watson's model emphasizes the nurse-patient caring relationship with the focus on carative behaviors (Table 7.1). A nurse communicates caring-healing to a patient through the nurse's consciousness. This takes place during a single caring moment between

nurse and patient when a connection forms. The model is **transformative** because the relationship influences both the nurse and the patient for better or for worse (Watson, 2008, 2010). Caring-healing consciousness promotes healing. Application of Watson’s caring model in practice enhances nurses’ caring practices (Box 7.2).

TABLE 7.1

Watson’s 10 Carative Factors

Carative Factor	Example in Practice
Forming a human-altruistic value system	Use loving kindness to extend yourself. Use self-disclosure appropriately to promote a therapeutic alliance with your patient (e.g., share a personal experience in common with your patient such as a child-rearing experience, an illness, or an experience with a parent who needs assistance).
Instilling faith-hope	Provide a connection with the patient that offers purpose and direction when trying to find the meaning of an illness.
Cultivating a sensitivity to one’s self and to others	Learn to accept yourself and others for their full potential. A caring nurse matures into becoming a self-actualized nurse.
Developing a helping, trusting, human caring relationship	Learn to develop and sustain helping, trusting, authentic caring relationships through effective communication with your patients.
Promoting and expressing positive and negative feelings	Support and accept your patients’ feelings. In connecting with your patients, you show a willingness to take risks in sharing in the relationship.
Using creative problem-solving, caring processes	Apply the nursing process in systematic, scientific problem-solving decision making in providing patient-centered care.
Promoting transpersonal teaching-learning	Learn together while educating the patient to acquire self-care skills. The patient assumes responsibility for learning.
Providing for a supportive, protective, and/or corrective mental, physical, societal, and spiritual environment	Create a healing environment at all levels, physical and nonphysical. This promotes wholeness, beauty, comfort, dignity, and peace.
Meeting human needs	Intentionally help patients meet basic needs with a caring consciousness.
Allowing for existential-phenomenological-spiritual forces	Allow spiritual forces to provide a better understanding of yourself and your patient.

Data from Watson J: *The philosophy and science of caring*, Boulder, CO, 2008, University Press of Colorado.

Box 7.2 Evidence-Based Practice Enhancing Caring

PICOT Question: Do patient satisfaction scores among adult patients who are hospitalized improve when carative nursing practices are used?

Evidence Summary

Researchers identify a strong, positive relationship between nurse caring behaviors and patient satisfaction. Patients noted that when the nurses listened to their stories and concerns, they felt that their care was individualized and reported greater satisfaction (Brewer and Watson, 2015). Evidence shows that patient and family caregiver satisfaction

improves when nurses demonstrate caring behaviors when accommodating patients' specific requests or communicating the reasons why these requests cannot be met immediately (Wyant et al., 2017). Promotion of caring, compassionate, supportive, and therapeutic environments for patients increases patient satisfaction and nurses' job satisfaction (Nightingale et al., 2018). Caring nursing practices also improve patients' functional status, self-efficacy, coping, and self-care (Arslan-Ozkan et al., 2013; Papastavrou et al., 2011). Finally, patient-centered care models emphasize that caring interventions promote patient advocacy and predict patient satisfaction (Compton et al., 2017; Porter et al., 2014).

Application to Nursing Practice

- Use the caring practices of listening, presence, and connectedness to partner with the patient and family through their illness. Use these practices with humility, love, kindness, and compassion (Nightingale et al., 2018; Dobrina et al., 2014).
- Ask patients whether they have questions about their illness, treatment, or home care needs (Compton et al., 2018)
- Knowing the patient enables you to partner with a patient and family to obtain vital health care information, understand the patient's expectations and fears, explore the meaning of the illness to the patient and family caregivers, and identify health care priorities (Compton et al., 2018; Zolnierek, 2014).
- Use every patient interaction to continuously "know" all patients better (Ragan and Kanter, 2017; Zolnierek, 2014).
- Being with and doing for a patient are components of presence, whether it is a dedicated one-on-one interaction or quietly sitting with a patient (Mohammadipour et al., 2017; Yagasaki and Komatsu, 2013). Presence often helps elicit important health care information from a patient and reduces patient fear and anxiety.
- Caring nursing practices also benefit nursing staff by reducing staff turnover, reducing workplace stress, and increasing job satisfaction (Nightingale et al., 2018).

Swanson's Theory of Caring

Kristen Swanson (1991) studied patients and professional caregivers to develop a theory of caring for nursing practice. This theory of caring was

developed from three perinatal studies involving interviews with women who miscarried, parents and health care professionals in a newborn intensive care unit, and mothers who were socially at risk and received long-term public health intervention (Swanson, 1999). After analyzing the stories and descriptions of the three groups, Swanson developed a theory of caring, which includes five caring processes (Table 7.2). Swanson (1991) defines caring as a nurturing way of relating to an individual (i.e., when one feels a personal sense of commitment and responsibility). The theory guides nurses in developing useful and effective caring strategies appropriate for multiple age-group and health care settings (Andershed and Olsson, 2009). Caring is a central nursing phenomenon that is not unique to nursing practice; it improves patient satisfaction and outcomes (Ortega Barco and de Rodriguez, 2018). Teaching students and new nurses how to use Swanson’s five caring processes helps new nurses gain confidence when providing patient-centered care (Moffa, 2015).

TABLE 7.2

Swanson's Theory of Caring

Caring Process	Definition	Subdimensions
Knowing	Striving to understand an event as it has meaning in the life of the other	Avoiding assumptions Centering on the one cared for Assessing thoroughly Seeking clues to clarify the event Engaging the self or both
Being with	Being emotionally present to the other	Being there Conveying ability Sharing feelings Not burdening
Doing for	Doing for the other as he or she would do for self if it were at all possible	Comforting Anticipating Performing skillfully Protecting Preserving dignity
Enabling	Facilitating the other's passage through life transitions (e.g., birth, death) and unfamiliar events	Informing/explaining Supporting/allowing Focusing Generating alternatives Validating/giving feedback
Maintaining belief	Sustaining faith in the other's capacity to get through an event or transition and face a future with meaning	Believing in/holding in esteem Maintaining a hope-filled attitude Offering realistic optimism "Going the distance"

Data from Swanson KM: Empirical development of a middle-range theory of caring, *Nurs Res*, 40(3):161, 1991.

Summary of Theoretical Views

Caring theories are valuable when assessing patient perceptions of being cared for in a multicultural environment (Suliman et al., 2009). There are common themes among the theoretical view of caring. Porter et al. (2014) support earlier findings and identify these commonalities as human interaction or communication, mutuality, appreciating the uniqueness of individuals, and improving the welfare of patients and families. Caring is relational, and in a health care setting a nurse and patient enter into a relationship that is much more than one person simply doing tasks for another. In a caring relationship a mutual give-and-take develops as nurse and patient begin to know and care for one another (Martin, 2015; Turpin, 2014; Arslan-Ozkan et al., 2013).

Caring is often invisible when a nurse and patient enter a relationship of respect, concern, and support. A nurse's empathy and compassion become a natural part of every patient encounter. However, it is obvious when caring is absent. For example, a nurse who shows disinterest or chooses to avoid a patient's request for help quickly conveys an uncaring attitude. Benner and Wrubel (1989) relate the story of a clinical nurse specialist who learned from a patient what caring is all about: "I felt that I was teaching him a lot, but actually he taught me. One day he said to me (probably after I had delivered some well-meaning technical information about his disease), 'You're doing an OK job, but I can tell that every time you walk in that door you're walking out.'" In this nurse's story the patient perceived that the nurse was simply going through the motions of teaching and showed little caring toward the patient. Patients quickly know when nurses fail to relate to them.

As you gain clinical experience, continue to practice caring, and your patients and their family caregivers will sense your commitment and willingness to enter into a relationship that allows you to understand their experiences of illness (Monsen, et al., 2017). In a study of patients receiving oral chemotherapy, patients noted that it was essential for nurses to develop a partnership and connect with them, to be attentive, and be proactive in providing committed patient support (Yagasaki and Komatsu, 2013). Thus, the nurse becomes a coach and partner rather than a detached provider of care.

One aspect of caring is enabling—when a nurse and patient work together to identify alternatives in approaches to care and resources. Consider a nurse working with a patient recently diagnosed with diabetes mellitus. The nurse enables the patient by allowing the patient to modify

lifestyle to incorporate diabetes self-management strategies, such as medication administration, exercise, and changes in diet.

Another common theme of caring is understanding the context of a person's life and illness. It is difficult to show caring for another without understanding who the person is and his or her perception of the illness. Ask your patients the following questions to understand their perceptions: How was your illness first recognized? How do you feel about the illness? How does your illness affect what you do each day? Knowing the context of a patient's illness helps you choose and individualize patient-centered interventions that will actually help the patient. This approach is more successful than simply selecting interventions on the basis of your patient's symptoms or disease process.

Patients' Perceptions of Caring

Theories of caring help nurses understand the behaviors and processes that characterize caring. Researchers have explored nurse caring behaviors as perceived by patients (Table 7.3). Their findings emphasize what patients expect from their caregivers and thus provide useful guidelines for your practice. Patients continue to value nurses' effectiveness in performing tasks; but clearly patients value the affective dimension of nursing care. Caring is a significant part of the art of nursing.

TABLE 7.3

Comparison of Research Studies Exploring Nurse Caring Behaviors (As Perceived by Patients)

Nurses' Caring Behaviors: The Perception of Patients With Cancer At the Time of Discharge After Surgery (Compton et al., 2018)	Learning the Patient's Stories (Ragan and Kanter, 2017)	The Need for a Nursing Presence in Oral Chemotherapy (Yagasaki and Komatsu, 2013)
<p>Used the Caring Assessment Tool (CAT, see Box 7.3) to determine patients' perceptions of nurse caring behaviors at the time of discharge. It was important to patients that nurses appreciated the unique impact of the illness on patient and family caregiver. Patients perceived that the nurses knew what was important to them. Caring behaviors, such as knowing, listening, and presence, contributed to patient satisfaction. Respecting the patient's values, beliefs, and health care choices, such as explaining choices, advocating for resources, and accepting patient decisions, were essential.</p>	<p>Learning and knowing the patient story is an essential element of caring nursing practice. Listening and presence help nurses know patients. Understanding the story establishes a nurse-patient relationship and maintains caring practice. To really hear a patient's story, start by refining listening skills and take the time to "sit and make eye contact" while listening. Knowing the patient and the story is critical to collecting clinical and personal information so that the nurse can better know and understand the patient's health care story and expectations for care, identify and correct missing information, and design patient-centered care.</p>	<p>Nursing presence contributes to knowing the patient. Illness and treatments often cause major changes in a patient's lifestyle. Nursing presence for patients receiving oral chemotherapy is as important as identifying those patients at risk for nonadherence. Nursing presence provides emotional and knowledge-based support for patients who are new to or receiving additional oral chemotherapy.</p>

You need to understand patients' perceptions because health care is placing greater emphasis on patient satisfaction (see Chapter 2). Health care consumers can search online for specific information about health care agencies with regard to their ratings by patients in various areas of performance. The Caring Assessment Tool (CAT) was developed to measure caring from a patient's perspective (Duffy et al., 2007). This tool and other caring assessments help you, as a beginning professional, to

appreciate the type of behaviors that patients in the hospital identify as caring (Box 7.3). When patients sense that health care providers are sensitive, sympathetic, compassionate, and interested in them as people, they usually become active partners in the plan of care. Suliman et al. (2009) studied the impact of Watson’s caring theory as an assessment framework in a multicultural environment. Patients in the study indicated that they did not perceive any cultural bias when they perceived nurses to be caring. As institutions strive to improve patient satisfaction, creating an environment of caring is a necessary and worthwhile goal. Patient satisfaction with nursing care is an important factor in a patient’s decision to return to a specific health care agency.

Box 7.3 Factors and Items Constituting the Caring Assessment Tool (CAT)

Each item begins with the stem: "Since I have been a patient here, the nurse(s)":	
<p>Mutual Problem Solving</p> <ul style="list-style-type: none"> • Help me understand how I am thinking. • Ask me how I think treatment is going. • Help me explore alternative ways of dealing. • Ask me what I know. • Help me figure out questions to ask. <p>Attentive Reassurance</p> <ul style="list-style-type: none"> • Are available. • Seem interested. • Support sense of hope. • Help me believe in self. • Anticipate my needs. <p>Human Respect</p> <ul style="list-style-type: none"> • Listen to me. • Accept me. • Treat me kindly. • Respect me. • Pay attention to me. <p>Encouraging Manner</p> <ul style="list-style-type: none"> • Support my beliefs. • Encourage me to ask questions. • Help me to see some good. • Encourage me to go on. • Help me deal with bad feelings. 	<p>Appreciation of Unique Meanings</p> <ul style="list-style-type: none"> • Are concerned with how I view things. • Know what is important to me. • Acknowledge my inner feelings. • Show respect for things having meaning. <p>Healing Environment</p> <ul style="list-style-type: none"> • Check up on me. • Pay attention to me when I am talking. • Make me feel comfortable. • Respect my privacy. • Treat my body carefully. <p>Affiliation Needs</p> <ul style="list-style-type: none"> • Are responsive to my family. • Talk openly with my family. • Allow my family to be involved. <p>Basic Human Needs</p> <ul style="list-style-type: none"> • Make sure I get food. • Help me with routine needs for sleep. • Help me feel less worried.

Modified from Duffy JR, et al: Dimensions of caring: psychometric evaluation of the Caring Assessment Tool, *Adv Nurs Sci* 30(3):235, 2007.

As you begin clinical practice, consider how patients perceive caring and the best approaches to provide care. Assess what your patient expects. Build a nurse-patient relationship to learn what is important to your

patients. For example, you are caring for a patient who had breast cancer 2 years ago. She needs another breast biopsy and is fearful of the outcome. Instead of giving a lengthy description of why the procedure is necessary, you obtain assistance from an oncology nurse specialist. Knowing your patients helps you select caring approaches that are most appropriate to their needs.

Ethic of Care

Caring is an interaction between the nurse and patient in an atmosphere of mutual respect and trust. In this collaborative environment, the nurse provides encouragement, hope, support, and compassion to help achieve desired outcomes. It is a professional, ethical covenant that nursing has with its public. Caring science provides a disciplinary foundation from which you deliver patient-centered care. [Chapter 22](#) explores the importance of ethics in professional nursing. The term *ethic* refers to the ideals of right and wrong behavior. In any patient encounter a nurse needs to know what behavior is ethically appropriate. Nurses do not make professional decisions based solely on intellectual or analytical principles. Instead, an ethic of care places caring at the center of decision making.

An **ethic of care** is concerned with relationships between people and with a nurse's character and attitude toward others. Nurses who function from an ethic of care are sensitive to unequal relationships that lead to an abuse of one person's power over another—intentional or otherwise. In health care settings patients and families are often on unequal footing with professionals because of a patient's illness, lack of information, regression caused by pain and suffering, and unfamiliar circumstances. An ethic of care places the nurse as the patient's advocate, solving ethical dilemmas by attending to relationships and giving priority to each patient's unique personhood.

REFLECT NOW

A patient requires a lot of physical and emotional care and is frequently using the nurse call system. The health care providers alternate answering the nurse call system, stating "I just did it" or "It's your turn."

Think about how these comments and actions affect the ethic of care. How would you convey your thoughts to the health care team?

Caring in Nursing Practice

It is impossible to determine when a nurse becomes a caring professional. As you deal with health and illness in your practice, you grow in your ability to care and develop caring behaviors. We learn from our patients. Our patients tell us that a simple touch, a simple phrase (e.g., “I’m here”), or a promise to remain at the bedside represent caring and compassion (Engle, 2010).

Caring is one of those human behaviors that we can give and receive. As a nurse it is important to assess both your caring needs and your caring behaviors. Recognize the importance of nurses’ self-care (see [Chapters 1 and 6](#)). You cannot give fully engaged, compassionate care when you feel depleted. Take time to recognize stressors and reach out to colleagues, family, and friends to help you cope. Use caring behavior to reach out to colleagues to care for them as well (Monsen et al., 2017; Jackson, 2012). Whether you are giving or receiving care, the value of caring in your nursing practice benefits your patients, your colleagues, and your health care agency.

Providing Presence

Nursing practice and patient satisfaction improve when “nursing presence” is part of the health care culture (Mohammadipour et al., 2017; Yagasaki and Komatsu, 2013). Providing **presence** is a person-to-person encounter conveying a closeness and sense of caring. Presence involves “being there” and “being with.” “Being there” is not only a physical presence; it also includes communication and understanding. Nursing presence is the connectedness between a nurse and a patient (Plessis, 2016; Kostovich, 2012).

Presence is an interpersonal process that is characterized by sensitivity, wholism, intimacy, vulnerability, and adaptation to unique circumstances. It results in improved mental well-being for nurses and patients and improved physical well-being in patients. The interpersonal relationship of “being there” requires a nurse to be attentive to the perspectives of the patient and family caregiver. It translates into an actual caring art that affects the healing and well-being of both the nurse and patient (Mohammadipour et al., 2017). Nurses use presence in conjunction with other interventions, such as establishing the nurse-patient relationship, providing comfort measures, providing patient education, and listening (Plessis, 2016). The outcomes of nursing presence include the relief of

suffering, a decrease in the sense of isolation and vulnerability, and personal growth.

Establishing presence strengthens your ability to provide effective patient-centered care. Presence is also valuable during patient- and family-centered rounds, during which nurses offer their presence to help patients achieve positive outcomes, diminish the intensity of unwanted feelings, promote reassurance, and guide family caregivers ([Sharma et al., 2014](#); [Yagasaki and Komatsu, 2013](#)). As a result, patients often are more satisfied with the nursing care and the health care system in general ([Penque and Kearney, 2015](#)).

“Being with” involves a nurse giving of himself or herself, which means being available and at a patient’s disposal. If a patient accepts a nurse, the patient will invite the nurse to see, share, and touch his or her vulnerability and suffering. One’s human presence never leaves one unaffected ([Watson, 2010](#)). The nurse enters the patient’s world, and the patient is able to identify feelings and solutions, see new directions, and make choices.

When a nurse establishes presence, eye contact, body language, voice tone, listening, and a positive and encouraging attitude act together to create openness and understanding. Establishing presence enhances a nurse’s ability to learn from patients, including their hopes, dreams, need for support, and expectations of care. Learning from a patient strengthens a nurse’s ability to provide adequate and appropriate nursing care ([Dobrina et al., 2014](#)).

It is especially important to establish presence and caring when patients are experiencing stressful events or situations. Awaiting a physician’s report of test results, preparing for an unfamiliar procedure, and planning for a return home after serious illness are just a few examples of events in the course of a person’s illness that can create unpredictability and dependency on care providers. A nurse’s presence and caring help to calm anxiety and fear related to stressful situations. Giving reassurance and thorough explanations about a procedure, remaining at the patient’s side, and coaching the patient through the experience all convey a presence that is invaluable to a patient’s well-being.

Touch

Patients face situations that are embarrassing, frightening, and painful. Whatever the feeling or symptom, they look to nurses to provide comfort.

The use of touch is one **comforting** approach that reaches out to patients to communicate concern and support (Hanley et al., 2017).

Touch is relational and leads to a connection between nurse and patient. It involves contact and noncontact touch. Contact touch involves obvious skin-to-skin contact and is referred to as “therapeutic touch” (Hanley et al., 2017). Before implementing touch, be aware of your patient’s cultural practices and past experiences. For some people a simple touch on the arm may be perceived as invasive, and for victims of abuse a simple touch may be perceived as a threat. Noncontact touch refers to eye contact. It is difficult to separate the two. Both provide a connectedness between a patient and nurse (Palese et al., 2011; Jackson, 2012).

Nurses use task-oriented touch when performing a task or procedure. The skillful and gentle performance of a nursing procedure conveys security and a sense of competence. An expert nurse learns that any procedure is more effective when it is explained and administered carefully and in consideration of any patient concern. For example, if a patient is anxious about having a procedure such as the insertion of a nasogastric tube, offer comfort through a full explanation of the procedure and what the patient will feel. Then perform the procedure safely, skillfully, and successfully. This is done as you prepare the supplies, position the patient, and gently manipulate and insert the nasogastric tube. Throughout a procedure talk quietly with the patient to provide reassurance and support.

Caring touch is a form of nonverbal communication, which successfully influences a patient’s comfort and security, enhances self-esteem, increases confidence of caregivers, and improves mental well-being. You express this in the way you hold a patient’s hand, give a back massage, gently position a patient, or participate in a conversation. When using a caring touch, you connect with the patient physically and emotionally.

Protective touch is a form of touch that protects a nurse and/or patient. A patient views it either positively or negatively. The most obvious form of protective touch is in preventing an accident (e.g., holding and bracing a patient to avoid a fall). Protective touch can also protect a nurse emotionally. A nurse withdraws or distances herself or himself from a patient when he or she is unable to tolerate suffering or needs to escape from a situation that is causing tension. When used in this way, protective touch elicits negative feelings in a patient.

Because touch conveys many messages, use it with discretion. Touch itself is a concern when crossing cultural boundaries of either the patient or the nurse (Benner et al., 2010). Patients generally permit task-oriented

touch because most individuals give nurses and physicians a license to enter their personal space to provide care (see [Box 7.1](#)). Know and understand whether patients accept touch and how they interpret your intentions.

Listening

Listening is necessary for meaningful interactions with patients. It is a planned and deliberate act in which the listener is present and engages the patient in a nonjudgmental and accepting manner. You “take in” what a patient says, interpreting and understanding what the patient is saying, and then give back that understanding to the patient. Listening to the meaning of what a patient says helps create a mutual relationship. True listening leads to knowing and responding to what really matters to a patient and family. Listening, especially when providing end-of-life-care, helps a patient and family caregiver address their concerns and preferences with dignity ([Harstade et al., 2018](#)).

Any critical or chronic illness affects all of a patient’s life choices and decisions, and sometimes the individual’s identity. Being able to tell the story about the illness and its meaning helps a patient break the distress of illness ([Borasio and Tamches, 2018](#); [Harstade et al., 2018](#)). The personal concerns that are part of a patient’s illness story determine what is at stake for the patient. Caring through listening enables you to become a participant in the patient’s life.

To listen effectively you need to silence yourself and listen with an open mind. Remain intentionally silent and concentrate on what the patient has to say. Give patients your full, focused attention as they tell their stories.

When a person chooses to tell his or her story, it involves reaching out to another human being ([Borasio and Tamches, 2018](#)). Telling the story implies a relationship that develops only if the clinician exchanges his or her stories as well. Some professionals do not recognize their own need to be known as part of a clinical relationship ([Frank, 1998](#)). Unless a professional acknowledges this need, there is no reciprocal relationship, only an interaction.

Through active listening you begin to truly know your patients and what is important to them. Learning to listen to a patient is sometimes difficult. It is easy to become distracted by tasks at hand, colleagues shouting instructions, or other patients waiting to have their needs met. However, the time you take to listen effectively is worthwhile, in both the information gained and the strengthening of the nurse-patient relationship

(Engle, 2010). Listening involves paying attention to an individual's words and tone of voice and entering his or her frame of reference (see [Chapter 24](#)). By observing the expressions and body language of a patient, you find cues to help the patient explore ways to achieve greater peace.

Knowing the Patient

Knowing the patient is a complex process that occurs over time and within the context of the nurse-patient relationship (Zolnierek, 2014). It is an essential element of nursing practice and is linked to patient satisfaction and successful outcomes of care (Kelley et al., 2013). One of the five caring processes described by Swanson (1991) is knowing the patient. Knowing emerges from a caring relationship between a nurse and a patient, in which the nurse engages in a continuous assessment, striving to understand and interpret the patient's needs across all dimensions (Kelley et al., 2013).

Knowing a patient is at the core of clinical decision making and patient-centered care. Through caring you develop an understanding that helps you to better know the patient as a unique individual and choose the most appropriate and effective nursing therapies (Potter and Savette, 2014). Knowing the patient helps you understand how illness, treatment, or rehabilitation affect the patient and family caregiver (Tyreman, 2015).

Two elements that facilitate knowing are continuity of care and clinical expertise. When patient care is fragmented, nurses have difficulty knowing a patient, compromising patient-centered care (Zolnierek, 2014). Knowing develops over time as a nurse learns the clinical conditions within a specialty and the behaviors and physiological responses of patients. Intimate knowing helps the nurse respond to what really matters to the patient. To know a patient provides the health care team with information to provide patient-focused, team-based interventions that improve patient satisfaction and outcomes (Shippe et al., 2018). Thus, the nurse engages in a caring relationship with the patient that reveals information and cues that facilitate critical thinking and clinical judgments (see [Chapter 15](#)).

Factors that contribute to knowing patients include time, continuity of care, teamwork of the nursing staff, trust, and experience. Barriers to knowing a patient are often related to the organizational structure of the organization and economic constraints. Organizational changes that result in decreasing the amount of time that nurses are able to spend with their patients affects nurse-patient relationships. Decreased length of stay also

reduces the interactions between nurses and their patients (Zolnierek, 2014).

Many consequences result from not knowing a patient. For example, in the acute care setting, not knowing the patient contributes to risk for falls and actual falls. Patients and their families don't understand the complexities of treatment and their participation in care (Kelley et al., 2013). Finally, patients do not adequately understand their discharge instructions and may administer their home medications or treatments incorrectly. A caring nurse-patient relationship helps you to better know the patient as a unique individual and choose the most appropriate and effective nursing therapies (WCSI, 2018).

A caring relationship coupled with your growing knowledge and experience provides a rich source of meaning when changes in a patient's clinical status occur. Expert nurses develop the ability to detect changes in patients' conditions almost effortlessly (Ragan and Kanter, 2017; Benner et al., 2010). Clinical decision making, perhaps the most important responsibility of a professional nurse, involves various aspects of knowing the patient: responses to therapies, routines and habits, coping resources, physical capacities and endurance, and body typology and characteristics. Experienced nurses know additional facts about their patients such as their experiences, behaviors, feelings, and perceptions (Benner et al., 2010). You will achieve improved patient satisfaction and patient health outcomes when you make clinical decisions accurately in the context of knowing a patient well (Zolnierek, 2014). When you base care on knowing a patient, the patient perceives care as personalized, comforting, supportive, and healing.

The most important thing for a beginning nurse to recognize is that knowing a patient is more than simply gathering data about a patient's clinical signs and condition. Success in knowing a patient is to enter into a caring, social process that also includes interaction with members of the health care team, which results in a deep nurse-patient relationship whereby the patient comes to feel known by the nurse (Ragan and Kanter, 2017; Kelley et al., 2013).

Building Competency in Patient-Centered Care

Mrs. Martinez is 72 years of age, has three married sons, and lives in a mother-in-law suite in the home of one son. There are two adult

grandchildren who are on their own. Mrs. Martinez's son and daughter-in-law have full-time jobs and are out of the house from 8:00 AM to 6:00 PM each day.

Each summer the other sons and their families visit Mrs. Martinez while the son with whom she lives and his wife go on vacations. Mrs. Martinez's sons and their families spend the holidays together.

Presently she is independent. She takes medication for high blood pressure and an irregular heartbeat. At times these medications make her "light-headed." She also has occasional dizziness from a middle ear problem when she changes position too fast. She is afraid that if she shared this information with her doctor, he'd think that she'd fall and say she must give up her activities. She equates this with losing her independence.

Given the information about her living situation, current level of independence, and symptoms of light-headedness and dizziness, how do you plan and implement patient-centered care?

Spiritual Caring

An individual achieves spiritual health after finding a balance between his or her own life values, goals, and belief systems and those of others (see [Chapter 35](#)). An individual's beliefs and expectations affect his or her own physical well-being.

Research shows that nurses who develop spiritual caring practices early in their career development are able to identify methods to incorporate these practices into routine care and do not perceive variables such as a lack of sufficient time or patient census as barriers ([Ronaldson et al., 2012](#)). Establishing a caring relationship with a patient involves interconnectedness between the nurse and the patient. This interconnectedness is why [Watson \(2008, 2010\)](#) describes the caring relationship in a spiritual sense. Spirituality offers a sense of connectedness: intrapersonally (connected with oneself), interpersonally (connected with others and the environment), and transpersonally (connected with the unseen, God, or a higher power). In a caring relationship the patient and the nurse come to know one another so that both move toward a healing relationship by ([Brewer and Watson, 2015](#); [WCSI, 2018](#)):

- Mobilizing hope for the patient and the nurse

- Finding an interpretation or understanding of illness, symptoms, or emotions that is acceptable to the patient
- Assisting the patient in using social, emotional, or spiritual resources
- Recognizing that caring relationships connect us human to human, spirit to spirit

Relieving Symptoms and Suffering

Relieving symptoms such as pain, nausea, and suffering is more than giving pain medications, repositioning a patient, cleaning a wound, or providing end-of-life care (see [Chapter 36](#)). Reducing symptoms and suffering requires patient-centered caring actions that give a patient comfort, dignity, respect, and peace and that provide comfort and support measures to the family and friends ([Baillie et al., 2018](#)).

Through skillful and accurate assessment of a patient's symptoms, your delivery of patient-centered care will improve a patient's level of comfort. You will use multiple interventions to relieve pain (see [Chapter 44](#)), nausea, and fatigue. However, knowing about a patient and the meaning of his or her symptoms guides your care ([Baillie et al., 2018](#)). Conveying a quiet, caring presence, touching a patient, or listening helps you to assess and understand the meaning of your patient's discomfort. The caring presence helps you and your patient design goals for symptom relief.

Human suffering is multifaceted, affecting a patient physically, emotionally, socially, and spiritually. It also affects a patient's family caregivers and other family members ([Given and Reinhard, 2017](#)). You may find yourself working with a young family whose newborn baby has multiple developmental challenges. Likewise, you may find yourself working with a family providing home care for a parent with dementia. In both of these examples, these families' emotional suffering encompasses anger, guilt, fear, or grief. You cannot fix it, but you can provide comfort through a listening, nonjudgmental caring presence. Patients and their families are comforted by a caring listener.

Family Care

Each person experiences life through relationships with others (see [Chapter 10](#)). Thus caring for an individual includes a person's family. As a nurse it is important to know the family and family caregivers as thoroughly as you know a patient ([Given and Reinhard, 2017](#)). The family

is an important resource (Fig. 7.2). Success with nursing interventions often depends on their willingness to share information about the patient, their acceptance and understanding of therapies, whether the interventions fit with their daily practices, and whether they support and deliver the therapies recommended.

FIG. 7.2 Nurse discusses patient's health care needs with the family.

Families of patients with cancer perceive many nurse caring behaviors to be helpful (Box 7.4). It is critical that a nurse ensures a patient's well-being and safety and helps the family members to be active participants. Although specific to families of patients with cancer, these behaviors offer useful guidelines for developing a caring relationship with all families. Begin a relationship by learning who makes up the patient's family and their roles in the patient's life (Chapter 10). Showing a family that you care for and are concerned about the patient creates an openness that then enables a relationship to form. Caring for the family takes into consideration the context of the patient's illness and the stress it imposes on all members.

Box 7.4 Nurse Caring Behaviors as Perceived by Families

- Providing honest, clear, and accurate information
- Listening to patient and family concerns, complaints, and fears
- Assisting family with implementing advanced directives
- Advocating for patient's care preferences and end-of-life decisions
- Involving family in care and teaching the family how to keep the relative physically comfortable
- Informing the patient and family about the types of nursing services and the people who may enter the personal care area
- Providing comfort (e.g., offering warm blanket, rubbing a patient's back)
- Reading patient passages from religious texts, favorite book, cards, or mail
- Assuring the patient that nursing services will be available
- Helping patients do as much for themselves as possible

Data from Maroon AM: Ethical palliative family nursing care: a new concept of caring for patients and families, *JONA's Healthc Law Ethics Regul* 14(4):115, 2012; Lusk JM, Fater K: A concept analysis of patient-centered care, *Nurs Forum* 48(2):89, 2013.

REFLECT NOW

Think about a clinical or personal situation in which you needed to provide caring support. Can you identify the caring behaviors you used? Critique your interaction. What was good and helpful? How could you have done better?

The Challenge of Caring

The concept of caring motivates people to become nurses. When nurses commit themselves to be caring individuals, they achieve a meaning and purpose in their lives (Benner et al., 2010). Nurses gain a sense of satisfaction when they know they have made a difference in patients' lives.

Today's health care system presents many challenges for nurses to provide a caring patient-centered plan of care (Percy and Richardson, 2018; Adams, 2016). Nurses have less time to spend with patients, making it much harder to know who they are. Our reliance on technology and cost-effective health care strategies and efforts to standardize and refine work processes all undermine the nature of caring. Nurses are often torn between the human caring model and the task-oriented biomedical model, institutional demands, and time constraints that consume their practice (Letourneau et al., 2017). Too often patients become just a number, with their real needs overlooked or ignored. In addition, nurses deal with multiple stressors (e.g., interdepartmental, technology, paperwork stressors, high patient acuity rates, and multiple patient care interruptions). As a result, nurses are at risk for compassion fatigue and burnout (Mason et al., 2014; Hunsaker et al., 2015).

The American Nurses Association (ANA), National League for Nursing (NLN), American Organization of Nurse Executives (AONE), and American Association of Colleges of Nursing (AACN) recommend strategies to reverse the current nursing shortage (see Chapter 1). A number of these strategies have potential for creating work environments that enable nurses to demonstrate more caring behaviors. In addition, the Robert Wood Johnson Foundation's "Future of Nursing: Campaign for Action" identifies methods to improve both patient care and satisfaction and nurse job satisfaction. This campaign focuses on increasing the amount of time nurses spend with their patients and families. Strategies include greater emphasis on improving the work environment to facilitate more nurse-patient interaction, improving nurse staffing, providing nurses with autonomy over their practice, and promoting increased educational requirements and opportunities (RWJF, 2014).

If health care is to make a positive difference, it must become more compassionate. Nurses play an important role in making care an integral part of health care delivery. This begins when institutions make caring a part of the philosophy and environment of the workplace and incorporate care concepts into standards of nursing care and guidelines for professional conduct.

Finally, during day-to-day practice with patients and families, nurses need to be committed to caring and willing to establish the relationships necessary for personal, competent, compassionate, and meaningful nursing care. “Consistent with the wisdom and vision of Nightingale, nursing is a lifetime journey of caring and healing, seeking to understand and preserve the wholeness of human existence and to offer compassionate, informed knowledgeable human caring ...” (Watson, 2009).

Key Points

- Caring is integral to a nurse’s ability to work with people in a respectful and therapeutic manner.
- Theories of caring help explain how caring behaviors are central to a nurse’s ability to work with all patients and family caregivers in a respectful and therapeutic way.
- Current evidence emphasizes what patients expect from their caregivers and thus provide useful guidelines for practice.
- An ethic of care is concerned with relationships between people and their values and with a nurse’s character and attitude toward others.
- Presence is a person-to-person interaction, conveying closeness and a sense of caring that involves “being there” and “being with” patients or family caregivers.
- Touch includes task-oriented, caring, and protective touch.
- Listening is a therapeutic skill that includes interpreting, understanding, and respecting what a patient or family caregiver is saying and expressing that understanding and respect.
- Knowing the patient is at the core of the process the nurse uses to make clinical decisions about patient-centered care.

- Maintaining compassion in all aspects of nursing care contributes to the health and well-being of patients and can also improve patient and nurse satisfaction.
- Caring involves a mutual give-and-take and is specific and relational for each nurse-patient encounter.

Reflective Learning

- Reflect on a recent clinical experience in which you interviewed the patient and obtained information about his or her current health care problem. How did you prepare to do the interview? Which caring skills did you use? Reflect on the discussion with the patient and determine if you gathered adequate and complete information.
- You enter a patient's room to do a morning assessment and find the patient crying. Think about which caring practices you might use to help this patient.
- Your family member is facing a potentially severe illness; he asks you to come with him to the diagnostic tests and his doctor's visit to discuss the test results. How will understanding how to provide presence and knowing your family member prepare you to support him?

Review Questions

1. An experienced nurse is explaining the use of touch from a caring perspective. What information does the nurse include in the discussion with the student about touch?
 1. Nurses touch patients only while performing procedures or doing assessments.
 2. Touch is a type of verbal communication.
 3. Nurses use touch only when a patient is in pain.

4. Touch forms a connection between nurse and patient.
2. Before implementing touch, what does a nurse need to know about touch? (Select all that apply.)
 1. Some cultures may have specific restrictions about non-skill-based touch.
 2. Touch is a type of verbal communication.
 3. Touch can successfully influence a patient's level of comfort.
 4. There is never a problem with using touch at any time.
 5. Touch only reduces physical pain.
3. A young woman comes to a clinic for the first time for a gynecological examination. Which nursing behavior applies Swanson's caring process of "knowing" the patient?
 1. Sharing feelings about the importance of having regular gynecological examinations
 2. Explaining risk factors for cervical cancer
 3. Recognizing that the patient is modest and maintaining her privacy during the examination
 4. Asking the patient what it means to have a vaginal examination
4. A patient is fearful of upcoming surgery and a possible cancer diagnosis. He discusses his love for the Bible with his nurse, who recommends a favorite Bible verse. Another nurse tells the patient's nurse that there is no place in nursing for spiritual caring. The patient's nurse replies:
 1. "You're correct; spiritual care should be left to a pastoral care professional."
 2. "You're correct; religion is a personal decision."
 3. "Nurses should explain their own religious beliefs to patients."
 4. "Spiritual, mind, and body connections can affect health."

5. Which of the following are strategies for creating work environments that support nurse caring interventions? (Select all that apply.)
 1. Increasing technological support
 2. Improving flexibility for scheduling
 3. Providing opportunities to discuss care
 4. Promoting autonomy of practice
 5. Encouraging increased input concerning nursing functions from health care providers
6. A nurse is caring for a patient newly diagnosed with testicular cancer. He asked the nurse to help him find the meaning of cancer by supporting beliefs about life. This is an example of:
 1. Instilling hope and faith.
 2. Forming a human-altruistic value system.
 3. Cultural caring.
 4. Being with.
7. An example of a nurse caring behavior that families of acutely ill patients perceive as important to patients' well-being is:
 1. Making health care decisions for patients.
 2. Having family members provide a patient's total personal hygiene.
 3. Injecting the nurse's perceptions about the level of care provided.
 4. Asking permission before performing a procedure on a patient.
8. A nurse demonstrates caring by helping family members to: (Select all that apply.)
 1. Become active participants in care.
 2. Remove themselves from personal care.
 3. Make health care decisions for the patient.

4. Plan uninterrupted time for family and patient to be together.
 5. Discuss their concerns.
9. A hospice nurse sits at the bedside of a male patient in the final stages of cancer. He and his parents made the decision that he would move home and they would help him in the final stages of his disease. The family participates in his care, but lately the nurse has increased the amount of time she spends with the family. Whenever she enters the room or approaches the patient to give care, she touches his shoulder and tells him that she is present. This is an example of what type of touch?
1. Caring touch
 2. Protective touch
 3. Task-oriented touch
 4. Interpersonal touch
10. Match the following caring behaviors with their definitions.

<ol style="list-style-type: none"> 1. Knowing 2. Being with 3. Doing for 4. Maintaining belief 	<ol style="list-style-type: none"> a. Sustaining faith in the other's capacity to get through an event or transition and face a future with meaning b. Striving to understand an event as it has meaning in the life of the other c. Being emotionally present to the other d. Doing for the other as he or she would do for self if it were at all possible

Caring for Patients With Chronic Illness

OBJECTIVES

- Describe the characteristics of chronic illness.
- Identify the interaction between genetics and environment as they relate to chronic illness.
- Understand the effects that living with a chronic illness has on patients and their families.
- Explain the components of the Chronic Care Model and the importance of self-management within this model.
- Describe the variation of physical limitations and emotional responses that patients with chronic illnesses frequently experience.
- Explain the role of a nurse in preventing chronic illness through screening, education about healthy lifestyle, and public policy.
- Describe essential components that enhance a patient's ability to self-manage a chronic disease.

Self-management, p. 101

Because of advancements in technology and medical treatment, many people are living longer with one or more chronic diseases that affect their daily lives. The increased prevalence of people living longer with multiple complex chronic diseases has greatly affected patients, families, communities, and the health care delivery system. Chronic diseases affect the physical, psychosocial, and economic aspects of a patient and family's life. Changes may occur in a person's interactions and relationships with others as well. Sometimes a disease becomes a person's identity. For example, a patient may be referred to as "the diabetic" or "the cancer patient" instead of a patient living with diabetes or a person diagnosed with cancer.

To care for patients experiencing chronic diseases, you need to understand not only the physical and psychological implications but also the economic impact. In your role in disease prevention, know the risk factors that contribute to the incidence of chronic disease. The Chronic Care Model provides a framework to guide patient care. The roles nurses play in caring for people with chronic diseases include prevention, early detection, and help in identifying effective strategies for patients to manage their chronic illnesses.

The Prevalence and Costs of Chronic Disease

Although they are separate concepts, the terms chronic disease and chronic illness are often used interchangeably. A **chronic disease** is a pathophysiologic condition that lasts more than 1 year, requires ongoing medical care, and often limits a person's usual activities of daily living due to symptoms of the disease or self-care activities required to manage the disease (CDC, 2019a). **Chronic illness** refers to a patient and family's subjective experience of and response to a chronic disease (Meiner and Yeager, 2019).

It is estimated that 60% of all adults in the United States have at least one chronic disease. In addition, 4 out of every 10 adults have two or more chronic conditions (CDC, 2019a). With each additional diagnosed chronic disease, the burden of disease for the individual increases; this translates into additional expenses, such as multiple medications and additional visits to health care providers. Living with two or more chronic diseases often creates the need for patients to make even greater changes to daily activities. Table 8.1 illustrates common chronic diseases listed by body system. Although this is not an exhaustive list, it represents the most common chronic diseases seen in the United States (CDC, 2019a).

Table 8.1**Examples of Chronic Diseases By Body System**

Body System	Disease Examples
Cardiac	Hypertension Heart failure Coronary artery disease
Digestive	Cirrhosis of the liver Ulcerative colitis Obesity
Endocrine	Diabetes mellitus
Pulmonary	Chronic bronchitis Emphysema Asthma Allergies
Musculoskeletal	Arthritis Osteoporosis
Neurologic/psychiatric	Alzheimer's disease Stroke Parkinson's disease Spinal cord injury Systemic lupus Epilepsy Depression Bipolar disorder Multiple sclerosis
Renal	Renal failure
Cancer	Colorectal, breast, cervical, skin, gynecologic
Metabolic	Obesity, metabolic syndrome

The financial burden created by caring for chronic diseases is staggering (Table 8.2). The Centers for Disease Control and Prevention (CDC) (2019b) estimates that 90% of the \$3.3 trillion spent on health care in the United States is used to care for people with chronic and mental health diseases. Disease prevention and better symptom management can greatly reduce these costs and potentially save billions of dollars spent yearly on health care (CDC, 2019b). For example, people who have diabetes spend an average of \$16,750 per year to manage their disease, which is 2.3 times higher than what people without diabetes spend on their health care (CDC, 2018a). Type 2 diabetes is often preventable or can be managed effectively with lifestyle modifications (e.g., dietary changes, regular exercise).

Table 8.2

Yearly Costs of Chronic Illness Care (2018-2019)

Chronic Disease	Yearly Cost of Medical Care in the United States
Cancer care (NCI, n.d.)	\$174 billion
Diabetes (ADA, 2019)	\$245 billion
Dementia (AIM, 2019)	\$290 billion
Heart disease and stroke (CDC, 2019b)	\$199 billion
Obesity (CDC, 2019c)	\$147 billion
Arthritis (CDC, 2018b)	\$140 billion

REFLECT NOW

What chronic diseases are most prevalent in your community?
Which are preventable? What effect would chronic disease prevention have on the health care dollars spent in your community?

Multifactorial Nature of Chronic Disease

Numerous factors come into play when describing how individuals develop chronic disease and the symptoms and impairments that result. Each patient presents a unique case for how genetic, environmental, and lifestyle factors collide to create disease. The physical and psychological portraits of patients with the same chronic disease will have commonalities but also important differences that will affect your nursing care. Understanding the interrelationship of the factors contributing to chronic disease better enables you to support patients' illness when they suffer chronic diseases.

Genetic Factors

Autosomal genetic disorders occur when there is a **genetic mutation** or abnormality in inherited genetic material. These genetic mutations cause some inherited chronic diseases. These disorders fall into two categories: autosomal dominant disorders and autosomal recessive disorders.

Autosomal dominant disorders such as Huntington's chorea, familial hypercholesterolemia, and neurofibromatosis occur when a person has one parent with the dominant genetic disorder or a new mutation in a gene occurs (NIH, 2019a). Each child born from parents in whom one has the dominant disorder has a 50% risk of having the disorder.

Autosomal recessive disorders such as cystic fibrosis and sickle cell anemia occur most commonly when both parents are carriers of the recessive genetic disorder. Although these parents are carriers of the genetic disease, they do not have the disease. Each child born from two parents who carry a recessive disorder has a 25% risk of having the disease. Both autosomal and recessive genetic disorders account for a small percentage of people with chronic diseases.

Influence of Genetics

Although almost all diseases have a genetic component, most are not the result of a single genetic cause (NIH, 2019b). Multifactorial inheritance, a combination of genetic factors, environmental elements, and lifestyle choices increase the risk for the development of most chronic illnesses (NIH, 2019b; Rappaport, 2016) (Fig. 8.1). Genetic factors are not modifiable. People are born with genetic material from their parents. Simply inheriting a gene mutation for a disease such as diabetes, cancer, or hypertension does not guarantee that a person will develop the disease.

Multifactorial inheritance explains why a person who carries genetic material for developing a chronic illness may or may not eventually be diagnosed with the disease (NIH, 2019b).

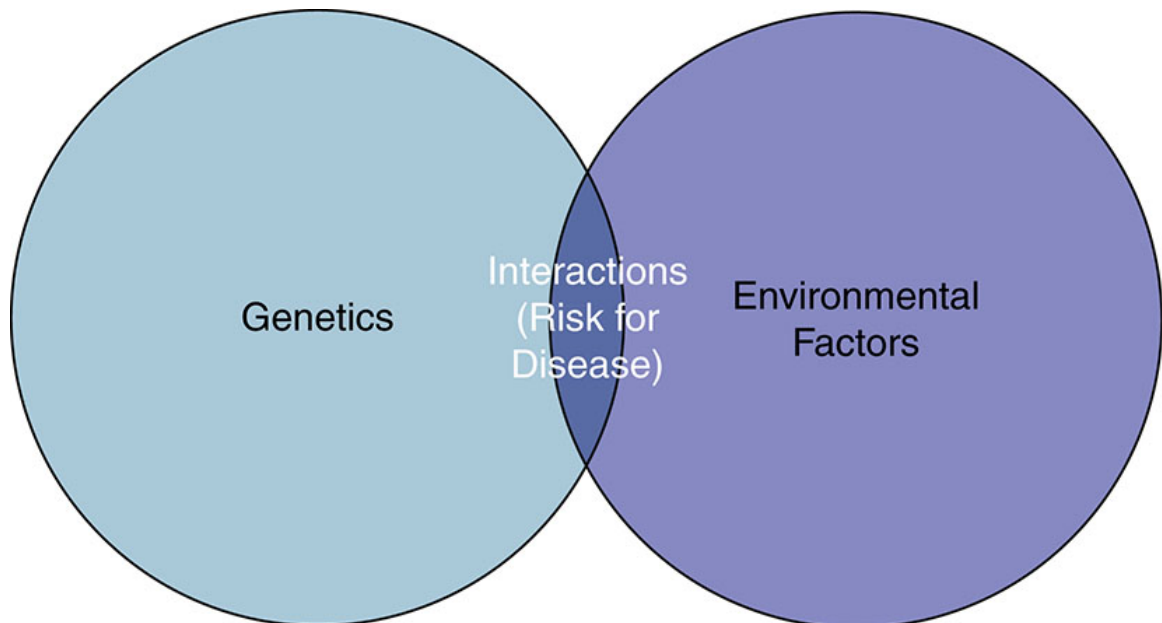

FIG. 8.1 Multifactorial inheritance: interaction of factors promoting chronic disease.

Modified from <https://www.genetics.edu.au/publications-and-resources/facts-sheets/fact-sheet-11-environmental-and-genetic-interactions/view>. Accessed July 16, 2019.

Family History

Identification of a chronic disease occurrence in a family over several generations is the starting point for determining a person's disease risk. In examining a family disease history, important factors to consider include a multigenerational examination for patterns of the same disease, the age of onset of the disease, and generational frequency of the disorder. If a strong disease pattern is identified in a family history, **genetic counseling** may be indicated. Genetic counselors clarify the risk of disease development based on family history, answer questions about the process, recommend screening tests for the disorder if necessary, discuss available genetic testing, and recommend lifestyle changes that may decrease the risk of developing the disease (NIH, 2019c).

Genetic Screening

The science of genetic screening is developing and evolving for chronic diseases. Genetic testing is available for more than 2000 rare and common conditions (NIH, 2018). There are a number of different types of genetic tests, including (1) diagnostic testing (identifies a genetic condition or disease that is making or in the future will make a person ill), (2) predictive and presymptomatic genetic testing (finds genetic variations that increase a person's chance of developing specific diseases), (3) carrier testing (tells people if they "carry" a genetic change that can cause a disease), and (4) prenatal testing (offered during pregnancy to help identify fetuses that have certain diseases) (NIH, 2018). These are just a few examples. Diagnostic testing is available for individuals at high risk for developing certain breast and colon cancers (HealthyPeople.gov, 2019). Women with a strong family history of breast, ovarian, tubal, or peritoneal cancer may benefit from genetic testing for a *BRCA1* or *BRCA2* mutation (US Preventive Services Task Force, 2013). A positive screen for the *BRCA1* or *BRCA2* genetic mutation indicates the genetic mutation exists in a woman's DNA, placing her at an increased risk for developing one of these cancers. It does not mean that the woman will develop one of these cancers. However, the test results help the woman make informed decisions about her health care and treatment based on scientific data. Knowledge of the presence of a *BRCA1* or *BRCA2* mutation can guide decisions about lifestyle changes, frequency of screening for these cancers, or early preventive therapy such as surgery before cancer develops.

People diagnosed with colon cancer may have an inheritable form of colon cancer called Lynch syndrome (ASCO, 2019). Researchers estimate that 1 in every 300 people carry the gene associated with Lynch syndrome (ASCO, 2019). Because Lynch syndrome is one of the more common hereditary cancer syndromes and because early detection improves survival, genetic screening for this type of colon cancer should be offered to first-degree family members to inform them of the potential risk of developing this cancer. If family members screen positive, more frequent screening for this disease increases the chance of early detection and early treatment to decrease death from this form of colon cancer (ASCO, 2019). Other cancers linked with Lynch syndrome include endometrial, ovarian, small bowel, pancreatic, prostate, urinary tract, liver, kidney, and bile duct cancers. Provide patient education about recommended cancer screenings related to patients diagnosed with Lynch syndrome (Stoffel et al., 2014).

REFLECT NOW

If you have a close relative diagnosed with Lynch syndrome, would you want to have genetic testing? What are the reasons you would want to be tested, and what would prevent you from going for the testing?

Genetic information is also being used to guide care for various chronic diseases, including several types of cancer. Health care providers use testing information to select medications to treat cancer based on how well the medications treated groups of patients with the same cancer type. For some cancers (e.g., lung, colon, melanoma, breast, ovarian), medication choice is often based on the genetic features of a patient's cancer cells (Cleveland Clinic, 2017). Application of knowledge of how genetics impacts people with diseases such as cancer, diabetes, hypertension, and cardiac disease will continue to be the future focus of research and disease treatment.

Environmental Factors

Ongoing exposure to toxic elements within the environment increases the risk for chronic disease. Public health initiatives are aimed at recognizing individuals' risks, chemical assessment of toxins, exposure reduction and remediation, monitoring, and avoidance (Sears and Genuis, 2012). In the United States the costs of environmental disease in children alone amounted to \$76.6 billion in 2008—just from lead poisoning, prenatal mercury exposure, childhood cancer, asthma, intellectual disability, autism, and attention deficit hyperactivity disorder (Sears and Genuis, 2012). However, this estimate is likely low because it does not consider the long-term societal losses for those children who have cognitive impairment such as IQ loss (Grandjean and Bellanger, 2017). Researchers are finding that environmental factors ranging from everyday stress to various chemical agents may alter an individual's DNA. The interaction of environmental toxins and genetic predisposition is likely stronger than genetic risk alone. As a nurse, your role in reducing environmental exposure to toxins involves patient education and risk assessment. Patients

are exposed to environmental toxins at home and in the workplace; contaminated water, pesticides, asbestos, mold, heavy metals, and food contamination are a few examples. By identifying exposures and informing individual patients regarding where and how they are being contaminated, you can empower patients to avoid further chemical contamination (Sears and Genuis, 2012).

Lifestyle and Risk Factors

Many risk factors increase the chance that individuals, families, or communities will develop a chronic illness. Some risk factors are modifiable while others are nonmodifiable (see Chapter 6). The most common modifiable risk factors are lifestyle choices or **risk behaviors** that contribute to the development of chronic illness (e.g., smoking cigarettes, exposure to secondhand smoke, poor nutrition, and excessive alcohol consumption) (CDC, 2019a). Lack of physical activity and obesity are associated with heart disease, obesity, diabetes, and some cancers (CDC, 2018c). It is estimated that \$117 billion in health care costs are paid yearly due to people who choose a sedentary lifestyle (USDHHS, 2015).

Tobacco Use

Cigarette smoking or extended exposure to secondhand smoke is the leading cause of preventable death in the United States (USDHHS, 2019). Sixteen different types of cancer have been linked to tobacco use, including lung, mouth and throat, bladder, stomach, and liver (Walsberger, 2016). Smoking has also been linked to pulmonary and cardiovascular disease. Although teen smokers are less likely to smoke cigarettes, the use of electronic cigarettes, or e-cigarettes, is on the rise in both middle and high school teens (CDC, 2019d; see Chapter 12). E-cigarettes contain nicotine and other chemicals that negatively affect a person's health (Singh et al., 2016; CDC 2019d). If young people did not start smoking and every smoker stopped smoking, it is estimated that \$170 billion could be saved yearly in medical costs (USDHHS, 2014).

Effects of Alcohol

The effects of alcohol on health are directly associated with the pattern, type, and amount of alcohol consumed (WHO, 2019a). Alcohol misuse puts people at increased risk for negative health and social effects. Excessive alcohol use is associated with 1 in 10 deaths in working adults

and costs approximately \$249 billion yearly in the United States when taking lost productivity, health care expenses, law enforcement, and other costs associated with the criminal justice system into consideration ([USDHHS, 2016](#)). Excess consumption of alcohol over a long period of time leads to an increase in chronic disease, including heart disease, liver disease, and several types of cancer.

Nutrition

The rates of chronic diet-related diseases have risen, due in part to changes in lifestyle behaviors. A history of poor eating and physical activity patterns have a cumulative effect and have contributed to significant nutrition-related and physical activity–related health challenges that now face the US population ([Health.gov, n.d.](#)). The CDC reports that about half of all adults in the United States have one or more preventable chronic diseases, many of which are related to poor quality eating patterns and physical inactivity. These diseases include cardiovascular disease, high blood pressure, type 2 diabetes, certain cancers, and poor bone health ([health.gov, n.d.](#)). Poor nutritional intake is related to a variety of issues, including limited financial resources, poor access to markets selling high-quality foods, limited transportation, and limited understanding of the components of a healthy diet (see [Chapter 45](#)). More than two-thirds of adults and nearly one-third of children and youth are overweight or obese, which highlights the enormity of this public health problem ([health.gov, n.d.](#)). The educational strategies that you can apply to reduce the health risks from poor nutrition are outlined in [Table 8.3](#).

Table 8.3

Strategies for Chronic Disease Prevention

Disease	Strategy
Obesity	Increasing physical activity, plus reducing intake of foods high in fat and foods and drinks high in sugars, can prevent unhealthy weight gain.
Type 2 diabetes	Increasing physical activity and maintaining a healthy weight play critical roles in the prevention and treatment of diabetes.
Cardiovascular disease	Reduced intake of saturated and trans fats; sufficient amounts of (omega-3 and omega-6) polyunsaturated fats, fruits, and vegetables; reduced salt intake; physical activity; and controlling weight can reduce the risk of cardiovascular disease.
Cancer	Maintaining a healthy weight will reduce the risk for cancers of the esophagus, colorectum, breast, endometrium, and kidney. Limiting alcohol intake will reduce the risk for cancers of the mouth, throat, esophagus, liver, and breast. Ensuring an adequate intake of fruit and vegetables should further reduce the risk for oral cavity, esophagus, stomach, and colorectal cancer.
Osteoporosis and bone fractures	An adequate intake of calcium (500 mg/day or more) and vitamin D in populations with high osteoporosis rates helps to reduce fracture risk. Sun exposure and physical activity to strengthen bones and muscles also helps to reduce the risk.
Dental disease	Limiting the frequency and amount of sugar consumption and increasing the use of fluoride can prevent tooth decay.

Adapted from World Health Organization: *Diet, nutrition and the prevention of chronic diseases: report of the joint WHO/FAO expert consultation*. WHO Technical Report Series, No. 916 (TRS 916), 2019, <https://www.who.int/dietphysicalactivity/publications/trs916/summary/en/>. Accessed August 8, 2019.

Physical Effects of Chronic Illness

The physical effects and limitations of chronic illness vary greatly depending on the disease process and treatments required. Determining patients' individual physical needs and providing patient-centered care are essential. For example, a person who is a cancer survivor may have residual side effects from chemotherapy and radiation treatments such as peripheral neuropathy (Knoerl et al., 2018), cardiac or pulmonary toxicity (Kourie and Klastersky, 2017), or cognitive impairment, called chemo brain, which may last for years (Armstrong, 2016). A person who has emphysema may depend on oxygen and have chronic physical changes such as clubbed fingers or a barrel chest. Other common physical symptoms include malnutrition as a result of difficulty in chewing and digesting food and decreased physical mobility due to poor oxygen reserve.

One person living with heart failure may need to take two medications every day and eat a no-added-salt diet. Another person with heart failure may be dependent on oxygen and confined to home, take continuous IV medications to increase the heart's ability to pump, take eight oral medications per day, and eat a 1-gram sodium diet due to the severity of heart disease. Although these two persons have the same diagnosis, great variations exist regarding their self-care needs.

Psychosocial Needs of Patients with Chronic Illness

A patient's experience with chronic illness encompasses more than the physical symptoms that result from the effects of the illness on different body systems. The emotional response to living with chronic illness(s) varies even more than a patient's physical response. Emotional responses affect how a person perceives and copes with an illness as well as the person's perceived degree of wellness.

Chronic illness has economic, functional, occupational, psychological, sexual, social, and spiritual effects on patients and families (Chang and Johnson, 2018). Each person with a chronic disease has a unique illness representation (Heid et al., 2018). Illness representations are the responses to bodily and functional changes that occur due to an illness that affect a patient's ability to self-manage an illness (Leventhal et al., 2016). Because every patient has a unique experience with a chronic illness, it is essential to assess patients thoroughly in order to provide patient-centered care.

Psychosocial nursing care for patients with chronic illnesses is very complex and involves many aspects of a patient's life. Patients often have physical and mental illnesses at the same time. Medications used to treat physical illnesses can affect a patient's mental health. Likewise, medications used to treat mental illnesses affect a patient's physical health (Parrish, 2018).

Your role in helping patients manage and cope with the psychosocial effects of a chronic illness depends on your patients' feelings, relationships with others, and ability to access resources. It is essential to develop a therapeutic relationship with patients to help them manage and discuss their feelings about their chronic illnesses.

Depression

Patients who live with chronic illness often experience depression related to frustration, fear about the future, and loss of control over one's life (Lorig et al., 2012). Patients living with chronic illnesses are at a higher risk of experiencing depression when compared with people who are healthy (Parrish, 2018). Patients who experience depression with chronic illness also often express higher levels of pain, fatigue, and social isolation and withdraw from daily activities, which can have an impact on the entire family (Corvin et al., 2017; Parrish, 2018). Depression associated with a

chronic illness can be difficult to manage, and it can negatively affect the ability to adhere to a treatment plan (Corvin et al., 2017).

Social Isolation

Social isolation often occurs as an illness or disability becomes more advanced or severe. Some people begin to withdraw as their illnesses become more difficult to manage, have a greater impact on their ability to function, or include symptoms a patient considers to be embarrassing. Managing the symptoms of the chronic illness becomes so overwhelming that the individual chooses to reduce social interactions with others. For some, it is easier to stay at home where the environment is more controllable (Meiner and Yeager, 2019).

For others, friends and family may withdraw from the individual experiencing chronic illness. Friends sometimes become tired of hearing about a patient's chronic illness experience. Physical and psychosocial limitations created by an illness can make friends and family uncomfortable. Some illnesses (e.g., HIV/AIDS, hepatitis) carry a stigma with them, which often leads to social isolation. Regardless of the cause for social isolation, it is essential to carefully assess patients for social isolation and loneliness and ensure that their needs for intimacy are met (Meiner and Yeager, 2019; Garcia-Sanjuan et al., 2018).

Loneliness

A patient's beliefs about treatment benefits often predict the degree of loneliness. People who believe in the treatment and its benefits report less loneliness than those who question the benefits of the treatment (Tuncay et al., 2018). The degree of loneliness a person experiences is negatively related to illness and emotional perception of the chronic disease as well as the person's opinion about the usefulness of the treatment (Tuncay et al., 2018).

People with chronic illness use a variety of personal strengths and strategies to cope with the psychosocial effects of chronic illness (Kristjansdottir, 2018). Internal strengths include being persistent; having a positive outlook; being kind and caring; experiencing positive emotions; being kind toward oneself; reconciling oneself with the situation; and having courage, knowledge and insight. External strengths include support from family, friends, peers, and health care providers. Self-management strategies include being active, planning and prioritizing, reducing stress, goal setting, and seeking knowledge and help. Encourage

patients dealing with chronic illnesses by guiding them to consider personal strengths that can be used to help them cope with the effects of the illness and its related treatment.

Building Competency in Patient-Centered Care

Mrs. Jones is a 63-year-old woman who was recently diagnosed with type 2 diabetes mellitus. You are making a home visit to check her progress with the disease. The health record shows that Mrs. Jones is to take an oral tablet twice a day; eat a low carbohydrate, calorie-controlled diet; exercise daily; and check her blood glucose twice a day using a home glucose monitor. You ask Mrs. Jones, "How are you doing?" She responds, "I am so scared and angry. I hate to even say the word 'diabetes'! I can't go out for lunch with my friends anymore. My neighbor has diabetes and just lost both of her legs. I just can't do all of this! What is going to happen to me?" What is the priority issue with Mrs. Jones? What do you plan to discuss with her first?

Growth AND Development Considerations

Patients who became chronically ill as children often experience depression and anxiety in adulthood (Secinti et al., 2017). Because the risk for mental health problems in children with chronic illnesses may persist into adulthood, you need to address mental health needs as part of a child's chronic illness treatment plan.

Serious chronic illnesses in children often have a negative effect on school attendance as well as their social engagement with other children, thus putting children with chronic illnesses at greater risk for failing to reach their potential at school (Lum et al., 2017). Some children with chronic illnesses experience poorer relationships with their teachers and are at a higher risk of having to repeat grades and achieving lower levels of educational success (Lum et al., 2017). The siblings of these children often have similar experiences, missing more days of school and experiencing changes in their interactions with their peers and teachers (Gan et al., 2017). Chronic illness also greatly affects children's parents, creating intense psychosocial responses, including chronic sorrow, fatigue, and depression (Coughlin and Sethares, 2017). Ensure that you take a family-centered approach when caring for children and their families affected by chronic illness (see Chapter 10). Be empathetic and compassionate while providing family-centered care. Help children and their families understand that the emotions they are experiencing because of the chronic illness are normal (Coughlin & Sethares, 2017). Involving interprofessional teams helps to ensure that the holistic needs of children and their families affected by chronic illnesses are met (Apple, 2017).

When caring for older adults with chronic illness, the focus of care is often on controlling symptoms, maintaining comfort, and preventing crisis (Meiner & Yeager, 2019). Every older adult patient is unique, and the presence of one or more chronic illnesses creates the need for individualized patient-centered care. Older adults who have chronic illnesses often experience powerlessness and depression because of changes in their body image, changes in their ability to provide self-care, or feelings of loss associated with their illness (Meiner and Yeager, 2019). Having more chronic illnesses is often associated with having more functional limitations and more depressive symptoms (Han, 2018). Older adults who have a negative self-perception of aging often experience more

depressive symptoms related to chronic illnesses than those with a positive view of aging ([Han, 2018](#)).

Thus you need to assess an older adult patient with chronic illness for depressive symptoms in addition to the patient's perception of aging to provide a foundation for discussing possible coping strategies ([Han, 2018](#)). Maximizing functional ability may also improve coping. Consult as needed with members of the interprofessional health care team, such as physical and occupational therapists, to increase a patient's abilities and decrease functional limitations.

Family Caregivers

Advances in disease management have led to more people living longer with chronic illness. As a result, more than 1 in 6 Americans who work either full-time or part-time are providing care for family members or friends with chronic illnesses or disabilities (Family Caregiver Alliance, 2016a). Family caregivers must learn how to perform new tasks and assume new responsibilities that are often time consuming as well as emotionally, psychosocially, and physically draining.

Family caregivers provide a significant amount of direct and indirect patient care for their family members, yet they often fail to address their own personal and health-related concerns (Family Caregiver Alliance, 2016b). They also often receive little help from others, which can lead to anxiety and increased caregiver burden (Moss et al., 2019). Family caregivers report that their personal health worsens over time. Spouses report the largest impact on their health (Family Caregiver Alliance, 2016b). Factors that put the caregiver at greatest risk for poor health outcomes include providing care for more than a year, being 65 years of age or older, providing care for a family member who has significant needs, caring for someone with Alzheimer's disease or other form of dementia, and living with the care recipient (Family Caregiver Alliance, 2016b).

Because chronic illnesses last a long time and their course is often unknown, the uncertainty related to the illness contributes to the stress of the family caregiver. The experience of the family caregiver is related to the characteristics of the chronic illness (Meiner and Yeager, 2019). For example, a family caregiver may report stress when a patient with cognitive changes no longer recognizes family members. Another family caregiver may experience more difficulty coping and managing caregiving when a patient with cancer experiences a relapse and requires more intense care. Ongoing care of a family member with a chronic illness is physically and emotionally draining. When a caregiver is the spouse of the patient, the marital relationship may be greatly affected.

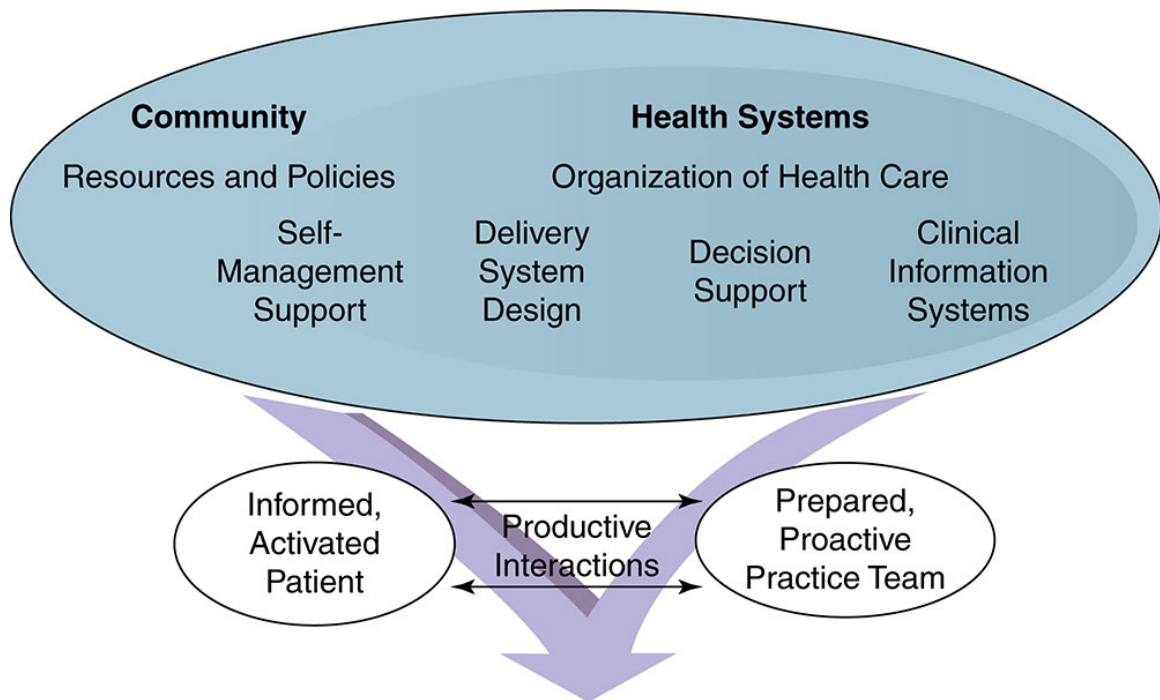

Caring for the family caregiver is essential (see Chapters 7 and 10). Develop a therapeutic relationship with your patients' family caregivers. Assess the physical, psychosocial, and financial effects of the chronic illness on the patient and family caregiver, and ensure that both members of the caregiving dyad have access to appropriate community resources and services, including respite care, social work, and counseling. Provide patient education when needed (see Chapter 25), and include the patient

and family caregiver as a part of the interprofessional health care team ([Ates et al., 2018](#)).

The Chronic Care Model

The **Chronic Care Model** provides a framework to guide health care delivery for patients living with chronic illnesses. This model considers the complex nature of factors that affect the care delivery needs of persons with a chronic illness. The Chronic Care Model (Fig. 8.2) illustrates how the community and health care systems interact to influence patient outcomes. The community component focuses on the availability of resources and policies that have the potential to impact health. An effective method to improve preventive health practices includes public policy changes. Examples of these measures include smoke-free legislation, alcohol taxation, or regulations eliminating trans fats in prepared food (Capewell and Capewell, 2018). These policy changes have great potential to enhance preventive health measures and decrease high-risk behaviors associated with the **incidence** (or new cases) of chronic disease. You need to be aware of this type of legislation, which focuses on decreasing exposure to health barriers through public policies and legislative changes.

The Chronic Care Model

Improved Outcomes

FIG. 8.2 The Chronic Care Model.

© 1996-2018 The MacColl Center. The Improving Chronic Illness Care program is supported by The Robert Wood Johnson Foundation, with direction and technical assistance provided by Group Health's MacColl Center for Health Care Innovation.

http://www.improvingchroniccare.org/index.php?p=The_Chronic_Care_Model&s=2. Accessed July 16, 2019.

The health care systems component focuses on how providers can best utilize the resources within their system and provide evidence-based care to improve patient outcomes. Using the chronic care model can improve coordination of planned interprofessional care, improve patient follow-up, and educate patients and families on how to manage patient illnesses. There are six essential elements of the Chronic Care Model (Improving Chronic Illness Care, 2006-2019):

1. *Health system*: Needs to constantly attempt to improve the management of chronic illnesses and focus on safety and quality of care.
2. *Delivery system design*: Uses evidence-based care that is patient-centered, preventive in nature, and occurs in a variety of acute, outpatient, and community settings.

3. *Decision support*: Used by health care providers to implement evidence-based guidelines, guide patient education, and encourage patients to participate in their care.
4. *Clinical information systems*: Maintain and share patient health information among providers and patients to ensure effective communication and quality patient care.
5. *Self-management support*: Places the patient in the center of disease management. Self-management support requires providers to collaborate with patients, which ultimately empowers patients to take responsibility for and manage their chronic diseases.
6. *Community*: Help develop partnerships to enhance the effectiveness of chronic disease management programs. Community partnerships between health systems and local, state, and national agencies help fill in the gaps that exist in different services and improve patient care.

Research supports the use of the Chronic Care Model in primary care settings. [Kadu and Stolee \(2015\)](#) reported that barriers and facilitators in implementing this model focused on readiness and climate of the organization, presence of supportive leadership, effective communication, and characteristics and attitudes of the health care providers. When these factors were positively aligned, implementation of the Chronic Care Model in primary care was successful. [Reynolds and colleagues \(2018\)](#) identified the primary care chronic disease management interventions most successful in creating positive patient outcomes and disease control. In their systematic review, almost half of the studies demonstrated that *self-management support* was the most effective element from the model for improving patient outcomes, such as improved control of type 2 diabetes and enhancing the quality of life in patients with arthritis and chronic obstructive pulmonary disease (COPD).

Implications for Nursing

The excess illness burden of chronic disease and billions of health care dollars could be saved each year if chronic diseases were prevented (CDC, 2019b). Nursing care of patients experiencing chronic illnesses is complex. It is important to promote healthy lifestyles and detect risks for chronic illness early (Fig. 8.3). You first need to thoroughly assess patients to plan appropriate care when the patient has risks for chronic disease or when a chronic disease is diagnosed. Helping patients develop a plan to manage their illness, as well as providing patient education, is essential.

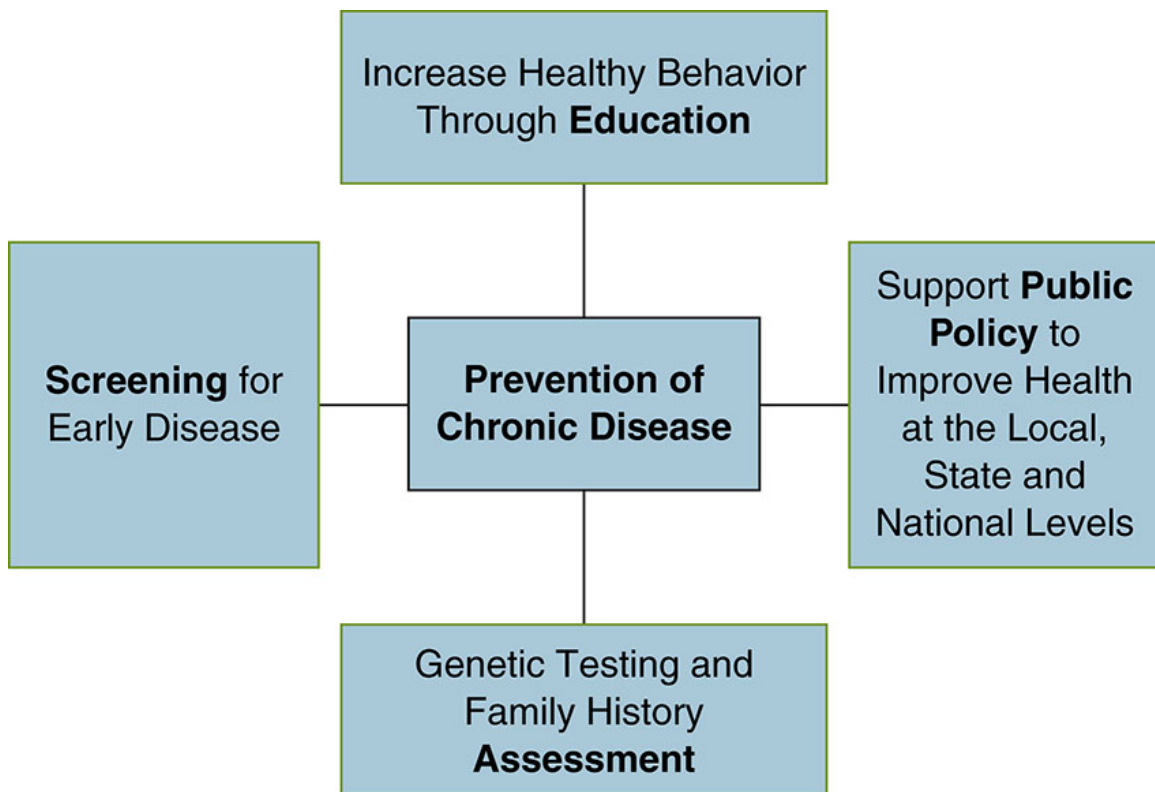

FIG. 8.3 The nurse's role in chronic disease prevention.

Assessing Patients with Chronic Illnesses

It is important to assess the effect a chronic disease has on your patients. When you collect a nursing history (see Chapters 16 and 30), encourage patients to tell you their stories about their chronic disease and how it affects various aspects of their lives (Tamura-Lis, 2017). The stories your

patients tell will provide contextual detail and allow you to better know your patients. As you explore a patient’s medical history and treatment, ask open-ended questions such as, “How did that come about?” as opposed to closed-ended questions that require a simple yes or no response (Table 8.4). Let the patient take you on a journey explaining his or her condition. You might ask, “Tell me how your disease most affects you right now” or “What are the biggest problems you are having now?” Encourage your patient to tell you stories that also help you better understand the psychosocial aspects of their illness. Be respectful and caring in your approach to encourage open patient communication (Tamura-Lis, 2017).

Table 8.4

Examples of Assessment Questions for Patients Experiencing Chronic Illness

Category	Examples of Questions
Symptoms	<p>Tell me about the symptoms you are experiencing from your illness and its treatment.</p> <p>Describe any pain or discomfort you are experiencing.</p> <p>Sometimes people with chronic illnesses experience changes in their sleep, appetite, or ability to cope. Describe any changes like these that you are experiencing.</p> <p>Tell me about any problems you are having following your treatment plan at home.</p>
Psychosocial problems	<p>How do your family members respond to you now that you have a chronic illness?</p> <p>What family members’ responses to your chronic illness concern you?</p> <p>How has your illness affected the way you see yourself?</p> <p>If you have experienced sexual changes because of your illness, which strategies have you tried to make things better? Have these strategies worked?</p> <p>Describe any problems you have affording the care your health care provider has prescribed for you.</p>

Adherence

Wide variation exists from patient to patient regarding adherence to chronic disease management and the effects of treatment on their lives.

Adherence depends on the number and type of chronic illnesses, the severity and duration of the chronic illness, and the complexity of a treatment plan. Patients will have different physical symptoms and different pharmacological and nonpharmacological treatments, all of which affect a patient’s ability to adhere to a treatment plan. How well a patient with a chronic illness and/or family manages a treatment plan is complex. Assess adherence by asking patients about how they take

medications regularly, follow diet plans, or perform routine exercise. Asking patients to keep diaries and then later checking their entries is helpful. Having patients create examples of menu plans is another way to determine if a patient knows how to plan a healthy meal. Family caregivers can also be very helpful in reporting adherence. There are assessment tools available to measure adherence. A standardized self-reported questionnaire, The Adherence in Chronic Diseases Scale (ACDS) assesses the level of adherence to treatment recommendations in chronically ill adults (Kosobucka et al., 2018). The tool was originally developed and validated in patients with coronary artery disease (CAD) (Kubica et al., 2017). The ACDS includes seven questions that focus primarily on how well a patient manages his or her medication regimen.

When patients are unable to adhere to a treatment plan, they often experience increased hospital admissions, poor health outcomes, and increased morbidity and mortality. Nonadherence also greatly increases health care expenses. Current estimates of the annual direct health care costs associated with nonadherence range from \$100 billion to \$300 billion in the United States (Neiman et al., 2017). Improving adherence is a nursing priority and requires an interprofessional approach (Giddens, 2017; Neiman et al., 2017) (Box 8.1).

Box 8.1 Evidence-Based Practice Strategies to

Enhance Adherence

PICOT Question: Do interprofessional interventions effectively promote adherence to treatment plans in patients experiencing chronic illness?

Evidence Summary

Chronic diseases require patients and families to make multiple important decisions about their health daily. However, the American health care system does a poor job in supporting self-management of diseases. Patients and providers often express frustration with the approach to chronic disease management, especially due to the many barriers that people who are from underserved populations experience (Stagg et al., 2017).

Current evidence supports the use of interprofessional interventions to enhance adherence to chronic disease management. For example, health care coaches with advanced training in behavioral science that maintain ongoing positive patient relationships have been effective in improving

adherence in patients with asthma and COPD (George, 2018). The Patient-Care Medical Home (PCMH) is a patient-care delivery model in which a primary care provider facilitates and coordinates interprofessional patient care to assure that patients receive culturally appropriate care when and where they need it. Patients living with chronic illnesses who used a PCMH recognized by the National Committee for Quality Assurance (NCQA) were better able to adhere to newly prescribed medications for the treatment of their chronic diseases when compared with patients who did not seek their care from a PCMH (Lauffenburger et al., 2017). In addition to interprofessional care, a patient's social support from family and friends is an essential component to patient adherence (Vahedparast et al., 2018).

Application to Nursing Practice

- Carefully assess patients who have difficulty adhering to their treatment plan to determine the factors that are preventing them from being successful. For example, ask: "Are you having difficulty affording your care?" "How many medications do you take on a daily basis and when do you take them?" "Describe the role your family plays in helping you manage your illness" (George, 2018; Vahedparast et al., 2018).
- Assess patients' understanding of their chronic diseases, and provide patient education to help them better manage their chronic illness and adhere to their medications (Yazdanpanah et al., 2019).
- Work with the interprofessional health care team across the continuum of care to enhance adherence to chronic disease treatment. For example, work with pharmacists and a patient's health care providers to ensure that the patient's treatment plan, including the medication regimen, is as simple and cost effective as possible. Make referrals to the health department and home health nurses, and use health information technology such as text messages and electronic health records to ensure continuity of care (Neiman et al., 2017).

Symptom Management

Symptom management is an ongoing problem for many patients with chronic diseases. Explore presenting symptoms as you conduct a physical examination (see [Chapter 30](#)) and ask patients to describe the symptoms that are affecting them the most. For example, if a patient is experiencing

pain from peripheral neuropathy from cancer treatment, ask whether the pain is affecting the patient's ability to sleep and assess the patient's gait. Explore each symptom that a patient identifies to gain a complete picture of his or her health status. Some patients are reluctant to describe or report their symptoms. Be patient, and when you identify a symptom, explore the extent to which it is currently affecting the patient.

Your review of the patient's medical record reveals the type and nature of chronic illness affecting a patient. Focus your physical assessment on the body systems most likely affected to supplement what you learn about symptoms. For example, if a patient tells you he has difficulty breathing, which affects his ability to perform self-care, examine the thorax, assessing lung sounds and degree of excursion.

Tobacco Use

Assess patients to determine their use of tobacco products, including e-cigarettes. Educate patients about the risks related to products of any type that contain nicotine because of the potential to cause disease (WHO, 2019c). Provide education about the benefits of smoking cessation and ways to stop smoking to promote health. Refer patients to resources such as the American Lung Association (www.lung.org), which has online resources for smoking cessation called "Freedom from Smoking Plus." This website provides encouragement and ideas about how to stop smoking, as well as information about why and how to stop.

REFLECT NOW

Go to the World Health Organization website and review global policy suggestions to decrease the use of tobacco (<https://www.who.int/health-topics/tobacco>). How could you use these guidelines when educating a patient about smoking cessation?

Alcohol Consumption

Assess the amount of alcohol patients drink on a typical day and in a typical week. Suspect alcohol misuse if a patient reports excess daily alcohol consumption (more than 4 drinks for men or more than 3 drinks a day for women) or excess total alcohol consumption (more than 14 drinks a week for men and more than 7 drinks a week for women) ([CDC, 2019e](#)). Often patients are reluctant to report the amount of alcohol they drink. The Alcohol Use Disorders Identification Test (AUDIT) is a 10-item screening tool developed by the World Health Organization (WHO) to assess alcohol consumption, drinking behaviors, and alcohol-related problems ([Babor et al., 2001](#)). The tool has been tested for its success in identifying patients with drinking problems. Both a clinician-administered version and a self-report version of the AUDIT are available.

In addition to providing information and support, refer patients to resources about alcohol use when appropriate. For example, the CDC ([2019e](#)) and National Institute on Alcohol Abuse and Alcoholism ([NIAAA, 2016](#)) provide information online on how to calculate alcohol intake and how to stop drinking, as well as available resources if patients have excessive alcohol intake.

Lifestyle

Chronic diseases affect all aspects of a patient's life. Be sure to explore patients' psychological, social, spiritual (see [Chapter 35](#)), and sexual (see [Chapter 34](#)) needs. If you are unable to identify all your patient's needs on initial assessment, incorporate more detailed assessment questions as you establish rapport and continue to provide care to your patient. Learning how a patient manages care at home is one of the most useful ways to know how an illness affects lifestyle routines. Talk about your patient's daily life and determine the extent to which the chronic illness has affected the patient's ability to perform self-care activities, attend social activities, participate in meals, and obtain adequate sleep. Observe the patient's interactions with family members and friends.

Health Promotion and Disease Prevention

As a nurse, you need to be actively engaged in health promotion and disease prevention (see [Chapter 6](#)). Patient education provides information patients require to understand the effects of their lifestyle behaviors on their health, make positive behavior changes, and lead a healthy lifestyle. Even when patients are diagnosed with a chronic illness, health promotion is important. Understand the nature of a patient's illness as well as the short- and long-term effects of the treatment to guide the topics you choose to teach and the screening interventions you use.

Provide specific evidence-based recommendations focusing on topics such as physical activity, food choices, smoking, and alcohol intake to help patients prevent the development of chronic disease. Use resources such as the World Health Organization's Recommendations to Prevent Chronic Noncommunicable Illnesses ([WHO, 2019b](#)) to help you better understand how people can have healthier lives and to guide your interventions ([Fig. 8.4](#)).

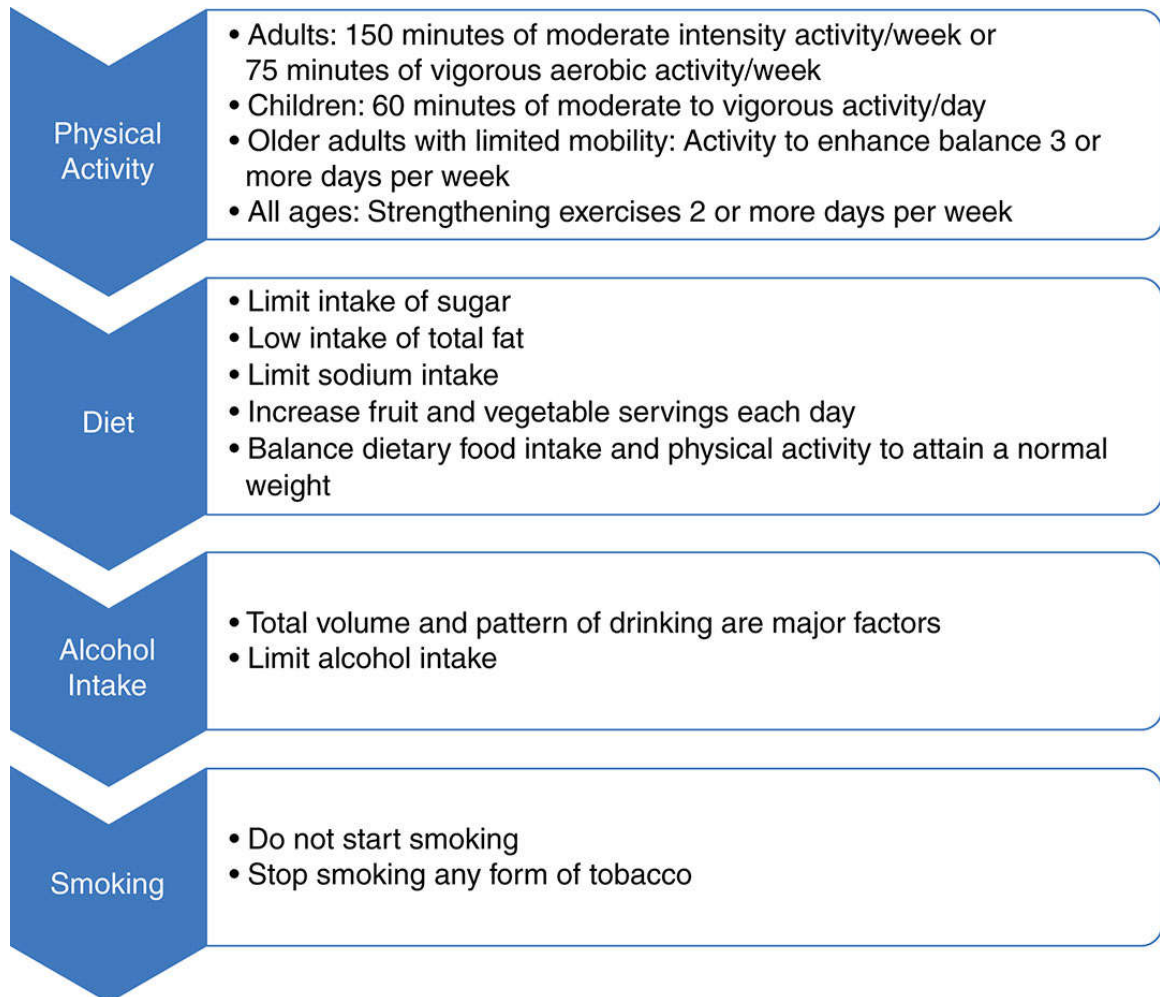

FIG. 8.4 World Health Organization recommendations to prevent chronic noncommunicable illnesses.

Source: <https://www.who.int/ncds/prevention/en/>. Accessed July 13, 2019.

Use physical activity guidelines for adults, children, and older adults to provide clear activity goals for all age-groups (ODPHP, 2019a; see Chapter 38). Discuss the importance of both the intensity and frequency of exercise. Encourage patients of all age-groups to engage in muscle strengthening 2 to 3 days a week as well. People with chronic diseases need to participate in the same amount of activity and muscle-strengthening as healthy people whenever possible (ODPHP, 2019a). Ensure that these patients consult with their health care provider regarding the types and amounts of activity that are appropriate.

Along with routine exercise, help patients make dietary choices that include an intake of appropriate nutrients to promote health and prevent obesity (see Chapter 45). Healthy food choices, which include a variety of fruits and vegetables, grains, fat-free or low-fat dairy, protein, and oils in

an appropriate calorie level, provide balanced nutritional intake (ODPHP, 2019b). Controlling sugar, sodium, fat, and alcohol intake assists in weight control. Refer to evidence-based nutritional guidelines, such as the *Dietary Guidelines for Americans*, available at <https://health.gov/dietaryguidelines/>, to help guide patient education.

Screening for Diseases

There are a variety of methods to detect disease in its earliest form. When diseases are detected early, treatment can begin, and the consequences of the disease can often be modified. Implement simple screening measures in children, such as blood pressure screening and height and weight screening to gather basic health information. Encourage all patients to have their blood pressure taken regularly. A person with hypertension usually has no symptoms (American Heart Association, 2017). Without routine blood pressure screening, a patient could have undiagnosed hypertension and without treatment could end up with heart, renal or cardiovascular disease. The earlier high blood pressure is recognized through screening, the earlier treatment can begin and disease can be prevented.

Use health risk assessment data to encourage your patients to have appropriate screenings for diseases such as breast, colon, cervix and prostate cancer. Routine screening at recommended intervals leads to early detection so that if these cancers exist, early treatment with a good prognosis is possible (American Cancer Society, 2019a). Reinforce the need for your patients to routinely participate in these screening processes.

You can also serve as a resource to provide basic information about genetic screening and its benefits based on family history of chronic disease. Genetic counseling is a very specialized area of practice. Refer your patients to reliable sources of information such as the Genetics Home Reference website available at <https://ghr.nlm.nih.gov/> (NIH, 2019d) and genetic specialists for expert advice when indicated to ensure that patients receive accurate detailed information about the effect of their genetics on their health.

Patient Education and Chronic Disease Self-Management

Patient education and disease **self-management** focus on the life changes that a person with a chronic illness must make to live well with his or her

illness ([Lorig et al., 2003](#)). Living with chronic illnesses requires patients to implement demanding self-care tasks as they learn about their illnesses, how to manage symptoms and emotions, and how to make lifestyle changes to manage their illnesses. Patients are at increased risk of hospitalization or readmission when they are unable to manage their chronic disease at home. Nurses play an instrumental role in patient education to improve home care. When patients are given the tools to manage their illnesses and incorporate healthy behaviors into their daily lives, they usually experience fewer complications and have improved quality of life ([CDC, 2018c](#)).

Provide patient education to help patients understand their illnesses and related treatment. Follow patient education principles (see [Chapter 25](#)) to help patients understand their treatment, medications, diet, activity, and what symptoms to report to their health care provider. Emphasize the consequences when treatment plans are not followed. Prepare patients to implement required self-care activities and assist them in making appropriate changes in their behavior. Ensure that patients receive essential information, starting from the time you first meet them. Include family caregivers as appropriate. The [AHRQ Health Literacy Universal Precautions Toolkit \(2018\)](#) provides a variety of evidence-based tools you can implement to help simplify patient communication to reduce miscommunication, make the health care system easier to navigate, and support patients in improving their health.

Ensure that your patients and their caregivers understand the information provided to them. Only 12% of adults in the United States have the health literacy skills required to manage the complex needs related to their health ([AHRQ, 2018](#)). Use teach-back to ensure that patients understand this information before discharge from an acute care setting, before leaving an outpatient clinic setting, or at the conclusion of home care visits ([AHRQ, 2018](#)).

Include the interprofessional health care team when providing patient education. Members of the interprofessional team include nurses, pharmacists, dietitians, and health care providers ([Fig. 8.5](#)). Together, the team explains and reinforces the necessary health behavior changes needed to manage a chronic illness.

FIG. 8.5 Patients may interact with several members of the health care team.

[iStock.com/monkeybusinessimages](https://www.istock.com/monkeybusinessimages).

Promoting Adherence

Although frequently researched, interventions that promote adherence are not well understood and often do not create changes that are maintained over time (Neiman et al., 2017; Meiner & Yeager, 2019). Many factors affect adherence, including the severity and duration of the illness, the treatment plan, socioeconomic status, patient characteristics (e.g., motivation; personal beliefs about health, illness, and the treatment plan; health literacy; mental health), and characteristics of the health care delivery system (e.g., relationship with health care providers, accessibility) (George, 2018).

One model that supports patients in self-managing their chronic disease is the Five As (AHRQ, 2012):

- **Assess:** Determine a patient's beliefs, behaviors, knowledge.
- **Advise:** Provide specific information regarding health risks and the benefits of changing behaviors.

- Agree: Collaborate with the patient to set realistic goals.
- Assist: Help the patient identify barriers, strategies, problem-solving skills, and available support.
- Arrange: Determine a follow-up plan such as return visits, phone calls, and text messages.

Your initial assessment provides information about how a patient feels about his or her health, the desire to change behavior (when change is needed), and personal goals for improving health. Motivational interviewing is one strategy that has been found to be very useful in assessing what motivates patients to change. You can advise and assist patients through patient education (see [Chapter 25](#)), coaching, providing reminders about treatments (e.g., text messages for taking medications), helping patients establish routines, simplifying treatment plans, being patient advocates, and shared decision making between patients and health care providers ([George, 2018](#); [SMRC, 2019](#)). Ongoing follow-up is especially important when your aim long-term is to change patient behavior.

Self-Management Education

Self-management education (SME) programs provide evidence-based interventions to help patients with chronic diseases manage their illness and its related symptoms. The Chronic Disease Self-Management Resource Program (CDSMRP) developed by Kate Lorig is one program that has consistently demonstrated improved patient outcomes for patients and their family caregivers by offering small, highly interactive group workshops that are facilitated by highly trained leaders who have health challenges of their own ([SMRC, 2019](#)). Small group participants meet for 2½ hours once a week for 6 weeks in a variety of community settings, such as churches, libraries, clinics, and hospitals. Workshops provide disease-specific information and include the elements of action planning, decision making, and problem solving. Participants identify personal goals and behavioral changes based on their needs and preferences ([SMRC, 2019](#)). Current evidence shows that these programs help patients experience improved overall health and use fewer health care resources ([Lorig et al., 2016](#); [Cutler et al., 2018](#)).

Refer patients, especially those who are living with multiple chronic diseases, and their caregivers to CDSMRPs whenever possible. Spend time with patients to motivate and promote positive behavioral changes in

addition to providing education about disease management. Place your patients at the center of chronic disease management care to enhance patient decision making and motivate change (Cutler, 2018). Providing strategies, such as how to deal with fatigue, pain, isolation, gait training, medication management, and effective communication with family, friends, and health care professionals, helps engage patients in making lifestyle changes for their health (Soderlung, 2018).

Many chronic disease management classes and tools that complement patient information and support provided by CDSMRPs are available (SMRC, 2019). Refer patients to disease-specific websites that offer reliable patient education materials and chronic disease guides to encourage maintaining health through consistent self-management (Table 8.5). For example, if you are caring for patients with heart failure, hypertension, or stroke, you can refer them to the American Heart Association’s website (www.heart.org). Some of the free tools provided on this website help you and other health care professionals better understand current evidence-based care and treatment, while other tools are specifically for patients. Patient tools include information on each disease and disease-management principles (e.g., when to seek medical attention, how to monitor blood pressure, and diet information). The American Heart Association’s website also provides a digital tracking mechanism with reminders for patients on when to monitor their blood pressure and a self-assessment of heart failure symptoms, including warning signs that are indicative of deterioration in health and when to seek medical attention.

TABLE 8.5

Selected Websites Related to Chronic Illness Management

Chronic Illness(es)	Organization and Website
Heart failure Stroke Hypertension	American Heart Association: www.heart.org
Cancer	American Cancer Society: www.cancer.org
Emphysema Asthma Lung cancer	American Lung Association: www.lung.org
Diabetes	American Diabetes Association: www.diabetes.org

Public Policy

Nurses are responsible to protect the public. Thus, as a nurse, you need to be aware and supportive of legislation that focuses on controlling external environmental factors that contribute to chronic disease development. Your professional nursing responsibility is awareness and support of public policy that decreases disease burden. Review publications and websites from reputable organizations about current policies that promote health, such as the [American Cancer Society \(2019b\)](#). For example, your support of a no-smoking law that prohibits smoking in public spaces, such as restaurants and bars, protects everyone who works and visits these spaces by limiting the exposure to secondhand smoke.

• • •

You will encounter many patients living with chronic illnesses. Use your knowledge and skills to promote health by educating patients about the major risk factors that increase the chance they will develop a chronic illness. Promote health and encourage patients to engage in screenings to detect diseases early to identify potential problems and intervene before permanent damage to health occurs. Helping patients understand how their lifestyle choices affect their health has the potential to decrease occurrence of chronic illness through exercise, healthy food choices, smoking cessation, controlled alcohol intake, and maintaining a healthy weight. Understanding how chronic illnesses affect your patients and their families will help you develop an appropriate patient-centered plan of care to promote optimal patient outcomes.

Key Points

- A chronic disease is a pathophysiologic condition that lasts more than 1 year, requires ongoing medical care, and often limits a person's usual activities of daily living.
- The Chronic Care Model emphasizes the importance of self-management and provides a framework to help members of the health care team understand how community resources and health care systems impact patient outcomes.
- Patients with chronic illnesses must make lifestyle changes and learn to control their illnesses through disease self-management.

- Patients with the same chronic illness often have different symptoms and treatment needs.
- Loneliness and depression may negatively influence a patient's ability to cope with chronic illness.
- Inherited genetics and environmental influences are associated with the onset of chronic illnesses.
- Detecting risk factors for chronic illness before a disease begins provides an opportunity for early intervention to prevent or delay disease onset.
- Teaching healthy lifestyle behaviors provides an opportunity for the nurse to help people identify needed life changes to prevent disease.
- Effective programs that help patients self-manage their chronic diseases provide disease-specific information and help patients make decisions about their care.
- Helping patients understand how to deal with different symptoms related to a chronic disease and its treatment and how to communicate with family, friends, and health care workers assists patients in making lifestyle changes required by their chronic disease.

Reflective Learning

- Consider a patient that you cared for recently in clinical practice. What chronic disease risk factors did this patient have? What focused teaching did you or could you provide to improve the patient's health?
- Assess your patient's or a peer's family history. What patterns of illnesses occur in this family? Based on the family history, what healthy behaviors would prevent the family pattern of illness?

- Evaluate a recent patient's ability to adhere to his or her treatment plan to manage a chronic disease. What factors affected the patient's ability to follow the treatment plan? What interventions may have enhanced the patient's adherence?

Review Questions

1. A health system upgraded its electronic health record across all its practice settings to enhance patient care and communication among health care providers. This is an example of which component of the Chronic Care Model?
 1. Health systems
 2. Decision support
 3. Clinical information systems
 4. Community
2. A nurse is providing education to a patient with type 2 diabetes. Which characteristics does the nurse include in her teaching to explain why type 2 diabetes is considered a chronic disease? (Select all that apply.)
 1. Type 2 diabetes lasts throughout a person's life.
 2. Genetic mutations drive the treatment for type 2 diabetes.
 3. People with type 2 diabetes have to modify some of their daily activities.
 4. Type 2 diabetes occurs in elderly people.
 5. People with type 2 diabetes require ongoing medical care.
3. Which of the family caregivers listed below will the nurse expect to be most at risk for experiencing poor health outcomes?
 1. A 20-year-old daughter caring for a mother who needs help setting up her medications weekly
 2. The 68-year-old spouse of a patient who is experiencing worsening dementia

3. A 32-year-old parent of a child who has an ear infection
4. A married couple who is sharing the caregiving responsibilities for a parent who was recently diagnosed with hypertension and coronary artery disease
4. A school nurse is planning a health fair for children in first, second, and third grade to promote healthy behaviors. The most appropriate health screening for this age-group would be: (Select all that apply.)
 1. Providing information about eating fruits and vegetables
 2. Taking the children's blood pressure
 3. Recording the children's height and weight on a growth chart
 4. Asking the students about their family history of cancer
 5. Teaching the students about the risks of secondhand smoke
5. A nurse is providing health promotion information at a health fair for female patients who are diagnosed with cancer. What information should the nurse include? (Select all that apply.)
 1. Recommending that they avoid drinking alcohol to prevent alcohol misuse
 2. Information from the local health department about smoking-cessation classes
 3. The need to avoid physical activity while receiving cancer treatment to lessen fatigue
 4. Strategies to talk with family and friends about the cancer diagnosis and the side effects from their treatment
 5. How nutritional needs may change based on the diagnosis of cancer and its treatment
6. The nurse is caring for a family where there is a strong family history of breast cancer. One of the family members says, "I am afraid of having genetic testing. If it is positive, I know I have cancer." What is the nurse's best response?

1. "It will help diagnose the cancer early if you have it."
 2. "If the results are positive, it means you have a higher risk for breast cancer, not that you have cancer."
 3. "If it is going to cause you to worry, don't have the screening done."
 4. "I am sure you will be fine. You are a healthy woman."
7. A patient tells the nurse, "My doctor told me to lose weight, exercise, stop smoking, and eat better. I am not sick at all. Why would he tell me that?" The nurse's best response would be:
1. "Since I was not there to hear the conversation, I am not exactly sure."
 2. "All of these things are behaviors that are good for you and your family. Why not just give it a try?"
 3. "I believe he is trying to get you to think about ways that you can be healthier. All these things help to prevent future health problems."
 4. "Eating a balanced, healthy diet and exercising regularly will help you lose weight. I know stopping smoking is really hard to do."
8. Two nurses are revising a self-management education program to help patients better manage their asthma. What strategies are most important for them to include in the program?
1. Have patients list the medications they are prescribed to take and describe any problems they are having with their medications.
 2. Create a common set of patient goals that the patients will work toward as a group.
 3. Look for group leaders who are health care providers that are respected by the community.

4. Provide information on how to balance activities during the day.
 5. Ask patients to discuss how other people in their family react to them now that they have asthma.
9. During a home visit, a patient states, "I am really upset about my heart failure. I can't go out to eat anymore with my friends, I have no energy, and I don't even want to talk on the phone. All I do is focus on how this disease has changed my life and how much time I have left to live." How should the nurse respond? (Select all that apply.)
1. "Let's talk about going out to lunch. What is making you hesitant about eating with your friends?"
 2. "Tell me about what types of activities you were doing before you knew you had heart failure."
 3. "Eventually you will get used to all of the changes. You are doing OK."
 4. "My mother has heart failure, and she has adjusted to diet, activity, and medication changes."
 5. "How has your heart failure affected your energy level?"
10. A nurse is taking care of a patient who has decided to stop smoking cigarettes. Which online resource would provide evidence-based information about smoking cessation?
1. The American Lung Association online toolkit for smoking cessation
 2. An online blog led by a nurse for people discussing smoking cessation
 3. A self-help website maintained by a hospital focusing on general wellness behaviors
 4. A CDC website that discusses addictive behavior and risk factors

Cultural Competence

OBJECTIVES

- Explain the concepts of cultural awareness, cultural knowledge, cultural skill, cultural encounter, and cultural desire in the cultural competence model.
- Describe social and cultural influences in health and illness.
- Describe health disparity and the social determinants that affect it.
- Describe the roles that communication and self-examination play in developing cultural competence.
- Explain the approaches to use in conducting a cultural nursing history and physical assessment.
- Describe how teach-back helps a patient with limited health literacy.
- Explain the principles to apply when using an interpreter.

KEY TERMS

Acculturation, p. 111

Assimilation, p. 111

Core measures, p. 111

Culture, p. 107

Cultural assessment, p. 113

Cultural awareness, p. 111

Cultural competence, p. 107

Cultural desire, p. 112

Cultural encounter, p. 112

Cultural knowledge, p. 112

Cultural respect, p. 111
Cultural skill, p. 112
Culturally congruent care, p. 107
Emic world view, p. 108
Ethnic/cultural identity, p. 110
Etic world view, p. 108
Health disparity, p. 108
Health literacy p. 115
Intersectionality, p. 110
Linguistic competence, p. 114
Marginalized groups, p. 109
Oppression, p. 110
Racial identity, p. 110
Social determinants of health, p. 109
Stereotype, p. 108
Unconscious/implicit bias, p. 107

The term **culture** refers to the learned and shared beliefs, values, norms, and traditions of a particular group, which guide our thinking, decisions, and actions (Giger, 2017; Leininger and McFarland, 2006). Culture also refers to ways of relating to one another, language and manner of speaking, work and lifestyle practice, social relationships, values, religious beliefs and rituals, and expression of thoughts and emotions (Ball et al., 2019; Giddens, 2017). Culture is a learned behavior, yet it is constantly changing in response to environmental, biological, political, and social influences.

Every one of us has some type of bias that is culturally driven. Such biases can be referred to as an **unconscious bias** or an **implicit bias**. Unconscious bias refers to a bias we are unaware of and that happens outside our control, which is influenced by our personal background, cultural environment, and personal experiences. Unconscious bias typically directs one to make quick judgments and assessments of people and situations. An implicit bias is similar; however, we are aware of the bias that is present. We are responsible for implicit bias and must recognize and acknowledge our actions as they impact our behavior, decisions, and patient-centered care provided. One might have a bias toward or against an individual based on his or her culture, such as a bias

toward an ethnic group, race, gender, nation, religion, social class, or political party. When you as the nurse hold a bias toward an individual patient or group of patients, it is very difficult to provide patient-centered transcultural care.

Culturally congruent care or transcultural care emphasizes the need to provide care based on an individual's cultural beliefs, practices, and values; therefore, effective communication is a critical skill in culturally competent care and helps you engage a patient and family in respectful, patient-centered dialogue ([Hadziabdic et al., 2015](#)). A patient-centered approach to providing transcultural care requires you to address your own implicit bias; be respectful of and responsive to individual patient preferences, needs, and values; and ensure that patient values guide all clinical care decisions ([Institute of Medicine \[IOM\], 2001](#)). This chapter explains the importance of **cultural competence** and its relationship to patient-centered care. Cultural competence means that professional health care must be culturally sensitive, culturally appropriate, and culturally competent to meet the multifaceted health care needs of each person, family, and community ([Spector, 2017](#)). Cultural beliefs, values, and practices are learned from birth, first in the home, then in the church or other places where people congregate, and then in educational and other social settings ([Purnell, 2013](#)). This cultural learning applies to both you and your patients. The process of cultural competence in delivering health care services is "a culturally conscious model of care in which a healthcare professional continually strives to achieve the ability and availability to effectively work within the cultural context of a client" (family, individual, or community) ([Transcultural C.A.R.E. Associates, 2015](#)). It is a process of becoming culturally competent, not being culturally competent ([Transcultural C.A.R.E. Associates, 2015](#)). The goal of delivering cultural care is to utilize research findings to provide culturally specific care that is safe and beneficial to the well-being of the diverse population ([McFarland and Wehbe-Alamah, 2015](#)).

The changing demographics of the US population create challenges for the health care system and health care providers. By the year 2060, the percentage of racial and ethnic minority groups in the United States is expected to climb to 32% of the population ([US Census Bureau, 2018](#)). The fastest-growing racial ethnic group in the United States is people whose ancestry is from two or more races, and this group is projected to grow by 200% by 2060 ([US Census Bureau, 2018](#)). The next fastest-growing is the Asian population, which is projected to double, followed by the Hispanic population ([US Census Bureau, 2018](#)). Nearly one in five of the total US

population is projected to be foreign born by 2060 (Colby and Ortman, 2015). According to the Administration for Community Living (2017), the population age 60 years and over will increase from 65 million in 2017 to 77 million in 2020 and is projected to reach 94.7 million by the year 2060. The wealth gap between blacks and whites is demonstrated in the fact that blacks lag behind whites in homeownership, household wealth, and median income. These differences remain even when controlling for levels of education (Pew Research Center, 2016). Additionally, the Centers for Disease Control and Prevention (CDC) (2018) reports that studies show adults who self-report the worst health also have the most limited literacy, numeracy, and health literacy skills. A growing body of evidence shows that individuals with the skills and confidence to become actively engaged in their health care have better health outcomes. Although death rates have declined overall in the United States over the past 50 years, people who are poorly educated and people living in poverty still die at a higher rate from the same conditions than people who are better educated and economically advantaged (Ball et al., 2019). These statistics reveal examples of cultural factors that influence the health care system and why issues such as health care resource accessibility, patient adherence to medical therapies, patient satisfaction, and health care outcomes are so difficult to manage.

The Joint Commission (TJC), the National Quality Forum (NQF), and the National Commission on Quality Assurance (NCQA) are a few of the influential organizations that have responded to these complexities in health care by implementing new standards focused on cultural competency, health literacy, and patient-centered and family-centered care. These standards recognize that valuing each patient's unique needs improves the overall safety and quality of a patient's care.

World View

Historical and social realities shape an individual's or group's world view, which determines how people perceive others, how they interact and relate to reality, and how they process information (Walker et al., 2010). World view is a set of assumptions that begins to develop during childhood and guides how one sees, thinks about, experiences, and interprets the world (The Substance Abuse and Mental Health Services Administration [SAMHSA], 2014). It creates a lens through which we view all of life's experiences through our own uniquely tinted view. Our world view evolves during a lifetime process of interacting with family, peers, communities, organizations, media, and institutions (Fig. 9.1). It is important for you to advocate for patients based on their world views. This requires a thorough ongoing assessment, flexibility, and planning in partnership with each patient to ensure that your care is safe, effective, and culturally sensitive.

How We Develop Our World View

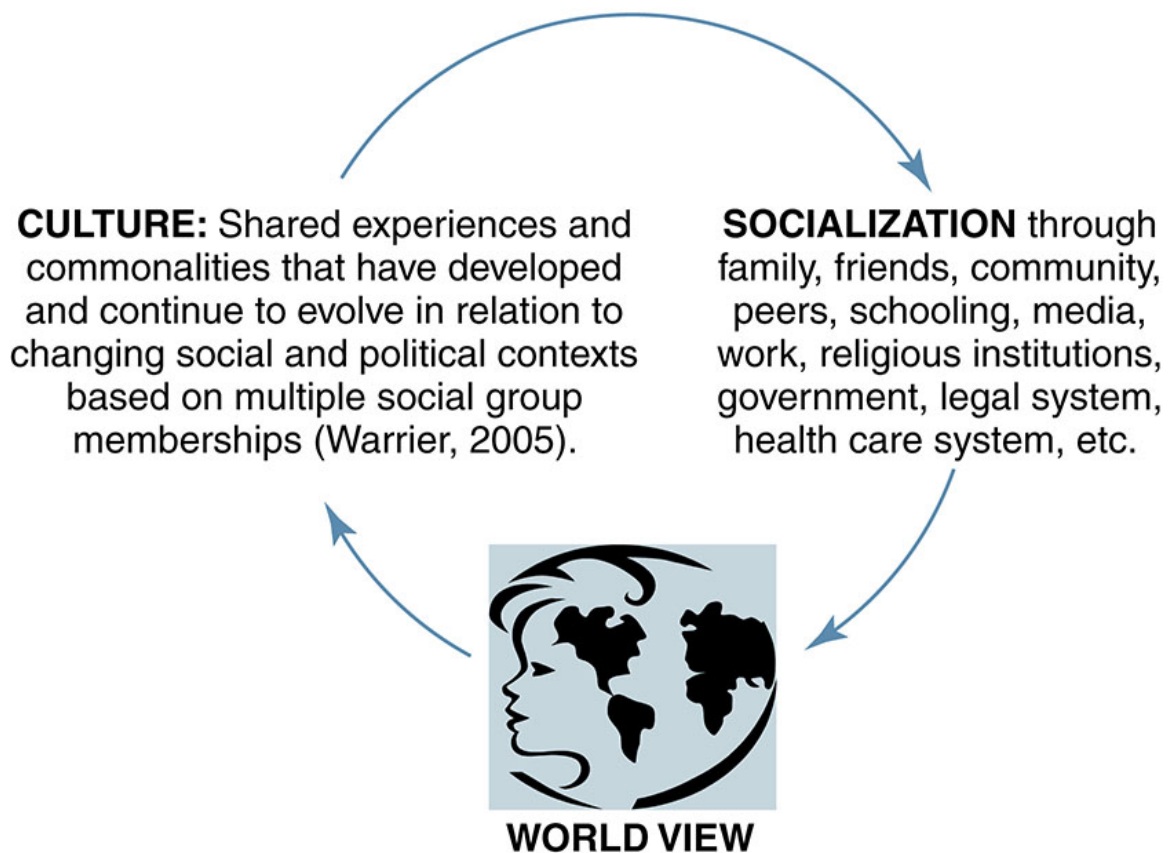

FIG. 9.1 How we develop our world view.
Copyright © 2011 Barnes-Jewish Hospital Center for Diversity and Cultural Competence.

In any intercultural encounter there is an insider perspective (**emic world view**) and an outsider perspective (**etic world view**). For example, a Korean woman requests seaweed soup for her first meal after giving birth. This request puzzles her nurse. The nurse has an emic world view of professional postpartum care but is an outsider to the Korean culture. As such, the nurse is not aware of the meal's significance to the patient. Conversely, the Korean patient has an etic world view of American professional postpartum care and assumes that the seaweed soup is available in the hospital because, according to her cultural beliefs, the soup cleanses the blood and promotes healing and lactation (Edelstein, 2011). Conflict arises when health care providers interpret the behaviors of patients through their own world view lens instead of trying to uncover the world view that guides the behavior of their patients.

A **stereotype** is an assumed belief regarding a particular group (Ellis-Fletcher, 2015). It is easy to stereotype various cultural groups after

reading general information about their ethnic values, practices, and beliefs. Avoid stereotypes or unwarranted generalizations about any particular group that prevents an inaccurate assessment of an individual's unique characteristics, talents, challenges reflected in the places they live, their socioeconomic circumstances, ethnic heritage, religion, language, abilities, characteristics, and world views ([Dayer-Berenson, 2014](#)). Instead, approach each person individually and ask questions to gain a better understanding of a patient's perspective and needs.

Health Disparities

More than a decade ago, a report by the IOM (2001) defined quality health care as health care that is safe, effective, patient centered, timely, efficient, and equitable or fair. Although the US health care system has improved in most of those areas since the IOM report was published, the system still does not emphasize equality of care (Mutha et al., 2012). As a result, many health care disparities remain. *Healthy People 2020* defines a **health disparity** as “a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage” (Office of Disease Prevention and Health Promotion [ODPHP], 2016) (Box 9.1). Poor health status, disease risk factors, poor health outcomes, and limited access to health care are types of disparities often interrelated and influenced by the conditions and social context in which people live (CDC, 2013).

Box 9.1 Examples of Health Disparities Identified by the Centers for Disease Control and Prevention

- Among adults aged 25 years and older in 2011, noncompletion of high school was generally more common among adults who were foreign born than adults born in the United States (CDC, 2013).
- In 2011, 30.3% of US census tracts did not have at least one healthier food retailer (supermarkets, large grocery stores, supercenters and warehouse clubs, or fruit and vegetable specialty stores) within the tract or within a mile of tract boundaries. This represents 83.6 million people, representing approximately 27% of the 2010 continental US population (CDC, 2013).
- Non-Hispanic black adults were at least 50% more likely to die of heart disease or stroke prematurely (i.e., before age 75 years) than their non-Hispanic white counterparts (CDC, 2013).
- Colorectal cancer incidence and mortality increased with advancing age. Incidence and death rates were highest among people aged 75 years and older. Non-Hispanic blacks had higher colorectal cancer incidence and death rates than non-Hispanic whites, Asians/Pacific Islanders, and American Indians/Alaska Natives (CDC, 2013).
- The number of individuals who had colorectal cancer screening (any of the test options) was greater among people aged 65 to 75 years

compared with people aged 50 to 64 years among non-Hispanics compared with Hispanics, among people with a disability compared with people with no disability, and among people with health insurance compared with people with no health insurance (CDC, 2013).

- American Indian and Alaska Native adults are twice as likely to be diagnosed with type 2 diabetes mellitus than non-Hispanic whites (CDC, 2016).
- Black and Hispanic children are hospitalized with complications of asthma much more often than are white children (CDC, 2016).

Adapted from Centers for Disease Control and Prevention (CDC): CDC health disparities and inequalities report—United States, 2013, *MMWR Morb Mortal Wkly Rep* 62(Suppl 3):1, 2013, <http://www.cdc.gov/mmwr/pdf/other/su6203.pdf>; Centers for Disease Control and Prevention (CDC): CDC selected CDC sponsored interventions—United States, 2016, <https://www.cdc.gov/minorityhealth/strategies2016/index.html>.

Social determinants of health are the conditions in which people are born, grow, live, work, and age (WHO, 2019). This includes conditions within a health care system. According to the World Health Organization (WHO) (2019), social determinants of health are mostly responsible for health disparities seen with and between countries. Social determinants of health include factors such as age, race, ethnicity, socioeconomic status, access to nutritious food, transportation resources, religion, sexual orientation, age, level of education, literacy level, disability (physical and cognitive), and geographical location (e.g., access to health care) (CDC, 2013). It is important that you understand how patients' cultural factors and their social determinants of health influence their health disparities. You also need to understand the implications this has on how you provide patient-centered care. According to the US Department of Health and Human Services (USDHHS) (n.d.), health care disparities can adversely affect communities, thus identifying a public health concern.

The 2016 National Healthcare Quality and Disparities Report by the Agency for Healthcare Research and Quality (AHRQ) (2017) offers some promise regarding health care access and quality. The report noted that access to health care did not demonstrate significant improvement (2000-2014); however, uninsured rates for Americans decreased from 2010 to

2016. Quality of health care improved overall from 2000 through 2014 to 2015, but the pace of improvement varied. Overall, some disparities were getting smaller from 2000 through 2014-2015, but disparities continue to persist, especially for poor and uninsured populations. People in poor households receive worse care than people in high-income households for almost all quality access measures. Black and Hispanic populations experience worse access to care compared with whites; however, improvements are noted in the number of Americans with a usual source of consistent medical care. The quality of health care improved generally through 2016 based on quality of measures such as patient safety, healthy living, effective treatment, and trends in care coordination ([AHRQ, 2017](#)).

In addition to disparity among cultural groups, people who are in **marginalized groups** are more likely to have poor health outcomes and die earlier because of a complex interaction among their individual behaviors, environment of the communities in which they live, the policies and practices of health care and governmental systems, and the clinical care they receive ([United Health Foundation, 2015](#)). Examples of marginalized groups include people who are gay, lesbian, bisexual, or transgender; people of color; people who are physically or mentally challenged; and people who are not college educated. Marginalization places or keeps someone in a powerless or an unimportant position within a society or group. Limited access to health care is one social determinant of health that contributes to health disparities. Access to primary care is an important indicator of broader access to health care services. A patient who regularly visits a primary care provider is more likely to receive adequate preventive care than a patient who lacks such access. Nursing intersects with a variety of people from different cultures; therefore, the awareness of marginalization is critical ([Hall and Carlson, 2016](#)).

Health care systems and health care providers sometimes contribute significantly to the problem of health care disparities. Disparities have been linked to inadequate resources, poor patient-provider communication, a lack of culturally competent care, and inadequate access to language services ([National Quality Forum \[NQF\], 2018](#)). Populations with a culture that differs from the culture of the health care provider tend to encounter decreased access to care, which leads to poor patient health outcomes ([Ingram, 2011](#)). To promote equal treatment for all patients who enter the health care system, we must be deliberate about addressing the impact of health care disparities ([NQF, 2018](#)).

Consider this example. *Ms. Millman is a 27-year-old African American. She is overweight and was diagnosed with type 2 diabetes 2 years ago and now*

requires insulin to control her blood sugar. She became homeless after losing her job and health insurance. She currently lives in housing provided through a neighborhood shelter. Ms. Millman was admitted to the hospital with a blood sugar of 322 mg/dL (her normal targeted range is 80 to 130 mg/dL) and a hemoglobin A1c of 11% (target for Ms. Millman is 7% or less). Hannah, a nursing student, is assigned to care for Ms. Millman. After reading her medical record, Hannah notices that Ms. Millman has come to the emergency department three times during the past 6 months for the same reason. Ms. Millman's previous health care providers documented that she verbalized an understanding of how to manage her diabetes but has difficulty following her treatment plan. Hannah teaches Ms. Millman that it is important to take her insulin as prescribed. She also explains how to make healthy food choices. As Hannah provides patient education, Ms. Millman nods. Hannah gives Ms. Millman a chance to ask questions, but Ms. Millman says she has none.

In the case study, Ms. Millman has a number of social determinants that affect her health status and ability to manage her diabetes: socioeconomic status (no employment or health insurance, no home, limited financial resources if any), no access to primary care (uses the emergency department), being female, and a questionable literacy problem indicated by her neutral reaction to Hannah's instruction. Hannah needs to consider all these factors to provide Ms. Millman a more culturally competent health care plan.

REFLECT NOW

Consider the community in which your nursing program is located. What health disparities are present within the community you serve? How do these disparities impact the health care of the population?

Intersectionality

Intersectionality is a research and policy model used to study the complexities of people's lives and experiences (Lopez and Gadsden, 2016). The model looks at how being marginalized affects people's health and

access to care. It serves to describe the forces, factors, and power structures that shape and influence life. Intersectionality is a way of understanding and analyzing our complex world by looking at the human experience (Lopez and Gadsden, 2016). Each of us is at the intersection of two categories: privilege and oppression. **Oppression** is a formal and informal system of advantages and disadvantages tied to membership in social groups, reinforced by societal norms, biases, interactions, and beliefs (Goldbach, 2019). Oppression occurs at individual and group experiences. For example, a patient experiencing oppression has limited access to resources, such as health care, housing, education, employment, and legal services. In contrast, a patient experiencing privilege has no difficulty accessing these resources. Individuals who support the theory of intersectionality believe that we must each determine how privileged and how oppressed we are to understand ourselves, the people around us, and the choices we make. Learning about a culture includes becoming familiar with the heritage of the people and understanding how discrimination, prejudice, and oppression can influence beliefs upheld in everyday life (Purnell, 2013). Then as health care providers, we are better able to identify the nature or source of patient's health care problems and how best to find solutions. Social groups affect our daily lives, shape our world view, control our access to resources, and ultimately determine our health outcomes. Whether we live in a disadvantaged community or in a community with access to social power and resources, we all are affected by the system of oppression. Understanding the different levels of oppression and where you stand helps you develop cultural competence (Fig. 9.2).

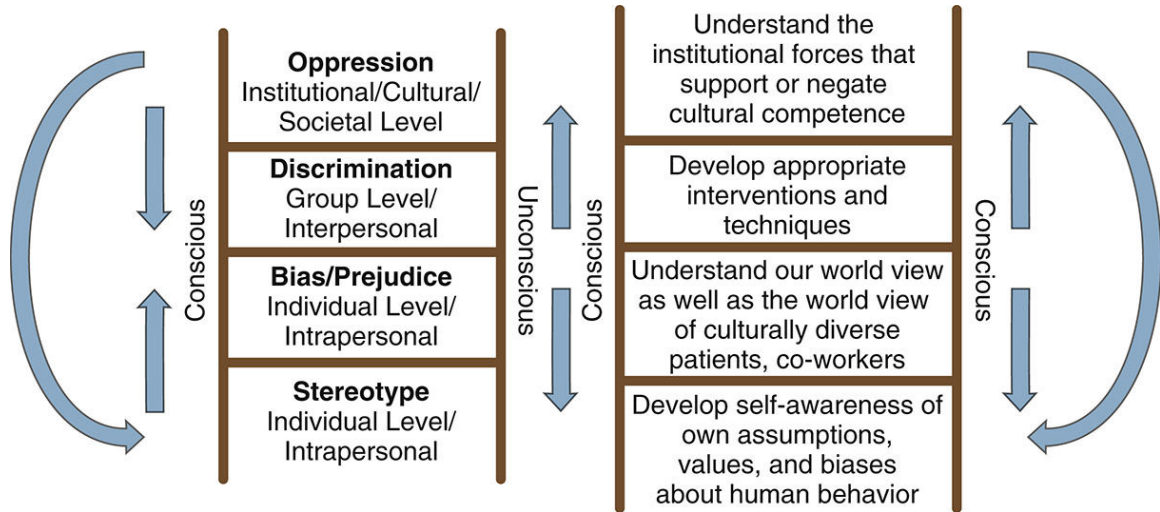

FIG. 9.2 Ladders of oppression and cultural competence. Each level of the ladder of cultural competence offers a response to the ladder of oppression. Because of the extensiveness and complexity of the systems of oppression, individuals and organizations move up and down both ladders simultaneously.

©2011 BJH Center for Diversity and Cultural Competence.

To apply the intersectionality model to daily nursing practice, think about the following patients who have been diagnosed with type 2 diabetes: a 25-year-old Hispanic woman who is homeless, an 85-year-old African-American retired nurse from rural Alabama, a 32-year-old Latina lesbian executive in San Francisco who is Catholic, and a woman who is an undocumented immigrant from Eastern Europe and has a 3-year-old child with a developmental disability. How may the experiences of each of these women compare with the experiences of other Americans? How do their experiences with the health care system differ? How does age affect their perspective? How would these answers change if you looked at their lives 15 years ago or 35 years ago? These scenarios are likely to draw a wide range of responses. The idea of intersectionality supports a broad view of culture by allowing consideration of a multitude of experiences within the context of power, privilege, and oppression.

Racial, Ethnic, and Cultural Identity

Cultural competence is “a dynamic, fluid, continuous process whereby an individual, system, or health care agency finds meaningful and useful care strategies based on knowledge of the cultural heritage, beliefs, attitudes, and behaviors of those to whom they render care” (Giger, 2017, p. 7). Cultural competence is challenging to achieve, but it begins with one’s ongoing development, while gaining an awareness of your own racial, ethnic, and cultural identity. That awareness prepares you to better understand patients within the context of their own racial, ethnic, and cultural identity.

As a nurse, you will counsel and comfort patients to help them better understand their health issues (e.g., medication adherence, ability to follow diet restrictions, knowledge of risk factors) and improve their willingness to partner with you in making important behavioral changes when necessary. Reflect on your own sense of how you identify with race and ethnicity within the context of your family, community, and cultural history (SAMHSA, 2014). Here are two classic definitions. **Racial identity** is based on one’s self-identification with one or more social groups in which a common heritage with a particular racial group is shared (US Census, 2018); **ethnic and cultural identity** is “the frame in which individuals identify consciously or unconsciously with those with whom they feel a common bond because of similar traditions, behaviors, values, and beliefs” (Chavez & Guido-DiBrito, 1999, p. 41). These definitions help us to understand how individuals negotiate their own and other cultures in life (SAMHSA, 2014). It is important for you to examine your own racial, ethnic, and cultural identity to better recognize and understand normal and abnormal behavior. If you fail to do this self-examination, you will be more likely to prejudge patients and not accurately assess their health care problems. A self-examination allows you to understand the cultural factors that shape a patient’s life experiences, a patient’s health care problems, a patient’s behavior, and how a patient might perceive those problems, thus supporting the belief that cultural awareness is essential to healing and building trust in the nurse-patient relationship (Conway-Klassen and Maness, 2017; SAMHSA, 2014).

In addition to one’s self-examination regarding racial, ethnic, and cultural identities, one must also understand the process of adaptation when transition occurs. The process of **acculturation** occurs when an individual or group transitions from one culture and develops traits of another culture (Purnell, 2013; Spector, 2017). In this transition, there will

be adaptation to the new cultures, traditions, customs, and language. This can lead to stress when the values of the transitioning culture differ from the accepted traits of another. **Assimilation** is the process in which the individual adapts to the host's cultural values and no longer prefers the components of the origin culture (Frazer, et al., 2017; Spector, 2017).

The [National Institutes of Health \(2018\)](#) has recently coined the term **cultural respect**, as opposed to cultural competence. Similar to cultural competence, cultural respect is critical to reducing health disparities and improving access to high-quality health care that is respectful and responsive to the needs of the diverse patient. With the growing number of diverse patient populations, the implementation of culturally respectful care is essential and benefits the consumers, stakeholders, and communities, leading to safe and positive health outcomes.

Disease and Illness

People react differently to disease based on their unique cultural perspective. Culture influences our thoughts regarding the way people uniquely define disease and illness. An understanding of the difference between disease and illness allows you to pursue ongoing cultural competence in providing patient care. Illness is the way in which individuals and families react to disease, whereas disease is a malfunctioning of biological or psychological processes. Most health care providers in the United States are primarily educated to treat disease, whereas most individuals seek health care because of their experience with illness. As an example, a patient may have a combination of symptoms that, based on previous experiences with family members and beliefs about illness, the patient believes are untreatable, whereas the patient's physician believes aggressive therapy might offer a cure. Such different perspectives between patients and their health care providers often frustrate patients and providers, fostering a lack of trust, lack of patient adherence to treatment plans, and poor health outcomes. Providing safe, quality care to all patients means taking into consideration both disease and illness ([Office of Minority Health \[OMH\], n.d.](#)).

Culture affects how an individual defines the meaning of illness (see [Chapter 6](#)). Some illnesses (e.g., human immunodeficiency virus [HIV], manic depression, cancer, or dementia) are embedded with meaning that is not always based on the physical nature of the condition. Cultural stigma can negatively affect those diagnosed; this can lead to lack of early detection, screening, or diagnosis based on the influence of cultural interpretation and decreased awareness. All illness is socially constructed through the experiences of people—specifically, how individuals come to understand and live with their illnesses ([Conrad and Barker, 2010](#); [Shiri et al, 2018](#)). This is particularly true with chronic disease. Patients learn the effects of their diseases and how to adapt to live as normally as possible.

Culture also provides the context in which a person interacts with family members, peers, community members, and institutions (e.g., educational, religious, media, health care, legal). Therefore, culture and life experiences shape a person's world view about health, illness, and health care.

Core Measures

The Centers for Medicare & Medicaid Services (CMS), commercial insurance plans, TJC, Medicare and Medicaid managed-care plans, physician and other care provider organizations, and consumers worked together through the Core Quality Measures Collaborative to identify a set of core measures, which aim to hold health care providers accountable for considering patients' unique cultural perspectives to provide safe quality care (CMS, 2017). The **core measures** are a set of evidence-based, scientifically researched standards of care (CMS, 2017; TJC, 2018). The core measures are key quality indicators that help health care institutions improve performance, increase accountability, and reduce costs. The measures apply to all patients. The core measures need to be meaningful to patients, consumers, and physicians while reducing variability in outcome measure selection, financial collection burden, and cost (CMS, 2017). All the core measures are consistent with national health priorities and are in the following eight sets (CMS, 2017):

- Accountable care organizations (ACOs), patient-centered medical homes (PCMH), and primary care
- Cardiology
- Gastroenterology
- HIV and hepatitis C
- Medical oncology
- Obstetrics and gynecology
- Orthopedics
- Pediatrics

In addition to improving the standard of care, the core measures are intended to reduce health disparities. When hospitals are held accountable to meet the core quality measures, all patients regardless of cultural and socioeconomic status are to be treated equally because the standard of care applies to all. For example, one obstetrics and gynecology core measure is that women are to receive breast cancer screening (CMS, 2017). In another example, patients who present with heart failure are to receive beta blocker therapy for left ventricular systolic dysfunction (CMS, 2017).

A Model of Cultural Competence

Ongoing development of cultural competence will present as your ability to interact effectively with people from different cultures, identifying the need to be respectful and responsive to the health belief practices or linguistic needs of our diverse population (SAMHSA, 2016). Cultural competence is a self-motivated developmental process that evolves over a lifetime as individuals engage with others and learn from their experiences (SAMHSA, 2016). One must look at cultural competency as a journey, not a destination (Montenery et al., 2013). Campinha-Bacote's model of cultural competency has five interrelated constructs (Transcultural C.A.R.E. Associates, 2015): cultural awareness, cultural knowledge, cultural skill, cultural encounters, and cultural desire. The five constructs provide a framework for you to practice in a culturally competent manner.

- **Cultural awareness** is the process of conducting a self-examination of one's own biases toward other cultures and the in-depth exploration of one's cultural and professional background. It also involves being aware of the existence of documented racism and other "isms" in health care delivery.
- **Cultural knowledge** is the process in which a health care professional seeks and obtains a sound educational base about culturally diverse groups. In acquiring this knowledge, health care professionals must focus on the integration of three specific issues: health-related beliefs and cultural values, care practices, and disease incidence and prevalence.
- **Cultural skill** is the ability to conduct a cultural assessment of a patient to collect relevant cultural data about a patient's presenting problem, as well as accurately conducting a culturally based physical assessment.
- **Cultural encounter** is a process that encourages health care professionals to directly engage in face-to-face cultural interactions and other types of encounters with patients from culturally diverse backgrounds. A cultural encounter aims to modify a health care provider's existing belief about a cultural group and to prevent possible stereotyping.
- **Cultural desire** is the motivation of a health care professional to "want to" (and not "have to") engage in the process of becoming culturally aware, culturally knowledgeable, and culturally skillful in seeking cultural encounters.

When you provide culturally competent care, you bridge cultural gaps to provide meaningful and supportive care for all patients. Transcultural care is culturally congruent when it fits a person's life patterns, values, and system of meaning. These patterns and meaning are generated by people themselves and not from biased, predetermined criteria. For example, during nursing school you are assigned to care for a female patient who observes Muslim beliefs. You notice the woman's discomfort with several of the male health care providers and you wonder if this discomfort is related to your patient's religious beliefs. While preparing for clinical, you learn that Muslims differ in their adherence to tradition but that modesty is an important Islamic ethic that pertains to interaction between the sexes. Thus you say to the patient, "I know that for many of our Muslim patients, modesty is very important. I want to respect your beliefs; is there some way I can make you more comfortable?" You do not assume that the information will automatically apply to this patient. Instead you combine your knowledge about a cultural group with an attitude of helpfulness and flexibility to provide quality, patient-centered, culturally congruent care. There is great diversity within cultural and racial groups themselves, and knowledge provides a general baseline, which is a great starting point in generating a positive patient outcome based on individual health care needs ([Giger, 2017](#)).

Cultural Awareness and Knowledge

Cultural awareness requires a self-examination of one's biases toward other cultures and an in-depth exploration of one's own cultural and professional background (Ingram, 2011; Campinha-Bacote, 2002). Self-examination helps you to understand your own world view of how you perceive and engage patients. Before you begin to assess the cultures, races, and ethnicities of your patients and use this information to improve their care, first examine and understand your own cultural history, racial and ethnic heritage, and cultural values and beliefs (SAMHSA, 2014). Every individual is constructed from a unique cultural background, which can influence an individual's opinions, perceptions, beliefs, biases, or thoughts, thus forming a unique individual identity (Giger, 2017). Nurses who understand themselves and their own cultural groups and perceptions are better equipped to respect patients with diverse belief systems. Being open to understanding a patient's beliefs and forming a partnership is more important than knowing everything about a patient's specific culture (Ball et al., 2019). For example, you are giving discharge instruction to your patient. You notice the patient is avoiding eye contact, and you perceive this as disrespectful or showing disinterest when, in fact, the patient's lack of eye contact is a sign of respect, as some cultures believe the lack of eye contact when in presence of an authority is expected. Becoming culturally aware is a first step in one's ability to provide positive patient-centered care.

Campinha-Bacote recommends that you begin to gain cultural awareness by not only asking yourself if you hold any biases but also questioning whether there are any "isms" where you work (Transcultural C.A.R.E. Associates, 2015). For example, are there ageism practices in how older adults have their pain treated (e.g., undertreatment)? Be mindful of such practices so that you can adopt care approaches that minimize biases.

Health care providers gain cultural knowledge by taking time to better understand the populations they serve and obtaining specific cultural knowledge as it relates to help seeking, treatment, and recovery (SAMHSA, 2014). Cultural knowledge is learning or becoming educated about the beliefs and values of other cultures and diverse ethnic groups (Campinha-Bacote, 2002). The health care provider must focus on their specific issues: (1) health-related beliefs and cultural values, (2) disease incidence and prevalence, and (3) treatment efficacy (Campinha-Bacote, 2002). Disease incidence and prevalence differ among ethnic groups. Epidemiological data are needed to guide treatment (Campinha-Bacote,

2002). Treatment efficacy is a critical step for providing care to culturally diverse populations.

One's health-related beliefs and cultural values explain how an illness is interpreted by a patient and will guide health care practices delivered throughout patient care. For example, certain cultures believe in the importance of balance and harmony to stay healthy. Aspects of this concept are evident among the beliefs of many Hispanic, Native American, Asian, and Middle Eastern groups (Ball et al., 2019). Box 9.2 summarizes the naturalistic or holistic balance that many people believe they can achieve by using "hot" and "cold" foods and medicines. However, people from different cultures define "hot" and "cold" differently. For example, people who are of Chinese heritage often uphold the philosophical concept of yin (cold) and yang (hot). To restore (treat) a disturbed balance requires the use of opposites (e.g., a "hot" remedy for a "cold" problem and vice versa). If you know about a specific culture's risks for disease, you can focus your nursing history more appropriately during your assessment. If you learn that an individual believes in a "hot" and "cold" balance when choosing certain foods to eat, support your patient's practices, and adapt this information into the patient's dietary plan.

Box 9.2 Balance of "HOT" and "COLD"

Cold Conditions	Hot Treatments	Hot Conditions	Cold Treatments
Cancer	Foods	Constipation	Foods
Cold, flu	Beef	Diarrhea	Barley water
Earaches	Cereals	Fever	Chicken
Headaches	Chili peppers	Infection	Dairy products
Joint pain	Chocolate	Kidney problems	Fresh vegetables
Menses	Eggs	Rash	Fruits
Pneumonia	Liquor	Sore throat	Honey
Stomach cramps	Onions		Medicines and Herbs
	Medicines and Herbs		Bicarbonate of soda
	Anise		Milk of Magnesia
	Aspirin		Sage
	Castor oil		
	Cinnamon		
	Garlic		
	Ginger root		
	Iron		
	Penicillin		

Adapted from Ball JW, et al: *Seidel's guide to physical examination*, ed 9, St Louis, 2019, Elsevier; and Purnell LD: *Transcultural health care: a culturally competent approach*, ed 4, Philadelphia, 2013, FA Davis.

Do not form inappropriate biases or stereotypes when you assess a patient's culture. It is easy to stereotype various cultural groups after reading general information about their ethnic values, practices, and beliefs. Avoid stereotypes or unwarranted generalizations about any particular group that prevents an accurate assessment of an individual's unique characteristics and world view. Instead approach each person individually and ask questions to gain a better understanding of a patient's perspective and needs. Stereotyping occurs in two cognitive phases. In the first phase there is an activation of a stereotype when an individual is categorized into a social group. When this occurs, beliefs and prejudices come to mind about what members of that particular group are like (Ball et al., 2019). Stereotypical views eventually occur without awareness automatically. In the second phase, people use these activated beliefs and feelings when they interact with individuals (Ball et al., 2019). Research shows that health care providers activate these stereotypes or unconscious biases routinely when communicating with and providing care to minority individuals (Dayer-Berenson, 2014). As a result, diagnoses and treatments of patients may be biased even in the absence of the practitioner's intent or awareness.

REFLECT NOW

Consider a patient that you cared for recently. How did the patient's health-related beliefs and cultural values impact the decisions he or she made regarding their health concerns?

Storytelling

One way to begin to understand a patient's cultural perspective is storytelling. Storytelling conveys culture, combining personal experience with the commonalities of all human experiences (Wilson et al., 2015). When you encourage a patient to tell a story or when you tell your own story, you frame important messages in ways that make them memorable for you and your patient. Telling stories engages a nurse and patient in a

way that broadens their relational understanding. Use storytelling to explore pertinent health care issues; for example, have patients describe previous surgical experiences, problems with childrearing, or approaches used with self-administration of medications. A story helps identify the real problems affecting a patient's health status and find culturally appropriate ways to intervene (Box 9.3).

Box 9.3 Evidence-Based Practice Use of Storytelling and Patient Involvement in Health Care.

PICOT Question: Does the use of storytelling compared with standard assessment approaches among adult and pediatric patients affect patient involvement in selecting health care interventions?

Evidence Summary

A patient's ability to understand the complexities of many health issues and to be able to become engaged in decision making requires the ability to discuss and clarify confusing issues. Storytelling allows patients to reflect on their illness experience and create meaning from it (Gucciardi et al., 2016; Hardy and Sumner, 2018). Storytelling enhances self-management of chronic disease (e.g., cancer, diabetes). A recent study involved patients telling stories about their aspirations for the future (Terkildsen and Wittrup, 2015). The shared information allowed clinicians to initiate interventions based on patient experiences of health problems. When patients are able to express their experiences, there is a negotiation with health care providers that leads to a mutual plan of care.

Digital storytelling is also widely used, especially in pediatric patients. Digital storytelling gives children and adolescents with cancer a platform for making sense of and sharing their cancer experience (Wilson et al, 2015). Houston et al. (2011) used DVDs to deliver stories of real patients with hypertension to patients treated for hypertension. Patients with baseline uncontrolled hypertension who watched the storytelling DVDs had a greater reduction in systolic and diastolic blood pressure at 3 months compared with patients watching an attention DVD (a DVD on general health topics unrelated to hypertension). Technology can have a significant impact on providing respect, trust, and justice in patient care (Hardy and Sumner, 2018). The act of telling a story is valuable, allowing a patient to initiate the process of reflection to gain understanding of the

self and the disease process (Gucciardi et al., 2016; Hardy & Sumner, 2018).

Application to Nursing Practice

- Create a safe, caring, and nonjudgmental environment when using storytelling (Gucciardi et al., 2016; Hardy and Sumner, 2018).
- Storytelling should be participant-centered; give patients substantial control over when and how to tell a story (Gucciardi et al., 2016).
- Use storytelling to clarify issues when performing a cultural assessment.
- When asking a patient to describe his or her major concerns about a health problem, try to use storytelling to frame the context of those concerns.
- Tell your own stories about patient experiences (respecting confidentiality) to help explain procedures or treatment plans.

World View of Providers and Patients

Health care has its own culture of hierarchies, power, values, beliefs, and practices. Most health care providers educated in Western traditions are immersed in the culture of science and biomedicine through their coursework and professional experience. Consequently, they often have a world view that differs from that of their patients. As a nurse, you need to assume that every patient encounter will be a cross-cultural one.

Patients and all their health care providers bring all their world views into the care process. The iceberg analogy is a tool that helps you visualize the visible and invisible aspects of your own world view (Fig. 9.3). Just as most of an iceberg lies beneath the surface of the water, most aspects of a person's world view lie outside his or her awareness and are invisible to those around the person. For example, a patient who has willingly agreed to be admitted to the hospital for a serious medical condition requiring surgery may refuse the surgery for religious reasons. In the patient's view, she came to the hospital for help to eliminate the pain and infection from her illness. At the same time, she believes that she needs to seek God for a decision that entails removing a body part. The patient's health care provider assumes the patient is in the hospital to receive care for a serious illness and is willing to accept any and all treatments to cure the illness. The patient's deeply held religious beliefs about removing a body part are not obvious by assessing for a religious preference. Thus the nurse needs

to conduct a comprehensive **cultural assessment** to understand how the patient's religious values will affect her willingness to receive care (Box 9.4). These deeply held values reside "underneath the iceberg." The observed behavior (in this case, coming to the hospital) is a visible sign of a person's world view, but the beliefs, attitudes, knowledge, and experiences that guide the behavior are not visible to others. Conflict arises when health care providers interpret the behaviors of patients through their own world view lens instead of trying to uncover the world view that guides the behavior of their patients.

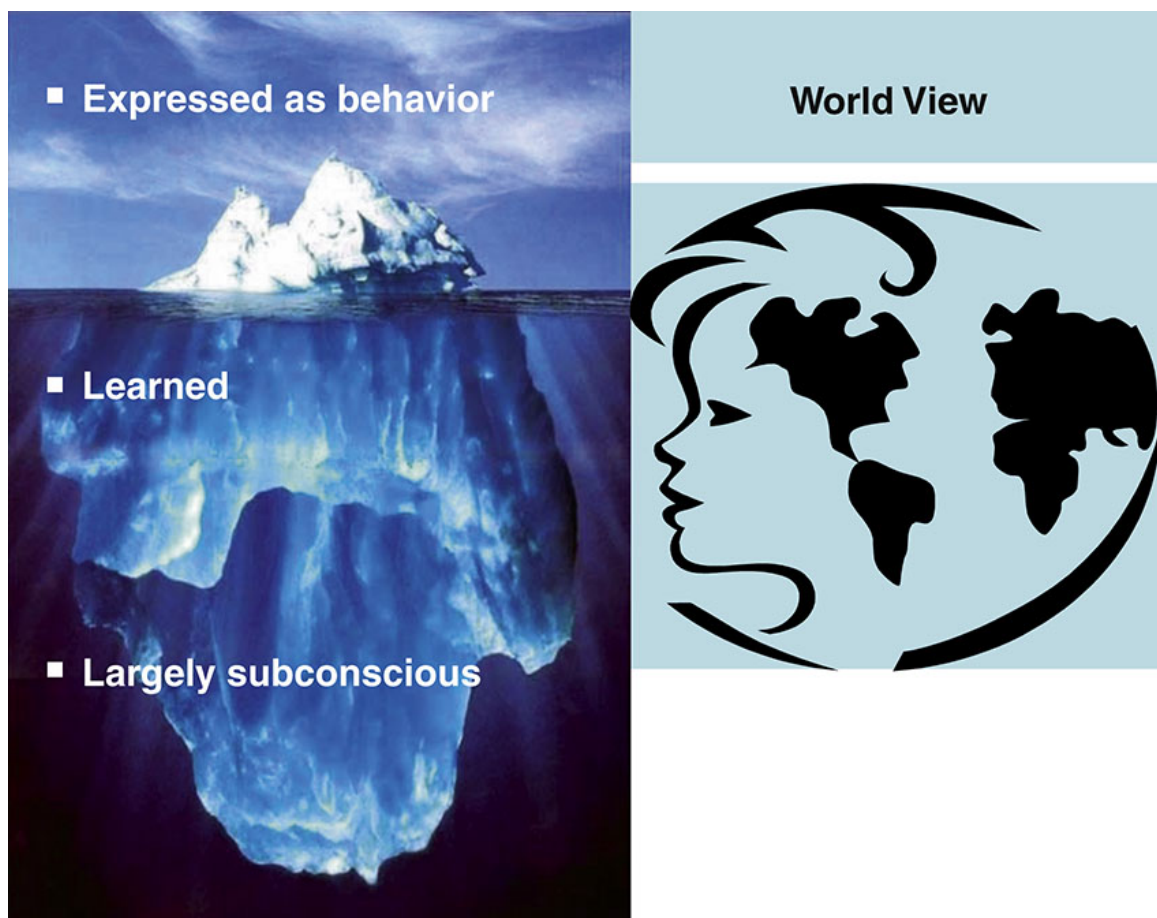

FIG. 9.3 Both nurse and patient act in accordance with their own world views. This model was adapted from Campinha-Bacote et al. (2005) Iceberg Analogy. It incorporates the Kleinman (1980) explanatory model. Copyright © 2011 Barnes-Jewish Hospital Center for Diversity and Cultural Competence.

Box 9.4 Cultural Assessment Guide: Aspects of Understanding Health Beliefs and Practices

- How does the patient define health and illness? How are feelings concerning pain, fatigue, and illness in general expressed?
- Are particular methods used for the treatment of illness?
- What is the attitude toward preventive health measures such as immunizations?
- Are there restrictions imposed by modesty that must be respected (e.g., constraints related to exposure of parts of the body, discussion of sexual health)?
- What are attitudes toward mental illness, pain, chronic disease, being handicapped, and death and dying?
- Is there a person in the family responsible for health-related decisions?
- Does the patient prefer a health professional of the same gender, age, and ethnic and racial background?

Faith-Based Influences and Special Rituals

- Is there a religion or faith to which the patient adheres?
- Is there a significant person to whom the patient looks for guidance?
- What events, rituals, and ceremonies are important within the life cycle of birth, puberty, marriage, and death?

Language and Communication

- What language is spoken in the home?
- How well does the patient understand spoken and written English?
- Are there special signs of demonstrating respect or disrespect?
- Is touch an acceptable form of communication?

Parenting Styles and Family Roles

- Who makes the decisions in the family?
- What is the composition of the family? How many generations are considered to be a single family?
- What is the role of and attitude toward children in the family?
- When do children need to be disciplined or punished, and how is this done?
- Do family members show physical affection toward each other and their children?
- What major events are important to the family, and how do they celebrate?

Sources of Support Beyond the Family

- Are there ethnic organizations that may influence the patient's approach to health care?
- Are there individuals in the patient's social network that influence perception of health and illness?
- Is there a particular cultural group with which the patient identifies?

Dietary Practices

- What does the family like to eat? Does everyone in the family have similar tastes in food?
- Who is responsible for food preparation?
- Are any foods forbidden by the culture, or are some foods a cultural requirement in observance of a rite or ceremony?
- How is food prepared and eaten?
- Are there periods of required fasting?

Cultural Skill

Collecting a culturally based nursing history, performing a culturally based physical assessment, and using teach-back with plain language are cultural skills that take practice and require you to apply your cultural awareness and knowledge. The summary of the domains of culture is a framework for the information you might choose to include in a nursing history (Purnell, 2013) (Box 9.5). It takes time to gather a comprehensive culturally based nursing history. If you work in a setting such as home health, school nursing, or a health clinic, you will be able to gather more information with each patient visit. When you are in an acute setting, you must focus your assessment on the domains most relevant to a patient's condition and the impending treatment plan. For example, if you know a patient will require extensive postoperative education, it will be important to assess the patient's and family's language, family roles, and health care practices.

Box 9.5 The Twelve Domains of Culture

- Overview, inhabited localities—country of origin and current residence
- Communication—interrelationship of verbal language skills, including dominant language, dialects, touch, contextual use of language, and willingness to share information
- Family roles and organization—defines relationship of insiders and outsiders; includes concepts related to head of household, gender roles, family goals and priorities, and developmental goals of family members
- Workforce issues—type of employment, location, autonomy, language barriers
- Biocultural ecology—skin color, heredity, genetics, drug metabolism
- High-risk behaviors—tobacco, alcohol, recreational drugs, physical activity, safety
- Nutrition—meaning of foods, common foods, deficiencies, rituals, limitations
- Pregnancy and childbearing practices—fertility practices, views toward pregnancy, birthing, postpartum

- Death rituals—bereavement, ceremonies
- Spirituality—religious practices, use of prayer, meaning of life
- Health care practices—focus of health care, traditional practices, responsibility for health, self-medication, pain, sick role, barriers
- Health care providers—perceptions of providers, folk practitioners, gender, and health care status

Adapted from Purnell LD: *Transcultural health care: a culturally competent approach*, ed 4, Philadelphia, 2013, FA Davis.

Collecting a Patient History

Begin a patient assessment by being mindful that cultural differences will exist. It is important to grasp exactly what the patient means and know exactly what the patient thinks you mean in words and actions (Ball et al., 2019). Do not make assumptions. Listen carefully, let patients tell their stories, rephrase statements for clarity, and validate any assumptions you make about the patient's condition or health care needs with the patient. As you perform an assessment, the patient may hesitate to offer his or her beliefs and fears, a hesitancy that can be overcome through respectful, nonjudgmental questioning (see Box 9.4). Have a patient help set the agenda for the visit to help you better understand the patient's needs.

A cultural assessment is intrusive and time consuming and requires a trusting relationship between participants. Misunderstandings due to inappropriate communication between a health care provider and the patient are a barrier to accessing health care (Hadziabdic et al., 2015). Misunderstandings occur because of language communication differences between and among participants and differences in interpreting one another's behaviors. **Linguistic competence** is the ability to communicate effectively and convey information in a manner that is easily understood by diverse audiences. You use transcultural communication skills to interpret a patient's behavior and to behave in a culturally congruent way.

The National Culturally and Linguistically Appropriate Services (CLAS) Standards are intended to advance health equity, improve quality, and help eliminate health care disparities by establishing a blueprint to help individuals and health care organizations implement culturally and linguistically appropriate services (Office of Minority Health [OMH], n.d.). The CLAS standards include standards for communication and language assistance. The standards apply when you care for patients who have

limited English proficiency and/or other communication needs. All US health care organizations must meet the following requirements:

- Provide language assistance resources (e.g., trained medical interpreters, qualified translators, telecommunication devices for the deaf) for individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all health care and services.
- Inform all individuals of the availability of language assistance services clearly and in their preferred language verbally and in writing.
- Ensure the competence of individuals providing language assistance. Do not use untrained individuals and/or minors as interpreters.
- Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations in the service area.

When you begin a cultural assessment there are some basic questions that can help you explore a patient's culture (Ball et al., 2019):

- What do you call your problem?
- What do you think caused it?
- Why do you think it started when it did?
- What does your sickness do to you?
- How long do you think it will last?
- How different is this problem from the one you had a month ago?
- What is the difference between what we are doing and what you think we should be doing for you?
- Why did you come to us for treatment?
- What benefit do you expect from the treatment?
- How do you typically deal with a problem with your health?

Each question requires an open-ended response, enabling you to gain important details about a patient's perceptions, values, and attitudes. A patient's answer to a question may allow you to explore his or her cultural background more thoroughly.

After realizing that Ms. Millman needs help to better understand the types of foods that are appropriate for a diabetic diet, Hannah refocuses her assessment on

some basic questions. How do you think the foods that you eat affect your diabetes? What does diabetes do to you if your blood sugar becomes too high? What benefit will you get from eating healthy foods? Tell me what you eat during a typical day.

Culture influences how feelings are expressed verbally and nonverbally. Verbal and nonverbal communication is an important core of all health care encounters ([Hadziabdic et al., 2015](#)). Touch, facial expressions, eye contact, movement, and body posture all have varying significance. The questions in [Box 9.4](#) can help provide further insight to particular situations and help avoid misunderstanding and miscommunication ([Ball et al., 2019](#)).

Assessing Health Literacy

Health literacy is the degree to which individuals have the capacity to obtain, process, and understand basic health information and the services needed to make appropriate health decisions ([AHRQ, 2015](#)). According to the IOM, 90 million adult Americans have limited health literacy, and 20 million Americans speak poor English and 10 million speak none ([NIH, n.d.](#)). Limited health literacy can be a problem for anyone. It is important to understand that even people with good literacy skills find that understanding health care information is a challenge. Patients and family members often do not understand medical vocabulary and the basic concepts in health and medicine, such as how the body works or how to navigate the health care system. During your assessment, be alert for patient behaviors that might reflect a literacy deficit such as having difficulty completing registration forms or health histories, failing to make follow-up appointments, asking few questions during a physical examination, and responding simply “yes” when asked whether explanations are understood. Use health literacy assessment tools to determine the level of a patient’s health literacy ([AHRQ, 2015](#)). Examples of these tools include:

- The Short Assessment of Health Literacy—Spanish and English (SAHL-S&E) is an instrument consisting of comparable tests in English and Spanish, with good reliability and validity in both languages ([Lee et al., 2010](#)).
- The Rapid Estimate of Adult Literacy in Medicine—Short Form (REALM-SF) is a seven-item word recognition test to provide clinicians with a valid quick assessment of patient health literacy

(Arozullah et al., 2007). The REALM-SF has been validated and field-tested in diverse research settings.

Assessing a patient's health literacy level is very important in planning appropriate patient education approaches (AHRQ, 2015) (see Chapter 25).

Culturally Based Physical Assessment

When performing a physical assessment, knowledge about a patient directs your physical assessment (see Chapter 30). For example, if you know a patient has diabetes for many years, you focus on the peripheral vascular examination because of the common incidence of circulatory problems in patients with diabetes. If a patient uses an inhaler for asthma, you perform a more detailed assessment of the lungs compared with what you might do for a healthy patient you see during a routine checkup.

Similarly, you learn to anticipate physical findings based on a patient's cultural health practices and distinguish physical characteristics of an ethnic or racial group. There are several ways individuals from one cultural group can differ biologically from members of other cultural groups (Giger, 2017). For example, Mongolian blue spots are a dark pigmented birthmark that may appear shortly after birth on the buttocks, lower back, arms, or legs of dark skin and should not be mistaken for bruising and a signs of abuse. Another example includes the practices of "coining" and "cupping," which are commonly used by some Asian subcultures to release excess force from the body and restore balance (Ball et al., 2019). The practices leave imprints and markings on the skin that can be wrongly interpreted as signs of abuse or disease. Thus it is always important to ask patients about their home remedies and practices. Another example of anticipating findings is to consider sickle cell anemia when blood tests reveal laboratory values that show anemia in a patient of African descent. As you practice and become more knowledgeable of different ethnic groups in your practice, you will more readily recognize physical characteristics of conditions unique to those groups.

Teach-Back and Plain Language

Linguistic competence requires the application of health literacy principles in providing readily available, culturally appropriate oral and written language services to patients and families with limited English proficiency (AHRQ, 2013). The dual challenges of caring for patients with limited

health literacy and cultural differences are likely to increase with an expanding, increasingly diverse, and older population. Evidence suggests that health care providers who attend to both issues help reduce medical errors and improve adherence, communication between provider and patient and family, and outcomes of care at both individual and population levels (Lie et al., 2012). Clear communication is essential for effective delivery of quality and safe health care, but most patients experience significant challenges when communicating with their health care providers. Studies show that 40% to 80% of the medical information given to patients during medical office visits is immediately forgotten, and nearly half of the information retained is incorrect (AHRQ, 2018b).

The use of plain language in communicating with patients makes any information you provide easy to read, understand, and use. Plain language is grammatically correct language that includes complete sentence structure and accurate word usage (National Institutes of Health [NIH], n.d.). The Federal Plain Language Guidelines (2011) provide guidance on improving communication through writing. Clear communication is a priority in providing patient care. Written education must be based on specific patient needs. You can find the tips for writing in plain language from the PlainLanguage.gov website: <https://www.plainlanguage.gov/media/FederalPLGuidelines.pdf>. Offering patients clear instructions and educational material written in plain language conveys to a learner exactly what to know without using unnecessary words or expressions.

Use the teach-back method following any patient instruction to confirm that you have explained what a patient needs to know in a manner that the patient understands (Fig. 9.4). The teach-back technique is an ongoing process of asking patients for feedback through explanation or demonstration and of presenting information in a new way until you feel confident that you communicated clearly and that your patient fully understands the information presented (Box 9.6). When a family caregiver is the recipient of your instruction, use teach-back to confirm his or her learning. You also use teach-back to identify explanations and communication strategies your patients most commonly understand (AHRQ, 2018a).

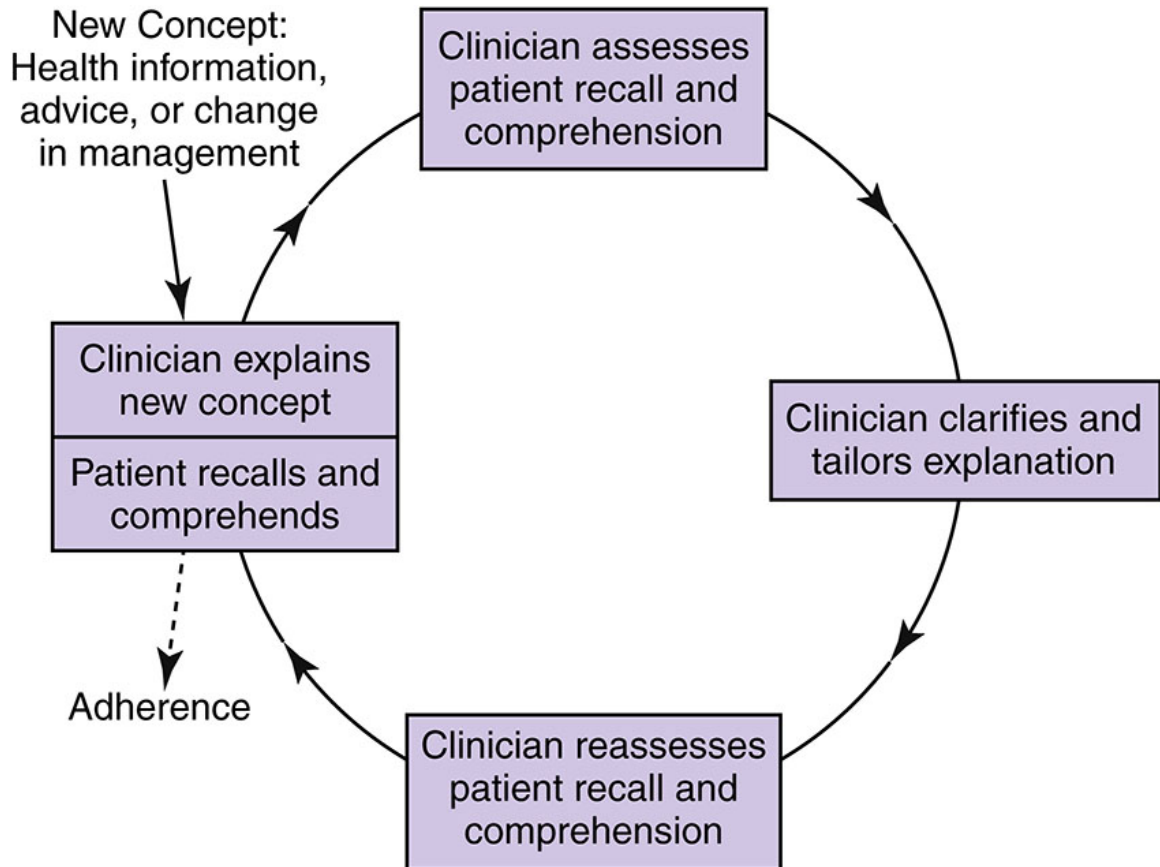

FIG. 9.4 Using the teach-back technique to close the loop. From the US Health Resources and Services Administration.

Box 9.6 Patient Teaching Medication and Nutritional Adherence

Hannah knows it is important for Ms. Millman to understand her health problems and prescribed treatments. Thus Hannah plans to use teach-back to ensure Ms. Millman understands how to effectively manage her diabetes.

Outcome

At the end of the teaching session, Ms. Millman will be able to:

- Describe how she plans to make healthy food choices at the shelter and neighborhood store.

Teaching Strategies

- Create a shame-free environment by demonstrating a general attitude of helpfulness.
- Use nonmedical language and define in plain language all medical terms.
- Sit instead of stand, and speak slowly.
- Use pictures, models, and written handouts to help Ms. Millman better remember relevant information.
- Have Ms. Millman prepare a meal plan.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me two strategies that you will use to make healthy food choices when shopping at your neighborhood grocery store.
- We've gone over a lot of information today about changes you plan to make to your diet. In your own words, please review what we talked about. Tell me how you will follow your diet?

When using the teach-back technique, do not ask a patient, "Do you understand?" or "Do you have any questions?" Instead ask open-ended questions to verify a patient's understanding. Some examples include:

- "I've given you a lot of information (e.g., about your insulin) to remember. Please explain it (e.g., how it affects your blood sugar) to me so that I can be sure that I gave you the information you want and need to take good care of yourself."
- "What will you tell your wife (or husband/partner/child) about the changes we made to your medications today?"
- "We've gone over a lot of information today about how you might change your diet, and I want to make sure I explained everything clearly. In your own words, please review what we talked about. How will you follow this diet at home?"

Teach-back is not intended to test a patient but rather to confirm the clarity of your communication ([AHRQ, 2018a](#)). Many patients are embarrassed by their inability to sort out health information or instructions. By regarding teach-back as a test of your communication skills, you take responsibility for the success or failure of the interaction and create a shame-free environment for your patients. Following are helpful hints to consider when trying the teach-back method ([AHRQ, 2018a](#)).

- Plan your approach. Think about how you will ask your patient to teach back in a shame-free way. Keep in mind that some situations are not appropriate for teach-back.
- Use handouts, pictures, and models to reinforce your teaching.
- “Chunk and check.” Do not wait until the end of the visit to initiate teach-back. Chunk out information into small segments and have the patient or family caregiver teach it back. Repeat several times during a visit.
- Clarify and check again. If teach-back uncovers a misunderstanding, explain things again using a different approach. Ask patients to teach-back again until they are able to correctly describe the information in their own words. If they parrot your words back to you, they may not have understood.
- Start slowly and use teach-back consistently. Practice. It will take a little time, but once it is part of your routine, teach-back can be done without awkwardness.
- Use the show-me method. When prescribing new medicines or changing a dose, research shows that even when patients correctly say when and how much medicine they will take, many will make mistakes when asked to demonstrate the dose.
- Clarify. If a patient cannot remember or accurately repeat your instructions, clarify your information, and allow him or her to teach it back again (see [Box 9.6](#)).
- Although it takes time to get used to teach-back, studies show that it does not take longer to perform once it becomes a part of your routine ([AHRQ, 2018a](#)). *Box 9.6 provides an example of how Hannah used some of these strategies to educate Ms. Millman on how to manage her diet.*

Working With Interpreters

The National CLAS Standards (OMH, n.d.) ensure that qualified translators (written words) and interpreters (verbal words) be provided to patients with limited English proficiency. The CLAS standards require you to notify patients both verbally and in writing of their rights to receive language assistance. If a health care setting does not have timely access to an interpreter, a more feasible option is the use of a telephone service that provides an on-call trained interpreter connected by phone (Juckett and Unger, 2014). Ensure that interpreters are competent in medical terminology and understand issues of confidentiality and impartiality. If available, a cultural broker may be utilized as an interpreter, advocate, or mediator that bridges between the individual or group (Dayer-Berenson, 2014). Do not use a patient's family members to interpret for you or other health care providers. The family member may include his or her own perception or opinion in translation, which can greatly reduce the accuracy of the translated information (Dayer-Berenson, 2014). When you begin a patient interview with an interpreter present, you should speak in the first person ("I" statements), not the third person (e.g., "tell her," "he said"), and speak directly to the patient, as the interpreter functions as an inconspicuous participant for the conversation (Juckett and Unger, 2014). Have the interpreter sit next to or slightly behind the patient. Look at the patient instead of looking at the interpreter and speak in short sentences; then wait for the interpreter to convey them (Juckett and Unger, 2014). Avoid using jargon, acronyms, and jokes; attempts at humor are often lost in interpretation. Ask the patient for feedback and clarification at regular intervals. Be observant of the patient's nonverbal and verbal behaviors. At the end of a conversation thank both the patient and the interpreter.

Cultural Encounter

In every health care setting you will directly interact with patients from culturally diverse backgrounds. This interaction is a cultural encounter, which has two goals ([Campinha-Bacote, 2007](#)). One goal is to communicate in a way that generates a wide variety of responses and to send and receive both verbal and nonverbal communication accurately and appropriately in each culturally different context. The second goal is to continuously interact with patients from culturally diverse backgrounds to validate, refine, or modify existing values, beliefs, and practices about a cultural group.

Cultural Desire

Engaging with people we perceive as “different” from us can be threatening and difficult. It generally takes more effort and patience than engaging with patients who are more similar to us. Cultural desire refers to having the motivation to engage patients so that you understand them from a cultural perspective. It is the pivotal and key construct of cultural competence, for it is a nurse’s desire that evokes the entire process of cultural competence (Campinha-Bacote, 2003). Cultural desire involves the concept of caring (see Chapter 7). Establishing a caring relationship with a patient requires you to enter into the patient’s world view. Cultural desire includes a genuine passion to be open and flexible with others, to accept differences and build on similarities, and to be willing to learn from others as cultural informants (Campinha-Bacote, 2003).

You will care for patients who display behaviors that may be in direct moral conflict with your own values (e.g., abortion, substance abuse, spouse abuse). For example, you are asked to care for a young male gang member whose beliefs about violence and respect for life are in direct contrast to yours. Yet you care for this patient nonjudgmentally and with respect. Acquiring the willingness to practice cultural desire requires a respect and acceptance of all human beings. The LEARN Model (Campinha-Bacote, 2003) can assist with this process. The mnemonic *LEARN* represents the process of listening, explaining, acknowledging, recommending, and negotiating:

- Listen to the patient’s perception of the problem. Be nonjudgmental and use encouraging comments, such as “Tell me more” or “I understand what you are saying.”
- Explain your perception of the problem.
- Acknowledge not only the differences between the two perceptions of the problem but also the similarities. Recognize the differences but build on the similarities.
- Recommendations must involve the patient.
- Negotiate a treatment plan, considering that it is beneficial to incorporate selected aspects of the patient’s culture into the plan.

Applying the LEARN mnemonic will help you to reflect at each patient encounter. You recognize that each patient is unique, but you are responsible for understanding what “unique” truly means so that you can engage patients in a patient-centered approach to care.

Building Competency in Patient-Centered Care

Mrs. Addelman is 28 years old and 39 weeks pregnant. She has been under medical care since the pregnancy was discovered. At this time, Mrs. Addelman is in labor, and an emergency C-section is needed. She refuses to allow the health care team to prepare her for the C-section until her husband arrives. Her family practices the Muslim faith. What are your concerns related to Mrs. Addelman? What are some steps you, as the nurse, can take to assist?

Key Points

- Cultural awareness self-examines the dynamics of personal biases, stereotypes, values, and beliefs related to others different from one's own heritage, while cultural encounter is directly interacting with patients of a diverse population other than one's own.
- Cultural desire is the pivotal and key construct of cultural competence. It is your desire to engage with patients who have cultural differences that evokes the entire process of cultural competence.
- A person's culture and life experiences shape his or her world view about health, illness, and health care.
- Poor health, disease risk factors, poor health outcomes, and limited access to health care are types of preventable health care disparities often interrelated and influenced by the conditions and social context in which people live.
- Disparities in access to quality health care, preventive health care, and health education contribute to poor population health.
- Social determinants of health are defined by conditions in which people are born, grow, live, work, and age.

- Health care systems and providers contribute to the problem of health disparities as a result of inadequate resources, poor patient-provider communication, a lack of culturally competent care, system fragmentation, and inadequate access to language services.
- People who are marginalized are more likely to have poor health outcomes and to die at an early age because of a complex interaction among individual behaviors, public and health policy, cultural factors, and access to and quality of health care.
- Gaining cultural knowledge and conducting a self-examination allows a health care provider to understand the cultural factors that shape a patient's life experiences, a patient's health care problems, a patient's behavior, and how a patient might perceive those problems while building a positive nurse-patient relationship.
- Cultural respect is critical to reducing health disparities and improving access to high-quality health care that is respectful and responsive to the needs of a diverse patient.
- Avoid forming inappropriate biases or stereotypes when assessing a patient's needs. Approach each person individually and ask questions to gain a better understanding of a patient's perspective and needs.
- Ongoing cultural competence and cultural skill are necessary for a nurse to complete a cultural assessment and provide culturally appropriate nursing care for each patient, regardless of the patient's cultural background.
- Knowledge about your patient directs your physical assessment, and the health care provider must learn to anticipate physical findings based on the patient's cultural health practices and the physical characteristics of an ethnic or racial group.

- Teach-back is an ongoing process of asking patients open-ended questions to gather feedback through explanation or demonstration until the health care provider feels confident in the patient's ability to understand and safely apply the new educational content.
- Linguistic competence is the ability to communicate effectively and convey information in a manner that is easily understood by diverse audiences.
- Effective communication is a critical skill in culturally competent care and helps you engage a patient and family in a respectful, patient-centered dialogue. Qualified translators (written words), interpreters (verbal words), and/or the use of a cultural broker (mediator) are options to be utilized to assist with linguistic needs related to effective communication.

Reflective Learning

- Consider a patient that you cared for recently on the clinical unit. How did knowledge of your patient's culture impact your nursing care?
- Discuss some of the social determinants of health that you identified while conducting your assessment of the patient. How have these impacted the health of the patient?
- Review your personal approach to patient education when working with a patient who has a different cultural background from your own. Remember, the teach-back method is a valuable tool for all health care providers to use with each patient. As the health care provider, did you do the following?
 - Use a caring tone of voice and attitude?
 - Display comfortable body language, make eye contact, and sit down at the patient's level?
 - Ask open-ended questions?

- Take responsibility for making sure the instructions were clear and understood?
- Use print materials that were reader friendly to support learning?
- Observe the patient's response to teach-back?

Review Questions

1. Which of the following is an example of a patient with a health disparity? (Select all that apply.)
 1. A patient who has a homosexual sexual preference
 2. A patient unable to access primary care services
 3. A patient living with a chronic disease
 4. A family who relies on public transportation
 5. A patient who has had a history of smoking for 10 years
2. A 35-year-old woman has Medicaid coverage for herself and two young children. She missed an appointment at the local health clinic to get an annual mammogram because she has no transportation. She gets the annual screening because her mother had breast cancer. Which of the following are social determinants of this woman's health? (Select all that apply.)
 1. Medicaid insurance
 2. Annual screening
 3. Mother's history of breast cancer
 4. Lack of transportation
 5. Woman's age
3. During a nursing assessment a patient displayed several behaviors. Which behavior suggests the patient may have a health literacy problem?

1. Patient has difficulty completing a registration form at a medical office
2. Patient asks for written information about a health topic
3. Patient speaks Spanish as primary language
4. Patient states unfamiliarity with a newly ordered medicine
4. A nurse desires to communicate with a young woman who is Serbian and who has limited experience with being in a hospital. The nurse has 10 years of experience caring for Serbian women. The patient was admitted for a serious pregnancy complication. Apply the LEARN model and match the nurse's behaviors with each step of the model.

1. L _____	a. The nurse notes that she has learned that fathers can visit mothers at any time in both Serbia and the United States.
2. E _____	b. The nurse shares her perception of the woman's experiences as a patient.
3. A _____	c. The nurse asks the patient how she can maintain bed rest when she returns home.
Table Continued	
4. R _____	d. The nurse attends to the patient and listens to her story about hospitals in Serbia.
5. N _____	e. The nurse involves the patient in a discussion of the treatment options for her condition.

5. Health care organizations must provide which of the following based on federal civil rights laws? (Select all that apply.)
 1. Provide language assistance services at all points of contact free of charge.
 2. Provide auxiliary aids and services, such as interpreters, note takers, and computer-aided transcription services.
 3. Use patients' family members to interpret difficult topics.
 4. Ensure that interpreters are competent in medical terminology.
 5. Provide language assistance to all patients who speak limited English or are deaf.
6. A nurse working in a large occupational health clinic knows that many of the workers at her company are marginalized and

at risk for poor health outcomes. Which of the following individuals are most likely to be marginalized?

1. Wives of the employees
 2. The head supervisors of the company
 3. Workers who have a high school education
 4. Workers employed for less than a year at the company
7. A mother is concerned about her child's flulike symptoms. You learn from the health assessment that the mother practices use of "hot" and "cold" foods to treat ailments. Which of the following foods do you expect the mother to use to treat her child?
1. Chicken
 2. Yogurt
 3. Fresh fruits
 4. Eggs
8. Which explanation provided by the nurse is the most accurate meaning for "providing culturally congruent care"?
1. It fits the patient's valued life patterns and set of meanings.
 2. It is the same set of values as those of the health care team member providing daily care.
 3. It holds one's own way of life as superior to those of others.
 4. It redirects the patient to a more socially expected set of values.
9. Which statement made by a new graduate nurse about the teach-back technique requires intervention and further instruction by the nurse's preceptor?
1. "After teaching a patient how to use an inhaler, I need to use the teach-back technique to test my patient's technique."
 2. "The teach-back technique is an ongoing process of asking patients for feedback."

3. "Using teach-back will help me identify explanations and communication strategies that my patients will most commonly understand."
4. "Using pictures, drawings, and models can enhance the effectiveness of the teach-back technique."

10. Match the cultural concepts on the left with the correct definitions on the right.

1. Etic world view ____	a. Factor that shapes how people perceive others and how they relate to reality
2. World view ____	b. Insider's perspective in an intercultural encounter
3. Cultural desire ____	c. A policy model that describes factors and power structures that shape and influence life
4. Intersectionality ____	d. An outsider's perspective in an intercultural encounter
5. Emic world view ____	e. The motivation of a health care professional to "want to" engage in cultural competency

Family Dynamics

OBJECTIVES

- Discuss how the term *family* reflects family diversity.
- Examine current trends affecting the American family.
- Discuss the role of families and family members as caregivers.
- Discuss factors that affect family forms and their impact on a family's health.
- Explain how the relationship between family structure and patterns of functioning affects the health of individuals within the family and the family as a whole.
- Compare nursing care that views family as context, family as patient, and family as a system and explain how these different perspectives influence nursing practice.
- Discuss factors that promote or impede family health.
- Use the nursing process to provide for the health care needs of the family.
- Discuss essential aspects of a family assessment.
- Plan family-centered care.
- Create individualized, family-centered interventions to help a family improve its health status.
- Evaluate the effectiveness of family-centered care.

KEY TERMS

Family, p. 122

Family as a system, p. 124

Family as context, p. 124

Family as patient, p. 124
Family caregiving, p. 123
Family diversity, p. 121
Family durability, p. 121
Family dynamics, p. 121
Family forms, p. 122
Family function, p. 124
Hardiness, p. 126
Resiliency, p. 126

The Family

Families are very important. They are made up of groups of people who have emotional connections with each other and function as a unit. However, the concept, structure, and function of a family unit continues to change over time. Families face many challenges, including the effects of health and illness, childbearing and childrearing, changes in family structure and dynamics, and caring for older family members. Family characteristics or attributes such as durability, resiliency, and diversity help families adapt to these challenges.

Family durability is a system of support and structure within a family that extends beyond the walls of the household. For example, marriages may end in divorce or death, and remarriage may occur, or children may leave home as adults, but in the end the “family” transcends long periods and inevitable lifestyle changes.

Family resiliency is the ability of a family to cope with expected and unexpected stressors. The family’s ability to adapt to role and structural changes, family members’ developmental milestones, and crises shows resilience. For example, a family is resilient when the wage earner loses a job and another member of the family takes on that role. A family survives and thrives because of the challenges encountered from stressors.

Family diversity is the uniqueness of each family unit. For example, some families experience marriage and have children in later life. Another family includes parents with young children and grandparents living in the home. Every person within a family unit has specific needs, strengths, and important developmental considerations (see [Chapter 11](#)).

As you care for patients and their families, you are responsible for understanding **family dynamics**, the interactions between family members that are affected by a family’s makeup (configuration), structure, function, problem solving, and coping capacity. Use this knowledge to build on a patient’s and family’s strengths and resources ([Duhamel, 2017](#)). The rapidly changing health care delivery system promotes early discharge of patients from acute care settings and even home health visits. Living as a family amid an illness is challenging; family functions, communications, and roles are altered ([Kokonya and Fitzsimons, 2018](#)). The goal of family-centered nursing care is to address the comprehensive health care needs of the family as a unit and to advocate, promote, support, and provide for the well-being and health of the patient and individual family members ([Coats et al., 2018](#); [Orchard et al., 2017](#)).

Concept of Family

The term *family* suggests a visual image of adults and children living together in a satisfying, harmonious manner (Fig. 10.1). For some this term has the opposite image—a single parent with multiple children living with a grandparent. Families represent more than a set of individuals, and a family is more than a sum of its individual members (Kaakinen et al., 2018). Families are as diverse as the individuals who compose them. Patients have deeply ingrained values about their families that deserve respect.

FIG. 10.1 Family celebrations and traditions strengthen the role of the family.

The specific relationships among patients, families, and health care providers are at the center of patient and family care. Unfortunately, these relationships are often defined and shaped by the beliefs of health care providers and not the needs of patients and family caregivers. As a nurse, you need to assess for and understand how your patients define their families and how they perceive the general state of member relationships. Think of a **family** as a set of relationships that a patient identifies as family or as a network of individuals who influence one another's lives, whether there are actual biological or legal ties.

Definition: What is a Family?

Defining *family* initially appears to be a simple undertaking. However, different definitions result in heated debates among social scientists who study the dynamics of families and legislators who set the public policies affecting families. The definition of family is significant and affects who is included on health insurance policies, who has access to children's school records, who files joint tax returns, and who is eligible for sick-leave benefits or public assistance programs.

A family is what an individual believes the family to be. It includes a set of interacting individuals who are related through biology or enduring commitments who usually socialize with each other (Kaakinen et al., 2018). For some patients, family includes only people related by marriage, birth, or adoption. To others, aunts, uncles, close friends, and pets are family. Understand that families take many forms and have diverse cultural and ethnic orientations. No two families are alike; each has its own strengths, weaknesses, resources, and challenges. You must care for both the family and the patient. Effective nursing administrators have a clear vision that caring for families is crucial to the mission of their health care agencies and the health of the nation (Orchard et al., 2017).

Family Forms and Current Trends

Family forms are patterns of people considered by family members to be included in a family (Box 10.1). Although all families have some things in common, each family form has unique problems and strengths. Remain open about who makes up a family to establish a therapeutic relationship with families and to ensure you are aware of a family's resources and concerns.

Box 10.1 Family Forms

Nuclear Family

A nuclear family consists of two adults (and sometimes one or more children).

Extended Family

An extended family includes relatives (aunts, uncles, grandparents, and cousins) in addition to the nuclear family.

Single-Parent Family

A single-parent family is formed when one parent leaves the nuclear family because of death, divorce, or desertion or when a single person decides to have or adopt a child.

Blended Family

A blended family is formed when parents bring children from previous marriages or other parenting relationships into a new joint-living situation.

Alternative Family

Relationships include multi-adult households, grand families (grandparents caring for grandchildren), communal groups with children, "nonfamilies" (adults living alone), and cohabitating partners.

Families are constantly changing. In some situations, people marry later or delay childbirth. Some choose to have children while others do not have any children. Approximately 50% of people 15 years of age and older are married (US Census Bureau, 2018). However, the number of people living alone is greatly increasing, with approximately 30% of households containing only one person (US Census Bureau, 2018). Calculating divorce rates in the United States is complicated and inaccurate. However, most

scholars agree that approximately 40% to 50% of marriages will end in divorce (APA, 2018). Divorce is becoming less common in younger adults but has doubled since the 1990s in adults age 50 and older (Stepler, 2017). Remarriage often results in a blended family with a complex set of relationships among all members.

Marital roles are also more complex as families increasingly have two wage earners. About 70% of mothers with children under 18 years of age are in the workforce, and mothers are the primary or sole earner for about 40% of households (DeWolf, 2017). Balancing employment and family life creates a variety of challenges in terms of child care and household work for both parents.

The number of single-parent families appears to be stabilizing. About 27% of children under the age of 18 live with one parent. Although mothers head most single-parent families, father-only families and the number of children living with other relatives are on the rise (US Census Bureau, 2018).

Although the birth rate for women has dropped 60% since 1991, 6% of all births in the United States occurred in women under 20 years of age in 2015 (Martin et al., 2018; Office of Adolescent Health, 2015). Thus, adolescent pregnancy remains a concern. Most adolescent mothers continue to live with their families. A teenage pregnancy has long-term consequences for the mother. Adolescent mothers are less likely to finish high school and are more likely to require public assistance, live in poverty, and have children with poorer educational, behavioral, and health outcomes (Office of Adolescent Health, 2015). The overwhelming task of being a parent while still being a teenager often severely stresses family relationships and resources. Stressors are also placed on teenage fathers when their partners become pregnant (Hunt, 2015). Teenage fathers usually have poorer support systems and fewer resources to teach them how to parent. Adolescent fatherhood is associated with lower socioeconomic status, lower educational attainment, and incarceration (Lau et al., 2015; Tremblay et al., 2017). Children of teenage fathers are more likely to have low birth weight, live in poverty, and have lower cognitive test scores (Lau et al., 2015). Both adolescent parents often struggle with the normal tasks of development and identity but must accept a parenting role that they are not ready for physically, emotionally, socially, and/or financially.

In 2015 the US Supreme Court issued a groundbreaking ruling that made same-sex marriages constitutional. Since this ruling, the number of same-sex marriages continues to increase, and most same-sex couples who

live together (61%) are married (Masci et al., 2017). Individuals in same-sex relationships have become more vocal about their legal rights. Public support for same-sex marriage has grown rapidly over the past 10 years (Masci et al., 2017).

The fastest-growing age-group in America is 65 years of age and over (US Census Bureau, 2017a). In 2016, 49.2 million Americans were 65 years of age or older. This number increased by 33% since 2006 and is expected to almost double to 98 million people in 2060 (ACL, AoA, 2018). This phenomenon, often referred to as the “Graying of America,” continues to affect the family life cycle, particularly the “sandwich generation” — composed of the children of older adults. These individuals, who are usually in their middle years, must meet their own needs along with those of their children and their aging family members. This balance of needs often occurs at the expense of their own well-being and resources.

More grandparents are raising their grandchildren (US Census Bureau, 2018). This new parenting responsibility is the result of several societal factors, such as military deployment, unemployment, adolescent pregnancy, substance abuse, and divorce resulting in single parenthood.

Factors Influencing Family Forms

Families face many challenges today, including changing structures and roles related to the changing economic status of society. Some families experience challenges related to chronic illness and aging family members. Family caregiving, poverty, homelessness, and domestic violence create challenges for families.

Family Caregivers

The increases in people living with chronic illnesses or disabilities and in the older adult population have created a greater need for **family caregiving** (FCA, 2019). Family caregivers are a crucial part of the health care team because they provide most of the physical and emotional care to patients wishing to remain in their homes (FCA, 2016b). In 2015, approximately 43.5 million caregivers provided unpaid caregiving to an adult or child. About 34.2 million caregivers cared for a family member who was 50 years of age or older, and most provided 17 to 22 hours of care per week (FCA, 2016a). More than 1 in 6 Americans who work full- or part-time are family caregivers (FCA, 2016b). Most working family caregivers rearrange their work schedule, decrease their hours, or take an unpaid leave to meet the caregiving needs of their family member (FCA,

2016b). Spouses in their 60s and 70s often are the major caregivers for one another. Older adult caregivers have special needs (Box 10.2).

Box 10.2 Focus on Older Adults Family Caregiver Concerns

- Families often need help to determine their caregiving roles for the various members of the family (e.g., providing additional financial support, designating someone to obtain groceries and medications, providing hands-on physical care).
- Risk factors related to poor physical health for the caregiving dyad include older age and high school education or lower (Schaffer et al., 2017).
- Risk factors associated with higher emotional distress include younger age, female gender, caring for a spouse, and living with the patient. A caregiver's mental health is often related to the mental health of the patient. (Schaffer et al., 2017).
- Many older adults use spirituality to make end-of-life decisions, cope with life changes, and maintain psychological well-being (Moss et al., 2018; Salamizadeh et al., 2017).
- Social networks and support from close family and friends help to alleviate the stress experienced by caregivers (Newcomb and Hymes, 2017; Kirby et al., 2016).
- Individualized caregiver instruction and support are essential. For example, caregivers who are younger and caring for their spouses often need help in addressing their own and their spouse's psychological distress. Caregivers who are older and less educated may need information about health behaviors and self-care to help them address their physical health (Schaffer et al., 2017).

Caring for a relative who is frail or chronically ill is an ongoing process in which families must continue to redefine their relationships and roles (Hashemi-Ghasemabadi et al., 2016; DePasquale et al., 2018). Family caregiving occurs within the context of a family and requires more than a simple series of tasks. It encompasses multiple cognitive, behavioral, and interpersonal processes. Caregiving activities include finding resources, providing personal care (bathing, feeding, or grooming), monitoring for

complications or side effects of an illness or treatment, and providing instrumental activities of daily living (shopping or housekeeping). Family caregivers also provide ongoing emotional support for their loved ones, making decisions about care options, being a patient advocate, monitoring finances, and maintaining the integrity of the family unit. Whether a husband is caring for his wife or a child is caring for a parent, caregiving is an interactional process. The interpersonal dynamic between family members influences the ultimate quality of caregiving.

Family caregiving can be positive and rewarding, but it can also create caregiver burden and strain. The physical and emotional demands are high. A patient's disease creates changes in the family structure and roles. Family caregivers often do not feel prepared to take on the demands of care for their loved ones. Caregivers have mixed experiences and feelings. For example, they sometimes worry about the patient's illness and how to manage it, experience many life changes and restrictions, need to help the patient cope with illness, and want to show love and affection to the patient despite the burden and anxiety they are feeling (Petruzzo et al., 2017).

Family caregivers are at risk for a variety of physical conditions, ranging from depression, cardiac illness, and eating disorders. In addition, the caregiver often does not consider his or her own health needs as a high priority and misses routine primary care visits, screenings, and dental care (Schaffer et al., 2017).

Poverty

Although the poverty rate in the United States has been falling since 2014, the impact of poverty on families is profound (US Census Bureau, 2017b). Female single-parent families and families with unrelated individuals are especially vulnerable (US Census Bureau, 2017c). Children continue to be the poorest age group in America, with the youngest children and children of color being the poorest (CDF, 2017). Individuals and families who live in poverty are more likely to be uninsured (US Census Bureau, 2017d). Approximately 24 million young adults (18 to 34 years of age) lived in their parents' homes in 2015; about 2.2 million of these adult children were not attending school or working, putting additional economic strains on families (US Census Bureau, 2017e).

Although the Affordable Care Act (ACA) improved access to affordable health insurance, the challenge to access appropriate health care continues, especially for individuals and families who are at or near the poverty level (Martinez and Ward, 2016). When caring for families who live in poverty,

be sensitive to their need for independence and help them obtain appropriate financial and health care resources. For example, help a family by providing information about resources within the community to obtain assistance with food, energy bills, dental and health care, and school supplies.

Homelessness

Homelessness is a major public health issue that affects the functioning, health, and well-being of the family and its members (CDF, 2017). Chronic homelessness is experienced by people who need to use homeless shelters for their long-term housing needs. In contrast, people who experience transitional episodic homelessness need shelter for one stay and for a short period of time (National Coalition for the Homeless, 2018). People who are homeless tend to be younger, with a catastrophic event requiring them to seek shelter.

Adults who are homeless face many health risks. They are more likely to have mental and chronic health problems (US Interagency Council on Homelessness, 2018). Exposure to the elements, poor nutritional status and poor access to health care affect the health of people who are homeless. They are also vulnerable to physical and emotional violence, injury, and trauma.

Poverty, domestic violence, reduced government support for families with dependent children, and lack of affordable housing contribute to homelessness in families (National Coalition for the Homeless, 2018). Children of families who are homeless are often in fair or poor health and have higher rates of asthma, ear infections, stomach problems, mental illness, poor dental health, and poor immunization documentation. The emergency department often becomes their only access to health care.

Children who are homeless face barriers such as meeting residency requirements for public schools and inability to obtain previous enrollment records when enrolling into and attending a new school. They often lack adult supervision to help them with homework and school-related issues. As a result, they are more likely to drop out of school, develop risky behaviors, and become unemployable (Barnes et al., 2018; National Alliance to End Homelessness, 2018). Homelessness increases the risk for developing long-term health, psychological, and socioeconomic problems, posing a major challenge for our entire society (Barnes et al., 2018; National Alliance to End Homelessness, 2018) (see Chapter 3).

Domestic Violence

Domestic violence includes not only intimate-partner relationships of spousal, live-in partners and dating relationships but also familial, elder, and child abuse. Emotional, physical, and sexual abuse occurs across all social classes ([Futures without Violence, 2018](#)).

Factors associated with family violence are complex and include stress, poverty, social isolation, psychopathology, and learned family behavior. Other factors such as alcohol and drug abuse, pregnancy, sexual orientation, and mental illness increase the incidence of abuse within a family ([Futures without Violence, 2018](#)). Although abuse sometimes ends when a person leaves a family environment, negative long-term physical and emotional consequences often linger. One of the consequences includes moving from one abusive situation to another. For example, a child sees marriage as a solution to leave a parents' abusive home and in turn marries a person who continues the abuse in the marriage ([Futures without Violence, 2018](#)).

Structure

Structure is based on the ongoing membership of the family and the pattern of relationships, which are often numerous and complex ([Kaakinen et al., 2018](#)). Each family has a unique structure and way of functioning. For example, a family member may have relationships with a spouse, child, employer, and work colleagues. Each of these relationships has different demands, roles, and expectations. The multiple relationships and their expectations are often sources for personal and family stress (see [Chapter 37](#)).

Structure either enhances or detracts from a family's ability to respond to the expected and unexpected stressors of daily life. Structures that are too rigid or flexible sometimes threaten family functioning. Rigid structures specify who accomplishes different tasks and limit the number of people outside the immediate family allowed to assume these tasks. For example, in one family with a rigid structure, the mother is the only acceptable person to provide emotional support for the children and/or to perform all the household chores. The father is the only acceptable person to provide financial support, maintain the vehicles, do the yard work, and make all the home repairs. A change in the health status of the person responsible for a task places a burden on a rigid family because no other person is available, willing, experienced, or considered acceptable to assume that task. An extremely flexible family structure also presents

problems for the family. The absence of stability sometimes prevents other family members from taking action during a crisis or rapid change.

Function

Family function is what a family does, such as how a family interacts to socialize younger family members, cooperates to meet economic needs, and relates to the larger society. Family function involves the processes used by a family to achieve its goals. Some processes include communication among family members, goal setting, conflict resolution, caregiving, nurturing, and the use of internal and external resources. Although family members pursue the family goals at various times during their development, they need emotional and psychosocial support throughout their life span to be successful.

Family Nursing

Family nursing assumes that all people, regardless of age, are members of some type of family form (Fig. 10.2). The goal of family nursing is to help a family and its individual members reach and maintain maximum health throughout and beyond the illness experience. Family nursing is the focus across all practice settings and is important in all health care environments.

FIG. 10.2 Family recreational activities strengthen family functioning. Courtesy Bill Branson, National Cancer Institute.

There are different approaches for family nursing practice. For the purposes of this chapter, family nursing practice has three levels of approaches: (1) **family as context**, (2) **family as patient**, and (3) **family as a system**. Family as a system includes both relational and transactional concepts. All approaches recognize that patient-centered care for one member influences all members and affects family functioning. Families are continually changing. As a result, the need for family support changes over time, and it is important for you to understand that the family is more complex than simply a combination of individual members.

Family As Context

When you view a family as context, the primary focus is on the health and development of an individual member existing within a specific family environment. Although you focus on the health of an individual family

member, also assess how much the family provides the individual's basic needs. Needs vary, depending on an individual's developmental level and situation. Consider the family's ability to help your patient meet physical as well as psychological needs when viewing a family as context.

Family As Patient

When you view a family as patient, the family's needs, processes, and relationships (e.g., parenting or family caregiving) are the primary focus of nursing care. Your nursing assessment focuses on family patterns versus characteristics of individual members. Concentrate on patterns and processes that are consistent with reaching and maintaining family and individual health. For example, in the case of family caregiving, determine who the family caregivers are, their different roles, and how they interact to meet a patient's needs. Plan care to meet the patient's and family's changing needs. Dealing with very complex family problems often requires an interprofessional approach. Know the limits of nursing practice, and make referrals when appropriate.

Family As a System

Although you make theoretical and practical distinctions between the family as context and the family as patient, they are not necessarily mutually exclusive. When you care for a family as a system, you are caring for each family member (family as context) and the family unit (family as patient), using all available environmental, social, psychological, and community resources.

The following clinical scenario illustrates three levels of approaches to family care.

You are assisting with end-of-life care for David Daniels, who is 35 years old and is a computer programmer. David and his wife, Lisa, have three school-age children. David expressed a wish to die at home. Lisa is on family leave from her job to help David through this period. Both Lisa and David are only children. David's parents are no longer living, but Lisa's mother is committed to staying with the family to help Lisa and David.

When you view this *family as context*, you focus first on the patient (David) as an individual. You assess and meet David's needs at end-of life, such as comfort, hygiene, and nutrition, as well as his social and emotional

needs. You determine how David is coping with knowing his life is coming to an end and how he perceives it will affect his family. When viewing *the family as patient*, you assess and meet the needs of David's wife and children. Determine to what extent the family's basic needs for normal activity, comfort, and nutrition are being met and whether they have resources for emotional and social support. You determine the family's need for rest (especially the wife) and their stage of coping (the older child shows much anger and fear). You determine the demands placed on David and the family, such as economic survival and well-being of the children. In addition, you continually assess the family's available resources such as time, coping skills, and energy level to support David through the end of life.

When viewing a *family as a system*, you use elements from both the context and patient perspectives and assess the resources available to the family system. Using the knowledge of the family as context, patient, and system, individualize care decisions based on your family assessment and clinical judgment. For example, based on assessment data, you determine that the family is not eating adequately. You also determine that Lisa is experiencing more stress, not sleeping well, and trying to "do it all" regarding her children's school and after-school activities. In addition, Lisa does not want to leave David's bedside when members of their church come to help. You recognize that this family is under enormous stress and that their basic needs such as nutrition, rest, and school activities are not adequately met. As a result, you determine that (1) the family needs help with meals, (2) Lisa needs time to rest, and (3) the family's church is eager to help with David's day-to-day care. Based on these insights, you have a family conference and set up a schedule among Lisa, her mother, and two close church members to provide Lisa with some time away from David's bedside. During the conference, David and Lisa determine when this time will be. Because of the church involvement, members of the church begin to purchase groceries and make all the meals for the family. In addition, other members of the church help with the children's school and after-school activities.

Family and Health

Although American families exist within the same US culture, there are cultural disparities, and individual family members vary greatly in their experiences, beliefs, and values. When a family is victim to low educational preparation, poverty, and decreased social support, these

factors compound one another, magnifying their effect on the health and well-being of the family. Economic stability increases a family's access to adequate health care, creates more opportunity for education, increases good nutrition, and decreases stress (CDF, 2017; National Coalition for the Homeless, 2018).

The family is the primary social context in which health promotion and disease prevention take place. A family's beliefs, values, and practices strongly influence the family's structure and function. They also affect family communication patterns, roles, and health-promoting practices. Providing culturally appropriate family-centered interventions and teaching can improve family functioning and self-care (Deek et al., 2016; Srisuk et al., 2017).

Some families do not place a high value on good health. In fact, harmful practices are accepted by some families. For example, some families use high-caloric food intake as an acceptable way to cope with stress. Sometimes a family member gives mixed messages about health. For example, a parent chooses to smoke while telling children that smoking is bad for them. Family environment is crucial because health behavior reinforced in early life has a strong influence on later health practices. In addition, the family environment is a crucial factor in an individual's adjustment to a crisis. Although relationships are strained when confronted with illness, research indicates that when family members receive support from health care professionals, they have the potential to adapt to the stressors and develop coping mechanisms (Phillips and Prezio, 2017).

Attributes of Healthy Families

The family is a dynamic unit; it is exposed to threats, strengths, changes, and challenges. Some families are crisis proof, whereas others are crisis prone. A crisis-proof, or effective, family combines the need for stability with the need for growth and change. This type of family has a flexible structure that allows different family members to complete tasks and accepts help from outside the family system. The structure is flexible enough to allow adaptability but not so flexible that the family lacks cohesiveness and a sense of stability. An effective family controls the environment and influences the immediate environment of home, neighborhood, and school. An ineffective, or crisis-prone, family lacks or believes it lacks control over its environment.

Hardiness and **resiliency** moderate a family's stress, thus affecting a family's health. Family hardiness is the internal strengths and durability of

the family unit. A sense of control over the outcome of life, a view of change as beneficial and growth producing, and an active rather than passive orientation in adapting to stressful events characterize family hardiness ([Resilience, Adaptation, and Well-Being, 2016](#)). Resiliency helps individuals and families respond in healthy ways when they experience stressful events. Family resiliency does not develop through evasion of risk but through successful application of protective factors such as family cohesion, self-efficacy, and peer acceptance to engage in adverse situations and emerge from them stronger ([Benzies and Mychasiuk, 2009](#)). Resources (e.g., adequate income, education) and techniques (e.g., coping resources) that a family or individuals within the family use to maintain a balance or level of health aid in understanding a family's level of resiliency.

Genetic Factors

Genetic factors reflect a family's heredity or genetic susceptibility to diseases that may or may not result in actual development of a disease. The scope of genomics in nursing care is broad and encompasses risk assessment, risk management, counseling and treatment options, and treatment decisions. Clinical applications of genetic and genomic knowledge for nurses have implications for care of people, families, communities, and populations across the life span ([NIH, 2018](#)).

Sometimes identification of genetic factors and genetic counseling help family members decide whether to test for the presence of a disease and/or to have children. Some families choose not to have children; others choose not to know genetic risks and have children; other families choose to know the risk and then determine whether to have children. Some of these diseases (e.g., heart or kidney disease) are manageable. With genetic risks for certain cancers such as some breast cancers, a woman may choose prophylactic bilateral mastectomy to reduce the risk for developing the disease. Families with genetic neurological diseases such as Huntington's disease may choose not to have children. When families know of these risks, they have the opportunity to make informed decisions about their lifestyle and health behaviors, are more vigilant about recognizing changes in their health, and in some cases seek medical intervention earlier.

Living With Acute/Chronic Illnesses or Trauma

Any acute or chronic illness influences an entire family economically, emotionally, socially, and functionally. Illness also affects a family's decision-making and coping resources. Hospitalization of a family

member is stressful for the whole family. Hospital environments are foreign, physicians and nurses are strangers, the medical language is difficult to understand or interpret, and family members are often separated from one another.

During an acute illness that requires hospitalization, family members are sometimes left in waiting rooms to receive information about their loved one. Communication among family members may be misunderstood from fear and worry. Previous family conflicts can rise to the surface, whereas others are suppressed. Interprofessional teams often are helpful in meeting the needs of families during acute illnesses.

Chronic illnesses present continuous challenges for families. Frequently family patterns and interactions, roles, social activities, work and household schedules, economic resources, and other family needs and functions must be reorganized around the chronic illness or disability (see [Chapter 8](#)).

Trauma is sudden, unplanned, and sometimes life threatening. Family members often struggle to cope with the challenges of a severe life-threatening event. For example, they often deal with stressors associated with a family member hospitalized in an intensive care environment, anxiety, depression, economic burden, and the impact of the trauma on family functioning and decision making ([Newcomb and Hymes, 2017](#)). The powerlessness that family members experience makes them very vulnerable and less able to make important decisions about the health of the family.

When implementing a family-centered care model for patients experiencing acute or chronic illnesses or trauma, patients' family members and surrogate decision makers become active partners in decision making and care. Involving family during a hand-off report from one care provider to another, for example, provides an opportunity to involve a patient and family in discussing the present and long-term plan of care ([Bigani and Correia, 2018](#)). When possible, patients and family caregivers want to participate in shared decision making about treatment and ongoing disease/symptom management ([Sebern et al., 2018](#)). Incorporating a patient's and family's cultural beliefs, values, and communication patterns is essential to provide individualized patient/family-centered care.

In caring for family members, advocate for the patient and family and answer their questions honestly ([Newcomb and Hymes, 2017](#)). When you do not know the answer, find someone who does. Ensure that the family knows all the members of the health care team. Provide realistic assurance;

giving false hope breaks the nurse-patient trust and affects how the family can adjust to “bad news” (Schultz et al., 2017). When a patient is hospitalized, take time to make sure that the family is comfortable. You can bring them something to eat or drink, give them a blanket, or encourage them to get a meal. Sometimes telling a family that you will stay with their loved one while they are gone is all they need to feel comfortable in leaving.

End-of-Life Care

You will encounter families with a member who is terminally ill. Although people equate terminal illness with cancer, many diseases have terminal aspects (e.g., heart failure, pulmonary and renal diseases, and neuromuscular diseases). Although some family members may be prepared for their loved one’s death, their need for information, support, assurance, and presence is great (see Chapter 36). Use presence to develop a therapeutic relationship with a patient and family (see Chapter 7). Also use therapeutic communication to enhance family members’ relationships with one another and to promote shared decision making (Brooks et al., 2017). The more you know about your patient’s family, how they interact with one another, their strengths, and their weaknesses, the better. Each family approaches and copes with end-of-life decisions differently. Encourage a patient and family to make decisions about care (e.g., pain control or preferred nonpharmacologic comfort measures) and specific therapies. Help a family set up home care if they desire, and make referrals for hospice and other appropriate resources, including grief support (Bickel et al., 2016). Provide information about the dying process and make sure family members know what to do at the time of death. If you are present at the time of death, be sensitive to a family’s needs (e.g., provide for privacy and allow sufficient time for saying goodbyes).

Family-Centered Care and the Nursing Process

Nurses interact with families in a variety of community-based and clinical settings. Apply the nursing process and use critical thinking to develop and implement family-centered nursing care. The approach to the nursing process is the same whether your focus is family as context, patient, or system. When caring for families, use the same process you use with individual patients, but also incorporate the needs of the family. You use the nursing process to care for an individual within a family (e.g., the family as context) or the entire family (e.g., the family as patient). When initiating the care of families, use these approaches to organize a family approach to the nursing process:

1. Assess all individuals within their family context.
2. Assess the family as patient.
3. Assess the family as a system.

Family Assessment

Using a family-centered approach to assessment allows you to establish a working relationship with a patient and his or her family. A complete assessment provides you a full picture of patient needs as a member of a family and of family needs as well. If your assessment is complete, it ensures that the patient and family needs are correctly identified and that mutual goals and interventions for health care can be established.

Often you will participate in conflict resolution between family members, so each member is able to confront and resolve problems in a healthy way. Ask assessment questions to help the family identify external and internal resources as necessary. For example, who in the family can run errands to get groceries while the patient is unable to drive? Are there members from the church who can come and provide respite care? Ultimately your aim is to help the family reach a point of optimal function, given the family's resources, capacities, and desire to become healthier.

You play an essential role in helping families adjust to acute, chronic, and terminal illness; but first you need to understand the family unit and what a patient's illness means to the family members and family functioning. You also need to understand how the illness affects the family structure and the support the family requires ([Kaakinen et al., 2018](#)).

Although the family as a whole differs from individual members, the measure of family health is more than a summary of the health of all members. The form, structure, function, and health of the family are areas unique to family assessment. Several culturally sensitive tools and models assess or measure family dynamics (Giddens, 2017). Box 10.3 provides examples of family assessment questions based on the Calgary Family Assessment Model (Shajani and Snell, 2019; Leahey and Wright, 2016).

Box 10.3 Family Assessment Questions

Family Structure

Determines members of the family, relationships among family members, and the context of the family

- Who are the members of your family? How are they related to you?
- Who lives with you?
- Has anyone recently moved out of your home?
- Is there anyone who doesn't live with you whom you consider to be family?

Developmental Assessment

Determines how families adapt during predictable and unpredictable changes and difficult times

- What transitions/changes (e.g., recent death, divorce, children leaving/returning home, new births) has your family experienced most recently?
- Are there any members of your family who are having problems (e.g., difficulty in school, acute or chronic illnesses) that are currently affecting your family?
- What aspects of your family do you enjoy the most?
- What plans have you or your family made to care for family members who are in poor health?

Family Functioning

Addresses how individuals behave in relation to one another; includes instrumental aspects, which are routine activities (e.g., making meals, doing laundry), and expressive aspects (e.g., communication, problem solving, roles, influence and power, beliefs)

- Describe a recent problem and how your family resolved it.
- Who is the caregiver for children or older adults?
- What coping strategies does your family use (e.g., exercise, avoidance, overeating, arguing)?
- What are your family beliefs about health/illness, end-of-life care, and advance directives?
- What does your family mean to you?
- How does your family celebrate holidays, birthdays, weddings?
- How do the members of your family manage their health? How do they manage care of a sick family member?
- When someone is ill, who is the caregiver? Is it always the same person?

While completing your assessment, consider knowledge of a patient's illness and its potential impact on the family. Because time is limited in many practice settings, it is critical for you to understand how significant a role the family will play in a patient's recovery. This factor will affect how comprehensive an assessment you conduct. Begin the family assessment by determining a patient's definition of and attitude toward the family. A person's concept of family is highly individualized. The patient's definition will influence how much you are able to incorporate the family into nursing care. When it becomes obvious that family is important for a patient, determine family form and membership by asking who the patient considers family or with whom the patient shares strong emotional feelings. If the patient is unable to express a concept of family, ask with whom he or she lives, spends time, and shares confidences and then ask whether he or she considers them to be family or like family. To further assess the family structure, ask questions that determine the power structure and patterning of roles and tasks (e.g., "Who decides where to go on vacation?" "How are tasks divided in your family?" "Who mows the lawn?" "Who usually prepares the meals?").

Assess family functions such as the ability to provide emotional support for members, the ability to cope with current health problems or situations, and the appropriateness of its goal setting. Also determine

whether the family has sufficient economic resources and whether its social network is extensive enough to provide support.

Cultural Aspects

Always recognize and respect a family's cultural background during your assessment (see [Chapter 9](#)). Culture is an important variable when assessing a family because race, ethnicity, language, and norms affect structure, function, health beliefs, values, and the way a family perceives events ([Box 10.4](#)). A comprehensive, culturally sensitive family assessment is critical to forming an understanding of family life, current changes in family life, overall goals and expectations, and planning family-centered care.

Box 10.4 Cultural Aspects of Care Family Nursing

Families have unique perspectives and characteristics, and they have differences in values, beliefs, and philosophies. The cultural heritage of a family or member of the family affects religious, childrearing, and health care practices; recreational activities; and nutritional preferences. Be culturally sensitive and respectful when caring for patients of all cultures. Incorporate individualized cultural preferences into your plan of care so that it is culturally congruent. Design your care to integrate the personal values, life patterns, and beliefs of the patient and family into prescribed therapies.

Implications for Patient-Centered Care

- Focus on the needs of the family, and understand the family's beliefs, values, customs, and roles when designing care (Deek et al., 2016). Perception of events and their impact on the family varies across cultural groups. For example, the care of the grandmother has a great significance to the extended family.
- Family caregiving values, practices, and roles and perceptions of the burden associated with family caregiving vary across cultures (Konerding et al., 2018).
- The family structure sometimes includes multiple generations living together. Intergenerational support and patterns of living arrangements are often related to cultural background (Cohen and Passel, 2018).

- In some cultures, it is a sign of disrespect to place older adults in nursing homes, even when an older adult family member has severe dementia (Giger, 2017).
- Modesty is a strong value among many cultures. Some women bring female family members to health care visits, and a female health care provider must examine the woman.
- In the presence of a critical or terminal illness, some cultures come in groups to pray together with the family at the patient's bedside (Giger, 2017).
- Health beliefs differ among various cultures; these differences affect the decisions of a family and its members about when and where to seek help.

Forming conclusions about families' needs based on cultural backgrounds requires critical thinking. It is imperative to remember that categorical generalizations are often misleading. Overgeneralizations in terms of racial and ethnic group characteristics do not lead to greater understanding of a culturally diverse family. Culturally different families vary in meaningful and significant ways; however, neglecting to examine similarities leads to inaccurate assumptions and stereotyping (Giger, 2017).

Knowing about a family's culture and the meaning of that culture to a family's structure and functioning, health practices, and family celebrations helps to design family-centered care (see Chapter 9). To determine the influence of culture on a family, ask the patient about his or her cultural background. Then ask questions concerning cultural practices. For example, "What type of foods do you eat?" "Who cares for sick family members?" "Have you or anyone in your family been hospitalized?" "Did family members remain at the hospital?" "Do you use any health practices of your culture such as acupuncture or meditation?" "What role do grandparents play in raising your children?"

A comprehensive, culturally sensitive family assessment is critical for you to understand family life, the current changes within it, and a family's overall goals and expectations. These data provide the foundation for family-centered nursing care (Sousza et al., 2017).

Discharge Planning

Discharge planning begins with the initiation of care and includes the family. You are responsible for an accurate assessment of who will provide caregiving and what will be needed for care in the home at the time of

discharge. Consider how the patient's physical and/or cognitive limitations will affect daily living activities and the impact this will have on the family. For example, if a patient who is an older adult is discharged to home after surgery and the patient's spouse cannot perform required dressing changes, you need to find out if anyone else in the family or neighborhood is willing and able to do this. If not, you will need to arrange for a home care referral. If the patient also needs exercise and strength training, you consult with the primary health care provider to recommend referral for physical therapy.

REFLECT NOW

Reflect on a family you know who is currently experiencing a life transition. What questions could you ask to assess their current needs?

Nursing Diagnoses for Families

After assessing a patient's and family's needs and situation, you identify nursing diagnoses. Several positive and negative ICNP® diagnoses can be used when caring for families. Examples of ICNP® nursing diagnoses applicable to family care are:

- *Conflicting Caregiver Attitude*
- *Impaired Family Coping*
- *Risk for Caregiver Stress*
- *Impaired Family Process*
- *Risk for Parent Child Attachment*
- *Family Able to Participate in Care Planning*
- *Family Knowledge of Disease*

Nursing diagnoses that relate to a family often focus on a family's ability to cope with its current situation. Appropriate use of resources helps a family cope with unexpected events that threaten health and stability. Nursing diagnoses often focus on changes in family processes or roles. For

example, a man who is married and has four children is in a motor vehicle accident. He sustained multiple fractures to his lower extremities and pelvis and is non-weight-bearing for 6 to 8 weeks after discharge. Thus, he cannot go to work and perform many of the activities (e.g., mowing the lawn, taking the children to school) that he normally performs. His spouse is feeling overwhelmed as she develops a plan to meet all the family's needs, which include her husband's needs for rehabilitation. Based on this data, you determine *Impaired Family Process related to immobility and temporary changes in family roles* is an appropriate nursing diagnosis for this family.

Planning Family-Centered Care

Once you identify pertinent nursing diagnoses, work together with patients and their families to develop plans of care that all members clearly understand and mutually agree to follow. The goals and outcomes you establish need to be concrete and realistic, compatible with the family members' developmental stages (see [Chapter 11](#)), and acceptable to family members and their lifestyle.

By offering alternatives for care activities and asking family members for their own ideas and suggestions, you help to include them in the decision making and better meet the patient's needs ([Stockwell-Smith et al., 2018](#)). For example, offering options for how to prepare a low-fat diet or how to rearrange the furnishings of a room to accommodate a family member's disability gives a family an opportunity to express their preferences, make choices, and ultimately feel as though they have contributed. Collaborating with other disciplines such as physical therapy and social services increases the likelihood of a comprehensive approach to a family's health care needs, and it ensures better continuity of care. Using other disciplines is particularly important when discharge planning from a health care agency to home or an extended-care facility is necessary.

Implementing Family-Centered Care

You will provide family-centered nursing care in a variety of health care settings, whether you are providing health promotion, acute care, or restorative and continuing care. It is important to develop individualized nursing interventions to meet the needs of your patients and their families.

Health Promotion

Although many people learn health behaviors from their families, the primary focus on health promotion has traditionally been on individuals. When implementing family nursing, health promotion interventions are designed to improve or maintain the physical, social, emotional, and spiritual well-being of the family unit and its members (Duhamel, 2017). Health promotion behaviors sometimes need to be tied to the developmental stages of the family members (e.g., adequate prenatal care for the childbearing family or adherence to immunization schedules for the childrearing family). Your interventions need to enable individual members and the total family to reach their optimal levels of wellness.

Whether you provide care for the family as context, patient, or system, evidence-based nursing interventions increase family members' ability to provide care, remove barriers to health care, and perform tasks the family is not currently able to do (Box 10.5). Assist a family in problem solving, and express a sense of acceptance and caring by listening carefully to family members' concerns and suggestions.

Box 10.5 Evidence-Based Practice Caregiving

Education for the Family Caregiver

PICOT Question: Do tailored nursing interventions designed for family caregivers reduce caregiver burden and enhance caregiver well-being?

Evidence Summary

When a family member has an acute or chronic illness or experiences a trauma that changes his or her physical or cognitive function, it is often a major life-changing event that affects all family members. The family faces many changes in family dynamics, social interactions, financial commitments, and emotional support systems (Caceres et al., 2016; Newcomb and Hymes, 2017). A patient's physical disabilities and altered mental status affect the family caregiver and other members of the family (Kung, 2015; Weisman de Mamani et al., 2018). As a result, family members report stress and burnout related to the continual demands of the caregiving role (Moriarty et al., 2018). Lower levels of caregiver burden are associated with better mental health in caregivers (Weisman de Mamani et al., 2018). Caregiver coping, especially during hospitalizations, is often influenced by their communication with providers, access to the patient, and the presence of staff helping explain

the patient's problems and treatment plan (Newcomb and Hymes, 2017). Providing interventions tailored to the needs of the caregiver reduces caregiver burden and improves caregiver coping and quality of life (Jaffray et al., 2016; Weisman de Mamani et al., 2018).

Application to Nursing Practice

- Teach family caregivers to focus on the present moment using mindfulness-based interventions (e.g., meditation, breathing exercises, guided imagery) to reduce caregiver burden and improve mental health. Current evidence shows mindfulness is often helpful, especially in caregivers for patients with dementia and who are terminally ill (Hicken et al., 2017; Jaffray et al., 2016; Weisman de Mamani et al., 2018).
- Carefully assess the mental health of the caregiver. Encourage caregivers to discuss their feelings about caregiving responsibilities and help shape their perceptions in a way to improve their mental health. For example, if a caregiver states, "I feel trapped by having to bathe my mother," encourage the caregiver to frame this in a more adaptive way, such as "I now have the opportunity to provide care for someone who used to take care of me" (Weisman de Mamani et al., 2018).
- Encourage family caregivers to remain engaged in a patient's care during hospitalizations (e.g., encourage mobilization, assist with meals, discuss patient education) (Newcomb and Hymes, 2017).
- Teach caregivers for patients living with dementia different ways to cope with and redirect behavioral disturbances associated with dementia to help improve the caregiver's sleep and reduce caregiver burden, distress, and risk for developing depression (Caceres et al., 2016).
- Be aware of and assess for cultural implications of different physical and mental illnesses and their effect on the caregiver. For example, having a mental illness such as schizophrenia is sometimes accompanied by social stigma and isolation in people who are Chinese. Refer caregivers to support groups to encourage them to share their feelings and experiences with others who are in similar situations, and help families communicate effectively with each other to avoid conflict (Kung, 2015).
- Assess the effect (e.g., physical, mental, financial) of a patient's disability on the family. Provide support and patient education

targeted to a patient's and family caregiver's needs. For example, some family caregivers of veterans who have posttraumatic stress disorder (PTSD) and/or traumatic brain injury (TBI) experience greater financial issues and depressive symptoms. Providing emotional support and helping families identify financial resources may reduce caregiver burden and improve coping with PTSD and TBI (Moriarty et al., 2018).

- Use telephone- or Internet-assisted technologies based on family caregiver preferences to provide support and patient education when it is difficult for the caregiver to receive effective support due to geographical constraints (e.g., in rural settings) (Hicken et al., 2017).

One of the roles you need to adopt is that of educator ([Fig. 10.3](#)). Health education is a process by which a nurse and patient share information (see [Chapter 25](#)). Sometimes you recognize family/patient needs for information through direct questioning, but the methods for recognizing these needs are generally subtle. For example, you recognize that a new father is fearful of cleaning his newborn's umbilical cord or that an older-adult woman is not using her cane or walker safely. Respectful communication is necessary. Often you find the subtle needs for information by saying, "I notice you are trying to not touch the umbilical cord. I see that a lot." Or "You use the cane the way I did before I was shown a way to keep from falling or tripping over it; do you mind if I show you?" When you are confident and skillful instead of coming across as an authority on the subject, your patient's defenses are down, making him or her more willing to listen without feeling embarrassed. You will also recognize patient and family learning needs based on a patient's health condition and physical and mental limitations. Your focus as an educator may be on the family caregiver to prepare that person to manage the skills and processes needed to manage a patient's needs within the home.

FIG. 10.3 Nurse providing family education.
From Hockenberry MJ, Wilson D, Rodgers CC: *Wong's nursing care of infants and children*, ed 11, St Louis, 2019, Mosby.

REFLECT NOW

Think about a time you provided education to a family to help them manage an illness. How did or could you use the teach-back method to evaluate the effectiveness of your teaching?

One approach for meeting goals and promoting health is the use of family strengths. Families do not always see their strengths. Help families use their strengths to improve their health and meet their goals. Family strengths may include clear communication, adaptability, healthy childrearing practices, and support and nurturing among family members. Other strengths exist in the form of the use of crisis for growth, a

commitment to one another and the family unit, a sense of well-being and cohesiveness, and spirituality. Help the family focus on their strengths instead of on problems and weaknesses. For example, point out that a couple's 30-year marriage has endured many crises and transitions. Therefore, they are likely to be able to adapt to this latest challenge. Refer families to health promotion programs aimed at enhancing these strengths as needed. For example, some communities have low-cost fitness activities for children and their families that are designed to reduce the risk for obesity ([Allar et al., 2017](#)).

Acute Care

The family must be a central focus of nursing care in the acute care setting. It is crucial to emphasize family needs within the context of today's acute health care delivery environment. The complex health care system requires you to be astute, use time wisely, and anticipate the type of interventions needed to support family and patient needs up to and including discharge. The Synergy Model recognizes the importance of the relationship between the nurse and the patient and family to create a healing environment ([Fournier, 2017](#)). According to this model, when caring for acutely ill patients and their families, integrate your professional knowledge, skills, experiences, and attitudes to meet the needs of patients and their families. The needs and characteristics of a patient and family drive nursing interventions. When there is synergy between a patient and family and a nurse, optimal patient outcomes result.

Include family caregivers in a patient's care during admission to better prepare them for their role and reduce stress following discharge ([Piccenna et al., 2016](#)). Because hospital stays are shortened, it is important to provide education and encourage families to take an active role in caregiving on admission. For example, if you are caring for a patient who will need to go home on multiple medications, including a subcutaneous injection, provide information to the patient and family about the medications and administration of injections throughout the patient's hospital stay.

One growing area in acute care for family caregivers is end-of-life care. You help family members in their caregiving role by allowing them to participate in decision making, ensuring clear communication between the family and the health care team, and supporting a family's resilience ([Benzies and Mychasiuk, 2009](#); [Stajduhar et al., 2017](#)). Help family caregivers find home care equipment and community resources and allow them to provide specific aspects of physical care they will need to perform

at home. Preparing family members for discharge helps caregiving become a meaningful experience for both caregiver and patient across health care settings.

Building Competency in Teamwork and Collaboration

You are caring for the Carlson family. The father, Gary, is a 47-year-old chemical engineer who was diagnosed with amyotrophic lateral sclerosis (Lou Gehrig's disease). He is experiencing a progressive degenerative disease affecting his muscles and is now hospitalized with aspiration pneumonia. He continues to weaken and is preparing to be discharged to home with a hospice consult. His wife, Kathy, is 48 years old and is an information technology specialist. They have two children. Karen is a junior at a local university and lives in the residence hall. Kristen is a high school senior. The family is committed to helping Gary remain at home. Gary has been receiving care from physical therapy, respiratory therapy, the palliative care team, and pastoral care during this hospital stay. What can you do at this time to promote the teamwork and collaboration needed to make the Carlson's transition to home successful?

Discharge Planning

Discharge planning with a family is important during the acute care phase of an illness. An open relationship between you and a patient and family leads to a family-centered plan of care at discharge, including coordination of resources in the community and the patient's home (Gaskin, 2018). For example, when a patient who needs home IV antibiotic therapy is discharged, the family caregiver needs to know how to take care of the peripherally inserted central catheter (PICC) line, how to administer the IV antibiotic, how to recognize complications, and when to contact the home health nurse. Be sure the family caregiver is prepared for discharge and knows where to obtain necessary supplies.

Communication

An acute care setting involves multiple health care providers, and therefore clear communication is essential. It is important for the health care team to use communication techniques that are supportive, clear to understand, and consistent and that advocate for a family's expectations

(Stajduhar et al., 2017). In addition, clear communication from the health care team helps to clarify medical terminology and enables the family to understand the health care issues, the types of decisions, and potential health care outcomes (see [Chapter 24](#)). Use clear plain language when you communicate, and provide professional interpreters if a patient or family does not speak English.

Help the family identify methods to maintain open lines of communication with you and the interprofessional health care team to anticipate your patient's and family members' needs. For example, when caring for a patient with ovarian cancer, how will you use caring practices to help her spouse inform family members about the patient's progress and plan of care? Identify who makes decisions for the family and consistently go to the decision maker. In some situations, the decision maker also needs assistance in developing a method to clearly communicate any decisions. In this electronic age, some families use blogs or social media as a way of providing consistent information. Help the family determine whether this is the best approach for their family needs and structure.

Restorative and Continuing Care

In restorative and continuing care settings, the challenge in family nursing is to maintain patients' functional abilities within the context of the family. This includes having home care nurses help patients remain in their homes following acute injuries or illnesses, surgery, or exacerbation of a chronic illness. It also requires finding ways to better the lives of individuals who are chronically ill or disabled and their families. Work closely with a patient and family to provide well-timed and targeted information, practical guidance, and instructions to help a family caregiver understand the specific care a patient will require in the home (Macleod et al., 2017).

When a patient's functional status changes, make sure that the home environment will accommodate a patient's strengths and limitations. Make a referral to home care. The patient may require other interprofessional care, such as occupational or physical therapy, as well. Clear, concise, and accurate communication with a home care nurse helps to provide continuity of care and facilitates transition from hospital to home. Educate family members about how they can participate in ongoing care and make changes in the home environment to help the patient be as self-sufficient as possible.

Family Caregiving

You help family caregivers by showing them how to perform specific aspects of physical care (e.g., dressing changes), by helping them find home care equipment (e.g., oxygen therapy), and by identifying other community resources (e.g., respite care facilities, rehab centers). Preparing members of the family for care activities and responsibilities helps caregiving become a meaningful experience for both the caregiver and the patient.

When family members become caregivers, their relationship with their significant other often changes. Whenever one individual becomes dependent on another family member for care, significant stress affects both the caregiver and the care recipient (Kaakinen, 2018). Thus, you have a key role in helping the family caregiver and patient develop communication and problem-solving skills to support the relationships needed for successful caregiving (Zhang, 2018).

Without adequate preparation and support from health care providers, caregiving puts the family at risk for serious problems, including a decline in the health of the caregiver and the care receiver, as well as dysfunctional and even abusive relationships (Pickering et al., 2017; Friedman et al., 2017). If your assessment reveals the relationship between potential caregivers and care recipients is not supportive, connect the patient and family with community services to provide the patient's caregiving needs.

You support a family caregiver in many ways. For example, listen to a caregiver's stories and help the caregiver continue to meet the demands of his or her usual lifestyle (e.g., working, raising children). Establish a caregiving schedule that enables all family members to participate, help patients to identify family members who can share the burdens posed by caregiving, and encourage distant relatives to communicate their support. Teach family caregivers to provide physical care for their family member. Recognize that family caregivers also have their own physical and emotional needs. Teach them how to meet their needs (Box 10.6) and set up respite times as appropriate to allow them time to care for themselves (Schaffer et al., 2017).

Box 10.6 Patient Teaching Family Caregiving:

Caregiver Role Strain

Objective

- Patient/family will adopt two interventions to reduce caregiver role strain.

Teaching Strategies

- Explain to all family caregivers the signs and symptoms of caregiver role strain such as:
 - Change in caregiver's appetite/weight, sleeping, or leisure activities.
 - Social withdrawal, irritability, anger, or changes in the caregiver's overall level of health.
 - Loss of interest in personal appearance.
- Discuss situations in which caregiver role strain may intensify (e.g., if the patient's health status changes or the patient needs to be hospitalized).
- Describe the importance of having family members set up alternating schedules to give the primary caregiver some rest.
- Provide information about community resources for transportation, respite care, and support groups.
- Offer an opportunity to ask questions and, when possible, provide a phone number for questions and assistance.
- Provide family members with the contact information of the patient's health care provider and instruct them to call if the caregiver has health problems, the caregiver seems overly exhausted, or they observe changes in the caregiver's interactions and attention to normal activities.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- "I want to be sure I explained the effects of being a caregiver so you can recognize when you are under stress. Describe two or three effects that caregiving can have on you."
- "Some families I have cared for have trouble coping with all the responsibilities they have with caring for a family member. Can you

explain to me what you are planning to do to help you feel less burdened or overwhelmed?”

- “There may be a time when you are going to need to call your mother’s health care provider. Where do you plan on keeping the health care provider’s contact information? What situations do you imagine might happen that would require you to call the health care provider?”

Connect family caregivers with community resources. National outreach programs such as the Family Caregiver Alliance (<https://www.caregiver.org/>), The Alzheimer’s Association (<https://www.alz.org/>), and the Caregiver Action Network (<https://caregiveraction.org/>) provide information and services that can help improve the lives of family caregivers and the care they provide to their loved ones.

Community resources are organizations that can provide needed services or respite care to give the family caregiver time away from the care recipient. Examples of services that are beneficial to families include caregiver support groups, housing and transportation services, food and nutrition services, housecleaning, legal and financial services, home care, hospice, and mental health resources. Before referring a family to a community resource, it is critical that you understand the family’s dynamics and their desire for support. Family caregivers sometimes resist help, feeling obligated to be the sole source of support to the care recipient. Be sensitive to family relationships and help caregivers understand the normalcy of caregiving demands. Given the appropriate resources, family caregivers are able to acquire the skills and knowledge necessary to effectively care for their loved ones within the context of the home while maintaining rich and rewarding personal relationships.

Evaluating the Outcomes of Family Care

Through the Patient’s and Family’s Eyes

It is important to obtain a family’s perspective of the nursing care you provided and compare whether it met the family’s goals. If your care did not meet the family’s expectations, determine what they believe is missing. Consider short-term and long-term goals. Does the family perceive the patient received adequate pain control? Does the family perceive knowing what to do if problems develop at home? Evaluation is continuous and

helps you decide when you need to modify your interventions or make referrals to other members of the health care team.

Patient and Family Outcomes

Evaluation is patient- and family-centered. When you care for a family as the context, focus on whether patient and family needs were met. Compare the response of a patient and family with the outcomes you set in the patient's plan of care.

When a family is the patient, your measure of family health becomes more than an evaluation of the health of all family members. You continue to focus on the outcomes you set based on the family-centered nursing diagnoses. For example, you evaluate a family's change in functioning and its satisfaction with the new level of functioning to determine whether a family is achieving its outcomes.

When you are caring for a family as a system, your evaluation focuses on the effects that the interventions had on the entire family, including extended family members. For example, if you are caring for an older adult who is receiving chemotherapy for a new cancer diagnosis, you evaluate how frequent trips to the oncology clinic and the cancer diagnosis affect the patient, the spouse, the children, and the grandchildren.

Evaluation is an ongoing process. Use critical thinking skills and clinical decision making to evaluate a family's response to interventions. Often a patient and/or family does not know how to best deliver care. For example, a family does not think that making dietary changes for a patient who is experiencing anorexia and nausea from chemotherapy is being effective. Evaluate the patient's nutritional status (e.g., laboratory values, weight, skin turgor), and explain to the family which evaluation data show that the dietary changes have been effective. Adjust the patient's diet if indicated.

Key Points

- Families are as diverse as the individuals who compose them. Some family members have different beliefs and traditions, even within the same generation.
- Families face many challenges, including changing structures and roles, especially as the laws, economic status, and

demographics of society change.

- Family caregiving is an interactive process that occurs within the context of the relationships among its members. Family caregivers are often spouses who are older adults or adult children trying to work full time and care for aging family members.
- Many factors, including the increased need for family caregivers, poverty, homelessness, and domestic violence, affect family forms and a family's health.
- A family's structure and functioning significantly influence the family's health, health needs, and ability to respond to health problems.
- Your decision to view a family as an important context for an individual family member or to view a family unit as the patient or as a system depends on the situation and the family's needs.
- The family is the primary social context in which health promotion and disease prevention take place. Family members influence one another's health beliefs, practices, and status.
- The concept of family is highly individual; focus the nursing process and nursing care on a patient's attitude and beliefs about family rather than on a traditional definition of family.
- As you provide family-centered care, you continually assess, analyze, and reflect on the changing needs and health care goals of patients and their families.
- The goal of family nursing is to help a family and its individual members reach and maintain maximum health throughout and beyond the illness experience.
- Whether you are caring for a patient with the family as context, patient, or a system, you direct your nursing interventions to

increase abilities of family members to function and perform, remove barriers to health care, and do things that the family cannot do for itself.

- Evaluation of nursing care of families is centered on the patient and family. Compare actual responses to care with the outcomes you set in the plan of care, and revise the care plan as needed.

Reflective Learning

- Think about a patient you were assigned to care for recently. Describe the patient's family and its structure. What effect did that structure have on your patient's health?
- Interview a peer about his or her family. How do the beliefs and values of your peer's family affect the family's structure, functioning, health practices, and family celebrations?
- Reflect on a patient you cared for who had a family caregiver. What responsibilities did the family caregiver assume for the patient? Describe how the family caregiver coped with the caregiving role. What stressors related to caregiving did the family caregiver experience?

Review Questions

1. A family includes a mother, a stepfather, two teenage biological daughters of the mother, and a biological daughter of the father. The father's daughter just moved home following the loss of her job in another city. The family is converting a study into a bedroom and is in the process of distributing household chores. Nursing assessment reveals all members of the family think that their family can adjust to lifestyle changes. This is an example of family:

1. Diversity.
 2. Durability.
 3. Resiliency.
 4. Configuration.
2. A mother and her two children are homeless and enter a free health care clinic. Which statements most likely describe the effects of homelessness on this family? (Select all that apply.)
1. The children have stability in their education.
 2. The family members may have symptoms of malnutrition, such as anemia.
 3. The family is at a low risk for experiencing violence.
 4. The children are at higher risk for developing ear infections.
 5. All family members may have mental health issues.
3. A nurse is caring for a 66-year-old patient who lives alone and is receiving chemotherapy and radiation for a new cancer diagnosis. He is unable to care for himself because of severe pain and fatigue. He moves into his 68-year-old brother's home so his brother can help care for him. Which assessment findings indicate that this family caregiving situation will be successful? (Select all that apply.)
1. Both the patient and his brother attend church together regularly.
 2. The brothers are living together and enjoy eating the same foods.
 3. Other siblings live in the same city and are willing to help.
 4. The patient and his brother have a close network of friends.
 5. The patient has obsessive-compulsive disorder and has difficulty throwing away possessions.
4. A family is facing job loss of the father, who is the major wage earner, and relocation to a new city where there is a new job.

The children will have to switch schools, and his wife will have to resign from the job she enjoys. Which of the following contribute to this family's hardiness? (Select all that apply.)

1. Family meetings
 2. Established family roles
 3. New neighborhood
 4. Willingness to change in time of stress
 5. Passive orientation to life
5. A patient who is newly diagnosed with breast cancer states, "Although I am really scared about what is going to happen to me, I know my family will learn from this experience, and we will be stronger in the end." What term does the nurse use in the patient's medical record to describe the characteristic displayed in this statement?
1. Resiliency
 2. End-of-life care
 3. Family functioning
 4. Family's culture
6. A hospice nurse is caring for a family that is providing end-of-life care for their grandmother, who has terminal breast cancer. The nurse focuses on symptom management for the grandmother and on helping the family with developing coping skills. This approach is an example of which of the following?
1. Family as context
 2. Family as patient
 3. Family as a system
 4. Family as structure
7. A 7-year-old child was recently diagnosed with asthma. A nurse is providing education to the child and her parents about the treatment and management of asthma and changes they need to

make in their home environment to promote her health. Which statement made by the parents requires follow-up by the nurse?

1. "We have made an appointment to talk with the school nurse about the change in our child's health."
 2. "We forgot to give our daughter her medications before bedtime, so we made a list of her medications to help us remember."
 3. "We have worked out a schedule to check on her before and after school."
 4. "We have not been spending time with our parents because we are so busy taking care of our daughter."
8. A family consisting of a grandparent, two adults, and three school-age children just immigrated to the United States. They come to a community wellness center to establish health care. Which of the following questions does the nurse ask to assess the family's function? (Select all that apply.)
1. "What does your family do to keep members healthy?"
 2. "How does your family usually make decisions?"
 3. "What health services are available in your neighborhood?"
 4. "Which rituals or celebrations are important for your family?"
 5. "Is there a lot of crime in your neighborhood?"
 6. "How many parks are there in your community?"
9. A married couple has three children. The youngest child just graduated from college and is moving to a different city to take a job. The other two children left the home several years ago. Both of their parents are older and are beginning to need help to maintain their home. What assessment questions will help the nurse determine the family's functioning? (Select all that apply).
1. Which transitions or changes in your family are you currently experiencing?

2. Are your children having any problems that are affecting your family right now?
 3. Describe a recent family conflict and how your family resolved it.
 4. What coping strategies do you typically use as a family?
 5. Who is involved in helping care for your parents?
10. During a visit to a family clinic, a nurse teaches a mother about immunizations, the use of car seats, and home safety for an infant and toddler. Which type of nursing interventions are these?
1. Restorative
 2. Health promotion
 3. Acute care
 4. Growth and development

Developmental Theories

OBJECTIVES

- Discuss theoretical underpinnings of growth and development.
- Describe and compare developmental theories.
- Apply developmental theories when planning interventions in the care of patients throughout the life span.
- Discuss nursing implications for the application of developmental principles to patient care.

KEY TERMS

Conventional reasoning, p. 140

Erikson's theory of psychosocial development, p. 137

Freud's psychoanalytical model of personality development, p. 136

Kohlberg's theory of moral development, p. 140

Piaget's theory of cognitive development, p. 138

Postconventional reasoning, p. 140

Temperament, p. 138

Understanding normal growth and development helps nurses predict, detect, and prevent deviations from patients' expected patterns. Growth encompasses the physical changes that occur from the prenatal period through older adulthood and also demonstrates both advancement and deterioration. Development refers to the biological, cognitive, and socioemotional changes that begin at conception and continue throughout a lifetime. Development is dynamic and includes progression. However, in some disease processes development is delayed or regresses.

Individuals have unique patterns of growth and development. The ability to progress through each developmental phase influences the

overall health of the individual. The success or failure experienced within a phase affects the ability to complete subsequent phases. If individuals have repeated developmental failures, inadequacies sometimes result. However, when an individual experiences repeated successes, health is promoted. For example, a child who does not walk by 20 months demonstrates delayed gross-motor ability that slows exploration and manipulation of the environment. In contrast, a child who walks by 10 months is able to explore and find stimulation in the environment.

When caring for patients, it is important to adopt a life span perspective of human development that takes into account all developmental stages. Traditionally development focused on childhood; however, an understanding of growth and development throughout the life span helps in planning questions for health screenings and health history, health promotion and maintenance, and health education for patients.

Developmental Theories

Developmental theories provide a framework for examining, describing, and appreciating human development. For example, knowledge of Erikson's psychosocial theory of development helps caregivers understand the importance of supporting the development of basic trust in the infancy stage. Trust establishes the foundation for all future relationships. Developmental theories are also important in helping nurses assess and treat a person's response to an illness. Understanding the specific task or need of each developmental stage guides caregivers in planning appropriate individualized care for patients.

Human development is a dynamic and complex process that cannot be explained by only one theory. This chapter presents biophysical, psychoanalytical/psychosocial, cognitive, and moral developmental theories. [Chapters 25](#) and [35](#) cover the areas of learning theory for patient teaching and spiritual development.

Biophysical Developmental Theories

Biophysical development is how our physical bodies grow and change. Health care providers compare the changes that occur as a newborn infant grows against established norms. How does the physical body age? What are the triggers that move the body from the physical characteristics of childhood, through adolescence, to the physical changes of adulthood?

Gesell's Theory of Development

Fundamental to Gesell's theory of development is that each child's pattern of growth is unique and this pattern is directed by gene activity ([Gesell, 1948](#)). Gesell noted that the pattern of maturation follows a fixed developmental sequence. Sequential development is evident in fetuses, in which there is a specified order of organ system development. Today we know that growth in humans is both cephalocaudal and proximodistal. The cephalocaudal pattern describes the sequence in which growth is fastest at the top (e.g., head and brain develop faster than arm and leg coordination). The proximodistal growth pattern starts at the center of the body and moves toward the extremities (e.g., organ systems in the trunk of the body develop before the arms and legs). Genes direct the sequence of development, but environmental factors also influence development, resulting in developmental changes. For example, genes direct the growth rate in height for an individual, but that growth is only maximized if

environmental conditions are adequate. Poor nutrition or chronic disease often affects the growth rate and results in smaller stature, regardless of a person’s genetic blueprint. However, adequate nutrition and the absence of disease cannot result in height beyond that determined by heredity.

Psychoanalytical/Psychosocial Theory

Theories of psychoanalytical/psychosocial development describe human development from the perspectives of personality, thinking, and behavior (Table 11.1). Psychoanalytical theory explains development as primarily unconscious and influenced by emotion. Psychoanalytical theorists maintain that these unconscious conflicts influence development through universal stages experienced by all individuals (Berger, 2017).

TABLE 11.1

Comparison of Major Developmental Theories

Developmental Stage/Age	Freud (Psychosexual Development)	Erikson (Psychosocial Development)	Piaget (Cognitive/Moral Development)	Kohlberg (Development of Moral Reasoning)
Infancy (birth to 18 months)	Oral stage	Trust vs. mistrust Ability to trust others	Sensorimotor period Progress from reflex activity to simple repetitive actions	
Early childhood/toddler (18 months to 3 years)	Anal stage	Autonomy vs. shame and doubt Self-control and independence	Preoperational period—thinking using symbols Egocentric	Preconventional level Punishment-obedience orientation
Preschool (3-5 years)	Phallic stage	Initiative vs. guilt Highly imaginative	Use of symbols Egocentric	Preconventional level Premoral Instrumental orientation
Middle childhood (6-12 years)	Latent stage	Industry vs. inferiority Engaged in tasks and activities	Concrete operations period Logical thinking	Conventional level Good boy–nice girl orientation
Adolescence (12-19 years)	Genital stage	Identity vs. role confusion Sexual maturity, “Who am I?”	Formal operations period Abstract thinking	Postconventional level Social contract orientation
Young Adult		Intimacy vs. isolation Affiliation vs. love		
Adult		Generativity vs. self-absorption and stagnation		
Old age		Integrity vs. despair		

Sigmund Freud

Freud’s psychoanalytical model of personality development states that individuals go through five stages of psychosexual development and that each stage is characterized by sexual pleasure in parts of the body: the mouth, the anus, and the genitals. Freud believed that adult personality is

the result of how an individual resolves conflicts between these sources of pleasure and the mandates of reality (Santrock, 2018).

Stage 1: Oral (Birth to 12 to 18 Months)

Initially sucking and oral satisfaction are not only vital to life but also extremely pleasurable in their own rights. Late in this stage the infant begins to realize that the mother/parent is something separate from self. Disruption in the physical or emotional availability of the parent (e.g., inadequate bonding or chronic illness) could affect an infant's development.

Stage 2: Anal (12 to 18 Months to 3 Years)

The focus of pleasure changes to the anal zone. Children become increasingly aware of the pleasurable sensations of this body region with interest in the products of their effort. Through the toilet-training process the child delays gratification to meet parental and societal expectations.

Stage 3: Phallic or Oedipal (3 to 6 Years)

The genital organs are the focus of pleasure during this stage. The boy becomes interested in the penis; the girl becomes aware of the absence of the penis, known as *penis envy*. This is a time of exploration and imagination as a child fantasizes about the parent of the opposite sex as his or her first love interest, known as the *Oedipus* or *Electra complex*. By the end of this stage the child attempts to reduce this conflict by identifying with the parent of the same sex as a way to win recognition and acceptance.

Stage 4: Latency (6 to 12 Years)

In this stage Freud believed that children repress and channel sexual urges from the earlier Oedipal stage into productive activities that are socially acceptable. Within the educational and social worlds of the child, there is much to learn and accomplish.

Stage 5: Genital (Puberty Through Adulthood)

In this final stage sexual urges reawaken and are directed to an individual outside the family circle. Unresolved prior conflicts surface during adolescence. Once the individual resolves conflicts, he or she is then capable of having a mature adult sexual relationship.

Freud believed that the components of the human personality develop in stages and regulate behavior. These components are the id, the ego, and the superego. The id (i.e., basic instinctual impulses driven to achieve pleasure) is the most primitive part of the personality and originates in the infant. The infant cannot tolerate delay and must have needs met immediately. The ego represents the reality component, mediating conflicts between the environment and the forces of the id. It helps people judge reality accurately, regulate impulses, and make good decisions. Ego is often referred to as one's sense of self. The third component, the superego, performs regulating, restraining, and prohibiting actions. Often referred to as the conscience, the superego is influenced by the standards of outside social forces (e.g., parent or teacher).

Some of Freud's critics contend that he based his analysis of personality development on biological determinants and ignored the influence of culture and experience. Others think that Freud's basic assumptions such as the Oedipus complex are not applicable across different cultures. Psychoanalysts today believe that the role of conscious thought is much greater than Freud imagined ([Santrock, 2017](#)).

Erik Erikson

Freud had a strong influence on his psychoanalytical followers, including Erik Erikson (1902-1994), who constructed a theory of development that differed from Freud's in one main aspect: Erikson's stages emphasize a person's relationship to family and culture rather than sexual urges ([Berger, 2017](#)).

According to **Erikson's theory of psychosocial development**, individuals need to accomplish a particular task before successfully mastering the stage and progressing to the next one. Each task is framed with opposing conflicts, and tasks once mastered are challenged and tested again during new situations or at times of conflict ([Hockenberry et al., 2019](#)).

Trust vs. Mistrust (Birth to 12 to 18 months)

Establishing a basic sense of trust is essential for the development of a healthy personality. An infant's successful resolution of this stage requires a consistent caregiver who is available to meet his needs. From this basic trust in parents, an infant is able to trust in herself or himself, in others, and in the world ([Hockenberry et al., 2019](#)). The formation of trust results in faith and optimism. A nurse's use of anticipatory guidance helps

parents cope with the hospitalization of an infant and the infant's behaviors when discharged to home.

Autonomy vs. Sense of Shame and Doubt (18 Months to 3 Years)

By this stage a growing child is more accomplished in some basic self-care activities, including walking, feeding, and toileting. This newfound independence is the result of maturation and imitation. A toddler develops his or her autonomy by making choices. Choices typical for the toddler age-group include activities related to relationships, desires, and playthings. There is also opportunity to learn that parents and society have expectations about these choices. Limiting choices and/or enacting harsh punishment leads to feelings of shame and doubt. A toddler who successfully masters this stage achieves self-control and willpower. The nurse models empathetic guidance that offers support for and understanding of the challenges of this stage. Available choices for the child must be simple in nature and safe.

Initiative vs. Guilt (3 to 6 Years)

Children like to pretend and try out new roles. Fantasy and imagination allow them to further explore their environment. Also at this time they are developing their superego, or conscience. Conflicts often occur between a child's desire to explore and the limits placed on his or her behavior. These conflicts sometimes lead to feelings of frustration and guilt. Guilt also occurs if a caregiver's responses are too harsh. Preschoolers learn to maintain a sense of initiative without imposing on the freedoms of others. Successful resolution of this stage results in direction and purpose. Teaching a child impulse control and cooperative behaviors helps a family avoid the risks of altered growth and development. Preschoolers frequently engage in animism, a developmental characteristic that makes them treat dolls or stuffed animals as if they have thoughts and feelings. Play therapy is also instrumental in helping a child successfully deal with the inherent threats related to hospitalization or chronic illness.

REFLECT NOW

You are observing a group of 4- to 5-year-old children in a hospital play group. You notice that some of the children are applying bandages to their stuffed animals. Think about how play activity may help these children cope with hospitalization.

Industry vs. Inferiority (6 to 12 Years)

School-age children are eager to apply themselves to learning socially productive skills and tools. They learn to work and play with their peers. They thrive on their accomplishments and praise. Without proper support for learning new skills or if skills are too difficult, they develop a sense of inadequacy and inferiority. Children at this age need to be able to experience real achievement to develop a sense of competency. Erikson believed that an adult's attitudes toward work are traced to successful achievement of this task (Erikson, 1963). During hospitalization it is important for a school-age child to understand the routines and participate, when possible, in his or her treatment. For example, some children enjoy keeping a record of their intake and output.

Identity vs. Role Confusion (Puberty)

Dramatic physiological changes associated with sexual maturation mark this stage. There is a marked preoccupation with appearance and body image. This stage, in which identity development begins with the goal of achieving some perspective or direction, answers the question "Who am I?" Acquiring a sense of identity is essential for making adult decisions such as choice of a vocation or marriage partner. Each adolescent moves in his or her unique way into society as an interdependent member. There are also new social demands, opportunities, and conflicts that relate to the emergent identity and separation from family. Erikson held that successful mastery of this stage resulted in devotion and fidelity to others and to their own ideals (Hockenberry et al., 2019).

The adolescent does not consistently perceive vulnerability associated with risk-taking behaviors (Faial et al., 2016). This perceived invulnerability contributes to risk-taking behaviors (Warner, 2018). Nurses

have the opportunity to provide education and anticipatory guidance for parents about the changes and challenges and risks to adolescents. When adolescents are hospitalized, help them deal with their illnesses by giving them enough information to help make some decisions about their treatment plan (see [Chapter 12](#)).

Intimacy vs. Isolation (Young Adult)

Young adults, having developed a sense of identity, deepen their capacity to love others and care for them. They search for meaningful friendships and an intimate relationship with another person. Erikson portrayed intimacy as finding the self and then losing it in another ([Santrock, 2017](#)). If the young adult is not able to establish companionship and intimacy, isolation results because he or she fears rejection and disappointment ([Berger, 2017](#)). Nurses must understand that during hospitalization a young adult's need for intimacy remains present; thus young adults benefit from the support of their partner or significant other during this time.

Generativity vs. Self-Absorption and Stagnation (Middle Age)

Following the development of an intimate relationship, an adult focuses on supporting future generations. The ability to expand one's personal and social involvement is critical to this stage of development. Middle-age adults achieve success in this stage by contributing to future generations through parenthood, teaching, mentoring, and community involvement. Achieving generativity results in caring for others as a basic strength. Inability to play a role in the development of the next generation results in stagnation ([Santrock, 2017](#)). Nurses help physically ill adults choose creative ways to foster social development. Middle-age people often find a sense of fulfillment by volunteering in a local school, hospital, or church.

Integrity vs. Despair (Old Age)

Many older adults review their lives with a sense of satisfaction, even with their inevitable mistakes. Others see themselves as failures, with their lives marked by despair and regret. Older adults often engage in a retrospective appraisal of their lives. They interpret their lives as a meaningful whole or experience regret because of goals not achieved ([Berger, 2017](#)). Because the aging process creates physical and social losses, some adults also suffer loss of status and function (e.g., through retirement or illness). You can enhance feelings of integrity by encouraging older adults to reflect on their

meaningful relationships, such as relationships with a higher power, family members, or the community (Touhy & Jett, 2016). These external struggles are met with internal struggles, such as the search for meaning in life. Meeting these challenges creates the potential for growth and the basic strength of wisdom (Fig. 11.1).

FIG. 11.1 Quilting keeps this older adult active.

Nurses are in positions of influence within their communities to help people feel valued, appreciated, and needed. Erikson stated, “Healthy children will not fear life, if their parents have integrity enough not to fear death” (Erikson, 1963). Although Erikson believed that problems in adult life resulted from unsuccessful resolution of earlier stages, his emphasis on family relationships and culture offers a broad, life span view of development. As a nurse you will use this knowledge of development as you deliver care in any health care setting.

Theories Related to Temperament

Temperament is a behavioral style that affects an individual’s emotional interactions with others. Temperamental traits identified in infancy may

continue to influence a child's behavior through middle school (Hockenberry et al., 2019). Personality and temperament are often closely linked, and individuals possess some enduring characteristics into adulthood. The individual differences that children display in responding to their environment significantly influence the way others respond to them and their needs. Knowledge of temperament helps parents better understand their child (Hockenberry et al., 2019).

Most children have one of these three broad temperamental traits—easy, slow to warm up, and difficult (Hockenberry et al., 2019):

- *The easy child*—Easygoing and even-tempered. This child is regular and predictable in his or her habits. An easy child is open and adaptable to change and displays a mild to moderately intense mood that is typically positive.
- *The slow-to-warm up child*—Typically displays discomfort when introduced to new situations and needs time to adjust to new environment, authority figures, and expectations. These children respond with tears, somatic complaints, or other maneuvers to avoid the situation (e.g., complaining of a stomachache to avoid going to school).
- *The difficult child*—Highly distracted, active, irritable, and irregular in habits. This child may benefit from “practice” or role playing to be successful with new skills, situations, or environments.

Knowledge of temperament and how it impacts the parent-child relationship is critical when providing anticipatory guidance for parents. With the birth of a second child, most parents find that the strategies that worked well with the first child no longer work at all. The nurse individualizes counseling to greatly improve the quality of interactions between parents and children (Hockenberry et al., 2019).

Perspectives on Adult Development

Early studies of development focused only on childhood; however, we now know that although the changes come more slowly, people continue to develop new abilities and adapt to shifting environments.

A life span approach accounts for the multiple life events occurring in adulthood. The contemporary life events approach takes into consideration the variations that occur for each individual. This view considers an individual's personal circumstances (health and family

support), how a person views and adjusts to changes, and the current social and historical context in which an individual is living. The increase in life expectancy has made popular the life span approach to development (Santrock, 2018). Life span development is lifelong, multidimensional, multidirectional, and contextual. Development is an interaction of biological, sociocultural, and individual factors (Baltes et al., 2005). Current research on successful aging is much more consistent with a life span approach that emphasizes age-related goals that are relationship oriented and socially oriented to support continued well-being (Nosraty et al., 2015).

Cognitive Developmental Theory

Psychoanalytical/psychosocial theories focus on an individual's unconscious thought and emotions; cognitive theories stress how people learn to think and make sense of their world. As with personality development, cognitive theorists have explored both childhood and adulthood. Some of the theories highlight qualitative changes in thinking; others expand to include social, cultural, and behavioral dimensions.

Jean Piaget

Jean Piaget was most interested in the development of children's intellectual organization: how they think, reason, and perceive the world (Piaget, 1952). **Piaget's theory of cognitive development** includes four periods that are related to age and demonstrate specific categories of knowing and understanding (see also Chapter 12). He built his theory on years of observing children as they explored, manipulated, and tried to make sense out of the world in which they lived. Piaget believed that individuals move from one stage to the other seeking cognitive equilibrium or a state of mental balance and that they build mental structures to help adapt to the world (Santrock, 2017). Within each of these primary periods of cognitive development are specific stages (see Table 11.1).

Period I: Sensorimotor (Birth to 2 Years)

Infants develop a schema or action pattern for dealing with the environment (Box 11.1). These schemas include hitting, looking, grasping, or kicking. Schemas become self-initiated activities (e.g., the infant learning that sucking achieves a pleasing result generalizes the action to

suck fingers, blanket, or clothing). Successful achievement leads to greater exploration. During this stage a child learns about himself and his environment through motor and reflex actions. He or she learns that he or she is separate from the environment and that aspects of the environment (e.g., parents or favorite toy) continue to exist even though they cannot always be seen. Piaget termed this understanding that objects continue to exist even when they cannot be seen, heard, or touched *object permanence* and considered it one of the child's most important accomplishments.

Box 11.1 Evidence-Based Practice Applying

Developmental Theory to Care of Infants

PICOT Question: In infants who are hospitalized, does parental emotional involvement at bedtime result in improved quality and length of infant sleep?

Evidence Summary

Twenty to thirty percent of infants have difficulty falling asleep and staying asleep (Ball, 2014; Shapiro-Mendoza et al., 2015). Mothers' emotional availability at bedtime has been linked to improved quality of sleep in infants and thought to be associated with infant feelings of safety and security. When mothers are emotionally available, infants are less distressed and sleep more throughout the night (Philbrook & Teti, 2016). In a different study, mothers who did not breastfeed at bedtime noted that increased participation by fathers during the bedtime ritual improved infant sleeping (Tikotzky et al., 2015). It is important that nurses apply developmental theory and recognize the importance of parental engagement in the quality of infant sleep.

Application to Nursing Practice

- Educate parents on how to realign their expectation regarding infant sleeping patterns (Ball, 2014).
- Be aware of the value of involving parents in infant care and feeding, particularly around bedtime (Ball, 2014).
- Help breastfeeding parents set up a bedtime ritual that involves the father (Tikotzky et al., 2015).
- Understand an infant's need for parental involvement in developing a sense of safety and security to enhance quality of sleep.

Period ii: Preoperational (2 to 7 Years)

During this time children learn to think with the use of symbols and mental images. They exhibit “egocentrism” in that they see objects and people from only one point of view, their own. They believe that everyone experiences the world exactly as they do. Early in this stage children demonstrate “animism,” in which they personify objects. They believe that inanimate objects have lifelike thought, wishes, and feelings. Their thinking is influenced greatly by fantasy and magical thinking. Children at this stage have difficulty conceptualizing time. Play becomes a primary means by which they foster their cognitive development and learn about the world (Fig. 11.2). Nursing interventions during this period recognize the use of play as the way the child understands the events taking place. Play therapy is a nursing intervention that helps the child work through invasive and intrusive procedures that may occur during hospitalization. In addition, play therapy helps the ill child progress developmentally.

FIG. 11.2 Play is important to a child's development.

Period iii: Concrete Operations (7 to 11 Years)

Children now are able to perform mental operations. For example, the child thinks about an action that before was performed physically. Children are now able to describe a process without actually doing it. At this time they are able to coordinate two concrete perspectives in social and scientific thinking, so they are able to appreciate the difference between their perspective and that of a friend. Reversibility is one of the primary characteristics of concrete operational thought. Children can now mentally picture a series of steps and reverse the steps to get back to the starting point. The ability to mentally classify objects according to their quantitative dimensions, known as *seriation*, is achieved. They are able to correctly order or sort objects by length, weight, or other characteristics. Another major accomplishment of this stage is *conservation*, or the ability to see objects or quantities as remaining the same despite a change in their physical appearance (Santrock, 2018).

Period Iv: Formal Operations (11 Years to Adulthood)

The transition from concrete to formal operational thinking occurs in stages during which there is a prevalence of egocentric thought. This egocentricity leads adolescents to demonstrate feelings and behaviors characterized by self-consciousness: a belief that their actions and appearance are constantly being scrutinized (an “imaginary audience”), that their thoughts and feelings are unique (the “personal fable”), and that they are invulnerable (Santrock, 2018). These feelings of invulnerability frequently lead to risk-taking behaviors, especially in early adolescence. As adolescents share experiences with peers, they learn that many of their thoughts and feelings are shared by almost everyone, helping them to know that they are not so different. As they mature, their thinking moves to abstract and theoretical subjects. They have the capacity to reason with respect to possibilities.

REFLECT NOW

What nursing actions based on developmental theory could you use to promote an adolescent's emotional well being?

Piaget noted that some aspects of objective performance emerge earlier, and other cognitive abilities can surface later in life. Many adults may not become formal operational thinkers and remain at the concrete stage, and others have cognitive development that goes beyond the stages that Piaget proposed (Santrock, 2018). Assessment of cognitive ability becomes critical as you provide health care teaching to patients and families.

Research in Adult Cognitive Development

Research into cognitive development in adulthood began in the 1970s and continues today. It supports that adults do not always arrive at one answer to a problem but frequently accept several possible solutions. Adults also incorporate emotions, logic, practicality, and flexibility when making decisions. On the basis of these observations, developmentalists proposed a fifth stage of cognitive development termed *postformal thought*. Within this stage adults demonstrate the ability to recognize that answers vary from situation to situation and that solutions need to be sensible. Also within this stage is a struggle with identity and “finding oneself” (Sinnott, 2017).

One of the earliest to develop a theory of adult cognition was William Perry (1913-1998), who studied college students and found that continued cognitive development involved increasing cognitive flexibility. As adolescents were able to move from a position of accepting only one answer to realizing that alternative explanations could be right, depending on one’s perspective, there was a significant cognitive change. Adults change how they use knowledge, and the emphasis shifts from attaining knowledge or skills to using knowledge for goal achievement.

Moral Developmental Theory

Moral development refers to the changes in a person’s thoughts, emotions, and behaviors that influence beliefs about what is right or wrong. It encompasses both *interpersonal* and *intrapersonal* dimensions as it governs how we interact with others (Santrock, 2018). Although various psychosocial and cognitive theorists address moral development within their respective theories, the theories of Piaget and Kohlberg are more widely known (see Table 11.1).

Kohlberg’s Theory of Moral Development

Kohlberg's theory of moral development expands on Piaget's cognitive theory. Kohlberg interviewed children, adolescents, and eventually adults and found that moral reasoning develops in stages. From an examination of responses to a series of moral dilemmas, he identified six stages of moral development under three levels (Kohlberg, 1981). It is important to note that Kohlberg's theory is applicable to age 4 until adulthood. Children younger than 4 do not understand morality.

Level I: Preconventional Reasoning

This is the premoral level, in which there is limited cognitive thinking and an individual's thinking is primarily egocentric. At this stage thinking is mostly based on likes and pleasures. This stage progresses toward having punishment guide behavior. A person's moral reason for acting, the "why," eventually relates to the consequences that the person believes will occur. These consequences come in the form of punishment or reward. It is at this level that children view illness as a punishment for fighting with their siblings or disobeying their parents. Nurses need to be aware of this egocentric thinking and reinforce that the child does not become ill because of wrongdoing.

Stage 1: Punishment and Obedience Orientation

In this first stage a child's response to a moral dilemma is in terms of absolute obedience to authority and rules. A child in this stage reasons, "I must follow the rules; otherwise I will be punished." Avoiding punishment or the unquestioning deference to authority is characteristic motivation to behave. Physical consequences guide right and wrong choices. If the child is caught, it must be wrong; if he or she escapes, it must be right.

Stage 2: Instrumental Relativist Orientation

In this stage the child recognizes that there is more than one right view; a teacher has one view that is different from that of the child's parent. The decision to do something morally right is based on satisfying one's own needs and occasionally the needs of others. The child perceives punishment not as proof of being wrong (as in stage 1) but as something that one wants to avoid. Children at this stage follow their parent's rule about being home in time for supper because they do not want to be confined to their room for the rest of the evening if they are late.

Level II: Conventional Reasoning

At level II, **conventional reasoning**, the person sees moral reasoning based on his or her own personal internalization of societal and others' expectations. A person wants to fulfill the expectations of the family, group, or nation and also develop a loyalty to and actively maintain, support, and justify the order. Moral decision making at this level moves from "What's in it for me?" to "How will it affect my relationships with others?" Emphasis now is on social rules and a community-centered approach (Berger, 2017). Nurses observe this when family members make end-of-life decisions for their loved ones. Individual members often struggle with this type of moral dilemma. Grief support involves an understanding of the level of moral decision making of each family member (see Chapter 36).

Stage 3: Good Boy–Nice Girl Orientation

The individual wants to win approval and maintain the expectations of one's immediate group. "Being good" is important and defined as having positive motives, showing concern for others, and keeping mutual relationships through trust, loyalty, respect, and gratitude. One earns approval by "being nice." For example, a person in this stage stays after school and does odd jobs to win the teacher's approval.

Stage 4: Society-Maintaining Orientation

During stage 4 individuals expand their focus from a relationship with others to societal concerns. Moral decisions take into account societal perspectives. Right behavior is doing one's duty, showing respect for authority, and maintaining the social order. Adolescents choose not to attend a party where they know beer will be served, not because they are afraid of getting caught but because they know that it is not right.

Level III: Postconventional Reasoning

The person finds a balance between basic human rights and obligations and societal rules and regulations in the level of **postconventional reasoning**. Individuals move away from moral decisions based on authority or conformity to groups to define their own moral values and principles. Individuals at this stage start to look at what an ideal society would be like. Moral principles and ideals come into prominence at this level (Berger, 2017).

Stage 5: Social Contract Orientation

Having reached stage 5, an individual follows the societal law but recognizes the possibility of changing the law to improve society. The individual also recognizes that different social groups have different values but believes that all rational people would agree on basic rights such as liberty and life. Individuals at this stage make more of an independent effort to determine what society *should* value rather than what the society as a group would value.

Stage 6: Universal Ethical Principle Orientation

Stage 6 defines “right” by the decision of conscience in accord with self-chosen ethical principles. These principles are abstract, like the Golden Rule, and appeal to logical comprehensiveness, universality, and consistency (Kohlberg, 1981). For example, the principle of justice requires the individual to treat everyone in an impartial manner, respecting the basic dignity of all people, and guides the individual to base decisions on an equal respect for all. Civil disobedience is one way to distinguish stage 5 from stage 6. Stage 5 emphasizes the basic rights, the democratic process, and following laws without question; whereas stage 6 defines the principles by which agreements will be most just. For example, a person in stage 5 follows a law, even if it is not fair to a certain racial group. An individual in stage 6 may not follow a law if it does not seem just to the racial group. For example, Martin Luther King believed that although we need laws and democratic processes, people who are committed to justice have an obligation to disobey unjust laws and accept the penalties for disobeying these laws (Crain, 1985).

Kohlberg’s Critics

Kohlberg constructed a systemized way of looking at moral development and is recognized as a leader in moral developmental theory. However, critics of his work raise questions about his choice of research subjects. For example, most of Kohlberg’s subjects were males raised in Western philosophical traditions. Research attempting to support Kohlberg’s theory with individuals raised in the Eastern philosophies found that individuals raised in Eastern philosophies never rose above stages 3 or 4 of Kohlberg’s model. To some, these findings suggest that people from Eastern philosophies have not reached higher levels of moral development, which is untrue. Others believe that Kohlberg’s research

design did not allow a way to measure those raised within a different culture.

Kohlberg has also been criticized for age and gender bias ([Zizick et al., 2015](#)). Carol Gilligan criticizes Kohlberg for his gender biases. She believes that he developed his theory on the basis of a justice perspective that focused on the rights of individuals. In contrast, Gilligan's research looked at moral development from a care perspective that viewed people in their interpersonal communications, relationships, and concern for others ([Gilligan, 1982](#); [Santrock, 2018](#)). Other researchers have examined Gilligan's theory in studies with children and have not found evidence to support gender differences ([Santrock, 2018](#)).

Moral Reasoning and Nursing Practice

Nurses need to recognize their own moral reasoning. Recognizing your own moral developmental level is essential in separating your beliefs from others when helping patients with their moral decision-making process. It is also important to recognize the level of moral and ethical reasoning used by other members of the health care team and its influence on a patient's care plan.

REFLECT NOW

A nurse is caring for a homeless person and believes that all patients deserve the same level of care. The case manager, who is responsible for resource allocation, complains about the amount of resources being expended. What types of moral frustrations is the nurse encountering and how might this impact his or her nursing practice?

Ideally all members of the health care team are on the same level, creating a unified outcome. Research indicates that nurses experience frustration when faced with barriers to doing the right thing rather than confusion over what is the right thing ([Rainer et al., 2018](#)).

Developmental theories help nurses use critical thinking skills when asking how and why people respond as they do. From the diverse set of

theories included in this chapter, the complexity of human development is evident. No one theory successfully describes all the intricacies of human growth and development. Today's nurse needs to be knowledgeable about several theoretical perspectives when working with patients.

Your assessment of a patient requires a thorough analysis and interpretation of data to form accurate conclusions about his or her developmental needs. Accurate identification of nursing diagnoses relies on your ability to consider developmental theory in data analysis. You compare normal developmental behaviors with those projected by developmental theory. Examples of nursing diagnoses applicable to patients with developmental problems include *impaired development (infant, child, adolescent, adult)*, *risk for delayed growth*, and *risk for disproportionate growth*.

Building Competency in Safety

Sam is an 84-year-old patient hospitalized for acute abdominal pain. He does not have any local family and lives in an assisted-housing community. He is confused and disoriented. How would your knowledge of developmental theories guide your nursing care for Sam in ensuring his safety?

Growth and development, as supported by a life span perspective, is multidimensional. The theories included are the basis for a meaningful observation of an individual's pattern of growth and development. They are guidelines for understanding important human processes, and they allow nurses to begin to predict human responses and to recognize deviations from the norm.

Key Points

- Development is not limited to childhood and adolescence; people grow and develop throughout the life span.
- Developmental theories are a way to explain and predict human behavior.

- Developmental theory provides a basis through which nurses can assess and understand their patients' cognitive responses and physical capabilities.
- Developmental theories are important guidelines for understanding human processes and assist nurses in predicting human responses and deviations from the norm.
- Developmental tasks are age-related cognitive, social, and physical achievements.

Reflective Learning

- Consider a patient experience you encountered recently and describe how you practiced moral reasoning in providing care.
- How did a patient's developmental stage impact the care you provided during a clinical experience?
- Consider two of your patients and compare their cognitive developmental stages. Describe how you adapted your nursing care.

Review Questions

1. The nurse is aware that preschoolers often display a developmental characteristic that makes them treat dolls or stuffed animals as if they have thoughts and feelings. This is an example of:
 1. Logical reasoning.
 2. Egocentrism.
 3. Concrete thinking.
 4. Animism.
2. A 9-year-old child has a difficult time making friends at school and being chosen to play on the team. He also has trouble

completing his homework and, as a result, receives little positive feedback from his parents or teacher. According to Erikson's theory, failure at this stage of development results in: (Select all that apply.)

1. Feelings of inadequacy.
 2. A sense of guilt.
 3. A poor sense of self.
 4. Feelings of inferiority.
 5. Mistrust.
3. The nurse teaches parents how to have their children learn impulse control and cooperative behaviors. This would be during which of Erikson's stages of development?
1. Trust versus mistrust
 2. Initiative versus guilt
 3. Industry versus inferiority
 4. Autonomy versus sense of shame and doubt
4. When Ryan was 3 months old, he had a toy train; when his view of the train was blocked, he did not search for it. Now that he is 9 months old, he looks for it, reflecting the presence of:
1. Object permanence.
 2. Sensorimotor play.
 3. Schemata.
 4. Magical thinking.
5. When preparing a 4-year-old child for a procedure, which method is developmentally most appropriate for the nurse to use?
1. Allowing the child to watch another child undergoing the same procedure
 2. Showing the child pictures of what he or she will experience
 3. Talking to the child in simple terms about what will happen

4. Preparing the child through play with a doll and toy medical equipment
6. A nurse is caring for a man who is recently retired and who appears withdrawn. He says he is "bored with life." The nurse helps this individual find meaning in life by:
 1. Encouraging him to reflect on his relationships with others.
 2. Encouraging relocation to a new city.
 3. Explaining the need to simplify life.
 4. Encouraging him to adopt a new pet.
7. According to Piaget's cognitive theory, a 12-year-old child is most likely to engage in which of the following activities? (Select all that apply.)
 1. Using building blocks to determine how houses are constructed
 2. Writing a story about a clown who wants to leave the circus
 3. Drawing pictures of a family using stick figures
 4. Writing an essay about patriotism
 5. Hanging out with a best friend
8. Elizabeth, who is having unprotected sex with her boyfriend, comments to her friends, "Did you hear about Kathy? You know, she fools around so much; I heard she was pregnant. That would never happen to me!" This is an example of adolescent:
 1. Imaginary audience.
 2. False-belief syndrome.
 3. Personal fable.
 4. Sense of invulnerability.
9. Which of the following are examples of the conventional reasoning form of cognitive development? (Select all that apply.)

1. A 35-year-old woman is speaking with you about her recent diagnosis of a chronic illness. She is concerned about her treatment options in relation to her ability to continue to care for her family. As she considers the options and alternatives, she incorporates information, her values, and emotions to decide which plan will be the best fit for her.
 2. A young father is considering whether or not to return to school for a graduate degree. He considers the impact the time commitment may have on the needs of his wife and infant son.
 3. A teenage girl is encouraged by her peers to engage in shoplifting. She decides not to join her peers in this activity because she is afraid of getting caught in the act.
 4. A single mother of two children is unhappy with her employer. She has been unable to secure alternate employment but decides to quit her current job.
 5. A young man drives over the speed limit regularly because he thinks he is an excellent driver and will not get into a car accident.
10. Dave reports being happy and satisfied with his life. What do we know about him?
1. He is in one of the later developmental periods, concerned with reviewing his life.
 2. He is atypical, since most people in any of the developmental stages report significant dissatisfaction with their lives.
 3. He is in one of the earlier developmental periods, concerned with establishing a career and satisfying long-term relationships.
 4. It is difficult to determine Dave's developmental stage since most people report overall satisfaction with their lives in all stages.

Conception Through Adolescence

OBJECTIVES

- Describe ways to promote health during pregnancy.
- Discuss common physical and psychosocial changes during the transition of a child from intrauterine to extrauterine life.
- Describe physical changes and growth from conception to adolescence.
- Describe cognitive and psychosocial development from birth to adolescence.
- Explain the role of play in the development of a child.
- Discuss ways in which a nurse is able to help parents meet their children's developmental needs.

KEY TERMS

Adolescence, p. 154

Apgar score, p. 144

Attachment, p. 144

Embryonic stage, p. 143

Fetal stage, p. 143

Fetus, p. 143

Infancy, p. 146

Neonatal period, p. 144

Preembryonic stage, p. 143

Preschool period, p. 151

Puberty, p. 154

School-age period, p. 154

Toddlerhood, p. 149

Stages of Growth and Development

Human growth and development are continuous and complex processes that are typically divided into stages organized by age-groups. Although this chronological division is somewhat arbitrary, it is based on the timing and sequence of developmental tasks that children accomplish in each stage. This chapter focuses on the physical, psychosocial, and cognitive changes, as well as the health risks and health promotion concerns relevant to each stage of growth and development.

Selecting a Developmental Framework for Nursing

Using a family-centered approach that incorporates knowledge of developmental stages and theories (see [Chapter 11](#)) provides a framework to appropriately assess and plan care that meets the needs of the child and family. This approach encourages organized care for the child's current level of functioning to motivate self-direction and health promotion. For example, nurses encourage toddlers to make simple choices and to feed themselves to advance their developing autonomy. Nurses also recognize that adolescents are developing independence and, therefore, that they should feel empowered to participate in decisions regarding their plan of care.

Intrauterine Life

From the moment of conception until birth, human development proceeds at a predictable and rapid rate. During gestation, or the prenatal period, the embryo grows from a single cell to a complex, physiological being. All major organ systems develop in utero, with some functioning before birth.

Pregnancy that reaches full term is calculated to last an average of 38 to 40 weeks and is commonly divided into equal phases of 3 months, called *trimesters*. Beginning on the day of fertilization, the first 14 days are referred to as the **preembryonic stage**, followed by the **embryonic stage**, which lasts from day 15 until the eighth week. These two stages are then followed by the **fetal stage**, which lasts from the end of the eighth week until birth (Murray et al., 2019).

The placenta begins development at the third week of the embryonic stage and produces essential hormones that help maintain the pregnancy. The placenta functions as the fetal lungs, kidneys, gastrointestinal tract, and an endocrine organ. Because the placenta is extremely porous, noxious materials such as viruses, chemicals, and drugs also pass from mother to child. These agents are called *teratogens* and can cause abnormal development of structures in the embryo. The effect of teratogens on the **fetus** depends on the developmental stage in which exposure takes place, individual genetic susceptibility, and the extent of the exposure. The embryonic stage is the most vulnerable since all body organs are formed by the eighth week. Some maternal infections can cross the placental barrier and negatively influence the health of the mother, fetus, or both. It is important to educate women about avoidable sources of teratogens and to help them make healthy lifestyle choices before and during pregnancy.

Health Promotion During Pregnancy

Women who are poorly nourished before pregnancy and who do not consume adequate nutrients and calories during pregnancy may not be able to meet the fetus' nutritional requirements. An increase in weight does not always indicate an increase in nutrients. In addition, the pattern of weight gain is important for tissue growth in a mother and fetus. For women who are at normal weight for height, the recommended weight gain during pregnancy is 25 to 35 pounds (11 to 15 kg) over three trimesters (Murray et al., 2019). As a nurse, you are in a key position to provide women with important nutritional education before conception and throughout pregnancy.

Pregnancy presents a developmental challenge that includes physiological, cognitive, and emotional states that are accompanied by stress and anxiety (see [Chapter 13](#)). The expectant woman will soon adopt a parenting role, and relationships within the family will change, whether or not there is a partner involved. Pregnancy can be a period of conflict or support; family dynamics impact fetal development. Parental reactions to pregnancy change throughout the gestational period. Listen carefully to concerns expressed by a mother and her partner, and offer support through each trimester.

The age of a woman sometimes plays a role in fertility, the health of the fetus, and maternal health. As women age, the risk of chromosomal defects and fertility difficulties increases. Pregnant adolescents often seek prenatal care late in the pregnancy or fail to seek prenatal care for a variety of reasons ([Murray et al., 2019](#)). Infants of teenage mothers have an increased risk of prematurity and low birth weight (less than 2500 g or 5.5 pounds) ([Murray et al., 2019](#)).

Fetal growth and hormonal changes during pregnancy often result in discomfort for the expectant mother. Common concerns expressed include problems such as nausea and vomiting, breast tenderness, urinary frequency, heartburn, constipation, ankle edema, and backache. Always anticipate these discomforts and provide self-care education throughout the pregnancy. Discussing the physiological causes of these discomforts and offering suggestions for safe treatment can be very helpful for expectant mothers and contribute to overall health during pregnancy ([Murray et al., 2019](#)).

When assessing a pregnant woman, include questions about the use of complementary and alternative therapies. Some therapies such as herbal supplements can be harmful during pregnancy ([Murray et al., 2019](#)). You can promote maternal and fetal health by providing accurate and complete information about health behaviors that support positive outcomes for pregnancy and childbirth.

Transition from Intrauterine to Extrauterine Life

The transition from intrauterine to extrauterine life requires profound physiological changes in the newborn and occurs during the first 24 hours of life. Assessment of the newborn during this period is essential to ensure that the transition is proceeding as expected. Gestational age and development and exposure to depressant drugs before or during labor may influence the adjustment to the external environment.

Physical Changes

An immediate assessment of the newborn's condition to determine the physiological functioning of the major organ systems occurs at birth. The most widely used assessment tool is the **Apgar score**. Heart rate, respiratory effort, muscle tone, reflex irritability, and color are rated to determine overall status of the newborn. The Apgar assessment generally is conducted at 1 and 5 minutes after birth and is sometimes repeated until the newborn's condition stabilizes. The most extreme physiological change occurs when the newborn leaves the utero circulation and develops independent circulatory and respiratory functioning.

Nursing interventions at birth include maintaining an open airway, stabilizing and maintaining body temperature, and protecting the newborn from infection. The removal of nasopharyngeal and oropharyngeal secretions with suction or a bulb syringe ensures airway patency. Newborns are susceptible to heat loss and cold stress. Because hypothermia increases oxygen needs, it is essential to stabilize and maintain a newborn's body temperature. A healthy newborn may be placed in a radiant warmer, placed directly on the mother's abdomen, or covered in warm blankets with a cap. Preventing infection is a major concern in the care of a newborn, whose immune system is immature. Good handwashing technique is the most important factor in protecting a newborn from infection. You can help prevent infection by instructing parents and visitors to wash their hands before touching the infant.

Psychosocial Changes

After immediate physical evaluation and application of identification bracelets, the nurse promotes early parent-child contact to encourage

parent-child **attachment**. Most healthy newborns are awake and alert for the first hour after birth. This is a good time for parent-child interaction to begin. Close body contact, often including breastfeeding, is a satisfying way for most families to start bonding through eye-to-eye contact and touch. If immediate contact is not possible, incorporate it into the care plan as early as possible, which means bringing the newborn to an ill parent or bringing the parents to an ill or premature child. Attachment is a process that begins during pregnancy and continues for many months after birth ([Hockenberry et al., 2019](#)).

Newborn

The **neonatal period** is the first 28 days of life. During this stage the newborn's physical functioning is mostly reflexive, and stabilization of major organ systems is the primary task of the body. Newborn behavior greatly influences interaction among the newborn, the environment, and parents/caregivers. For example, a 2-week-old may smile spontaneously and look at the parent's face, eliciting a positive response from the parent. Alternately, the newborn may cry, which is generally a reflexive response to an unmet need such as hunger, fatigue, or discomfort ([Hockenberry et al., 2019](#)). If the newborn is crying when hungry, the nurse may counsel the parents to feed the baby on demand rather than on a rigid schedule. Nurses must use knowledge of growth and development to plan care for the parent and newborn.

Physical Changes

Perform a comprehensive nursing assessment as soon as a newborn's physiological functioning is stable, generally within a few hours after birth. At this time, measure height, weight, head and chest circumference, temperature, pulse, and respirations and observe general appearance, body functions, sensory capabilities, reflexes, and responsiveness. Following a comprehensive physical assessment, assess gestational age and interactions between newborn and parent that indicate successful attachment ([Hockenberry et al., 2019](#)).

The average newborn is 6 to 9 pounds (2700 to 4000 g), is 19 to 21 inches (48 to 53 cm) in length, and has a head circumference of 13 to 14 inches (33 to 35 cm). Neonates lose up to 10% of birth weight in the first few days of life, primarily through fluid losses by respiration, urination, defecation, and low fluid intake. They usually regain birth weight by the second week of life, and a gradual pattern of increase in weight, height, and head circumference is evident. Accurate measurement as soon as possible after birth provides a baseline for future comparison ([Murray et al., 2019](#)).

Normal physical characteristics of the newborn include the continued presence of lanugo (fine downy hair) on the skin of the back; cyanosis of the hands and feet for the first 24 hours; and a soft, protuberant abdomen. Skin color varies according to racial and genetic heritage and gradually changes during infancy. Molding, or overlapping of the soft skull bones, allows the fetal head to adjust to various diameters of the maternal pelvis and is a common occurrence with vaginal births. The bones readjust

within a few days, producing a rounded appearance to the head. The sutures and fontanel are usually palpable at birth. Fig. 12.1 shows the diamond shape of the anterior fontanel and the triangular shape of the posterior fontanel between the unfused bones of the skull. The anterior fontanel usually closes by 12 to 18 months, whereas the posterior fontanel closes by the end of the second or third month.

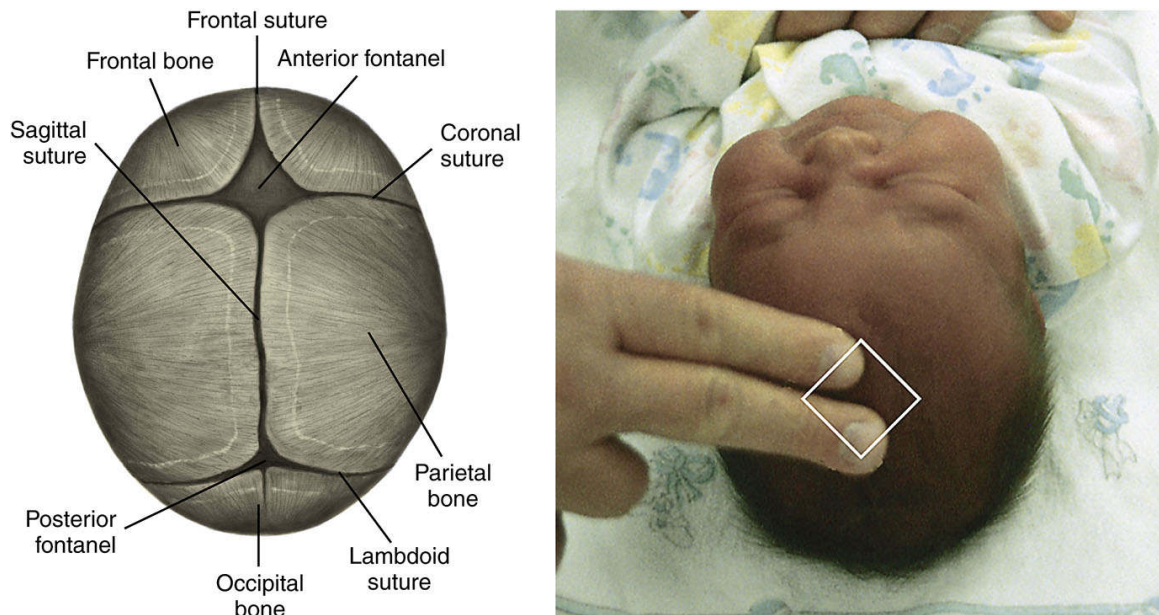

FIG. 12.1 Fontanels and suture lines.
From Hockenberry MJ, et al: *Wong's nursing care of infants and children*, ed 11, St Louis, 2019, Elsevier.

Assess neurological function by observing the newborn's level of activity, alertness, irritability, and responsiveness to stimuli and the presence and strength of reflexes. Normal reflexes include blinking in response to bright lights, startling in response to sudden loud noises or movement, sucking, rooting, grasping, yawning, coughing, sneezing, swallowing, palmar grasp, plantar grasp, and Babinski. Assessment of these reflexes is vital because the newborn depends largely on reflexes for survival and in response to its environment. Fig. 12.2 shows the tonic neck reflex in the newborn.

FIG. 12.2 Tonic neck reflex. Newborns assume this position while supine.
From Hockenberry MJ, et al: *Wong's nursing care of infants and children*, ed
11, St Louis, 2019, Elsevier.

Normal behavioral characteristics of the newborn include periods of sucking, crying, sleeping, and activity. Movements are generally sporadic, but they are symmetrical and involve all four extremities. The relatively flexed fetal position of intrauterine life continues as the newborn attempts to maintain an enclosed, secure feeling. Newborns normally watch the caregiver's face, have a nonsocial reflexive smile, and respond to sensory stimuli, particularly the primary caregiver's face, voice, and touch.

Cognitive Changes

Early cognitive development begins with innate behavior, reflexes, and sensory functions. Newborns initiate reflex activities, learn behaviors, and learn their desires. At birth, newborns are able to focus on objects about 8 to 12 inches (20 to 30 cm) from their faces and perceive forms. Newborns respond to human faces, black and white contrasting patterns, and bright colors (Murray et al., 2019). Teach parents about the importance of

providing sensory stimulation such as talking to their baby and holding the baby to see the parent's face. This allows newborns to seek or take in stimuli, thereby enhancing learning and promoting cognitive development.

Crying is a means by which newborns communicate to provide cues to parents. Some babies cry because their diapers are wet or they are hungry or want to be held. Others cry just to make noise or because they need a change in position or activity. The crying may frustrate the parents if they cannot see an apparent cause. With the nurse's help, parents learn to recognize the newborn's cry patterns and take appropriate action when necessary.

Psychosocial Changes

During the first month of life most parents and newborns normally develop a strong bond that grows into a deep attachment. Feeding, hygiene, and comfort measures consume much of newborns' waking time. These interactions provide a foundation for the formation of deep attachments. Early on, parents can allow siblings to participate in age-appropriate aspects of the newborn's care ([Murray et al., 2019](#)). Family involvement helps support growth and development and promotes nurturing ([Fig. 12.3](#)).

FIG. 12.3 Siblings should be involved in newborn care.
Copyright © romrodinka/iStock/Thinkstock.

If parents or children experience health complications after birth, this *may* compromise the attachment process. These newborns' behavioral cues are sometimes weak or absent, and caregiving may be less mutually satisfying. Some tired or ill parents have difficulty interpreting and responding to their newborns. Preterm babies and those born with congenital anomalies are often too weak to be responsive to parental cues and require special supportive nursing care. For example, babies born with heart defects tire easily during feedings. Nurses can support parental attachment by pointing out positive qualities and responses of the newborn and acknowledging how difficult the separation can be for parents and newborn.

Health Promotion

Screening

Newborn screening tests are administered before babies leave the hospital to identify serious or life-threatening conditions before symptoms begin.

Results of the screening tests are sent directly to the pediatrician. If a screening test suggests a problem, the baby's physician usually follows up with further testing and may refer the baby to a specialist for treatment if needed. Blood tests help detect inborn errors of metabolism (IEMs). These are genetic disorders caused by the absence or deficiency of a substance, usually an enzyme, essential to cellular metabolism that results in abnormal protein, carbohydrate, or fat metabolism. Although IEMs are rare, neonatal screening is done to detect phenylketonuria (PKU), hypothyroidism, galactosemia, and other diseases to allow appropriate treatment that prevents permanent mental retardation and other health problems.

Studies have indicated that hearing loss is the most common congenital abnormality in newborns. The American Academy of Pediatrics (AAP) recommends universal screening of newborn hearing before discharge or within the first month of life. Early detection of hearing difficulties leads to early treatment and can prevent or decrease developmental delays, especially those related to communication ([Murray et al., 2019](#)).

Car Seats

An essential component of discharge teaching is the use of a federally approved car seat for transporting the newborn from the hospital or birthing center to home. Automobile injuries are a leading cause of death in children in the United States. Many of these deaths occur when the child is not properly restrained ([Hockenberry et al., 2019](#)). Parents need to learn how to fit the child in the restraint and install the car seat properly. All infants and toddlers should ride in a rear-facing car safety seat until they are 2 years of age or until they reach the highest weight or height allowed by the manufacturer or their car safety seat ([AAP, 2018b](#)). Placing an infant in a rear-facing restraint in the front seat of a vehicle is extremely dangerous in any vehicle with a passenger-side air bag. Nurses are responsible for providing education on the use of a car seat before discharge from the hospital.

Sleep and Cribs

In accordance with the recommendations of the [AAP \(2016c\)](#), position infants for sleep on their backs on a firm sleep surface to decrease the risk of sudden infant death syndrome (SIDS). Newborns establish their individual sleep-activity cycle, and parents develop sensitivity to their baby's cues. Co-sleeping or bed sharing (see [Chapter 43](#)) is associated with

an increased risk for SIDS ([AAP, 2016c](#)). Safeguards to reduce the risk for SIDS include proper positioning; removing stuffed animals, soft bedding and crib bumper pads, and pillows; and avoiding overheating the infant. Individuals should avoid smoking during pregnancy and around the infant because it places the infant at greater risk for SIDS ([AAP, 2016c](#)). Nurses play an important role in educating parents about safe sleeping for infants.

Federal safety standards now prohibit the manufacture or sale of cribs with drop-side rails and require more durable mattress supports and crib slats ([AAP, 2014](#)). New cribs sold in the United States must meet these governmental standards for safety. Unsafe cribs that do not meet the safety standards should be disassembled and thrown away ([AAP, 2014](#)). Parents also need to inspect an older crib to make sure the slats are no more than 6 cm (2.4 inches) apart. The crib mattress should fit snugly, and crib toys or mobiles should be attached firmly with no hanging strings or straps. Instruct parents to remove mobiles as soon as the baby is able to reach them ([Hockenberry et al., 2019](#)).

Infant

During **infancy**, the period from 1 month to 1 year of age, rapid physical growth and change occur. This is the only period distinguished by such dramatic physical changes and marked development. Psychosocial developmental advances are aided by the progression from reflexive to more purposeful behavior. Interaction between infants and the environment becomes greater and more meaningful for an infant. During this first year of life, you can easily observe the adaptive potential of infants because changes in growth and development occur so rapidly.

Physical Changes

Steady and proportional growth of an infant is more important than absolute growth values. Charts of normal age- and gender-related growth measurements enable you to compare growth with norms for a child's age. For infants born prematurely, norms will be adjusted based on gestational age. Measurements recorded over time are the best way to monitor growth and identify problems. Size increases rapidly during the first year of life; birth weight doubles in approximately 5 months and triples by 12 months. Height increases an average of 2.5 cm (1 inch) during each of the first 6 months and about 1.2 cm ($\frac{1}{2}$ inch) each month until 12 months ([Hockenberry et al., 2019](#)).

Throughout the first year, an infant's vision and hearing continue to develop. Patterns of body function also stabilize, as evidenced by predictable sleep, elimination, and feeding routines. Some reflexes that are present in the newborn, such as blinking, yawning, and coughing, remain throughout life, whereas others, such as grasping, rooting, sucking, and the Moro or startle reflex, disappear after several months.

Motor development proceeds in a cephalocaudal (head-to-toe) and proximodistal (central-to-peripheral) pattern, as does myelination of nerves ([Hockenberry et al., 2019](#)). Gross-motor skills involve large muscle activities and are usually closely monitored by parents, who easily report recently achieved milestones. Newborns can only momentarily hold their heads up, but by 4 months most infants have no head lag. The same rapid development is evident as infants learn to sit, stand, and walk. Fine-motor skills involve small body movements and are more difficult to achieve than gross-motor skills. Maturation of eye-and-hand coordination occurs over the first 2 years of life as infants move from being able to grasp a rattle briefly at 2 months to drawing an arc with a pencil by 24 months.

Development proceeds at a variable pace for each individual but usually follows the same pattern and occurs within the same time frame (Table 12.1).

TABLE 12.1

Gross Motor and Fine Motor Development in Infancy

Age	Gross Motor Skill	Fine Motor Skill
Birth to 1 month	Complete head lag persists Cannot sit upright Primitive reflexes present	Reflexive grasp
2 to 4 months	When prone, lifts head and chest and bears weight on forearms With support, able to sit erect with good head control Can turn from back to side	Holds rattle for short periods but cannot pick it up if dropped Looks at and plays with hands Able to bring objects to mouth
4 to 6 months	Turns from abdomen to back at 5 months and then back to abdomen at 6 months Can support much of own weight when pulled to stand No head lag when pulled to sit	Grasps objects at will and can drop them to pick up another object Pulls feet to mouth to explore Can hold a bottle
6 to 8 months	Sits alone without support Bears full weight on feet and can hold on to furniture while standing	Bangs objects together Transfers objects from hand to hand
8 to 10 months	Scoots or crawls on hands and knees Pulls self to standing position	Picks up small objects Begins to use pincer grasp Shows hand preference
10 to 12 months	Walks holding onto furniture Stands alone, for short periods May attempt first step alone	Can place objects into containers Can turn book pages (more than one page at a time)

Adapted from Hockenberry M, Wilson D: *Wong’s nursing care of infants and children*, ed 10, St Louis, 2015, Mosby.

Cognitive Changes

The complex brain development during the first year is demonstrated by an infant’s changing behaviors. As he or she receives stimulation through the developing senses of vision, hearing, and touch, the developing brain interprets the stimuli. Thus, an infant learns by experiencing and manipulating the environment. Developing motor skills and increasing mobility expand an infant’s environment and, with developing visual and auditory skills, enhance cognitive development. For these reasons Piaget (1952) named his first stage of cognitive development, which extends until around the third birthday, the sensorimotor period (see Chapter 11). In this stage of cognitive development, infants explore their world through senses. They learn by experimentation and trial and error. They shake and throw things and put things in their mouths. By the age of 7 to 9 months, they begin to realize that things still exist that can no longer be seen. This

is known as object permanence and is an important developmental milestone because it demonstrates that their memory is beginning to develop.

Infants need opportunities to develop and use their senses. Assess the appropriateness and adequacy of these opportunities, especially when a child is sick or injured. You must provide alternatives for a child. For example, ill or hospitalized infants sometimes lack the energy to interact with their environment, thereby slowing their cognitive development. Infants need to be stimulated according to their temperament, energy, and age. A nurse may stimulate an infant on tube feeding by offering a pacifier and talking to the child, thereby maximizing development while conserving energy.

Language

Speech is an important aspect of cognition that develops during the first year. Infants proceed from crying, cooing, and laughing to imitating sounds, comprehending the meaning of simple commands, and repeating words with knowledge of their meaning. According to Piaget this demonstrates that an infant is demonstrating some symbolic abilities. By 1 year, infants not only recognize their own names but are also able to say three to five words and understand almost 100 words ([Hockenberry et al., 2019](#)). As a nurse, you promote language development by encouraging parents to name objects on which their infant's attention is focused. You also assess the infant's language development to identify developmental delays or potential abnormalities.

Psychosocial Changes

Separation and Individuation

During their first year, infants begin to differentiate themselves from others as separate beings capable of acting on their own. Initially infants are unaware of the boundaries of self; but, through repeated experiences with the environment, they learn where the self ends and the external world begins. As they determine their physical boundaries, they begin to respond to others ([Fig. 12.4](#)).

FIG. 12.4 Smiling at and talking to an infant encourage bonding.
From Murray SS, McKinney ES: *Foundations of maternal-newborn and women's health nursing*, ed 6, St Louis, 2014, Saunders.

Two- and 3-month-old infants begin to smile responsively rather than reflexively. Similarly they recognize differences in people when their sensory and cognitive capabilities improve. By 8 months most infants are able to differentiate a stranger from a familiar person and respond differently to the two. Close attachment to their primary caregivers, most often parents, usually occurs by this age. Infants seek out these people for support and comfort during times of stress. The ability to distinguish self from others allows infants to interact and socialize more within their environments. For example, by 9 months infants play simple social games such as patty-cake and peek-a-boo. More complex interactive games such as hide-and-seek involving objects are possible by age 1.

[Erikson \(1963\)](#) describes the psychosocial developmental crisis for an infant as trust versus mistrust. He explains that the quality of parent-infant interactions determines development of trust or mistrust. The infant learns to trust self, others, and the world through the relationship between the parent and child and the care the child receives ([Hockenberry et al., 2019](#)). During infancy a child's temperament or behavioral style becomes apparent and influences the interactions between parent and child. You can help parents understand their child's temperament and determine appropriate childrearing practices.

Assess the availability and appropriateness of experiences contributing to psychosocial development. Hospitalized infants often have difficulty

establishing physical boundaries because of repeated bodily intrusions and painful sensations. Limiting these negative experiences and providing pleasurable sensations are interventions that support early psychosocial development. Extended separations from parents complicate the attachment process and increase the number of caregivers with whom the infant must interact. Parents cannot always be present to provide care during hospitalization. When parents are not present, make an attempt to limit the number of different caregivers who have contact with the infant and to follow the parents' directions for care. These interventions foster the infant's continuing development of trust.

Play

Play is important for development of cognitive, social, and motor skills. Much of infant play is solitary and exploratory as infants use their senses to observe and examine their own bodies and objects of interest in their surroundings. Adults facilitate infant learning by planning activities that promote the development of milestones and providing toys that are safe for infants to explore with their mouth and manipulate with their hands such as rattles, wooden blocks, plastic stacking rings, squeezable stuffed animals, and busy boxes.

Health Risks

Injury Prevention

Unintentional injury from all accidents, such as motor vehicle accidents, suffocation, falls, or poisoning, is a major cause of death in children 6 to 12 months old (Kochanek et al., 2017). An understanding of the major developmental accomplishments during this time period allows for injury-prevention planning. As a child achieves gains in motor development and becomes increasingly curious about the environment, constant watchfulness and supervision are critical for injury prevention.

Child Maltreatment

Child maltreatment includes intentional physical abuse or neglect, emotional abuse or neglect, and sexual abuse of children, usually by adults (Hockenberry et al., 2019). More children suffer from neglect than any other type of maltreatment. Children of any age can suffer from maltreatment, but the youngest are the most vulnerable. In addition, many

children suffer from more than one type of maltreatment. No one profile fits a victim of maltreatment, and the signs and symptoms vary (Box 12.1).

Box 12.1 Warning Signs of Abuse

- Physical evidence of abuse or neglect over time; this includes previous injuries, emergency department visits
- Conflicting stories about the accident/trauma
- Injury blamed on sibling or another party
- History is not compatible with the pattern or degree of injury
- History inconsistent with the child's developmental age (e.g., a 6-month-old burned by turning on the hot water)
- An initial complaint not associated with the signs and symptoms present (e.g., bringing the child to the clinic for a cold when there is evidence of physical trauma)
- Inappropriate response of the child, especially an older child (e.g., not wanting to be touched, looking at caregiver before answering any questions)
- Previous reports of abuse in the family
- Frequent emergency department or clinic visits at multiple facilities

Adapted from Hockenberry MJ, et al: *Wong's nursing care of infants and children*, ed. 11, St Louis, 2019, Elsevier.

A combination of signs and symptoms or a pattern of injury should arouse suspicion. By law, nurses are mandated reporters and must report suspected child maltreatment to authorities. Children who are hospitalized for maltreatment have the same developmental needs as other children their age (Hockenberry et al., 2019).

Health Promotion

Nutrition

The quality and quantity of nutrition profoundly influence an infant's growth and development. Many women have already selected a feeding

method well before an infant's birth; others will have questions later in the pregnancy. Nurses are in a unique position to help parents select and provide a nutritionally adequate diet for their infant. Understand that factors such as support, culture, role demands, and previous experiences influence feeding methods ([Hockenberry et al., 2019](#)).

Breastfeeding is recommended for infant nutrition because breast milk contains the essential nutrients of protein, fats, carbohydrates, and immunoglobulins that bolster the ability to resist infection. Both the AAP and the US Department of Health and Human Services (USDHHS) recommend human milk for the first year of life ([Hockenberry et al., 2019](#)). However, if breastfeeding is not possible or if the parent does not desire it, an acceptable alternative is iron-fortified commercially prepared formula. Recent advances in the preparation of infant formula include the addition of nucleotides and long-chain fatty acids, which augment immune function and increase brain development. The use of whole cow's milk, 2% cow's milk, or alternate milk products before the age of 12 months is not recommended. Also, breastfed or formula-fed infants under 4 months of age should not receive supplemental fluids, especially water or juice ([Hockenberry et al., 2019](#)).

The average 1-month-old infant consumes approximately 18 to 21 ounces of breast milk or formula per day. This amount increases slightly during the first 6 months and decreases after introducing solid foods. The amount of formula per feeding and the number of feedings vary among infants. The addition of solid foods is not recommended before the age of 6 months because developmentally, infants are not ready for solid food before 6 months. The gastrointestinal tract is not sufficiently mature to handle these complex nutrients, and infants are exposed to food antigens that produce food protein allergies. To identify food sensitivities, one food should be introduced and consumed for approximately 1 week before introducing the next food. This allows for easier identification of which food causes the reaction. The use of fruit juices and nonnutritive drinks such as fruit-flavored drinks or soda should be avoided since these do not provide sufficient and appropriate calories during this period ([Hockenberry et al., 2019](#)).

Supplementation

The need for dietary vitamin and mineral supplements depends on an infant's diet. Full-term infants are born with some iron stores. The breastfed infant absorbs adequate iron from breast milk during the first 4 to 6 months of life. After 6 months iron-fortified cereal is generally an

adequate supplemental source. Because iron in formula is less readily absorbed than that in breast milk, formula-fed infants need to receive iron-fortified formula throughout the first year.

Fluoride is an essential mineral required for development of healthy teeth. To ensure adequate fluoride ingestion, fluoride is often added to drinking water, toothpaste, and infant formula. Adequate concentrations of fluoride are not available in human milk; however, supplementation in breastfed infants under 6 months of age is generally not needed. In areas where fluoridation of water is inadequate, fluoride supplementation may be indicated. A recent concern is the use of complementary and alternative medical therapies in children that may or may not be safe. Inquire about the use of such products to help the parent determine whether the product is truly safe for the child ([Hockenberry et al., 2019](#)).

Immunizations

The widespread use of immunizations has resulted in the dramatic decline of infectious diseases over the past 50 years and therefore is a most important factor in health promotion during childhood. Although most immunizations can be given to people of any age, it is recommended that the administration of the primary series begin soon after birth and be completed during early childhood. Vaccines are among the safest and most reliable drugs used. Minor side effects sometimes occur; however, serious reactions are rare. Parents need instructions regarding the importance of immunizations and common side effects such as low-grade fever and local tenderness. The recommended schedule for immunizations changes as new vaccines are developed and advances are made in the field of immunology. Stay informed of the current policies and direct parents to the primary caregiver for their child's schedule. The AAP maintains the most current schedule on their Internet website ([AAP, 2018a](#)). Research documents that infants experience pain with invasive procedures. It is important to be aware of measures such as auditory stimulus or swaddling to reduce or eliminate pain with procedures such as an immunization injection ([Azarmnejad et al., 2017](#); [Ho et al., 2016](#)).

Sleep

Sleep patterns vary among infants, with many having their days and nights reversed until 3 to 4 months of age. While young infants may sleep during the day, by 6 months most infants demonstrate nocturnal sleep patterns, sleeping between 9 and 11 hours at night. Most infants take one

or two naps a day by the end of the first year. Many parents have concerns regarding their infant's sleep patterns, especially if there is difficulty such as sleep refusal or frequent waking during the night. Carefully assess the individual problem before suggesting interventions to address their concern.

Building Competency in Patient-Centered Care

Children rely extensively on their parents and caregivers for their daily needs and health care. Describe how a nurse can best engage in family-centered care that respects the values, preferences, and needs of both the child and the family.

Toddler

Toddlerhood is the period from 12 to 36 months of age during which children enjoy increasing independence bolstered by greater physical mobility and cognitive abilities. Toddlers are increasingly aware of their abilities to control and are pleased with successful efforts with this new skill. This success leads them to repeated attempts to control their environments. Unsuccessful attempts at control result in negative behavior and temper tantrums. These behaviors are most common when parents stop the initial independent action. Parents cite these as the most problematic behaviors during the toddler years and at times express frustration with trying to set consistent and firm limits while simultaneously encouraging independence. Nurses and parents should limit the opportunities for a “no” answer, known as negativism. For example, do not ask the toddler, “Do you want to take your medicine now?” Instead, tell the child that it is time to take medicine, and offer a choice of water or juice to drink with it.

Physical Changes

The average toddler grows 7.5 cm (3 inches) in height, mostly through elongation of the legs, and gains approximately 4 to 6 pounds (1.8 to 2.7 kg) each year (Hockenberry et al., 2019). The rapid development of motor skills allows the child to participate in self-care activities such as feeding, dressing, and toileting. In the beginning the toddler walks in an upright position with a broad stance and gait, protuberant abdomen, and arms out to the sides for balance. Soon the child begins to navigate stairs, using a rail or the wall to maintain balance while progressing upward, placing both feet on the same step before continuing. Success provides courage to attempt the upright mode for descending the stairs in the same manner. Locomotion skills soon include running, jumping, standing on one foot for several seconds, and kicking a ball. Most toddlers ride tricycles and run well by their third birthday.

Fine-motor capabilities progress from spontaneous scribbling to accurately drawing circles and crosses. By 3 years, the child is usually able to stack a small tower of blocks. Toddlers learn to hold crayons with their fingers rather than with their fists and can imitate vertical and horizontal strokes. They are able to manage feeding themselves with a spoon without rotating it and can drink well from a cup without spilling. Toddlers can

turn pages of a book one at a time and can easily turn doorknobs ([Hockenberry et al., 2019](#)).

Cognitive Changes

Toddlers increase their ability to remember events and begin to put thoughts into words at about 2 years of age. They recognize that they are separate beings from their mothers, but they are unable to assume the view of another. A toddler's reasoning is based on their own experience of an event. They use symbols to represent objects, places, and people. Children demonstrate this function as they imitate the behavior of another that they viewed earlier (e.g., pretend to shave like daddy), pretend that one object is another (e.g., use a finger as a gun), and use language to stand for absent objects (e.g., request bottle).

Language

The 18-month-old child uses approximately 10 words. The 24-month-old child has a vocabulary of up to 300 words and is generally able to speak in two-word sentences, although the ability to understand speech is much greater than the number of words acquired ([Hockenberry et al., 2019](#)). According to Piaget, the preoperational stage of development begins in toddlerhood. Children begin to think about things more symbolically as their vocabulary develops ([Piaget, 1952](#)). "Who's that?" and "What's that?" are typical questions children ask during this period. Verbal expressions such as "me do it" and "that's mine" demonstrate the 2-year-old child's use of pronouns and desire for independence and control. By 36 months, the child can use simple sentences, follow some grammatical rules, and learn to use five or six new words each day. Parents can facilitate language development best by talking and reading to their children. Reading to children helps expand their vocabulary, knowledge, and imagination. Screen activities such as television, surface pads, or smart phones should not be used to replace parent-child interaction, as it has been shown to delay language development ([Canadian Paediatric Society, 2017](#); [Hockenberry et al., 2019](#)).

Psychosocial Changes

According to [Erikson \(1963\)](#) a sense of autonomy emerges during toddlerhood. Children strive for independence by using their developing muscles to do everything for themselves and become the master of their

bodily functions. Their strong wills are frequently exhibited in negative behavior when caregivers attempt to direct their actions. Temper tantrums result when parental restrictions frustrate toddlers. Parents need to provide toddlers with graded independence, allowing them to do things that do not result in harm to themselves or others. For example, young toddlers who want to learn to hold their own cups often benefit from two-handled cups with spouts and plastic bibs with pockets to collect the milk that spills during the learning process.

Play

During the preoperational stage of development the child's imagination develops, and children begin to discern the difference between past and future, although they still do not grasp more complex concepts such as cause and effect (Piaget, 1952). Socially, toddlers remain strongly attached to their parents and fear separation from them. In their presence they feel safe, and their curiosity is evident in their exploration of the environment. The child continues to engage in solitary play during toddlerhood but also begins to participate in parallel play, which is playing *beside* rather than *with* another child. Play expands the child's cognitive and psychosocial development. It is always important to consider the safety of a toy and whether the toy supports development of the child.

Health Risks

The newly developed locomotion abilities and insatiable curiosity of toddlers make them at risk for injury. Toddlers need close supervision at all times and particularly when in environments that are not childproofed (Fig. 12.5).

FIG. 12.5 Safety precautions should be provided for toddlers.
Courtesy Elaine Polan, RNC, BSN, MS.

Poisonings occur frequently because children near 2 years of age are interested in placing any object or substance in their mouths to learn about it. The prudent parent removes or locks up all possible poisons, including plants, cleaning materials, and medications. These parental actions create a safer environment for exploratory behavior. Lead poisoning continues to be a serious health hazard in the United States. Children may ingest or inhale lead, often from chipping of lead-based paint particles in older homes ([Hockenberry et al., 2019](#)).

Toddlers' lack of awareness regarding the danger of water and their newly developed walking skills make drowning a major cause of accidental death in this age-group. Limit setting is extremely important for toddlers' safety. Motor vehicle accidents are a significant cause of death in toddlers ([Kochanek et al., 2017](#)). Some of these deaths occurred because children were unrestrained or caregivers failed to use car seat safety guidelines when restraining children ([AAP, 2018b](#); [Hockenberry et al., 2019](#)).

Toddlers who become ill and require hospitalization are most stressed by the separation from their parents. Nurses encourage parents to stay with their child as much as possible and actively participate in providing care. Creating an environment that supports parents helps greatly in gaining the trust and cooperation of the toddler. Establishing a trusting relationship with the parents often results in toddler acceptance of treatment.

Health Promotion

Nutrition

Childhood obesity and the associated chronic diseases that result are sources of concern for all health care providers. Children establish lifetime eating habits in early childhood, and there is increased emphasis on food choices. They increasingly meet nutritional needs by eating solid foods. The healthy toddler requires a balanced daily intake of bread and grains, vegetables, fruit, dairy products, and proteins. Because the consumption of more than a quart of milk per day usually decreases a child's appetite for these essential solid foods and results in inadequate iron intake, advise parents to limit milk intake to 2 to 3 cups per day. Children should not be offered low-fat or skim milk until age 2 because they need the fat for satisfactory physical and intellectual growth ([Hockenberry et al., 2019](#)).

Mealtime has psychosocial and physical significance. If the parents struggle to control toddlers' dietary intake, problem behavior and conflicts can result. Toddlers often develop "food jags," or the desire to eat one food repeatedly. Rather than becoming disturbed by this behavior, encourage parents to offer a variety of nutritious foods at meals and to provide only nutritious snacks between meals. Serving finger foods to toddlers allows them to eat by themselves and to satisfy their need for independence and control. Small, reasonable servings allow toddlers to eat all of their meals.

Toilet Training

Increased locomotion skills, the ability to undress, and development of sphincter control allow toilet training if a toddler has developed the necessary language and cognitive abilities. Assisting parents in the recognition of the child's patterns and urge to urinate and defecate is crucial in determining a child's readiness. The toddler must also be motivated to hold on to please the parent rather than letting go to please

the self to successfully accomplish toilet training ([Hockenberry et al., 2019](#)). Remind parents that patience, consistency, and a calm attitude, in addition to the child's readiness, are essential to successful toilet training.

Preschoolers

The **preschool period** refers to the years between ages 3 and 5. Children refine the mastery of their bodies and eagerly await the beginning of formal education. Many people consider these the most intriguing years of parenting because children are less negative, more accurately share their thoughts, and more effectively interact and communicate. Physical development occurs at a slower pace than cognitive and psychosocial development.

Physical Changes

Several aspects of physical development continue to stabilize in the preschool years. Children have an average annual weight gain of about 4.5 to 6.5 pounds (2 to 3 kg) and grow 6.5 to 9 cm (2.5 to 3.5 inches) per year and stand an average of 110 cm (43.5 inches) tall by their fifth birthday. The elongation of the legs results in more slender-appearing children and little difference exists between the sexes ([Hockenberry et al., 2019](#)).

Gross- and fine-motor coordination improves in the preschool years as evidenced by running well, walking up and down steps with ease, and learning to hop. By 5 years they usually skip on alternate feet, jump rope, and begin to skate and swim. Improving fine-motor skills allows intricate manipulations. They learn to copy crosses and squares. Triangles and diamonds are usually mastered between ages 5 and 6 ([Hockenberry et al., 2019](#)). Scribbling and drawing help to develop fine-motor skills and the hand-eye coordination needed for the printing of letters and numbers.

Children need opportunities to learn and practice new physical skills. Nursing care of healthy and ill children includes an assessment of the availability of these opportunities. Although children with acute illnesses benefit from rest and exclusion from usual daily activities, children who have chronic conditions or who have been hospitalized for long periods need ongoing exposure to developmental opportunities. The parents and nurses weave these opportunities into the children's daily experiences, depending on their abilities, needs, and energy level.

Cognitive Changes

Preschoolers' cognitive development continues as they accomplish developmental tasks that prepare them for scholastic learning. Much of their development is through imaginative play and interactions with

others. Though they begin to recognize others' viewpoints, they remain egocentric in their communication and believe others think as they do. Children have increased social interaction, as is illustrated by the 5-year-old child who offers a bandage to a child with a cut finger.

Preschoolers begin to become aware of cause-and-effect relationships, as illustrated by the statement, "The sun sets because people want to go to bed." Early causal thinking is also evident in preschoolers. For example, if two events are related in time or space, children link them in a causal fashion. For example, the hospitalized child reasons, "I cried last night, and that's why the nurse gave me the shot." As children near age 5, they begin to use or learn to use rules to understand causation. They then begin to reason from the general to the particular. This forms the basis for more formal logical thought. The child now reasons, "I get a shot twice a day, and that's why I got one last night." Children in this stage also believe that inanimate objects have lifelike qualities and are capable of action, as seen through comments such as, "Trees cry when their branches get broken."

Preschoolers' knowledge of the world remains closely linked to concrete (perceived by the senses) experiences. Even their rich fantasy life is grounded in their perception of reality. Preschoolers believe that if a rule is broken, punishment results immediately. During these years they believe that a punishment is automatically connected to an act and do not yet realize that it is socially mediated (Hockenberry et al., 2019).

The greatest fear of this age-group appears to be that of bodily harm. This is evident in children's fear of the dark, animals, thunderstorms, and medical personnel. This fear often interferes with their willingness to allow nursing interventions such as measurement of vital signs. Preschoolers cooperate if they are allowed to help the nurse measure the blood pressure of a parent or to manipulate the nurse's equipment.

Language

Preschoolers' vocabularies continue to increase rapidly; by the age of 5 children have an average of 2100 words that they use to define familiar objects, identify colors, and express their desires and frustrations. They combine four to five words into sentences and use pronouns, prepositions, adjectives, and verbs. Language is more social, and preschoolers often question "Why?" and ask the same question repeatedly until answered. Phonetically similar words such as *die* and *dye* or *wood* and *would* cause confusion in preschool children. Avoid such words when preparing them for procedures and assess comprehension of explanations.

Psychosocial Changes

The world of preschoolers expands beyond the family into the neighborhood where children meet other children and adults. Their curiosity and developing initiative lead to actively exploring the environment, developing new skills, and making new friends.

Preschoolers have a surplus of energy that permits them to plan and attempt many activities that are beyond their capabilities, such as pouring milk from a gallon container into their cereal bowls. Guilt arises within children when they overstep the limits of their abilities and think that they have not behaved correctly. Preschoolers also exhibit magical thinking and believe that if they simply think something, it will happen. Children who in anger wished that their sibling were dead experience guilt if that sibling becomes ill. Children need to learn that “wishing” for something to happen does not make it occur. [Erikson \(1963\)](#) recommends that parents help their children strike a healthy balance between initiative and guilt by allowing them to do things on their own while setting firm limits and providing guidance.

Sources of stress for preschoolers can include changes in caregiving arrangements, starting school, the birth of a sibling, parental marital distress, relocation to a new home, or an illness. During these times of stress, preschoolers sometimes revert to bed-wetting or thumb-sucking and want the parents to feed, dress, and hold them. Reassure parents that these are some of the child’s normal coping behaviors. Provide experiences that these children are able to master. Such successes help them return to their prior level of independent functioning. As language skills develop, encourage children to talk about their feelings. Play is also an excellent way for preschoolers to vent frustration or anger and is a socially acceptable way to deal with stress.

Play

The play of preschool children becomes more social after the third birthday as it shifts from parallel to associative play. Children playing together engage in similar if not identical activity; however, there is no division of labor or rigid organization or rules. Most 3-year-old children are able to play with one other child in a cooperative manner in which they make something or play designated roles such as mother and baby. By age 4, children play in groups of two or three, and by 5 years the group has a temporary leader for each activity.

During the preoperational stage of growth and development the child begins to engage in make-believe play (Piaget, 1952). Pretend play allows children to learn to understand others' points of view, develop skills in solving social problems, and become more creative. Some children have imaginary playmates. These playmates serve many purposes, are a sign of health, and allow the child to distinguish between reality and fantasy (Hockenberry et al., 2019).

Television (TV), videos, electronic games, and computer programs also help support development and the learning of basic skills. However, these should be only one part of the child's total play activities. The AAP (2016a) advises no more than one hour per day of educational, nonviolent TV programs, which should be viewed by parents or other responsible adults in the home. Limiting TV viewing will provide more time for children to read, engage in physical activity, and socialize with others (Hockenberry et al., 2019).

Health Risks

As fine- and gross-motor skills develop and a child becomes more coordinated with better balance, falls become much less of a problem. Many of the guidelines for injury prevention in the toddler also apply to the preschooler. Children need to learn about safety, and parents need to continue close supervision of activities. Children at this age are great imitators, so parental example is important. For instance, parental use of a helmet while bicycling sets an appropriate example for the preschooler.

Health Promotion

Little research has explored preschoolers' perceptions of their own health. Parental beliefs about health, children's bodily sensations, and their ability to perform usual daily activities help children develop attitudes about their health. Preschoolers are usually quite independent in washing, dressing, and feeding. Alterations in this independence influence their feelings about their own health.

Nutrition

Nutritional requirements for the preschooler vary little from those of the toddler. The average daily intake is 1800 calories. Parents often worry about the amount of food their child is consuming, and this is a relevant concern because of the problem of childhood obesity. However, the quality

of the food is more important than quantity in most situations. Preschoolers consume about half of average adult portion sizes. Finicky eating habits are characteristic of the 4-year-old; however, preschoolers engaged in meal preparation are more likely to try new things (Hockenberry et al., 2019).

Sleep

Preschoolers average 12 hours of sleep a night and take infrequent naps. Sleep disturbances are common during these years (Hockenberry et al., 2019). Disturbances range from trouble getting to sleep to nightmares to prolonging bedtime with extensive rituals. Frequently children in this playful age-group have had an overabundance of activity and stimulation. Helping them slow down before bedtime usually results in better sleeping habits.

Vision

Vision screening usually begins in the preschool years and needs to occur at regular intervals. One of the most important tests is to determine the presence of nonbinocular vision or strabismus. Early detection and treatment of strabismus must occur by age 6 to prevent amblyopia (Hockenberry et al., 2019).

REFLECT NOW

Nurses must be careful to recognize their own biases and assumptions when caring for children and families. How can you avoid imposing your beliefs and value system on the families with children that you care for?

School-Age Children and Adolescents

The developmental changes between ages 6 and 18 are diverse and span all areas of growth and development. Children develop, expand, refine, and synchronize physical, psychosocial, cognitive, and moral skills so that the individual is able to become an accepted and productive member of society. The environment in which the individual develops skills also expands and diversifies. Instead of the boundaries of family and close friends, the environment now includes the school, community, and church. With age-specific assessment, you need to review the appropriate developmental expectations for each age-group. You can promote health by helping children and adolescents achieve a necessary developmental balance.

School-Age Children

During these “middle years” of childhood from age 6 to about age 12, the foundation for adult roles in work, recreation, and social interaction is laid. Puberty marks the end of these middle years and the beginning of adolescence. Children make great developmental strides during these years as they develop competencies in physical, cognitive, and psychosocial skills.

The school or educational experience expands the child’s world and is a transition from a life of relatively free play to one of structured play, learning, and work. The school and home influence growth and development, requiring adjustment by the parents and child. The child learns to cope with rules and expectations presented by the school and peers. Parents have to learn to allow their child to make decisions, accept responsibility, and learn from the experiences of life.

Physical Changes

The rate of growth during these early school years is slow and consistent, a relative calm before the growth spurt of adolescence. The school-age child appears slimmer than the preschooler as a result of changes in fat distribution and thickness. Many children double their weight during these middle childhood years, and most girls exceed boys in both height and weight by the end of the school years ([Hockenberry et al., 2019](#)).

School-age children become more graceful during the school years because their large-muscle coordination improves and their strength doubles. Most children practice the basic gross-motor skills of running, jumping, balancing, throwing, and catching during play, resulting in refinement of neuromuscular function and skills. Individual differences in the rate of mastering skills and ultimate skill achievement become apparent during their participation in many activities and games.

Fine-motor skills improve, which allows proficiency in a wide range of activities, including handwriting, drawing, and playing. Most 6-year-old children are able to hold a pencil adeptly and print letters and words; by age 12 a child is able to make detailed drawings and write sentences in script. Painting, drawing, playing computer games, and modeling allow children to practice and improve newly refined skills. The improved fine-motor capabilities of children in middle childhood allow them to become very independent in bathing, dressing, and taking care of other personal needs. They develop strong personal preferences in the way these needs

are met. Illness and hospitalization threaten children's control in these areas. Therefore, whenever possible, it is important to allow them to participate in care and maintain as much independence as possible. For example, children can help decide the type of fluids and help keep a record of their intake.

As skeletal growth progresses, a child's body appearance and posture change. Earlier the child's posture was stoop shouldered, with slight lordosis and a prominent abdomen. The posture of a school-age child is more erect. The [AAP \(2016b\)](#) recommends screening of scoliosis, the lateral curvature of the spine, in females at age 10 and 12 and in males at age 13 to 14. Early treatment of scoliosis can limit the progression of the curve and the resulting effects.

Eye shape alters because of skeletal growth. This improves visual acuity, and normal adult 20/20 vision is achievable. Screening for vision and hearing problems is easier, and results are more reliable because school-age children more fully understand and cooperate with the test directions. The school nurse typically assesses the growth, visual, and auditory status of school-age children and refers those with possible deviations to a health care provider such as their family practitioner or pediatrician.

Cognitive Changes

According to Piaget, children begin to transition into the concrete-operational stage of growth and development around the age of 7, when they begin to demonstrate logical, more concrete thinking. They become less egocentric and begin to understand that their thoughts and feelings may not be shared by others ([Piaget, 1952](#)). Cognitive changes provide the school-age child with the ability to think in a logical manner about the here and now and to understand how one thing relates to another. They are now able to use their developed thinking abilities to experience events without having to act them out ([Hockenberry et al., 2019](#)). Their thoughts are no longer dominated by their perceptions; thus their ability to understand the world greatly expands.

School-age children have the ability to concentrate on more than one aspect of a situation. They begin to understand that others do not always see things as they do and even begin to understand another viewpoint. They now have the ability to recognize that the amount or quantity of a substance remains the same even when its shape or appearance changes. For instance, two balls of clay of equal size remain the same amount of

clay even when one is flattened and the other remains in the shape of a ball.

The young child is able to separate objects into groups according to shape or color, whereas the school-age child understands that the same element can exist in two classes at the same time. School-age children frequently have collections such as baseball cards or stuffed animals that demonstrate this new cognitive skill. Part of the joy of collecting is the ordering and reordering of items in the collection ([Hockenberry et al., 2019](#)).

Language Development

Language growth is rapid during middle childhood. Children improve their use of language and expand their structural knowledge. They become more aware of the rules of syntax, the rules for linking words into phrases and sentences. They also identify generalizations and exceptions to rules. They accept language as a means for representing the world in a subjective manner and realize that words have arbitrary rather than absolute meanings. Children begin to think about language, which enables them to appreciate jokes and riddles. They are not as likely to use a literal interpretation of a word, but rather they reason about its meaning within a context ([Hockenberry et al., 2019](#)).

Psychosocial Changes

[Erikson \(1963\)](#) identifies the developmental task for school-age children as industry versus inferiority. During this time children strive to acquire competence and skills necessary for them to function as adults. School-age children who are positively recognized for success feel a sense of worth. Those faced with failure often feel a sense of mediocrity or unworthiness, which sometimes results in withdrawal from school and peers.

School-age children begin to define themselves on the basis of internal more than external characteristics. They begin to define their self-concept and develop self-esteem through ongoing self-evaluation. Interaction with peers allows them to define their own accomplishments in relation to others as they work to develop a positive self-image ([Hockenberry et al., 2019](#)).

According to Piaget, school-age children around the age of 11 may begin to enter the fourth and final stage of intellectual development, formal operations. In this stage they begin to ponder abstract relationships. They can formulate hypotheses and consider different possibilities. Piaget

believed that this was the final stage of cognitive development and that the continued intellectual development in teenagers and adults depended on the accumulation of knowledge (Piaget, 1952).

Peer Relationships

Group and personal achievements become important to the school-age child. Success is important in physical and cognitive activities. Play involves peers and the pursuit of group goals. Although solitary activities are not eliminated, group play overshadows them. Learning to contribute, collaborate, and work cooperatively toward a common goal becomes a measure of success (Fig. 12.6).

FIG. 12.6 School-age children gain a sense of achievement from working and playing with peers.

From Hockenberry MJ, et al: *Wong's nursing care of infants and children*, ed 11, St Louis, 2019, Elsevier.

The school-age child prefers same-sex peers. Peer influence becomes quite diverse during this stage of development, and clubs and peer groups become prominent. School-age children often develop “best friends” with whom they share secrets and with whom they look forward to interacting on a daily basis. Group identity increases as the school-age child approaches adolescence.

Sexual Identity

Freud described middle childhood as the latency period because he believed that children of this period had little interest in their sexuality. Children are curious about their sexuality. Children's curiosity about adult magazines or meanings of sexually explicit words is an example of their sexual interest. This is the time for them to have exposure to sex education, including topics about sexual maturation, reproduction, and relationships (Hockenberry et al., 2019).

Stress

Today's children experience more stress than children in earlier generations. Stress comes from parental expectations, peer expectations, the school environment, and violence in the family, school, or community. Some school-age children care for themselves before or after school without adult supervision. Latchkey children sometimes feel increased stress and are at greater risk for injury and unsafe behaviors (Hockenberry et al., 2019). A nurse helps the child cope with stress by helping the parents and child identify potential stressors and designing interventions to minimize stress and the child's stress response. Deep-breathing techniques, positive imagery, and progressive relaxation of muscle groups are interventions that most children can learn (see Chapter 37). Include the parent, child, and teacher in the intervention for maximal success.

Health Risks

Accidents and injuries are a major health problem affecting school-age children (Hockenberry et al., 2019). They are exposed to various environments and less supervision, but their developed cognitive and motor skills make them less likely to suffer from unintentional injury. Some school-age children are risk takers and attempt activities that are beyond their abilities. Motor vehicle injuries as a passenger or pedestrian are among the most common in this age-group (CDC, 2018b).

Infections account for the majority of all childhood illnesses. Poverty and the prevalence of illness are highly correlated. Access to primary care is often very limited, and health promotion and preventive health measures are minimal. School nurses play a major role in providing access to meet children's health needs by providing health education and direct care services to children in the school setting.

Health Promotion

Perceptions

During the school-age years identity and self-concept become stronger and more individualized. Perception of wellness is based on readily observable facts such as presence or absence of illness and adequacy of eating or sleeping. Functional ability is the standard by which personal health and the health of others are judged. Children are aware of their body and are modest and sensitive about being exposed. Always provide for privacy when offering explanations of common procedures.

Health Education

Health education during the school-age years is critical to establish behaviors for a healthy adult life. Promotion of good health practices is a nursing responsibility, and effective health education must be developmentally appropriate. Programs directed at health education are frequently organized and conducted in the school. Effective health education teaches children about their bodies and how choices, such as nutrition and routine exercise, impact their health ([Hockenberry et al., 2019](#)).

Health Maintenance

Parents need to recognize the importance of annual health maintenance visits for immunizations, screenings, and dental care. When their school-age child reaches 10 years of age, parents need to begin discussions in preparation for upcoming pubertal changes. Topics include introductory information regarding menstruation, sexual intercourse, reproduction, and sexually transmitted infections (STIs). Human papillomavirus (HPV) is a widespread virus that will infect nearly 1 in 4 Americans in their lifetime ([AAP, 2018c](#)). For many individuals HPV clears spontaneously, but for others it can cause significant consequences. Females can develop cervical, vaginal, and vulvar cancers and genital warts; and males can develop genital warts. Since it is not possible to determine who will or will not develop disease from the virus, the [AAP \(2017\)](#) recommends routine HPV vaccination for girls and boys, with the first dose given at age 11 to 12. For those who miss this recommended age window, vaccination is still recommended through age 26.

Safety

Because accidents are the leading cause of death and injury in the **school-age period**, safety is a priority health teaching consideration ([Hockenberry](#)

[et al., 2019](#)). At this age, encourage children to take responsibility for their own safety, such as wearing helmets during bike riding and wearing seat belts when in motor vehicles.

Nutrition

Growth often slows during the school-age period as compared with infancy and adolescence. School-age children are developing eating patterns that are independent of parental supervision. The availability of snacks and fast-food restaurants makes it increasingly difficult for children to make healthy choices. The prevalence of obesity among children 6 to 11 years of age increased from 6.5% in 1980 to 18.4% in 2015 to 2016. In addition, the incidence of adolescents ages 12 to 19 years who were obese increased from 5% to almost 21% during the same period of time ([CDC, 2017a](#)). Childhood obesity has become a prominent health problem, resulting in increased risk for hypertension, diabetes, coronary heart disease, fatty liver disease, pulmonary complications such as sleep apnea, musculoskeletal problems, dyslipidemia, and potential for psychological problems ([Hockenberry et al., 2019](#)). Nurses promote healthy lifestyle habits, including nutrition and exercise. School-age children need to participate in educational programs that enable them to plan, select, and prepare healthy meals and snacks. These meals and snacks need adequate caloric intake for growth throughout childhood accompanied by activity for continued gross-motor development.

Adolescents

Adolescence is the period during which the individual makes the transition from childhood to adulthood, usually between ages 13 and 20 years. The term *adolescent* usually refers to psychological maturation of the individual, whereas **puberty** refers to the point at which reproduction becomes possible. The hormonal changes of puberty result in changes in the appearance of the young person, and cognitive development results in the ability to hypothesize and deal with abstractions. Adjustments and adaptations are necessary to cope with these simultaneous changes and the attempt to establish a mature sense of identity.

Understanding development helps teenagers and parents anticipate and cope with the stresses of adolescence. Nursing activities, particularly education, promote healthy development. These activities occur in a variety of settings and can be developed for the adolescent, parents, or both. For example, a nurse conducts seminars in a high school to provide practical suggestions to a large group of students for solving problems of concern, such as treating acne or making responsible decisions about drugs or alcohol use. Similarly, a group education program for parents about how to cope with teenagers would promote parental understanding of adolescent development.

Physical Changes

Physical changes occur rapidly in adolescence. Sexual maturation occurs with the development of primary and secondary sexual characteristics. The four main physical changes are:

1. Increased growth rate of skeleton, muscle, and viscera
2. Sex-specific changes, such as changes in shoulder and hip width
3. Alteration in distribution of muscle and fat
4. Development of the reproductive system and secondary sex characteristics

Wide variation exists between sexes and within the same sex in the timing of physical changes associated with puberty. Girls generally have prepubescent changes 1 to 2 years before boys do ([Hockenberry et al., 2019](#)). The rates of height and weight gain are usually proportional, and the sequence of pubertal growth changes is the same in most individuals.

Hormonal changes within the body create change when the body produces gonadotropin-releasing hormones that stimulate ovarian cells to produce estrogen and testicular cells to produce testosterone. These hormones contribute to the development of secondary sex characteristics, such as hair growth and voice changes, and play an essential role in reproduction. The changing concentrations of these hormones are also linked to acne and body odor. Understanding these hormonal changes enables you to reassure adolescents and educate them about body care needs.

Being like peers is extremely important for adolescents (Fig. 12.7). Any deviation in the timing of their physical changes is extremely difficult for them to accept. It is important to provide emotional support for those undergoing early or delayed puberty. Even adolescents whose physical changes are occurring at the normal times seek confirmation of and reassurance about their normalcy.

FIG. 12.7 Peer interactions help increase self-esteem during puberty.
Copyright © MachineHeadz/iStock/Thinkstock.

Height and weight increases during adolescence, with peak height velocity occurring at about 12 years in girls and at about 14 years in boys. Girls' height increases 5 to 20 cm (2 to 8 inches), and weight increases by 15.5 to 55 pounds (7 to 25 kg). Girls grow less than 2 inches following

menarche (the onset of menstruation), reaching their full height by 16 to 17 years of age. Boys' height increases approximately 10 to 30 cm (4 to 12 inches), and weight increases by 15.5 to 66 pounds (7 to 30 kg). Boys continue to grow taller until 18 to 20 years of age ([Hockenberry et al., 2019](#)).

Although individual and gender differences exist, growth follows a similar pattern for both sexes. Personal growth curves help nurses assess physical development. However, an individual's sustained progression along the curve is more important than a comparison to the norm.

Cognitive Changes

The adolescent develops the ability to determine and rank possibilities, solve problems, and make decisions through logical operations. The teenager thinks abstractly and deals effectively with hypothetical problems. When confronted with a problem, the adolescent considers an infinite variety of causes and solutions. For the first time the young person moves beyond the physical or concrete properties of a situation and uses reasoning powers to understand the abstract. School-age individuals think about what is, whereas adolescents are able to imagine what might be.

Adolescents are now able to think in terms of the future rather than just current events. These newly developed abilities allow an individual to have more insight and skill in playing video, computer, and board games that require abstract thinking and deductive reasoning about many possible strategies. A teenager even solves problems requiring simultaneous manipulation of several abstract concepts. Development of this ability is important in the pursuit of an identity. For example, newly acquired cognitive skills allow the teenager to define appropriate, effective, and comfortable sex-role behaviors and to consider their impact on peers, family, and society. A higher level of cognitive functioning makes the adolescent receptive to more detailed and diverse information about sexuality and sexual behaviors. For example, sex education includes an explanation of physiological sexual changes and birth control measures.

Adolescents also develop the ability to understand how an individual's ideas or actions influence others. Although adolescents have the capability to think as well as an adult, they do not have experiences on which to build. It is common for teenagers to consider their parents too narrow minded or materialistic. At this time adolescents believe that they are unique and the exception, giving rise to their risk-taking behaviors. In other words, they think that they are invincible. For example, an

adolescent might believe that he or she is able to drive fast and not have an accident or may argue that e-cigarettes will not impact his or her health.

Language Skills

Language development is fairly complete by adolescence, although vocabulary continues to expand. The primary focus becomes communication skills that an adolescent uses effectively in various situations. Adolescents need to communicate thoughts, feelings, and facts to peers, parents, teachers, and other people of authority. The skills used in these diverse communication situations vary. Adolescents select the people with whom to communicate, decide on the exact message, and choose the way to transmit it. For example, how teenagers tell parents about failing grades is not the same as how they tell friends. Good communication skills are critical for adolescents in overcoming peer pressure and unhealthy behaviors. The following are some hints for communicating with adolescents ([Hockenberry et al., 2019](#)):

- Provide privacy and a nonthreatening environment. As adolescents become more autonomous, interviews should be conducted without parents present.
- Ensure confidentiality and explain the limitations of confidentiality, such as disclosure of abuse or suicidal ideations.
- Be nonjudgmental and display genuine interest in the adolescent's perspective.
- Ask open-ended questions (see [Chapter 24](#)).
- Start with less sensitive topics and then move to more sensitive issues. Asking questions about sex, drugs, and school opens the channels for further discussion.

Psychosocial Changes

The search for personal identity is the major task of adolescent psychosocial development. Teenagers establish close peer relationships or remain socially isolated. [Erikson \(1963\)](#) sees identity (or role) confusion as the prime danger of this stage and suggests that the cliquish behavior and intolerance of differences seen in adolescent behavior are defenses against identity confusion ([Erikson, 1968](#)). Adolescents become more emotionally independent from their parents ([Hockenberry et al., 2019](#)). In addition, they develop their own ethical systems based on personal values. They begin to make choices about vocation, future education, and lifestyle. The

various components of total identity evolve from these tasks and compose an adult personal identity that is unique to the individual.

Sexual Identity

Physical changes of puberty enhance achievement of sexual identity (see [Chapter 34](#)). The physical evidence of maturity encourages the development of masculine and feminine behaviors. Adolescents depend on these physical clues because they want assurance of maleness or femaleness and they do not wish to be different from peers. Also, development of sexual identity involves identification of sexual orientation. By late adolescence, most individuals identify themselves as heterosexual, and a small number identify as bisexual, gay, or lesbian.

Peer Group Identity

Adolescents seek a group identity because they need self-esteem and acceptance. Similarity in dress or speech is common in teenage groups. Peer groups provide the adolescent with a sense of belonging, approval, and the opportunity to learn acceptable behavior. Popularity with opposite-sex and same-sex peers is important. Supportive peer groups can have a positive influence on health choices, while poor peer group selection can lead to poor decision making and negative health outcomes. Nurses should encourage parents to communicate with their adolescents and provide supervision to promote selection of positive peer groups.

Family Identity

Adolescents begin to place more value on peer relationships than on parents. Although financial independence for adolescents is not the norm in American society, many work part-time, using their income to bolster independence. When they cannot have a part-time job because of studies, school-related activities, and other factors, parents can provide allowances for clothing and incidentals, which encourage them to develop decision making and budgeting skills.

Some adolescents and families have more difficulty during these years than others. Adolescents need to make choices, act independently, and experience the consequences of their actions. Nurses help families consider appropriate ways for them to foster the independence of their adolescent while maintaining family structure.

Health Identity

Another component of personal identity is perception of health. This component is of specific interest to health care providers. Healthy adolescents evaluate their own health according to feelings of well-being, ability to function normally, and absence of symptoms (Hockenberry et al., 2019). They also often include health maintenance and health promotion behaviors as important concerns.

Adolescents try new roles, begin to stabilize their identity, and acquire values and behaviors from which their adult lifestyle will evolve. The rapid changes during this period make health promotion programs especially crucial. They are able to identify behaviors such as smoking and substance abuse as threatening to health in general terms but frequently tend to underestimate the effect of the potentially negative consequences of their own actions. Health promotion strategies should focus not only on reducing risk behaviors but also on maximizing protective factors such as coping and adapting (Hockenberry et al., 2019).

Health Risks

Accidents

In the United States, unintentional injury is the leading cause of death in adolescents. Motor vehicle accidents are the most common cause of death (USDHHS, 2018). Adolescents are at particular risk because of lack of driving experience and risk-taking behaviors such as driving too fast, drinking and driving, or riding with someone under the influence (USDHHS, 2014; Hockenberry et al., 2019). The majority of deaths from injury occur in boys. Other frequent causes of accidental death in teenagers are drowning and the use of firearms. Adolescents think that they are invincible, which leads to risk-taking behaviors. The use of alcohol precedes many injuries, and adolescents continue to be both the victims and perpetrators of violence. An objective for *Healthy People 2020* is to reduce the percentage of middle and public high schools that have violent incidents (USDHHS, 2014).

Violence and Homicide

Homicide is the second leading cause of death in adolescents in the United States and is the leading cause of death in African-American teenagers (Hockenberry et al., 2019). Youth Risk Behavior Surveillance System reports that, in 2017, 15.7% of high school students had carried a weapon (e.g., gun, club, or knife) at some point during the preceding 30 days

(CDC, 2018c). Teenagers are most likely to be killed by an acquaintance or gang member and most often with a firearm. Because having a gun in the home raises the risk of homicide and suicide for adolescents, include assessment of gun presence in the home and discuss gun safety when counseling families (Hockenberry et al., 2019).

Violence among adolescents has become a national concern. School shootings are increasingly common and contribute to stress in childhood and adolescence. Violence includes physical assaults and fighting, threats and intimidation, sexual harassment or violence, human trafficking (Box 12.2), bullying, or theft. Nurses working with adolescents need to be aware of the potential for school violence and include screening questions when providing health care, regardless of the setting.

Box 12.2 Evidence-Based Practice Education Programs to Address Sex Trafficking of Children

PICOT Question: For child and adolescent victims of sex trafficking, will education programs for health care providers and mandatory reporters on the signs and risk factors of sex trafficking victimization improve early identification and intervention?

Evidence Summary

Educational programs on sex trafficking for health care providers are essential to identifying victims and intervening appropriately (Bauer et al., 2019). Sex trafficking of minors is a type of human trafficking involving crimes of a sexual nature committed against children and adolescents. This exploitation may involve prostitution; performing in sexual venues such as strip clubs; survival sex by which a minor performs sex acts for money, food, shelter, or other necessities; pornography; and sex tourism, such as mail-order bride trade or early marriage (Ulibarri, et al., 2017). Because trafficked children do not often disclose that they are victims and there is no uniform data collection system in place to track minor sex trafficking, the prevalence is largely unknown (Bauer et al., 2019; Hartinger-Saunders et al., 2017).

Victims of sex trafficking come from every demographic, but they typically share risk factors that make them vulnerable to exploitation. Common risk factors include history of abuse or neglect, family violence or dysfunction, poverty, substance misuse, mental health issues,

runaway/homelessness, and those who identify as lesbian, gay, bisexual, transgender, queer, or questioning (Greenbaum, 2017).

Many sex trafficking victims are “trapped and controlled through assault, threats, false promises, perceived sense of protection, isolation, shaming, and debt” (CDC, 2018e), yet many do not recognize they are being trafficked, do not identify themselves as victims (Perkins and Ruiz, 2017), and may even protect their abuser (Hartinger-Saunders et al., 2017). Common health issues of sex trafficking victims include sexually transmitted infections, HIV/AIDS, pregnancy, physical injury, posttraumatic stress disorder, and depression (Bauer et al., 2019; Greenbaum, 2017).

Application to Nursing Practice

- Develop educational programs that assist health care providers to identify victims of sex trafficking, including how to safely separate the potential victim from the trafficker and knowledge of immediate resources to protect the victim (Bauer et al., 2019).
- Nurses are mandatory reporters and must recognize signs of victimization and know how to intervene (Powell et al., 2017).
- Design “Sex Trafficking Indicator” checklist and educate health care providers on its use (Bauer et al., 2019).
- Use a standardized, evidence-based education program on human trafficking with patient-outcome metrics to educate other health care providers and mandatory reporters to recognize the risk factors and signs of sex traffic victimization (Hartinger-Saunders et al., 2017; Powell et al., 2017).
- Coordinate care and tailor interventions for sex trafficking survivors (Twigg, 2017).
- Lead or participate in research on the best way to educate health care professionals about sex trafficking (Powell et al., 2017).

REFLECT NOW

School violence and school shootings are on the rise in the United States. Reflect on what you now know about an adolescent's development. How can nurses intervene with this age group to decrease the prevalence of this phenomenon?

Suicide

Suicide is a major leading cause of death in adolescence. A recent survey of high school students in the United States found that 16% of students reported seriously considering suicide, while 8% reported attempting suicide within the past year ([CDC, 2017b](#)). Depression and social isolation commonly precede a suicide attempt, but suicide probably results from a combination of several factors. Nurses must be able to identify the factors associated with adolescent depression and suicide risk and precipitating events. Screen for the following changes in behavior:

- Decrease in school performance
- Withdrawal
- Loss of initiative
- Loneliness, sadness, and crying
- Appetite and sleep disturbances
- Verbalization of suicidal thought

If your assessment indicates depression or suicide risk, make immediate referrals to mental health professionals. Guidance helps them focus on the positive aspects of life and strengthen coping abilities.

Substance Abuse

Substance abuse is a concern for all who work with adolescents. Adolescents often believe that mood-altering substances create a sense of well-being or improve level of performance. All adolescents are at risk for experimental or recreational substance use ([Hockenberry et al., 2019](#)). The misuse of opioids in high school students has decreased considerably over

the past 10 years, while the daily use of marijuana among 12th graders increased from 1.9% in 1992 to 5.9% in 2017 (NIH, 2017).

Tobacco use continues to be a health problem among adolescents. The use of cigarettes by high school students decreased from 15.8% in 2011 to 7.6% in 2017, while the use of electronic cigarettes increased from 1.5% in 2011 to 11.7% in 2017 and spiked to 20.8% in 2018 (CDC, 2018a; CDC, 2018d). This huge increase led to new Food and Drug Administration (FDA) regulations to reduce the sale of electronic cigarettes to youth (FDA, 2018). While electronic cigarettes may be less harmful than cigarettes, they should not be considered safe, as they can harm adolescent brain development and increase the presence of cancer-causing chemicals in the body (CDC, 2018c). In addition, vaping has been associated with serious lung problems likely related to irritation or allergic reactions to contaminants (Shmerling, 2019). The increased use of e-cigarettes and vaping does not reduce the addictive or health effects of nicotine use (CDC, 2018a,d). The long-term effects of nicotine from e-cigarettes and vaping may lead to subsequent frequency of smoking and vaping (Goldenson et al., 2017). Nurses must educate teenagers about smoking cessation and the safety risks associated with smoking and substance and alcohol use.

Eating Disorders

Eating disorders include anorexia nervosa, bulimia nervosa, and binge eating disorder. The highest incidence of eating disorders occurs in 15- to 19-year-olds, so routine nutritional screening should be a part of the health care provided to all adolescents. Areas to include in the assessment are past and present diet history, food records, eating habits, attitudes, health beliefs, and socioeconomic and psychosocial factors (Hockenberry et al., 2019). An important psychosocial factor is assessment of an adolescent's perception of his or her body image and self-esteem or any sources of depression (Laporta-Herrero et al., 2018).

Anorexia nervosa is more common in girls and is a clinical syndrome with both physical and psychosocial components of anxiety and depression. People with anorexia nervosa have an intense fear of gaining weight and refuse to maintain body weight at the minimal normal weight for their age and height. Over time this condition affects both physiological and psychosocial function and impacts quality of life (Carrot et al., 2017).

Bulimia nervosa is most identified with binge eating and behaviors to prevent weight gain. Unlike anorexia, bulimia occurs within a normal

weight range; thus it is much more difficult to detect. Behaviors of individuals with eating disorders include self-induced vomiting, misuse of laxatives and other medications, and excessive exercise. It is important to take a thorough dietary history because, if left undetected and untreated, these disorders lead to significant morbidity and mortality ([Hockenberry et al., 2019](#)).

Sexually Transmitted Infections

Sexually transmitted infections (STIs) annually affect millions of sexually active adolescents. This high degree of incidence makes it imperative that sexually active adolescents be screened for STIs, even when they have no symptoms. The annual physical examination of a sexually active adolescent includes a thorough sexual history and a careful examination of the genitalia so that STIs are not missed. Be proactive by using the interview process to identify risk factors in the adolescent, and provide education to prevent STIs, including human immunodeficiency virus (HIV) and HPV, and unwanted pregnancies ([Hockenberry et al., 2019](#)). As discussed earlier for school-age children, immunization for HPV infection should be considered at this time if not already administered.

Pregnancy

The United States has the highest rate of teenage pregnancy and childbearing annually compared with other industrialized nations ([Hockenberry et al., 2019](#)). Adolescent birth rates continue to decline due to improvements in contraceptive use, the use of long-acting reversible contraception, and safe sex practices ([Lindberg et al., 2018](#)). However, adolescent pregnancy continues to be a major social challenge. Adolescent pregnancy occurs across socioeconomic classes, in public and private schools, among all ethnic and religious backgrounds, and in all parts of the country. Pregnant teens need special attention to nutrition, health supervision, and psychological support. Adolescent mothers also need help in planning for the future and obtaining competent day care for their infants.

Health Promotion

Health Education

Community and school-based health programs for adolescents focus on health promotion and illness prevention. Nurses need to be sensitive to the

emotional cues from adolescents before initiating health teaching to know when the teen is ready to discuss concerns. In addition, discussions with adolescents need to be private and confidential. Adolescents define health in much the same way as adults and look for opportunities to reach their physical, mental, and emotional potential. Large numbers of school-based clinics have been developed and implemented to respond to adolescents' needs. Adolescents are much more likely to use these health care services if they encounter providers who are caring and respectful ([Hockenberry et al., 2019](#)).

Nurses play an important role in preventing injuries and accidental deaths. For example, discussing alternatives to substance-impaired driving or riding with someone under the influence of drugs or alcohol prepares them to consider alternatives when such an occasion arises. As a nurse, identify adolescents at risk for abuse, provide education to prevent accidents related to substance abuse, and provide resources to those in need of mental health care.

Minority Adolescents

African-American, Hispanic, Latino, Asian, Native American, and Alaska Native adolescents are the fastest-growing segment in the US population. Minority adolescents experience a greater percentage of health problems and barriers to health care ([Hockenberry et al., 2019](#)). Issues of concern for these adolescents living in a high-risk environment include childhood trauma, cyberbullying, death related to violence, unintentional injuries, learning or emotional difficulties, and an increased rate for adolescent pregnancy and STIs ([Larson et al., 2017](#)). Poverty is a major factor that negatively affects the lives of many minority adolescents. Limited access to health services is common ([Duarte et al., 2018](#)). Nurses are able to make a significant contribution to improving access to appropriate health care for adolescents. With knowledge about various cultures and the means to care for minority adolescents, nurses act as advocates to ensure accessibility of appropriate services.

Gay, Lesbian, and Bisexual Adolescents

Sexual orientation refers to patterns of sexual and emotional attraction to persons of the same gender, opposite gender, or both males and females. While most adolescents identify themselves as heterosexual, many identify themselves as homosexual or bisexual. It is widely known that, although some adolescents participate in same-gender sexual activity, they do not

necessarily become homosexual as adults ([Hockenberry et al., 2019](#)). Adolescents who believe that they have a homosexual or bisexual orientation often try to keep it hidden to avoid any associated stigma, victimization, or bullying. This increases their vulnerability to depression and suicide. The teens who choose to disclose a homosexual or bisexual orientation become at risk for violence, harassment, and family abuse ([Mustanski et al., 2016](#)). If a teen chooses to disclose sexual orientation to you, help the adolescent consider how to discuss with family or friends and to construct a safety plan before telling his or her family or friends in case their response is not supportive ([Hockenberry et al., 2019](#)).

Key Points

- Nurses promote the health of pregnant women by addressing nutritional requirements, physical changes, and psychosocial needs.
- At birth, newborns develop independent circulatory and respiratory functioning.
- Promotion of parent-child attachment can begin immediately after birth.
- Physical changes include maturation of organ systems, fine and gross motor development, and physical growth. These changes occur in a regular pattern and are monitored to identify developmental concerns.
- Cognitive and psychosocial development throughout childhood is rapid, and a multitude of factors can foster or hinder a child's development.
- Play provides opportunities for development of cognitive, social, and motor skills. Play evolves from solitary to interactive play throughout childhood.
- Through anticipatory guidance, nurses can prepare parents to reduce their children's health risks and to promote achievement of developmental tasks.

Reflective Learning

- Considering what you know about childhood development, how would your approach to assessment of cognitive function be different if a child were of school age versus an adolescent?
- What anticipatory guidance could you provide for a family you cared for to minimize health risks for their child?
- Family support, including financial and child care assistance, for the adolescent mother significantly increases the likelihood that she will complete her education and gain skills for the job market. How can you support these goals for an adolescent mother who does not have sufficient family support?

Review Questions

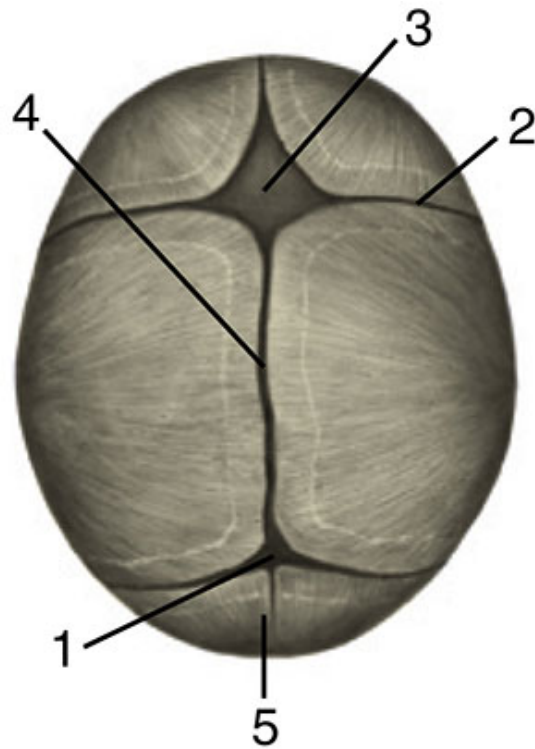

1. Which of the following should be included in health teaching for a pregnant patient? (Select all that apply.)
 1. Exposure of the fetus to alcohol, drugs, or tobacco can cause abnormal development.
 2. Nutritional needs increase during pregnancy, and eating healthy foods is important.
 3. Complementary and alternative therapies should always be avoided during pregnancy.
 4. Provide education on self-care to reduce common discomforts of pregnancy, such as nausea.
 5. Recommend birthing classes to prepare the mother for the birthing process.
2. A parent has brought her 6-month-old infant in for a well-child check. Which of her statements indicates a need for further teaching?
 1. "I can start giving her whole milk at about 12 months."

2. "I can continue to breastfeed for another 6 months."
 3. "I can give her plenty of fruit juice to increase her vitamin intake."
 4. "I can start giving her solid food now, introducing one food at a time."
3. A nurse is teaching the mother of a young infant about prevention of sudden infant death syndrome (SIDS). Which of the following statements indicates that the teaching has been effective? (Select all that apply.)
1. "I'll let the baby sleep in bed with me so I can watch her."
 2. "I'll remove stuffed animals and pillows from the crib."
 3. "I'll place my baby on her back for sleep."
 4. "I'll be sure to keep my baby's room cool."
 5. "I'll keep a crib bumper in the bed to prevent drafts."
4. Sequence the skills in the expected order of gross-motor development in an infant, beginning with the earliest skill.
1. Can lift head 45 degrees off table, when prone
 2. Pulls self to standing position
 3. Sits upright without support
 4. Rolls from back to abdomen
 5. Rolls from abdomen to back
5. Parents are concerned about their toddler's negativism. To avoid a negative response, which of the following is the best way for a nurse to demonstrate asking the toddler to eat lunch?
1. Would you like to eat your lunch now?
 2. Would you like to sit at the big table to eat?
 3. When would you like to eat your lunch with your friends?
 4. Would you like apple slices or applesauce with your sandwich?

6. When nurses are communicating with adolescents, they should:
 1. Ask closed-ended questions to get straight answers.
 2. Ask the adolescent to collaborate on plan of care.
 3. Avoid looking for meaning behind adolescents' words or actions.
 4. Avoid discussing sensitive issues such as sex and drugs.
7. You are caring for a 4-year-old child who is hospitalized for an infection. He tells you that he is sick because he was "bad." Which is the most correct interpretation of his comment?
 1. Indicative of maladaptive stress response
 2. Representative of his cognitive development
 3. Suggestive of excessive discipline at home
 4. Indicative of his developing sense of inferiority
8. At a well-child examination, the mother comments that her toddler eats little at mealtime, will sit only briefly at the table, and wants snacks all the time. Which of the following should the nurse recommend? (Select all that apply.)
 1. Provide nutritious snacks for a healthy diet.
 2. Offer rewards for eating at mealtimes.
 3. Avoid snacks so she is hungry at mealtime.
 4. Offer finger foods so she can eat as she walks.
 5. Explain to her why eating at mealtime is important.
9. A 15-year-old patient tells the nurse that she is sexually active. What is the best action by the nurse?
 1. Contact her parents to alert them of her need for birth control.
 2. Explain that having sex is not appropriate for her age-group.
 3. Counsel her on safe sex practices and on minimizing health risks.
 4. Ask her to have her partner come to the clinic for STI testing.

10. A 4-month-old infant has not been feeling well for 2 days.
Which number on the image identifies the area of the infant's head where the nurse can assess for dehydration?

- 1. 1
- 2. 2
- 3. 3
- 4. 4
- 5. 5

Young and Middle Adults

OBJECTIVES

- Discuss developmental theories of young and middle adults.
- List and discuss major life events of young and middle adults and the childbearing family.
- Describe developmental tasks of the young adult, the childbearing family, and the middle adult.
- Discuss the significance of family in the life of the young and middle adult.
- Describe normal physical changes in young and middle adulthood and pregnancy.
- Discuss cognitive and psychosocial changes occurring during the young and middle adult years.
- Describe health concerns of the young adult, the childbearing family, and the middle adult.
- Describe intimate partner violence.

Young and middle adulthood are developmental periods that pose challenges, rewards, and crises. Challenges often include the demands of working and raising families and other crises, such as caring for aging parents or the possibility of job loss in a changing economic environment. Classic works by developmental theorists such as [Diekelmann \(1976\)](#) and [Erikson \(1963, 1982\)](#) attempted to describe the phases of young and middle adulthood and related developmental tasks (see [Chapter 11](#)). More recent work has identified an additional phase of development in the young adult: emerging adulthood.

Faced with a societal structure that differs greatly from the norms of 20 or 30 years ago, both men and women are assuming different roles in today's society. Men were traditionally the primary supporters of the family. Today many women pursue careers and contribute significantly to their families' incomes. Women comprise half of the workforce. They are the sole or co-breadwinner in half of American families with children. However, women on average earn less than men in almost every occupation. Women from minority groups and those in lower socioeconomic levels have an even greater wage gap ([Institute for Women's Policy Research \[IWPR\], 2019](#)).

Developmental theories help explain the life events and developmental tasks of the young and middle adult (see [Chapter 11](#)). Patients present challenges to nurses who themselves are often young or middle adults coping with the demands of their respective developmental period. Nurses need to recognize the needs of their patients even if they are not experiencing the same challenges and events.

Young Adults

Young adulthood is the period between the late teens and the mid to late 30s ([Edelman and Kudzma, 2018](#)). In the past several decades, the period of life called **emerging adulthood** has been identified as lasting from the late teens to mid-twenties ([Fioretti et al., 2017](#)). This stage of development is unique from young adulthood and extended adolescence. It is a stage that is much freer from parental control and much more a period of independent exploration compared with adolescence. It differs from young adulthood since most young people in their twenties have not made those transitions historically associated with adult status, especially marriage and parenthood. In this stage young adults are faced with the tasks of identity development, who they want to be, and how to attain their goals ([Layland et al., 2018](#)).

It is estimated that in 2017 young adults 20 to 34 years of age made up approximately 22% to 24% of the population ([US Census Bureau, 2018](#)). According to the [Pew Research Center \(2019\)](#), today's young adults are history's first "always-connected" generation, with digital technology and social media as major aspects of their lives. They adapt well to new experiences and are more ethnically and racially diverse than previous generations. Young adults increasingly move away from their families of origin, establish career goals, and decide whether to marry or remain single and whether to begin families.

Physical Changes

The young adult usually completes physical growth by the age of 20. An exception to this is the pregnant or lactating woman. The physical, cognitive, and psychosocial changes and the health concerns of the pregnant woman and the childbearing family are extensive.

Young adults are usually quite active, experience severe illnesses less frequently than older age-groups, tend to ignore physical symptoms, and often postpone seeking health care. Physical strength typically peaks, and physical characteristics of young adults begin to change as middle age approaches. Physical changes in weight and muscle mass often occur as a result of diet, exercise, and lifestyle patterns. Assessment findings are generally within normal limits unless an illness is present.

Cognitive Changes

Critical thinking habits increase steadily through the young adult years. Formal and informal educational experiences, general life experiences, and occupational opportunities dramatically increase the individual's conceptual, problem-solving, and motor skills.

Identifying an occupational direction is a major task of young adults. When people know their skills, talents, and personality characteristics, educational preparation and occupational choices are easier and more satisfying. Some young adults pursue postsecondary education to attain their occupational goals. Postsecondary education, which includes vocational training (e.g., carpentry, welding) and earned degrees from colleges or universities (e.g., associate, baccalaureate, and graduate degrees), is often the entry-level educational requirement for many of the fastest-growing occupations in the United States ([US Department of Labor, 2019](#)).

An understanding of how adults learn helps nurses develop patient education plans (see [Chapter 25](#)). Adults enter the teaching-learning situation with a background of unique life experiences, including illness and injuries. Their adherence to regimens such as medications, treatments, or lifestyle changes such as smoking cessation involves decision-making processes. When determining the amount of information that an individual needs to make decisions about the prescribed course of therapy, consider factors that possibly affect his or her adherence to the regimen, including educational level, lifestyle habits, socioeconomic factors, and motivation and desire to learn.

Because young adults are continually evolving and adjusting to changes in the home, workplace, and social lives, their decision-making processes need to be flexible. The more secure young adults are in their roles, the more flexible and open they are to change. People who are insecure tend to be more rigid in making decisions ([Edelman and Kudzma, 2018](#)).

Psychosocial Changes

The emotional health of a young adult is related to the ability to address and resolve personal and social tasks. The young adult is often caught between wanting to prolong some of the freedom of adolescence and assume adult commitments. However, certain trends are relatively predictable. Between the ages of 23 and 28, the person refines self-perception and ability for intimacy. From 29 to 34 the person directs enormous energy toward achievement and mastery of the surrounding world. The years from 35 to 40 are a time of vigorous examination of life

goals and relationships. Sometimes as a result of this reexamination people make changes in personal, social, and occupational areas.

Cultural factors such as ethnicity and gender have a sociological and psychological influence in a young adult's life, and these factors pose challenges for nursing care (see [Chapter 9](#)). Each person holds individualized definitions of health and illness and the behaviors necessary to stay healthy. Nurses and other health professionals bring with them distinct practices for the prevention and treatment of illness. Knowing too little about a patient's self-perception or beliefs regarding health and illness may create conflict between a nurse and patient.

Changes in the traditional role expectations of both men and women in young adulthood lead to challenges for nursing care. For example, young adults often struggle with balancing job demands, personal relationships, the needs of the family, and socialization ([Brough et al., 2018](#)). Thus the struggle to balance these factors is a potential source of stress for the young adult, which may impact coping resources, health promotion behaviors, and level of health ([Amnie, 2018](#)).

Health is not merely the absence of disease; it also involves wellness in all human dimensions (see [Chapter 6](#)). Through patient education the nurse provides a young adult with access to health promotion resources and appropriate referrals to improve coping and health behaviors. The young adult needs to make decisions concerning career, marriage, and parenthood. Although each person makes these decisions based on individual factors, a nurse needs to understand the general principles involved in these aspects of psychosocial development while assessing the young adult's psychosocial status.

Lifestyle

Family history of cardiovascular, renal, endocrine, or neoplastic disease increases a young adult's risk of illness. In addition, young adults, especially young men, are more likely to participate in some health risk behaviors, such as dangerous driving practices, smoking, substance abuse, overexposure to sun, binge drinking, and increased unprotected sexual activity ([Masiero et al., 2018](#)). Your role in health promotion is to identify unique modifiable factors and provide gender and culturally specific patient education and support to reduce unhealthy lifestyle behaviors ([Kritsotakis et al., 2016](#)). These lifestyle changes can include diet and exercise modifications, use of seat belts, and reduction in risky sex practices.

A personal lifestyle assessment (see [Chapter 6](#)) helps nurses and patients identify habits that increase the risk for cardiac, malignant, pulmonary, renal, or other chronic diseases. The assessment includes general life satisfaction, hobbies, and interests; habits such as diet, sleeping, exercise, sexual habits, and use of caffeine, tobacco, alcohol, and illicit drugs; home conditions and pets; economics, including type of health insurance; occupational environment, including type of work and exposure to hazardous substances; and physical or mental stress. Military records, including dates and geographical area of assignments, may also be useful in assessing the young adult for risk factors. Prolonged stress from lifestyle choices increases wear and tear on the adaptive capacities of the body, and stress-related illnesses, such as ulcers, emotional disorders, and infections, sometimes occur (see [Chapter 37](#)).

Career

Successful employment is important in the lives of most men and women. This not only helps to ensure economic security but also leads to fulfillment, friendships, social activities, support, and respect from co-workers.

The average adult under age 35 has an average debt of \$67,400 ([Renzulli, 2018](#)). The greatest percentage of that debt is educational. The average millennial household owes \$14,800 in student loans ([Renzulli, 2018](#)). Therefore many young adults choose a two-career family, which has benefits and liabilities. In addition to increasing the family's financial base, the person who works outside the home is able to expand friendships, activities, and interests. However, stress exists in a two-career family as well. These stressors result from a transfer to a new city; increased expenditures of physical, mental, or emotional energy; child care demands; or household needs. When partners share decision making and responsibilities, the stressors related to a two-career family decrease. For example, some families may decide to limit recreational expenses and instead hire someone to do routine housework.

Sexuality

The development of secondary sex characteristics occurs during the adolescent years (see [Chapter 12](#)). Physical development is accompanied by sexual maturation. The young adult usually has emotional maturity to complement the physical ability and therefore is able to develop mature sexual relationships and establish intimacy. Young adults who have failed

to achieve the developmental task of personal integration sometimes develop relationships that are superficial and stereotyped (Varcarolis, 2017).

The psychodynamic aspect of sexual activity is as important as the type or frequency of sexual intercourse to young adults (see Chapter 34). To maintain total wellness, encourage young adults to assess their sexual activity and practice safe sex. Assist them to realize that their sexual needs and concerns are normal and may change over time (Shaw and Rogge, 2017). When necessary, help to identify risky sexual behaviors, such as unprotected sex or multiple sexual partners. Ensure that these young adults have adequate sexual health education regarding birth control and the prevention of sexually transmitted infections (STIs).

Childbearing Cycle

Conception, pregnancy, birth, and the **puerperium** are major phases of the childbearing cycle. The changes during these phases are complex. Childbirth education classes can prepare pregnant women, their partners, and other support people to participate in the birthing process (Fig. 13.1). Some health care agencies provide either professional labor support or a lay **doula**, a support person to be present during labor to assist women who have no other source of support. The stress that many women experience after childbirth may have a significant impact on postpartum women's health.

FIG. 13.1 Nurse providing Lamaze class for expectant young adults.

Types of Families

During young adulthood most individuals experience singlehood and the opportunity to be on their own. Those who eventually marry or establish long-term partnerships encounter several changes as they take on new responsibilities. For example, many couples choose to become parents (Fig. 13.2). Some young adults choose alternative lifestyles, and different family forms emerge (see Chapter 10).

FIG. 13.2 Parent-child nurturing is important in adapting to a newborn.
From Hockenberry MJ, Wilson D: *Wong's nursing care of infants and children*, ed 10, St Louis, 2015, Mosby.

Singlehood

The social pressure to get married has changed, and some young adults may choose not to marry until their late 20s or early 30s or not at all. For young adults who remain single, parents and siblings become the nucleus for a family. Some view close friends and associates as “family.” One cause for the increased single population is the expanding career opportunities for women. Women enter the job market with greater career potential and have greater opportunities for financial independence. More single individuals are choosing to live together outside marriage and become parents either biologically or through adoption. Similarly, many married couples choose to separate or divorce if they find their marital situation unsatisfactory.

Parenthood

Knowledge about sexuality and the availability of contraception help people decide when and if to start a family. Sometimes social pressures

encourage young adults to have children. Economic considerations frequently enter into the decision-making process because of the expense of childrearing. General health status and age are also considerations in decisions about parenthood.

Alternative Family Structures and Parenting

Changing norms and values about family life in the United States reveal basic shifts in attitudes about family structure (see [Chapter 10](#)). The trend toward greater acceptance of cohabitation without marriage is a factor in the greater numbers of infants being born to single women. In addition, approximately 6 million American children and adults have parents who are lesbian, gay, bisexual, transgender, or queer (LGBTQ). Approximately 131,000 same-sex households include children under the age of 18 ([Rossi, 2018](#); [Bos et al., 2016](#)). The American Academy of Pediatrics (AAP), in recognizing the needs of gay and lesbian parents and their children, published a policy statement supporting adoption of children and the parenting role by same-sex parents ([AAP, 2013](#)). Research demonstrates that there is no difference in child health outcomes between same-sex and different-sex parent households ([Bos et al., 2016](#)).

Emotional Health

Young adults need physical and emotional resources and support systems to meet the many challenges, tasks, and responsibilities they face. During psychosocial assessment of young adults, assess for signs of emotional health that support successful maturation in this developmental stage (e.g., satisfaction with personal growth and development, satisfaction with relationships, and attainment of long-term goals related to education, employment, housing, and relationships).

Health Risks

Health risk factors for a young adult originate in the community, lifestyle patterns, and family history. The lifestyle habits that activate the stress response (see [Chapter 37](#)) increase the risk of illness. Young adults may have optimistic bias related to specific behaviors, such as smoking and alcohol consumption. When optimistic bias is present, young adults do not perceive that associated health risks for cancer and chronic cardiac and pulmonary diseases will affect their level of health ([Masiero et al., 2018](#)). Smoking is a well-documented risk factor for pulmonary, cardiac, and

vascular diseases in smokers and the individuals who receive secondhand smoke. Electronic cigarette (e-cigarette) or vaping of substances, such as tobacco or cannabis, has the potential for health risks developing over time due to the inhaled pollutants (Sommerfeld et al., 2018). The nicotine in tobacco is a vasoconstrictor that acts on the coronary arteries, increasing the risk of angina, myocardial infarction, and coronary artery disease. Nicotine also causes peripheral vasoconstriction and leads to vascular problems.

Family History

A family history of a disease sometimes puts a young adult at risk for developing it in the middle- or older-adult years. For example, a young man whose father and paternal grandfather had myocardial infarctions (heart attacks) in their 50s has a risk for a future myocardial infarction. The presence of chronic illnesses such as diabetes mellitus or certain cancers in the family increases the family member's risk of developing the diseases (see Chapter 8). Regular physical examinations and screenings are important since certain conditions such as high blood pressure, high blood sugar, and high cholesterol levels may not have any symptoms in the early stages. In addition, the American Cancer Society (2018) now recommends early routine screening for colorectal cancer and even earlier screening for individuals with a family history of colorectal cancers. Genomic science and resultant technologies identify people at risk for disease through the use of genetic screening. Understanding the role genomics plays in the health of individuals and families enables clinicians to better advise young adults related to current and future health care.

Personal Hygiene Habits

As in all age-groups, some personal hygiene habits in the young adult are risk factors. Sharing eating utensils with a person who has a contagious illness increases the risk of illness. Poor dental hygiene increases the risk of periodontal disease. Individuals avoid gingivitis (inflammation of the gums) and periodontitis (loss of tooth support) through oral hygiene (see Chapter 40).

Violent Death and Injury

Violence is a common cause of mortality and morbidity in the young-adult population (Shane et al., 2018). Factors that predispose individuals to violence, injury, or death include poverty, family breakdown, child abuse

and neglect, opioid and other drug use (dealing or illegal use), repeated exposure to violence, and ready access to guns. It is important to perform a thorough psychosocial assessment, including such factors as behavioral patterns, history of physical and substance abuse, education, work history, and social support systems to detect personal and environmental risk factors for violence. Death and injury primarily occur from physical assaults, motor vehicle or other accidents, and suicide attempts in young adults ([Shane et al., 2018](#)).

Intimate Partner Violence

Intimate partner violence (IPV), formerly referred to as domestic violence, is a global public health problem. It exists along a continuum from a single episode of violence to ongoing battering. IPV often begins with emotional or mental abuse and may progress to physical or sexual assault. Each year women in the United States experience approximately 4.8 million intimate partner-related physical assaults and rapes, and men are the victims of approximately 2.9 million intimate partner-related physical assaults ([Roberts et al., 2018](#)). Physical injuries from IPV range from minor cuts and bruises to broken bones, internal bleeding, head trauma, and death. IPV is linked to such harmful health behaviors as smoking, alcohol abuse, drug use, and risky sexual activity. Risk factors to look for in an assessment that suggest perpetration of IPV include using drugs or alcohol, especially heavy drinking; unemployment; low self-esteem; gambling; antisocial or borderline personality traits; desire for power and control in relationships; and being a victim of physical or psychological abuse ([Roberts et al., 2018](#); [Bonomi et al., 2014](#)). An increased risk of violence occurs during the reproductive years, and a pregnant woman has a greater risk of being a victim of IPV than a nonpregnant woman. Women experiencing IPV may be more likely to delay prenatal care and are at increased risk for multiple poor maternal and infant health outcomes, such as low maternal weight gain, infections, high blood pressure, vaginal bleeding, and delivery of a preterm or low-birth-weight infant ([Ferdos et al., 2018](#)).

Building Competency in Patient-Centered Care

You are caring for Joan, a 25-year-old patient who has come alone to the clinic because she is experiencing insomnia. Throughout the assessment

interview Joan is slightly withdrawn, speaks quietly, and does not make eye contact. She does not work outside the home, and she acknowledges that her relationship with her husband, an engineer who lost his job as a result of downsizing 6 months ago, is “not going well.” Physical examination reveals scratches and bruises on Joan’s breasts, abdomen, and back. Refer to the CDC’s Intimate Partner Violence resource page (<https://www.cdc.gov/violenceprevention/intimatepartnerviolence/index.html>) to determine which assessment questions, approaches, and tools you can use to determine whether Joan is a victim of IPV. If Joan is experiencing IPV, what resources may help her?

Substance Abuse

Substance abuse is a social problem that directly or indirectly contributes to mortality and morbidity in young adults. Substance abuse includes alcohol and drugs. Young adults who are under the influence of substances sometimes are involved in motor vehicle accidents, often resulting in severe injuries, permanent disability, or death to everyone involved in the accident.

Dependence on stimulant or depressant drugs sometimes results in death. Overdose of a stimulant drug (“upper”) stresses the cardiovascular and nervous systems to the extent that death occurs. The use of depressants (“downers”) leads to an accidental or intentional overdose and death.

There is an ongoing opioid abuse crisis affecting young adults, which often occurs from overuse of opioid prescriptions (Beneitz and Gil-Alegre, 2017). This abuse is the result of the need to take regular and increasing doses of a drug in order to feel good or to avoid feeling bad. The abuse can cause several acute and toxic consequences (Beneitz and Gil-Alegre, 2017). Addiction is an illness that affects the individual, family, and friends; thus it is important to recommend that family and friends participate in the treatment process (Kelly et al., 2017).

Substance abuse can be difficult to diagnose, particularly in its early stages. Nonjudgmental questions about the use of legal drugs (prescribed drugs, tobacco, and alcohol), soft drugs (marijuana), and more problematic drugs (cocaine or heroin) are a routine part of any health assessment. The National Institute on Drug Abuse (NIDA, n.d.) recommends starting a conversation about substance abuse using these questions:

In the past year, how many times have you used the following:

- Alcohol—for men 5 or more in a day; for women 4 or more drinks in a day?
- Tobacco products?
- Prescription drugs for nonmedical reasons?
- Illegal drugs?

If the screening test suggests a patient is at risk, there are online tests available for further assessment, including the NIDA-Modified Alcohol, Smoking, and Substance Involvement Screening Test (NMASSIST). Explain that it is your role as a nurse to convey health recommendations. Recommend quitting before problems (or more problems) develop. Urge patients to talk with their health care providers about the specific medical reasons for quitting ([NIDA, n.d.](#)).

Caffeine is a naturally occurring legal stimulant that is readily available in a variety of foods and beverages and in over-the-counter medications such as cold tablets or allergy and analgesic preparations. Caffeine stimulates catecholamine release, which in turn stimulates the central nervous system; it also increases gastric acid secretion, heart rate, and basal metabolic rate. This alters blood pressure, increases diuresis, and relaxes smooth muscle. Consumption of large amounts of caffeine results in restlessness, anxiety, irritability, agitation, muscle tremor, sensory disturbances, heart palpitations, nausea or vomiting, and diarrhea in some individuals.

Human Trafficking

A significant social problem is the number of youth and young adults who run away or are homeless. Many risk becoming involved in illegal and dangerous activities to survive, including human trafficking ([Ashe-Goins, 2018](#)). The [United Nations Office on Drugs and Crime \(2019\)](#) defines human trafficking as the recruitment, transport, transfer, harboring, or receipt of a person by threat or use of force for the purpose of exploitation. Nurses in a variety of settings, such as emergency departments, clinics, and public health agencies, are one of the first lines of health professionals who can identify victims of human trafficking and identify safe living and health care and social resources ([Egyud et al., 2017](#)). Although human trafficking is often a hidden crime and accurate statistics are difficult to obtain, estimates indicate that over 80% of trafficking victims are female and 50% are children.

Unplanned Pregnancies

Unplanned pregnancies create stress that may result in adverse health outcomes for the mother, infant, and family. Often young adults have educational and career goals that take precedence over family development. Interference with these goals often affects future relationships and parent-child relationships.

The determination of situational factors that affect the progress and outcome of an unplanned pregnancy is important. Exploration of problems such as financial, career, and living accommodations; family support systems; potential parenting disorders; depression; and coping mechanisms is important in assessing the woman with an unplanned pregnancy.

Sexually Transmitted Infections

STIs are a major health problem in young adults. Examples of STIs include syphilis, chlamydia, gonorrhea, genital herpes, human papillomavirus (HPV), and acquired immunodeficiency syndrome (AIDS). STIs have immediate physical effects such as genital discharge, discomfort, and infection. They also lead to chronic disorders, cancer, infertility, or even death. They remain a major public health problem for sexually active people, with almost half of all new infections occurring in men and women younger than 24 years of age ([USDHHS, CDC, 2017](#)). Some young adults with STIs also experience intimate partner violence. The US Preventive Services Task Force has relevant recommendations for people with STIs and intimate partner violence. Safe and effective vaccines are available for some STIs. For example, HPV, which can cause several types of cancer, can be prevented through vaccination with Gardasil or Cervarix, both Food and Drug Administration (FDA)–approved vaccines for the prevention of HPV. As young people enter sexual relationships, it is important that health care providers acknowledge the normalcy of these relationships and assess which types of sexual activity young adult patients engage in to determine appropriate screening tests and preventive measures ([Gibson, 2016](#)). Also routinely screen for interpersonal violence and refer patients to appropriate community resources.

Environmental or Occupational Factors

A common environmental or occupational risk factor is exposure to work-related hazards or agents that cause diseases and cancer ([Table 13.1](#)). Examples include lung diseases, such as silicosis from inhalation of talcum

and silicon dust and emphysema from inhalation of smoke. Cancers resulting from occupational exposures may involve the lung, liver, brain, blood, or skin. Include questions regarding occupational exposure to hazardous material as a routine part of your assessment.

TABLE 13.1

Occupational Hazards/Exposures Associated with Diseases and Cancers

Job Category	Occupational Hazard/Exposure	Work-Related Condition/Cancer
Agricultural workers	Pesticides, infectious agents, gases, sunlight	Pesticide poisoning, "farmer's lung," skin cancer
Anesthetists	Anesthetic gases	Reproductive effects, cancer
Automobile workers	Asbestos, plastics, lead, solvents	Asbestosis, dermatitis
Carpenters	Wood dust, wood preservatives, adhesives	Nasopharyngeal cancer, dermatitis
Cement workers	Cement dust, metals	Dermatitis, bronchitis
Dry cleaners	Solvents	Liver disease, dermatitis
Dye workers	Dyestuffs, metals, solvents	Bladder cancer, dermatitis
Glass workers	Heat, solvents, metal powders	Cataracts
Hospital workers	Infectious agents, cleansers, latex gloves, radiation	Infections, latex allergies, unintentional injuries
Insulators	Asbestos, fibrous glass	Asbestosis, lung cancer, mesothelioma
Jackhammer operators	Vibration	Raynaud's phenomenon
Lathe operators	Metal dusts, cutting oils	Lung disease, cancer
Office computer workers	Repetitive wrist motion on computers, eyestrain	Tendinitis, carpal tunnel syndrome, tenosynovitis

Health Concerns

Health Promotion

Some lifestyle choices (e.g., use of tobacco or alcohol, sexual practices) put young adults at risk for illnesses or disabilities during their middle- or older-adult years. Young adults are genetically susceptible to certain chronic diseases such as diabetes mellitus and familial hypercholesterolemia (Huether and McCance, 2017). Making lifestyle changes may prevent these types of diseases in later years. Also encourage adults to perform monthly skin, breast, or male genital self-examination (see Chapter 30). Breast cancer is the most common major cancer among women in the United States, with a steadily increasing incidence. Although the incidence is low in the young adult age-group, every year approximately 1000 women under age 40 die from breast cancer. When breast cancer does develop in young adult women, they face unique challenges (Young Survivors Coalition, 2019):

- The possibility of early menopause and body image concerns and sexual dysfunction
- Potential fertility issues (e.g., the risks associated with pregnancy after diagnosis and treatment)
- Needing to sometimes balance raising small children while enduring treatment and subsequent side effects
- Coping with psychosocial issues (e.g., anxiety, depression).

Your role as patient educator is extremely important in teaching female patients about breast self-examinations (BSEs) and current breast screening recommendations. Prolonged exposure to ultraviolet rays of the sun by adolescents and young adults increases the risk for development of skin cancer later in life. Crohn's disease, a chronic inflammatory disease of the small intestine, most commonly occurs between 15 and 35 years of age. Many young adults have misconceptions regarding transmission and treatment of STIs. Encourage partners to know one another's sexual history and practices. Be alert for STIs when patients come to clinics with complaints of urological or gynecological problems (see [Chapter 34](#)). Assess young adults for knowledge and use of safe-sex practices and genital self-examinations.

Psychosocial Health

The psychosocial health concerns of the young adult are often related to job (money and job stability) and family stressors. Stress is valuable because it motivates a patient to change. However, if the stress is prolonged and the patient is unable to adapt to the stressor, health problems develop (see [Chapter 37](#)). Some mental health disorders such as depression also begin in this age-group. These conditions may manifest during young adulthood, but symptoms and treatment often continue into middle adulthood and beyond ([Varcarolis, 2017](#)).

Job Stress

Job stress can occur every day or from time to time. Most young adults are able to handle day-to-day crises ([Fig. 13.3](#)). Situational job stress can occur when a new boss enters the workplace, a deadline is approaching, the worker has new or greater numbers of responsibilities, or there is a risk for or actual corporate downsizing. Job stress affects health behaviors, and there is greater use of tobacco and alcohol, poor eating habits, impaired sleeping, and lack of exercise ([Wang et al., 2018](#)). Because individuals

perceive jobs differently, the types of job stressors, coping strategies, and changes in health behaviors vary from patient to patient (Box 13.1). Your assessment of a young adult includes a description of the usual work performed, changes in job demands, changes in sleep or eating habits, and evidence of an increase in irritability or nervousness.

FIG. 13.3 The ability to handle day-to-day challenges at work minimizes stress.

Box 13.1 Evidence-Based Practice Assessing for Workplace Job Stress

PICOT Question: Do health promotion behaviors affect workplace job stress in young adults?

Evidence Summary

Workplace job stress is an important factor affecting the health of the working population. In addition, workplace job stressors affect personal

relationships, including those in the home and family. Likewise, relationship, home, and family stressors can affect workplace stressors and subsequently job performance and satisfaction (Padkapayeva et al., 2018). Poor health promotion behaviors have the potential to decrease a person's ability to cope with these stressors. However, research shows that incorporating consistent positive health promotion behaviors can improve perception of the stressor and job performance (Wang et al., 2018; Padkapayeva et al., 2018). In the health care professions, especially the nursing profession, workplace stressors are associated with high nurse turnover and psychosomatic complaints (Williams et al., 2018).

Application to Nursing Practice

- Ask patients about potential job-related stressors and whether these stressors have any impact on work-life balance (Conroy and Tabbenhoff, 2018; Padkapayeva et al., 2018).
- Assess patient's health promotion behaviors (e.g., diet, sleep, exercise habits) (Williams et al., 2018).
- Assist patients to identify and use personal coping strategies (Brough et al., 2018).
- Help patients identify sources of social and employer support (Conroy and Tabbenhoff, 2018).
- Partner with patients to identify positive changes in health promotion behaviors (Wang et al., 2018; Williams, et al., 2018)

REFLECT NOW

One of your classmates had a difficult time in yesterday's clinical and is having difficulty participating in the skills lab exercise. During the break she confides that the nurses on the clinical unit don't help her find any equipment, and all she could do last night was think about how "stressful" the clinical site appears to be. Think about what you need to know about how your classmate copes with stress and her health promotion behaviors. How does she prepare for her clinical or skills lab experience?

Family Stress

Because of the multiplicity of changing relationships and structures in the emerging young-adult family, stress is frequently high (see [Chapter 10](#)). Situational family stressors occur during events such as births, deaths, illnesses, marriages, and job losses. Stress is often related to a number of variables, including the career paths and job stressors for both partners, and leads to dysfunction in the young-adult family ([Padkapayeva et al., 2018](#)). When a patient seeks health care and presents stress-related symptoms, you need to assess for the occurrence of a life-change event.

Each family member has certain predictable roles or jobs. These roles enable a family to function and be an effective part of society. When they change as a result of illness, a situational crisis often occurs. Assess environmental and familial factors, including support systems and coping mechanisms commonly used by family members.

Infertility

[According to the American Society for Reproductive Medicine \(1996-2019\)](#), **infertility** is the result of a disease (an interruption, cessation, or disorder of body functions, systems, or organs) of the male or female reproductive tract that prevents the conception of a child or the ability to carry a pregnancy to delivery. Infertility evaluation begins after a couple has unprotected intercourse for about 12 months with the failure to conceive. An estimated 10% to 15% of reproductive couples are infertile, and many are young adults. However, approximately half of the couples evaluated

and treated in infertility clinics become pregnant. For some infertile couples a nurse is the first resource they identify. Nursing assessment of the infertile couple includes comprehensive histories of both the male and female partners to determine factors that have affected fertility and pertinent physical findings (see [Chapter 30](#)).

Obesity

Obesity is a major health problem. Approximately 16% of emerging adults are at risk for significant weight gain, which places them at risk for health problems in later life ([Johnson and Annesi, 2018](#)). It is influenced by poor diet, including eating fast food, excessive sugar intake from soft drinks, and increases in portion size, and a steady decline in physical activity ([Sahoo et al., 2015](#)). These factors are further complicated by family characteristics, such as parenting style, parents' lifestyles, and environmental factors such as school policies and demographics. Obesity in young adults is further associated with a variety of life events, such as enrolling in college, getting married, and beginning a family ([Lanoye et al., 2016](#)). Obesity is linked to the development of conditions such as type 2 diabetes, hypertension, high cholesterol, asthma, and joint problems. In addition, obesity in this age group increases the risk for cancer, morbidity, and mortality ([Berger, 2018](#)). Nursing assessment of diet and physical activity of young adults is an important part of data collection

Exercise

People of all ages, both male and female, benefit from regular physical activity (see [Chapter 38](#)); however, young many adults spend more time with technology and less time engaged in physical activity. Exercise in young adults is important to prevent or decrease obesity and the development of chronic health conditions such as high blood pressure, diabetes, and specific cancers ([Berger, 2018](#)). Conduct a thorough musculoskeletal assessment and exercise history to develop a realistic exercise plan. Encourage regular exercise within the patient's daily schedule.

Pregnant Woman and the Childbearing Family

A developmental task for many young adult couples is the decision to begin a family. Although the physiological changes of pregnancy and childbirth occur only in the woman, cognitive and psychosocial changes and health concerns affect the entire childbearing family, including the

baby's father, siblings, and grandparents. Young single-parent families tend to be particularly vulnerable, both economically and socially.

Prenatal Care

Women who are anticipating pregnancy benefit from good health practices before conception, including a balanced diet, folic acid, exercise, dental checkups, prenatal care, avoidance of alcohol, and cessation of smoking once conception occurs.

Prenatal care is the routine examination of the pregnant woman by an obstetrician or advanced practice nurse such as a nurse practitioner or certified nurse-midwife. Prenatal care includes a thorough physical assessment of a pregnant woman during regularly scheduled intervals; provision of information regarding STIs, other vaginal infections, and urinary infections that adversely affect the fetus; and counseling about exercise patterns, diet, and child care. Regular prenatal care addresses health concerns that may arise during the pregnancy.

Physiological Changes

The physiological changes and needs of the pregnant woman vary with each trimester. Be familiar with them, their causes, and implications for nursing. All women experience some physiological changes in the first trimester. For example, they commonly have morning sickness, breast enlargement and tenderness, and fatigue. During the second trimester growth of the uterus and fetus results in some of the physical signs of pregnancy. During the third trimester increases in **Braxton Hicks contractions** (irregular, short contractions), fatigue, and urinary frequency occur.

Postpartum

Postpartum is a period of approximately 6 weeks after delivery. During this time a woman's body reverts to its pre-pregnant physical status. Determine the woman's knowledge of and ability to care for both herself and her newborn baby. Assessment of parenting skills and maternal-infant interactions is particularly important. The process of **lactation**, or breastfeeding, offers many advantages to both the new mother and baby. For the inexperienced mother breastfeeding can be a source of anxiety and frustration. Be alert for signs that the mother needs information and assistance (e.g., the breastfed baby fails to "latch" to the mother's breast or infant weight gain is low).

Needs for Education

The entire childbearing family needs education about pregnancy, labor, delivery, breastfeeding, and integration of the newborn into the family structure.

Psychosocial Changes

Like the physiological changes of pregnancy, psychosocial changes occur at various times during the 9 months of pregnancy and in the puerperium. [Table 13.2](#) summarizes the major categories of psychosocial changes and implications for nursing intervention.

TABLE 13.2

Major Psychosocial Changes During Pregnancy

Category	Implications for Nursing
Body image	Morning sickness and fatigue contribute to poor body image. Increase in breast size sometimes makes the woman feel more feminine and sexually appealing. Encourage her to take extra time with hygiene and grooming, trying new hairstyles and makeup. Woman begins to “show” during the second trimester and starts to plan maternity wardrobe. Woman has general feeling of well-being when she feels the baby move and hears the heartbeat. Woman feels big, awkward, and unattractive during third trimester when fetus is growing more rapidly.
Role changes	Both partners think about and have feelings of uncertainty about impending role changes. Both partners have feelings of ambivalence about becoming parents and concern about ability to be parents.
Sexuality	Woman needs reassurance that sexual activity will not harm fetus. Woman's desire for sexual activity is influenced by body image. Woman sometimes desires cuddling and holding rather than sexual intercourse.
Coping mechanisms	Woman needs reassurance that childbirth and child-rearing are natural and positive experiences but are also stressful. When indicated, assist her to cope with particular stressors such as finding new housing, preparing the nursery, or participating in childbirth classes.
Stresses during puerperium	Woman returns home from hospital fatigued and unfamiliar with infant care. Woman experiences physical discomfort or feelings of anxiety or depression. Woman may experience subsequent feelings of guilt, anxiety, or possibly a sense of freedom or relief if she must return to work soon after delivery.

Health Concerns

The pregnant woman and her partner have many health questions. For example, they wonder whether the pregnancy and baby will be normal and whether they have the resources to properly care for the infant. Proper prenatal care has the potential to identify risks and pregnancy problems and meet most of the expectant mother's emotional and physical health needs. For some women, postpartum depression may occur. It is important to educate the mother and family members about common signs, such as overwhelming sadness, mood swings, impaired sleeping, withdrawal, and difficulty bonding with the infant ([NIMH, n.d.](#)).

Acute Care

Young adults typically require acute care for accidents, substance abuse, exposure to environmental and occupational hazards, stress-related illnesses, respiratory infections, gastroenteritis, influenza, urinary tract infections, and minor surgery. An acute minor illness causes a disruption in life activities of young adults and can increase stress in an already hectic lifestyle. Lack of insurance or underinsurance, dependency, and limitations posed by treatment regimens also increase frustration. To give them a sense of maintaining control of their health care choices, it is important to keep young adults informed about their health status and involve them in health care decisions.

Restorative and Continuing Care

The young adult's need for restorative and continuing care often results from motor vehicle accidents, trauma from violence, or chronic diseases affecting the young adult population, such as multiple sclerosis, rheumatoid arthritis, AIDS, and cancer. In general other chronic illnesses such as hypertension, coronary artery disease, and diabetes may not be recognized until later in life. When present, chronic illness or disability threatens a young adult's independence and results in the need to change personal, family, and career goals. Nursing interventions for the young adult faced with chronic illness or disability may need to focus on problems related to sense of identity, establishing independence, reorganizing intimate relationships, and family structure (see [Chapter 8](#)).

Middle Adults

The [US Census Bureau \(2018\)](#) reports that approximately 38% of the population are middle-age adults (ages 35 to 64). In middle adulthood an individual makes lasting contributions through involvement with others. During this period personal and career achievements have often already been experienced (see [Chapter 11](#)). Many middle adults find joy in helping their children and other young people become productive and responsible adults ([Fig. 13.4](#)). They also begin to help aging parents while being responsible for their own children, placing them in the **sandwich generation**. Using leisure time in satisfying and creative ways is a challenge that, if met satisfactorily, enables middle adults to prepare for retirement.

FIG. 13.4 Middle adults enjoy helping young people become productive and responsible adults.

Men and women need to adjust to inevitable biological changes. As in adolescence, middle adults use considerable energy to adapt self-concept and body image to physiological realities and changes in physical appearance. High self-esteem, a favorable body image, and a positive attitude toward physiological changes occur when middle adults engage in physical exercise, eat balanced diets, obtain adequate sleep, and follow good hygiene practices that promote vigorous, healthy bodies.

Physical Changes

Major physiological changes occur between 40 and 65 years of age. Because of this it is important to assess the middle adult's general health status. A comprehensive assessment offers direction for health promotion recommendations and planning and implementing any acutely needed interventions. The most visible changes during middle adulthood are graying of the hair, wrinkling of the skin, and thickening of the waist. Decreases in hearing and visual acuity are often evident during this period. Often these physiological changes during middle adulthood have an impact on self-concept and body image. [Table 13.3](#) summarizes abnormal findings to consider when conducting a physical examination (see [Chapter 30](#)). The most significant physiological changes during middle age are menopause in women and the climacteric in men.

TABLE 13.3**Abnormal Physical Assessment Findings in the Middle Adult**

Body System	Assessment Findings
Integument	Very thin skin Rough, flaky, dry skin Lesions
Scalp and hair	Excessive generalized hair loss or patchy hair loss Excessive scales
Head and neck	Large, thick skull and facial bones Asymmetry in movement of head and/or neck Drooping of one side of the face
Eyes	Reduced peripheral vision Asymmetrical position of the light reflex Drooping of the upper lid (ptosis) Redness or crusting around the eyelids
Ears	Discharge of any kind Reddened, swollen ear canals
Nose, sinuses, and throat	Nasal tenderness Occlusion of nostril Swollen and pale pink or bluish-gray nasal mucosa Sinuses tender to palpation or on percussion Asymmetrical movement or loss of movement of uvula Tonsils red or enlarged
Thorax and lungs	Unequal chest expansion Unequal fremitus, hyperresonance, diminished or absent breath sounds Adventitious lung sounds such as crackles and wheezes
Heart and vascular system	Pulse inequality, weak pulses, bounding pulses, or variations in strength of pulse from beat to beat Bradycardia or tachycardia Hypertension Hypotension
Breasts—female	Recent increase in size of one breast Pigskin-like or orange-peel appearance Redness or painful breasts
Breasts—male	Soft, fatty enlargement of breast tissue
Abdomen	Bruises, areas of local discoloration; purple discoloration; pale, taut skin Generalized abdominal distention Hypoactive, hyperactive, decreased, or absent bowel sounds
Female genitalia	Asymmetrical labia Swelling, pain, or discharge from Bartholin's glands Decreased tone of vaginal musculature Cervical enlargement or projection into the vagina Reddened areas or lesions in the vagina
Male genitalia	Rashes, lesions, or lumps on skin of shaft of penis Discharge from penis Enlarged scrotal sac Bulges that appear at the external inguinal ring or femoral canal when the patient bears down
Musculoskeletal system	Uneven weight bearing Decreased range of joint motion; swollen, red, or enlarged joint; painful joints Decreased strength against resistance
Neurological system	Lethargy Inadequate motor responses Abnormal sensory system responses: inability to smell certain aromas, loss of visual fields, inability to feel and correctly identify facial stimuli, absent gag reflex

Perimenopause and Menopause

Menstruation and ovulation occur in a cyclical rhythm in women from adolescence into middle adulthood. Perimenopause is the period during which ovarian function declines, resulting in a diminishing number of ova and irregular menstrual cycles; it generally lasts 1 to 3 years. **Menopause** is the disruption of this cycle, primarily because of the inability of the neurohormonal system to maintain its periodic stimulation of the endocrine system. The ovaries no longer produce estrogen and progesterone, and the blood levels of these hormones drop markedly. Menopause typically occurs between 45 and 60 years of age (see [Chapter 34](#)). Approximately 10% of women have no symptoms of menopause other than cessation of menstruation, 70% to 80% are aware of other changes but have no problems, and approximately 10% experience changes severe enough to interfere with activities of daily living.

Climacteric

The **climacteric** occurs in men in their late 40s or early 50s (see [Chapter 34](#)). Decreased levels of androgens cause climacteric. Throughout this period and thereafter a man is still capable of producing fertile sperm and fathering a child. However, penile erection is less firm, ejaculation is less frequent, and the refractory period is longer.

Cognitive Changes

Changes in the cognitive function of middle adults are rare except with illness or trauma. Some middle adults enter educational or vocational programs to prepare themselves with new skills and information for entering the job market or changing jobs.

Psychosocial Changes

The psychosocial changes in the middle adult involve expected events, such as children moving away from home, and unexpected events, such as separation from a partner or the death of a partner or close friend. You need to assess for major life changes and the impact that the changes have on the middle adult's state of health. Include individual psychosocial factors such as coping mechanisms and sources of social support in your assessment.

In the middle-adult years, as children depart from the household, the family enters the postparental family stage. Time and financial demands on the parents typically decrease, and the couple faces the task of

redefining their own relationship. It is during this period that many middle adults take on healthier lifestyles. Assessment of health promotion needs for the middle adult includes regular screening examinations, amount of rest, leisure activities, nutritional intake, and regular exercise. Also assess for the use of tobacco, alcohol, or illicit drugs. Assess the middle adult's social environment, including relationship concerns; communication and relationships with children, grandchildren, and aging parents; and caregiver concerns with parents or an ill spouse.

Career Transition

Career changes occur by choice or as a result of changes in the workplace or society. In recent decades middle adults change occupations more often for a variety of reasons, including limited upward mobility, decreasing availability of jobs, and seeking an occupation that is more challenging. In some cases downsizing, technological advances, or other changes force middle adults to seek new jobs. Such changes, particularly when unanticipated, result in stress that affects health, family relationships, self-concept, and other dimensions.

Sexuality

After the departure of their last child from the home, many couples redefine their relationships and find increased marital and sexual satisfaction. The onset of menopause and the climacteric affect the sexual health of the middle adult. Some women may desire increased sexual activity because pregnancy is no longer possible. Middle-aged men and women are able to engage in satisfying sexual relationships (see [Chapter 34](#) for physical changes).

Other factors influencing sexuality during this period include job stress, diminished health of one or both partners, and effects of some prescription medications. For example, antihypertensive agents have side effects that influence sexual desire or functioning. Antihypertensive medications, diuretics, and beta blockers can cause erectile dysfunction (ED) in men ([Burcham and Rosenthal, 2019](#)). Sometimes both partners experience sexual dysfunction caused by stresses related to sexual changes or a conflict between their sexual needs and self-perceptions and social attitudes or expectations.

Family Psychosocial Factors

Psychosocial factors involving the family include the stresses of singlehood, marital changes, transition of the family as children leave home, and the care of aging parents.

Singlehood

Many adults over 35 years of age in the United States have never been married. Many are college-educated people who embrace the philosophy of choice and freedom, delayed marriage, and delayed parenthood. Some middle adults choose to remain single but also opt to become parents either biologically or through adoption. Many single middle adults have no relatives but share a family type of relationship with close friends or work associates. Consequently some single middle adults may feel isolated during traditional “family” holidays such as Thanksgiving or Christmas. In times of illness middle adults who choose to remain single and childless rely on other relatives or friends, increasing caregiving demands of family members who also have other responsibilities. Nursing assessment of single middle adults needs to include a thorough assessment of psychosocial factors, including an individual’s definition of family and available support systems.

Marital Changes

Marital changes occurring during middle age include death of a spouse, separation, divorce, and the choice of remarrying or remaining single. A widowed, separated, or divorced patient goes through a period of grief and loss in which it is necessary to adapt to the change in marital status. Normal grieving progresses back and forth through a series of phases, and resolution of grief often takes a year or more. Assess the level of coping of the middle adult to the grief and loss associated with life changes (see [Chapter 36](#)).

Family Transitions

The departure of the last child from the home is also a stressor. Many parents welcome freedom from childrearing responsibilities, whereas others feel lonely or without direction. *Empty nest syndrome* is the term used to describe the sadness and loneliness that accompany children leaving home. Eventually parents need to reassess their marriage and try to resolve conflicts and plan for the future. Occasionally this readjustment phase leads to marital conflicts, separation, and divorce (see [Chapter 10](#)).

Care of Aging Parents

Increasing life spans in the United States and Canada have led to increased numbers of older adults in the population. Many middle adults find themselves caught between the responsibilities of caring for dependent children and those of caring for aging and ailing parents. Thus they find themselves in the sandwich generation, in which the challenges of caregiving can be stressful. The needs of family caregivers are being given more emphasis in the health care system.

The middle-adult and older-adult parents often have conflicting relationship priorities when the older adult strives to remain independent, such as maintaining his or her own living space or finances. Negotiation and compromise help to define and resolve problems. When meeting family caregivers, take the time to identify the health needs of both groups, and assist the multigenerational family in determining the health and community resources available to them as they make decisions and plans (Liu and Huang, 2018). Evaluate family relationships to determine family members' perceptions of responsibility, willingness and perceived loyalty in relation to caring for older-adult members (Ellington et al., 2018).

REFLECT NOW

You are caring for a middle-age couple who have decided to bring the wife's widowed mother, who has stage 4 metastatic breast cancer, to their home for end-of-life care. In order to help the family unit during the early phase of caregiving, think about information you might need, such as expectations the family may have about caregiving, what resources are available to the family, what other resources they might need, and how the family/couple solves problems.

Health Concerns

Health Promotion and Stress Reduction

Because middle adults experience physiological changes and face certain health realities, their perceptions of health and health behaviors are often important factors in maintaining health. It is important that middle adults maintain regular fitness as they grow older. Routine exercise, 20 to 30 minutes five or six times a week, promotes health (see [Chapter 38](#)). For example, there is an association between activity, cardiopulmonary fitness, and long-term health outcomes, especially pertaining to cardiovascular disease ([Benck et al., 2018](#)). For women and men with risks for osteoporosis, physical activity several times a week helps to maintain bone health ([Tabor et al., 2016](#)).

Stress across the life span is a health concern. Today's complex world makes individuals more prone to stress-related illnesses such as heart attacks and hypertension (see [Chapter 37](#)). When adults seek health care, nurses in outpatient and home health settings design targeted, culturally appropriate stress management programs focusing on wellness and guide patients to evaluate health behaviors, lifestyle, and environment ([Amnie, 2018](#); [Madva, 2018](#)).

Work with the patient to identify approaches to preventing stressful situations, such as habituation, change avoidance, time blocking, time management, and environmental modification (e.g., adding ramps, removing obstacles). Then help the patient to increase stress resistance (e.g., increase self-esteem, improve assertiveness, redirect goal alternatives, and reorient cognitive appraisal). Finally, help patients learn how to avoid the physiological response to stress. Encourage use of relaxation techniques, imagery, yoga, meditation, and biofeedback to recondition the patient's response to stress (see [Chapter 37](#)).

Obesity

Obesity is a growing, expensive health concern for middle adults. It is a complicated, multifactorial disease, with genetic, behavioral, socioeconomic, and environmental origins; obesity reduces quality of life and increases the risk for many serious chronic diseases and premature death ([Hruby and Hu, 2015](#)). A *Healthy People 2020* ([USDHHS, 2019](#)) goal relates to improvement of health-related quality of life and well-being, including physical well-being. Health consequences of obesity include high blood pressure, high blood cholesterol, type 2 diabetes, coronary heart disease, osteoarthritis, and obstructive sleep apnea. Research shows that the type of diet a patient chooses to follow is not as important as caloric restriction, which is associated with better weight outcomes ([Hruby and Hu, 2015](#)).

Forming Positive Health Habits

Positive health habits help maintain optimal function and reduce risk for chronic illnesses. Some habits support health (e.g., exercise and brushing and flossing the teeth each day) or prevent disease. For example, a middle-age woman's health care provider may encourage the patient to take vitamin D and calcium to enhance bone health and prevent osteopenia and osteoporosis (Tai et al., 2015; National Academies of Sciences, 2010).

During assessment obtain data on your patient's health behaviors. Learn what is important to a patient with regard to maintaining his or her health. Then determine which behaviors are positive and negative. Examples of positive health behaviors include regular exercise (see Chapter 38), adherence to healthy dietary habits, avoidance of excess consumption of alcohol, participation in routine screening and diagnostic tests for disease prevention and health promotion (e.g., laboratory screening for serum cholesterol or mammography), and lifestyle changes to reduce stress. Other habits involve risk factors to health (e.g., smoking or eating foods with little or no nutritional value).

To help patients form positive health habits, you act as a teacher and facilitator. By providing information about how the body functions and how patients can form and change habits relative to their own goals, patients' levels of knowledge regarding the potential impact of behavior on health are raised (Amnie, 2018). Offer positive reinforcement (such as praise and rewards) for health-directed behaviors and decisions. Such reinforcement increases the likelihood that the behavior will be repeated.

Help middle adults consider factors such as avoidance of STIs, prevention of opioid and substance abuse, and accident prevention in relation to decreasing health risks. For example, provide patients with information on STI causes, symptoms, and transmission. Discuss methods of protection during sexual activity with a patient in an open and nonjudgmental manner and reinforce the importance of practicing safe sex (see Chapter 34).

Changing poor health habits is hard; recognize that barriers to change exist (Box 13.2). Help patients recognize and modify unsafe and potential health hazards. You must partner with patients and families to minimize or eliminate these barriers.

Box 13.2 Barriers to Change

External Barriers

- Lack of facilities
- Lack of resources and materials
- Limited social support
- Lack of motivation
- Poor access to care

Internal Barriers

- Lack of knowledge
- Insufficient skills or motivation to change health habits
- Undefined short- and long-term goals

Health Literacy

Health literacy is defined as the cognitive and social skills that determine the motivation and ability of individuals to gain access to, understand, and use information in ways that promote and maintain good health (see [Chapter 25](#)). Health literacy is essential for a person to take responsibility for his or her own health. Lower health literacy may affect the ability to understand basic written health information or to read a prescription bottle correctly. There is a relationship between health literacy and health promoting behaviors, especially in patients with chronic illnesses, such as diabetes. Therefore, it is important to improve patients' health literacy while providing patient education to enhance health outcomes ([Chahardah-Cherik et al, 2018](#)).

People for whom English is a second language are at risk for low health literacy and may be unable to self-manage their health with lifestyle risk-factor modification to prevent the development of chronic diseases ([Nierengarten, 2018](#); [Fernandez-Gutierrez et al., 2018](#)). A professional interpreter may be necessary to ensure understanding of health information.

Psychosocial Health

Anxiety

Anxiety is a critical maturational phenomenon related to change, conflict, and perceived control of the environment. Adults often experience anxiety in response to the physiological and psychosocial changes of middle age. Such anxiety motivates an adult to rethink life goals and stimulates productivity. However, for some adults anxiety precipitates psychosomatic illness and preoccupation with death. In this case a middle adult views life as being half or more over and thinks in terms of the time left to live (Varcarolis, 2017).

Clearly, a life-threatening illness, marital transition, loss of a spouse or partner, or job stressor increases the anxiety of a patient and family. Use crisis intervention or stress-management techniques to help a patient adapt to the changes of the middle-adult years (see Chapter 37).

Depression

Depression is a mood disorder that manifests itself in many ways. Although the most frequent age of onset is between ages 14 and 44, it is common among adults in the middle years and has many causes. The risk factors for depression include a family history of depression, being female, being a member of the LGBTQ community, the postpartum period, a lack of social support, chronic illness, and negative stressful life events (Varcarolis, 2017). People with chronic illness or caregivers of family members with chronic and long-term illnesses have a greater level of depression (Madva et al., 2018). Symptoms vary with the individual and may include depressed mood, loss of interest in activities, impaired concentration, or feelings of worthlessness or guilt (Maurer, 2012). Symptoms can also be nonspecific, such as back pain, weight gain or loss, constipation, headaches, or fatigue. The abuse of alcohol or other substances makes depression worse.

Nursing assessment of a middle adult diagnosed with depression will depend on the setting in which you work. A focused data collection regarding individual and family history of depression, mood changes, cognitive changes, behavioral and social changes, and physical changes is ideal. However, there are useful and valid screening tools for depression, including the Patient Health Questionnaire (PHQ)-2, which may rule out, but not definitively diagnose, depression (Whooley et al., 1997). The PHQ-2 contains only two questions, using a Likert scale of 0 to 3: Over the past two weeks, how often have you been bothered by any of the following problems: Little interest or pleasure in doing things; Feeling down, depressed or hopeless. Collect assessment data from both the patient and

the patient's family because family data are often particularly important, depending on the level of depression the middle adult is experiencing.

Early-Onset Dementia

Early-onset dementia (EOD), or "presenile dementia," defines all dementia-related conditions before age 65 (Vieria et al., 2013). Depression and anxiety are prominent. As EOD progresses, agitation, apathy, and irritability worsen (Tanaka et al., 2015). EOD has major devastating psychological consequences, affecting people during their productive and leisure years, and also impacts family responsibilities. Patients and families need assistance to maintain independence in decision making and activities (Sakamoto et al., 2017).

Community Health Programs

Community health programs in clinics, self-help groups, and primary care practices offer services to prevent illness, promote health, and detect disease in the early stages. Nurses make valuable contributions to the health of the community by taking an active part in planning screening and teaching programs and support groups for middle adults (see Chapter 3).

Health education programs promote changes in behavior and lifestyle. As a health teacher, offer information that enables patients to make informed decisions about health practices within the context of health promotion. Make sure that educational programs are culturally appropriate (Williams et al., 2018). Changes to more positive health practices during young and middle adulthood lead to fewer or less complicated health problems as an older adult. During health counseling, collaborate with your patient to design a plan of action that addresses his or her health and well-being. Through objective problem solving you can help your patient grow and change (Edelman and Kudzma, 2018).

Acute Care

Acute illnesses and conditions experienced in middle adulthood are similar to those of young adulthood. However, injuries and acute illnesses in middle adulthood require a longer recovery period because of the slowing of healing processes. In addition, they are more likely to become chronic conditions. For middle adults in the sandwich generation, stress levels also increase as they balance responsibilities related to employment,

family life, care of children, and care of aging parents while recovering from an injury or acute illness.

Restorative and Continuing Care

Chronic illnesses affect the roles and responsibilities of middle adults. Some results of chronic illness are strained family relationships, modifications in family activities, increased health care tasks, increased financial stress, the need for housing adaptation, social isolation, medical concerns, and grieving. The degree of disability and a patient's perception of both the illness and the disability determine the extent to which lifestyle changes occur. A few examples of the problems experienced by patients who develop debilitating chronic illness during adulthood include role reversal, changes in sexual behavior, and alterations in self-image. Along with the current health status of a middle adult living with a chronic illness, you need to assess the knowledge base of both the patient and family. This assessment includes the medical course of the illness and the prognosis for the patient. You need to determine the coping mechanisms of the patient and family. In addition, you need to assess adherence to treatment and rehabilitation regimens, evaluate the need for community and social services, and make appropriate referrals.

Key Points

- Young and middle adult development involves orderly and sequential changes in characteristics and attitudes and is often related to the natural process of maturation.
- Young adults are in a stable period of normal physical development, which includes changes related to pregnancy.
- Cognitive development continues throughout the young- and middle-adult years.
- Emotional health of young and middle adults is correlated with the ability to address and resolve personal and social problems.
- Pregnant women need to understand physiological changes occurring in each trimester.

- Psychosocial changes and health concerns during pregnancy and the postpartum affect the parents, the siblings, and often the extended family.
- Health concerns of the young adult usually focus on health promotion habits and fertility and pregnancy issues.
- Intimate partner violence, formerly referred to as domestic violence, is a global public health problem. It exists along a continuum from a single episode of violence to ongoing battering.
- Midlife transition begins when a person becomes aware that physiological and psychosocial changes signify passage to another stage in life.
- Cognitive changes in middle age are often related to acute illnesses, early-onset dementia, or physical trauma.
- Psychosocial changes for middle adults often include career transition, sexuality, marital changes, family transition, and care of aging parents.
- Health concerns of middle adults commonly involve stress-related illnesses, health assessment, adoption of positive health habits, and issues with health literacy.

Reflective Learning

- A 24-year-old patient who smokes two packs of cigarettes per day comes to talk with you about quitting smoking. She began smoking when she was 14 years old. She states, "I just can't seem to kick the habit, no matter how hard I try."
 - What information do you need to know to help this patient quit smoking?
 - Which factors will have the greatest impact on health promotion related to smoking cessation in this patient?

- Think about your own health habits. How would you improve them? Select one that you would like to improve. What information would you need to be successful in changing this one habit?
- You have a clinical experience in a community-based clinic. In this clinic there is a young family who is homeless. What are the health risks of the young adult mother in this family?

Review Questions

1. A nurse is completing an assessment on a 27-year-old female patient. Which questions best assess the psychosocial aspects of this young woman's health? (Select all that apply.)
 1. Do you feel safe in your home and at work?
 2. How many fruits and vegetables do you typically eat every day?
 3. Describe your relationship with your family.
 4. Have you had the vaccine to prevent HPV?
 5. What are your long-term career goals?
2. Which factor affects a middle-age adult's adherence to a treatment plan?
 1. Gender
 2. Lifestyle
 3. Motivation
 4. Family history
3. A 36-year-old patient newly diagnosed with type 1 diabetes shares with you that he is frustrated with the time it takes to prepare meals and monitor his exercise and blood sugar. He also is having trouble understanding his insulin schedule. Which of the following suggestions would be most appropriate? (Select all that apply.)

1. Provide patient education materials that are easy to read.
 2. Refer this patient to a diabetes support group.
 3. Refer the patient to his endocrinologist.
 4. Suggest that the patient make an appointment with a registered dietitian.
 5. Suggest ways to modify his schedule.
4. Chronic illness (e.g., diabetes mellitus, hypertension, rheumatoid arthritis) may affect a person's roles and responsibilities during middle adulthood. When assessing the health-related knowledge base of both the middle-age patient with a chronic illness and his or her family, the assessment should include which of the following? (Select all that apply.)
1. Medical course of the illness
 2. Prognosis for the patient
 3. Coping mechanisms of the patient and family
 4. Socioeconomic status
 5. Need for community and social services.
5. A 50-year-old woman has elevated serum cholesterol levels that increase her risk for cardiovascular disease. One method to control this risk factor is to identify the patient's current diet trends and describe dietary changes to reduce the risk. This nursing activity is a form of:
1. Referral.
 2. Counseling.
 3. Health education.
 4. Stress-management techniques.
6. Intimate partner violence (IPV) is linked to which of the following factors? (Select all that apply.)
1. Alcohol abuse
 2. Marriage

3. Pregnancy
 4. Unemployment
 5. Drug use
7. Which are examples of positive health habits that may prevent the development of chronic illness later in life? (Select all that apply.)
1. Routine screening and diagnostic tests
 2. Unprotected sexual activity
 3. Regular exercise
 4. Consistent seat belt use
 5. Excess alcohol consumption
8. A 45-year-old woman who is obese tells a nurse that she wants to lose weight. Which assessment findings may be contributing factors to the woman's obesity? (Select all that apply.)
1. The woman works in an executive position that is very demanding.
 2. The woman says that she has little time to prepare meals at home and eats out at least four nights a week.
 3. The woman works out at the corporate gym at 5 AM three mornings per week.
 4. The woman says that she tries to eat "low-cholesterol" foods to help lose weight.
 5. The woman says that she vacations annually to reduce stress.
9. A 34-year-old female executive has a job with frequent deadlines. She notes that when the deadlines appear, she tends to eat high-fat, high-carbohydrate foods. She also explains that she gets frequent headaches and stomach pain during these deadlines. After receiving health education from the nurse, the executive decides to try yoga. In this scenario yoga is used as a(n):

1. Outpatient referral.
2. Counseling technique.
3. Health promotion activity.
4. Stress-management technique.

10. A nurse is completing an assessment on a male patient, age 24. Following the assessment, the nurse notes that his family history is not significant for chronic illnesses, and his physical and laboratory findings are within normal limits. Because of these findings, nursing interventions are directed toward activities related to: (Select all that apply.)

1. Instructing him to return in 2 years.
2. Instructing him in secondary prevention.
3. Instructing him in health promotion activities.
4. Instructing him about routine screenings.
5. Instructing him about proper vaccinations.

Answers: 1.1, 3, 5; 2.3; 3.1, 2, 4, 5; 4.1, 2, 3, 5; 5.3; 6.1, 3, 4, 5; 7.1, 3, 4; 8.1, 2; 9.4; 10.3, 4, 5.

Older Adults

OBJECTIVES

- Identify common myths and stereotypes about older adults.
- Discuss common developmental tasks of older adults.
- Describe common physiological changes of aging.
- Differentiate among delirium, dementia, and depression.
- Discuss issues related to psychosocial changes of aging.
- Describe the multifaceted aspects of elder mistreatment.
- Describe selected health concerns of older adults.
- Identify nursing interventions related to the physiological, cognitive, and psychosocial changes of aging.

KEY TERMS

Ageism, p. 176

Delirium, p. 181

Dementia, p. 181

Depression, p. 181

Elder mistreatment, p. 190

Gerontological nursing, p. 177

Gerontology, p. 176

Reality orientation, p. 191

Reminiscence, p. 192

Validation therapy, p. 191

People who are 65 years old are in the lower boundary for “old age” in demographics and social policy within the United States. However, many

older adults consider themselves to be “middle age” well into their seventh decade. Chronological age often has little relation to the reality of aging for an older adult. Each person ages in his or her own way. Every older adult is unique. As a nurse you need to approach each person as an individual.

The number of older adults in the United States is growing quickly. In 2016, there were 49.2 million adults over age 65 in the United States, representing 15.2% of the population or one in seven Americans (AOA, 2017). This represents an increase of 33% since 2006. Part of this increase is caused by the increase of the average life span. The aging population is expected to continue to grow to 21.7% of the population by the year 2040. The racial and ethnic diversity of the population over age 65 is also increasing. Between 2014 and 2060, the non-Hispanic white segment of the population is expected to decrease from 78.3% to 54.6% (Population Reference Bureau, 2018). As a nurse, you need to take cultural diversity into account as you care for older adults. The aging of the baby-boom generation and the growth of the population segment over age 85 contribute to the projected increase in the number of older adults. The baby boomers were born between 1946 and 1964. The first baby boomers reached age 65 in 2011. Social and health care programs will need to adapt to meet the needs of this growing segment of the population. The challenge is to gain new knowledge and skills to provide culturally sensitive and linguistically appropriate care (see [Chapter 9](#)).

Variability Among Older Adults

Nursing care of older adults poses special challenges because of variations in their physiological, cognitive, and psychosocial health. Older adults also have a wide range of functional ability. Most older adults are active and involved in their communities. A smaller number have lost the ability to care for themselves, are confused or withdrawn, and/or are unable to make decisions concerning their needs. Most older adults live in noninstitutional settings. In 2017 59% of older adults in noninstitutional settings lived with a spouse/partner (48% of older women, 72% of older men); 28% lived alone (34% of older women, 20% of older men); and only 3.1% of all older adults resided in institutions, primarily nursing homes. As would be expected, the percentage of those living in a nursing home increases with age. Only 1% of the 65 to 74 age-group live in a nursing home, while 9% of those 85 and older do ([AOA, 2017](#)).

The physical and psychosocial aspects of aging are closely related. A reduced ability to respond to stress, the experience of multiple losses, and the physical changes associated with normal aging combine to place people at high risk for illness and functional deterioration. Most older adults remain functionally independent despite the increasing prevalence of chronic disease. Nursing assessment provides valuable clues to the effects of a disease or illness on a patient's functional status. Chronic conditions add to the complexity of assessment and care of the older adult. Most older people have at least one chronic condition, and many have multiple conditions. Although the interaction of these physical and psychosocial factors may be serious, do not assume that all older adults have signs, symptoms, or behaviors representing disease and decline or that these are the only factors you need to assess. You also need to identify an older adult's strengths and abilities during the assessment and encourage independence as an integral part of your plan of care ([Jett, 2018a](#)).

Myths and Stereotypes

Despite ongoing research in the field of **gerontology**, myths and stereotypes about older adults persist. These include false perceptions about their physical and psychosocial characteristics and lifestyles. When health care providers hold negative stereotypes about aging, their actions often negatively affect the quality of patient care. It is important to correctly assess older adults' functional, physiological, psychosocial, and emotional status.

Some people stereotype older adults as ill, disabled, and physically unattractive. Others believe that older adults are forgetful, confused, rigid, bored, and unfriendly and that they are unable to understand and learn new information. Yet specialists in the field of gerontology view centenarians, the oldest of the old, as having an optimistic outlook on life, good memories, broad social contacts and interests, and tolerance for others. Although changes in vision or hearing and reduced energy and endurance sometimes affect the process of learning, older adults are lifelong learners.

Stereotypes about lifestyles often include mistaken ideas about living arrangements and finances. Misconceptions about financial status range from beliefs that many are affluent to beliefs that many are poor. According to the US Census Bureau, only 9.3% of people over age 65 had incomes below the poverty level. Older women report a significantly lower income than men. Social Security benefits serve as the primary source of income for most older adults ([US Census Bureau, 2017](#)).

In a society that values attractiveness, energy, and youth, these myths and stereotypes lead to the undervaluing of older adults. Some people equate worth with productivity; therefore they think that older adults become worthless after they leave the workforce. Others consider their knowledge and experience too outdated to have any current value. These ideas demonstrate **ageism**, which is discrimination against people because of increasing age, just as people who are racists and sexists discriminate because of skin color and gender. According to experts in the field of gerontology, ageism typically undermines the self-confidence of older adults, limits their access to care, and distorts caregivers' understanding of the uniqueness of each older adult. Nurses should promote a positive perception regarding the aging process when establishing therapeutic relationships and value the experiences of older adults.

Current laws ban age discrimination. The economic and political power of older adults challenges ageist views. Older adults are a significant

proportion of the consumer economy. As voters and activists in various issues, they have a major influence in the formation of public policy. Participation of older adults on voting issues adds a unique perspective on social, economic, and technological issues because they have experienced almost a century of developments. Some older adults lived through or were born during the Great Depression of 1929. They also experienced two world wars and wars in Korea, Vietnam, and Iraq and are now experiencing the war on terrorism. They have seen tremendous changes in technology. Changes in health care also impact older adults as the era of the family physician gave way to the age of specialization and managed care. After witnessing the government initiatives establishing the Social Security system, Medicare, and Medicaid, older adults are currently living with the changes imposed by health care reform.

Nurses' Attitudes Toward Older Adults

It is important to assess your own attitudes toward older adults, your own aging, and the aging of your family, friends, and patients. Nurses' attitudes come from personal experiences with older adults, education, employment experiences, and attitudes of co-workers and employing institutions. Given the increasing number of older adults in health care settings, forming positive attitudes toward them and gaining specialized knowledge about aging and the health care needs of older adults are priorities for all nurses. Positive attitudes are based in part on a realistic portrayal of the characteristics and health care needs of older adults. It is critical for you to respect older adults and actively involve them in care decisions and activities. In the past institutional settings such as hospitals and nursing centers often treated older adults as objects rather than independent, dignified people. The time has come for nurses to recognize and address ageism by questioning prevailing negative attitudes and stereotypes and reinforcing the realities of aging as they care for older adults in all settings.

REFLECT NOW

Think about how you feel about caring for older adults. Reflect on positive and negative experiences you have had with older adults and how this may affect your nursing care of older adults.

Developmental Tasks for Older Adults

Theories of aging are closely linked to the concept of developmental tasks appropriate for distinct stages of life (see [Chapter 11](#)). Although no two individuals age in the same way, either biologically or psychosocially, there are common developmental tasks for older adults that are associated with varying degrees of change and loss ([Box 14.1](#)). More common changes include alterations in health status, loss of significant others, a decreased sense of usefulness, and decreases in socialization, income, and independent living. How older adults adjust to these changes is individualized. For some, adaptation and adjustment are relatively easy. For others, coping with the changes brought on by aging requires the assistance of family, friends, and health care professionals. Be sensitive to the effect of losses on older adults and their families, and be prepared to offer support.

Box 14.1 Developmental Tasks for Older Adults

- Adjusting to changes in health and physical strength
- Adjusting to retirement and reduced or fixed income
- Adjusting to death of a spouse, children, siblings, friends
- Accepting self as aging person
- Maintaining satisfactory living arrangements
- Redefining relationships with adult children and siblings
- Maintaining quality of life

Older adults need to adjust to the physical changes that accompany aging. The extent and timing of these changes vary by individual, but as body systems age, changes in appearance and functioning occur. These changes are not associated with a disease; they are normal. The presence of disease sometimes alters the timing of the changes or their impact on daily life. The section on physiological changes describes structural and functional changes of aging.

Some older adults, both men and women, find it difficult to accept aging. This is apparent when they understate their ages when asked, adopt younger styles of clothing, or attempt to hide physical evidence of

aging with cosmetics. Others deny their aging in ways that are potentially problematic. For example, some older adults deny functional declines and refuse to ask for help with tasks, placing their safety at great risk. Others avoid activities designed for their benefit, such as senior citizens' centers and senior health promotion activities and thus do not receive the benefits these programs offer. Acceptance of personal aging does not mean retreat into inactivity, but it does require a realistic review of strengths and limitations.

Retirement poses challenges, such as adjusting to the loss of the work role and daily interaction with professional colleagues. Some welcome retirement as a time to pursue new interests and hobbies, volunteer in their communities, continue their education, or start new careers. Retirement plans for others include changing residence by moving to a different city or state or to a different type of housing within the same area. Reasons other than retirement also lead to changes of residence. For example, physical impairments sometimes require relocation to a smaller, single-level home or nursing center. A change in living arrangements for the older adult usually requires an extended period of adjustment, during which assistance and support from health care professionals, friends, and family members are necessary.

Many older adults cope with the death of a spouse. In 2017, 33% of all older women were widows, and 11% of older men were widowers ([AOA, 2017](#)). They also may need to cope with deaths of adult children and grandchildren and lifelong friends. These deaths represent losses and reminders of personal mortality. Coming to terms with them is often difficult. By helping older adults through the grieving process ([Chapter 36](#)), you can help them resolve some of these issues.

Redefining relationships with children continues as older adults experience the challenges of aging. A variety of issues sometimes occur, including control of decision making, dependence, conflict, guilt, and loss. How these issues surface in situations and how they are resolved depend in part on the past relationship between the older adult and his or her adult children. When adult children become their parents' caregivers, they must try to balance the demands of their own children and careers with the many challenges of family caregiving. As adult children and aging parents negotiate the aspects of changing roles, nurses are in the position to act as counselors for the entire family. Helping older adults maintain their quality of life is often a priority. What defines quality of life is unique for each person.

Community-Based and Institutional Health Care Services

You will encounter older-adult patients in a wide variety of community and institutional health care settings. Outside of an acute care hospital, nurses care for older adults in clinics, private homes and apartments, retirement communities, adult day care centers, assisted-living residences, and nursing centers (extended care, intermediate care, and skilled nursing facilities). [Chapter 2](#) describes these settings and the services provided in detail.

Sorting through the options for care of older adults can be overwhelming. Nurses and social workers can help older adults and their families by providing information and answering questions as they review care options. Your assistance is especially valuable when patients and families need to make decisions about moving to a nursing center. Some family caregivers consider nursing center placement when in-home care becomes increasingly difficult or when convalescence (recovery) from hospitalization requires more assistance than the family is able to provide. Although the decision to enter a nursing center is never final and a nursing center resident is sometimes discharged to home or another less acute setting, many older adults view the nursing center as their final residence. Results of state and federal inspections of nursing centers are available to the public at the nursing center, online, and at the inspectors' offices. The best way to evaluate the quality of a nursing center is for the patient and family to visit the center and inspect it personally. The Centers for Medicare and Medicaid ([CMS, 2018](#); website <http://www.Medicare.gov/NHcompare>) provides an excellent resource for you to learn about the quality rating of a nursing center on the basis of health inspections, staffing, and quality measures ([Box 14.2](#)). It also offers a nursing center checklist (<https://www.medicare.gov/NursingHomeCompare/checklist.pdf>).

Box 14.2 Focus on Older Adults Selection of a Nursing Center or Home

An important step in the process of selecting a nursing center is to visit it. A quality nursing home has the following features:

- It is a home, a place where people live. Residents are encouraged to personalize their rooms. Privacy is respected.
- Is Medicare and Medicaid certified.
- Has adequate, qualified staff members who have passed criminal background checks.
- Does not feel like a hospital. However, the nursing center provides quality care. In addition to assistance with basic activities of daily living such as bathing, dressing, eating, oral hygiene, and toileting, staff regularly help residents with social and recreational activities.
- Offers quality food and mealtime choices.
- Welcomes families when they visit the center. Staff always encourage family involvement, whether families wish to provide information, ask questions, participate in care planning, or help with social activities or physical care.
- Is clean. There are no pervasive odors. The environment feels “homelike.”
- Provides active communication from staff to patient and family.
- Attends quickly to resident requests. Staff are actively involved with assisting the residents. They focus on the person, not on the task.

Modified from the Centers for Medicare & Medicaid Services (CMS): *Your guide to choosing a nursing home or other long-term care*, Baltimore, MD, 2018, CMS, <https://www.medicare.gov/Pubs/pdf/02174-Nursing-Home-Other-Long-Term-Services.pdf>. Accessed June 15, 2019.

Assessing the Needs of Older Adults

Gerontological nursing provides care that addresses mutually established goals for an older adult, his or her family, and health care team members. A comprehensive assessment, including strengths, limitations, and resources, provides a baseline of the older adult's health and functional status. Nursing diagnoses and interventions are selected to either maintain or enhance physical abilities and activity (see [Chapter 38](#)) and to create environments for psychosocial and spiritual well-being (see [Chapter 35](#)). To complete a thorough assessment, actively engage older adults and provide adequate time, allowing them to share important information about their past and current health. Caring for older adults often requires creative strategies that will maximize the potential of older adults.

Nursing assessment takes into account three key points to ensure an age-specific approach: (1) the interrelation between physical and psychosocial aspects of aging, (2) the effects of disease and disability on functional status, and (3) tailoring the nursing assessment to an older person ([Yeager, 2019c](#)). A comprehensive assessment of an older adult takes more time than the assessment of a younger adult because of the longer life and medical history and potential complexity of the history. During the physical examination allow rest periods as needed or conduct the assessment in several sessions if a patient has reduced energy or limited endurance. Review both prescription and over-the-counter medications carefully with each patient.

Sensory changes associated with aging may affect data gathering. Your choice of communication techniques depends on an older adult's visual or hearing impairments. If an older adult is unable to understand your visual or auditory cues, your assessment data will likely be inaccurate or misleading, leading you to incorrectly conclude that the older adult is confused.

When a person has a hearing impairment, move to a quiet area to reduce background noise, face the patient, and speak directly in clear, low-pitched tones. When caring for people with visual impairments, sit or stand at eye level and face them, and always encourage the use of assistive devices such as glasses and hearing aids. [Chapter 49](#) details techniques to use when communicating with older adults who have sensory deficits.

Memory deficits, if present, affect the accuracy and completeness of your assessment. Information contributed by a family member or other caregiver is sometimes necessary to supplement an older adult's recollection of past medical events and information about current self-care

habits, medication adherence, allergies, and immunizations. Use tact when involving another person in the assessment interview. The additional person provides supplemental information with the consent of the older adult, but the older adult should remain the primary source of information whenever possible.

During all aspects of an assessment, you are responsible for providing culturally competent care. Your ability to recognize and process your own biases related to ageism, social norms, and racism affects your ability to provide culturally competent care (see [Chapter 9](#)). During an assessment, use caution when interpreting signs and symptoms of diseases and laboratory values. Historically, researchers used younger populations to establish these signs and norms. However, the classic signs and symptoms of diseases are sometimes absent, blunted, or atypical in older adults ([Jett, 2018a](#)). This is especially true in the cases of bacterial infection, pain, acute myocardial infarction, and heart failure. The masquerading of disease is possibly caused by age-related changes in organ systems and homeostatic mechanisms, progressive loss of physiological and functional reserves, or coexisting acute or chronic conditions. As a result an older adult with a urinary tract infection (UTI) sometimes presents with incontinence, falls, and only a slight elevation of body temperature (within normal limits) instead of having fever, dysuria, frequency, or urgency. Some older adults with pneumonia have tachycardia, tachypnea, and confusion with decreased appetite and functioning, without the more common symptoms of fever and productive cough. Instead of crushing substernal chest pain and diaphoresis, some older adults experience a sudden onset of dyspnea often accompanied by anxiety and confusion when having a myocardial infarction. Variations from the usual norms for laboratory values are sometimes caused by age-related changes in cardiac, pulmonary, renal, and metabolic function.

It is important to recognize early indicators of acute illness in older adults. The [Fulmer \(2019\)](#) SPICES framework ([Box 14.3](#)) can be used to guide assessment of an older adult. [Box 14.4](#) provides setting-specific examples of altered presentation of illness. A key principle of providing age-appropriate nursing care is timely detection of these cardinal signs of illness so that early treatment can begin. Mental status changes commonly occur as a result of disease and psychological issues. Some mental changes are often drug related, caused by drug toxicity or adverse drug events.

Box 14.3 SPICES Tool for Overall Assessment of Older Adults

- S:** Sleep disorders
- P:** Problems with eating or feeding
- I:** Incontinence
- C:** Confusion
- E:** Evidence of falls
- S:** Skin breakdown

The nurse should complete further assessment if an older adult demonstrates changes in any of these areas (Fulmer, 2019).

Box 14.4 Examples of Altered Presentation of Illnesses in Older Adults Occurring in Various Health Care Settings

Hospital

- Confusion is not inevitable. Look for an acute illness, neurological events, new medication, or the presence of risk factors for delirium.
- Many hospitalized older adults have chronic dehydration exacerbated by acute illness (Touhy, 2018e).
- Not all older adults have fevers with infection. Symptoms instead include increased respiratory rate, falls, incontinence, or confusion (Yeager, 2019c).

Nursing Home

- Health care providers often undertreat pain in older adults, especially those with dementia. Look for nonverbal cues of pain presence, such as grimacing or resistance to care (Alderman, 2019).
- Decline in functional ability (even a minor one such as the inability to sit upright in a chair) is a signal of new illness.

- Residents with less muscle mass—both the frail and the obese—are at a much higher risk for toxicity from protein-binding drugs such as phenytoin (Dilantin) and warfarin (Coumadin) (Yeager, 2019b).
- New urinary and/or fecal incontinence is often a sign of the onset of a new illness.

Ambulatory Care

- Fatigue or decreased ability to do usual activities are often signs of anemia, thyroid problems, depression, or neurological or cardiac problems (Yeager, 2019c).
- Severe gastrointestinal problems in older adults do not always present with the same acute symptoms seen in younger patients. Ask about constipation, cramping sensations, and changes in bowel habits.
- Older adults reporting increased dyspnea and confusion, especially those with a cardiac history, need to go to the emergency department because these are the most common manifestations of myocardial infarction in this population (Yeager, 2019c).
- Depression is common among older adults with chronic illnesses. Watch for lack of interest in former activities, significant personal losses, or changes in role or home life.

Home Care

- Investigate all falls, focusing on balance, lower extremity strength, gait, and neurological issues (e.g., loss of sensation).
- Monitor older adults with late-stage heart disease for loss of appetite as an early symptom of impending heart failure (Yeager, 2019c).
- Drug-drug and drug-food interactions in older patients who are seeing more than one provider and taking multiple medications are common. Watch for signs of interactions (Yeager, 2019b).

Falls are complex and often cause life-changing injury. They are sometimes costly, affect functional status, level of independence, and can be a common event for an older adult. You need to investigate every fall carefully to find out whether it was the result of environmental causes or the symptom of a new-onset illness. A fall may be the only symptom in

new problems with the cardiac, respiratory, musculoskeletal, neurological, urological, and sensory body systems.

Dehydration is common in older adults because of decreased oral intake related to a reduced thirst response and less free water as a consequence of a decrease in muscle mass. Additionally, older adults may decrease their intake to avoid additional trips to the bathroom. This is especially true in those with impaired mobility. When vomiting and diarrhea accompany the onset of an acute illness, an older adult is at risk for further dehydration. Decrease in appetite is a common symptom with the onset of pneumonia, heart failure, and UTI.

Loss of functional ability may occur in a subtle fashion over time, or it may occur suddenly, depending on the underlying cause. Thyroid disease, infection, cardiac or pulmonary conditions, metabolic disturbances, and anemia are common causes of functional decline. The nurse is in a position to recognize even subtle changes in the condition of an older adult. You play an essential role in early identification, referral, and treatment of health problems.

Physiological Changes

Perception of well-being defines quality of life. Understanding an older adult's perceptions about health status is essential for accurate assessment and development of clinically relevant interventions. Older adults' concepts of health generally depend on personal perceptions of functional ability. Therefore older adults engaged in activities of daily living (ADLs) usually consider themselves healthy, whereas those who have physical, emotional, or social impairments that limit their activities perceive themselves as ill.

There are common physiological changes associated with normal aging ([Table 14.1](#)). These changes are not pathological in themselves, but they can make older adults more vulnerable to common clinical conditions and diseases ([Jett, 2018b](#)). Some older adults experience all of these changes, and others experience only a few. The body changes continuously with age, and specific effects on particular older adults depend on health, lifestyle, stressors, and environmental conditions. You need to understand these normal, more common changes to provide appropriate care for older adults and help with adaptation to associated changes.

TABLE 14.1**Common Physiological Changes with Aging At a Glance**

System	Common Changes
Integumentary	Loss of skin elasticity with fat loss in extremities; pigmentation changes; glandular atrophy (oil, moisture, sweat glands); thinning hair, with hair turning gray-white (facial hair: decreased in men, increased in women); slower nail growth; atrophy of epidermal arterioles
Respiratory	Decreased cough reflex and ciliary activity; increased anterior-posterior chest diameter; increased chest wall rigidity; fewer alveoli, increased airway resistance
Cardiovascular	Thickening of blood vessel walls, narrowing of vessel lumen, loss of vessel elasticity, lower cardiac output, decreased number of heart muscle fibers, decreased elasticity and calcification of heart valves, decreased baroreceptor sensitivity, decreased efficiency of venous valves, increased pulmonary vascular tension, increased systolic blood pressure, decreased peripheral circulation
Gastrointestinal	Periodontal disease; decrease in saliva, gastric secretions, and pancreatic enzymes; smooth-muscle changes with decreased peristalsis and small intestinal motility; gastric atrophy; decreased production of intrinsic factor; increased stomach pH; loss of smooth muscle in the stomach; hemorrhoids; rectal prolapse; and impaired rectal sensation.
Musculoskeletal	Decreased muscle mass and strength, decalcification of bones, degenerative joint changes, dehydration of intervertebral disks, fat tissue increases
Neurological	Degeneration of nerve cells, decrease in neurotransmitters, decrease in rate of conduction of impulses
Sensory	
Eyes	Decreased accommodation to near/far vision (presbyopia), difficulty adjusting to changes from light to dark, yellowing of the lens, altered color perception, increased sensitivity to glare, smaller pupils
Ears	Loss of acuity for high-frequency tones (presbycusis), thickening of tympanic membrane, sclerosis of inner ear, buildup of earwax (cerumen)
Taste	Often diminished; often fewer taste buds
Smell	Often diminished
Touch	Decreased skin receptors
Proprioception	Decreased awareness of body positioning in space
Genitourinary	Fewer nephrons, 50% decrease in renal blood flow by age 80, decreased bladder capacity Male—enlargement of prostate Female—reduced sphincter tone
Reproductive	Male—sperm count diminished, smaller testes, erections less firm and slow to develop Female—decreased estrogen production; degeneration of ovaries; atrophy of vagina, uterus, and breasts; dryness of vaginal mucosa
Endocrine	General—alterations in hormone production with decreased ability to respond to stress Thyroid—diminished secretions Cortisol, glucocorticoids—increased anti-inflammatory hormone Pancreas—increased fibrosis, decreased secretion of enzymes and hormones, decreased sensitivity to insulin
Immune	Thymus decreases in size and volume T-cell function decreases Core temperature elevation is lowered

Modified from Jett K: Biological theories of aging and age-related physiological changes. In Touhy T, Jett K: *Ebersole and Hess' gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Elsevier.

General Survey

Your general survey begins during the initial nurse-patient encounter and includes a quick but careful head-to-toe scan of the older adult that you document in a brief description (see [Chapter 30](#)). Initial inspection may reveal some universal aging changes (e.g., facial wrinkles, gray hair, loss of body mass in the extremities, an increase of body mass in the trunk). It is

also important at this time to observe range of joint motion, grooming, and communication skills.

Integumentary System

With aging, the skin loses resilience and moisture. The epithelial layer thins, and elastic collagen fibers shrink and become rigid. Wrinkles of the face and neck reflect lifelong patterns of muscle activity and facial expressions, the pull of gravity on tissue, and diminished elasticity. Spots and lesions are often present on the skin. Smooth, brown, irregularly shaped spots (age spots or senile lentigo) initially appear on the backs of the hands and on forearms. Small, round, red or brown cherry angiomas occur on the trunk. Seborrheic lesions or keratoses appear as irregular, round or oval, brown, watery lesions. Years of sun exposure contribute to the aging of the skin and lead to premalignant and malignant lesions. You need to rule out these three malignancies related to sun exposure when examining skin lesions: melanoma, basal cell carcinoma, and squamous cell carcinoma (see [Chapter 30](#)).

Head and Neck

The facial features of an older adult sometimes become more pronounced from loss of subcutaneous fat and skin elasticity. Facial features may appear asymmetrical because of missing teeth or improperly fitting dentures. In addition, common vocal changes include a rise in pitch and a loss of power and range.

Visual acuity declines with age. This is often the result of retinal damage, reduced pupil size, development of opacities in the lens, or loss of lens elasticity. Presbyopia, a progressive decline in the ability of the eyes to accommodate from near to far vision, is common. More ambient light is necessary for tasks such as reading and other ADLs. Older adults have increased sensitivity to the effects of glare. Pupils are smaller and react slower. Objects do not appear bright, and older adults may have difficulty when moving from bright to dark environments. Changes in color vision and discoloration of the lens make it difficult to distinguish between blues and greens and among pastel shades. Dark colors such as blue and black appear the same. Diseases of the older eye include cataract, macular degeneration (decrease in central vision), diabetic retinopathy (creates visual field loss), and retinal detachment (separation of the retina from surface of the eye, causing increased floaters, flashes of light, and loss of vision). Cataracts, a loss of the transparency of the lens, are a prevalent

disorder among older adults. They normally result in blurred vision, sensitivity to glare, and gradual loss of vision. Surgical treatment of cataracts has become a common outpatient procedure that is relatively safe. [Chapter 49](#) outlines nursing interventions for helping patients adapt to their visual changes.

Auditory changes are often subtle. Most of the time older adults ignore the early signs of hearing loss until friends and family members comment on compensatory attempts, such as either turning up the volume on televisions or avoiding social conversations. A common age-related change in auditory acuity is presbycusis. Presbycusis affects the ability to hear high-pitched sounds and conversational speech and is typically bilateral, affecting more men than women. Before the nurse assumes presbycusis, it is necessary to inspect the external auditory canal for the presence of cerumen. Impacted cerumen, a common cause of diminished hearing acuity, is easy to treat.

Salivary secretion is reduced, and taste buds atrophy and lose sensitivity. An older adult is less able to differentiate among salty, sweet, sour, and bitter tastes. The sense of smell also decreases, further reducing taste. Health conditions, treatments, and/or medications often alter taste. It is often a challenge to promote optimal nutrition in an older patient because of the loss of smell and changes in taste.

Thorax and Lungs

Because of changes in the musculoskeletal system, the configuration of the thorax sometimes changes. Respiratory muscle strength begins to decrease, and the anteroposterior diameter of the thorax increases. Vertebral changes caused by osteoporosis lead to dorsal kyphosis, the curvature of the thoracic spine. Calcification of the costal cartilage causes decreased mobility of the ribs. The chest wall gradually becomes stiffer. Lung expansion decreases, and the person is less able to cough deeply. If kyphosis or chronic obstructive lung disease is present, breath sounds become distant. As a result, an older adult is more susceptible to pneumonia and other bacterial or viral infections.

Heart and Vascular System

Decreased contractile strength of the myocardium results in decreased cardiac output. The decrease is significant when an older adult experiences anxiety, excitement, illness, or strenuous activity. The body tries to compensate for decreased cardiac output by increasing the heart rate

during exercise. However, after exercising it may take longer for an older adult's heart rate to return to baseline if the person does not regularly exercise or has underlying cardiac disease. Systolic and/or diastolic blood pressures are sometimes abnormally high. Although a common chronic condition, hypertension is not a normal aging change and predisposes older adults to heart failure, stroke, renal failure, coronary heart disease, and peripheral vascular disease.

Peripheral pulses frequently are still palpable but weaker in lower extremities. Older adults sometimes state that their lower extremities are cold, particularly at night. Changes in the peripheral pulses in the upper extremities are less common.

Breasts

As estrogen production diminishes, the milk ducts of the breasts are replaced by fat, making breast tissue less firm. Decreased muscle mass, tone, and elasticity result in smaller breasts in older women. Atrophy of glandular tissue coupled with more fat deposits results in a slightly smaller, less dense, and less nodular breast. Gynecomastia, enlarged breasts in men, is often the result of medication side effects, hormonal changes, or obesity.

Gastrointestinal System and Abdomen

Aging leads to an increase in the amount of fatty tissue in the trunk and abdomen. Because muscle tone and elasticity decrease, the abdomen becomes more protuberant. Gastrointestinal function changes include a slowing of peristalsis and alterations in secretions. An older adult experiences these changes by becoming less tolerant of certain foods and having discomfort from delayed gastric emptying. Alterations in the lower gastrointestinal tract lead to constipation, flatulence, or diarrhea.

Reproductive System

Changes in the structure and function of the reproductive system occur as the result of hormonal alterations. Women experience a reduced responsiveness of the ovaries to pituitary hormones and a resultant decrease in estrogen and progesterone levels. This can cause dryness of the vaginal mucosa, causing irritation and pain with intercourse, and may also cause a decreased libido. Aging men typically experience an erection that is less firm and has a less forceful ejaculation (Jett, 2018a).

Testosterone lessens with age and sometimes leads to a loss of libido. Spermatogenesis begins to decline during the fourth decade and continues into the ninth. However, for both men and women sexual desires, thoughts, and actions continue throughout all decades of life. Less frequent sexual activity often results from illness, death of a sexual partner, or decreased socialization.

Urinary System

Hypertrophy of the prostate gland is frequently seen in older men. This hypertrophy enlarges the gland and places pressure on the neck of the bladder. As a result, urinary retention, frequency, incontinence, and UTIs occur. In addition, prostatic hypertrophy results in difficulty initiating voiding and maintaining a urinary stream and does not always indicate a malignancy. However, when men develop symptoms of prostatic hypertrophy, it is important that this condition is evaluated by a health care provider to differentiate benign prostatic hypertrophy (BPH) from cancer of the prostate. Cancer of the prostate is the second leading cause of cancer death in American men, behind lung cancer. The American Cancer Society estimates that one in nine men will be diagnosed with prostate cancer and 1 in 41 will die ([ACS, 2018](#)).

Urinary incontinence is an abnormal and typically embarrassing condition. Older women, particularly those who have had children, experience stress incontinence, an involuntary release of urine that occurs when they cough, laugh, sneeze, or lift an object. This is a result of a weakening of the perineal and bladder muscles. Other types of urinary incontinence are urgency, overflow, functional, and mixed incontinence. The risk factors for urinary incontinence include age, menopause, diabetes, hysterectomy, stroke, and obesity. Men can also experience incontinence but are sometimes reluctant to discuss this with their health care providers because they think that it is a “woman’s disease.” It is important that male incontinence be evaluated as well.

Musculoskeletal System

With aging, muscle fibers become smaller. Muscle strength diminishes in proportion to the decline in muscle mass. Muscle mass begins to decline when individuals reach their 50s; by the time they reach their 80s, muscle mass is typically 30% to 40% of what it was at the age of 30 ([Jett, 2018b](#)). Beginning in the 30s, bone density and bone mass decline in men and women. Older adults who exercise regularly do not lose as much bone and

muscle mass or muscle tone as those who are inactive. Osteoporosis is a major public health threat. Fifty-four million Americans have osteoporosis or low bone mass, and approximately one in two women and one in four men over the age of 50 will break a bone because of osteoporosis ([National Osteoporosis Foundation, 2018](#)). Postmenopausal women experience a greater rate of bone demineralization than older men. Women who maintain calcium intake throughout life and into menopause have less bone demineralization than women with low calcium intake. Older men with poor nutrition and decreased mobility are also at risk for bone demineralization.

Neurological System

A decrease in the number and size of neurons in the nervous system begins in the middle of the second decade. Neurotransmitters, chemical substances that enhance or inhibit nerve impulse transmission, change with aging as a result of the decrease in neurons. All voluntary reflexes are slower, and individuals often have less of an ability to respond to multiple stimuli. In addition, older adults frequently report alterations in the quality and the quantity of sleep (see [Chapter 43](#)), including difficulty falling asleep, difficulty staying asleep, difficulty falling asleep again after waking during the night, waking too early in the morning, and excessive daytime napping. These problems are believed to be caused by age-related changes in the sleep-wake cycle.

Functional Changes

Physical function is a dynamic process. It changes as individuals interact with their environments. Functional status in older adults includes the day-to-day ADLs involving activities within physical, psychological, cognitive, and social domains. A decline in function is often linked to illness or disease and its degree of chronicity. However, ultimately it is the complex relationship among all of these areas that influences an older adult's functional abilities and overall well-being.

Keep in mind that it may be difficult for older adults to accept the changes that occur in all areas of their lives, which in turn have a profound effect on functional status. Some deny the changes and continue to expect the same personal performance, regardless of age. Conversely some overemphasize them and prematurely limit their activities and involvement in life. The fear of becoming dependent is overwhelming for an older adult who is experiencing functional decline as a result of aging.

Educate older adults to promote understanding of age-related changes, appropriate lifestyle adjustments, and effective coping. Factors that promote the highest level of function include a healthy, well-balanced diet; paced and appropriate activity; regularly scheduled visits with a health care provider; regular participation in meaningful activities; use of stress-management techniques; and avoidance of alcohol, tobacco, or illicit drugs.

Functional status in older adults refers to the capacity and safe performance of ADLs and instrumental ADLs (IADLs). It is a sensitive indicator of health or illness in the older adult. ADLs (such as bathing, dressing, and toileting) and IADLs (such as the ability to write a check, shop, prepare meals, or make phone calls) are essential to independent living; therefore carefully assess whether an older adult has changed the way he or she completes these tasks. Occupational and physical therapists are your best resources for a comprehensive assessment of functional impairment. A sudden change in function, as evidenced by a decline or change in an older adult's ability to perform any one or a combination of ADLs, is often a sign of either an acute illness (e.g., pneumonia, UTI, or electrolyte imbalance) or worsening of a chronic problem (e.g., diabetes or cardiovascular disease) (Jett, 2018a). An online collection of functional assessment tools used most commonly with older adults is available at the geriatric nursing website of the Hartford Institute for Geriatric Nursing, <https://consultgeri.org/>. When you identify a decline in a patient's functional status, focus your nursing interventions on maintaining, restoring, and maximizing an older adult's functional status to maintain independence while preserving safety and dignity.

Cognitive Changes

A common misconception about aging is that cognitive impairments are widespread among older adults. Because of this misconception, older adults often fear that they are, or soon will be, cognitively impaired. Younger adults often assume that older adults will become confused and no longer able to handle their affairs. Forgetfulness as an expected consequence of aging is a myth and not a fact or expectation. Some structural and physiological changes within the brain are associated with cognitive impairment. Reduction in the number of brain cells, deposition of lipofuscin and amyloid in cells, and changes in neurotransmitter levels occur in older adults both with and without cognitive impairment. Symptoms of cognitive impairment such as disorientation, loss of

language skills, loss of the ability to calculate, and poor judgment *are not* normal aging changes and require you to further assess patients for underlying causes. There are standard assessment forms for determining a patient’s mental status, including the Mini-Mental State Exam-2 (MMSE-2), the Mini-Cog, and the Clock Drawing Test (Jett, 2018a).

The three common conditions affecting cognition are **delirium**, **dementia**, and **depression** (Table 14.2). Distinguishing among these three conditions is challenging. A careful and thorough assessment of older adults with cognitive changes to distinguish among them should be completed. Select appropriate nursing interventions that are specific to the cause of the cognitive impairment.

TABLE 14.2

Comparison of Clinical Features of Delirium, Dementia, and Depression

Clinical Feature	Delirium	Dementia	Depression
Onset	Sudden/abrupt; depends on cause	Insidious/slow and often unrecognized	Happens with major life changes; often abrupt but can be gradual
Course	Short, daily fluctuations in symptoms; worse at night, in darkness, and on awakening	Long, no diurnal effects; slow progression over time; some deficits with increased stress	Diurnal effects, typically worse in the morning; situational fluctuations but less than with delirium
Progression	Abrupt	Slow over months and years	Variable; rapid or slow but even
Duration	Hours to less than 1 month; longer if unrecognized and untreated	Months to years	Variable; may be chronic
Consciousness	Reduced/disturbed	Awake	Awake
Alertness	Fluctuates; lethargic or hypervigilant	Generally normal	Normal
Attention	Impaired; fluctuates; inattention	Generally normal	Minimal impairment
Orientation	Generally impaired; severity varies	Generally normal to person but not to place or time	Usually normal
Psychomotor behavior	Variable; hypoactive, hyperactive, or mixed	Normal; some have apraxia	Variable; psychomotor retardation or agitation
Speech	Often incoherent; may call out repeatedly or with the same phrase	Difficulty finding words; perseveration	May be slow
Affect	Variable, but may appear disturbed, frightened	Slowed response; may be labile	Flat

Modified from Touhy T: Care of individuals with neurocognitive disorders. In Touhy T, Jett K: *Ebersole & Hess’ gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Elsevier.

Delirium

Delirium, or acute confusional state, is a potentially reversible cognitive impairment that occurs suddenly and worsens at night (Touhy, 2018d). Delirium often has a physiological cause. Physiological causes include electrolyte imbalances, untreated pain, infection, cerebral anoxia,

hypoglycemia, medication effects, tumors, subdural hematomas, and cerebrovascular infarction or hemorrhage. A new onset of delirium should trigger the nurse to assess for signs and symptoms of infections such as pneumonia and UTI. Delirium may also be caused by environmental factors such as sensory deprivation or overstimulation, unfamiliar surroundings, or sleep deprivation or psychosocial factors such as emotional distress. Although it occurs in any setting, an older adult in the acute care setting is especially at risk because of predisposing factors (physiological, psychosocial, and environmental) in combination with underlying medical conditions. Between 11% and 42% of hospitalized older adults develop delirium (Touhy, 2018d). Dementia is an additional risk factor that greatly increases the risk for delirium; it is possible for delirium and dementia to occur at the same time. The presence of delirium is a medical emergency and requires prompt assessment and intervention. Nurses are at the bedside 24/7 and in a position to recognize delirium development and report it. The cognitive impairment usually reverses once health care providers identify and treat the cause of delirium.

Dementia

Dementia is a generalized impairment of intellectual functioning that interferes with social and occupational functioning. It is an umbrella term that includes Alzheimer's disease (most common type), Lewy body disease, frontal-temporal dementia, and vascular dementia (Alzheimer's Association, 2018). Cognitive function deterioration leads to a decline in the ability to perform basic ADLs and IADLs. Unlike delirium, dementia is characterized by a gradual, progressive, and irreversible decline in cerebral function (Touhy, 2018d). Because of the similarity between delirium and dementia, you need to assess carefully to rule out the presence of delirium whenever you suspect dementia.

Nursing management of older adults with any form of dementia always considers the safety and physical and psychosocial needs of the older adult and the family. These needs change as the progressive nature of dementia leads to increased cognitive deterioration. To meet the needs of older adults, individualize nursing care to enhance quality of life and maximize functional performance by improving cognition, mood, and behavior. Persons with dementia may exhibit behaviors that may be unsafe, putting them at risk for falls and other injuries. These behaviors are an expression of an unmet need, such as hunger, pain, anxiety, or the need to void or defecate. Therefore, the nurse should consider the meaning behind a person's actions. Nonpharmacological measures should be used

first, before administering medications that may be sedating or have other undesirable effects. [Box 14.5](#) lists general nursing principles for the care of older adults with dementia. Support and education about Alzheimer's disease for patients, families, and professionals can be found at the Alzheimer's Association website (www.alz.org).

Box 14.5 Dementia Care Practice Recommendations

Person-Centered Care

- Know the person as an individual. Information should include past social and work history, values, interests, and preferences.
- Recognize and accept the person's reality. Do not attempt to reorient the person. Instead, the nurse should recognize that the person's behavior is a form of communication.
- Support opportunities for meaningful interactions. By knowing the person's preferences, interactions are more likely to be effective and meet the needs of the individual. Promote social interaction when possible.
- Nurture authentic, caring relationships. Nurses should focus more on the interaction than the task needing to be accomplished.
- Maintain a supportive community for the person with dementia, the person's family, and staff.

Detection and Diagnosis of Dementia

- Provide information about brain health and related disorders, along with referral to specialists in dementia care.
- Attend to concerns about cognitive changes from family members and other care providers.
- Following a diagnosis of dementia, support and educate the person and family members, including referral to appropriate agencies and support groups.

Person-Centered Assessment and Care Planning

- Ensure that regular ongoing assessments of persons with dementia are conducted. This is an opportunity to support and educate the person, family, and caregivers.
- Involve multiple disciplines when developing a plan of care.
- Regularly evaluate the plan of care for relevance and accuracy.
- Encourage advanced care planning to optimize physical, psychosocial, and fiscal well-being.

Medical Management

- Utilize a holistic approach and manage co-morbidities.
- Encourage nonpharmacological interventions for common behavioral and psychological symptoms.
- Pharmacological measures should be used cautiously and only after attempting nonpharmacological measures. Minimize polypharmacy by decreasing the risk for drug interactions and adverse reactions.

Education and Support of Those Diagnosed With Dementia and Their Families

- Provide education and support early in the disease to better prepare for future events.
- Encourage families and caregivers to work together.
- Educational programming should be culturally sensitive.
- Use technology to reach out to families. Two-way video technology, such as Skype or FaceTime, can be used to enhance family involvement.

Managing Behavioral and Psychological Symptoms of Dementia

- Identify social and environmental triggers of negative behavioral symptoms. Symptoms are individualized responses to the dementia disease process and can vary widely.

- Implement nonpharmacological practices that are tailored to the individual's needs. These include:
 - Sensory practices: aromatherapy, massage, multisensory stimulation, and bright light therapy
 - Psychosocial practices: validation therapy, reminiscence therapy, music therapy, pet therapy, and meaningful activities
 - Structured care protocols (bathing and mouth care)
- Hand in Hand is a training course for direct care providers on safe, effective strategies for caring with persons with dementia. It is available at:
<https://surveyortraining.cms.hhs.gov/pubs/HandinHand.aspx>.

Supporting Activities of Daily Living

- Allow individuals to be involved in their care to the extent of their cognitive abilities, with a focus on preserving self-dignity.
- Provide limited choices with simple instructions.
- Provide dignity and respect in the toileting process by being attuned to cues indicating a need to void/defecate. Toilet continent individuals on a regular basis.
- Support eating nutritious meals and consider food preferences. A quiet homelike atmosphere is conducive to adequate nutritional intake. For some, finger foods may be easier to manipulate than feeding oneself with utensils.
- Monitor and support fluid intake.
- Encourage physical activity. Make sure that the environment is safe for mobility, and promote way-finding with pictures or cues.
- Ensure that assistive devices (hearing aids, glasses, dentures) are functioning and used appropriately.

Recommendations for Staffing

- Provide a thorough orientation that focuses on the care of individuals diagnosed with dementia.
- Provide consistent staff so that the staff member can learn more about the person, as well as the person and their family being able to

develop a relationship with staff members.

- Encourage patients, families, and staff to develop and sustain professional, caring relationships.

Providing a Supportive and Therapeutic Environment

- Promote safety, comfort, and dignity.
- Allow for choice for those with dementia to promote safe independence.

Transitions of Care

- Prepare persons living with dementia and their families for common transitions of care by discussing the risks and benefits of a transfer to a new environment (e.g., care facility, hospital).
- Promote timely and effective communication across care settings. Utilizing transfer reports available in the electronic medical record can enhance the quality and timeliness of information sharing.

Modified from Fazio S, et al: Alzheimer's Association dementia care practice recommendations, *Gerontologist* 58(S1):S1–S9, 2018.

Depression

Older adults sometimes experience late-life depression, but it is not a normal part of aging. Depression is the most common, yet most undetected and untreated, impairment in older adulthood. It sometimes exists and is exacerbated in patients with other health problems such as stroke, diabetes, dementia, Parkinson's disease, heart disease, cancer, and pain-provoking diseases such as arthritis. Loss of a significant loved one or admission to a nursing center sometimes causes depression. The Geriatric Depression Scale is an easy-to-use screening tool that can be used in conjunction with an interview with the older adult (Jett, 2018a). Clinical depression is treatable. Treatment includes medication, psychotherapy, or a combination of both. Electroconvulsant therapy (ECT) is sometimes used for treatment of resistant depression when medications and psychotherapy do not help. Of special note, suicide attempts in older

older adults are often successful. Suicide rates in all age-groups are on the rise over the past several years; the age-group of 85 years of age and older has the second highest suicide rate of all age-groups ([American Foundation for Suicide Prevention, 2018](#)). Therefore, suicide prevention considerations for older adults are similar to those for the general population.

Psychosocial Changes

As previously discussed, psychosocial changes occurring during aging involve life transitions and loss. Life transitions, of which loss is a major component, include retirement and the associated financial changes, changes in roles and relationships, alterations in health and functional ability, changes in one's social network, and relocation.

It is important to assess both the nature of the psychosocial changes that occur in older adults as a result of life transitions and the loss and the adaptations to the changes. During your assessment ask how an older adult feels about self, self in relation to others, and self as one who is aging, and ask which coping methods and skills have been beneficial. Areas to address during the assessment include family, intimate relationships, past and present role changes, finances, housing, social networks, activities, health and wellness, and spirituality. Specific topics related to these areas include retirement, social isolation, sexuality, housing and environment, and death.

Retirement

Many often mistakenly associate retirement with passivity and seclusion. In actuality it is a stage of life characterized by transitions and role changes and may occupy 30 or more years of one's life. This transition requires letting go of certain habits and structure and developing new ones ([Touhy, 2018b](#)). The psychosocial stresses of retirement are usually related to role changes with a spouse or within the family and to loss of the work role. Sometimes problems related to social isolation and finances are present. The age of retirement varies; but whether it occurs at age 55, 65, or 75, it is one of the major turning points in life.

Meaningful retirement planning is critical as the population continues to age. Retirement affects more than just the retired. It also affects the spouse, adult children, and even grandchildren. When the spouse is still working, the retired person faces time alone. There may be new expectations of the retired person. For example, a working spouse has new ideas about the amount of housework expected of the retired person. Problems develop

when the plans of the retired person conflict with the work responsibilities of the working spouse. The roles of the retiree and the working spouse need clarification. Some adult children expect the retired person to always care for the grandchildren, forgetting that this is a time for the retired person to pursue other personal interests.

Loss of the work role has a major effect on some retired people. When so much of life has revolved around work and the personal relationships at work, the loss of the work role is sometimes devastating. Personal identity is often rooted in the work role, and with retirement individuals need to construct a new identity. They also lose the structure imposed on daily life when they no longer have a work schedule. The social exchanges and interpersonal support that occur in the workplace are lost. In the adjustment to retirement an older adult has to develop a personally meaningful schedule and a supportive social network.

Factors that influence a retired person's satisfaction with life are health status and sufficient income. Positive preretirement expectations also contribute to satisfaction in retirement. You can help the older adult and family prepare for retirement by discussing with them several key areas, including relations with spouse and children; meaningful activities and interests; building social networks; issues related to income; health promotion and maintenance; and long-range planning, including wills and advance directives. This information should be considered part of your psychosocial assessment and provides context for other concerns expressed by the older adult.

Social Isolation

Many older adults experience social isolation. Isolation is sometimes a choice, the result of a desire not to interact with others. Older adults who experience social isolation become vulnerable to its consequences because of the absence of the support of other adults. Impaired sensory function, functional impairment, chronic illness, reduced mobility, and cognitive changes all contribute to reduced interaction with others and often place an older adult at risk for isolation.

Assess patients' potential for social isolation by identifying their social network, access to transportation, and willingness and desire to interact with others. Use your findings to help a lonely older adult rebuild social networks and reverse patterns of isolation. Many communities have outreach programs designed to make contact with isolated older adults. Outreach programs such as daily telephone calls by volunteers or planned social outings also meet socialization needs. A wide range of organizations

welcomes older adults as volunteers and provides the opportunity for them to serve while meeting their socialization or other needs. Churches, colleges, community centers, and libraries offer a variety of programs for older adults that increase the opportunity to meet people with similar interests and needs.

Sexuality

All older adults, whether healthy or frail, need to express their need for intimacy and sexual feelings. Sexuality involves love, warmth, sharing, and touching, not just the act of intercourse. It plays an important role in helping the older adult maintain self-esteem. To help an older adult achieve or maintain sexual health, you need to understand the physical changes in a person's sexual response (see [Chapter 34](#)). You need to provide privacy for any discussion of sexuality and maintain a nonjudgmental attitude. Open-ended questions should be used to elicit information and concerns related to sex and sexuality. Include information about the prevention of sexually transmitted infections when appropriate. Sexuality and the need to express sexual feelings remain throughout the human life span.

When considering an older adult's need for sexual expression, do not ignore the important need to touch and be touched. Touch is an overt expression with many meanings and is an important part of intimacy ([Yeager, 2019a](#)). Touch complements traditional sexual methods or serves as an alternative sexual expression when physical intercourse is not desired or possible. Knowing an older adult's sexual needs allows you to incorporate this information into the nursing care plan. The sexual preferences of older adults are as diverse as those of the younger population. Clearly not all older adults are heterosexual; research is emerging on older adult lesbian, gay, bisexual, and transgender individuals and their health care needs. Nurses often find that they are called on to help other health care professionals understand the sexual needs of older adults. Not all nurses feel comfortable counseling older adults about sexual health and intimacy-related needs. Be prepared to refer older adults to an appropriate professional counselor.

Housing and Environment

Older adults' ability to live independently influences housing choices. However, it is difficult to anticipate what services will be needed by an older adult over the course of several years. For example, a housing unit

with only one floor and without exterior steps is a prudent choice for an older adult with severe arthritis who has already had lower-extremity joint replacement surgery and anticipates the need for future operations. A broad range of housing options, with numerous variations, exist. The options may be overwhelming to the older adults and their family.

Aging in place is a concept that is gaining popularity. It is intended to promote successful aging by allowing an older adult to stay in one place while providing the needed supplemental services ([National Institute of Health, 2017](#)). Some aging in place initiatives are formal organizations, while others are more loosely organized. Aging in place requires the older adult to anticipate the health and personal services that will be needed and how to access those services, as well as creating a safe physical environment that is accessible in the event of impaired mobility. Some older adults choose to live with family members. Others prefer their own homes or other housing options near their families. Leisure or retirement communities provide older people with living and social opportunities in a one-generation setting. Federally subsidized housing, where available, offers apartments with communal, social, and in some cases food-service arrangements.

The goal of your assessment of a patient's environment is to consider resources that promote safety, independence, and functional ability. Assessment of safety, a major component of an older adult's environment, includes risks within the environment and the older adult's ability to recognize and respond to the risks (see [Chapter 27](#)). Bathroom safety is central in an acceptable environment. The bathroom should have:

- Grab bars that can assist with moving and can be reached in case of a potential or actual fall
- Non-slip surfaces on the floor and tub/shower
- Needed supplies in easy reach
- Minimal obstacles (rugs, furniture, equipment)
- Adequate lighting, especially at night

Other considerations include the removal of clutter and throw rugs to decrease the risk of falls. Lighting should be adequate, particularly in walkways and stairs. Water heaters should not be set higher than 120°F. Smoke and carbon monoxide detectors should be installed and batteries changed regularly ([Health in Aging, 2019](#)).

Housing and environment can either support or hinder physical and social functioning, enhance or drain energy, and complement or tax

existing physical changes such as vision and hearing. For example, furnishings with red, orange, and yellow colors are easiest for older adults to see. Shiny waxed floors may appear to be wet. Ensure that door frames and baseboards are an appropriate color that contrasts with the color of the wall to improve perception of the boundaries of halls and rooms, keeping in mind that older adults often have difficulty distinguishing among pastel shades and between green and blue. Walkways leading to the house need to be flat, even, and in good repair, and stairs need to have a color contrast at the edge of the step so that an older person knows where the stair ends. Glare from highly polished floors, metallic fixtures, or windows is difficult for an older adult to tolerate.

Furniture needs to be comfortable and safe. Older adults need to examine furniture carefully for size, comfort, and function before purchasing it. Furniture should have adequate back support and allow a person to get into and out of the chair or sofa easily and safely. Test dining room chairs for comfort during meals and for height in relation to the table. Many older adults find that armrests on chairs make sitting down and getting up easier. Older adults often prefer to transfer out of a wheelchair to another chair for meals because some styles of wheelchairs do not allow a person to sit close enough to the table to eat comfortably. Raising the table to clear the wheelchair arms brings the table closer to the older adult but makes it too high to eat comfortably. To make getting out of bed easier and safer, ensure that the height of the bed allows an older adult's feet to be flat on the floor when he or she is sitting on the side of the bed.

Building Competency in Safety

Mr. Sousa is an energetic 76-year-old man who is ready for discharge from the hospital. He does not "look" 76, as he appears very fit and states that he is active in social activities and volunteering. He was admitted to the hospital 3 days ago for a right total knee replacement and is doing well after surgery; he now walks with the assistance of one person and is using a walker. He is able to walk to the bathroom and has walked 125 feet in the hallway 3 times today. He will get home health care and home physical therapy rather than going to the hospital rehabilitation unit. He insists on going home because of his dog, Benji, a black Labrador retriever. Mr. Sousa's daughter is going to pick up Benji from the boarding kennel and take him home. Mr. Sousa's wife of 50 years died

recently, leaving him alone at home, but he has been getting along well. His daughter lives within 25 miles of his home and will visit him daily. When considering safety for this patient in the home setting, which assessment questions and teaching approaches and resources can you use to enhance his safety in the home environment?

Death

Part of one's life history is the experience of loss through the death of relatives and friends (see [Chapter 36](#)). This includes the loss of older generations of families and sometimes, sadly, the loss of a child. However, death of a spouse or significant other is the loss that most affects the lives of older people. Do not assume that an older adult is comfortable with death. You play a key role in helping older adults understand and cope with loss.

Current evidence supports that older people have a wide variety of attitudes and beliefs about death but fear of their own death is uncommon. Rather they are concerned with fear of being a burden, experiencing suffering, being alone, and the use of life-prolonging measures ([Bub, 2019](#)). The stereotype that the death of an older adult is a blessing does not apply to every older adult. Even as death approaches, many older adults still have unfinished business and are not prepared for it. Families and friends are not always ready to let go of their older significant others. Older adults and family members or friends will often turn to you for assistance. Thus you need knowledge of the grieving process (see [Chapter 36](#)), excellent communication skills (see [Chapter 24](#)), understanding of legal issues and advance care planning (see [Chapter 23](#)), familiarity with community resources, and awareness of one's own feelings, limitations, and strengths as they relate to care of those confronting death.

REFLECT NOW

Reflect on how you would start a conversation with an older adult about end-of-life care, with the intent of determining his or her wishes/goals for care.

Addressing the Health Concerns of Older Adults

As the population ages and life expectancy increases, emphasis on health promotion, health maintenance, and disease prevention increases (see [Chapter 6](#)). Older adults are becoming more enthusiastic and motivated about healthy lifestyles ([AOA, 2017](#)). A number of national programs and projects address preventive practices in the older-adult population. The national initiative *Healthy People 2020* ([Office of Disease Prevention and Health Promotion, 2019](#)) has an overarching goal to improve the health, function, and quality of life of older adults. More specifically, *Healthy People 2020* for older adults focuses on:

- Understanding the health services provided to older adults
- Chronic disease management
- Injury prevention
- Caregivers in the home

The challenges of health promotion and disease prevention for older adults are complex and affect health care providers as well. Previous health care experiences, personal motivation, health beliefs, culture, health literacy, and non-health-related factors such as transportation and finances often create barriers for older adults. The interests and desires of older adults should be considered when planning health promotion activities ([Campbell et al., 2018](#)). Barriers for health care providers include beliefs and attitudes about which services and programs to provide, their effectiveness and the lack of consistent guidelines, and absence of a coordinated approach. Your role is to focus interventions on maintaining and promoting patients' function and quality of life. You can empower older adults to make their own health care decisions and realize their optimum level of health, function, and quality of life ([Davis, 2019](#)). Always be open to recognizing an older adult's concerns so that you can adjust a plan of care accordingly. Although various interventions cross all three levels of care (i.e., health promotion, acute care, and restorative care), some approaches are unique to each level.

Learning Needs

Managing the complexities of chronic disease and the cognitive and sensory changes that may be associated with aging add to the challenges of teaching older adults. As you assess the various physical, cognitive, functional, and psychosocial problems of older adults, it is important to also assess their associated learning needs. For example, during a cognitive and psychosocial assessment, you will gain information that indicates a patient's ability to follow a recommended treatment plan. When assessing a patient's medication history, have the patient describe when he or she takes the medication at home and the dosage. If a patient has slow responses or reaction time when performing physical activities, it is necessary to consider these limitations when teaching new psychomotor skills. During your assessment, carefully consider a patient's learning needs and capability to learn.

Educating Older Adults

Inadequate health literacy disproportionately affects older adults in the United States, causing misunderstanding of health information and subsequent nonadherence, which results in negative outcomes (Cutilli et al., 2018). The World Health Organization (2018) defines health literacy as the ability of individuals to “gain access to, understand and use information in ways which promote and maintain good health” for themselves, their families and their communities. The older adult expects that the patient education delivered is relevant to his or her own situation (Touhy, 2018a). It is important to know how to adapt routine patient education strategies to effectively meet the specific learning needs of older adults (see Box 14.6). When patients do not receive correct and necessary information from an educational session, they may turn to other sources, such as the Internet, relatives, or friends, for information, which may have incomplete or inaccurate information. Thus, nurses have an obligation to provide accurate information in a manner that meets the needs of the older adult.

Box 14.6 Patient Teaching Adapting Instruction for Older Adults With Health Literacy Limitations Objective

- Patient will verbalize an understanding of instructional materials.

Teaching Strategies

- Ensure the patient is ready to learn. Be alert for cues of pain and fatigue.
- Create a comfortable environment (e.g., seating, temperature).
- Allow time to process information and ask questions.
- Adapt teaching materials for culture, language, and health literacy.
- Focus on concrete information and relate to past experiences as appropriate.
- Use printed materials with large black font on either cream or white paper.
- Use clear, concise language; avoid medical terminology.
- Use pictures, demonstrations, videos, and other methods to augment spoken language.

Evaluation

Use the principles of teach-back to evaluate patient/family caregiver learning:

- Tell me the times that you would take your medication.
- Explain three ways that you can improve the safety of your home.
- Show me how you will change the dressing on wound

Modified from Touhy T: Social, psychological, spiritual, and cognitive aspects of aging. In Touhy T, Jett K: *Ebersole and Hess' gerontological nursing and healthy aging*, ed 5, St Louis, 2018, Mosby.

Health Promotion and Maintenance: Physiological Concerns

The desire and abilities of older adults to participate in health promotion activities vary. Therefore use an individualized approach, taking into account a person's beliefs about the importance of staying healthy and remaining independent. The [Federal Interagency Forum on Aging-Related](#)

[Statistics \(2016\)](#) reported that in 2014, 22% of older people 65 years and older reported a functional limitation (i.e., difficulty in hearing, vision, cognition, ambulation, self-care, communication), with older women reporting higher levels of functional limitations than men. Difficulties with mobility were the most commonly reported limitation. Some of these disabilities are relatively minor, but others cause people to require assistance to meet important personal needs. The incidence of disability increases with age. Limitations in ADLs limit the ability to live independently. The ADL limitations most often reported include walking, showering and bathing, getting in and out of bed and chair, dressing, toileting, and eating. Healthy Aging in Action (<https://www.surgeongeneral.gov/priorities/prevention/about/healthy-aging-in-action-final.pdf>) is a resource for promoting healthy aging and improving health and well-being in later life. Evidence-based health promotion programs are highlighted, including community safety and services, walking/physical activity, community engagement, preventive health services, and fall prevention ([National Prevention, Health Promotion, and Public Health Council, 2016](#)).

General preventive health measures to recommend to older adults include:

- Regular primary care, dental, vision, and hearing visits (if patient has a hearing aid)
- Participation in recommended screening activities as indicated by age (e.g., blood pressure, mammography, depression, vision and hearing, colonoscopy)
- Immunization for seasonal influenza, tetanus, diphtheria and pertussis, shingles, and pneumococcal disease
- Regular exercise, smoking cessation, and stress management
- Attaining and maintaining target weight
- Eating a low-fat, well-balanced diet or adhering to a specific diet (e.g. diabetic diet, low-sodium diet)
- Moderate alcohol use
- Socialization
- Good handwashing

Those who die from influenza are predominantly older adults. Providers strongly recommend annual immunization of all older adults for influenza, with special emphasis on residents of nursing homes or residential or long-term care facilities.

Other vaccinations, such as pneumonia or shingles, are often recommended. In addition, not all older adults are current with their booster injections, and some never received the primary series of injections. Ask about the current status of all immunizations, provide information about the immunizations, and make arrangements for them to receive immunizations as needed.

Most older adults are interested in their health and are able to take charge of their lives. They want to maintain or improve their health, remain independent, and prevent disability (Fig. 14.1). Initial screenings establish baseline data to determine wellness, identify health needs, and design health maintenance programs. Following initial screening sessions, share with older adults information on nutrition, exercise, medications, stress management, and safety. You can also provide information on specific conditions such as hypertension, arthritis, and diabetes and self-care procedures such as foot and skin care. By providing information about health promotion and self-care, you significantly improve the health and well-being of older adults.

FIG. 14.1 This older adult works part time at a sporting goods store.

Heart Disease

Heart disease and cancer are the leading causes of death in older adults (Xu et al., 2018). Common cardiovascular disorders are hypertension and

coronary artery disease. Hypertension is a silent killer because older adults, especially African Americans, are often unaware that their blood pressure is elevated (see [Chapter 29](#)). The fact that hypertension is common does not make it normal or harmless. Only about half of those diagnosed with hypertension have the condition under control. Treatment is linked to reduced incidence of myocardial infarction, chronic kidney disease, stroke, and heart failure. In coronary artery disease, partial or complete blockage of one or more coronary arteries leads to myocardial ischemia and myocardial infarction. The risk factors for both hypertension and coronary artery disease include smoking, obesity, lack of exercise, and stress. Additional risk factors for coronary artery disease include hypertension, hyperlipidemia, and diabetes mellitus ([American Heart Association, 2016](#)).

Nursing interventions for hypertension and coronary artery disease include patient teaching on weight reduction, exercise, dietary changes, limiting salt and fat intake, stress management, and smoking cessation. Additional patient teaching includes information about medication management, blood-pressure monitoring, and the symptoms indicating the need for emergency care.

Cancer

Malignant neoplasms are the second most common cause of death among older adults. Nurses educate older adults about early detection, treatment, and cancer risk factors. Education topics include low-fat diet, smoking cessation, breast self-examination (see [Chapter 30](#)), and encouraging all older adults to have recommended annual screening for fecal occult blood. It is also important to educate older adults about the signs of cancer and to encourage prompt reporting of nonhealing skin lesions, unexpected bleeding, change in bowel habits, nagging cough, lump in breast or another part of body, change in a mole, difficulty swallowing, and unexplained weight loss.

Chronic Lung Disease

Chronic lung disease, specifically chronic obstructive pulmonary disease (COPD), is the third leading cause of death in those 65 and older. More women than men die from COPD ([American Lung Association, 2018a](#)). Lung injury from inhalants such as tobacco smoke, exposure to secondhand smoke, and fumes from hair dyes, artificial nail products, and paints can lead to COPD, causing airflow blockage and breathing-related

difficulty ([American Lung Association, 2018a](#)). Tobacco smoke and exposure to secondhand smoke are key factors in the development and progression of COPD. It is important to provide patients with information about smoking cessation programs. In addition, depending on the severity of a patient's disease, you will teach a patient about proper exercise, how to use inhalers, and techniques for the removal of mucus from the airways (see [Chapter 41](#)). Supervised exercise training is a major component of pulmonary rehabilitation programs and is an established safe and effective intervention for improving patients' physical capacity and quality of life ([American Lung Association, 2018b](#)).

Stroke (Cerebrovascular Accident)

Cerebrovascular accidents (CVAs) are the fourth leading cause of death in the United States and occur as either brain ischemia (inadequate blood supply to areas of brain caused by arterial blockage) or brain hemorrhage (subarachnoid or intercerebral bleeds). Risk factors include hypertension, hyperlipidemia, diabetes mellitus, history of transient ischemic attacks, and family history of cardiovascular disease ([American Heart Association, 2018](#)). CVAs often impair a person's functional abilities and lead to loss of independence and nursing home admission. The scope of nursing interventions ranges from teaching older adults about risk-reduction strategies to teaching family caregivers the early warning signs of a stroke and ways to support a patient during recovery and rehabilitation.

Smoking

Cigarette smoking is a risk factor for the four most common causes of death: heart disease, cancer, lung disease, and stroke ([American Heart Association, 2016, 2018](#)). Smoking is the most preventable cause of disease and death in the United States. Smoking cessation is a health promotion strategy for older adults just as it is for younger adults. Older smokers still benefit from smoking cessation. In addition to reducing risk, it sometimes stabilizes existing conditions such as COPD and coronary artery disease. Smoking cessation after age 50 reduces the risk of dying prematurely by 50% compared with those who continue to smoke ([NCI, 2017](#)). Smoking cessation programs include individual, group, and telephone counseling and the use of nicotine (gum and patch) or non-nicotine medications. If a patient rejects smoking cessation, suggest at least a reduction in smoking. Finally, set a quit or reduction date and a follow-up visit with the older

adult to discuss the quit attempt. At follow-up visits, offer encouragement and assistance in modifying the plan as necessary.

Alcohol Abuse

Studies of alcohol abuse in older adults report two patterns: a lifelong pattern of continuous heavy drinking and a pattern of heavy drinking that begins late in life (Lewis et al., 2018). Frequently cited causes of excessive alcohol use include chronic illness, depression, loneliness, and lack of social support.

Alcohol use and late-onset alcohol use disorder (AUD) are often underidentified in older adults. The clues of alcohol abuse in the older adult include stress, role/identity loss, encouragement/approval by friends, multiple chronic health problems, and coexisting dementia or depression (Gibson et al., 2017; Emiliussen et al., 2017). Your suspicion of alcohol abuse increases when there is a history of repeated falls and accidents, social isolation, recurring episodes of memory loss and confusion, failure to meet home and work obligations, a history of skipping meals or medications, and difficulty in managing household tasks and finances. When you suspect that an older adult is abusing alcohol, realize that a variety of treatment options are available. Treatment includes age-specific approaches that acknowledge the stresses experienced by an older adult and encourage involvement in activities that match his or her interests and increase feelings of self-worth. Identifying and treating coexisting depression is also important. The continuum of interventions ranges from simple education about risks to formalized treatment programs that include pharmacotherapy, psychotherapy, and rehabilitation.

Nutrition

Lifelong eating habits and situational factors influence how older adults achieve good nutrition. These habits are based in tradition, cultural habits, and preferences. Religious beliefs influence food choices and preparation. Situational factors affecting nutrition include access to grocery stores, finances, physical and cognitive capability for food preparation, and a place to store food and prepare meals. Older adults' levels of activity and clinical conditions affect their nutritional needs. In addition, conditions such as dementia, poor dentition or ill-fitting dentures, dysphagia, and cardiopulmonary, gastrointestinal, renal, or liver diseases impact nutrition. Healthy nutrition for older adults includes appropriate caloric intake and limited intake of fat, salt, refined sugars, and alcohol. When caring for

older adults with dementia and other chronic conditions, routinely monitor weight and food intake; provide small, frequent meals and serve food that is easy to eat such as finger foods (e.g., chicken strips, sandwiches, cut-up vegetables, and fruit), provide assistance with eating, and offer food supplements that the patient likes and are easy to swallow (Brook, 2018). Consult with a registered dietitian when planning nutritional interventions for your patients.

Protein intake is sometimes lower than recommended if older adults have reduced financial resources or limited access to grocery stores. Fat and sodium intake is sometimes higher than usual because of quick and convenient frozen meals or the substitution of fast-food restaurant meals for meals prepared at home. Home-prepared meals that are fried or made with canned goods also are high in fat and sodium. Some use extra salt and sugar while cooking or at the table to compensate for a diminished sense of taste. Home-delivered meals, such as Meals on Wheels, are an excellent source of nutrition for older adults. Newer online ordering and home delivery services can improve access to quality food sources but may require assistance from family members to order appropriately.

Dental Problems

Dental problems with natural teeth and dentures are common in older adults. Dental caries, gingivitis, broken or missing teeth, and ill-fitting or missing dentures affect nutritional adequacy, cause pain, and lead to infection. Weight loss may contribute to ill-fitting dentures. Dentures are a frequent problem because the cost is not covered by Medicare, and dentures tend to be quite expensive. Help prevent dental and gum disease through education about routine dental care (see Chapter 40).

Exercise

Older adults need to maintain physical exercise and activity. The primary benefits of exercise include maintaining and strengthening functional ability and promoting a sense of enhanced well-being and quality of life (Kaushal et al., 2018). Regular daily exercise such as walking builds endurance, increases muscle tone, improves joint flexibility, strengthens bones, reduces stress, and contributes to weight loss. There is some evidence that exercise has some protective effects on cognition and brain health (Tyndall et al., 2018). Other benefits include improved cardiovascular function, increased metabolic rate, increased gastrointestinal transit time, decreased depression, and improved sleep

quality. Older adults who participate in group exercise programs, individually tailored balance and strength programs, or planned walking programs often experience improved mobility, gait, and balance, resulting in fewer falls ([CDC, 2015](#)).

Many factors influence an individual's willingness to participate in an exercise program. These include general beliefs about the benefits of exercise, past experience with exercise, personal goals, personality, and any unpleasant sensations associated with exercise. A patient's health care provider should be consulted before initiating an exercise program to be sure there are no medical contraindications. Exercise programs for sedentary older adults who have not been exercising regularly need to begin conservatively and progress slowly. An exercise program should be appropriate to the older adult's physical ability while being enjoyable, increasing the likelihood of maintaining the program.

Developing a habit of routine exercise is not only beneficial for the physiological effects but also improves mood and quality of life and helps to incorporate activity into a person's lifestyle ([Kendrick et al., 2018](#)). Walking is one type of exercise many older adults enjoy ([Fig. 14.2](#)). Walking and other low-impact exercises such as riding a stationary exercise bicycle or water exercises in a swimming pool protect the musculoskeletal system and joints. Include other exercises in the older adult's daily routine. For example, have an older adult perform arm and leg circles while watching television.

FIG. 14.2 This couple enjoys walking together.

Safety considerations for exercise include wearing supportive shoes and appropriate clothing, drinking water before and after exercising, avoiding outdoor exercise in extreme temperatures, and exercising with a partner. Instruct older adults to stop exercising and seek help if they experience chest pain or tightness, shortness of breath, dizziness or light-headedness, joint pain, or palpitations during exercise.

Falls

There are multiple risks for falls in the older-adult population (see [Box 14.7](#)). Falls are a safety concern of many older adults. Falls are the leading cause of fatal injury and are the most common nonfatal trauma-related reason for hospital admission (National Council on Aging, n.d.). When a fall occurs in an older adult, it may lead to other life-changing events such as hip fracture, spine fracture, or head injury and admission to a nursing center. Fall-related injuries are often associated with a person's preexisting medical conditions such as osteoporosis and bleeding tendencies. Hospitalized older adults require extra attention to decrease the risk of falls. Each year about 3 million nonfatal falls among older adults are treated in emergency departments, and more than 800,000 of these patients

are hospitalized. The direct medical costs of those falls adjusted for inflation was more than \$50 billion (CDC, 2017). Older adults who have fallen will often develop a fear of falling, which in turn often causes them to walk less naturally or to limit their activities, leading to reduced mobility and loss of physical fitness. Routine exercise and activity can help reduce the risk for falls (Roller et al., 2018; Kaushal et al., 2018). See Chapter 38 for a description of fall prevention interventions.

Box 14.7 Risk Factors for Falls in Older Adults

Intrinsic Factors

- History of a previous fall
- Fear of falling
- Muscle weakness
- Impaired vision
- Postural hypotension
- Problems with balance and gait
- Adverse medication reactions (sedatives, hypnotics, anticonvulsants, opioids)
- Chronic conditions, including arthritis, stroke, incontinence, diabetes, Parkinson's disease, dementia

Extrinsic Factors

- Poor lighting (interior and exterior)
- Lack of handrails on stairs (interior and exterior)
- Poor design of stairwells
- Lack of bathroom grab bars and nonslip surfaces
- Hazards and obstacles (furniture, cords, throw rugs) that contribute to tripping
- Slippery or uneven surfaces
- Improper use of assistive devices
- Inappropriate footwear

Sensory Impairments

Because of common sensory impairments experienced by older adults, you need to promote existing sensory function and be sure that patients live in safe environments. Whenever you provide care activities, make sure that patients wear assistive devices such as a hearing aid or glasses so that they can fully participate in care. [Chapter 49](#) describes in detail the nursing interventions used to maintain and improve sensory function.

Pain

Pain is a symptom and a sensation of distress, alerting a person that something is wrong. It is prevalent in the older-adult population and may be acute or chronic. The consequences of persistent pain include depression, loss of appetite, sleep difficulties, changes in gait and mobility, and decreased socialization. Many factors influence the management of pain, including cultural influences on the meaning and expression of pain for older adults, fears related to the use of analgesic medications, and the problem of pain assessment with older adults who are cognitively impaired. Nurses caring for older adults have to advocate for appropriate and effective pain management (see [Chapter 44](#)). Again, the goal of nursing management of pain in older adults is to maximize and maintain function and improve quality of life.

Medication Use

One of the greatest challenges for older adults is safe medication use. Medication categories such as analgesics, anticoagulants, antidepressants, antihistamines, antihypertensives, sedative-hypnotics, and muscle relaxants create a high likelihood of adverse effects in older adults. They are at risk for adverse medication effects because of age-related changes in the absorption, distribution, metabolism, and excretion of drugs, collectively referred to as the process of pharmacokinetics (see [Chapter 31](#)). Medications sometimes interact with one another, adding to or negating the effect of another drug. Examples of adverse effects include confusion, impaired balance, dizziness, nausea, and vomiting. Because of these effects, some older adults are unwilling to take medications; others do not adhere to the prescribed dosing schedule, or they try to medicate themselves with herbal and over-the-counter medications.

Polypharmacy, the concurrent use of many medications, increases the risk for adverse drug effects ([Box 14.8](#)). Although polypharmacy often reflects inappropriate prescribing, the concurrent use of multiple

medications is often necessary when an older adult has multiple acute and chronic conditions (Andrew et al., 2018). For example, your patient may be taking one or more medications for hypertension, diabetes, and arthritis. Your role as a nurse is to ensure the greatest therapeutic benefit with the least amount of harm by educating patients about safe medication use. You need to question the efficacy and safety of combinations of prescribed medications by conferring with pharmacists or health care providers. Advocate for the older adult to prevent adverse reactions. Older adults often use over-the-counter or herbal medications. The mix of over-the-counter and herbal medications with prescription medications can create serious adverse reactions.

Box 14.8 Evidence-Based Practice Polypharmacy in Older Adults

PICOT Question: Does the use of structured programs to evaluate an older adult's medication regimen decrease the number of potentially inappropriate medications?

Evidence Summary

Polypharmacy is prevalent in older adults due to multiple chronic illnesses and is associated with potentially dangerous outcomes. Health care team members must be alert to potentially harmful medications, as well as adverse reactions and interactions. Studies related to medication management have been conducted in the community, clinics, hospitals, and long-term care facilities. In one study, over half of community-dwelling older adults had questions about their drug regimen, primarily medication side effects and timing (Kovacevic et al., 2017). Additionally, 39.5% reported some sort of practical problem, primarily dosing and remembering instructions that were not written down. Approximately 75% found having a consultation with a pharmacist as beneficial. Another study looked at nursing home residents and older adults receiving home care services (Lenander et al., 2018). The researchers found that 84% of the sample had medication-related problems, including high-risk drugs affecting the nervous, cardiac, and metabolic systems. As a result of the consultation, statistically significant reductions in potentially inappropriate medications and antipsychotics were achieved. A nursing home study compared the number and appropriateness of medications before and after implementing Care by Design, which used an

interprofessional team approach and a physician dedicated to each nursing unit (Andrew et al., 2018). While polypharmacy remained high, a statistically significant reduction in polypharmacy was achieved. Additionally, the number of medications identified by the American Geriatric Society's Beers criteria was reduced; however, the reduction was not statistically significant. One hospital study used an interprofessional team to evaluate appropriateness of medications (Van der Linden et al., 2018). The results demonstrated that the older adults were discharged on fewer medications than they were taking upon admission.

There are two tools to guide appropriate prescribing for older adults. The first tool, the *Beers Criteria for Potentially Inappropriate Medication Use in Older Adults* (American Geriatrics Society, 2015), helps health care providers recognize potentially inappropriate medications. The second, *Screening Tool of Older Person's Prescriptions* and *Screening Tool to Alert Doctors to Right Treatment* (STOPP-START), screens for drug interactions and potentially inappropriate prescribing in older adults (O'Mahony et al., 2015).

Application to Nursing Practice

- Older adults must maintain an accurate listing of all medications being used. Herbal supplements, vitamins, and over-the-counter medications should be included along with prescription medications (Kovacevic et al., 2017).
- If an older adult sees several providers (specialists), there should be one provider that keeps track of the patient's overall medication regimen.
- Older adults can benefit from ongoing education regarding appropriate use of medications and potential adverse effects (Kovacevic et al., 2017).
- The use of a systematic approach to medication reviews has been shown to reduce the number of medications prescribed, including potentially inappropriate medications (Andrew et al., 2018; Lenander et al., 2018).
- The Beers criteria and STOPP-START criteria are two structured tools that provide guidelines for appropriate medication usage (American Geriatric Society, 2015; O'Mahony et al., 2015).
- A number of computer programs and applications can assist with identifying inappropriate medications. These programs are not effective unless the listing of medications is accurate.

For some older adults safely managing medications is complex and often becomes overwhelming. This problem is even more complicated when limited health literacy is an issue. Some take their medications incorrectly because they do not understand the administration instructions, thereby complicating your assessment of medication effects and side effects. Medications that need to be taken more than once or twice a day are a concern because a patient may not remember to take them as scheduled. As a nurse you are in a position to help older-adult patients as they carry out this important self-care activity (see [Chapter 31](#)).

The cost of prescriptions is often prohibitive. The Medicare Prescription Drug Benefit, Medicare Part D, was created in 2003 as part of the Medicare Modernization Act of 2003. This is not one plan but a designation of many plans that are approved by the Centers for Medicare and Medicaid Services ([CMS, n.d.](#)). Although accompanied by a deductible dependent on the number and expense of the medications prescribed, this benefit is of great help to aging adults. In addition, you advocate for patients who need certain medications by working with pharmacies or drug companies to provide the needed medication at less cost. Often a generic medication that will provide the desired effect is available at a reduced cost.

Work collaboratively with older adults and review their medications to ensure safe and appropriate use of all medications, both prescribed and over-the-counter. Teach an older adult the names of all medications that he or she is taking, when and how to take them, and desirable and undesirable effects ([Lenander et al., 2018](#)). Pill organizers, bubble packs, and medication calendars help older adults track their doses. Explain how to avoid adverse effects and/or interactions of medications and how to establish and follow an appropriate self-administration pattern. Strategies for reducing the risk for adverse medication effects include reviewing the medications with older adults at each visit, examining for potential interactions with food or other medications, simplifying and individualizing medication regimens, taking every opportunity to inform older adults and their family caregivers about all aspects of medication use, and encouraging older adults to question their health care providers about all prescribed and over-the-counter medications ([Van der Linden et al., 2018](#)).

The use of medications to manage confusion should be weighed carefully. Sedatives and tranquilizers sometimes prescribed for older adults who are acutely confused often cause or exacerbate confusion and increase risks for falls or other injuries. Carefully monitor patients who receive these medications, taking into account age-related changes in body

systems that affect pharmacokinetic activity. When confusion has a physiological cause (such as an infection), health care providers need to treat the cause rather than the confused behavior. When confusion varies by time of day or is related to environmental factors, use creative, nonpharmacological measures such as making the environment more meaningful, providing adequate light, encouraging use of assistive devices, or even calling friends or family members to let older adults hear reassuring voices.

Health Promotion and Maintenance: Psychosocial Health Concerns

Interventions supporting the psychosocial health of older adults resemble those for other age-groups. However, some interventions are more crucial for older adults experiencing social isolation; cognitive impairment; or stresses related to retirement, relocation, or approaching death.

Elder Mistreatment

Elder mistreatment is complex and multifaceted and encompasses a broad range of abuses. It is found across all areas of nursing practice and socioeconomic settings. Elder abuse is defined as an intentional act or failure to act that causes or creates a risk for harm to an older adult (CDC, 2016). Your ability to screen and assess for it is essential to the safety, health, and well-being of the older adult. Types of elder mistreatment include physical abuse, emotional abuse, financial exploitation, sexual abuse, and neglect (intentional and unintentional) (Table 14.3). Although cases remain underreported, data suggest that 10% of older adults in the United States experience some form of elder mistreatment (CDC, 2016). It is also common for vulnerable older adults to experience a combination of the various types of abuse (Acierno et al., 2018).

TABLE 14.3**Elder Mistreatment: Types, Descriptions, and Examples**

Type	Description	Examples
Physical abuse	Occurs when older adults experience illness, pain, or injury as the result of physical force or the threat of physical injury.	Hitting, beating, pushing, slapping, kicking, physical restraint, inappropriate use of drugs, fractures, lacerations, rope burns, untreated injuries
Psychosocial/emotional abuse	Verbal and nonverbal acts that inflict mental pain, anguish, fear, and distress	Insults, threats, humiliation, intimidation, harassment, social isolation, destroying property
Financial abuse	Illegal taking, misuse, or concealment of money, benefits, property, or assets belonging to an elderly person	Check cashing without permission, forging a signature, stealing money or possessions, coercing a signature on legal documents (e.g., will, trust), forcing or improper use of durable power of attorney, unpaid bills, unauthorized credit card use
Sexual abuse	Nonconsensual sexual contact or activity of any kind; coercing an elder to witness sexual behaviors	Unwanted touching, rape, sodomy, forced watching of pornography, coerced nudity, sexually explicit photography
Neglect	Refusal or failure by those responsible to meet basic needs	Refusal or failure to provide basic necessities such as food, water, shelter, hygiene, and medical care

Modified from Centers for Disease Control and Prevention (CDC), National Center for Injury Prevention and Control: *Understanding elder abuse*, 2016, <https://www.cdc.gov/violenceprevention/pdf/em-factsheet-a.pdf>. Accessed June 15, 2019.

Most perpetrators are relative caregivers, making abuse cases more complex to identify because of denial, fear of reporting, and the refusal of community services (Rosen et al., 2018). Higher rates of elder mistreatment occur when there is a greater reliance on the caregiver because of functional and cognitive impairment. Vulnerable older adults may not reach out for help for fear of further retribution, fear of nursing home placement, or because they have become completely isolated from others. They may feel foolish or blame themselves for allowing someone to mistreat them or not want to get caregivers in legal or financial trouble (NIH, 2016).

Elder mistreatment has become the focus of national and international organizations, public and social policy, and research. Established by the US Administration on Aging, the National Center for Elder Abuse

(<https://ncea.acl.gov/>) is a resource center dedicated to the prevention of elder mistreatment. The Elder Justice Act of 2009 is widely regarded as the most comprehensive bill ever passed to address and battle elder mistreatment, providing federal funding to state Adult Protective Services (APS). In most states APS caseworkers are the first responders to reports of abuse, neglect, and exploitation of vulnerable adults. Services include receiving reports of adult abuse, exploitation, or neglect; investigating these reports; case management; monitoring; and evaluation. In addition to casework services, APS arranges medical, social, economic, legal, housing, and law enforcement or other protective emergency or supportive services (National Center on Elder Abuse, n.d.).

You are in a unique position to screen for elder mistreatment and assess for physical and emotional signs of abuse. A necessary part of your assessment is completing the interview and assessment privately away from the caregiver. It is definitely a “red flag” if the caregiver refuses to leave the room or area so that you can ask questions confidentially. State laws differ on reporting and investigation of elder mistreatment. However, if you suspect that an older adult is being mistreated, notify your supervisor, who will refer you to the appropriate reporting channels. It is your responsibility to know the reporting provisions of your jurisdiction (Touhy, 2018c).

Therapeutic Communication

Therapeutic communication skills enable you to perceive and respect the older adult’s uniqueness and health care expectations. Attentive nurses provide care in a timely fashion, meeting a patient’s expressed or unexpressed needs. A caring nurse expresses attitudes of concern, kindness, and compassion. Knowledgeable nurses not only demonstrate procedural competence but also recognize needs and relay information skillfully. Patients accept and respect nurses who meet these expectations and communicate effectively about concern for the older adult’s welfare. However, you cannot simply enter an older adult’s environment and immediately establish a therapeutic relationship. First, you have to be knowledgeable and skilled in communication techniques (see [Chapter 24](#)). Sitting down and engaging an older adult eye to eye goes a long way in establishing a therapeutic relationship.

Touch

Touch is a therapeutic tool that can be used to help comfort older adults. It provides sensory stimulation, induces relaxation, provides physical and emotional comfort, conveys warmth, and communicates interest. It is a powerful physical expression of a relationship. In addition, gentle touch is a technique to use when administering any type of procedure that requires physical contact or repositioning and moving a patient.

Older adults are often deprived of touch when separated from family or friends. An older adult who is isolated, dependent, or ill; who fears death; or who lacks self-esteem has a greater need for touch. You recognize touch deprivation by behaviors as simple as an older adult reaching for the nurse's hand or standing close to the nurse. Unfortunately, older men are sometimes wrongly accused of sexual advances when they reach out to touch others. When you use touch, be aware of cultural variations and individual preferences (see [Chapters 7](#) and [9](#)). Use touch to convey respect and sensitivity. Do not use it in a condescending way such as patting an older adult on the head. When you reach out to an older adult, do not be surprised if he or she reciprocates.

Reality Orientation

Reality orientation is a communication technique that makes an older adult more aware of person, place, and time. The purposes of reality orientation include restoring a sense of reality; improving the level of awareness; promoting socialization; elevating independent functioning; and minimizing confusion, disorientation, and physical regression. Although you use reality orientation techniques in any health care setting, they are especially useful in the acute care setting. The older adult experiencing a change in environment, surgery, illness, or emotional stress is at risk for becoming disoriented ([Chiu et al., 2018](#)). Environmental changes such as bright lights, unfamiliar noises, and lack of windows in specialized units of a hospital often lead to disorientation and confusion. Absence of familiar caregivers is also disorienting. The use of anesthesia, sedatives, tranquilizers, analgesics, and physical restraints in older patients increases disorientation. Anticipate and monitor for disorientation and confusion as possible consequences of hospitalization, relocation, surgery, loss, or illness, and incorporate interventions on the basis of reality orientation into the plan of care.

The principles of reality orientation offer useful guidelines for communicating with individuals who are acutely confused. The key elements of reality orientation include frequent reminders of person, place, and time; the use of familiar environmental aids such as clocks, calendars,

and personal belongings; and stability of the environment, routine, and staff (Chiu et al., 2018).

Validation Therapy

Validation therapy is an alternative approach to communication with an older adult who is confused. Whereas reality orientation insists that the confused older adult agree with statements of time, place, and person, validation therapy accepts the description of time and place as stated by the older adult. You do not challenge or argue with statements and behaviors of the older adult. Instead the focus is the emotional aspect of the conversation, which represents an inner need or feeling (Scales, 2018). For example, a patient insists that the day is actually a different day because of high anxiety. Caregivers should acknowledge the distress the individual is experiencing. Validation does not involve reinforcing the older adult's misperceptions; it reflects sensitivity to hidden meanings in statements and behaviors. By listening with sensitivity and validating what the patient is expressing, you convey respect, reassurance, and understanding. Validating or respecting older adults' feelings in the time and place that is real to them is more important than insisting on the literally correct time and place.

Reminiscence

Reminiscence is recalling the past. Many older adults enjoy sharing past experiences. As a therapy, reminiscence uses the recollection of the past to bring meaning and understanding to the present and resolve current conflicts. Looking back to positive resolutions of problems reminds an older adult of coping strategies used successfully in the past. Reminiscing is also a way to express personal identity. Reflection on past achievements supports self-esteem (Scales, 2018). For some older adults the process of looking back on past events uncovers new meanings for those events.

During the assessment process use reminiscence to assess self-esteem, cognitive function, emotional stability, unresolved conflicts, coping ability, and expectations for the future. For example, have a patient talk about a previous loss to assess coping. You can also reminisce during direct care activities. Taking time to ask questions about past experiences and listening attentively conveys to an older adult your attitudes of respect and concern.

Although many use reminiscence in a one-on-one situation, it is also used as a group therapy for older adults who are cognitively impaired or

depressed ([Siverova and Buzgova, 2018](#)). You begin by organizing the group and selecting strategies to start a conversation. For example, you ask the group to discuss family activities or childhood memories, adapting questions to the group's size, structure, process, goals, and activities to meet its members' needs.

Body Image Interventions

The way older adults present themselves influences body image and feelings of isolation (see [Chapter 33](#)). Some physical characteristics of older adulthood such as distinguished-looking gray hair are socially desirable. Other features, such as a lined face that displays character or wrinkled hands that show a lifetime of hard work, are also impressive.

Consequences of illness and aging that threaten an older adult's body image include invasive diagnostic procedures, pain, surgery, loss of sensation in a body part, skin changes, and incontinence. The use of devices such as dentures, hearing aids, artificial limbs, indwelling catheters, ostomy devices, and enteral feeding tubes also affects body image.

You need to consider the importance to an older adult of presenting a socially acceptable image. When older adults have acute or chronic illnesses, the related physical dependence makes it difficult for them to maintain body image. Help them with grooming and hygiene. It takes little effort to help an older adult comb hair, clean dentures, shave, or change clothing. He or she does not choose to have an objectionable appearance. Be sensitive to odors in the environment. Odors created by urine and some illnesses are often present. By controlling odors you may prevent visitors from shortening their stay or not coming at all.

Older Adults and the Acute Care Setting

Older adults in the acute care setting need special attention to help them adjust to the acute care environment and meet their basic needs. The acute care setting poses increased risk for adverse events such as delirium, dehydration, malnutrition, health care–associated infections (HAIs), urinary incontinence, and falls. The risk for delirium increases when hospitalized older adults experience immobilization, sleep deprivation, infection, dehydration, pain, sensory impairment, drug interactions, anesthesia, and hypoxia. Nonmedical causes of delirium include unfamiliar surroundings, unfamiliar staff, bed rest, separation from support systems, and stress. Refer to the discussion of delirium, dementia, and depression earlier in the chapter on distinguishing between these three conditions. Impaired vision or hearing contributes to confusion and interferes with attempts to reorient an older adult.

When the prevention of delirium fails, nursing management begins with identifying and treating the cause. Supportive interventions include encouraging family visits, providing memory cues (clocks, calendars, and name tags), and compensating for sensory deficits. Reality orientation techniques are often useful.

Older adults are at greater risk for dehydration and malnutrition during hospitalization because of standard procedures such as limiting food and fluids in preparation for diagnostic tests and medications that decrease appetite. The risk for dehydration and malnutrition increases when older adults are unable to reach beverages or feed themselves while in bed or connected to medical equipment. Interventions include getting the patient out of bed, providing beverages and snacks frequently, and including favorite foods and beverages in the diet plan.

The increased risk for HAIs in older adults is associated with the decreased immune system response related to advancing age in addition to other chronic conditions that make older adults more susceptible, along with invasive procedures and devices. The most common HAI are central line-associated bloodstream infections (CLABSIs), catheter-associated UTIs (CAUTIs), surgical site infection, and ventilator-associated pneumonia (VAP) (CDC, 2018). The leading preventive measure is hand hygiene combined with proper isolation policy and procedures to prevent and control the transmission of infection (see [Chapter 28](#)).

Older hospitalized adults are at risk for becoming incontinent of urine (transient incontinence). Causes of incontinence include delirium, untreated UTIs, medications, restricted mobility, or need for assistance to

get to the bathroom. Individualized interventions to decrease incontinence include voiding opportunities and modification of the environment to improve access to the toilet. It is important to avoid indwelling urinary catheterization (see [Chapter 46](#)).

The increased risk for skin breakdown and the development of pressure injuries is related to changes in aging skin and to situations that occur in the acute care setting such as immobility, incontinence, and malnutrition. The key points in the prevention of skin breakdown are using a mattress appropriate for the risk of skin breakdown with proper positioning, reducing shear and friction, providing meticulous skin care and moisture management, and providing nutritional support (see [Chapter 48](#)).

Older adults in the acute care setting are also at greater risk for falling and sustaining injuries. The cause of a fall is typically multifactorial and composed of intrinsic or extrinsic factors (see [Box 14.7](#)). Sedative and hypnotic medications increase unsteadiness. Lower extremity weakness and general fatigue and deconditioning can make it difficult for a patient to get out of bed. Once the patient does get out of bed, often he or she is very unsteady and prone to falling. Medications causing orthostatic hypotension also increases the risk for falls because the blood pressure drops when an older adult gets out of a bed or chair. The increase in urine output from diuretics increases the risk for falling by increasing the number of attempts to get out of bed to void. Equipment such as wires from monitors, intravenous tubing, urinary catheters, and other medical devices become obstacles to safe ambulation. Impaired vision prevents an older adult from seeing tripping hazards such as trash cans.

Physical restraints are used only as an intervention of last resort and require a health care provider's order. Many hospitals use bed and chair alarms. Making hourly rounds focusing on toileting needs, pain management, and personal needs of the patient often reduces falls ([Christiansen, et al., 2018](#)).

Older Adults and Restorative Care

Restorative care refers to two types of ongoing care: the continuation of the recovery from acute illness or surgery that began in the acute care setting and support of chronic conditions that affect day-to-day functioning. Both types of restorative care take place in private homes and long-term care settings.

Interventions during convalescence from acute illness or surgery aim at regaining or improving patients' prior level of independence in ADLs. Continue interventions that began in the acute care setting and later modify them as convalescence progresses. To achieve this continuation, ensure that discharge information provided by the acute care setting includes information on required ongoing interventions (e.g., exercise routines, wound care routines, medication schedules, and blood glucose monitoring). Interventions also need to address the restoration of interpersonal relationships and activities at either their previous level or the level desired by the older adult. When restorative care addresses chronic conditions, the goals of care include stabilizing the chronic condition and maximizing independence in ADLs.

Interventions to promote independence in ADLs address a person's physical and cognitive ability and safety. The physical ability to perform ADLs requires strength, flexibility, and balance. You need to make accommodations for impairments of vision, hearing, and touch. The cognitive ability to perform ADLs requires the ability to recognize, judge, and remember. Cognitive impairments such as dementia interfere with safe performance of ADLs, although an older adult is still physically capable of the activities. Adapt interventions to promote independence in ADLs to meet the needs and lifestyle of the older adult. Although safety is paramount, an older adult needs to be able to perform ADLs with a level of risk that is acceptable to him or her. Collaborate with an occupational therapist, who is trained in selecting the correct type of assistive devices for patients.

You need to support an older adult's ability to perform IADLs such as using a telephone, doing laundry, cleaning the home or apartment, handling money, paying bills, and driving an automobile. To live independently at home or in an apartment, older adults need to be able to perform IADLs, purchase services by outside workers, or have a supportive network of family and friends who help with these tasks. Occupational therapists are an important resource for helping people adapt when IADLs are difficult to perform. Also, it might be appropriate

to have a family caregiver assume more responsibility by completing IADLs for patients.

Restorative care measures focus on activities that allow older adults to remain functional and safe within their living environments. Collaborate with an older adult to establish priorities of care and patient goals, determine expected outcomes, and select appropriate interventions. Patient collaboration promotes a patient's understanding about care and minimizes conflicts. Consideration of an older adult's lifetime experiences, values, and sociocultural patterns serves as the basis for planning individual care. When an older adult's cognitive status prevents participation in health care decisions, you need to include the family caregivers. Family and friends are rich sources of data because they knew the older adult before the impairment. Frequently they provide explanations for the older adult's behaviors and suggest methods of management. Thoughtful assessment and planning lead to goals of care that consider the influence of normal aging changes, facilitate an optimal level of comfort and coping, and promote independence in self-care activities.

Key Points

- Nurses must be aware of and avoid any preconceived biases against older adults. Instead they must promote a positive perception of older adults.
- Nurses collaborate with older adults in assisting them to achieve their developmental tasks in a healthy manner.
- It is important to differentiate normal changes in aging with disease manifestations.
- Delirium, dementia, and depression share some common symptoms, but an accurate diagnosis is essential for appropriate management.
- Nurses can assist older adults to adapt to psychosocial issues commonly seen in aging.

- There are different types of elder mistreatment; nurses must be alert to cues of mistreatment and report appropriately.
- Nurses should be alert to atypical presentation of illness in older adults.
- Nursing interventions should focus on maintaining maximal functioning and independence.

Reflective Learning

Consider an older patient you have recently encountered and consider the following:

- What safety concerns might you have for this person? If the older adult were to return to his or her previous living arrangement, what safety concerns will exist there?
- Describe any concerns you have about how they are adapting to the aging process.
- How have you adapted your communication strategies for this person? Was it effective?

Review Questions

1. A patient's family member is considering having her mother placed in a nursing center. The nurse has talked with the family before and knows that this is a difficult decision. Which of the following criteria does the nurse recommend in choosing a nursing center? (Select all that apply.)
 1. The center needs to be clean, and rooms should look like a hospital room.
 2. Adequate staffing is available on all shifts.
 3. Social activities are available for all residents.
 4. The center provides three meals daily with a set menu and serving schedule.

5. Staff encourage family involvement in care planning and assisting with physical care.
2. A nurse conducted an assessment of a new patient who came to the medical clinic. The patient is 82 years old and has had osteoarthritis for 10 years and diabetes mellitus for 20 years. He is alert but becomes easily distracted during the assessment. He recently moved to a new apartment, and his pet beagle died just 2 months ago. He is most likely experiencing:
 1. Dementia.
 2. Depression.
 3. Delirium.
 4. Anxiety.
3. A nurse is completing a health history with the daughter of a newly admitted patient who is confused and agitated. The daughter reports that her mother was diagnosed with Alzheimer's disease 1 year ago but became extremely confused last evening and was hallucinating. She was unable to calm her, and her mother thought she was a stranger. On the basis of this history, the nurse suspects that the patient is experiencing:
 1. Normal aging.
 2. Delirium.
 3. Depression.
 4. Worsening dementia.
4. Older adults frequently experience a change in sexual activity. Which best explains this change?
 1. The need to touch and be touched is decreased.
 2. The sexual preferences of older adults are not as diverse.
 3. Medication side effects often impact sexual functioning.
 4. Frequency and opportunities for sexual activity may decline.

5. A nurse sees a 76-year-old woman in the outpatient clinic. She states that she recently started to notice a glare in the lights at home. Her vision is blurred, and she is unable to play cards with her friends, read, or do her needlework. Which of the following nursing interventions are appropriate? (Select all that apply.)
1. Refer her to an ophthalmologist.
 2. Suggest large-print books and playing cards.
 3. Reassure her that this is part of normal aging.
 4. Suggest lower-wattage light bulbs to decrease glare.
 5. Assess her home environment for safety.
6. A 63-year-old patient is retiring from his job at an accounting firm where he was in a management role for the past 20 years. He has been with the same company for 42 years and was a dedicated employee. His wife is a homemaker. She raised their five children, babysits for her grandchildren as needed, and belongs to numerous church committees. What are the major concerns for this patient? (Select all that apply.)
1. The loss of his work role
 2. The risk of social isolation
 3. A determination on whether the wife will need to start working
 4. How the wife expects household tasks to be divided in the home in retirement
 5. The age the patient chose to retire
7. A nurse is assessing an older adult brought to the emergency department following a fall and wrist fracture. The patient is very thin and unkempt, has a stage 3 pressure injury on her coccyx, and has old bruising to the extremities in addition to her new bruises from the fall. She defers all of the questions to her

caregiver son, who accompanied her to the hospital. What is the nurse's next step?

1. Call social services to begin nursing home placement.
 2. Ask the son to step out of the room so that she can complete her assessment.
 3. Call adult protective services because you suspect elder mistreatment.
 4. Assess the patient's cognitive status.
8. A nurse is participating in a health and wellness event at the local community center. A woman approaches and relates that she is worried that her widowed father is becoming more functionally impaired and may need to move in with her. The nurse asks about his ability to complete activities of daily living (ADLs). ADLs include independence with: (Select all that apply.)
1. Driving.
 2. Toileting.
 3. Bathing.
 4. Daily exercise.
 5. Eating.
9. During a home health visit a nurse talks with a patient and his family caregiver about the patient's medications. The patient has hypertension and renal disease. Which of the following findings place him at risk for an adverse drug event? (Select all that apply.)
1. Taking two medications for hypertension
 2. Taking a total of eight different medications during the day
 3. Having one physician who reviews all medications
 4. Patient's health history of renal disease

5. Involvement of the caregiver in helping with medication administration

10. A 71-year-old patient enters the emergency department after falling down stairs at church. The nurse is conducting a fall history with the patient and his wife. They live in a one-level ranch home. He has had diabetes for over 15 years and experiences some numbness in his feet. He wears bifocal glasses. His blood pressure is stable at 130/70. The patient does not exercise regularly and states that he experiences weakness in his legs when climbing stairs. He is alert, oriented, and able to answer questions clearly. What are the fall risk factors for this patient? (Select all that apply.)

1. Impaired vision

2. Residence design

3. Blood pressure

4. Leg weakness

5. Exercise history

Answers: 1. 2, 3, 5; 2. 2; 3. 2; 4. 4; 5. 1, 2, 5; 6. 1, 4; 7. 2; 8. 2, 3, 5; 9. 2, 4; 10. 1, 4,

Critical Thinking in Nursing Practice

OUTLINE

15. Critical Thinking in Nursing Practice
16. Nursing Assessment
17. Nursing Diagnosis
18. Planning Nursing Care
19. Implementing Nursing Care
20. Evaluation
21. Managing Patient Care

Critical Thinking in Nursing Practice

OBJECTIVES

- Describe the nature of clinical judgments in nursing practice.
- Explain how questioning promotes critical thinking.
- Discuss how reflection improves a nurse's capacity for making future clinical decisions.
- Compare and contrast the three levels of critical thinking.
- Explain the importance of problem solving in nursing practice.
- Describe processes of inductive and deductive reasoning in decision making.
- Describe the components of a critical thinking model for clinical decision making.
- Describe approaches for developing critical thinking skills.

KEY TERMS

Clinical decision making, p. 197

Clinical judgment, p. 197

Concept map, p. 207

Critical thinking, p. 197

Decision making, p. 201

Deductive reasoning, p. 202

Diagnostic reasoning, p. 201

Evidence-based knowledge, p. 197

Inductive reasoning, p. 202

Inference, p. 202

Knowing the patient, p. 202

Nursing process, p. 202

Problem solving, p. 200

Reflection, p. 198

Scientific method, p. 200

Being a nurse is very challenging. Nurses frequently begin their clinical experiences in hospital settings. In the acute care hospital environment there is a great emphasis on patient-centered care, recognizing a patient or family member as the source of control and full partner in providing compassionate and coordinated care based on a patient's preferences, values, and needs (QSEN, 2018). In addition, hospitals expect evidence-based practice (see Chapter 5) to be routinely applied to ensure better patient outcomes. Amid these expectations is the need to also address patients' satisfaction in care while dealing with ongoing and demanding staffing issues (Chan, 2013). Outpatient clinics, home care agencies, and community health programs also have many of the same expectations as hospitals but with different types of demands. To be competent within any complex health care environment, critical thinking is an essential skill (Chan, 2013).

Every day you think critically without realizing it. If your computer flashes an error warning or your cell phone does not take you to the application you wish, you think about the actions you took before the error, consider possible causes of the problem, and correct a key stroke or reboot the device. If you decide to walk your dogs, go to the door, and notice that it is raining, you decide to change into your raincoat. These simple examples show how you use basic critical thinking skills each day.

As a professional nurse, critical thinking is a bit more complicated. You care for patients with unique, complex health care problems that can change within minutes. Critical thinking becomes embedded in your everyday practice, as it involves knowing as much as possible about each patient and sorting out the information into patterns to clarify problems, recognize changes, and make appropriate care decisions under pressure. Critical thinking is an essential process for safe, efficient, and skillful nursing intervention (Papathanasiou, 2014). Sound critical thinking enables you to face each new experience and problem involving a patient's care with open-mindedness, confidence, and continual inquiry. Critical thinkers do not passively accept information from others or look at

information in a cursory way. Instead, thinkers question, seek, and look for answers and deeper meanings ([Chan, 2013](#)).

Critical thinking improves patients' outcomes because it helps nurses perform evidence-based practices rather than guessing the facts ([Profetto-McGrath, 2005](#); [Chan, 2013](#)). Critical thinking is not a simple step-by-step, linear process that you learn overnight. It is a process gained only through experience, commitment, and an active curiosity toward learning.

Clinical Judgment in Nursing Practice

Registered nurses (RNs) are responsible for making accurate and appropriate clinical decisions or judgments that ensure patients receive appropriate, timely, and effective nursing interventions. A **clinical judgment** is a conclusion about a patient's needs or health problems and/or the decisions to take or avoid action, use or modify standard approaches, or create new approaches based on the patient's response (Tanner, 2006). **Clinical decision making** separates professional nurses from assistive personnel (AP). For example, an RN observes for changes in patient's conditions, collects data about the changes, recognizes and identifies new and potential problems, plans nursing strategies, and takes immediate action when a patient's clinical condition worsens. Nurses direct AP to perform basic aspects of care based on patient need; AP do not have the knowledge or critical thinking skills to analyze why or when patients' clinical conditions change and what strategies are required. Good clinical decision making requires you to investigate and analyze all aspects of a clinical problem and then apply scientific and nursing knowledge to choose the best course of action.

In 2006, Dr. Christine Tanner described a research-based model of clinical judgment in nursing. It included the following conclusions:

- Clinical judgments are influenced more by a nurse's experience and knowledge than by the objective data about the situation at hand. Experience is crucial in knowing how to interpret the data.
- Sound clinical judgment partly relies on knowing the patient and his or her typical pattern of responses, as well as engaging with the patient about his or her concerns.
- Clinical judgments are influenced by the context of clinical situations and the culture of patient care settings.
- Nurses use a variety of reasoning approaches in combination, such as problem solving and reflection to understand patient problems and create an individualized plan of care.

Most patients have health care problems for which there are no clear textbook solutions. Each patient's health problems are unique, a product of the patient's physical health, lifestyle, culture, relationship with family and friends, living environment, and experiences. Thus, as a nurse you do not always have a clear picture of a patient's needs and the appropriate actions to take when first meeting a patient. Instead you must learn to

question, wonder, and explore different perspectives and interpretations to find a solution that benefits the patient. With experience you learn to creatively seek new knowledge, act quickly when events change, and make quality decisions for patients' well-being.

Critical Thinking Defined

*Mr. Lawson is a 68-year-old patient who had abdominal surgery for a colon resection and removal of a tumor yesterday. His nurse, Tonya, finds the patient lying supine in bed with his arms held tightly over his abdomen. His facial expression is tense. When Tonya checks the patient's surgical wound, she notes that he winces when she gently places her hands to palpate around the surgical incision. She asks Mr. Lawson when he last turned onto his side, and he responds, "Not since last night." Tonya asks Mr. Lawson if he is having pain around his incision, and he nods yes, saying, "It hurts too much to move." Tonya assesses Mr. Lawson with a pain-rating scale. He rates his pain at a 7 on a scale of 0 to 10. Tonya considers the information she observed and learned from the patient to determine that he is in pain and has reduced mobility because of it. She decides to take action by administering an ordered analgesic. In this case example Tonya observes the patient's clinical situation. She asks questions and reflects on her previous experiences caring for patients who had abdominal surgery. She considers what she knows and has learned about managing postoperative pain and about preventing complications related to immobility. Tonya makes a clinical decision by applying **critical thinking**, the ability to think in a systematic and logical manner with openness to question and reflect on the reasoning process.*

Critical thinking involves open-mindedness, continual inquiry, and perseverance, combined with a willingness to look at each unique patient situation and determine which identified assumptions are true and relevant. A nurse learns to recognize that a patient problem exists, analyzes information about the problem (e.g., clinical data, observation of patient behavior), interprets the information (reviewing assumptions and evidence, recognizing patterns), and makes conclusions so that he or she can act appropriately. A critical thinker considers what is important in each clinical situation, imagines and explores alternatives, considers ethical principles, and makes informed decisions about the care of patients. The aim of critical thinking is the ability to focus on the important issues at hand in any clinical situation and make decisions that produce desired outcomes ([Raterink, 2011](#)).

Critical thinkers question, seek, and examine information for answers and deeper meanings in order to understand their patients ([Chan, 2013](#)). *Tonya first learned about the importance of early mobility after surgery when she read the nursing and scientific literature on the concept of mobility and deconditioning. She also learned that pain reduces mobility when she cared for*

previous patients. Critical thinking is a way of thinking about clinical situations by asking questions such as:

- “Why does the patient have this condition?”
- “Are the signs and symptoms shown by the patient what I would expect for the condition or situation?”
- “What do I really know about this patient’s situation?”
- “What other ways can I collect data to help me understand the problem?”
- “What care options do I have?”

Evidence-based knowledge, or knowledge based on research or clinical expertise, makes nurses better informed critical thinkers (see [Chapter 5](#)). Thinking critically and learning about the scientific concepts of deconditioning, comfort, and mobility prepare Tonya to better anticipate Mr. Lawson’s needs, identify problems more quickly, and provide appropriate care.

Tonya’s review of her observations and the patient’s report of pain confirmed her knowledge that pain was likely a problem. Her decision is to give Mr. Lawson an ordered analgesic and wait until it takes effect so that she is able to reposition and make him more comfortable. Once he has less acute pain, Tonya plans to teach Mr. Lawson some relaxation exercises to maintain his comfort. As the patient gains relief, Tonya will consider when to begin the mobility protocol to increase Mr. Lawson’s activity level.

You learn to think critically early in your practice. For example, as you learn about giving baths and providing other hygiene measures, take time to read your textbook, online resources, and the scientific literature about the concept of comfort. What are the criteria for comfort? How does a patient’s culture affect perceptions of comfort? What are the many factors that promote comfort? When you apply core critical thinking skills to your nursing care, you are using the complex process of clinical decision making ([Table 15.1](#)). Being able to apply all of these skills takes practice. You also need to have a sound knowledge base and thoughtfully consider what you learn when caring for patients.

TABLE 15.1**Critical Thinking and Clinical Judgment Skills**

Skill	Nursing Practice Applications
Interpretation	Be orderly in collecting data about patients. Apply reasoning while looking for patterns to emerge. Categorize the data (e.g., nursing diagnoses [see Chapter 17]). Gather additional data and clarify any data about which you are uncertain.
Analysis	Be open-minded as you look at information about a patient. Do not make careless assumptions. Does the data reveal a problem or trend that you believe is true, or are there other options?
Inference	Look at the meaning and significance of findings. Are there relationships among findings? Do data about the patient help you see that a problem exists?
Evaluation	Look at all situations objectively. Use criteria (e.g., expected outcomes, pain characteristics, learning objectives) to determine results of nursing actions. Reflect on your own behavior.
Explanation	Support your findings and conclusions. Use knowledge and experience to choose strategies to use in the care of patients.
Self-regulation	Reflect on your experiences. Be responsible for connecting your actions with outcomes. Identify the ways you can improve your own performance. What will make you believe that you have been successful?

Modified from Facione P: Critical thinking: a statement of expert consensus for purposes of educational assessment and instruction. *The Delphi report: research findings and recommendations prepared for the American Philosophical Association*, ERIC Doc No. ED 315, Washington, DC, 1990, ERIC.; and Tanner CA: Thinking like a nurse: a research-based model of clinical judgment in nursing, *J Nurs Educ* 45(6):204, 2006.

Nurses who apply critical thinking in their work are able to see the big picture from all possible perspectives. They focus clearly on options for solving problems and making decisions rather than quickly and carelessly forming quick solutions ([Kataoka-Yahiro and Saylor, 1994](#)). Learning to think critically helps you care for patients as their advocate, or supporter, and make better-informed choices about their care. [Facione and Facione \(1996\)](#) identified concepts for thinking critically ([Table 15.2](#)). Critical thinking is more than just problem solving. It is a continuous attempt to improve how you apply your knowledge and experience when faced with problems in patient care ([Erickson, 2017](#)).

TABLE 15.2

Concepts for a Critical Thinker

Concept	Critical Thinking Behavior
Truth seeking	Seek the true meaning of a situation. Be courageous, honest, and objective about asking questions.
Open-mindedness	Be tolerant of different views; be sensitive to the possibility of your own prejudices; respect the right of others to have different opinions.
Analyticity	Analyze potentially problematic situations; anticipate possible results or consequences; value reason; use evidence-based knowledge.
Systematicity	Be organized, focused; work hard in any inquiry.
Self-confidence	Trust in your own reasoning processes.
Inquisitiveness	Be eager to acquire knowledge and learn explanations even when applications of the knowledge are not immediately clear. Value learning for learning's sake.
Maturity	Multiple solutions are acceptable. Reflect on your own judgments; have cognitive maturity.

Modified from Facione N, Facione P: Externalizing the critical thinking in knowledge development and clinical judgment, *Nurs Outlook* 44(3):129, 1996.

REFLECT NOW

Consider a patient you have been assigned to recently. Based on that individual patient's needs and health problems, what evidence-based information might you seek to provide evidence-based nursing care?

Reflection

As you care for patients, you will often review your practice experiences to describe, analyze, and evaluate results (Barksby et al., 2015). Such a review is **reflection**, a part of critical thinking that involves purposefully reviewing a situation to discover its purpose or meaning. After caring for a patient, you might ask yourself:

- How did I act?
- Why did I choose such an action?
- What could I have done differently?
- Were the results what I expected?
- What should I do in a similar situation in the future?

As a nurse you will reflect on the purpose and meaning of each patient's situation, as well as the purpose and meaning of your actions in that situation. *For example, before Tonya makes a conclusion about Mr. Lawson's problems, she thinks about previous surgical patients for whom she cared and how they responded to incisional pain. She recalls a patient who had a serious pulmonary embolus (clot in the lung) after surgery and how that pain differed from incisional pain. Reflecting on previous clinical situations prepares Tonya to act knowledgeably and quickly in caring for Mr. Lawson.* Research has shown that when nurses reflect on past experiences, they perceive that their knowledge increases, and their critical thinking moves to a higher level (Kaddoura, 2013).

Reflection is like instant replay. It is not intuitive. It involves purposefully visualizing a past situation and taking the time to honestly review everything you remember about it. This reflection allows you to gain new knowledge and raise questions about your practice, which can lead to a search for better approaches using evidence for practice (Barksby et al., 2015) Research shows that reflective reasoning improves the accuracy of making diagnostic conclusions (see Chapter 17) (Mamede et al., 2012). This means that gathering information about a patient, reflecting on the meaning of your findings, and exploring the possible meaning of those findings improve your ability to problem solve. Reflection lessens the guesswork in decision making. By reviewing your previous actions, you see successes and opportunities for improvement. Always be cautious in using reflection. Reliance on it can block thinking and not allow you to look at newer evidence or subtle aspects of situations that you have not encountered. Box 15.1 lists steps of a model for using reflection in your practice.

Box 15.1 Model for Reflection

REFLECT: This model can be used individually or as a process shared with others.

- R Recall** the events. Review the facts about a situation and describe what happened.
- E Examine your responses.** Think about or discuss your thoughts and actions at the time of the situation.
- F Acknowledge Feelings:** Identify any feelings you had during the situation.
- L Learn** from the experience: Review and highlight what you learned from the situation—for example, your patient’s responses and your actions.
- E Explore options:** Think about or discuss your options for similar situations in the future.
- C Create** a plan of action: Create a plan for how to act in future similar situations.
- T Set a Time:** Set a time by which your plan of action will be completed.

Adapted from Barksby J, et al: A new model of reflection for clinical practice, *Nurs Times* 111(34/35):21-23, 2015.

Building Competency in Patient-Centered Care

Think about a patient you recently cared for. Describe how you would use each of the elements of the REFLECT model to incorporate principles of patient-centered care.

Levels of Critical Thinking in Nursing

Your ability to think critically grows as you gain new knowledge and experience in nursing practice. [Kataoka-Yahiro and Saylor \(1994\)](#) developed a critical thinking model ([Fig. 15.1](#)) that includes three levels: basic, complex, and commitment.

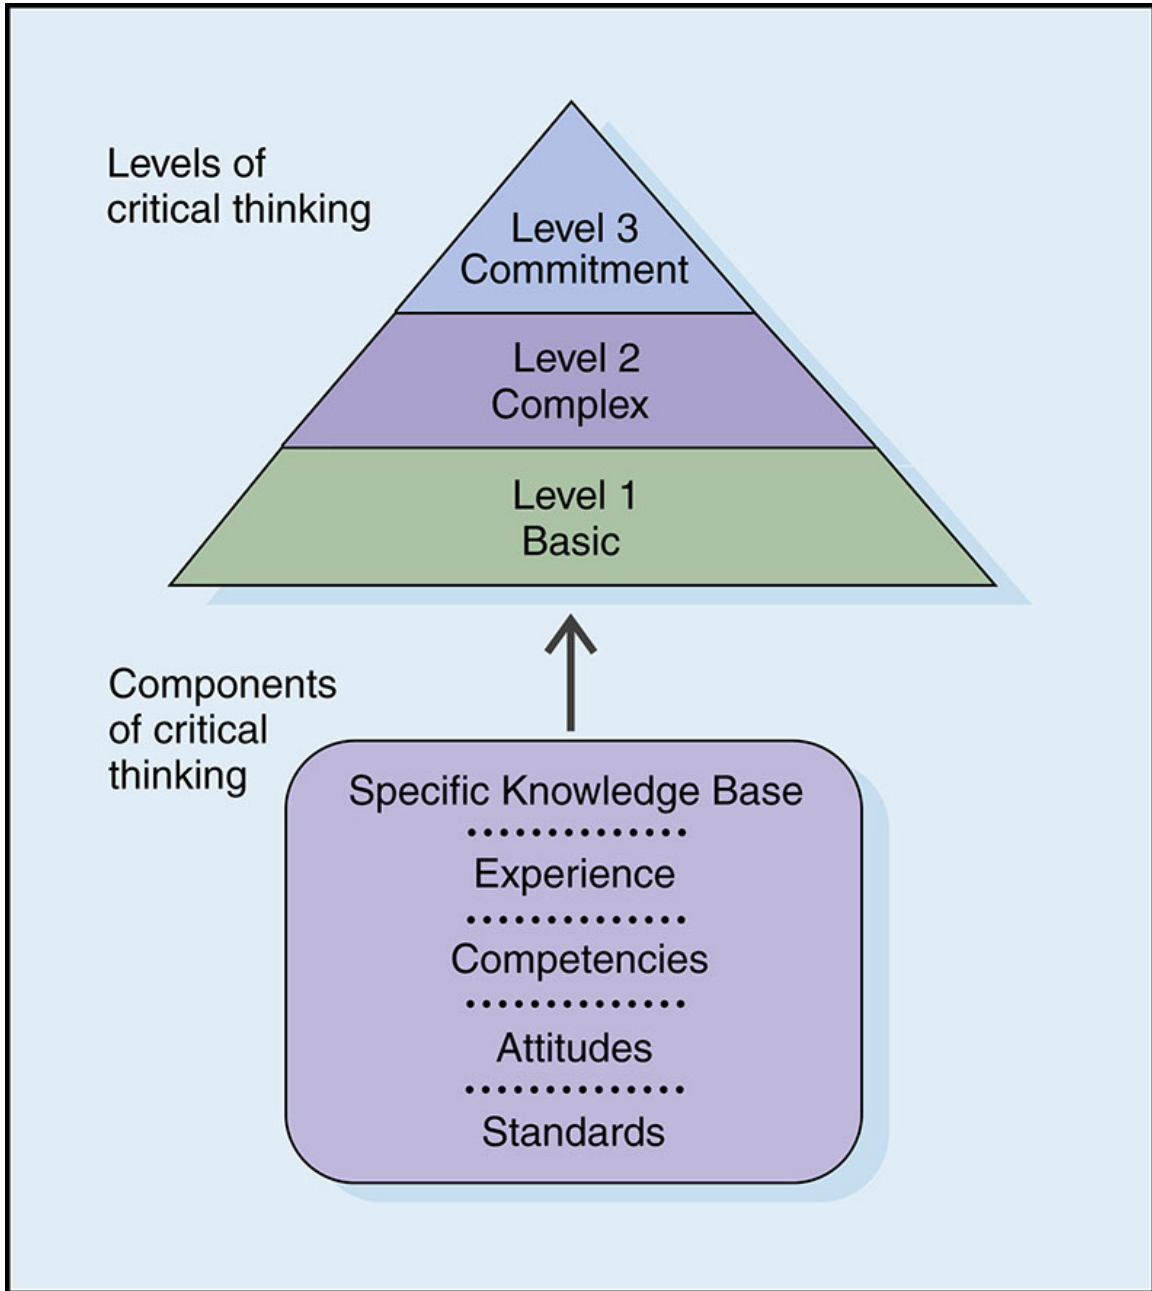

FIG. 15.1 Critical thinking model for nursing judgment.

Redrawn from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Modified from Glaser E: *An experiment in the development of critical thinking*, New York, 1941, Bureau of Publications, Teachers College, Columbia University; Miller M, Malcolm N: Critical thinking in the nursing curriculum, *Nurs Health Care* 11:67, 1990; Paul RW: The art of redesigning instruction. In Willsen J, Blinks AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world*, Santa Rosa, CA, 1993, Foundation for Critical Thinking; and Perry W: *Forms of intellectual and ethical development in the college years: a scheme*, New York, 1979, Holt, Rinehart, & Winston.

Basic Critical Thinking

Beginning nursing students are task oriented as they focus on performing skills and organizing nursing care activities. At the basic level of critical thinking a learner trusts that experts have the right answers for every problem. Thinking is concrete and based on a set of rules or principles. For example, as a nursing student you use a hospital procedure manual to confirm how to change an intravenous (IV) dressing. You are likely to follow the procedure step by step without adjusting it to meet a patient's unique needs (e.g., positioning to minimize the patient's pain or mobility restrictions). You do not have enough experience to anticipate how to individualize the procedure when problems arise. At this level answers to complex problems are perceived as either right or wrong (e.g., when the IV is not infusing correctly, the rate must not be regulated correctly), and a single solution usually resolves each problem (e.g., adjusting the rate instead of trying to position the patient's arm to prevent catheter kinking). Basic critical thinking is an early step in developing reasoning ([Kataoka-Yahiro and Saylor, 1994](#)). A basic critical thinker learns to accept the diverse opinions and values of experts (e.g., instructors and staff nurse preceptors). However, inexperience, weak competencies, and inflexible attitudes restrict a person's ability to move to the next level of critical thinking ([Erickson, 2017](#)).

Complex Critical Thinking

Complex critical thinkers begin to rely less on experts and trust their own decisions more. For example, while teaching a patient how to use an inhaler, you recognize that your patient cannot deliver a dose correctly. Rather than refer to a procedure manual and repeat the same approach, you adapt by offering an inhaler the patient can activate and instruct the patient on how to better coordinate inhaling with delivery of a medication dose. You analyze the clinical situation (e.g., weakness in patient's hands) and examine choices more independently. Critical thinking combined with creativity allows nurses to become more flexible and find original solutions to specific problems when traditional interventions are not effective ([Papathanasiou et al., 2014](#)). Creativity also allows nurses to generate many ideas quickly, be able to change viewpoints, and create original problem solutions. A person's thinking abilities and initiative to look beyond expert opinion begin to change. As a nurse you learn that alternative and perhaps conflicting solutions exist.

Consider Mr. Lawson's case. His pain was partially relieved after receiving an analgesic (rating of 4 on scale of 0 to 10), and Tonya has helped him out of bed and into a chair. However, the patient becomes restless, cannot get comfortable, and begins to feel short of breath. Tonya wonders if something other than the incision is causing Mr. Lawson's discomfort. She sits down next to him and asks, "Is the pain you're feeling now different from before I gave you your medication?" The patient tells her that the pain feels sharper, in his chest. Tonya quickly takes a set of vital signs. His heart rate, which was 88 and regular 1 hour ago, is now 102 and irregular. Tonya calls the physician and notifies her of the changes in Mr. Lawson's condition. Tonya thought outside the box. Rather than assume that Mr. Lawson's continued pain was from his incision, she gathered more data and recognized that the patient possibly was experiencing a life-threatening condition, a pulmonary embolus.

In complex critical thinking each solution has benefits and risks that you weigh before making a final decision. There are options. Thinking becomes more innovative. A complex critical thinker considers different options from routine procedures. You gather additional information and take a variety of different approaches for the same therapy.

Commitment

The third level of critical thinking is commitment ([Kataoka-Yahiro and Saylor, 1994](#)). At this level you anticipate when to make choices without assistance from others and accept accountability for decisions made. As a nurse you do more than just consider the complex alternatives that a problem poses. At the commitment level you choose an action or belief that is based on the available alternatives and support it. Sometimes an action is your decision to not act or to delay an action until a later time based on your experience and knowledge. Because you take accountability for the decision, you consider the results of the decision and determine whether it was appropriate.

Critical Thinking Competencies

Critical thinking competencies are the cognitive processes a nurse uses to make judgments about the clinical care of patients (Kataoka-Yahiro and Saylor, 1994). These include general critical thinking, specific critical thinking in clinical situations, and specific critical thinking in nursing. General critical thinking processes are not unique to nursing. They include the scientific method, problem solving, and decision making. Specific critical thinking competencies include diagnostic reasoning, clinical inference, and clinical decision making. The specific critical thinking competency in nursing is the nursing process, which involves each of the specific critical thinking competencies.

General Critical Thinking

Scientific Method

The scientific method is a methodical way to solve problems using reasoning. It is a systematic, ordered approach to gather data and solve problems. This approach looks for the truth or verifies that a set of facts agrees with reality. Health care researchers, including nurse scientists, use the **scientific method** when testing research questions (see Chapter 5). The scientific method has five steps:

1. Identify the problem.
2. Collect data.
3. Formulate a question or hypothesis.
4. Test the question or hypothesis.
5. Evaluate results of the test or study.

Table 15.3 offers an example of a nursing practice issue solved by applying the scientific method in a research study.

TABLE 15.3**Using the Scientific Method to Solve Nursing Practice Questions**

Clinical Problem: The incidence of a health care–associated infection, <i>Clostridium difficile</i> infection, has increased on a hospital general medicine unit. The nursing staff on the unit practice committee, an infection control specialist, and a clinical nurse specialist in medicine meet to discuss factors that may be contributing to the problem. They note that visitors are inconsistent in the use of antiseptic hand rubs. A staff member questions whether the use of hand rubs is the best approach for this type of infection.	
Identify the problem.	The incidence of <i>C. difficile</i> has increased among patients on a general medicine unit.
Collect data.	Staff members review the literature about the nature of <i>C. difficile</i> infection and the hand antiseptic techniques recommended to prevent the infection. Staff members search the literature for studies that have investigated hand-hygiene practices of visitors of hospitalized patients. Staff members review performance improvement reports to monitor the occurrence of <i>C. difficile</i> on the unit. The infection control specialist is asked to discuss the trends within the hospital in the incidence of <i>C. difficile</i> .
Form a research question to study the problem.	Does visitor use of antiseptic hand rub with chlorhexidine vs. handwashing with soap and water reduce incidence of <i>C. difficile</i> infection in medical patients?
Answer the question.	The nurse specialist and a small team of staff members create a 4-month study approved by the hospital research board. Patients' visitors are asked to use a chlorhexidine rub on their hands before entering and leaving patient rooms. Visitors switch to handwashing with soap and water for the next 2 months. The infection control specialist tracks the incidence of <i>C. difficile</i> infection over the 4 months.
Evaluate the results of the study. Does the study answer the research question?	Compare the incidence of <i>C. difficile</i> infection for the 2-month period when each hand-hygiene method was used.

Problem Solving

Patients routinely present problems in nursing practice. For example, a home care nurse learns that a patient has difficulty taking her medications regularly. The patient is unable to describe which medications she has taken for the past 3 days. The medication bottles are labeled and filled. The nurse has to solve the problem of why the patient is not adhering to or following her medication schedule. The nurse knows that when the patient was discharged from the hospital, she had five medications ordered. The patient tells the nurse that she also takes two over-the-counter medications regularly. When the nurse asks her to show the medications that she takes in the morning, the nurse notices that the patient has difficulty seeing the medication labels. The patient is able to describe the medications that she is to take but is uncertain about the times of administration. The nurse recommends having the patient's pharmacy relabel the medications in larger lettering. In addition, the nurse shows the patient examples of pill organizers that will help her sort her medications by time of day for a period of 7 days.

A problem is an unsettled or unsteady state. Effective **problem solving** requires one to obtain information that clarifies the nature of a problem, suggest possible solutions, and try the solution over time to make sure that

it is effective. In the case of patient care, a solution to a problem should be consistently effective, allowing a patient to return to a stable condition or situation. It becomes necessary to try different options if a problem recurs. From the previous example, during a follow-up visit the nurse finds that the patient has organized her medications correctly and is able to read the labels without difficulty. The nurse obtained information that correctly clarified the cause of the patient's problem and tested a solution that proved successful. Having solved a problem in one situation adds to a nurse's experience in practice, which allows the nurse to apply that knowledge in future patient situations (Papathanasiou et al, 2014).

Decision Making

When you face a problem and choose a course of action from several options, you are making a decision. Decision making goes hand in hand with problem solving and problem resolution. Following a set of criteria helps you make a thorough and thoughtful decision. The criteria may be personal, based on an organizational policy or standard, or in the case of nursing, based on a professional standard.

For example, a person makes a decision when he or she chooses a health care provider. The individual must first recognize and define the problem (the need for a health care provider) and assess all options (e.g., consider a recommended health care provider or choose one whose office is close to home). The person weighs each option against a set of personal criteria (experience, friendliness, reputation, location), tests possible options (talks directly with the different health care providers), considers the consequences of the decision (examines pros and cons of selecting one provider over another), and makes a final decision. Although the set of criteria follows a sequence of steps, decision making involves moving back and forth when considering all criteria. This process leads to informed conclusions that are supported by evidence and reason. A similar process occurs in clinical nursing.

Specific Critical Thinking

Diagnostic Reasoning

Once you gather information about a patient, as Tonya did in collecting information about Mr. Lawson's discomfort, **diagnostic reasoning** begins. It is a form of decision making. Diagnostic reasoning involves being able to understand and think through clinical problems, look for clues,

understand the meaning of evidence, and know when there is enough information to make an accurate diagnosis, consider different causes of the problem, and then select interventions that best meet the needs of a patient (Resnick, 2016; Croskerry and Nimmo, 2011). Accurate recognition of a patient's problems (e.g., nursing diagnoses, collaborative problems) is necessary before choosing solutions and implementing action (Erickson, 2017). The Institute of Medicine (2015) reports that the right diagnosis is a key aspect of health care because it explains a patient's health problem(s) and informs subsequent health care decisions. It requires you to assign meaning to the behaviors and physical signs and symptoms presented by a patient. *For example, what does Mr. Lawson's restlessness, shortness of breath, and developing chest pain indicate? Diagnostic reasoning begins when you interact with a patient or make physical or behavioral observations. An expert nurse sees the context of a patient situation (e.g., Mr. Lawson just had major surgery; has been inactive; and is at risk for blood pooling in the lower extremities, which can cause clots to form in the circulation), observes patterns and themes (e.g., symptoms that include shortness of breath, sharp chest pain, and irregular heart rate), and makes decisions quickly (e.g., a clot may have dislodged and traveled to the patient's lung, requiring a quick medical response).* The information that a nurse collects and analyzes leads to a diagnosis of a patient's condition. Nurses do not make medical diagnoses, but they do assess and monitor each patient closely and compare a patient's signs and symptoms with those that are common to a medical diagnosis (e.g., in the case of Mr. Lawson, a pulmonary embolus). Nurses make nursing diagnoses (see Chapter 17). Through diagnostic reasoning nurses understand the nature of a problem more quickly and select proper therapies.

Part of diagnostic reasoning is the decision-making skill of clinical inference. When making an inference, you form patterns of information from data before making a diagnosis. *In the initial scenario Tonya noted that Mr. Lawson was lying in a position to splint movement of his incision, had a tense facial expression, and experienced tenderness when his wound was palpated. Tonya infers that Mr. Lawson has a level of discomfort.* She demonstrates diagnostic reasoning by identifying the nursing diagnosis *Acute Pain* (see Chapter 17).

Through diagnostic reasoning Tonya gathered and analyzed patient data logically, considered evidence as to the typical problems to expect in a patient after surgery, and recognized a problem. As a student, confirm any judgments you make about nursing diagnoses or a medical problem you believe is developing with experienced nurses. At times you may be

wrong, but consulting with nurse experts gives you feedback to build on future clinical situations. Communication is essential with peers due to the complex nature of many clinical problems nurses face.

Often you cannot make a precise diagnosis during your first meeting with a patient. Sometimes you sense that a problem exists but do not have enough data to make a specific diagnosis. Some patients' physical conditions limit their ability to tell you about symptoms. Others choose to not share sensitive and important information during your initial assessment. Some patients' behaviors and physical responses become observable only under conditions not present during your initial assessment. When uncertain of a diagnosis, continue to collect data. Critically analyze changing clinical situations until you are able to determine a patient's unique situation (Croskerry and Nimmo, 2011). Any diagnostic conclusions that you make will help health care providers identify the nature of a problem more quickly and select appropriate medical therapies.

Clinical Decision Making

When you face a clinical problem or situation with a patient and need to choose a course of action from several options, you are making a clinical decision. **Decision making** is a product of critical thinking that focuses on resolving a patient's problem such as a nursing diagnosis (see Chapter 17). When you approach a clinical problem, such as a patient who is less mobile and develops an area of redness over the hip, you make a decision that identifies the problem (impaired skin integrity in the form of a pressure injury) and choose the best nursing interventions (skin care, special bed surface, and a turning schedule). Nurses make clinical decisions all the time to improve a patient's health or maintain wellness by reducing the severity of the problem or resolving the problem completely.

Effective clinical decision making requires inductive and deductive reasoning and making valid inferences. A nurse faces a problem or situation by critically analyzing data to determine important information and ideas and then discards unnecessary data until a later time (Papathanasiou et al., 2014). Following a set of questions or criteria about the data helps a nurse make thorough and thoughtful decisions (Box 15.2). Socratic questioning is a technique for looking beneath the surface, recognizing and examining assumptions, searching for inconsistencies, examining multiple points of view, and differentiating what one knows from what one merely believes (Papathanasiou et al., 2014). These types of

questions are common when a nurse completes an end of shift or reviews a patient's history and progress.

Box 15.2 Decision-Making Questions

Questions About a Problem

- Is the problem clear and understandable?
- Is the problem important or a priority in the patient's care?

Questions About Your Perspective

- You are looking at the problem from the view of _____. Why?
- How might someone with an opposite view see the problem?
- How does your view compare with that of the patient?

Questions About Assumptions

- You are assuming _____. How does that affect your analysis of the problem?
- What might you assume instead? Is there another option?

Questions About Evidence

- What evidence supports your assumption?
- Is there a reason to doubt the evidence? Does it apply to this specific situation?
- What further evidence is needed?

After you answer decision-making questions, you begin to form inferences and make conclusions. A set of assessment facts (e.g., objective clinical findings, diagnostic test results) and observations about a patient leads a nurse to begin making generalizations and to then perform inductive reasoning. When viewed together, the facts and observations

suggest a particular interpretation. **Inductive reasoning** moves from reviewing specific data elements to making an **inference** by forming a conclusion about the related pieces of evidence. Previous experience with the evidence is also considered. For example, a nurse who observes a patient who has weakness of lower extremities, an unsteady gait, and a previous history of a fall, considers previous patients cared for and concludes this specific patient is at risk for falling. In contrast, **deductive reasoning** moves from the general to the specific. A nurse will start analysis of the facts and observations from a conceptual viewpoint, such as prioritization of needs by Maslow or Nola Pender's health promotion model. Then the nurse forms an inference and eventually interprets the patient's condition with respect to the conceptual view (Papathanasiou et al., 2014).

Skilled clinical decision making occurs through **knowing the patient** (Zolnierek, 2014). Knowing the patient is an in-depth knowledge of a patient's patterns of responses within a clinical situation and knowing the patient as a person (Tanner et al., 1993). While nurses use prior clinical experiences and interactions with patients as key sources of knowledge, these sources are limited for nurses with less experience and in care situations in which the patient's ability to interact may be affected by developmental age (e.g., an infant) or medical state (e.g., intubated) (Kelley et al., 2013). Nonetheless, you need to know your patients to develop your clinical expertise. Knowing a patient has two components: a nurse's understanding of a specific patient and his or her subsequent selection of interventions. It relates to a nurse's experience with caring for patients, time spent in a specific clinical area, and having a sense of closeness with patients. For example, an expert nurse who has worked on a general surgery unit for many years has cared for a patient the past 2 days. The nurse is familiar with how the patient is progressing physically and mentally. When the patient begins to experience a change (e.g., a slight fall in blood pressure, becoming less responsive), the nurse knows that something is wrong, suspects the patient may be bleeding internally, and takes action. Because of the nurse's clinical experience and knowing the patient, the expert nurse can make a clinical decision and act more quickly than a new nurse can be expected to act.

Knowing the patient is central to individualizing nursing care so that a patient feels cared for and cared about (Zolnierek, 2014). Knowing offers a nurse "the big picture" and "knowing the whole person" so that he or she can make suitable decisions to protect patients from harm. Henneman et al. (2010) found that knowing the patient enabled nurses to identify

problems and potential errors and thus rescue their patients from potential adverse events. A critical aspect to knowing patients and thus being able to make timely and appropriate decisions is spending time establishing relationships with them ([Zolnierek, 2014](#)). Forming relationships builds your ability to make clinical decisions and enhances your ability to know your patients. Follow these tips:

- Spend enough time during initial and follow-up patient assessments to observe patient behavior and measure physical and psychosocial findings as a way to improve knowledge of your patients. Determine what is important to them, and make a positive emotional connection. Patients perceive meaningful time as that involving personal rather than task-oriented conversation.
- Know trends and normative patterns in a patient's clinical condition over time so that you can identify when patients require a change in their treatment plan ([Kelley et al., 2013](#)).
- Know a patient's typical behaviors, schedules, and preferences at home to help guide you with their stay in a hospital or extended-care setting ([Kelley et al., 2013](#)). This allows you to adjust and provide individualized patient-centered care.
- When talking with patients, listen to their accounts of their experiences with illness, watch them, and come to understand how they typically respond ([Tanner, 2006](#)).
- Consistently check on patients to assess and monitor problems to help you identify how clinical changes develop over time.
- Ask to have the same patient assigned to you over consecutive days. Researchers have noted that a nurse-patient relationship develops from getting to know a patient and building a foundation for connecting on the first day of care, to deepening understanding of the patient and sustaining a connection by the second day, to being comfortable with the patient by the third day ([Lotzkar and Bottorff, 2010](#)).
- Engaging patients in conversations and being able to care for them over time (e.g., days or visits) develops knowing and nurse-patient relationships ([Zolnierek, 2014](#)).

Always keep a patient as your center of focus when solving clinical problems. Making accurate patient-centered clinical decisions allows you to prioritize the interventions to implement first (see [Chapter 18](#)). Do not assume that certain health situations produce automatic priorities. For

example, a patient who has surgery is anticipated to experience a certain level of postoperative pain, which often becomes a priority for care. However, if a patient is having severe anxiety that increases pain perception, you need to focus on ways to relieve the anxiety before pain-relief measures will be effective.

Critical thinking and clinical decision making are complicated because nurses care for multiple patients in fast-paced and unpredictable environments. When you provide patient care, use decision criteria that include the clinical condition of the patient, Maslow's hierarchy of needs (see [Chapter 6](#)), the risks involved in treatment delays, environmental factors (staff resources available), and patients' expectations of care to determine which patients have the greatest priorities. For example, a patient who is having a sudden drop in blood pressure along with a change in consciousness requires your immediate attention as opposed to a patient who needs you to collect a urine specimen or one who needs your help to walk down the hallway. Critical thinking in decision making allows you to attend to a patient whose condition is changing quickly and delegate the specimen collection and ambulation to assistive personnel. For you to manage the wide variety of problems associated with groups of patients, skillful, prioritized clinical decision making is critical ([Box 15.3](#)).

Box 15.3 Clinical Decision Making for Groups of Patients

- Identify the nursing diagnoses and collaborative problems of each patient (see Chapter 17).
- Analyze the diagnoses/problems and decide which are most urgent on the basis of basic needs, the patients' changing or unstable status, and problem complexity (see Chapter 18).
- Consider the time it will take to care for patients whose problems are of high priority (e.g., do you have the time to restart a critical intravenous [IV] line when medication is due for a different patient?).
- Consider the resources you have to manage each problem, assistive personnel assigned with you, other health care providers, and patients' family members.
- Involve patients and/or their family as decision makers and participants in care.

- Decide how to combine activities to resolve more than one patient problem at a time.
- Decide which, if any, nursing care procedures to delegate to assistive personnel so that you are able to spend your time on activities requiring professional nursing knowledge.
- Discuss complex cases with other members of the health care team. This ensures a smooth transition in care throughout a patient's health care experience.

REFLECT NOW

Ask a nurse who works in one of the health care agencies where you have clinicals to spend a moment talking to you about knowing patients. Ask the nurse what he or she does to know patients. Also discuss the barriers that make knowing patients difficult.

Nursing Process Competency

Nurses apply the **nursing process** as a competency when delivering patient care (Kataoka-Yahiro and Saylor, 1994). The American Nurses Association (ANA) (2010) standards provide the framework necessary for critical thinking in the application of the five-step nursing process: assessment, diagnosis, planning, implementation, and evaluation. The purpose of the nursing process is to diagnose and treat human responses (e.g., patient symptoms, need for knowledge) to actual or potential health problems (ANA, 2010). Use of the process allows nurses to help patients meet agreed-on outcomes for better health (Fig. 15.2). The nursing process requires a nurse to use the general and specific critical thinking competencies described earlier to focus on a patient's unique needs. The format for the nursing process is unique to the discipline of nursing and provides a common language and process for nurses to "think through" patients' clinical problems (Kataoka-Yahiro and Saylor, 1994).

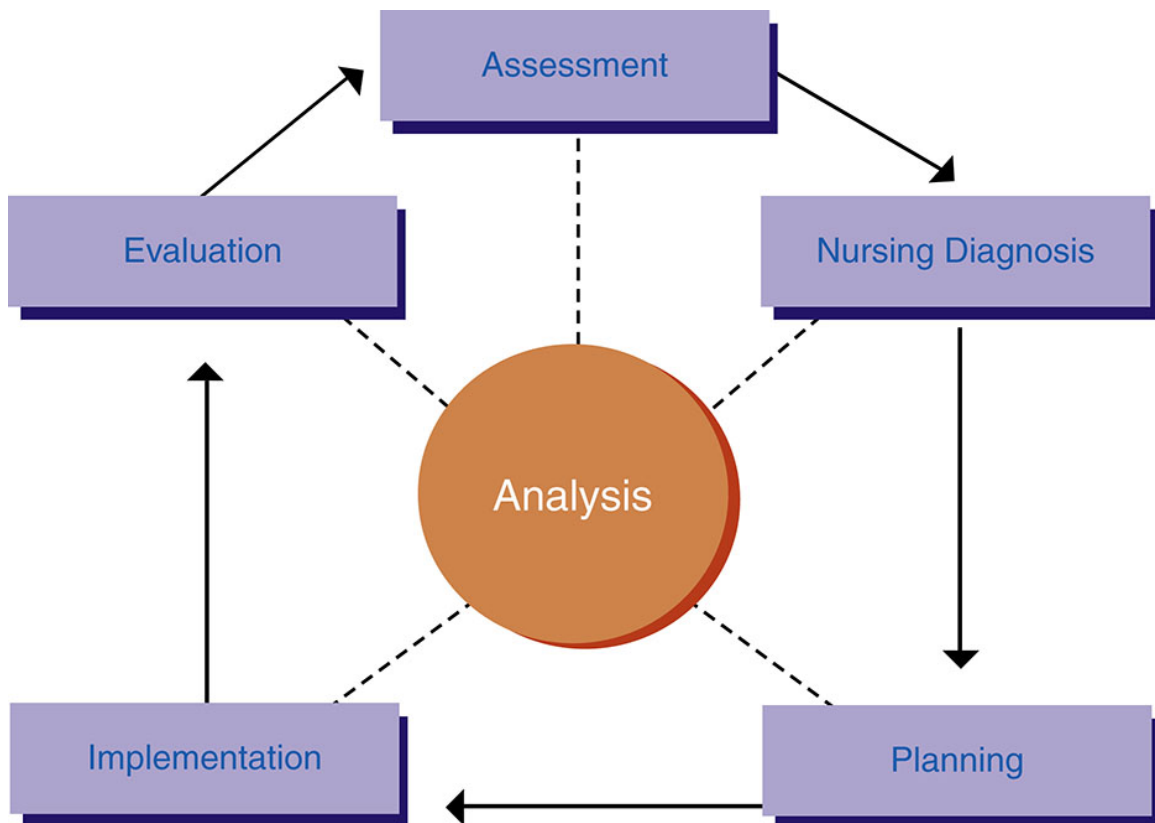

FIG. 15.2 Five-step nursing process model.

A Critical Thinking Model for Clinical Decision Making

Because critical thinking is complex, a model helps explain the steps in making clinical decisions and judgments about your patients. [Kataoka-Yahiro and Saylor \(1994\)](#) developed a model of critical thinking for nursing judgment based in part on previous works by [Paul \(1993\)](#) and [Miller and Malcolm \(1990\)](#) (see [Fig. 15.1](#)). This model is still relevant today. It defines the outcome of critical thinking: nursing judgment that is relevant to nursing problems in a variety of health care settings. The model includes five elements of critical thinking in nursing judgment: competence (e.g., problem solving and clinical decision-making ability), knowledge, experience, attitudes, and standards (intellectual and professional). The five elements combined guide nurses in making clinical decisions that lead to safe, effective nursing care ([Box 15.4](#)). Throughout this text the model helps you to apply critical thinking as part of the nursing process. Graphic illustration of the model in the clinical chapters shows you how to apply critical thinking in assessing patients, planning and delivering interventions, and evaluating the results. Applying elements of the model will help you become a more confident and effective professional.

Box 15.4 Components of Critical Thinking in Nursing

- I. Specific knowledge base in nursing
- II. Experience
- III. Critical thinking competencies
 - A General critical thinking
 - B Specific critical thinking
 - C Specific critical thinking in nursing: nursing process
- IV. Attitudes for critical thinking
 - Confidence, independence, fairness, responsibility, risk taking, discipline, perseverance, creativity, curiosity, intellectual integrity, humility
- V. Standards for critical thinking
 - A Intellectual standards

Clear—Plain and understandable (e.g., clarity in how one communicates).
Precise—Exact and specific (e.g., focusing on one problem and possible solution).
Specific—To mention, describe, or define in detail
Accurate—True and free from error; getting to the facts (objective and subjective)
Relevant—Essential and crucial to a situation (e.g., a patient’s changing clinical status)
Plausible—Reasonable or probable
Consistent—Expressing consistent beliefs or values
Logical—Engaging in correct reasoning from what one believes in a given instance to the conclusions that follow
Deep—Containing complexities and multiple relationships
Broad—Covering multiple viewpoints (e.g., patient and family)
Complete—Thoroughly thinking and evaluating
Significant—Focusing on what is important and not trivial
Adequate (for purpose)—Satisfactory in quality or amount
Fair—Being open-minded and impartial

B. Professional standards

1. Ethical criteria for nursing judgment
2. Criteria for evaluation
3. Professional responsibility

Modified from Kataoka-Yahiro M, Saylor C: A critical thinking model for nursing judgment, *J Nurs Educ* 33(8):351, 1994. Data from Paul RW: The art of redesigning instruction. In Willson J, Blinker AJA, editors: *Critical thinking: how to prepare students for a rapidly changing world*, Santa Rosa, CA, 1993, Foundation for Critical Thinking.

Competence

The first element of critical thinking is competence—in this case, competence in the use of the nursing process. Competence also involves

the ability to perform nursing skills (e.g., hands-on procedures, physical examination techniques) proficiently. Until your nursing skills become like second nature, they create a distraction, making it difficult for you as a new nurse to focus on important critical thinking competencies such as gathering data, problem solving, and clinical decision making. You will develop competence as you continue to practice and perform nursing skills.

Specific Knowledge Base

A nurse's specific knowledge base varies according to educational experience that includes basic nursing education, continuing education courses, and additional college degrees. A nurse also builds knowledge by reading the nursing literature (especially research-based literature) to maintain current knowledge of nursing science and theory. Knowledge prepares a nurse to better anticipate and identify patient problems by understanding their origin and nature.

A nurse's knowledge base includes information and theory from the basic sciences, humanities, behavioral sciences, and nursing science. Nurses use this knowledge base in a different way than other health care disciplines because they think holistically about patient problems. For example, a nurse's broad knowledge base offers a physical, psychological, social, moral, ethical, and cultural view of patients and their health care needs. The depth and extent of knowledge influence your ability to think critically about nursing problems.

Tonya previously earned a bachelor's degree in education and taught high school for 1 year. She is now in her second year as an RN. She is taking additional classes to further her education, including courses in health ethics and population health. Her experience as a staff nurse has allowed her to develop knowledge about a variety of surgical procedures, the effects of different medications, and responses patients typically show to their treatment. Although she is still new to nursing, her experiences as a teacher and her preparation and knowledge base in nursing help her know how to interact and form relationships with patients that help her make clinical decisions about patients' health promotion practices.

Experience

Nursing is a practice discipline. Clinical learning experiences are necessary to acquire clinical decision-making skills. Knowledge combined with clinical expertise from experience defines critical thinking. In clinical

situations you learn from observing, sensing, talking with patients and families, and reflecting actively on all experiences. Clinical experience is the laboratory for developing and testing approaches that you safely adapt or revise to fit the setting, a patient's unique qualities, and the experiences you have from caring for previous patients. Research has shown that a clinical environment that is safe and encourages free discussion and expression of thought promotes critical thinking (Chan, 2013). With experience you begin to understand clinical situations, anticipate and recognize cues of patients' health patterns, and interpret the cues as relevant or irrelevant. Learn to value all patient experiences, which become stepping-stones for building new knowledge and inspiring innovative thinking.

When Tonya was finishing her last year in nursing school, she worked as a nurse assistant in a nursing home. Through this experience she spent time interacting with older-adult patients and giving basic nursing care. Each patient provided her with valuable learning experiences, which she applied in her work with other patients. Specifically, she developed good interviewing skills, gained an understanding of the importance of the family in an individual's health, and learned to become a patient advocate. She also learned that older adults need more time to perform activities such as eating, bathing, and grooming; therefore, she has adapted these skill techniques.

The Nursing Process Competency

The nursing process competency is the third component of the critical thinking model. In your practice you will apply critical thinking components during each step of the nursing process. Chapters 16 through 20 describe each step of the nursing process.

Attitudes for Critical Thinking

The fourth component of the critical thinking model is attitudes. Paul (1993) defined 11 attitudes that define the central features of a critical thinker and how a successful critical thinker approaches a problem (see Box 15.4). In a consensus statement on critical thinking in nursing, an international panel of nurse experts defined additional attitudes that included contextual perspective, flexibility, and open-mindedness (Scheffer and Rubenfeld, 2000). Papathanasiou and colleagues (2014) also describe spiritual courage as a critical thinking attitude.

An example of applying critical thinking attitudes involves a patient who complains of anxiety before a diagnostic procedure. A curious nurse seeks an explanation and information by asking several questions to learn what the patient does not know and the nature of the patient's concerns (Kaddoura, 2013). The nurse shows discipline in forming questions and collecting a thorough assessment to find the source of the patient's anxiety. Attitudes of inquiry involve an ability to recognize that problems exist, to consider the context of those problems, and to recognize that there is a need for evidence to support what you think is true. Critical thinking attitudes are guidelines for how to approach a problem or decision-making situation. Important parts of critical thinking are interpreting, evaluating, and making judgments about the adequacy of various arguments and available data. Knowing when you need more information, knowing when information is misleading, and recognizing your own knowledge limits are examples of how critical thinking attitudes guide decision making. [Table 15.4](#) summarizes the use of critical thinking attitudes in nursing practice.

TABLE 15.4**Critical Thinking Attitudes and Applications in Nursing Practice**

Critical Thinking Attitude	Application in Practice
Confidence	The nurse, gaining more experience in reasoning and decision making, does not hesitate to disagree and be troubled, thereby acting as a role model to colleagues (Papathanasiou et al., 2014). Speak with conviction to a patient when you begin an intervention. Do not lead a patient to think that you are unable to perform care safely. Always be well prepared before performing a nursing activity. Encourage a patient to ask questions.
Thinking independently	As you acquire new knowledge and experiences, examine your beliefs under new evidence (Papathanasiou et al., 2014). Be open-minded about different interventions. Read the scientific literature, especially when there are different views on the same subject. Talk with other nurses and share ideas about nursing interventions.
Fairness	Listen to both sides of a discussion. If a patient or family member complains about a co-worker, listen to the story and speak with the co-worker as well. If a staff member labels a patient uncooperative, assume the care of that patient with openness and a desire to meet the patient's needs.
Responsibility and authority	Ask for help if you are uncertain about how to perform a nursing skill. Refer to a policy and procedure manual to review steps of a skill. Report any problems immediately. Follow standards of practice in your care.
Risk taking	If your knowledge causes you to question a health care provider's order, do so. Be willing to recommend alternative approaches to nursing care when colleagues are having little success with patients, especially if your ideas are supported with scientific evidence.
Discipline	Be thorough in whatever you do. Use known scientific and practice-based criteria for activities such as assessment and evaluation. Take time to be thorough and manage your time effectively.
Perseverance	Be cautious of an easy answer that avoids uncomfortable situations. If co-workers give you information about a patient and some fact seems to be missing, clarify the information or talk to the patient directly. If problems of the same type continue to occur on a nursing division, bring co-workers together, look for a pattern, and find a solution.
Creativity	Look for different approaches if interventions are not working for a patient. For example, a patient in pain may need a different positioning or distraction technique. When appropriate, involve the patient's family in adapting your approaches to care methods used at home.
Curiosity	Always ask why. Be willing to challenge tradition. A clinical sign or symptom often indicates a variety of problems. Explore and learn more about a patient so as to make appropriate clinical judgments.
Integrity	Recognize when your opinions conflict with those of a patient; review your position and decide how best to proceed to reach outcomes that will satisfy everyone. Do not compromise nursing standards or honesty in delivering nursing care.
Humility	Recognize when you need more information to make a decision. When you are new to a clinical division, ask for an orientation to the area. Ask registered nurses (RNs) regularly assigned to the area for assistance with approaches to care.

Confidence

Confidence is the belief in oneself, one's judgment and psychomotor skills, and one's possession of the knowledge and the ability to think critically.

When you are confident, you feel certain about accomplishing a task or goal such as performing a procedure or making a diagnosis. Confidence grows with experience in recognizing your strengths and limitations. You shift your focus from your own needs (e.g., remembering what assessment data mean or how to perform a procedure) to a patient's needs. When you are not confident in knowing whether a patient is clinically changing or in performing a nursing skill, you become anxious about not knowing what to do. This prevents you from attending to the patient. Always be aware of the extent and limits of your knowledge. If you question the meaning of a clinical situation and you don't know whether the information you have is important, discuss it with your nursing instructor first. Never perform a procedure unless you have the knowledge base and feel confident. Patient safety is of the utmost importance. When you show confidence, your patients recognize it by how you communicate and the way you perform nursing care. Confidence builds trust between you and your patients.

Thinking Independently

As you gain new knowledge, you learn to consider a wide range of ideas and concepts before forming an opinion or making a judgment. You are not limited by what you learn in school but become open-minded to new concepts and interventions ([Papathanasiou et al., 2014](#)). This does not mean that you ignore other people's ideas. Instead you learn to consider all sides of a situation. A critical thinker does not accept another person's ideas without question. When thinking independently, you challenge the ways that others think and look for rational and logical answers to problems. You raise important questions about your practice. For example, why is one type of surgical dressing ordered over another, or why do patients on your nursing unit fall? When nurses ask questions and look for the evidence behind clinical problems, they are thinking independently; this is an important step in evidence-based practice (see [Chapter 5](#)). Independent thinking and reasoning are essential to the improvement and expansion of nursing practice.

Fairness

A critical thinker deals with situations justly. This means that you do not let bias or prejudice affect your decisions. For example, regardless of how you feel about obesity, you do not allow personal attitudes to influence the way you care for a patient who is overweight. Look at a situation objectively and consider all viewpoints to understand the situation

completely before making a decision. Having a sense of imagination helps you develop an attitude of fairness. Imagining what it is like to be in your patient's situation helps you see it with new eyes and appreciate its complexity.

Responsibility and Accountability

Responsibility is the knowledge that you are accountable for your decisions, actions, and critical thinking. When caring for patients, you are responsible for correctly performing nursing care activities on the basis of standards of practice. Standards of practice are the minimum level of performance accepted to ensure high-quality care. For example, you do not take shortcuts or work-arounds when you give a patient a medication (e.g., skipping a step—failing to identify a patient, preparing medication doses for multiple patients at the same time). Professional nurses are responsible for competently performing nursing therapies and making clinical decisions about patients. As a nurse you are answerable or accountable for your decisions, the outcomes of your actions, and knowing the limits and scope of your practice.

Risk Taking

People often associate taking risks with danger. Driving 30 miles an hour over the speed limit is a risk that sometimes results in injury to a driver and an unlucky pedestrian. But risk taking does not always have negative outcomes. Risk taking is desirable, particularly when the result is a positive outcome. A critical thinker will take risks when trying different ways to solve problems. The willingness to take risks comes from experience with similar problems. Risk taking often leads to advances in patient care. In the past nurses have taken risks when trying different approaches to skin and wound care and pain management, to name a few. When taking a risk, follow safety guidelines, analyze any potential dangers to a patient, and act in a well-reasoned, logical, and thoughtful manner. Risk taking does not eliminate the need to incorporate evidence into practice approaches.

Discipline

A disciplined thinker misses few details and is orderly or systematic when collecting information, making decisions, or taking action. For example, you have a patient who is in pain. Instead of only asking the patient, "How severe is your pain on a scale of 0 to 10?" you also ask more specific

questions about the character of pain (e.g., “What makes the pain worse? Where does it hurt? How long have you noticed it?”). Being disciplined helps you identify problems more accurately and select the most appropriate interventions.

Perseverance

A critical thinker is determined to find effective solutions to patient care problems. This is especially important when problems remain unresolved or recur. Learn as much as possible about a problem and try various approaches to care. Persevering means to keep looking for more resources until you find a successful approach. It often requires creativity. For example, a patient who is unable to speak following throat surgery poses challenges for the nurse to communicate effectively. Perseverance leads the nurse to try different communication approaches (e.g., message boards or alarm bells) until he or she finds a method that is effective. A critical thinker who perseveres is not satisfied with minimal effort but works to achieve the highest level of quality care.

Creativity

Creativity involves original thinking. This means that you find solutions outside the standard routines of care while still following standards of practice. Creativity motivates you to think of options and unique approaches. A patient’s clinical problems, social support systems, and living environment are just a few examples of factors that make the simplest nursing procedure more complicated. For example, a home care nurse has to find a way to help an older patient with arthritis have greater mobility in the home. The patient has difficulty lowering and raising herself in a chair because of pain and limited range of motion in her knees. The nurse uses wooden blocks to elevate the chair legs so that the patient is able to sit and stand with little discomfort while making sure that the chair is safe to use.

Curiosity

A critical thinker’s favorite question is “Why?” In any clinical situation you learn a great deal of information about a patient. As you analyze patient information, data patterns appear that are not always clear. Having a sense of curiosity (asking yourself, “What if?”) motivates you to inquire further (e.g., question family or physician, review the scientific literature)

and investigate a clinical situation so that you get all the information you need to make a decision.

Integrity

Critical thinkers question and test their own knowledge and beliefs. Your personal integrity as a nurse builds trust from your co-workers. Nurses face many dilemmas or problems in everyday clinical practice, and everyone makes mistakes at times. A person of integrity is honest and willing to admit to mistakes or inconsistencies in his or her own behavior, ideas, and beliefs. A professional nurse always tries to follow the highest standards of practice.

Humility

It is important for you to admit to any limitations in your knowledge and skill. Critical thinkers admit what they do not know and try to find the knowledge needed to make proper decisions. It is common for a nurse to be an expert in one area of clinical practice but a novice in another because the knowledge in all areas of nursing is unlimited. A patient's safety and welfare are at risk if you do not admit your inability to deal with a practice problem. You have to rethink a situation; learn more; and use the new information to form opinions, draw conclusions, and take action.

Mr. Lawson continues to have chest pain and shortness of breath. As Tonya waits for the medical team to arrive, she knows that she is responsible for his welfare until treatment can be initiated. Tonya acts independently by keeping Mr. Lawson comfortable in the chair, not moving him (to avoid worsening of his condition) and gathering additional assessment data. She displays discipline in further assessing Mr. Lawson's condition: rechecking vital signs, observing his abdominal wound and incision, and talking with him to notice if there is a change in consciousness. Tonya knows that she cannot diagnose medically. When the health care provider arrives, she objectively reports what happened with Mr. Lawson once he sat up in the chair, the symptoms he displayed, and how those symptoms have changed.

Standards for Critical Thinking

The fifth component of the critical thinking model includes intellectual and professional standards ([Kataoka-Yahiro and Saylor, 1994](#)).

Intellectual Standards

Paul (1993) identified 14 intellectual standards (see Box 15.4) universal for critical thinking. An intellectual standard is a guideline or principle for rational thought. You apply these standards during all steps of the nursing process. For example, when you consider a patient problem, apply the intellectual standards of preciseness, accuracy, and consistency in measurement to make sure that you have all the data you need to make sound clinical decisions. During planning, apply standards such as being logical and significant so that the plan of care is meaningful and relevant to a patient's needs. A thorough use of intellectual standards in clinical practice prevents you from performing critical thinking haphazardly.

The health care provider orders a lung scan and chest x-ray and places Mr. Lawson on bed rest. Blood tests are also ordered in anticipation of placing the patient on anticoagulation (to prevent further clot formation). Tonya asks the physician whether there are risks to be considered regarding Mr. Lawson's wound should the patient receive an anticoagulant (relevant question). She also asks if she can give additional pain medication at this time to manage the patient's surgical incision pain during the x-ray procedures (logical decision). By applying intellectual standards, Tonya is a competent partner in managing the patient's care, showing her ability to anticipate possible clinical problems.

Professional Standards

Professional standards for critical thinking refer to ethical criteria for nursing judgments, evidence-based criteria used for evaluation, and criteria for professional responsibility (Paul, 1993). Application of professional standards requires you to use critical thinking for the good of individuals or groups (Kataoka-Yahiro and Saylor, 1994). Professional practice standards improve patient outcomes and maintain a high level of quality nursing care.

Excellent nursing practice is a reflection of ethical standards (see Chapter 22). Being able to focus on a patient's values and beliefs helps you make clinical decisions that are just, respectful of a patient's choices, and beneficial to a patient's well-being. Critical thinkers maintain a sense of self-awareness through conscious awareness of their own beliefs, values, and feelings and the multiple perspectives that patients, family members, and peers present in clinical situations. Critical thinking also requires the use of evidence-based criteria for making clinical judgments. These criteria are sometimes scientifically based on research findings (see Chapter 5) or practice based on standards developed by clinical experts and performance improvement initiatives of an institution. Examples are the clinical practice guidelines developed by individual clinical agencies and

national organizations such as the American Association of Critical Care Nurses (AACN) or Oncology Nursing Society (ONS). A clinical practice guideline includes standards for the treatment of select clinical conditions such as stroke, deep vein thrombosis, and pressure injuries. Another example is clinical criteria used to categorize clinical conditions such as the criteria for staging pressure injuries (see [Chapter 48](#)) and rating phlebitis (see [Chapter 42](#)). Evidence-based evaluation criteria set the minimum requirements necessary to ensure appropriate and high-quality care.

The standards of professional responsibility that a nurse tries to achieve are the standards cited in Nurse Practice Acts, institutional practice guidelines, and professional organizations' standards of practice (e.g., The ANA Standards of Professional Performance (see [Chapter 1](#))). These standards "raise the bar" for the responsibilities and accountabilities that a nurse assumes in guaranteeing quality health care to the public.

Developing Critical Thinking Skills

Although you will need time to develop critical thinking skills, start now by actively engaging patients who are in your care. Apply the principles of the critical thinking model that have been presented in this chapter. Many factors in health care settings pose barriers to critical thinking. Rising patient acuity, decreasing length of stay, and conflicts in professional relationships are a few of the factors that challenge even experienced nurses who are adept at critical thinking.

Reflective Journaling

Reflective journaling is a tool for developing critical thought and reflection by clarifying concepts (Raterink, 2016). It involves keeping a written record of your clinical experiences in your own words in a personal journal. Remember to keep your journal entries confidential so that if someone else reads your journal, patient identity is protected. Returning to the journal after each clinical experience gives you the chance to record the perceptions you had during patient care and better develop the ability to apply theory in practice. Oftentimes reflections are on things that go wrong; however, reflecting on things that went well can be just as rewarding and useful to build confidence in your practice (Kiron et al., 2017). Journaling also improves your observational and descriptive skills. Writing skills improve as you learn to clearly describe concepts applied in practice (e.g., suffering, hope, powerlessness). A journal increases your experiential learning during clinical experiences (Silvia, 2013). Here are examples of questions to pose in a journal:

- What did I learn from the experience?
- Did I respond appropriately in this situation? If not, how should I have responded?
- What were the consequences of my actions? Whom did they affect and in what way?
- How might I act differently in the future?
- Was I working from tradition or evidence-based practices?

Meeting with Colleagues

A way to develop critical thinking skills is to regularly meet with colleagues such as fellow students or nurses, faculty members, or

preceptors to discuss and examine work experiences and validate decisions. Connecting with others helps you learn that you do not need to know everything because support is available from other colleagues. When nurses have a formal means to discuss their experiences, such as a staff meeting or unit practice council, the dialogue allows for questions, differing viewpoints, and sharing of experiences. When they are able to discuss their practices, the process validates good practice and also offers challenges and constructive criticism. A discussion of critical incidents that occur in the live clinical setting is invaluable for developing critical thinking (LaMartina and Ward-Smith, 2014). Much can be learned by drawing from others' experiences and perspectives to promote reflective critical thinking.

Concept Mapping

As a nurse you will care for patients who have multiple nursing diagnoses and/or collaborative problems. A **concept map** is a visual representation of patient problems and interventions that shows their relationships to one another. It is a nonlinear picture of a patient to be used for comprehensive care planning. Research shows that when compared with traditional educational methods, concept mapping can improve students' critical thinking ability as measured by various critical thinking skills tests and scales (Yue et al., 2017). However, more high-quality studies are needed to support these findings.

Concept maps help you better synthesize relevant data about a patient, including assessment data, nursing diagnoses, health needs, nursing interventions, and evaluation measures. Through drawing a concept map, you learn to organize or connect information in a unique way, so the diverse information that you have about a patient begins to form meaningful patterns and concepts. You begin to see a more holistic view of a patient. When you see the relationship between the various patient diagnoses and the data that support them, you better understand a patient's clinical situation. Sample concept maps can be found in the clinical chapters of this text (see Units V and VI).

Managing Stress

The connection between stress in a health care setting and its effects on a nurse's mental and physiological state is receiving more attention. Autonomic control of decision making, error detection, speech, memory, and emotions during stressful situations are disrupted because of continued sympathetic nervous system stimulation. Research has shown that the stress of working 12-hour shifts, for example, can impair nursing judgment, in part because of the way stress affects attention (McClelland et al., 2013). The work of professional nursing is difficult as you see patients endure suffering from disease and painful therapies and as you try to manage care responsibilities in busy, fast-paced work settings (Box 15.5). Stress over a prolonged period or when extreme can lead to poor work productivity, impaired decision making and communication, and reduced ability to cope with clinical situations. Chapter 37 offers perspectives on ways to better manage stress so that you can make clear, thoughtful decisions and communicate effectively with health care colleagues.

Box 15.5 Evidence-Based Practice Stress Management

PICOT Question: For staff nurses who experience stress in clinical settings, does stress management compared with no intervention reduce stress?

Evidence Summary

In a qualitative study by van Graan and colleagues (2016), practicing nurses recognized clinical practice as a stressful experience, more so for a novice nurse. A positive relationship between the nursing staff on a unit and nursing students is a crucial factor in creating a positive learning environment. The study participants proposed that the first clinical experience of novice nursing students should be positive and an example of what nursing entails (van Graan et al., 2016). A high level of anxiety can lead to decreased learning as students focus on their anxiety and being accepted rather than on learning. Concern regarding the stress nurses face has resulted in the American Nurses Association (ANA) creating the goal of improving the work life of health care providers, along with an original aim of improving the care experience (Cipriano, 2016). Improving work life means ensuring an ethical practice environment and one that supports emotional caregiving; that is free of the toxic effects of workplace

incivility, violence, and bullying; and that promotes safe staffing and safe patient handling. A randomized controlled trial of a web-based program designed to reduce nurses' perceived stress was successful in building staff resiliency (Hersch et al., 2016).

Application to Nursing Practice:

Hersch and colleagues (2016) recommend the following:

- Nurses should take advantage of educational and self-help programs for stress management. Programs such as *BREATHE* focus on areas of nursing stress that nurses could address either by changing the way they view stressors, changing how they respond to stress, or, when possible, changing the stressful situation.
- Exercises on grieving and coping with the demands of caring for dying patients can minimize stress and improve overall care of patients who are terminally or critically ill.
- Nurses should learn assertive communication, conflict resolution, and problem solving strategies to reduce the stress associated with different interactions with other nurses or health care providers.

Critical Thinking Synthesis

Critical thinking is a reasoning process by which you reflect on and analyze your thoughts, action, and knowledge. As a beginning nurse, it is important to learn the steps of the nursing process and incorporate the elements of critical thinking (Fig. 15.3). The two processes go hand in hand in making quality decisions about patient care. This text provides a model to show you how important critical thinking is in the practice of the nursing process.

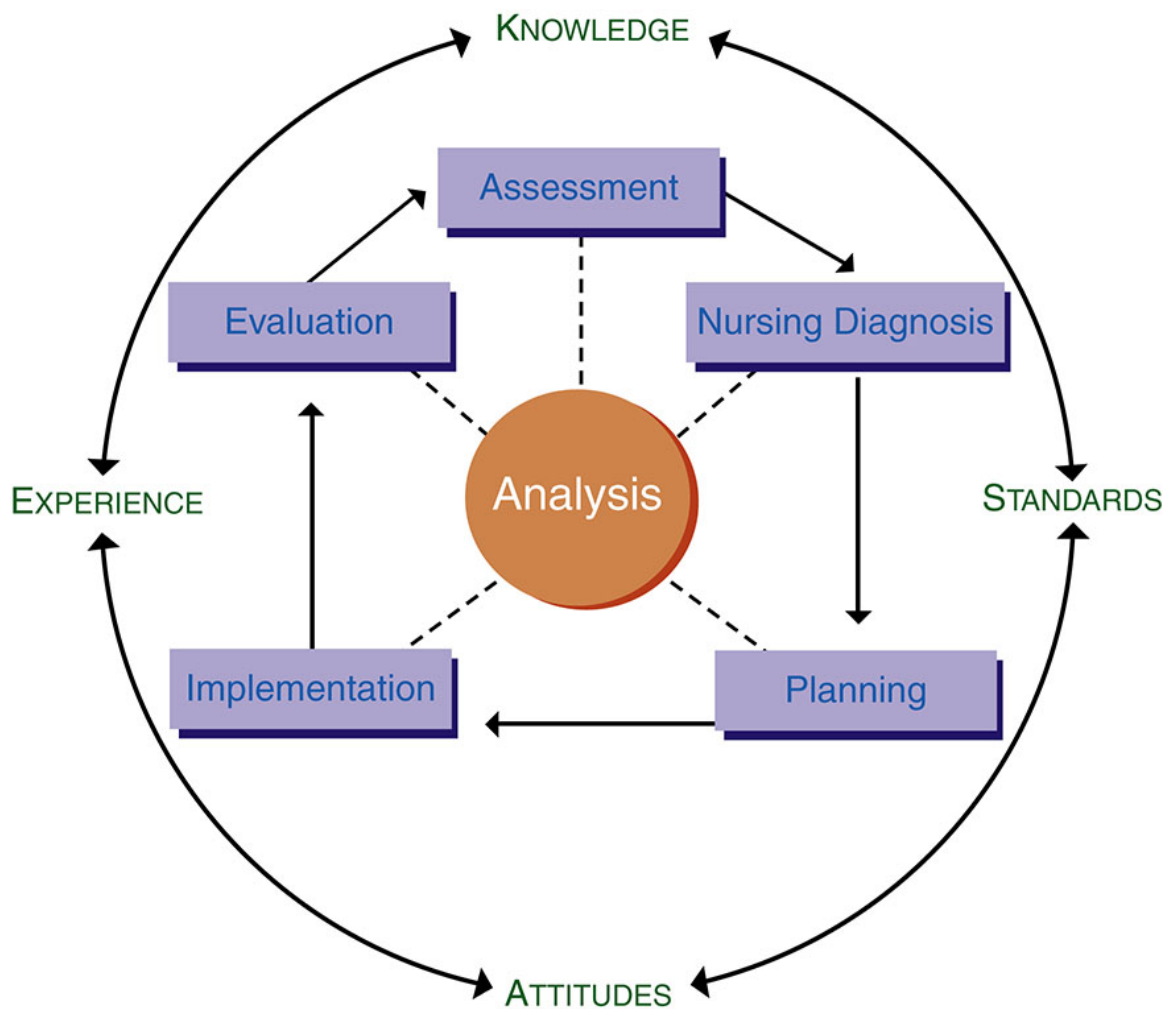

FIG. 15.3 Synthesis of critical thinking with the nursing process competency.

Key Points

- Clinical judgments are influenced by a nurse's experience and knowledge and a reliance on knowing the patient and his or her typical pattern of responses, as well as engaging with the patient and his or her concerns.
- The ability to ask questions and to seek and examine information for answers and deeper meanings is essential in critical thinking.
- Purposefully reflecting on a past situation and taking the time to honestly review everything you remember about it allows you to gain new knowledge and raise questions about your practice.
- A basic critical thinker learns to accept the diverse opinions and values of experts, while complex critical thinkers begin to rely less on experts.
- Effective problem solving involves obtaining information that clarifies the nature of a problem, suggesting possible solutions, and trying the solution over time to ensure it is effective, thus adding to nurses' knowledge in future patient situations.
- In inductive reasoning one reviews a specific set of facts and observations about a patient, forms generalizations, and then interprets the data and makes a conclusion about the related pieces of evidence.
- In deductive reasoning one analyzes facts and observations from a conceptual viewpoint, then forms an inference and interprets the patient's condition with respect to the conceptual view.
- The critical thinking model for decision making includes five elements of critical thinking in nursing judgment: competence, knowledge, experience, attitudes, and standards (intellectual and professional).

- Competence involves the ability to perform nursing skills proficiently, while knowledge prepares a nurse to better anticipate and identify patient problems by understanding their origin and nature.
- Intellectual standards provide guidelines for rational thought and decision making that you apply during all steps of the nursing process.
- Reflective journaling involves keeping a written record of clinical experiences to develop critical thought and reflection so that you can improve practices and apply theory in practice in the future.

Reflective Learning

- Consider a patient you recently cared for during a clinical experience. Identify three critical thinking attitudes you applied as you implemented the nursing process.
- Have a conversation with a staff nurse on the clinical unit to which you are assigned. Ask the nurse the type of stressors in the workplace that affect his or her ability to think and make clinical decisions correctly.
- Make a journal entry of your most recent clinical experience. Remember to respect your patients' confidentiality. Review it and compare the elements you included with elements of the REFLECT model.

Review Questions

1. A nurse enters a patient's room at the beginning of a shift to conduct an assessment of his condition following a blood transfusion. The nurse cared for the patient on the previous day as well. The patient has a number of issues he wishes to share

with the nurse, who takes time to explore each issue. The nurse also assesses the patient and finds no signs or symptoms of a reaction to the blood product. The nurse observed the patient the prior day and sees a change in his behavior, a reluctance to get out of bed and ambulate. Which of the following actions improve the nurse's ability to make clinical decisions about this patient? (Select all that apply.)

1. Working the same shift each day
 2. Spending time during the patient assessment
 3. Knowing the early mobility protocol guidelines
 4. Caring for the patient on consecutive days.
 5. Knowing the pattern of patient behavior about ambulation
2. Match the concepts for a critical thinker on the right with the application of the term on the left.

Term Application	Concepts for Critical Thinkers
a. Anticipate how a patient might respond to a treatment.	<input type="checkbox"/> 1. Truth seeking
b. Organize assessment on the basis of patient priorities.	<input type="checkbox"/> 2. Open-mindedness
c. Be objective in asking questions of a patient.	<input type="checkbox"/> 3. Analyticity
d. Be tolerant of the patient's views and beliefs.	<input type="checkbox"/> 4. Systematicity

3. A nurse has seen many cancer patients struggle with pain management because they are afraid of becoming addicted to the medicine. Pain control is a priority for cancer care. By helping patients focus on their values and beliefs about pain control, a nurse can best make clinical decisions. This is an example of:
1. Creativity.
 2. Fairness.
 3. Clinical reasoning.
 4. Applying ethical criteria.

4. The REFLECT model can improve learning after providing patient care. Place the steps of this model in the correct order:
 1. Think about your thoughts and actions at the time of a situation.
 2. Review the knowledge you gained from the experience.
 3. Review the facts of the situation.
 4. Set a schedule for completing your plan of action.
 5. Consider options for handling a similar situation in the future.
 6. Recall any feelings you had at the time of the situation.
 7. Create a plan for future situations.
5. One element of clinical decision making is knowing the patient. Which of the following activities affect a nurse's ability to know patients better? (Select all that apply.)
 1. Caring for similar groups of patients over time
 2. Reading the evidence-based practices appropriate to patients
 3. Learning how patients typically respond to their clinical situations
 4. Observing patients
 5. Engaging with patients experiencing illness
6. A nurse is preparing medications for a patient. The nurse checks the name of the medication on the label with the name of the medication on the doctor's order. At the bedside the nurse checks the patient's name against the medication order as well. The nurse is following which critical thinking attitude?
 1. Responsibility
 2. Humility
 3. Accurate
 4. Fairness

7. A nurse has been caring for a patient with a chronic wound that has not been healing. The nurse talks with a nurse specialist in wound care to find alternative approaches from what the health care provider ordered for dressing the wound. The two decide that because of the patient's allergy to tape a nonallergenic dressing will be used. The nurse obtains an order from the health care provider for the new dressing. After two days there is improvement in the wound. This is an example of which critical thinking standards? (Select all that apply.)

1. Clear
2. Broad
3. Relevant
4. Risk taking
5. Creativity

8. A nurse is assigned to care for a woman who is expecting her first child. The nurse organizes herself and plans to gather data about the patient by applying Pender's health promotion model, including the patient's characteristics and experiences and situational influences. She plans to observe patient behavior and consider the patient's psychosocial issues. Such data will offer a clear understanding to help the nurse identify the patient's needs. This is an example of which of the following concepts? (Select all that apply.)

1. Diagnostic reasoning
2. Deductive reasoning
3. Inductive reasoning
4. Assessment
5. Problem solving

9. A nurse is caring for a patient who has poor pain control. The patient has a history of opioid abuse. During the day the patient made frequent requests for a pain medication. In order to make

an effective clinical decision about this patient, the nurse needs to ask questions about the data available on the patient to make a thorough and thoughtful decision. The nurse asks herself, "How does my view about the patient's pain tolerance compare with the patient's, and does that pose a problem?" This is an example of:

1. A question about assumptions.
 2. A question about evidence.
 3. A question about procedure.
 4. A question about perspective.
10. Which of the following describes a nurse's application of a specific knowledge base during critical thinking? (Select all that apply.)
1. Initiative in reading current evidence from the literature
 2. Application of nursing theory
 3. Reviewing a policy and procedure manual
 4. Considering a colleague's view of a patient's needs
 5. Previous time caring for a specific group of patients

Nursing Assessment

OBJECTIVES

- Explain the two steps involved in nursing assessment.
- Describe the three types of nursing assessments.
- Explain principles to follow in the use of data sources during assessment.
- Explain the importance of building a nurse-patient relationship before a formal nursing assessment.
- Describe skills to apply when conducting a patient interview during a nursing history.
- Explain communication approaches to use during the working phase of a patient-centered interview.
- Explain how to maintain professionalism during history taking.
- Identify components of a nursing health history.
- Describe elements of the assessment process.

Validation, p. 223

The **nursing process** is a critical thinking five-step process that professional nurses use to apply the best available evidence to deliver nursing care. The steps of the nursing process (assessment, diagnosis, planning and outcome identification, implementation, and evaluation [Fig. 16.1]) are the essential core of nursing practice developed by the American Nurses Association (ANA) that all registered nurses, regardless of role, population, or specialty, are expected to competently perform (ANA, n.d.). The nursing process enables nurses to deliver holistic, patient-centered care (ANA, n.d.). The Quality and Safety Education for Nurses (QSEN) Institute defines patient-centered care as recognizing a patient or a person selected by the patient as a full partner in providing compassionate and coordinated care based on respect for a patient's preferences, values, and needs (QSEN, 2018). Thus, you use the essential first step of the nursing process, assessment, to learn as much as you can about each patient's health condition and health problems by partnering with the patient and family caregivers in a therapeutic relationship. Consider the following case study that was also described in Chapter 15.

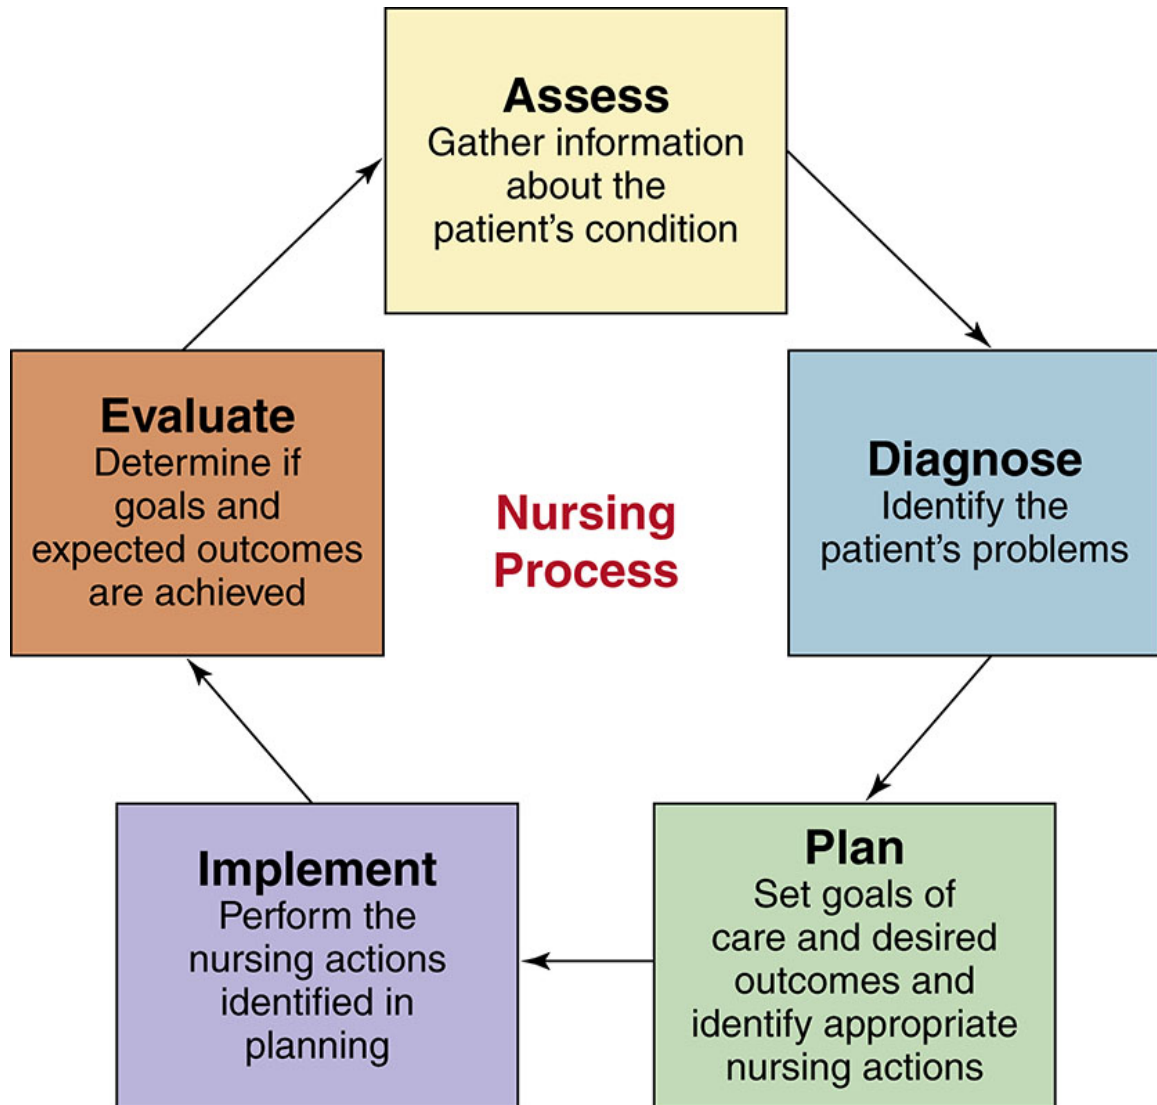

FIG. 16.1 Five-step nursing process.

Mr. Lawson is a 62-year-old patient who had abdominal surgery for a colon resection and removal of a tumor 1 day ago. His nurse, Tonya, completed an initial assessment when she first cared for Mr. Lawson yesterday. She noted from the previous shift's nurses notes that the patient had been having fairly good control of his postoperative pain. She implemented pain control strategies to help him become more mobile so that recovery could proceed. His recovery plan involves early ambulation, and up until now he has had a pain rating at a level of 4 on a scale of 0 to 10. Mr. Lawson continues to guard his incision by placing his hand over the wound when he gets out of bed.

Mr. Lawson weighs 109 kg (240 lb) and is 5 feet, 11 inches tall. He has tried to cough more during his postoperative deep-breathing exercises. Tonya is caring for him for the second day in a row and begins the evening shift by inspecting his surgical wound. The wound is approximately 15 cm (6 inches) in length and closed with steel sutures. Tonya notices separation of the wound between two sutures at the bottom of the incision. There is a small amount of serous drainage. The area is inflamed, and Tonya asks the patient if the incision is tender when she gently palpates it. Mr. Lawson states, "Ow, that feels sore there. I think I pulled it when I coughed last night." He also rates pain at this time as being at a level of 5. Tonya checks the patient's vital signs and notes that his temperature is 37.5°C (99.6°F), slightly above his average temperature of 37.2°C (99.0°F). Tonya also inspects the intravenous (IV) access site in the patient's left forearm. It is intact, and there are no signs of phlebitis.

The nursing process is a type of scientific reasoning. Practicing the five steps of the nursing process ensures a rigorous, systematic, and dynamic way to approach your practice. During the first step of **assessment**, you collect a comprehensive set of data about a patient and recognize and identify patterns that begin to reflect the meaning of a patient's response to health problems. In the case study involving Tonya and Mr. Lawson, Tonya gathers information to fully understand Mr. Lawson's condition, using observational and interview techniques. Having an accurate and complete database about a patient allows you to make a clinical judgment in the form of a nursing diagnosis and then plan and implement relevant and appropriate nursing interventions. Your assessment also provides the standards for later evaluating the outcomes of care. Each time you interact with a patient you apply the nursing process, as you will see Tonya do throughout the case study.

Critical Thinking in Assessment

Think about what you do when you study or consider a problem. For example, why is my child or spouse acting this way? You collect data about the problem. In the case of a family member behaving differently, you consider his or her previous behavior, specifically how he or she is behaving now (voice tone, mannerisms, what he or she says to you) and perhaps how the behavior is affecting others in the family. You assess the situation. You gather as much information as possible in an effort to understand the true nature of the problem (e.g., my family member does not feel well, is angry, or just received bad news at work). The collection, review, and analysis of data make up the process of assessment.

A nursing assessment is the deliberate and systematic collection of data about a patient. Assessment includes not only physiological data but also psychosocial, cultural, spiritual, and lifestyle factors (ANA, n.d.). The data you gather during an assessment reveal your patient's current and past health status, functional status, and present and past coping patterns (Carpenito, 2017). Nursing assessment involves two steps:

- Collection of information from a primary source (a patient) and secondary sources (e.g., family caregiver, family members or friends, health professionals, medical record).
- The interpretation and validation of data to determine whether more data are needed or the database is complete.

In the case study Tonya collects information from Mr. Lawson through observation and asking questions. She saw the inflammation in the incisional area and validated its presence by asking the patient whether it was tender. She begins to interpret the meaning of her findings. An open area of an incision (skin breakdown), draining fluid, and tenderness around the site indicate a pattern of localized and altered wound healing. She also measured Mr. Lawson's body temperature to determine whether an early sign of a systemic infection is present.

If you practice in a hospital setting, you will usually care for more than one patient, and any of your patients' conditions can change quickly. In the home and community setting, your patients' conditions will also change. Sometimes their changes will be acute, but most often the change they experience is subtle and develops over time. An assessment database

changes as a patient's condition changes. Thus assessment is an ongoing process.

Mr. Lawson presents with signs of altered wound healing. Tonya reports these findings to the patient's surgeon, who orders antibiotics intravenously (IV) for 24 hours but also plans for the patient's discharge tomorrow. Mr. Lawson's priorities are to transition from immediate recovery from surgery to planning for discharge home. Tonya also needs to assess the patient's response to the IV therapy. She continues to manage Mr. Lawson's pain but also has to further assess the patient's knowledge, observe his behaviors, ask questions about his ability to care for his wound when he goes home, observe the nonverbal cues he provides, and determine whether there are problems that will affect discharge planning.

Critical thinking is a vital part of assessment (see [Chapter 15](#)). While gathering data about a patient, you synthesize relevant knowledge, recall prior clinical experiences, apply critical thinking standards and attitudes, and use professional standards of practice to direct your assessment in a meaningful and purposeful way ([Fig. 16.2](#)). You apply knowledge from the physical, biological, and social sciences to ask relevant questions and collect a complete history and physical. Clinical decision making is complex, requiring a broad knowledge base and access to reliable sources of information, as well as working in a supportive environment ([Björk and Hamilton, 2011](#)). Your ultimate goal in assessment is to gather all of the information necessary to reveal a patient's health care needs.

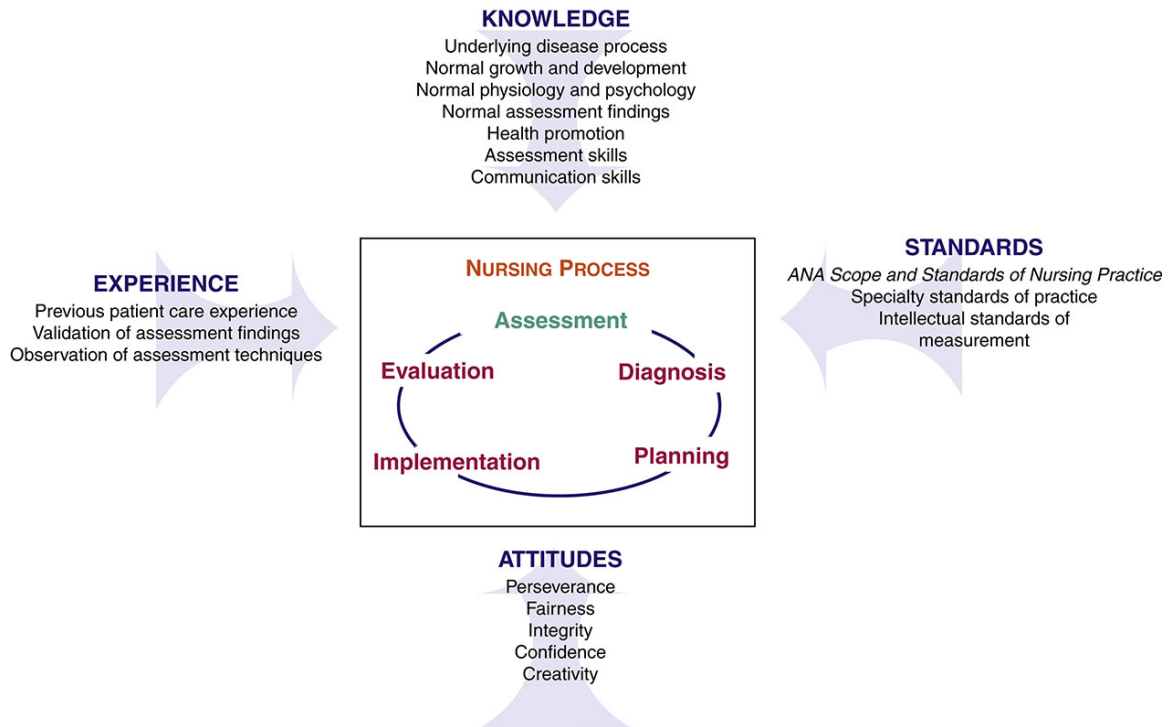

FIG. 16.2 Critical thinking and the assessment process.

Tonya knows that Mr. Lawson had a colectomy to remove the part of his colon that had a cancerous tumor. She reviewed her medical-surgical nursing textbook and learned how a colectomy alters gastrointestinal function and poses risks for blood clots in the legs (venous thrombosis) after surgery. This knowledge leads her to assess Mr. Lawson's bowel sounds, ask him if he is passing flatus, and assess the circulation in his legs. Tonya has learned from previous experiences in caring for patients with abdominal surgery that they have activity restrictions after surgery to reduce strain on the incision. Mr. Lawson's incision has a small separation; thus Tonya knows that she needs to assess what he has learned so far about activity restrictions in the home. Using good communication skills through interviewing and applying critical thinking intellectual standards, such as relevance (which activities the patient performs at home) and a broad review (including patient's wife in assessment), will enable Tonya to collect a complete, accurate, and relevant database.

The decisions nurses make while assessing their patients influence their effectiveness in clinical practice and make an impact on patients' lives and

experiences with health care in any setting in which they practice ([Björk and Hamilton, 2011](#)).

Types of Assessments

Assessment requires accurate and thorough data collection. There are different types of assessments:

- Patient-centered interview (conducted during a nursing history)
- Periodic assessments (conducted during ongoing contact with patients)
- Physical examination (conducted during a nursing history and at any time a patient presents a symptom)

Each type of assessment is either comprehensive or problem focused. Use a patient-centered interview when you conduct a comprehensive nursing history (i.e., a detailed assessment of a patient's physical, psychosocial, cultural, spiritual, and lifestyle needs). Usually you include categories of information in the patient's history that follow a structured database format based on an accepted framework or practice standard. [Marjory Gordon's "Functional Health Patterns" \(1994\)](#), [Nola Pender's "Health Promotion Model" \(2015\)](#), and the Long Term Care Minimum Data Set ([Centers for Medicare and Medicaid Services, 2010](#)) for residents in certified Medicare long-term care agencies are a few examples. A theory or practice standard provides the categories of information for you to assess. Pender's model is outlined in [Chapter 6](#). Gordon's 11 functional health patterns include health perception and management, nutritional-metabolic, elimination, activity-exercise, sleep-rest, cognitive-perceptual, self-concept, role-relationship, sexuality-reproduction, coping-stress tolerance, and value-beliefs. A health care agency often relies on the nursing history model included in the electronic health record (EHR) as the organizing framework for an assessment. Often EHR frameworks are medically driven. Frameworks developed from nursing theories are holistic and provide for a comprehensive patient review. *Tonya plans to further assess Mr. Lawson's cognitive-perceptual pattern using the questions included in her agency's EHR assessment form. She wants to learn more about what the patient knows about recovery from surgery, restrictions recommended by his surgeon, and how Mr. Lawson prefers to learn and make decisions about his care.*

Periodic problem-focused assessments collected during rounding or while you administer patient care include quick screenings to rule out or follow up on patient problems. For example, an emergency department nurse uses the Airway, Breathing, Circulation, Disability, Exposure (ABCDE) approach in all clinical emergencies for immediate assessment and treatment of patients who are injured or critically ill (Thim et al., 2012). This quick screening approach allows nurses to assess critical physiologic functions and make quick treatment decisions. Another example is a medical-surgical nurse who performs a quick screening of a patient who is demonstrating incisional pain. The quick screening focuses on the patient’s incisional pain, which is a priority problem.

Another type of problem-focused approach begins with a patient’s presenting situation and specific problematic areas (expected as well as unexpected), such as incisional pain or limited understanding of postoperative recovery. You ask the patient follow-up questions to clarify and expand your assessment so that you better understand the full nature of the problem. Then you perform a physical examination focusing on the same problem areas to confirm your observations. *For example, Tonya chooses to focus on Mr. Lawson’s symptoms the first 48 hours after surgery, the expected healing response, and signs of potential complications. She inspects the condition of the patient’s surgical wound, looking for signs of healing and observes his progress in ambulating. She later expands her assessment to determine how Mr. Lawson is adjusting emotionally to surgery and his cancer diagnosis and whether he is prepared for discharge.* Table 16.1 offers an example of a problem-focused assessment.

TABLE 16.1

Example of Problem-Focused Patient Assessment: Pain

Problem and Associated Factors	Questions for Assessment	Physical Examination
Nature of pain	Describe your pain. Tell me how the pain is affecting your daily life.	Observe for nonverbal cues (e.g., facial grimacing, crying).
Precipitating factors causing pain	What causes your pain to worsen during the day? Is your pain associated with movement? Anything else?	Observe if patient demonstrates nonverbal signs of pain during movement (e.g., positioning, swallowing, walking).
Severity of pain	Rate your pain on a scale of 0 to 10.	Inspect area of discomfort. Palpate area for tenderness.

A physical examination is a comprehensive review of all major body systems (see [Chapter 30](#)), providing objective data about a patient's clinical status. Portions of a physical exam are typically included in a nursing history (e.g., height and weight, inspection of the skin, lung sounds). You also use physical examination techniques to validate your observations with data, as in the case of Tonya when she palpated Mr. Lawson's tender incision line. Patient symptoms such as pain, shortness of breath, or nausea will direct you to examine various bodily functions (shortness of breath: long sounds and chest excursion; nausea: bowel sounds, abdominal distention).

Types of Data

There are two primary types of data: subjective and objective. **Subjective data** are your patients' verbal descriptions of their health problems. Subjective data include patient feelings, perceptions, and self-reported symptoms. For example, Mr. Lawson's self-report of pain at the area where his incision slightly separated is an example of subjective data. Only patients provide subjective data relevant to their health condition. The data often reflect physiological or psychological changes. You explore physiological changes through objective physical examination of body systems.

Objective data are the findings resulting from direct observation or measurement, including what you see, hear, and touch ([Ball et al., 2019](#)). Inspecting the condition of a wound, observing a patient walk down the floor, measuring blood pressure, and describing specifically an observed behavior (patient seizure) are examples of objective data. Objective data are measured on the basis of an accepted standard such as the Fahrenheit or Celsius measure on a thermometer, inches or centimeters on a measuring tape, or a pain rating scale. When you collect objective data, apply critical thinking intellectual standards (e.g., clear, precise, and consistent) so that you can correctly interpret your findings.

Assessment Data Sources

A variety of sources provide information about a patient's current and past level of wellness and functional status, anticipated prognosis, risk factors for health problems, health and lifestyle practices, goals, cultural background, responses to previous treatment, and patterns of health and illness.

Patient

A patient is your best source of information. Patients who are conscious, alert, and able to answer questions appropriately provide the most accurate information. Those with cognitive changes—such as patients who are inattentive or easily distracted, those who are diagnosed with dementia, or who have psychological symptoms such as anxiety or fear—can be less reliable sources. When a patient is not a reliable source, you may refer to the family. Always consider the setting for your assessment and your patient's condition. A patient experiencing acute symptoms in an emergency department will not offer as much information as one who comes to an outpatient clinic for a routine checkup. Also, know your patient's health literacy level. A patient with limited health literacy has difficulty obtaining, processing, and understanding basic health information (AHRQ, 2016). This means that patients do not always understand some of the questions you use during assessment, especially if you use more clinically focused words or terms or do not speak their language. You will not gather accurate information if a patient does not understand assessment questions. The [Agency for Healthcare Research and Quality \(2016\)](#) offers tools for assessment of health literacy, including Short Assessment of Health Literacy (Spanish and English), Rapid Estimate of Adult Literacy in Medicine (short form), and Short Assessment of Health Literacy for Spanish Adults ([Box 16.1](#)).

Box 16.1 Evidence-Based Practice Assessment of Health Literacy

PICOT Question: In adults does the use of formal literacy screening tools versus asking basic screening questions identify patients with inadequate health literacy?

Evidence Summary

Numerous instruments are available to assess health literacy. However, most were developed for use in research. Although they capture health literacy comprehensively and measure many factors associated with health literacy, they are not always useful in clinical practice, especially when time is limited (Altin et al., 2014). Commonly used instruments include the Rapid Estimate of Adult Literacy in Medicine (REALM), the Short Test of Functional Health Literacy in Adults (S-TOFHLA), and the Newest Vital Sign (NVS) (Weiss et al., 2005). However, the Single Item

Literacy Screener (SILS) asks respondents only one question: How often do you need to have someone help you when you read instructions, pamphlets, or other written material from your doctor or pharmacy? This question allows health care providers to do an initial quick screen and then target additional assessment of health literacy skills (Morris et al., 2006). Routinely screening patients for health literacy has not been shown to improve outcomes. Instead, using universal health literacy precautions to provide understandable and accessible information to all patients is recommended, regardless of their literacy or education levels (Hersh et al., 2015).

Application to Nursing Practice

- Use the literacy screening tools made available at your health care institution with all patients.
- Follow universal health literacy precautions (Hersh et al., 2015):
- Avoid use of medical jargon.
- Break down information or instructions into small concrete steps.
- Limit the focus of a visit (such as a patient assessment) to three key points.
- Assess a patient's understanding of any instruction.
- Ensure printed information is written at or below a fifth- to sixth-grade reading level.

An older adult often requires more time for assessment than a younger patient if his or her hearing or cognitive function is impaired. However, physiological age and chronological age may not match. It is important to recognize that not all adults experience the same changes and that changes occur at different rates (Ball et al., 2019). Some older adults have sensory alterations (visual and hearing) that make it more difficult to communicate. Use short (but not leading) questions, keep your language uncomplicated, and listen to a patient carefully (Ball et al., 2019) (Box 16.2). Consult family members, when appropriate, to fill in any gaps in information. Always be attentive, be engaged, and show a caring presence with patients (see Chapter 7). Patients are more likely to fully reveal the nature of health care problems when you show interest, avoid distractions by activities around them, and focus on their concerns.

Box 16.2 Focus on Older Adults Approaches for Assessing Older Adults

- Listen patiently; older adults are a rich source of wisdom and experience.
- Allow for pauses and give patients time to tell their story.
- Recognize normal changes associated with aging (see Chapter 14). Older adults' symptoms are often muted or less obvious, vague, or nonspecific compared with younger adults.
- Some patients may not report symptoms because they attribute them to old age or they think nothing can be done for them (Ball et al., 2019).
- If a patient has limited hearing or visual deficits, use nonverbal communication when conducting your interview (see Chapter 49):
 - **Patient-directed eye gaze:** Maintain eye contact with the patient. This allows you or a patient who is speaking to check whether information is understood. It is a signal for readiness to initiate interaction with a patient. Eye contact shows interest in what the other person is saying.
 - **Affirmative head nodding:** This has an important social function. It regulates an interaction (especially when alternate people speak), supports spoken language, and allows for comments on the interaction.
 - **Smiling:** A positive sign that indicates good humor, warmth, and immediacy. Smiles help when first establishing the nurse-patient relationship.
 - **Forward leaning:** This shows awareness, attention, and immediacy. During an interaction it also suggests interest in the person.

Family Caregivers and Significant Others

Family caregivers, other family members, and significant others are primary sources of information for infants or children, critically ill adults, and patients who have intellectual disabilities or cognitive impairments. In cases of severe illness or emergency situations, family members are often your only source of information. The family and significant others are also important secondary sources of information for alert and responsive patients. They confirm findings or identify important health patterns (e.g.,

whether a patient takes medications regularly, is able to sleep well, and the type of diet the patient regularly eats). Include the family in an assessment when appropriate. Patients do not always want you to question or involve their families. In some cultures, including the family is inappropriate. Some health care agencies require a patient's oral or written permission to collect data from family members. A spouse or close friend who sits in during an assessment can provide his or her view of a patient's health problems or needs. Not only do they supply information about a patient's current health status, but they are also able to tell when changes in the patient's condition have occurred. Family members are often well informed because of their experiences living with a patient and observing how his or her health affects daily living activities. They can make important observations about patients' needs that will influence the way you deliver care (e.g., how a patient eats a meal, makes choices, or performs hygiene). A strong nurse-family relationship is important for you to gather the information you need.

Health Care Team

You will frequently communicate with other health care team members when gathering information about patients. In acute care settings the change-of-shift report or patient hand-off is the way for nurses to communicate the most recent information about patients to nurses or other health care providers on oncoming shifts (see [Chapter 26](#)). A hand-off report is defined by The Joint Commission (TJC) as a transfer and acceptance of patient care responsibility achieved through effective communication. It is a real-time process of passing patient-specific information from one caregiver to another or from one team of health care providers to another for the purpose of ensuring the continuity and safety of the patient's care ([TJC, 2014](#)). Hand-offs also occur when patients are transferred from one unit or area of care to another. Effective communication through hand-offs can improve health care providers' perceptions of accuracy, completeness, and types of interventions provided to patients during a previous shift or level of care. Typically when nurses and other health care providers consult on a patient's condition, each contributes information about the patient. There can be problems with hand-off communication unless each member of the team assumes responsibility for either giving or receiving a complete and accurate report ([TJC, 2017](#)) ([Box 16.3](#)). Potential for patient harm is introduced when the receiver gets information that is inaccurate, incomplete, not timely, misinterpreted, or otherwise not what is needed to

provide care (TJC, 2017). Hand-off information is vital for you to be able to assess and understand a patient's most current health care needs.

Box 16.3 Hand-Off Communication

- Patient safety is at risk when the receiver of a hand-off report gets information that is inaccurate, incomplete, not timely, misinterpreted, or unneeded.
- A hand-off is an opportunity for care providers to share information: the patient's condition, care, treatment, medications, services, and any recent or anticipated changes.
- Hand-offs need to be structured and focused to ensure continuity of care. Many agencies use forms or structured processes for hand-offs, such as the program I-PASS (Illness severity, Patient summary, Action list, Situation awareness and contingency plans, and Synthesis by receiver).
- Avoid barriers to effective hand-offs when possible, such as delays in reporting, inattention, or lack of knowledge about the patient being transferred from receivers.
- Provide hand-offs through face-to-face communication; do not make hand-offs using solely electronic or paper communications.

Adapted from The Joint Commission: *The Joint Commission Center for Transforming Healthcare. Improving transitions of care: hand-off communications*. Oakbrook Terrace, IL: The Joint Commission, 2014.

Medical Records

The medical record is a valuable resource for your patient assessment. It contains a patient's medical history, laboratory and diagnostic test results, current physical findings, and a health care provider's treatment plan. In some cases medical records also contain consultation notes. There are health care agencies that hold medical records for all of a patient's visits within the agency system, including inpatient and outpatient. Data in the records offer baseline and ongoing information about a patient's response to illness and progress to date. The Health Insurance Portability and Accountability Act (HIPAA) of 1996 has a privacy rule that came into effect

in 2003 to set standards for the protection of health information ([USDHHS, 2003](#)). Information in a patient's medical record is confidential. A nurse can review a patient's medical record for assessment data but needs to know the agency policies governing how to share the information with other staff. The record is a valuable tool to check the consistency and similarities of your own observations and measurements.

Other Records and the Scientific Literature

Educational, military, and employment records often contain significant data about a patient (e.g., immunizations, prior illnesses). If a patient received services at a community clinic or a different hospital, you need written permission from the patient or guardian to access the record. The HIPAA regulations protect access. The privacy rule allows health care providers to share protected information as long as they use reasonable safeguards. Consult agency policies and participate in annual HIPAA training as required.

Reviewing recent nursing, medical, and pharmacological literature about a patient's illness or treatments provides up-to-date information that helps you to anticipate patient needs and to implement evidence-based interventions (see [Chapter 18](#)). This review increases your knowledge about expected signs and symptoms, treatment options, and established standards of therapeutic practice. Always be sure to review the most current literature available (see [Chapter 5](#)).

Nurse's Experience

Your experience in caring for patients is a source of data. Through clinical experience you observe other patients' behaviors and physical signs and symptoms; track trends and recognize clinical changes; and learn the types of questions to ask, choosing the questions that will give the most useful information. This experience builds your ability to know patients, knowing the pattern of responses shown by similar patients. As a new nurse, you will use a systematic and analytical method to make decisions when you analyze data and ultimately make a nursing diagnosis ([Muntean, 2012](#)) (see [Chapter 17](#)). The tendency for a new nurse is to just focus on data and not consider the whole context of a patient's situation. New nurses have not had that kind of experience. However, as you gain more practice, you will eventually make fluid intuitive decisions that account for all of the patient's data and the mental connections to data gained from previous experiences. That intuition is a feeling of knowing

something without conscious use of reason, but is a critical part of clinical decision making ([Muntean, 2012](#)). Practical experience and the opportunity to make clinical decisions strengthen your critical thinking.

REFLECT NOW

The next time you assess a patient, consider the data you collect and identify what information is subjective versus objective. Is the information you collect complete, and if not, how might you gather additional information?

The Nurse-Patient Relationship in Assessment

Effective communication is the foundation for creating nurse-patient relationships that enable patients to tell their stories and nurses to understand patients and the experiences they express (Kourkouta and Papathanasiou, 2014). It requires skills and simultaneously the sincere intention of a nurse to understand what concerns a patient. Only to understand a patient is insufficient; the nurse must also convey the message that the patient is understandable and acceptable (Kourkouta and Papathanasiou, 2014). Trust is central to an effective nurse-patient relationship and necessary to ensure that you are able to learn the information needed to care for a patient.

Typically there is much information to consider about a patient. Where should you begin? Start by taking quality time to be present with a patient, even if it is for a few minutes. This can be difficult when you are faced with interruptions, the care of other patients, other home visits, or the restricted time given to you in a health care provider's office. Having quality time should occur during admission of a patient to a hospital unit, during rounds when you begin a shift of care, during a follow-up home or clinic visit, or in any encounter with a patient. Connecting with a patient by showing interest in his or her problems and concerns helps you collect a relevant database. Research shows that hearing accounts of patients' health and illness experiences, watching them, and coming to understand how they typically respond develops a type of knowing that fosters good clinical judgments (Tanner, 2006). Visiting a hospitalized patient at set intervals (called rounding) allows you to address essential care needs and patient experiences and helps organize your workload. Rounding is a vital opportunity to build trust with patients, increasing the likelihood that you will gain more information that will help you identify and communicate their health-related problems. Chapter 24 reviews how to establish a nurse-patient relationship and the skills of effective communication.

The Patient-Centered Interview

When conducting an assessment of a patient you will use interview and observational skills. A patient-centered interview is relationship based and is an organized conversation focused on learning about a patient's concerns and needs. If you are to prevent misinterpretation of information and misperceptions, you must make every effort to sense the world of an individual patient as he or she senses it (Ball et al., 2019). An empathic, patient-centered interview strengthens a patient's sense of self-esteem and lessens the feelings of helplessness that often accompany an episode of illness. Research has shown that interview skills contribute significantly to problem detection, diagnostic accuracy, patient satisfaction, patient adjustment to stress and illness, patient recall of information, patient adherence to therapy, and patient health outcomes (Keifenheim et al., 2015). The most extensive patient-centered interview is the one used during collection of a nursing history. Primary objectives while taking an initial nursing history are to discover details about a patient's concerns, explore expectations for the health care visit, and display genuine interest and partnership.

One type of patient-centered interview is motivational interviewing. It is a technique used often in counseling and patient education that allows you to become a helper in the change process. Motivational interviewing addresses a patient's ambivalence or uncertainty about following medically indicated behavioral changes and supports patients in making health care decisions in cases in which there is more than one reasonable option (Elwyn et al., 2014).

Interview Preparation

Before you begin an interview, especially for a nursing history, be prepared. Review a patient's medical record when information is available. If your interview is performed at patient admission, there may be little information in the record except for an admitting diagnosis and the patient's chief complaint. In other cases review the previous medical entries or nurses' notes. Were problems identified that remain a part of the patient's treatment plan? Do any of those problems require clarification or follow-up? Does a patient's admitting diagnosis or do other diagnoses suggest lines of questioning? For example, in the case of a patient with a history of chronic lung disease, you would include questions about the patient's respiratory status, effects of disease symptoms on lifestyle, and

the patient's acceptance and understanding of a chronic disease. The information you obtain during a hand-off report at the beginning of a shift will help you frame clinical questions to address the problems you decide to explore.

Communication Skills

Effective communication with patients during an assessment interview requires the following skills (Ball et al., 2019):

- **Courtesy**
 - Greet patients by the name by which they prefer to be addressed. Ask, "Would you prefer I call you by Mrs. Silver or by your first name?" It is all right to shake hands.
 - Introduce yourself and explain your role the first time you meet. For example, "My name is Julia, and I will be your nursing student today. I would like to ask you questions about how you are feeling right now. Is that okay with you?"
 - Ensure confidentiality of the information the patient chooses to share.
 - Meet and acknowledge visitors in the patient's room and learn their names and roles.
 - Sit down next to the patient and do not make an effort to exit the room too soon.
 - Remember to ask the patient's permission to conduct an interview in a visitor's presence.
 - Try to take notes sparingly; remember key words.
- **Comfort**
 - Ensure that your patient is comfortable. If a patient is in pain or has nausea or fatigue, it is difficult to gather a thorough and accurate history. Provide necessary comfort measures before beginning the interview. When patients have symptoms, keep questions short and focused.
 - Maintain privacy. Close room curtains or doors and provide a comfortable room temperature.
 - Select a location for the interview that is quiet and free of interruptions. Do not answer your pager during the interview unless there is an emergency. If possible, set

aside a 10- to 15-minute period when no other activities are planned.

- Avoid overtiring the patient. You do not need to complete the interview in one session.

- **Connection**

- It is important to make a good first impression. Avoid staring at a computer screen while filling in required data fields or talking on a cell phone; patients will perceive you are uncaring or uninterested in what they have to say.
- Stiff formality may inhibit a patient, but being too casual may not instill confidence. Do not be careless with your choice of words; what you think is a harmless or innocent phrase may seem very important to a patient who is anxious to understand you.
- Begin with open-ended questions that encourage patients to tell their stories (e.g., “How have you been feeling?” “What questions would you like to discuss?” “Tell me how you want us to help you”).
- Allow patients to fully describe their symptoms without interrupting them (Muhler, 2014).
- Do not dominate a discussion or assume that you know the nature of a patient’s problems. Listen and be attentive.
- Use your observational skills. Note the patient’s tone of voice, posture, and level of energy when talking.
- Respect silence and be flexible. Let the patient’s needs, concerns, or questions guide your follow-up questions. Health problems can have multiple causes; do not leap to one cause too quickly.

- **Confirmation**

- At the end of an interview, ask the patient to summarize the discussion so that there are no uncertainties. Be open to further clarification or discussion. Ask the patient, “Is there something else you want to talk about?” (Muhler, 2014).
- If there are questions you cannot answer, say so and promise that you will return with follow-up if possible.

Phases of the Interview

When you begin a formal patient-centered interview for the purpose of collecting a nursing history, you will go through the traditional three interview phases: (1) orientation or setting an agenda, (2) working phase—collecting assessment data, and (3) termination of the interview (see [Chapter 24](#)).

Orientation and Setting an Agenda

Begin by introducing yourself, and explain why you are collecting data. Assure patients that information will be kept confidential. Your aim is to set an agenda for the interview, including how you will gather information about a patient's chief concerns or problems (e.g., asking questions and performing a physical exam). Focus on a patient's goals, preferences, and concerns, not your personal agenda. This is a time that allows a patient to feel comfortable speaking with you and becoming an active partner in decisions about care. The professionalism and competence that you show when interviewing strengthens the nurse-patient relationship.

Tonya is doing a follow-up interview to learn more about Mr. Lawson's home situation. She explains, "Mr. Lawson, it looks as if your doctor wants to send you home tomorrow. It's important for us to know more about how you care for yourself at home. Are you comfortable, and can I take a few minutes to talk about your discharge now?" Mr. Lawson replies, "I feel a bit better, and, yes, I've been thinking about some questions I want to ask." Tonya replies, "Good. We'll start there."

Working Phase—Collecting Data

Whether you are conducting a complete nursing history or gathering ongoing assessment information, the working phase of a relationship involves gathering accurate, relevant, and complete information about a patient's condition. Beginning an interview with open-ended questions allows patients to describe their concerns and problems clearly. For example, begin by having patients explain their symptoms or physical or psychological concerns. Ask them to describe what they know about their health problems or to describe their health care expectations. Use attentive listening and summarize key issues to validate your understanding with the patient, and encourage him or her to tell a full story (see [Chapter 24](#)). Do not rush to an opinion about what the patient tells you. When a patient describes a symptom, such as dizziness, queasy stomach, or weakness,

clarify what the patient means. For example, say, "Describe how you feel when you are dizzy." Be willing to wait for the patient to respond no matter how long it takes (Muhrrer, 2014). If you ask direct questions (e.g., "Does the room spin?" or "Do you feel faint?" in the case of dizziness), most patients will say yes to most of your questions (Muhrrer, 2014). However, this may not reveal the true problem. This is important because symptoms often reflect multiple disorders. Dizziness can indicate the patient has an ear disorder, cardiovascular disease, an anxiety disorder, or a neurological problem. Unless you listen and get a full description of the patient's symptoms and how they affect him or her, you will not identify the true problem.

The verbal cues that a patient expresses will help you stay focused so that you can direct an assessment appropriately. Do not rush a patient. An initial interview is more extensive. Gather information about a patient's concerns and then complete all relevant sections of the nursing history. Ongoing interviews, which occur each time you interact with your patient, do not need to be as extensive. Organize your time with a patient and focus on priority areas to assess. An ongoing interview also allows you to update a patient's status and concerns, focus on changes previously identified, and review new problems.

Tonya: "Mr. Lawson, you said you had some questions. Can you tell me what they are?"

Mr. Lawson: "Well, the doctor told me that I would not be able to lift anything heavy for a while, and I'm not sure if I understand. The way my incision looks, will I need to do something to it?"

Tonya: "Let's start with your question about lifting. Tell me what you think that means."

Mr. Lawson: "Well, I suppose it is anything big, but I do not plan to move furniture or do any work around the house until I feel better."

Tonya: "Tell me the types of things you lift regularly at home and approximately how much they weigh."

Mr. Lawson: "Well, when our grandchildren visit, they like to be picked up. We have a pet schnauzer, but he just jumps up on the chair with me. My wife does grocery shopping, but I come out to unload the car."

Tonya: "Anything else?"

Mr. Lawson: "Hmmm, occasionally I lift the laundry basket and take it downstairs."

Tonya: "Okay, and about your incision, yes, you will need to care for it. Can you tell me the signs of infection?"

Mr. Lawson: "Not sure I can, but I guess it would hurt more. Is infection common?"

Tonya: "No, but you and your wife need to know the signs, so if something happens once you return home, you can know to call your doctor quickly. Has your doctor or the nurse practitioner talked to you about incision care?"

Mr. Lawson: "No, they have not mentioned anything about that yet."

Tonya: "Okay, I'll explain everything you need to know and take the time to be sure you understand. Do you think you learn best by reading information or listening to explanations?"

Mr. Lawson: "I think I do okay with both."

Tonya's assessment focuses on the patient's questions and how they pertain to the information he will need to learn to go home and assume self-care.

Interview Techniques

How you conduct the interview is just as important as the questions you ask. During an interview you direct the flow of the discussion so that patients have the opportunity to freely describe their health problems to enable you to get a detailed picture of their needs. Remember, some interviews are focused, while others are more comprehensive. Because a patient's report will contain subjective information, validate subjective data later with objective information. For example, if a patient reports difficulty breathing, you will further assess the patient's respiratory rate and lungs sounds during the physical examination.

Observation

Observation is powerful. Observe a patient's verbal and nonverbal behaviors, such as the use of eye contact, body language and positioning, or tone of voice. While observing nonverbal behavior, appearance, and the patient's interaction with the environment, determine whether the data you obtained are consistent with what the patient states verbally. Your observations will lead you to pursue further objective information to form thorough and accurate conclusions. Patients are also observant during interviews. If you establish trust, the patient feels comfortable asking you questions about the health care environment, planned treatments, diagnostic testing, and available resources. A patient needs this information to partner in making decisions and planning the goals of care.

An important aspect of observation includes a patient's level of function: the physical, developmental, psychological, and social aspects of everyday living. Observation of level of function involves watching what a patient

does when eating, performing hygiene, or making a decision about preparing a medication. It is not what the patient tells you that he or she can do. Observation of function often occurs in the home or in a health care setting during a return demonstration.

Open-Ended Questions

During a patient-centered interview you try to learn, in the patient's own words, his or her concerns or problems, possible causes, and any health care goals. Open-ended questions elicit the patient's unique story. An open-ended question gives a patient discretion about the extent of his or her answer (Ball et al., 2019). For example, "So, tell me more about" or "What are your concerns about this?" or "Tell me how you have been feeling." This approach does not presuppose a specific answer. You are exploring with the patient. The use of open-ended questions prompts patients to describe a situation in more than just one or two words, allowing patients to actively describe their health status. This interaction strengthens your relationship together. The open-ended question shows that you want to hear a patient's thoughts and feelings. Listen carefully and do not interrupt the patient. When you interrupt, you will not gather complete information and you also may end up disagreeing with the patient about his or her views of the illness or purpose of the health visit (Muhrer, 2014).

Direct Closed-Ended Questions

As you obtain information from a patient you will sometimes ask direct **closed-ended questions** to seek specific information about a problem or situation. Direct questions are not ideal when you wish a patient to be thorough in describing a health problem. However, this problem-seeking technique reveals details to identify a patient's specific problems accurately and more fully. For example, a patient reports having indigestion over the course of several days and acknowledges having some diarrhea and loss of appetite. The patient's explanation for the cause relates to a recent series of trips that changed his eating habits. The nurse focuses on the symptoms the patient identifies and the general indigestion problem by asking closed-ended questions that limit answers to one or two words such as "yes" or "no" or a number or frequency of a symptom. For example, the nurse asks, "How often does the diarrhea occur?" and "Do you have pain or cramping?" This technique requires short answers and clarifies previous information to provide a more comprehensive

database. The questions do not encourage patients to volunteer more information than you request.

Leading Questions

These types of interview questions are risky because they can limit the information a patient will provide to what a patient thinks you want to know (Ball et al., 2019). Two examples of leading questions are (1) “It seems to me this is bothering you quite a bit. Is that true?” and (2) “That wasn’t very hard to do, was it?” When asking how often a symptom or problem occurs, allow a patient to define “often.” Do not ask, “It didn’t happen too often, did it?” A patient may not understand what you are asking and may say so (Ball et al., 2019).

Back Channeling

Reinforce your interest in what a patient has to say through the use of good eye contact and listening. Also use **back channeling**, which includes active listening prompts such as “all right,” “go on,” or “uh-huh.” This technique shows that you have heard what a patient says, are interested in hearing the full story, and are encouraging the patient to give more details.

Probing

As a patient tells his or her story, encourage a full description without trying to control the story’s direction. This requires you to probe with more open-ended questions, such as “Is there anything else you can tell me?” or “What else is bothering you?” Each time a patient offers more detail, probe again until the patient has nothing else to say and has told the full description. Always be observant. If a patient becomes fatigued or uncomfortable, know that it is time to postpone the interview until later.

Interpret

Ultimately it is important to come to the correct conclusion and decision about a patient’s problems based on your assessment. By interpreting, you repeat what you have heard to confirm the patient’s meaning (Ball et al., 2019). Clarity is critical before you analyze your data to make a diagnostic conclusion (see Chapter 17).

Building Competency in Patient-Centered Care

Describe how you would conduct a patient-centered interview with Mr. Lawson about his expectations for going home after surgery during the working phase of the interview.

Termination Phase

You summarize your discussion with a patient and check for accuracy of the information you collected during the termination phase of an interview. Let your patient know when the interview is coming to an end. For example, say, "I have just two more questions. We'll be finished in a few more minutes." This helps a patient maintain direct attention without being distracted by wondering when the interview will end. This approach also gives the patient an opportunity to ask additional questions. End the interview in a friendly manner, telling the patient when you will return to provide care.

Tonya: "You've given me a good idea of which topics we need to cover and the plans we need to make to get you ready to go home. And we'll include your wife in these decisions if that is okay?"

Mr. Lawson: "Yes, for sure. She always helps me when I need it."

Tonya: "I'll come back after I check on two other patients, okay?"

Mr. Lawson: "Yes, you have already been very helpful."

REFLECT NOW

Before your next clinical assignment, consider how to plan a patient-centered interview. What ways can you connect early with a patient? What questions might be appropriate based on the patient's health situation?

Nursing Health History

The nursing health history typically contains similar information regardless of the health care setting and EHR software or form used to gather and document patient information. Data gleaned from the health history are used to inform a patient's nursing care. You will gather a **nursing health history** during an initial or early contact with a patient. The history is a key component of your comprehensive assessment. Most health history forms (electronic and manual) are structured. However, on the basis of information you gain as you conduct the patient-centered interview, you learn which components of the history to explore fully and which require less detail. As you gain more experience, you will learn to refine and broaden questions as needed to correctly identify a patient's unique needs. Your patient's priorities and needs and the amount of time you have available determine how complete a history will be. A comprehensive history covers all health dimensions ([Fig. 16.3](#)).

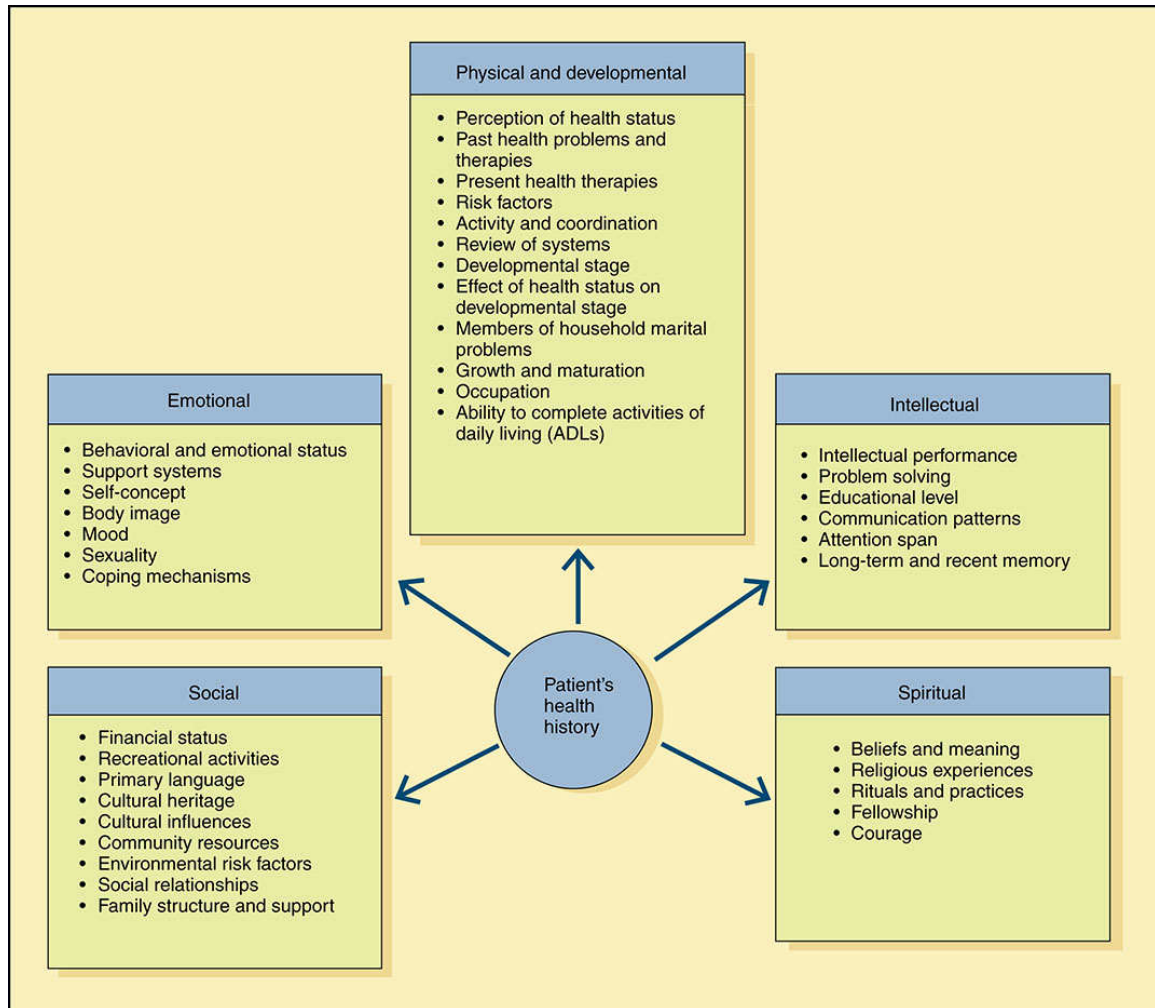

FIG. 16.3 Dimensions for gathering data for a health history.

Cultural Considerations

Obtaining a nursing health history requires cultural competence (see [Chapter 9](#)). This involves self-awareness, reflective practice, and knowledge of a patient's core cultural background. It is critical for you to adapt each assessment to the uniqueness of each patient. Cultural humility requires you to recognize your own knowledge limitations and cultural perspective and thus be open to new perspectives ([Ball et al., 2019](#)). Without humility you are at risk for being biased and misinterpreting assessment findings.

Show your patients respect and understand their individual needs and differences; do not impose your own attitudes, biases, and beliefs. Having a genuine curiosity about a patient's beliefs and values lays a foundation

for a trusting and strong nurse-patient relationship (Ball et al., 2019). Consider a patient's cultural background when you begin history taking. For clarity, explain the intent of any questions you have. Avoid making stereotypes; the assumptions tied to stereotypes (e.g., obese patients do not exercise regularly) can lead to the collection of inaccurate information. Draw on knowledge gained from your assessment and ask questions in a constructive and probing way to allow you to truly know who a patient is (Box 16.4).

Box 16.4 Cultural Aspects of Care **Developing a Patient-Centered Approach**

To successfully explore a patient's illness or health care problems, use a patient-centered approach. Elicit patient values, preferences, and expressed needs as part of your clinical interview (QSEN, 2018). Ensure the interview is inclusive. When patients desire involvement of family members, remove any barriers to having families present (QSEN, 2018). Use a professional interpreter if there is a language difference.

Implications for Patient-Centered Care

- When talking about a patient's illness, try to understand it "through the patient's eyes."
 - What do you think is wrong with you?
 - What worries you most about your illness?
 - How do you define health and illness? How do you feel about pain, your illness, or death?
- When talking about treatments, value a patient's expertise with own health and symptoms.
 - What should we do to control or eliminate your problem?
 - Which types of treatment do you use at home?
 - What benefits do you expect from the planned treatment?
- Learn about a patient's sources of support (Ball et al., 2019).
 - Who makes decisions in the family?
 - What is the family composition? How many generations are considered part of the family?
 - Are there individuals in the patient's social network that can influence perception of health and illness?

- Is there a particular cultural group with which the patient identifies?

Professionalism in History Taking

Most health care institutions use computerized software programs to enter data into the Electronic Health History (EHR). In many cases computers are at each patient's bedside. To display professionalism and a caring approach during an interview, look at the patient and not the computer screen. Use the computer if you must, but position it in a way that does not distract from your focus on the patient (Ball et al., 2019). In an observational study involving physicians and patients during routine clinic visits, fewer than half (48%) of the patients who had physicians with heavy computer use and focus during clinical encounters rated the care they received as excellent on patient experience surveys. In contrast the majority (83%) of patients whose physicians were less engaged (more patient focused) with their computers during the clinic visit felt the care they received was excellent (Ratanawongsa et al., 2016). The same study showed that high computer use by physicians was associated with observable communication differences—less patient engagement and more negative rapport. Do not let a computer program guide your assessment. Ask patients to explain why they have come for health care, listen actively, proceed at a reasonable pace, and ask open-ended questions (Ball et al., 2019).

Components of the Nursing Health History

Biographical Information

Biographical information is factual demographic data that include a patient's age, gender, address, insurance information, occupation, working status, marital status, and referral source. The staff who work in the admitting office usually collect this information.

Chief Concern or Reason for Seeking Health Care

The chief concern is a brief statement about why a patient (in his or her own words) is seeking health care (Ball et al., 2019). This information offers a focus to explore a patient's concerns and issues. Once you learn a patient's chief concerns, you will compare those findings with what you learn during your assessment. Often you will learn much more. Ask a

patient why he or she is seeking health care (e.g., “Tell me, Ms. Richard, what brought you to the clinic today?”). Once you learn a chief concern, you then gather more comprehensive data and probe for a full description of the patient’s health status. You record a patient’s response in quotations to indicate a subjective statement. As you explore a patient’s reason for seeking health care, you will learn the chronological and sequential history of his or her health problems.

Patient Expectations

It is important to assess a patient’s expectations of health care providers (e.g., being diagnosed correctly, obtaining pain relief, or being treated for a disease). Patient satisfaction, a standard measure of quality for all hospitals throughout the country, can be perceived by patients as poor if their expectations are unmet (see [Chapter 2](#)). Patients typically expect to receive information about their treatments, prognosis, and a plan of care for their return home (whether they are inpatients or outpatients). In addition, they expect relief of pain and other symptoms and to have caring expressed by health care providers. During the initial interview have a patient express expectations when entering the health care setting. Later, as the patient interacts with health care providers, assess whether these expectations changed or were met.

Present Illness or Health Concerns

If a patient presents with an illness, collect essential and relevant data about its course and symptoms. Go slowly as you try to give context to the present illness or problem, giving it a chronological and sequential framework ([Ball et al., 2019](#)). Apply critical thinking intellectual standards (see [Chapter 15](#)), and use the acronym (PQRST) to guide your assessment:

P—Provokes (precipitating and relieving factors): How did it come about? What might be the causes for the symptom? What makes it better or worse? Are there activities (e.g., exercise, sleep) that affect it?

Q—Quality What does the symptom feel like? (Have the patient explain in his or her own words.) If the patient has difficulty in describing symptoms, offer probes (e.g., “Is the pain sharp? Dull?” or “Do you feel light-headed, dizzy, off balance?”). What does the illness or symptom mean to the patient?

R—Radiate: Where is the symptom located? Is it in one place? Does it go anywhere else? Have the patient be as precise as possible.

S—Severity: Ask a patient to rate the severity of a symptom on a scale of 0 to 10 (with no symptom at 0 and the worst intensity at 10). This gives you a baseline with which to compare in follow-up assessments.

T—Time: Assess the onset and duration of symptoms. When did a symptom start? Does it come and go? If so, how often and for how long? What time of day or on what day of the week does it occur?

Also assess whether the patient is experiencing other symptoms along with the primary symptom. For example, does nausea accompany pain? Does the patient have pain along with shortness of breath?

Past Health History

A health history provides a holistic view of a patient's health care experiences and current health habits (see [Fig. 16.3](#)). Assess whether a patient has ever been hospitalized or injured or has had surgery. Has any illness or injury limited the patient's ability to function? Include a complete medication history (including past, current, and recent medications). Review the use of any prescription medications, herbal supplements, and over-the-counter (OTC) drugs. Also essential are descriptions of allergies, including allergic reactions to food, latex, drugs, or contact agents (e.g., soap). Asking patients whether they have had problems with medications or food clarifies the type and amount of agent, the specific reaction, and whether a patient has required treatment. If the patient has an allergy, note the specific reaction and treatment on the assessment form and the special armband provided. When considering allergies, also ask if the patient has ever had a blood product transfusion and whether any reactions occurred.

The history also includes a description of a patient's habits, emotional status, and lifestyle patterns. Assessing for the use of alcohol, tobacco, caffeine, or recreational drugs (e.g., methamphetamine or cocaine) determines a patient's risk for diseases involving the liver, lungs, heart, or nervous system. It is essential to gather information about the type of habit and the frequency and duration of use. Assessing patterns of coping (see [Chapter 37](#)), sleep (see [Chapter 43](#)), exercise (see [Chapter 38](#)), and nutrition (see [Chapter 45](#)) are also important when planning nursing care. Your aim is to match a patient's lifestyle patterns with interventions in the plan of care as much as possible.

Family History

The family history includes data about immediate and blood relatives. Your objective is to determine whether a patient is at risk for illnesses of a genetic or familial nature and to identify areas of health promotion and illness prevention (see [Chapter 6](#)). A complete and accurate family history guides your risk assessment and recommendations for risk-guided prevention strategies ([Orlando et al., 2013](#)). There are clinical treatment guidelines for patients and family members based on risk factors for conditions such as breast and ovarian cancer, colon cancer, thrombosis, cardiovascular disease, cerebrovascular disease, inherited cardiomyopathies and arrhythmias, and inherited neurological conditions. For example, a patient with a strong family history of breast cancer will be recommended to pursue mammography more often, and female children may be recommended for genetic counseling.

A patient's family history also reveals information about family structure, interaction, support, and function that is useful in planning care, such as when a family caregiver is needed (see [Chapter 10](#)). *In the case study Tonya assesses the level of support that Mrs. Lawson is willing to provide. Mrs. Lawson tells Tonya that the two have been married 32 years and states, "I feel I can do whatever is needed for him." Tonya's assessment shows a pattern that Mrs. Lawson is supportive and able to help her husband adjust to activity limitations when he returns home. Tonya's assessment ultimately allows her to include Mrs. Lawson when she provides patient education.* If a patient's family is not supportive, do not involve the family in care. Stressful family relationships are sometimes a significant barrier when you try to help patients with problems involving loss, self-concept, spiritual health, and personal relationships.

Psychosocial History

A psychosocial history provides information about a patient's support system, which often includes a spouse or partner, children, other family members, and close friends. The history also includes information about ways in which a patient and family typically cope with stress (see [Chapter 37](#)). Behaviors that patients use at home to cope with stress such as walking, reading, or talking with a friend can also be used as nursing interventions if the patient experiences stress while receiving health care. In addition, you need to learn whether the patient has experienced any recent losses that create a sense of grief (see [Chapter 36](#)).

Spiritual Health

Life experiences and events shape a person's spirituality. The spiritual dimension represents the totality of one's being and is difficult to assess quickly (see [Chapter 35](#)). Review with patients their beliefs about life, their source for guidance in acting on beliefs, and the relationship they have with family in exercising their faith. Also assess rituals and religious practices that patients use to express their spirituality. Patients may request availability of these practices while in a health care setting.

Review of Systems

The **review of systems (ROS)** is a systematic approach for collecting subjective information from patients about the presence or absence of health-related issues in each body system ([Ball et al., 2019](#)). During the ROS ask the patient about the normal functioning of each body system and any noted changes. You are more likely to conduct a comprehensive review of all systems during a nonemergent admission to a clinic or an initial home visit. A problem-focused review is common in emergent situations within acute care. Use a series of questions to assess each system as needed. For example, the review of the skin, hair, and nails includes assessment of whether a patient has noticed any rash or skin lesions or has itching or abnormal nail or hair growth. When using a structured admission form, you probably will not cover all of the questions for each body system every time you collect a history. When a patient mentions any unexpected signs or symptoms, explore the affected system(s) more in depth. The systems you assess thoroughly depend on a patient's condition and the urgency in starting care.

Along with the ROS, you conduct a physical examination (see [Chapter 30](#)) to further explore and confirm patient information. The physical examination involves use of the techniques of inspection, palpation, percussion, auscultation, and smell. An accurate history helps focus the physical examination, making it more productive and time efficient. As you gain experience, you will learn to look for more data, challenge any interpretations that you made solely based on the history, and persevere to gather accurate and complete assessment data.

Observation of Patient Behavior

Throughout a patient-centered interview and physical examination it is important to closely observe a patient's verbal and nonverbal behaviors. This information adds depth to your objective database. You determine

whether data obtained by observation matches what a patient communicates verbally. For example, a patient expresses no concern about an upcoming diagnostic test but shows poor eye contact, shakiness, and restlessness, all suggesting anxiety and verbal and nonverbal data conflict. Observations direct you to gather additional objective information to form accurate conclusions about the patient's condition.

An important aspect of observation includes a patient's level of function: the physical, developmental, psychological, and social aspects of everyday living. Observation of level of function differs from observations you make during an interview. You assess level of function by watching what a patient does when eating or making a decision about preparing a medication rather than what the patient tells you that he or she can do. Observation of function often occurs in the home or in a health care setting during a return demonstration.

Diagnostic and Laboratory Data

The results of diagnostic and laboratory tests provide further explanation of alterations or problems identified during the health history and physical examination. For example, during the history a patient reports having a bad cold for 6 days and currently has a productive cough with brown sputum and mild shortness of breath. On physical examination you notice an elevated temperature, increased respirations, and decreased breath sounds in the right lower lobe. You review the results of a complete blood count and note that the white blood cell count is elevated (indicating an infection). You report your results to the patient's health care provider, who orders a chest x-ray film. When the results of the x-ray film show the presence of a right lower lobe infiltrate, the health care provider makes the medical diagnosis of pneumonia. Your assessment leads to the associated nursing diagnosis of *Impaired Gas Exchange*.

Some patients collect and monitor laboratory data in the home. For example, patients with diabetes mellitus often measure blood glucose daily and those with asthma measure forced expiratory volumes. Ask patients about their routine results to determine their response to illness and information about the effects of treatment measures. Compare laboratory data with the established norms for a particular test, age-group, and gender.

Data Documentation

Record the results of the nursing health history and physical examination in a clear, concise manner using appropriate terminology. This information becomes the baseline to identify a patient's nursing diagnoses and health problems, to plan and implement care, and to evaluate a patient's response to interventions. Standardized forms, especially electronic forms, make it easy to enter assessment data as a patient responds to questions. A timely clear, concise record is necessary for use by other health care professionals (see [Chapter 26](#)). If you do not record an assessment finding or a suspected problem, it is lost and unavailable to anyone else caring for the patient. If information is not specific, the reader is left with only general impressions. Observing and recording patient status are legal and professional responsibilities for all nurses. The Nurse Practice Acts in all states and the American Nurses Association Nursing's Social Policy Statement ([ANA, 2010](#)) require accurate data collection and recording as independent functions essential to the role of the professional nurse.

A basic rule in documentation of an assessment is to record all observations succinctly. When recording data, pay attention to facts, and be as descriptive as possible. You need to report anything you hear, see, feel, or smell precisely. Record objective information in accurate terminology (e.g., weighs 77.2 kg [170 lb], abdomen is soft and nontender to palpation). Record any subjective information by using quotation marks. Do not generalize or form judgments through written communication when entering data. Conclusions about such data become nursing diagnoses and thus must be factual and accurate. As you gain experience and learn clusters and patterns of signs and symptoms, you will correctly conclude the existence of a health problem. Review [Chapter 26](#) for details on documentation.

The Assessment Process

When you conduct an assessment, think critically about what to assess for a patient's specific situation. As you form your relationship with a patient during the working phase of your interview, the quality of your connection with your patient will affect what the patient chooses to share with you. Determine which questions or measurements are appropriate on the basis of what you initially learn from a patient about his or her health concerns and history, your clinical knowledge, and your experience with other patients.

Data Collection

Use information about a patient's needs to adapt your data collection. Whether you conduct a comprehensive or problem-focused assessment, be sure your data are as thorough as possible. Support subjective findings with objective information. Use all sources for data gathering.

Interpretation

As you gather data, you begin to differentiate important data from all the data you collect. Critically interpret assessment data to determine whether abnormal findings are present. Your clinical reasoning allows you to recognize that further observations are needed to clarify information and begin to identify a patient's health problems. A **cue** is information you obtain through the use of senses. The cues you gather are the signs and symptoms that you obtain through observation and measurement. You begin to cluster cues that relate together, make inferences, and identify emerging patterns. Clinical **inference** is part of the clinical decision-making process that occurs before you determine what your patient's problems are. It is the interpretation of the cues ([Fig. 16.4](#)). For example, a patient crying is a cue that possibly infers fear, pain, or sadness. You ask the patient about any concerns and make known any nonverbal expressions that you notice in an effort to direct the patient to share his or her feelings. As you see patterns in a patient's signs and systems, you may confirm a pattern by adding more data or refute a pattern based on a different assessment finding. Eventually you will identify potential problems and nursing diagnoses from the patient's data (see [Chapter 17](#)).

Male patient in bed looks uncomfortable

Patient presents with discomfort in surgical area

- Cues**
- Lies still with arms along sides; tense
 - States has not turned for some time
 - Reports pain a 7 on a scale of 0 to 10

- Inferences**
- Pain is severe
 - Pain limits patient's ability to move and reposition self

FIG. 16.4 Use of cues to form inferences.

To assess a patient well you critically anticipate, which means that you continuously think about what the data tell you and decide whether more data are needed. Remember to always have supporting signs and symptoms before you make an inference. Your inferences direct you to further questions. Once you ask a patient a question or make an observation, patterns form, and the information branches to an additional series of questions or observations (Fig. 16.5). Knowing how to probe and frame questions is an assessment skill that grows with experience. You learn to decide which questions are relevant to a situation and attend to accurate data interpretation on the basis of inferences and experience.

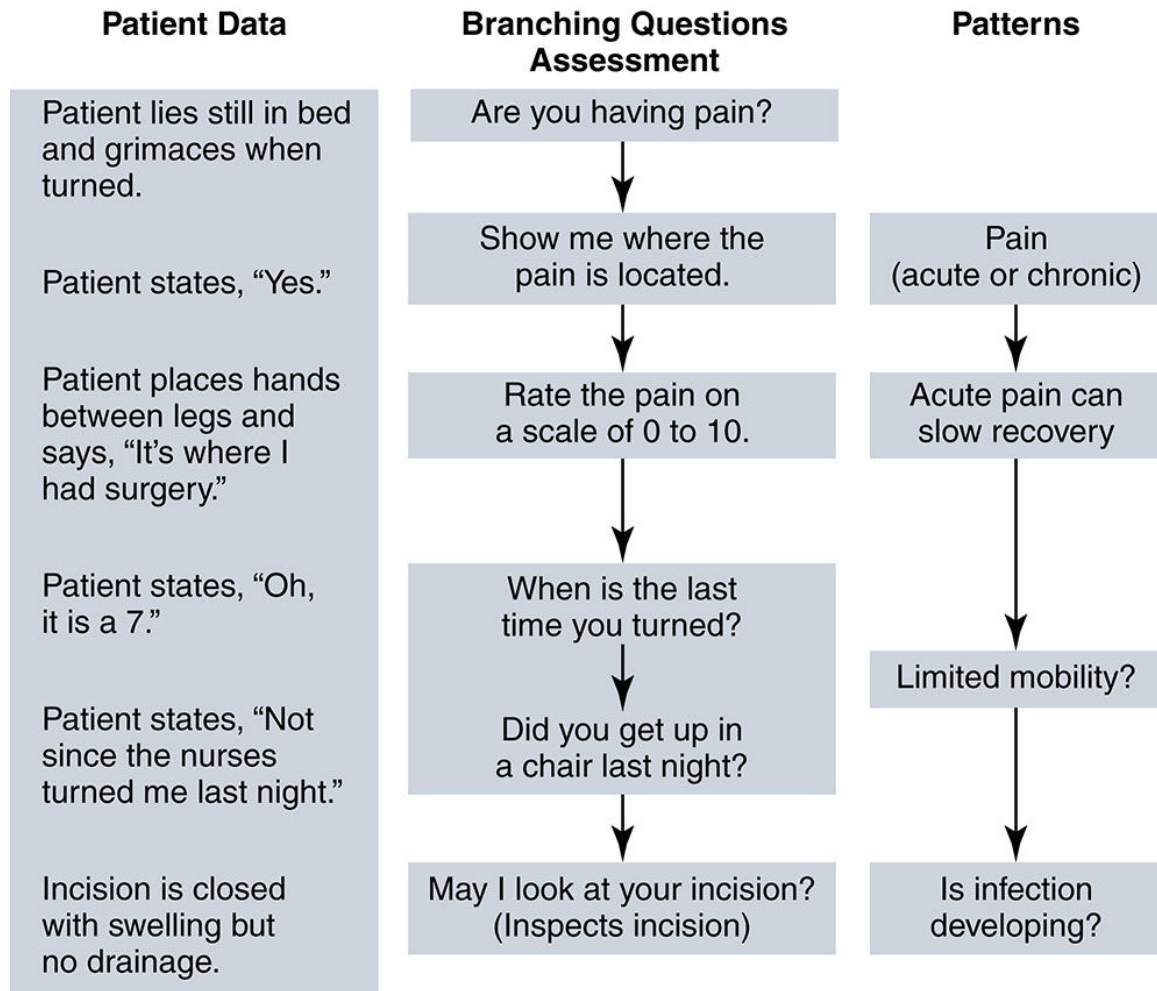

FIG. 16.5 Example of branching logic for selecting additional assessment questions.

Validation

Before you complete data interpretation, validate the information you have collected to avoid making incorrect inferences. **Validation** of assessment data is the comparison of data with another source to determine data accuracy. For example, you observe a patient crying and logically infer that it is related to hospitalization or a medical diagnosis. Making such an initial inference is not wrong, but problems result if you do not validate the inference with the patient. Instead ask, "I notice that you have been crying. Can you tell me about it?" By validating you discover the real reason for the patient's crying behavior. Ask patients to validate unclear information obtained during an interview and history. Validate findings from the physical examination and observation of patient behavior by comparing data in the medical record and consulting with

other nurses or health care team members. Often family or friends validate your assessment information.

Validation opens the door for gathering more assessment data because it involves clarifying vague or unclear data. Occasionally you need to reassess previously covered areas of the nursing history or gather further physical examination data. Continually analyze to make concise, accurate, and meaningful interpretations. Critical thinking applied to assessment enables you to fully understand a patient's problems, judge the extent of the problems carefully, and discover possible relationships among the problems.

Tonya has gathered assessment data to better understand Mr. Lawson's health care needs. The focus of her assessment switched from pain to that of physical characteristics of the surgical incision because the patient's condition changed. Her findings suggest that the patient is at risk for infection. She also assessed the patient's knowledge and learning needs so that she can adequately formulate a plan of care to prepare him for discharge. She applied critical thinking in her assessment as she considered the need to include Mr. Lawson's wife in the assessment. In addition, she reflected on her knowledge base concerning the care of patients following a colectomy and anticipated what she needed to assess to plan Mr. Lawson's discharge teaching. When Tonya saw the need for more information, she directed her assessment to learn more about Mr. Lawson's concerns about the success of his surgery and what to expect during recovery.

Concept Mapping

Most patients will present with more than one health problem. A concept map is a visual representation that allows you to graphically show the connections among a patient's many health problems. The concept map is a strategy that develops critical thinking skills by helping a learner understand the relationships that exist among patient problems (Bittencourt et al., 2013). Concept maps foster reflection and help students evaluate critical thinking patterns and see the reasons for nursing care. Your first step in concept mapping is to organize the assessment data you collect. Placing all of the cues together into the clusters that form patterns leads you to the next step of the nursing process, nursing diagnosis (see Chapter 17). Through concept mapping you obtain a holistic perspective of your patient's health care needs, which ultimately leads you to making

better clinical decisions. Fig. 16.6 shows the first step in a concept map that Tonya develops for Mr. Lawson as a result of her nursing assessment. Tonya begins to identify patterns reflecting Mr. Lawson's problems. As a result of the assessment, she has continuing discomfort over the incision, the risk for development of infection, and the need for instruction about surgical postoperative care. The next step (see Chapter 17) is to identify specific nursing diagnoses so you can plan appropriate nursing interventions.

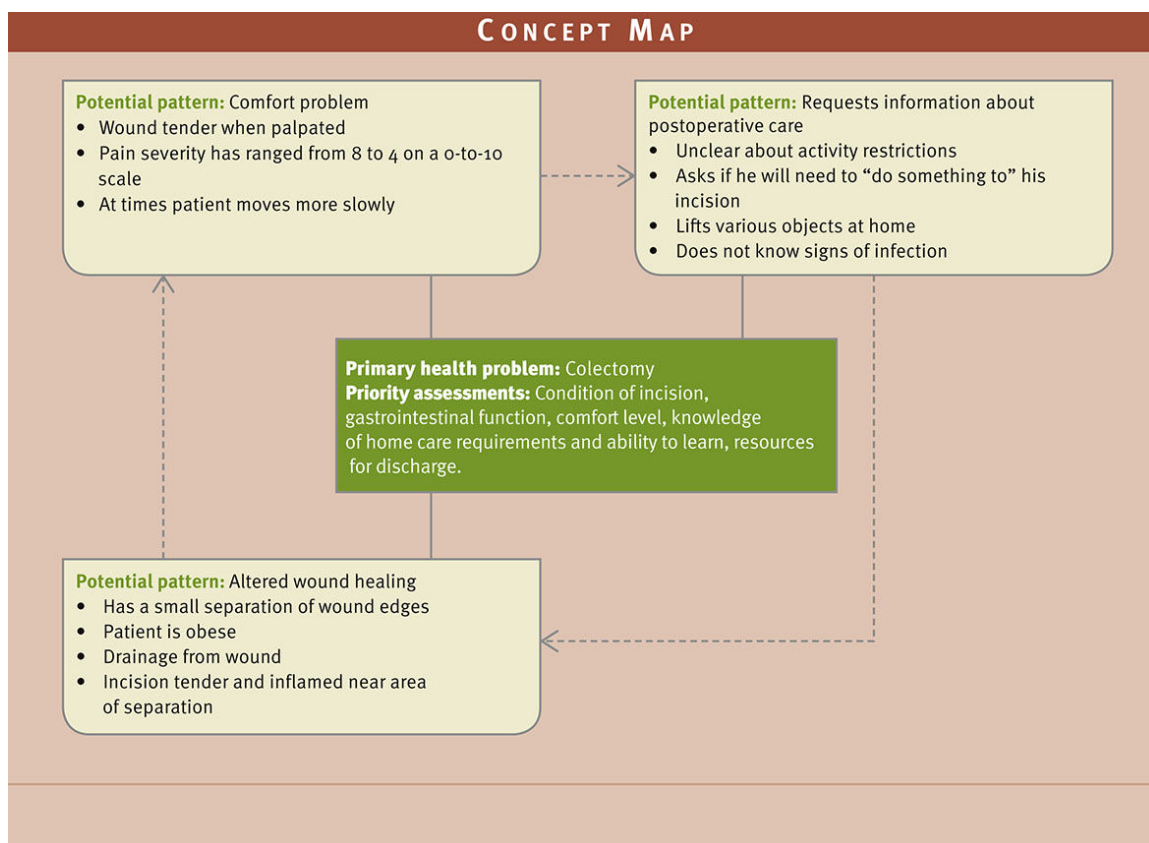

FIG. 16.6 Concept map for Mr. Lawson: Assessment data patterns.

Key Points

- Nursing assessment includes the collection of information from primary and all secondary sources and the interpretation and validation of the data collected.

- A patient-centered interview is utilized when you conduct a comprehensive nursing history about a patient.
- Periodic assessments collected during rounding or while you administer patient care include quick screenings to rule out or follow up on patient problems.
- A physical examination, conducted during a nursing history and at any time a patient presents a symptom, provides objective data about a patient's clinical status.
- A patient is the primary source of assessment information. Be sure to consider the setting for your assessment and your patient's condition.
- Family members, when appropriate, are useful data sources for confirming assessment findings or identifying important health patterns of the patient.
- A therapeutic nurse-patient relationship enables patients to tell their stories and enables nurses to understand patients and the experiences they express.
- Demonstrate courtesy by introducing yourself, ensuring confidentiality of information shared by the patient, and sitting down next to the patient. Avoid exiting the room too soon. Take time to be present during patient interactions.
- When making a connection with patients, begin with open-ended questions that encourage patients to tell their stories, and do not interrupt patients to allow them to fully describe their symptoms.
- During the working phase of a patient interview use open-ended questions, attentively listen to the patient's response, and summarize key issues to validate your understanding of the patient's story.

- To display professionalism during an interview, look at the patient, not the computer screen, and do not let the computer distract you during history taking.
- A nursing health history includes a patient's chief concern, expectations, and a thorough review of present illness and past health history.
- During the assessment process you determine which questions or measurements are appropriate based on what you initially learn from a patient. You identify cues and form patterns as you make inferences and interpret the clinical meaning of the data.

Reflective Learning

- Think about a patient you recently were assigned to care for during a clinical experience. How did you apply critical thinking when you engaged your patient in a patient-centered interview? How did you prepare in advance for the interview?
- Did you conduct the interview to understand the patient's health concerns "through the patient's eyes"? If yes, explain how you accomplished this. If no, explain why you had difficulty with this aspect of patient assessment. How would you approach this patient differently in the future to better understand the patient's concerns?
- What information did you gather from your patient's family and psychosocial history? How did this information guide your care?

Review Questions

1. A nurse completes the following steps during her shift of care. Which are the steps of nursing assessment? (Select all that apply.)

1. The review of patient data in the medical record
 2. Confirming a patient's self-report of abdominal pain by inspecting the abdomen
 3. Reporting results of an ongoing assessment to a nurse working the next scheduled shift
 4. Analyzing a set of signs revealing lower leg weakness and unsteady gait with a pattern of mobility alteration
 5. Conducting an interview of a family caregiver
2. Match the assessment activity on the left with the type of assessment on the right.

<ol style="list-style-type: none"> 1. Assessment conducted at beginning of a nurse's shift 2. Review of a patient's chief complaint 3. Completion of admitting history at time of patient admission to a hospital 4. Completion of the Long Term Care Minimum Data Set during an elderly patient admission to a nursing home 	<ol style="list-style-type: none"> A. Problem focused B. Comprehensive
--	--

3. A nurse initiates a brief interview with a patient who has come to the medical clinic because of self-reported hoarseness, sore throat, and chest congestion. The nurse observes that the patient has a slumped posture and is using intercostal muscles to breathe. The nurse auscultates the patient's lungs and hears crackles in the left lower lobe. The patient's respiratory rate is 20 per minute compared with an average of 16 per minute during previous clinic visits. The patient tells the nurse, "It is hard for me to get a breath." Which of the following data sets are examples of subjective data? (Select all that apply.)
1. Heart rate of 20 per minute and chest congestion
 2. Lung sounds revealing crackles and use of intercostal muscles to breathe
 3. Patient statement, "It's hard for me to get a breath"
 4. Slumped posture and previous respiratory rate of 16 per minute
 5. Patient report of sore throat and hoarseness

4. The nurse asks a patient the following series of questions:
“Describe for me how much you exercise each day.” “How do you tolerate the exercise?” “Is the amount of exercise you get each day the same, less, or more than what you did a year ago?”
This series of questions would likely occur during which phase of a patient-centered interview?
 1. Orientation
 2. Working phase
 3. Data interpretation
 4. Termination
5. A young male patient enters the emergency department with fever and signs of a possible sexually transmitted infection. The nurse enters the patient’s cubicle and begins to enter a history on the computer screen. Before beginning the nurse introduces himself and tells the patient all information will be held confidentially. The nurse starts data collection by establishing eye contact with the patient and then looks at the computer prompts to select a series of questions. As the nurse fills out questions on the computer, the patient asks a question about his treatment. The nurse states, “Let me get through these questions first.” Which action interferes with the nurse’s ability to use connection as a communication skill.
 1. Introducing self to patient
 2. Using the computer as a prompt for questions
 3. Making the nurse’s questions a priority
 4. Assuring the patient all information is confidential
6. A nurse observes a patient walking down the hall with a shuffling gait. When the patient returns to bed, the nurse checks the strength in both of the patient’s legs. The nurse applies the information gained to suspect that the patient has a mobility problem. This conclusion is an example of:

1. Reflection.
 2. Clinical inference.
 3. Cue.
 4. Validation.
7. Place the following steps of the assessment process in the correct order.
1. Compare data with another source to determine data accuracy.
 2. As a pattern forms, probe and frame further questions.
 3. Interview a patient, observe behavior, and gather physical assessment findings.
 4. Cluster cues that relate together, make inferences, and identify emerging patterns.
 5. Differentiate important data from the total data you collect.
8. In preparing to collect a nursing history for a patient admitted for elective surgery, which of the following data are part of the review of present illness in the nursing health history?
1. Current medications
 2. Patient expectations of planned surgery
 3. Review of patient's family support system
 4. History of allergies
 5. Patient's explanation for what might be the cause of symptoms that require surgery
9. A nurse is conducting a patient-centered interview. Place the statements from the interview in the correct order, beginning with the first statement a nurse would ask.
1. "You say you've lost weight. Tell me how much weight you've lost in the past month."
 2. "My name is Terry. I'll be the nurse taking care of you today."

3. "I have no further questions. Is there anything else you wish to ask me?"
 4. "Tell me what brought you to the hospital."
 5. "So, to summarize, you've lost about 6 pounds in the past month, and your appetite has been poor—correct?"
10. Which of the following approaches are recommended when gathering assessment data from an 82-year-old male patient entering a primary care clinic for the first time? (Select all that apply.)
1. Recognize normal changes associated with aging.
 2. Avoid direct eye contact.
 3. Lean forward and smile as you pose questions.
 4. Allow for pauses as patient tells his story.
 5. Use the list of questions from the clinic assessment form to complete all data.

Answers: 1. 1, 2, 4, 5; 2. 1A, 2A, 3B, 4B; 3. 3, 5; 4. 2; 5. 3; 6. 2; 7. 3, 5, 4, 2, 1; 8. 5; 9. 2, 4, 1, 5, 3; 10. 1, 3, 4.

Nursing Diagnosis

OBJECTIVES

- Compare a nursing diagnosis with a medical diagnosis and a collaborative problem.
- Discuss the importance of having a standardized language of nursing diagnoses.
- Describe the diagnostic reasoning process.
- Describe components of a nursing diagnostic statement.
- Explain the difference between finding data patterns and data interpretation.
- Form a nursing diagnostic statement correctly.
- Identify sources of nursing diagnostic errors.

KEY TERMS

Collaborative problem, p. 228

Data cluster, p. 230

International Classification for Nursing Practice (ICNP®), p. 229

Medical diagnosis, p. 227

NANDA International (NANDA-I), p. 229

Nursing diagnosis, p. 228

Risk diagnosis, p. 229

Nurses continuously collect assessment data. Data collection begins when a nurse cares for a patient the first time, and it continues every time the nurse cares for that patient. Other health care providers also collect data when caring for the patient. All members of the health care team need to share and review the data they collect to provide safe and effective patient care. The nurse constantly observes, interacts, and applies physical examination techniques ([Chapter 30](#)) to gather information about a patient's condition to identify

accurate and relevant health problems. The American Nurses Association defines nursing as “the protection, promotion, and optimization of health and abilities, prevention of illness and injury, alleviation of suffering through the diagnosis and treatment of human response, and advocacy in the care of individuals, families, communities, and populations” (ANA, 2015). A key word in this definition is *diagnosis*. A nursing diagnosis is made when a nurse identifies a health-related problem or the potential to develop a problem based on patient data. Unless a nurse correctly identifies or diagnoses the nature of a patient’s illness or health condition, a patient’s real problems will remain unidentified and untreated. While gathering information about a patient, a nurse is constantly sorting data to determine what the data mean. What are the patterns of data that ultimately point to a clear problem or phenomenon? Nursing diagnosis is the second step of the nursing process. Nurses deliberately use critical thinking to make nursing diagnoses that accurately identify a patient’s responses to illness.

Types of Diagnoses

When making a diagnosis, a clear label or term that is familiar to all those involved in a patient's care is necessary to understand a patient's needs. For example, the terms *anger* or *impaired breathing* are terms that will prompt nurses to consider similar problem areas: emotional and behavioral versus respiratory or ventilatory. Using standardized terminology is essential for diagnostic clarity and effective team communication. Standard nursing terminology allows nurses to formulate nursing diagnoses with associated interventions and to assess the outcomes of nursing care (Mynaříková and Žiaková, 2014). Using nursing diagnosis in practice is supported by health care technologies. For example, it is critical that electronic health records contain standard terminologies that nurses, health care providers, and others can use to communicate a patient's condition and the impact of his or her care to the entire interprofessional team. Within nursing practice there are three types of diagnoses or problem statements.

Medical Diagnoses

The use of medical diagnosis began in ancient China, Egypt, and Greece. Practitioners used diagnoses to describe the symptoms for many illnesses thousands of years ago. When physicians or certified advanced practice nurses identify and confirm common medical diagnoses such as rheumatoid arthritis or diabetes mellitus today, they know the meaning of the diagnoses, the implications, and the standard approaches for treatment. A **medical diagnosis** is the identification of a disease condition based on a specific evaluation of physical signs and symptoms, a patient's medical history, and the results of diagnostic tests and procedures (Table 17.1). Physicians and advanced practice nurses, such as nurse practitioners and midwives, are licensed to treat diseases and conditions described in medical diagnostic statements. For example, in the case of diabetes, health care practitioners will order various medications and tests such as a hemoglobin A1c (HbA1c) to manage a patient's blood glucose. Medical diagnosis is the language medical practitioners use to communicate a patient's health problem and associated treatments and response.

TABLE 17.1**Example of a Diagnosis With Diagnostic and Assessment Findings**

Medical Diagnosis	Diagnostic Findings	Nursing Diagnostic Label	Assessment Findings
Pneumonia	Abnormal lung sounds: crackles, rales Chest x-ray Chest pain with productive cough Confusion Shortness of breath Positive blood culture for pneumococcus	Impaired Respiratory System—impaired gas exchange (ICNP, 2017)	Irregular respirations Tachycardia Orthopnea Hypercapnia Diaphoresis Productive cough Restlessness Confusion Dyspnea

Nursing Diagnosis

A **nursing diagnosis** is a clinical judgment made by a nurse to describe a patient's response or vulnerability to health conditions or life events that a nurse is licensed and competent to treat (NANDA-I, 2018b). It is a diagnostic label that classifies an individual's, family's, or community's response to illness so that all nurses understand a specific patient's health care needs. Nursing prescribes for and treats client and group *responses* to situations that include five categories (Carpenito, 2017): pathophysiological (e.g., myocardial infarction, borderline personality), treatment-related (e.g., anticoagulant therapy, dialysis), personal (e.g., dying, divorce), environmental (e.g., overcrowded school, safety barriers in home), and maturational (e.g., peer pressure, parenthood). Just as health care providers make a medical diagnosis, a nurse identifies a nursing diagnosis by recognizing patterns of assessment data associated with a specific problem (see Table 17.1). Nurses cannot treat medical diagnoses; they cannot order an HgA1c or insulin. Nurses instead treat patients' responses to health conditions. A patient with rheumatoid arthritis will have pain and mobility alterations. Nurses provide interventions to minimize and control pain (e.g., application of heat or cold to an injured area) and improve mobility (e.g., implement early mobility protocols). Nursing diagnoses such as *Acute Pain* or *Activity Intolerance* provide clear direction as to the type of nursing interventions (see Chapter 19) nurses are licensed to provide independently.

Collaborative Problems

A **collaborative problem** is a problem that requires both medicine and nursing interventions to treat (Carpenito, 2017). Nurses practice with other health care professions to manage certain types of collaborative problems using physician-prescribed and nursing-prescribed interventions to minimize complications of

the events (Carpenito, 2017). For example, in the case of a patient who enters a clinic with an infected leg wound, the patient’s health care provider prescribes antibiotics, the nurse monitors for fever and provides wound care, a dietitian recommends an appropriate therapeutic diet high in protein, and the patient collaborates in learning good hand hygiene and wound care practices. In the case of a patient who is paralyzed from a spinal cord injury, a nurse uses proper positioning and transfer techniques for patient safety while a physical therapist recommends exercises for the patient’s extremities.

All physiological complications are not collaborative problems. If a nurse can prevent the onset of a complication or provide the primary treatment for it, then the diagnosis is a nursing diagnosis (Carpenito, 2017). For example:

Nurses Can Prevent	Nursing Diagnosis (ICNP, 2017)
Pressure injuries Thrombophlebitis Aspiration	Risk for Pressure Ulcer Impaired Circulatory System Function Risk for Aspiration
Nurses Can Treat	Nursing Diagnosis
Stage I or II pressure injuries Swallowing problems	Impaired Tissue Integrity Impaired Swallowing
Nurses Cannot Prevent	Collaborative Problems
Seizures Bleeding	Seizures Bleeding

Interprofessional collaboration in managing patient problems is based on the assumption that when health care providers from various disciplines and patients communicate and consider one another’s unique perspectives, they will better manage the multiple factors that influence the health of individuals, families, and communities (Sullivan et al., 2015).

REFLECT NOW

Review the electronic health record of a patient to whom you are assigned to care for. Look at the list of all health problems identified. Sort those problem out by nursing diagnoses, medical diagnoses, and collaborative problems.

Terminologies for Nursing Diagnoses

Nurses work in a variety of settings, even within a single health care institution such as a hospital. Therefore, in order for you to be able to communicate knowledge in a meaningful way that can be shared across all disciplines and care settings, common terminologies are necessary. Using standard terms when communicating nursing diagnoses and the associated interventions and patient outcomes resulting from nursing care contributes to effective communication. Health care communicated in unspecific, unclear wording leads to inconsistencies due to differences in naming patients' care needs (nursing diagnoses), nursing interventions, and treatment goals among providers, teams, or facilities (Rabelo-Silva et al., 2016). Standard terminology is a key component of electronic health record systems (EHRs) (see Chapter 26). Common terminologies in EHRs used in the United States include the **NANDA International (NANDA-I) (formerly known as the North American Nursing Diagnosis Association)**, Nursing Intervention Classification (NIC), Nursing Outcome Classification (NOC), Omaha System, and the SNOMED CT for clinical terminology (Lundberg et al., 2008). A standard terminology system used across the world is the **International Classification for Nursing Practice (ICNP®)**, which was developed by The **International Council of Nurses (ICN, 2017)**. The ICN is a federation of more than 130 national nurses associations (NNAs), representing more than 20 million nurses worldwide (ICN, 2017).

It is common for a health care institution to work with vendors of EHRs to create a standard language or set of terminologies unique to the institution. At times these terminologies are based on medical diagnoses only and the opinions or expertise of the institution's health care staff. Nursing diagnosis terminology may or may not be integrated. When it is not integrated, it is up to an individual nurse to specifically identify a patient's relevant nursing diagnoses as they pertain to the patient's health condition.

The nursing diagnosis classification and taxonomy system of NANDA-I was developed in 1982, when nurse educators recognized that assessment data needed to be analyzed and clustered into patterns and interpreted before nurses could make accurate nursing diagnoses (NANDA-I, 2018a). Soon diagnosis became part of the five-step nursing process. The NANDA-I diagnostic classification system has grown to currently include 244 diagnoses (NANDA-I, 2018b). You cannot plan and intervene correctly for patients if you do not know the health problems or conditions you are dealing with. The NANDA-I terminology is one system that provides standard, formal diagnostic statements (including definitions, defining characteristics, and related or risk factors). The NANDA-I system aims to achieve the following outcomes (NANDA-I, 2018b):

- Provide a precise definition of a patient's human responses to health problems and life processes.
- Develop, refine, and disseminate evidence-based terminology representing clinical judgments by professional nurses.
- Allow nurses to communicate (e.g., verbally and in writing) what to do among themselves and with other health care professionals and the public.
- Foster the development of nursing knowledge through research.
- Contribute to the development of informatics and information standards.
- Document care for reimbursement of nursing services.

Many of these same outcomes describe the purposes of the ICNP® system. The ICN developed the International Classification for Nursing Practice (ICNP®) as a unified nursing language system to support standardized nursing documentation at the patient's bedside or point of care (ICN, 2017). It is a wide-ranging, understandable reference terminology that can adapt to multiple purposes (e.g., documentation, research categories, practice guidelines) in different countries and that serves as a primary resource to describe nursing practices (Rabelo-Silva et al., 2016). The ICNP is a classification of nursing phenomena (diagnoses), nursing actions or interventions, and nursing outcomes that describes nursing practice. The ICNP® system currently uses a model that has 7 axes (Box 17.1). With multi-axial terminology, terms from different axes are combined to create a concept. For example, the term "pain" (from the ICNP® Focus of Nursing Practice Axis) can be combined with "chronic" (from the ICNP® Duration Axis) to create the diagnosis "chronic pain." Nurses and other hospital staff can use the data-based information from ICNP® for planning and managing nursing care, financial forecasting, analysis of patient outcomes, and health policy development (ICN, 2017).

Box 17.1 ICNP 7 Axes With Definitions

- Focus: The area of attention that is relevant to nursing (e.g., pain, homelessness, elimination, life expectancy, knowledge).
- Judgment: Clinical opinion or determination related to the focus of nursing practice (e.g., decreasing level, risk, enhanced, interrupted, abnormal).
- Client: Subject to whom a diagnosis refers and who is the recipient of an intervention (e.g., newborn, caregiver, family, community).

- Action: An intentional process applied to or performed by a client (e.g., educating, changing, administering, monitoring).
- Means: A manner or method of accomplishing an intervention (e.g., bandage, bladder-training technique)
- Location: Anatomical and spatial orientation of a diagnosis or intervention (e.g., posterior, abdomen, school, community health center).
- Time: The point, period, instance, interval, or duration of an occurrence (e.g., admission, childbirth, chronic).

Adapted from Garcia TR, Nobrega MML: The International Classification for Nursing Practice: participation of Brazilian nurses in the project of the International Council of Nurses, *Acta Paul Enferm* 22(Especial - 70 Anos):875-9, 2009.

In addition to improving communication among health care providers, using standard nursing terminology creates a scientific knowledge base for nursing. Advances in the discipline of nursing involve the development of interconnections among three elements: theory, research, and nursing practice. The use of a clear, well-established terminology system such as nursing diagnoses forms the basis of classification systems in nursing care. Such classification systems help nurses recognize phenomena, make correct decisions, and perform research activities in clinical settings that build new knowledge within the profession of nursing (Mynaříková and Žiaková, 2014).

There are similarities in the language of NANDA-I and the ICNP. The ICNP taxonomy or model refers to nursing diagnoses, while NANDA-I officially refers to diagnostic labels. The two classification systems have many of the same labels for certain diagnoses, while there is also much variation in labels describing similar responses to health conditions.

Building Competency in Teamwork and Collaboration

A nurse is caring for a 73-year-old patient who fell while in the hospital. The patient has cardiac and respiratory health problems that affect her ability to tolerate exercise. The nurse is attending a discharge planning conference with the physical therapist and social worker. Describe how this nurse can enhance interprofessional collaboration with the other health care providers in the use of nursing diagnosis.

Types of Nursing Diagnostic Statements

NANDA-I categorizes nursing diagnoses into three types: problem-focused, **risk diagnosis**, and health promotion (NANDA-I, 2018b). The ICNP® categorizes diagnoses as positive or negative nursing diagnoses with associated outcomes. The focus of diagnoses from both classifications is similar. Problem-focused nursing diagnoses or negative diagnoses identify an undesirable human response to existing problems or concerns of a patient. Examples include *Acute Pain* or *Urinary Retention* (NANDA-I, 2018b) or *Acute Pain* and *Impaired Urination* (ICN, 2017). Risk nursing diagnoses are diagnoses that apply when there is an increased potential or vulnerability for a patient to develop a problem or complication (NANDA-I, 2018b). Examples include *Risk for Fall* (ICN, 2017) and *Risk for Unstable Blood Pressure* (NANDA-I, 2018b). Health promotion nursing diagnoses and positive diagnoses identify the desire or motivation to improve health status through a positive behavioral change. Examples include *Readiness for Enhanced Relationship* and *Readiness for Enhanced Power* (NANDA-I, 2018b) and *Positive Family Support* and *Hope* (ICN, 2017). Although many nursing diagnoses are used to identify problems being experienced by individual patients, you will apply some nursing diagnoses to families, groups of individuals, and communities.

Critical Thinking and the Nursing Diagnostic Process

Use the nursing diagnostic process to accurately identify a patient’s nursing diagnoses. Critical thinking (see [Chapter 15](#)), with the application of knowledge, experience, critical thinking attitudes, and intellectual standards during the collection of a comprehensive assessment database about a patient, will improve diagnostic accuracy ([Fig. 17.1](#)). When practicing nursing, it is important for you to know the nursing diagnosis classification system used within your school and clinical practice sites. You will also need to become familiar with the definitions, related or causative factors, and the defining characteristics or assessment findings that apply to each diagnosis. It is impossible to memorize the information needed for every type of nursing diagnosis, no matter what system you use. However, you need to know how to access this information easily within the agency in which you work. Sources of information about nursing diagnoses include faculty, advanced practice nurses, clinical staff, documentation systems, and practice guidelines.

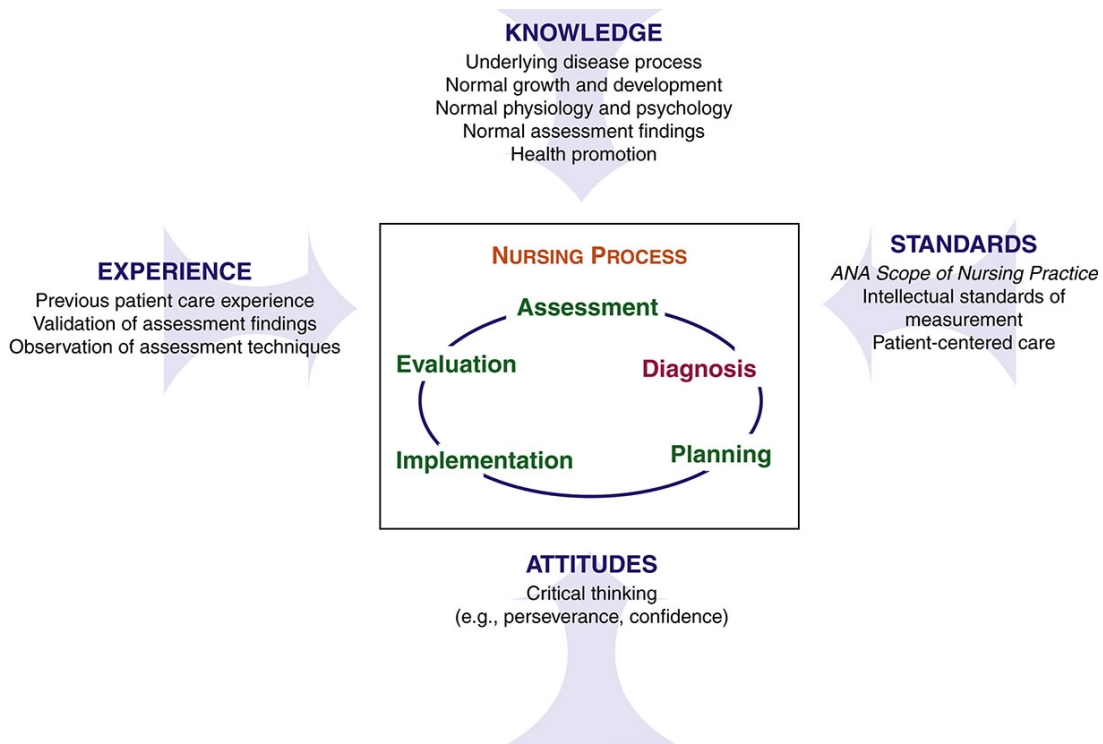

FIG. 17.1 Critical thinking and the nursing diagnostic process.

Use patient assessment data during the diagnostic reasoning process to logically explain a clinical judgment, in this case a nursing diagnosis. You

gather a comprehensive set of data, validate your information, and add additional data if you find information is lacking. You then interpret the data by identifying clusters or patterns that lead to identification of nursing diagnoses and other problems. The diagnostic process flows from the assessment process and includes decision-making steps ([Fig. 17.2](#)).

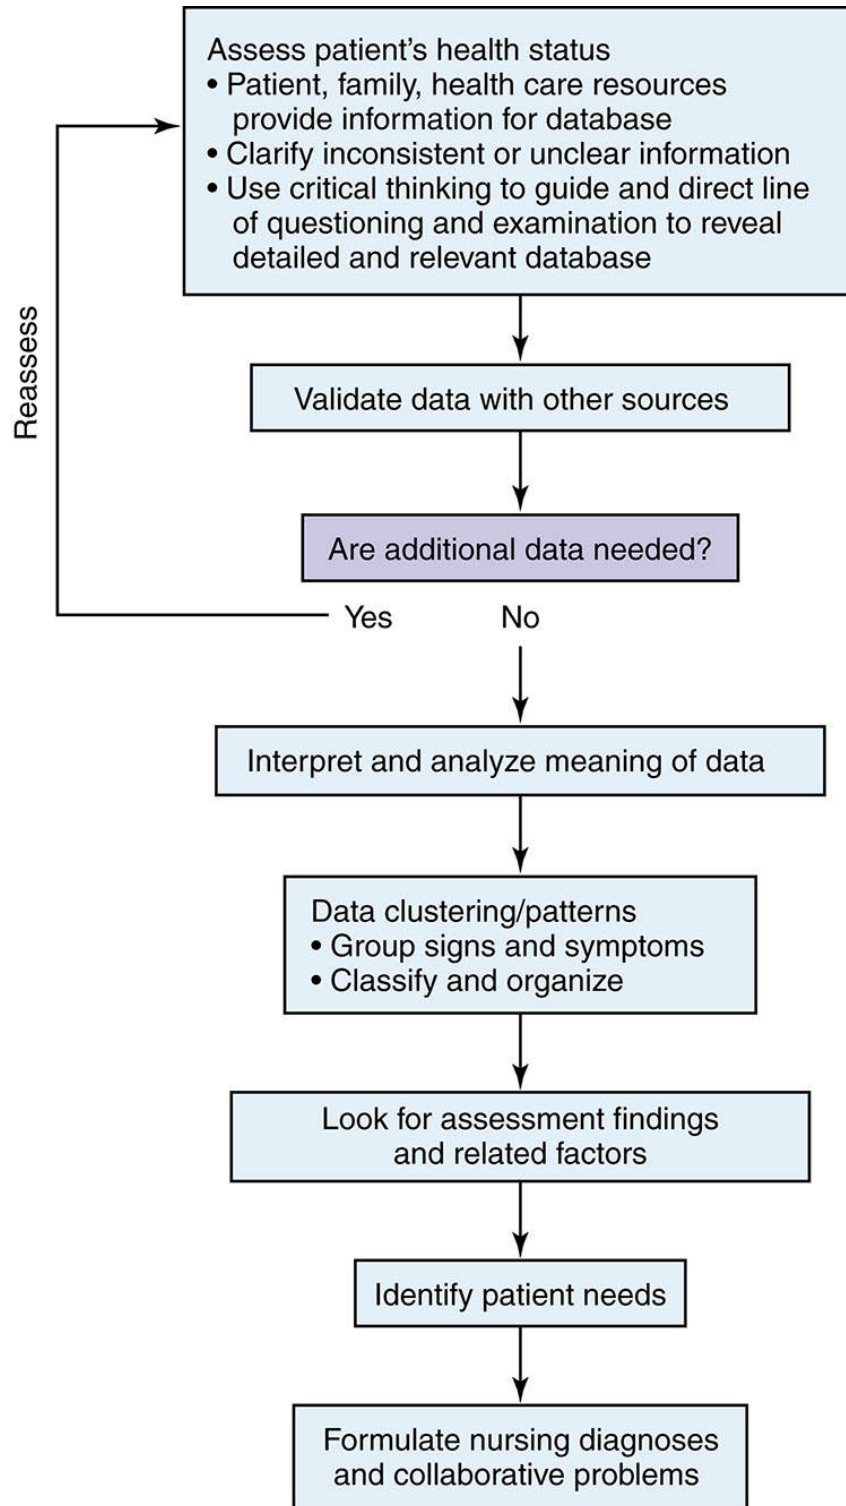

FIG. 17.2 Nursing diagnostic process.

Data Clustering and Finding Patterns

Your review and analysis of assessment data involve critically organizing all data elements about a patient into meaningful patterns, also called **data clusters** or sets of assessment findings/defining characteristics. A set of assessment findings is a group of data elements, the signs or symptoms gathered during assessment. Each data element is an objective or subjective sign, symptom, or risk factor that leads you into making a diagnostic conclusion (see [Chapter 16](#)). As you analyze data, you begin to see data elements that offer cues to a type of health problem. For example, shortness of breath, walking only 100 feet before becoming breathless, and an increased respiratory rate suggest a breathing problem pattern. A patient who reports having no immediate family, does not initiate conversation, and who just lost his vision shows a coping problem pattern. It is these patterns or data clusters that begin to shape a more formal label or description.

While looking for a pattern, compare a patient's data with information that is consistent with normal, healthy patterns. Use accepted norms as the basis for comparison and judgment, norms such as laboratory test values, professional standards, and normal physiological limits. Also determine whether the grouped signs and symptoms are expected for a patient (e.g., consider current condition and history) and whether they are within the range of healthy responses. Separate out data that are not within healthy norms to allow you to identify a pattern correctly.

During assessment you collect individual data points either intentionally or unintentionally. An intentional assessment includes the deliberate collection of data through physical examination or interviewing during a health history. Unintentional assessment is noticing data points that are important without planning to collect them ([NANDA-I, 2018b](#)). For example, an unintentional data point is seeing a patient grimace and hold a body part while you turn and reposition the patient in bed.

Finding a data cluster helps you think less about individual data points and instead focus on pattern recognition. Your ability to recognize a pattern or cluster comes with clinical experience and intentional practice. At first you will not notice some of the subtleties you find when observing or examining patients. For example, the first time you look at a patient's surgical wound you will notice the length of an incision and general color of the surrounding skin, but you might not notice an individual suture that has loosened or minor swelling at the end of the incision.

While clustering data you will find that some data are descriptive (e.g., patient's age) and do not necessarily fit a pattern with other data. You also will find data that relate to the cause or nature of a patient's problem (e.g., history of stroke, poor adherence to therapy). A specific assessment finding may apply to one or more patterns of data (e.g., moving a limb slowly can reveal a mobility problem, as well as a problem with comfort). As you recognize data elements, you will cluster or group them together in patterns in a logical way

that during interpretation will reveal the nursing diagnoses that describe how a patient is responding to a health condition or life process.

When assessment data reveal risk factors (i.e., the factors that increase a patient's vulnerability to an unhealthy event), you will recognize patterns, compare the patterns with expected data for a risk diagnosis, and then select the correct risk nursing diagnosis.

During her assessment in [Chapter 16](#) Tonya gathered information suggesting that Mr. Lawson possibly has several health problems. The data about Mr. Lawson are cues that form patterns in three areas: comfort, requesting information about postoperative care for impending discharge, and the potential for infection at his wound site. Selecting specific diagnoses for these problem areas will allow Tonya to develop a relevant and appropriate plan of care.

Data Interpretation

Data interpretation involves placing a label on your data pattern or cluster to clearly identify a patient's response to health problems. Selecting a diagnosis cannot be casual or simply intuitive. Critical thinking is necessary. Your interpretation of data clusters or patterns leads to the selection of various nursing diagnoses that apply to your patient. It is important to compare the data in a cluster with the data standards for a diagnosis to come to a reasoned conclusion about a patient's response to a health problem.

In the case of the NANDA-I classification, the standards are the defining characteristics or risk factors ([NANDA-I, 2018b](#)) used to form a diagnosis. When ICNP® is used as the diagnosis system, the institution where you work will have set standards for the assessment findings and risk factors that form a pattern for a nursing diagnosis ([Fig. 17.3](#)). Nurses who use ICNP® in their care settings have contributed to the development of clinically relevant sets of diagnosis, outcome, and intervention statements for a variety of health priorities and delivery settings ([Coenen et al., 2012](#)). Users of ICNP have created catalogs of nursing data subsets for specified health phenomena (nursing diagnoses such as pain), diseases (e.g., HIV/AIDS, depression), care specialties (e.g., palliative care), and care settings (e.g., neonatal nursery). These catalogs are then used to build health information systems ([Rabelo-Silva et al., 2016](#)).

FIG. 17.3 Comparing assessment data with standards.

Regardless of the diagnostic system you use, you compare your data with the assessment findings standard for select nursing diagnoses to select the specific diagnosis that fits your patient. The recognition of data in a logical cluster or pattern reveals the nursing diagnoses, how a patient is responding to a health condition or life process.

*Tonya clusters the data she has learned from Mr. Lawson, analyzes the data, and recognizes patterns of a knowledge problem. As Tonya considers Mr. Lawson's request for information, there are different nursing diagnoses for problems related to knowledge, including **Lack of Knowledge, Readiness for Enhanced Knowledge, and Adequate Knowledge**. Knowing the differences among these diagnoses and identifying which one applies comes from thoughtful interpretation of data. Lack of Knowledge suggests the patient has insufficient knowledge about a topic or area of interest. Readiness for Enhanced Knowledge or Adequate Knowledge infers that the individual has knowledge about a topic but needs further information to strengthen understanding. Tonya learns that this was Mr. Lawson's first experience with major surgery. His earlier questions about lifting and incision care suggest he has limited knowledge of postoperative care.*

Working with similar patients over a period of time helps you recognize patterns of assessment findings, but remember that each patient is unique and requires an individualized diagnostic approach. It can be a challenge to select a diagnosis when assessment findings for two different diagnoses are similar. For example, having insufficient knowledge to set up a medication schedule and being unable to identify the purpose of a medication might be considered assessment findings for the diagnoses of *Lack of Knowledge* (ICNP, 2017) or *Impaired Ability To Manage Medication Regime* (ICNP, 2017). Further exploration is needed to determine if the patient's problem is a knowledge issue only or if the patient has physical limitations that prevent him or her from following a medication schedule. Remember, as you gather data and see clusters or patterns, confirm your data with your source of standards for the diagnostic

system you use. It is critical to select the correct diagnosis for each of a patient's health problem responses.

Formulating the Diagnostic Statement

The way you phrase or word a nursing diagnostic statement affects how you communicate a patient's problems to other health care staff, which nursing interventions you choose, and how you evaluate patient outcomes. Clarity and precision are essential. When forming a diagnosis, each type of diagnosis has a different format. You write problem-focused nursing diagnostic statements with three parts: a diagnosis label, related factors, and major defining characteristics (NANDA-I, 2018b, p. 113). Risk nursing diagnoses have two segments: a diagnosis and the associated risk factors preceded by the phrase *as evidenced by* (NANDA-I, 2018b, p. 114). Health promotion nursing diagnoses also are written with only two sections: the diagnosis label and defining characteristics or assessment findings. Unless you use the correct format for a nursing diagnosis, the label for the diagnosis is meaningless and can easily be misunderstood (NANDA-I, 2018b).

The same formats can be used for ICNP® diagnoses as well. However, establishing a nursing diagnosis in the ICNP system requires that a clinical nurse select at least one term from two axes, namely, the axes "focus" and "judgment" (Rabelo-Silva et al., 2016). The focus is the area of relevance to nursing practice, e.g., physiological status or knowledge, whereas judgment is the clinical opinion related to the selected focus, e.g., decreasing level, risk, or enhanced. If you use ICNP® diagnoses, choose among the assessment findings that have formed a pattern for a specific diagnosis; then you can also include a related factor from the data gathered.

Components

Diagnostic Label or Diagnosis—A diagnostic label or diagnosis is the name of a nursing diagnosis approved by NANDA-I, ICNP®, or any other system used by your institution. The NANDA-I system offers definitions for each diagnosis to describe the characteristics of the human response identified.

Related Factors—A patient's response to a health problem is related to a set of conditions that caused or influenced the response. Related factors are etiologies, circumstances, facts, or influences that have a relationship with the nursing diagnosis (NANDA-I, 2018b).

*Tonya uses a critical thinking approach to identify the correct diagnosis that applies to Mr. Lawson's situation. She selects **Lack of Knowledge** as the nursing diagnosis because the patient has not undergone surgery and is*

*unfamiliar with postoperative routines. She further clarifies the statement as **Lack of Knowledge regarding postoperative care**. She then selects the related factor as the patient's inexperience. She words the formal diagnosis as **Lack of Knowledge regarding postoperative care related to inexperience with surgery**.*

A review of your assessment data will identify the related factor that applies to your patient. The value of having a related factor in the diagnostic statement is that it directs the type of interventions appropriate for a patient's care. For example, the nursing diagnosis *Body Weight Problem* from the ICNP® system is a clearer statement when written as *Body Weight Problem related to nausea and inadequate nutrient intake*. Appropriate interventions for this diagnosis include adjusting the type of diet (e.g., switching from solid foods to liquids), controlling the patient's mealtime environment by eliminating noxious odors, and administering prescribed antiemetics (collaborative intervention). In contrast, for the diagnosis *Body Weight Problem related to excess calorie intake and limited knowledge about healthy food choices*, the choice of interventions is very different (e.g., patient education regarding healthy diet, patient creating a weekly menu, adding an exercise plan).

Related factors for NANDA-I diagnoses have been categorized into four groups: pathophysiological (biological or psychological), treatment-related, situational (environmental or personal), and maturational (Carpenito, 2017). The ICNP® system has not defined sets of possible related factors for nursing diagnoses. A related factor is not intended as a cause-and-effect statement. It instead indicates that the etiology contributes to or is associated with the patient's diagnosis (Fig. 17.4). Risk diagnoses do not have related factors because you are identifying a vulnerability in a patient for a potential problem; a problem does not yet exist (NANDA-I, 2018b).

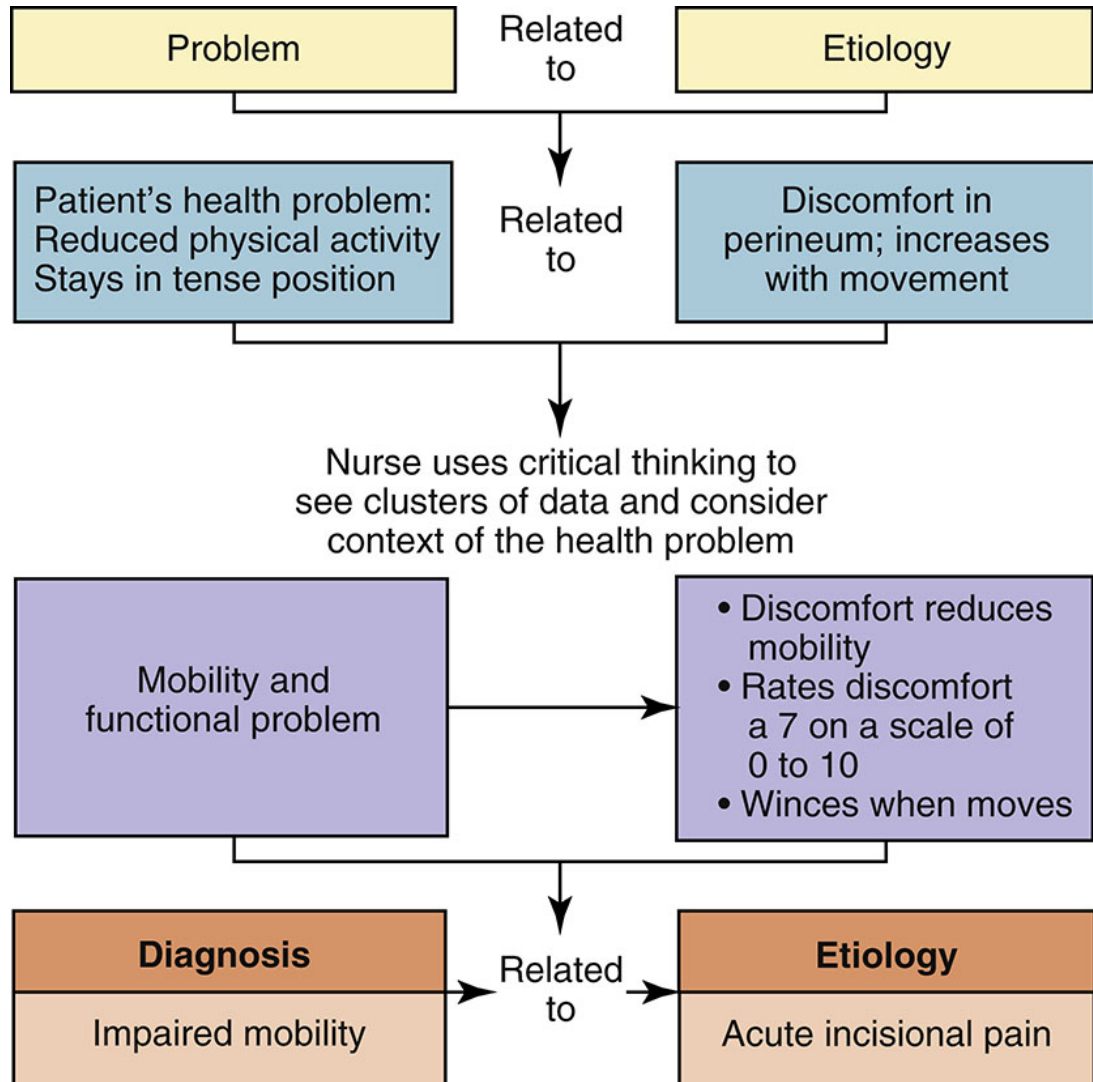

FIG. 17.4 Relationship between a diagnosis and related factor or etiology.

Major Assessment Findings—Further clarity is added to a diagnostic statement if you list major assessment findings or defining characteristics that were used to select a diagnosis. Highlighting a patient's major assessment findings offers guidelines for how you will evaluate the efficacy of nursing care. For example, in the diagnosis *Body Weight Problem: Underweight related to nausea and inadequate nutrient intake*, adding the phrase "as evidenced by 10-lb weight loss in 1 month and oral pain" offers more information to plan nursing care. Outcomes for a patient with this problem will include a specific targeted monthly weight gain and the patient's report of reduced or absent oral pain (see [Chapter 20](#)).

In the case of Mr. Lawson, Tonya offers further clarity to the patient's diagnosis, entering the final diagnostic statement in his plan of care, "Lack of Knowledge

regarding postoperative care related to inexperience with surgery as evidenced by frequent queries about postoperative routines.”

A complete, accurate diagnostic statement is necessary to deliver appropriate patient-centered care. [Table 17.2](#) shows further examples of the benefits of diagnostic clarity.

TABLE 17.2

Comparison of Interventions for Nursing Diagnoses With Different Related Factors

Nursing Diagnoses	Related Factor	Assessment Findings	Interventions
Patient A			
Anxiety	Uncertainty over surgery	Patient asks, “What type of pain will I have?” Restless and unable to sleep	Provide detailed instruction about surgery, recovery process, expected postoperative care. Plan formal time for patient to ask questions.
Impaired Mobility	Acute pain	Pain rated a 7 on scale of 1 to 10 Limits movement of right leg	Administer analgesic 30 minutes before planned exercise. Instruct patient on how to splint painful site during activity.
Patient B			
Anxiety	Loss of Job	Fired from position 1 month ago Primary source of family income	Consult with social worker to arrange for job counseling. Encourage health promotion activities (e.g., exercise, routine social activities).
Impaired Mobility	Musculoskeletal injury	Weakness in right leg Reduced extension in right leg	Perform active range-of-motion exercises to right leg every 2 hours. Instruct patient on use of 3-point crutch gait.

Diagnostic Validity

Before identifying a diagnosis, refer to the official ICNP[®] or NANDA-I list to ensure accuracy of the diagnostic statement. This is essential for clear communication with all health care team members. Standard diagnostic terminology must be used in any electronic health record using nursing diagnosis. Accurate nursing diagnoses are foundational to the development of an effective, personalized plan of care ([Yoost and Crawford, 2020](#)).

REFLECT NOW

Share a case summary of assessment findings from a patient you cared for with a student colleague. Compare the nursing diagnoses you make with those your colleague makes. Discuss the similarities and differences.

Use of Nursing Diagnosis in Practice

Patients usually present with a variety of health problems, and these problems can cause numerous types of human responses. For example, a medical diagnosis of cerebrovascular accident or stroke often results in altered human responses, including changes in mobility, speech, thought processes, behavioral coping, and family support. Therefore, a single nursing diagnosis such as altered mobility is insufficient to truly design a comprehensive patient-centered approach to care. The assessment findings you obtain will often apply to one or more nursing diagnoses. For example, the subjective finding of “Patient hesitant to perform range-of-motion exercises” may apply to the diagnoses of *Impaired Exercise Behaviour* and *Lack of Knowledge*. The patient’s hesitancy to perform the exercise may be due to the patient’s unwillingness to accept his health problem, or it may also be due to the patient’s insufficient knowledge to perform the exercise correctly. Thoroughly interpreting assessment findings leads to a broader picture of a patient’s various health responses. One way to communicate the relationship between a patient’s multiple nursing diagnoses is through Concept Mapping.

Concept Mapping

In [Chapter 16](#) you learned how concept mapping offers a graphic look at the connections among patients’ multiple health responses to problems. It is challenging to prioritize and focus on all of a patient’s nursing diagnoses. The challenge is compounded when you care for multiple patients in clinical practice. A concept map helps you critically think about a patient’s diagnoses and how they relate to one another. Many educators use concept mapping to help students develop critical thinking ([Aein and Aliakbari, 2017](#)). Concept mapping organizes and links data about a patient’s multiple diagnoses in a logical way. It graphically represents the connections among concepts (e.g., nursing diagnoses, assessment findings, and interventions) that relate to a central subject (the patient’s primary health problems). In [Fig. 17.5](#) the dotted lines between nursing diagnoses show that one diagnosis is directly related to another. Concept mapping develops skills that provide nurses with expertise in flexible, individualized, situation-specific problem solving for each patient ([Aein and Aliakbari, 2017](#)).

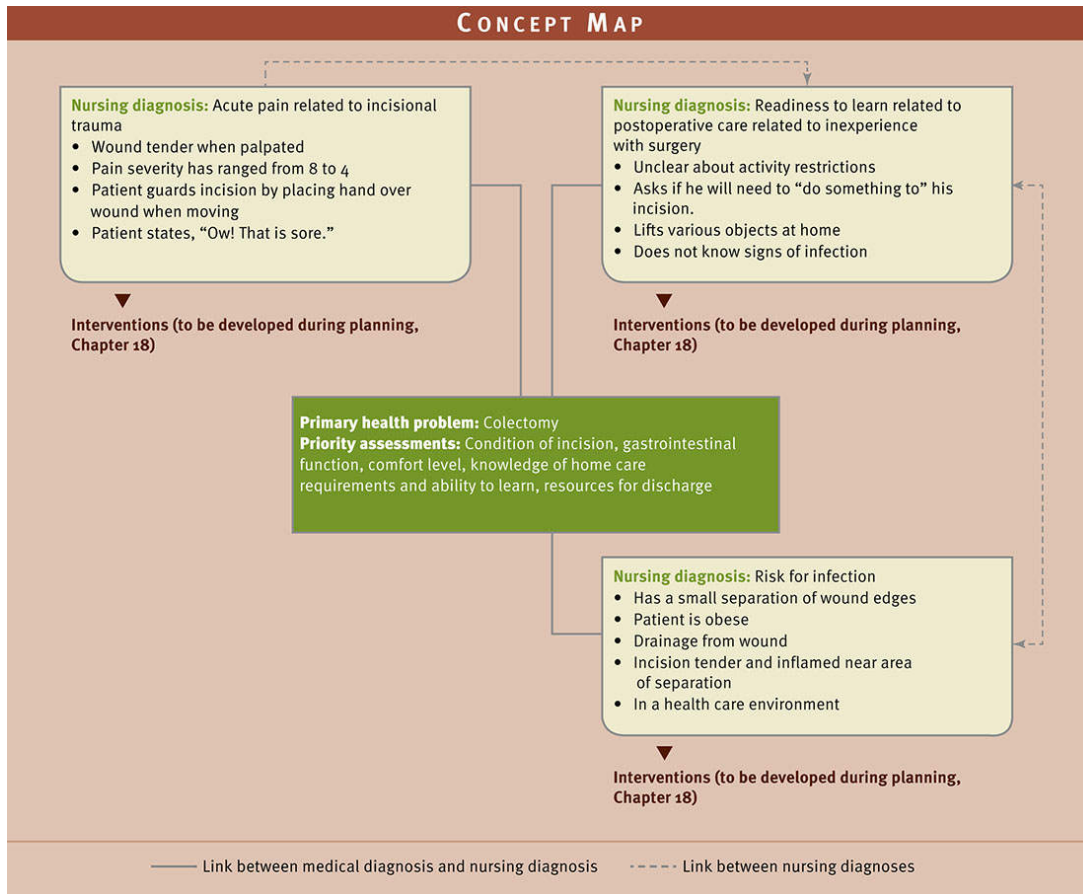

FIG. 17.5 Concept map for Mr. Lawson: Nursing diagnoses identified.

*In Fig. 17.5, the concept map for Mr. Lawson, three nursing diagnoses have been developed and linked together to communicate Mr. Lawson's health care needs. The diagnosis of **Acute Pain** has a direct impact on the patient's **Lack of Knowledge**, which will require Tonya and the other nurses to consider teaching approaches that take Mr. Lawson's comfort level into consideration (see [Chapter 18](#)). Pain reduces a patient's attentiveness. The patient's **Lack of Knowledge** affects his **Risk for Infection** because Mr. Lawson must understand wound care before he goes home. As Tonya reviews the concept map, she sees the interrelationships of his nursing diagnoses and ultimately the interventions that she includes in his plan of care.*

An advantage of a concept map is its central focus on a patient rather than on a disease or health alteration, even though the patient's health problems are central. This holistic focus encourages nurses to concentrate on patients' specific health problems and nursing diagnoses rather than using one approach for all patients with similar problems.

Cultural Relevance in Diagnostics

When you select nursing diagnoses, consider your patients' cultural diversity, including ethnicity, values, beliefs, language, and health practices (see [Chapter 9](#)). This includes knowing the cultural differences that affect how your patients define health and illness and their preferences or choices for treatment. For example, [Lai et al. \(2013\)](#) explored how nursing diagnoses affected the quality of professional nursing from the perspective of Taiwanese nurses. Their work found that certain diagnoses were difficult for nurses to apply considering the cultural beliefs of the traditional Chinese health care setting, which emphasizes holistic harmony and balance. It is important to know yourself, consider your patient's culture, and practice cultural competence to accurately identify a patient's health care problems and to provide patient-centered nursing care.

Consider the example of the ICNP® nursing diagnosis *Conflicting Caregiver Attitude*, where differences of opinion are found to exist between family caregivers of a patient near the end of life. It would be easy to apply your own cultural bias in selecting this diagnosis, depending on your beliefs, past experiences, and comfort in counseling caregivers about death. It would also be easy to apply the diagnosis inappropriately without considering the patient's and family members' values and beliefs. Attitudes and behaviors of families and care providers toward patients and their relationships with patients can affect patients' dignity significantly ([Guo and Jacelon, 2014](#)). The inappropriate selection of a nursing diagnosis based on your values or beliefs potentially results in the implementation of interventions that a patient or family caregiver is unlikely to accept. Consider asking these questions to make culturally competent nursing diagnoses:

- How has this health problem affected you and your family?
- What do you believe will help or fix the problem?
- What worries you the most about this problem?
- Which cultural practices do you observe to keep yourself and your family well?

When you ask questions such as these, you use a patient-centered approach that allows you to see a patient's health situation through his or her eyes. This is necessary to identify relevant assessment data pertaining to a patient's health problems.

Sources of Diagnostic Error

Errors occur in the nursing diagnostic process during data collection, analysis of data clusters or patterns, and interpretation in choosing a nursing diagnostic statement (Mynaříková and Žiaková, 2014). Accuracy is a critical thinking element for selection of a nursing diagnosis. Do not skip any of the steps in the nursing diagnostic process, and be sure you complete every step.

Errors in Data Collection

During assessment (see Chapter 16) be knowledgeable, thorough, and skillful. Avoid inaccurate or missing data. Be willing to confirm a finding with another nurse. If you do not think you have complete data, consider what other questions you might ask the patient or family. Was your physical examination thorough and relevant to the symptoms a patient reported? Be thorough as you collect data applicable to the patient's health problems. Validate that your measurable, objective physical findings support subjective data. For example, when a patient reports "difficulty breathing," you also listen to lung sounds, assess respiratory rate, and measure a patient's chest excursion (see Chapter 30). Current evidence shows that insufficient identification of defining characteristics/assessment findings or related factors is common when making diagnoses (Mynaříková and Žiaková, 2014).

Errors in Data Clustering

Errors occur if you cluster data prematurely, incorrectly, or not at all. Premature clustering occurs when you make a nursing diagnosis before grouping all patient data. For example, a patient reports having occasional incontinence and urinary frequency. You cluster the available data and begin to identify an alteration in urination. Incorrect clustering occurs when you try to make a diagnosis fit a limited set of signs and symptoms that you gather. In this example, further assessment reveals that the patient has incontinence in small volumes with coughing or exercise. The patient does not leak urine at nighttime. The complete data cluster helps you to focus more specifically on an incontinence problem. Before analyzing your assessment data to identify clusters or patterns, validate the accuracy and completeness of your data one more time. You can do this by reassessing for a particular symptom, confirming data from the health record, or consulting with another nurse. When you are unable to validate data, this is a warning that there may be an inaccurate match between clinical data elements and the nursing diagnosis you want to select.

Errors in Analysis and Interpretation of Data

During analysis and interpretation, be careful to consider any conflicting data elements and determine whether there are sufficient data to form a diagnosis. Remember, a single symptom is insufficient for selecting a nursing diagnosis. For example, a patient wincing may be responding to pain, nausea, or even fear, all valid nursing diagnoses.

In the example of the patient displaying incontinence symptoms of urinary frequency and occasional incontinence in small volumes following exercise and coughing, a review of assessment findings for associated urinary alteration diagnoses is necessary. The assessment findings identified for this patient best fit criteria for *Stress Incontinence of Urine*. The patient does not leak urine during nighttime or report a constant urge to void, so a nursing diagnosis of *Urge Incontinence of Urine* is probably inappropriate. You learn to sort out the data you have collected and match them with assessment findings standard to a diagnosis to select an appropriate nursing diagnosis. Interpretation is accurate only when you carefully review nursing diagnoses with similar assessment findings to choose the one that best fits your patient's condition.

Errors in a Diagnostic Statement

Clinical reasoning leads to an accurate nursing diagnosis, which eventually leads to individualized, specific, and effective nursing interventions. Successful selection of nursing interventions depends on having the correct related or etiologic factors or risk factors for a nursing diagnosis. An accurate diagnostic statement with relevant assessment findings guides you and the patient in the selection of appropriate patient outcomes. Unfortunately, research shows that nurses are not always methodical in the way they form nursing diagnoses (Box 17.2). You can reduce errors in diagnostic statements by selecting appropriate, concise, and precise language. Be sure that the etiology or related factor is within the scope of nursing practice to diagnose and treat. The following guidelines will assist you in reducing diagnostic errors.

Box 17.2 Evidence-Based Practice Sources of Error and Frequency of Nursing Diagnoses Used in Clinical Practice

PICOT Question: Among practicing nurses what is the level of accuracy in the making of nursing diagnostic statements?

Evidence Summary

A review of 39 studies conducted internationally examined the most frequently occurring mistakes in nursing diagnostics and the frequency of nursing diagnoses used in clinical practice (Mynaříková and Žiaková, 2014).

The literature review included formal studies as well as expert reviews and educational texts. The review found deficiencies in the formation of nursing diagnostic conclusions, including identification of diagnostic elements (e.g., defining characteristics or related factors). In addition, the researchers found that nursing diagnoses are very often determined based on irrelevant or invalid data (Mynaříková and Žiaková, 2014). Studies that examined documentation of nursing diagnoses in a wide variety of settings found that diagnoses pertaining to dysfunctional body functions were more commonly identified, whereas diagnoses from the psychosocial area are identified much less often. Because nurses commonly use the same nursing diagnoses for individual medical diagnoses or conditions, they may be less comfortable identifying mental, social, and spiritual diagnoses. For example, any time a patient has a hip replacement, nurses will identify acute pain and impaired mobility regardless of what other data may indicate.

Application to Nursing Practice

- Because accuracy in selecting nursing diagnoses involves critical thinking, take the time to analyze data carefully before forming a statement.
 - Avoid identifying irreversible related factors, which cannot be changed with nursing interventions.
 - Do not predefine a nursing diagnosis based on a patient's medical diagnosis. Base your diagnosis selection on complete patient-specific data.
-
- Identify a patient's response to a health problem, not a medical diagnosis (Carpenito, 2017). A medical diagnosis requires medical interventions; thus, it is inappropriate to include your patient's medical diagnosis in a nursing diagnostic statement. For example, instead of the diagnosis of hypertension, select the nursing diagnosis *Altered Blood Pressure* (ICN, 2017).
 - Identify a diagnostic statement rather than a symptom. Identify nursing diagnoses from a cluster of assessment findings and not just a single symptom. One assessment finding is insufficient for diagnosis identification. For example, dyspnea alone does not lead you to a diagnosis. A pattern of dyspnea, reduced chest excursion, and tachypnea are assessment findings for the diagnosis of *Impaired Breathing*.
 - Identify a related factor or risk factor treatable through nursing intervention. A diagnostic test or a chronic condition is not an etiology that a nursing intervention is able to treat. A patient with fractured ribs probably has pain when inhaling, impaired chest excursion, and slower, shallow respirations. An x-ray may show collapse of alveoli in

the affected area. The nursing diagnosis of “*Impaired Breathing* related to shallow respirations” is incorrect. There are no interventions that directly make respirations less shallow. The diagnosis of “*Impaired Breathing* related to chest pain from rib fracture evidenced by reduced excursion and dyspnea” is correct. Nursing interventions directed toward pain relief will lead to improved breathing.

- Identify a problem caused by the treatment or diagnostic study rather than the treatment or study itself. Patients experience many responses to diagnostic tests and medical treatments. These responses are the focus of nursing care. The patient who has chest pain and is scheduled for a cardiac catheterization possibly has a nursing diagnosis of “*Anxiety* related to lack of knowledge about cardiac testing, evidenced by inability to describe cardiac catheterization after repeated questioning.” An incorrect diagnosis is “*Anxiety* related to cardiac catheterization.”
- Identify a patient response to the equipment rather than the equipment itself. Patients are often unfamiliar with medical technology and its use. The diagnosis of “*Lack of Knowledge* regarding the need for cardiac monitoring related to inexperience” is accurate compared with the statement “*Lack of Knowledge* related to cardiac monitoring.”
- Identify a patient’s problems rather than your problems with nursing care. Nursing diagnoses are patient-centered and form the basis for goal-directed care. Consider a patient with a peripheral intravenous (IV) infusion. “*Potential Intravenous Complications* related to poor vascular access” indicates a nursing problem in maintaining the infusion. The diagnosis “*Risk for Infection* evidenced by swollen IV site, pain at site, and slowed infusion” properly centers attention on the patient’s potential needs.
- Identify a patient problem rather than a nursing intervention. You plan nursing interventions after identifying a nursing diagnosis. The intervention “Offer bedpan frequently because of incontinence” is not a diagnostic statement. Instead, with the proper assessment data, the correct diagnostic statement would be “*Diarrhea* related to food intolerance evidenced by 3 stools daily and soft formed stools.” A correct diagnosis will more likely result in the selection of appropriate interventions to solve the patient’s problem.
- Identify a patient need rather than the goal of care. You establish goals during the planning step of the nursing process ([Chapter 18](#)). Goals based on accurate identification of a patient’s problems serve as a basis to determine problem resolution. Change the goal-phrased statement of “Patient needs high-protein diet related to potential alteration in nutrition” to “*Impaired Nutritional Intake* related to difficulty

swallowing evidenced by inability to eat solid foods and painful mouth.”

- Make professional rather than prejudgmental statements. Base nursing diagnoses on subjective and objective patient data and do not include your personal beliefs and values. Remove your judgment from “*Impaired Skin Integrity* related to poor hygiene habits” by changing the diagnostic statement to read “*Impaired Skin Integrity* related to inadequate knowledge about perineal care evidenced by inability to cleanse perineum and inability to explain cleansing techniques.”
- Avoid legally inadvisable statements in a diagnostic statement (Carpenito, 2017). Statements that imply blame, negligence, or malpractice (see Chapter 23) have the potential to result in a lawsuit. The statement “*Acute Pain* related to insufficient medication” implies an inadequate prescription by a health care provider. Correct problem identification is *Acute Pain* related to insufficient knowledge of analgesic schedule evidenced by self-report of pain intensity and inability to describe dosage plan.
- Identify the problem and etiology to avoid a circular statement. Circular statements are vague and give no direction to nursing care. Change the statement “*Impaired Breathing* related to shallow breathing” to identify the real patient problem and cause, *Impaired Breathing* related to incision pain evidenced by splinting and increased respiratory rate.
- Identify only one patient problem in the diagnostic statement. Every problem has different expected outcomes (see Chapter 18). Confusion during the planning of care occurs when you include multiple problems in a nursing diagnosis. It also can result in choosing an insufficient number of nursing interventions or inappropriate interventions. For example, *Pain* and *Anxiety* related to difficulty in ambulating are two diagnoses combined in this example of one nursing diagnosis statement. Two separate diagnoses for *Pain* and *Anxiety* are more accurate. It is permissible to include multiple etiologies contributing to one patient problem, as in *Dysfunctional Grief* related to diagnosis of a terminal illness and change in family role.

Documentation and Informatics

Accuracy and consistency in the way information is shared among health care providers are essential. Standardized formats used in electronic health records (EHRs) enable nurses and other care providers to share information about the care they provide to sustain life, enable recovery, and promote health (Lundberg et al., 2008). The use of standard, familiar terminology in an EHR can provide nurses greater ease in their selection of nursing diagnoses and interventions in planning patient care (Estrada and Dunn, 2012). Many state-of-the-art EHRs contain nursing diagnoses with NANDA-I diagnoses, related factors, defining characteristics, and Nursing Intervention Classifications (NIC) and Nursing Outcome Classifications (NOC) (NANDA-I, 2018b). The ICNP develops catalogs (nursing data subsets) for specified health situations that are used in building health information systems for a variety of settings (Tastan et al., 2014; Rabelo-Silva, 2016). The use of standard language in an EHR is also valuable for making it easier to capture and analyze nursing practice information for research (Rabelo-Silva, 2016).

Once you identify a patient's nursing diagnoses, enter them in the EHR of the agency. The agency information system will dictate how the diagnosis is disseminated throughout the record, such as in a formal care plan, a daily task sheet, or nurses' notes. In advanced systems a nurse enters assessment data into the EHR, and the computer software program organizes the data into patterns that enhance the ability to select accurate nursing diagnoses. Once diagnoses are selected, the computer system directs the nurse to outcome and intervention options to select for the specific patient, allowing for individualized care. The value of the NANDA-I system is that many of the nursing diagnoses are evidence based. Select diagnoses developed since 2002 are based on the research and work of professional nurses around the world (NANDA-I, 2018b).

List nursing diagnoses chronologically as you identify them. When initiating an original care plan, place the highest-priority nursing diagnosis first. This will depend on a patient's condition and the nature of the nursing diagnosis (see Chapter 18). Thereafter add nursing diagnoses to the list. Date a nursing diagnosis at the time of initiation. When caring for a patient, review the list and first identify nursing diagnoses with the greatest priority, regardless of chronological order.

Nursing Diagnoses Application to Care Planning

Nursing diagnosis provides a universal and standardized way for professional nurses to communicate among themselves and across other health care disciplines. It enhances interprofessional collaboration (see [Chapter 18](#)). Diagnoses direct the planning process and the selection of nursing interventions to achieve desired outcomes for patients. Just as a medical diagnosis of diabetes leads a health care provider to prescribe a low-carbohydrate diet and medication for blood glucose control, the nursing diagnosis of *Impaired Health Maintenance* will lead a nurse to design appropriate educational and social support interventions. In [Chapter 18](#) you will learn how combining nursing diagnostic statements with the Nursing Interventions Classification (NIC) and Nursing Outcomes Classification (NOC) systems facilitates the process of patient-centered care planning. The care plan (see [Chapter 18](#)) is a road map for delivering nursing care and demonstrates your accountability for patient care. By making accurate nursing diagnoses, your subsequent care plan communicates a patient's health care responses to problems to all health care professionals and ensures high-quality care.

Key Points

- When making a diagnosis, a clear label or term that is familiar to all those involved in a patient's care is necessary to understand a patient's needs.
- Nursing diagnoses provide clear direction as to the types of nursing interventions nurses are licensed to provide independently.
- Nurses cannot treat medical diagnoses; instead, they treat patients' responses to the medical health conditions.
- Nurses intervene in collaboration with personnel from other health care professions to manage collaborative problems.
- Using standardized terminology leads to diagnostic clarity and effective communication and enables nurses to formulate nursing diagnoses, associated interventions, and to assess the outcomes of nursing care.

- The nursing diagnostic reasoning process involves using the assessment data gathered about a patient to logically explain a clinical judgment in the form of a nursing diagnosis.
- Your review and analysis of assessment data involve critically organizing all data elements about a patient into meaningful patterns, also called data clusters or sets of assessment findings/defining characteristics.
- As you recognize data elements from an assessment, you will cluster or group them together in meaningful patterns in a logical way that during interpretation will reveal the nursing diagnoses.
- Data interpretation involves placing a label on a data pattern or cluster to clearly identify a patient's responses to health problems.
- Errors occur in the nursing diagnostic process during data collection; analysis of data, clusters, or patterns; and interpretation in choosing a nursing diagnostic statement.
- Identify nursing diagnoses from a cluster of assessment findings and not just a single symptom.
- Identify a patient need rather than the goal of care when forming a diagnostic statement.

Reflective Learning

After you complete an assessment of a patient in a clinical area or in a simulation laboratory, review your data and apply critical thinking.

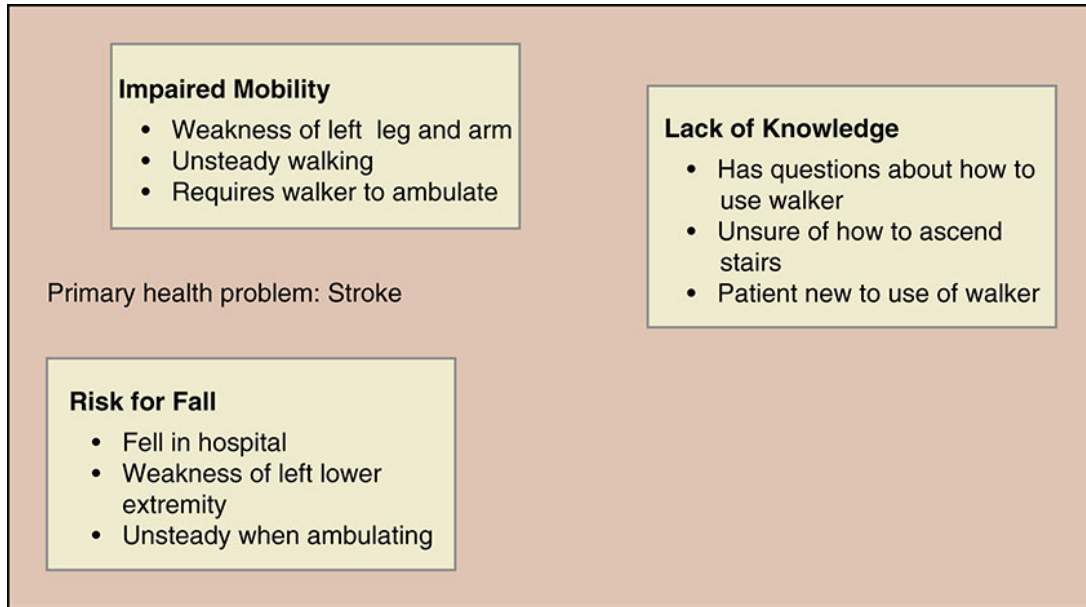

- What patterns of data appear logically together as you analyze all the information?
- As you look at the data in each pattern, are there cases in which an individual data element falls into more than one pattern? What does that suggest?
- Take a data pattern that you have identified and form a nursing diagnostic statement.

Review Questions

1. A nursing student is working with a faculty member to identify a nursing diagnosis for an assigned patient. The student has assessed that the patient is undergoing radiation treatment, has liquid stool, and the skin is clean and intact. The student selects the nursing diagnosis *Impaired Skin Integrity*. The faculty member explains that the student has made a diagnostic error for which of the following reasons?
 1. Incorrect clustering of data
 2. Wrong diagnosis
 3. Condition is a collaborative problem
 4. Premature ending assessment
2. A nurse conducts an assessment of a 42-year-old woman at a health clinic. The woman is married and lives in a condo with her husband. She reports having frequent voiding and pain when she passes urine. The nurse asks whether she has to go to the bathroom at night, and the patient responds, "Yes, usually twice or more." The patient had an episode of diarrhea 1 week ago. She weighs 300 lb and reports having difficulty cleansing herself after voiding or passing stool. Which of the following demonstrate assessment findings that cluster to indicate the nursing diagnosis *Impaired Urination*. (Select all that apply.)
 1. Age 42
 2. Dysuria
 3. Difficulty performing perineal hygiene
 4. Nocturia
 5. Episode of diarrhea
3. Review the following nursing diagnoses and identify the diagnoses that are stated correctly. (Select all that apply.)
 1. Offer frequent skin care because of *Impaired Skin Integrity*
 2. *Risk of Infection*
 3. *Chronic Pain* related to osteoarthritis

4. *Activity Intolerance* related to physical deconditioning
 5. *Lack of Knowledge* related to laser surgery
4. Which of the following best describe a collaborative health problem?
(Select all that apply.)
1. An actual or potential physiological complication that nurses monitor to detect the onset of changes in a patient's health status
 2. The language medical practitioners use to communicate a patient's health problem and associated treatments and response
 3. A diagnostic label that classifies a patient's response to illness so that all nurses can be familiar with a specific patient's health care needs
 4. A language used by health care providers to communicate and consider each other's unique perspective, so they can better manage the multiple factors that influence the health of individuals
 5. A diagnosis that provides clear direction as to the type of nursing interventions nurses are licensed to provide independently
5. Which of the following is a diagnostic error involving identification of a goal of care rather than a patient need?
1. Patient obtains social support care related to caregiver stress
 2. *Fear* related to open-heart surgery
 3. *Acute Pain* related to splinting of incision
 4. *Impaired Family Coping* related to insufficient caregiver support
6. A nurse is assigned to a new patient admitted to the medical unit. The nurse collects a nursing history and interviews the patient. Place the following steps for making a nursing diagnosis in the correct order.
1. Consider the context of patient's health problem and select a related factor.
 2. Review assessment data, noting objective and subjective clinical information.
 3. Cluster clinical data elements that form a pattern.

4. Identify appropriate assessment findings for diagnosis.
5. Identify a nursing diagnosis.
7. A nurse interviews and conducts a physical examination of a patient that includes the following findings: reduced movement of lower leg, reduced range of motion in left knee, and difficulty turning in bed without assistance. This data set is an example of:
 1. Collaborative data set.
 2. Diagnostic label.
 3. Related factors.
 4. Data cluster.
8. A nurse reviews data gathered regarding a patient's response to a diagnosis of cancer. The nurse notes that the patient is restless, avoids eye contact, has increased blood pressure, and expresses a sense of helplessness. The nurse compares the pattern of assessment findings for *Anxiety* with those of *Fear* and selects *Anxiety* as the correct diagnosis. This is an example of the nurse avoiding an error in? (Select all that apply.)
 1. Data collection
 2. Data clustering
 3. Data interpretation
 4. Making a diagnostic statement
 5. Goal setting
9. A nursing assessment reveals a patient in the home setting who has reduced mobility following recovery from a stroke. The patient has weakness in the left leg and arm. The patient has a walker, which he has never used before, and his wife tells the nurse that he is unsteady in using the walker. The patient fell while in the hospital. The physical therapist came to the home, but the wife tells the nurse, "We are not sure how to get my husband upstairs. The therapist explained how to use the walker, but we have questions." The nurse developed the following concept map. Place the links between the nursing diagnoses in the correct direction.

10. Fill in the Blank:

A(n) _____ diagnosis is one that applies when there is an increased potential or vulnerability for a patient to develop a problem.

Answers: 1. 2; 2. 2, 4; 3. 2, 4; 4. 1, 4; 5. 1; 6. 2, 3, 5, 1, 4; 7. 4; 8. 2, 3, 4; 9. See Evolve; 10. Risk diagnosis.

Planning Nursing Care

OBJECTIVES

- Explain the relationship of planning to nursing diagnosis.
- Discuss criteria used in priority setting.
- Discuss the difference between a goal and an expected outcome.
- Use the SMART model for writing goal and outcome statements.
- Discuss the differences between independent and dependent nursing interventions.
- Discuss benefits of nursing care plans.
- Describe the consultation process.
- Explain the process of interprofessional collaboration.

KEY TERMS

Consultation, p. 253

Dependent nursing interventions, p. 246

Expected outcome, p. 244

Goal, p. 242

Independent nursing interventions, p. 246

Interprofessional care plans, p.249

Interprofessional collaboration, p. 244

Long-term goal, p. 243

Nursing care plan, p. 249

Nursing Interventions Classification (NIC), p. 247

Nursing Outcomes Classification (NOC), p. 245

Nursing-sensitive patient outcome, p. 245

Other provider interventions, p. 246

Patient-centered goal, p. 240

Planning, p. 240

Priority setting, p. 241

Scientific rationale, p. 246

Short-term goal, p. 243

*Tonya conducted a thorough assessment of Mr. Lawson's health status and identified three nursing diagnoses: **Acute Pain** related to trauma of surgical incision, **Lack of Knowledge** regarding postoperative care related to inexperience with surgery, and **Risk for Infection**. Tonya is responsible for the initial planning of Mr. Lawson's nursing care after identifying relevant nursing diagnoses. The care that she plans will continue to be implemented and updated during Mr. Lawson's hospital stay by the other nurses involved in Mr. Lawson's care. If Tonya plans well, the individualized interventions that she selects will prepare the patient for a smooth transition home. Collaboration with the patient and his wife will be critical for a plan of care to be successful. Using input from Mr. Lawson, Tonya identifies the goals and expected outcomes for each of his nursing diagnoses. The goals and outcomes direct Tonya in selecting appropriate therapeutic nursing interventions. Tonya knows that Mrs. Lawson must be involved in her husband's care because of the ongoing support that she provides and because she will be a key care provider once Mr. Lawson returns home. Consultation and collaboration with other health care providers such as home health ensures that the right resources will be used in planning care. In addition, Tonya poses a PICOT question about Mr. Lawson: Does the use of visual aids compared with standard discharge literature affect adult patients' ability to learn infection control principles? Tonya will use results of her literature search to build interventions for Mr. Lawson's care. Careful planning involves seeing the relationships among a patient's problems, recognizing that certain problems take precedence over others, identifying the most appropriate interventions, and proceeding with planning a safe and efficient approach to care.*

How well do you plan? After reviewing the food products in your kitchen pantry, do you make a list and plan meals over the course of a week? As a mother or father do you collaborate with a spouse after considering a week's activities and plan for what to do over a weekend? Planning is the process of identifying a problem (missing food products in the pantry) and making or carrying out a plan of action that is often goal oriented. You select foods you need for the kitchen pantry, plan the trip to

the grocery store, and then select and prepare the types of meals that best use the products you purchased.

Planning nursing care is much more complicated, but it involves basic elements of reviewing a patient's problems or needs, determining the best course of action to meet those problems, setting goals and outcomes to guide the plan of care, and developing a plan of interventions to be used in patient care.

After identifying a patient's nursing diagnoses and collaborative problems, you begin the **planning** step of the nursing process. Planning involves setting priorities based on patient diagnoses and collaborative problems, identifying **patient-centered goals** and expected outcomes, and prescribing nursing interventions appropriate for each diagnosis. The most important principle in planning is the individualization of a patient-centered plan of care for each patient's unique needs. The patient's nursing diagnoses direct your mutual selection of nursing interventions and the goals and outcomes you hope your patient achieves (Flagg, 2015). Planning requires critical thinking applied through deliberate decision making and problem solving. It also requires communicating closely with patients, their families, and the health care team and ongoing collaboration with team members. Know that any plan of care is dynamic and changes as a patient's needs change.

Establishing Priorities

A single patient often has multiple nursing diagnoses and collaborative problems. When you enter nursing practice, you will care for multiple patients. You must collaborate with patients and family caregivers (as applicable) and health care team members to determine the urgency of an identified problem for each patient and to prioritize patient diagnoses ([Ackley et al., 2017](#)). **Priority setting** is the ordering of nursing diagnoses or patient problems to establish a preferential order for nursing interventions. Generally, problem-focused diagnoses and problems take priority over wellness, possible risk, and health promotion problems. Short-term acute patient care needs and problems typically take priority over longer-term chronic needs ([NCLEX, n.d.](#)). Priority setting is not the ordering of a list of care tasks but an organization of the desired outcomes for a patient.

Use your nursing and scientific knowledge base to recognize patterns of symptoms from your patient assessment and certain knowledge triggers to help you understand which diagnoses require intervention and when you need to intervene to plan effective nursing care ([Ackley et al., 2017](#)). This requires you to identify symptoms that patients have related to their illness, understand which symptom patterns require action, and identify the associated time frame for effective intervention. Some knowledge triggers include pathophysiology and pharmacology, your experiences with other patients who have had similar problems, and what you know about your select patient you are caring for now. For example, a nurse is caring for a patient who suddenly spikes a fever following surgery. The nurse connects this symptom with other symptoms of purulent drainage and tenderness over a surgical wound and an inflamed incision. The pattern of symptoms tells the nurse that the patient most likely has developed an infection, which requires immediate action.

As you care for a patient or multiple patients, you must deal with certain aspects of care before others. By ranking a patient's nursing diagnoses in order of importance and always monitoring changing signs and symptoms of patient problems, you attend to each patient's most important needs and better organize ongoing care activities. Priorities help you anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems. You also set priorities by selecting mutually agreed-on priorities with a patient based on the urgency of the problems, the patient's safety and desires, the nature of the treatment indicated, and the relationship among the diagnoses.

Priority setting is not a matter of numbering the nursing diagnoses based on severity or physiological importance. Such a numbering system does not always reflect actual clinical changes in patients. Instead, you establish priorities in relation to their ongoing clinical importance.

Methods for Prioritizing

Classify patients' priorities as high, intermediate, or low importance. Nursing diagnoses that, if untreated, result in harm to a patient or others (e.g., those related to airway status, circulation, safety, and pain) have the highest priorities. Prioritize nursing diagnoses first by considering patients' immediate needs based on ABC (airway, breathing, and circulation) (Ackley et al., 2017). The highest priority can also be determined by using Maslow's hierarchy of needs (see Chapter 6). For example, *Risk for Violence*, *Impaired Gas Exchange*, and *Impaired Cardiac Function* are examples of high-priority nursing diagnoses that drive the priorities of safety, adequate oxygenation, and adequate circulation. However, it is always important to consider each patient's unique situation. Avoid classifying only physiological nursing diagnoses as high priority. Consider Mr. Lawson's case. Among his nursing diagnoses, **Acute Pain** was an initial priority because Tonya knew that she needed to relieve Mr. Lawson's acute pain for him to be ready for discharge education. Now that his pain is controlled reasonably well, **Lack of Knowledge** became the priority because of the patient's expressed concern for how to care for himself and the urgent need to prepare him adequately for his upcoming discharge.

Intermediate-priority nursing diagnoses are nonemergent and not life threatening. In Mr. Lawson's case, *Risk for Infection* is an intermediate diagnosis. The nursing staff will continue to monitor his wound healing, and it is important for Mr. and Mrs. Lawson to learn the signs of infection and understand what to observe once the patient returns home. In this case focused and individualized instruction from all members of the health care team about infection prevention is necessary throughout the patient's hospitalization.

Low-priority nursing diagnoses are not always directly related to a specific illness or prognosis but affect a patient's future well-being. Many low-priority diagnoses focus on a patient's long-term health care needs. You learned in Chapter 17 that Mr. Lawson shares a concern with Tonya, "I'm worried about being able to return to work on time." When instructing the patient, Tonya noticed that he was having trouble attending to what she had to say. Tonya has not yet identified a nursing diagnosis related to Mr. Lawson's

concern about returning to work. She will need to assess him more fully, but a nursing diagnosis such as **Anxiety** may be of low priority compared with others. However, if the patient's anxiety is left unaddressed, it could become a higher priority if it interferes with his ability to learn discharge information.

Patients' priorities change as their conditions and needs change, sometimes within a matter of minutes. Each time you begin to care for a patient, such as at the beginning of a hospital shift or during a clinic visit, review patient priorities. For example, when Tonya first met Mr. Lawson, he rated his pain at a 7, and it was apparent that administering an analgesic and repositioning the patient were greater priorities than trying to prepare him for instruction. Later, after receiving the analgesic, Mr. Lawson's pain lessened to a level of 4, and Tonya was able to gather more assessment information and begin to focus on his problem of **Lack of Knowledge**. Ongoing patient assessment is critical to determine the status of a patient's nursing diagnoses. The appropriate ordering of priorities ensures that you meet a patient's needs in a safe, timely, and effective way.

Priority setting includes determining which nursing interventions you plan to use with a patient and the order in which you need to implement them. For example, as Tonya considers the high-priority diagnosis of **Acute Pain** for Mr. Lawson, she includes in her plan of care these options: timely administration of an analgesic, repositioning, and teaching relaxation exercises. With each clinical encounter, Tonya applies critical thinking to prioritize which intervention to use first. Tonya knows that a certain degree of pain relief is necessary before a patient can participate in relaxation exercises. When she is in the patient's room, she might decide to turn and reposition Mr. Lawson first and then prepare the analgesic. However, if Mr. Lawson expresses that pain is a high level and he is too uncomfortable to turn, Tonya chooses obtaining and administering the analgesic as her first priority. Later, with Mr. Lawson's pain more under control, she considers whether relaxation is appropriate.

Involve patients in priority setting whenever possible. Patient-centered care requires you to know a patient's preferences, values, and expressed needs. Sometimes a patient assigns priorities differently from those you select. Resolve these differences through open communication. Consulting with and knowing a patient's concerns do not relieve you of the responsibility to act in a patient's best interests. Always assign priorities based on good nursing judgment.

Ethical care is a part of priority setting (see [Chapter 22](#)). When ethical issues cloud priorities, you must maintain an open dialogue with the patient, family members, and other health care providers. For example, when caring for patients with cancer, discuss the situation with them and

understand their expectations, understand your professional responsibility in protecting the patients from harm, know their health care provider's therapeutic or palliative goals, and then form appropriate plans of care.

Priorities in Practice

Many factors within the health care environment affect your ability to set priorities (Fig. 18.1). For example, in a hospital setting the model for delivering care (see Chapter 21), the workflow routine of a nursing unit, staffing levels, availability of material resources, and interruptions from other care providers affect the minute-by-minute determination of patient care priorities. In the home health setting the number of visits scheduled for a day and the availability of family caregivers and resources within a patient's home affect a patient's priorities. Nurses should have a plan of action to effectively manage their time, avoid unnecessary interruptions, and avoid helping others when this could potentially jeopardize their patients' priorities of care (NCLEX, n.d.). Remember, however, a colleague might ask for assistance when his or her patient has a priority needing immediate attention.

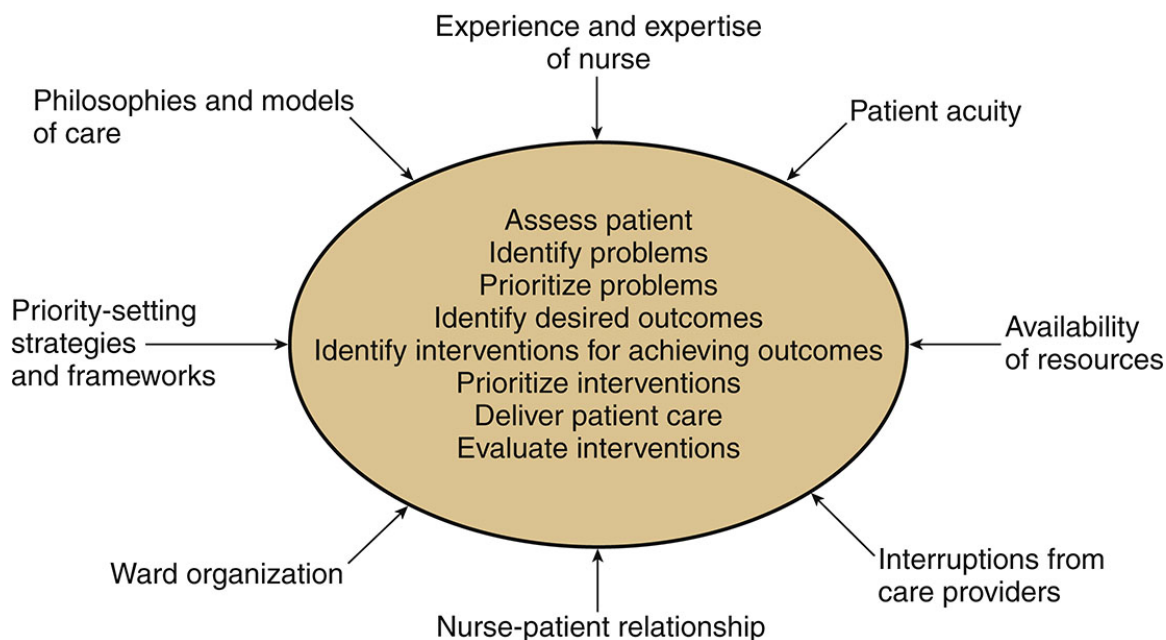

FIG. 18.1 A model for priority setting.
Modified from Hendry C, Walker A: Priority setting in clinical nursing practice, *J Adv Nurs* 47(4):427, 2004.

Successful priority setting involves collaborating with the health care team. When you work with assistive personnel (AP), discuss the purpose of each patient's hospitalization, the picture of how the patient should look at the end of the shift, the plan for achieving desired outcomes, and the part you and the AP will play. You agree on priorities at the beginning of a shift, but you will most likely need to change them several times before the next shift due to changes in your patients' needs and changes in your patient assignment due to discharges, transfers, and admissions.

The same factors that influence your ability to prioritize nursing actions minute by minute affect your ability to prioritize nursing diagnoses and plan care for groups of patients. The nature of nursing work challenges you to attend to a given patient's priorities when you care for more than one patient. The nursing care process is nonlinear. Often you complete an assessment and identify nursing diagnoses for one patient, leave the room to perform an intervention for a second patient, and move on to evaluate the care of a third patient. Nurses exercise "cognitive shifts" (i.e., shifts in attention from one patient to another during the conduct of the nursing process). This shifting of attention occurs in response to changing patient needs, new procedures being ordered, or environmental processes interacting (e.g., call lights, alarms). Because of these cognitive shifts, it becomes important to stay organized and know your patients' priorities. Work from your plan of care and use patients' priorities to organize the order for delivering interventions and organizing documentation of care.

Critical Thinking in Setting Goals and Expected Outcomes

The planning process involves application of your knowledge, knowledge about a specific patient, clinical experiences, standards, and critical thinking attitudes (Fig. 18.2). It is a dynamic process, changing as a patient's needs change. Apply critical thinking after you identify a patient's nursing diagnoses or collaborative problems and ask yourself these questions:

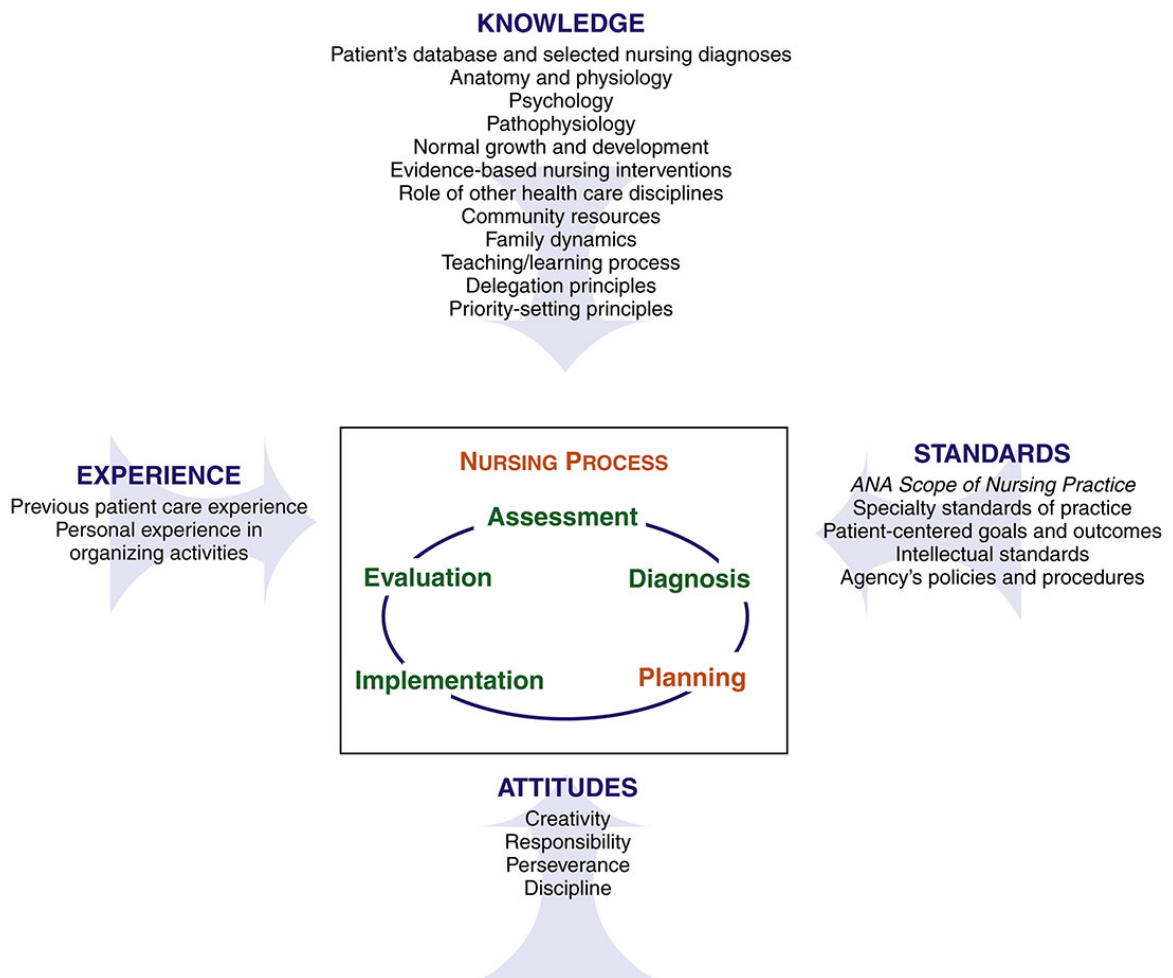

FIG. 18.2 Critical thinking and the process of planning care.

- What is the best approach to address and resolve the problem?

- What does my patient need to achieve (physically, psychologically, socially, and spiritually)? What are the goals and outcomes related to these needs?
- How will I know when my patient has achieved the goals and outcomes?

Goals and expected outcomes are specific statements of patient behavior or physiological responses that you select to resolve a nursing diagnosis or collaborative problem. They serve two purposes: to set a clear direction for the selection and use of nursing interventions and to set specific measures for evaluating the effectiveness of meeting goals and outcomes. In the case of Mr. Lawson, Tonya sets the goal of the patient being “infection free.” The expected outcomes for achieving that goal include the patient remaining afebrile, without wound drainage, and with wound edges healing. Expected outcomes are time limited, measurable ways of determining whether a goal is met (Table 18.1).

TABLE 18.1

Examples of Goal Setting with Expected Outcomes for Mr. Lawson

Nursing Diagnoses	Goals	Expected Outcomes
<i>Acute Pain related to trauma of surgical incision</i>	Mr. Lawson will achieve pain relief by day of discharge.	Mr. Lawson reports pain at a level of 3 or below by discharge. Mr. Lawson walks to chair with no increase in pain in 24 hours. Mr. Lawson’s incisional area shows signs of wound healing by discharge.
<i>Lack of Knowledge regarding postoperative care related to inexperience with surgery</i>	Mr. Lawson will express understanding of how to minimize postoperative risks by discharge.	Mr. Lawson describes activity restrictions to follow by discharge in 48 hours. Mr. Lawson demonstrates how to cleanse surgical wound by discharge day. Mr. Lawson describes three risks for infection in 24 hours.
<i>Risk for Infection</i>	Mr. Lawson will remain infection free by discharge.	Mr. Lawson remains afebrile by discharge. Mr. Lawson’s wound shows no purulent drainage by discharge. Mr. Lawson’s wound closes at site of incision separation by discharge

Goals

A **goal** is a broad statement that describes a desired change in a patient’s condition, perceptions, or behavior. Mr. Lawson has the diagnosis of *Lack of Knowledge*. A goal of care for this diagnosis includes, “Patient will express understanding of how to minimize postoperative risks within 24

hours.” A goal is realistic and based on patient needs, preferences, and resources. It predicts resolution of a problem, evidence of progress toward problem resolution, progress toward improved health status, or continued maintenance of good health or function (Carpenito, 2017).

Each goal is time limited, so the health care team has a common timeline for problem resolution. The time frame depends on the nature of the problem, etiology, overall condition of the patient, and treatment setting. A **short-term goal** is an objective behavior or response that you expect the patient to achieve in a short time, usually less than a week. In an acute care setting short-term goals may be set for just a few hours. A **long-term goal** is an objective behavior or response that you expect the patient to achieve, usually over several days, weeks, or months.

Goals are often based on standards of care or clinical guidelines established for minimal safe practice. For example, the Infusion Nurses Society (INS) has standards of care to prevent IV complications of phlebitis, and the Association of Operating Room Nurses (AORN) has standards of care for patient recovery after surgery.

Role of Patients in Goal Setting

Patient-centered care includes the involvement of patient, family, and friends (as appropriate) (QSEN, 2018). Always collaborate with your patients during goal setting. Mutual goal setting helps you prioritize the goals of care and develop a realistic and relevant plan of care for a patient (Fig. 18.3). Unless goals are mutually set and include a clear plan of action, patients or family caregivers may not fully participate. Patients need to understand and see the value of nursing therapies even though they are often totally dependent on you as the nurse.

FIG. 18.3 Collaborative goal setting with patient and family member.

Role of Health Care Team in Goal Setting

Interprofessional collaboration is a complex process that is formed between two or more people from various professional fields to achieve common goals for a patient (Mahdizadeh et al., 2015). The need for interprofessional team collaboration is increasing as a result of an aging population with more complex needs associated with chronic diseases, increasing complexity of skills required to deliver care, knowledge required to provide comprehensive care to patients, and increasing specialization within health professions (Nancarrow et al., 2013). The elements that must be in place before interprofessional collaboration can be successful are interprofessional education, role awareness as a member of the team, interpersonal relationship skills, deliberate intervention, and support of the interprofessional team (Petri, 2010). Nancarrow and colleagues (2013) add that positive leadership and management attributes, communication structures, personal rewards, appropriate resources and procedures, appropriate skill mix, and clarity of vision are also necessary. Interprofessional team-based care involves care delivered by intentionally created, usually small work groups in health care who are recognized by others as well as by themselves as having a collective identity and shared

responsibility for a group of patients (e.g., rapid response team, palliative care team) ([Interprofessional Education Collaborative, 2016](#)).

Nurses play a key role in interprofessional collaboration, especially in communicating patient needs to all members of the health care team, clarifying priorities, and ensuring a continuum of care. When interprofessional collaboration functions well, the outcomes are improvements in patient care, improvements in health care providers' and nurses' satisfaction, control of costs, reduction in clinical errors, and improvements in patient safety ([Mahdizadeh et al., 2015](#)).

Expected Outcomes

*The goal for Mr. Lawson to understand the risks associated with his type of surgery gives Tonya a clear focus on the topics to include in her instruction (e.g., wound care, activity restriction). For Tonya to know whether Mr. Lawson understands his postoperative risks, the patient must meet expected outcomes. An **expected outcome** is the measurable change (patient behavior, physical state, or perception) that must be achieved to reach a goal. In Mr. Lawson's case, after Tonya provides an educational intervention, the expected outcome would be "Patient identifies signs and symptoms of wound infection before discharge." Tonya will perform teach-back after instruction to determine whether outcomes are met. In this case she wishes to have Mr. Lawson learn three different signs of wound infection—wound drainage, fever, and increased tenderness around the wound. Sometimes an outcome includes several measures that must be met for a single outcome. In all cases the goal and expected outcomes should align with the patient's nursing diagnoses or collaborative problems.*

In health care, the terms *goals* and *outcomes* are sometimes interchanged and thus cause confusion. Outcome measurement is a priority within health care institutions; however, the way in which electronic health records (EHRs) label goal/outcome categories that nurses use to complete care plans can be unclear. Think of a *goal* as an ultimate outcome and *expected outcomes* as the measurable changes that a patient achieves to reach a goal.

Planning nursing care requires you to critically assess your patient's nursing diagnoses, the urgency or priority of the problems, and the resources of the patient and the health care delivery system. Apply knowledge from the medical, sociobehavioral, and nursing sciences to plan patient care. When Tonya selected her PICOT question about approaches for teaching infection control, she applied the knowledge she

gained in selecting a specific teaching approach. The selection of goals, expected outcomes, and interventions requires consideration of your previous experience with patients who had similar problems and any established standards for clinical problem management. The goals and outcomes need to meet established intellectual standards by being relevant to patient needs, specific, singular, observable, measurable, and time limited. You also use critical thinking attitudes in selecting interventions with the greatest likelihood of success.

*Tonya has a discussion with Mr. Lawson and his wife about setting the plan for the diagnosis of **Lack of Knowledge**. Tonya explains the topics that they need to discuss so that the couple understands Mr. Lawson's postoperative risks. In addition, she talks about a program available on hospital TV about infection control that the couple can watch in their room. Tonya applied knowledge learned from her PICOT question literature search and chose the visual aid strategy. They plan for the couple to view the TV program when Mrs. Lawson visits. Mr. Lawson asks Tonya to also provide specific instruction about the activities he can and cannot do once he returns home. Tonya agrees and consults with the surgeon to be sure that her information is accurate and realistic.*

Selecting Goals and Expected Outcomes

A patient-centered goal reflects a patient's highest possible level of wellness and independence in function. It is realistic and based on patient needs, abilities, and resources. A patient-centered goal and associated outcome reflect a patient's specific behavior, not your own goals or nursing interventions. Typically all health care providers contribute to achievement of patient outcomes. However, nurses monitor and manage patient conditions and diagnose problems that can be treated with nursing interventions. The clinical reasoning and decision making of nurses are key parts of quality health care (Moorhead et al., 2018). Thus it becomes important to measure patient outcomes that are influenced by nursing care. A **nursing-sensitive patient outcome** is a measurable patient, family, or community behavior or perception that is measured along a continuum in response to nursing interventions (Moorhead et al., p viii, 2018). Examples of nursing-sensitive outcomes include reduction in pain frequency and severity and incidence of pressure injuries and falls. In comparison, medical outcomes are largely influenced by medical interventions. Examples include patient mortality, surgical wound infection, and hospital readmissions. For the nursing profession to become a full participant in clinical evaluation research, policy development, and

interprofessional collaboration, nurses need to identify and measure patient outcomes influenced by nursing interventions.

Nursing Outcomes Classification

A valuable resource in selecting patient goals and outcomes is the **Nursing Outcomes Classification** (NOC), which links outcomes to NANDA International (NANDA-I) nursing diagnoses ([Moorhead et al., 2018](#)). This resource is an option that you can use in selecting goals and outcomes for your patients. For each nursing diagnosis there are multiple evidence-based outcomes (goals). The outcomes have labels for describing the focus of nursing care and include indicators (expected outcomes) to use in evaluating the success with nursing interventions. The indicators for each NOC outcome allow for measurement at any point on a five-point Likert scale from most negative to most positive ([Moorhead et al., 2018](#)). The rating system adds objectivity to judging a patient's progress. The use of NOC facilitates the evaluation of the effects of nursing interventions over time and across a variety of health care settings. Using a common language for outcomes allows nurses to plan effective patient care and provides a standardized way to measure whether nursing interventions are successful.

What NOC describes as an outcome, such as anxiety level, appetite, or physical comfort, is a very abstract term, which in real clinical practice comes closer to a goal statement. For example, in NOC terminology the outcome for the nursing diagnosis of *Acute Pain* is described as "pain control" or pain relief, the goal set for Mr. Lawson. The NOC outcome indicators are the same for what most clinicians set as expected outcomes. In the example of pain control, the expected outcomes include symptom severity measured on a pain scale or mobility level. [Table 18.2](#) offers more examples of how to use NOC terminology for describing the focus or goals of nursing care and outcome indicators as they relate to nursing diagnoses.

TABLE 18.2**Examples of Nursing Diagnoses and Suggested NOC Linkages**

Nursing Diagnosis	Examples of NOC Outcomes (Consider as Goal Statements)	Outcome Indicators (Examples)
<i>Impaired Oral Mucous Membrane</i>	Oral Health	Knowledge of infection management Self-care oral hygiene
	Tissue Integrity	Hydration Infection severity
<i>Activity Intolerance</i>	Activity Tolerance	Oxygen saturation with activity Pulse rate with activity Respiratory rate with activity
	Self-Care Status	Bathes self Dresses self Prepares food and fluid for eating

NOC, Nursing Outcomes Classification.

Adapted from Moorhead S, et al: *Nursing Outcomes Classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Writing Goals and Expected Outcomes

Goals and expected outcomes direct your nursing care. After you set a patient-centered goal for a nursing diagnosis, the expected outcomes set the desired physiological, psychological, social, developmental, or spiritual responses that indicate resolution of the patient's health problems. Use the *SMART* acronym (*Specific, Measurable, Attainable, Realistic, Timed*) to write goals and outcome statements ([Ackley et al., 2017](#)).

1. **Specific**—Outcomes and goals reflect a specific patient behavior or response. A correct goal statement is: "Patient will ambulate independently in 3 days." A correct outcome statement is: "Patient ambulates in the hall 3 times a day by 4/22." A common error is to write an intervention: "Ambulate patient in the hall."

A specific outcome addresses only one behavior or response. For example, an incorrect outcome reads, "Patient's lungs are clear to auscultation, and respiratory rate is 24 breaths/minute by 8/22." How would you evaluate the outcome when you determine that the lungs are clear but the respiratory rate is 28 breaths/min? You would be unable to do so. It is preferable that each

outcome be separate. A focus on a single outcome enables you to decide whether you need to modify a plan of care.

2. **Measurable**—You must be able to measure or observe whether a change takes place in a patient’s status. Changes occur in physiological findings and in a patient’s knowledge, perceptions, and behavior. Examples such as “Body temperature will remain below 98.6°F (37°C)” and “Apical pulse will remain between 60 and 100 beats/min” allow you to objectively measure physical changes in a patient’s status. The outcome statement “Patient’s pain is less than 4 on a scale of 0 to 10 in 48 hours” allows you to objectively measure patient perception using a pain-rating scale. Do not use vague qualifiers such as “normal,” “acceptable,” or “stable” in an expected outcome statement. Vague terms result in guesswork in determining a patient’s response to care. Terms describing quality, quantity, frequency, length, or weight allow you to evaluate outcomes precisely.
3. **Attainable**—A goal and an outcome are more attainable or achievable when you mutually set them with a patient. This ensures that you and your patient agree on the direction and time limits of care. Mutual goal setting (e.g., distance to walk, topics to learn about, medications) increases a patient’s motivation and cooperation. As a patient advocate, apply standards of practice, evidence-based knowledge, safety principles, and basic human needs when helping patients set goals. Use your knowledge about and experience with patients’ typical responses to clinical interventions to help your patients select goals and outcomes. Always consider patients’ desires to recover and their physical and psychological condition to set goals and outcomes.
4. **Realistic**—Set goals and expected outcomes that are realistic or relevant for patients. Consider the patient’s preferences and needs and the resources of the health care agency, family, and patient. Be aware of a patient’s physiological, emotional, cognitive, and sociocultural potential and the economic cost and resources available to reach expected outcomes in a timely manner. For example, are the patient’s cultural beliefs reflected in the goals you set? Does the patient have a family caregiver to assist with an intervention to be performed in the home? You set realistic goals and outcomes within the patient’s limitations and abilities. For example, an initial goal is “Patient will wash hands and face in 72 hours.” Your assessment and collaboration with occupational

therapy will determine whether the goal is realistic for the level of the patient's weakness. Setting realistic goals and outcomes often requires you to communicate these goals and outcomes to caregivers in other settings who will assume responsibility for patient care (e.g., home health, rehabilitation).

5. **Timed**—Set a time for each goal and outcome to be met. This helps the health care team collaborate to resolve patient problems. For example, the goal of “patient will achieve pain relief” for Mr. Lawson is complete by adding the time frame “by day of discharge.” With this goal in place, all members of the nursing team will aim to manage and reduce the patient's pain while he is hospitalized. At the time of discharge, evaluation of expected outcomes (e.g., pain-rating score, signs of grimacing, level of movement) show whether the goal was met. Always collaborate with patients to set realistic and reasonable time frames. Time frames also help you and a patient determine whether the patient is making progress at a reasonable rate. If not, you must revise the plan of care. Time frames also promote accountability in delivering and managing nursing care.

Critical Thinking in Planning Nursing Care

During planning you make clinical decisions by choosing the nursing interventions most appropriate for a patient's nursing diagnosis and collaborative problems. The actual implementation of these interventions occurs during implementation, the fourth step of the nursing process (see [Chapter 19](#)). Choosing suitable nursing interventions involves critical thinking and applying the best evidence for a patient's health problems. Nursing interventions are any treatments or actions based on clinical judgment and knowledge that nurses perform to enhance patient outcomes ([Butcher et al., 2018](#)). During planning you select interventions designed to help patients move from their present level of health to the level described in the goal and measured by the expected outcomes.

Tonya identified a PICOT question to help her select instructional interventions for enhancing Mr. and Mrs. Lawson's knowledge about infection control. She also chooses interventions based on what she has learned about the related factors behind his learning needs. Mr. Lawson has not experienced postoperative care, he is facing restrictions with which he is unfamiliar, and the condition of his incision requires wound care at home. Tonya will plan instructional topics to address postoperative risks in a way that will be relevant to Mr. Lawson and his usual routines. She learned the patient enjoys walking his dog, household maintenance, and gardening. Some of these activities will be limited or not allowed until the patient recovers. The instruction will include Mrs. Lawson since she is the patient's family caregiver.

Types of Interventions

Nursing interventions include direct and indirect care measures aimed at individual patients, families, and/or the community ([Butcher et al., 2018](#)). In addition, nursing interventions are classified as nurse-initiated, health care provider-initiated, and other provider-initiated (e.g., pharmacist, respiratory therapist) interventions ([Butcher et al., 2018](#)). Some patients require all three classifications, whereas others need only nurse- and health care provider-initiated interventions. Direct care measures are those treatments or procedures performed through interaction with a patient involving the laying on of hands. Examples include bathing, wound care, and inserting an IV catheter. Indirect care measures are those treatments or procedures performed away from a patient but on behalf of

a patient (Butcher et al., 2018). Examples include managing the patient care environment and consultation.

Nurse-initiated interventions are the **independent nursing interventions** that a nurse initiates in response to a nursing diagnosis without supervision, direction, or orders from others. Examples include positioning patients to prevent pressure injury formation, initiating early mobility protocols, offering counseling for coping, or instructing patients in side effects of medications. Nurse-initiated interventions are autonomous actions based on **scientific rationale**. Such interventions benefit a patient in a predicted way related to nursing diagnoses and patient goals (Butcher et al., 2018). Each state within the United States has a Nurse Practice Act that defines the legal scope of nursing practice (see Chapter 23). According to the Nurse Practice Acts in a majority of states, independent nursing interventions pertain to activities of daily living, health education and promotion, and counseling. *For Mr. Lawson, Tonya selects the following nursing interventions to resolve his acute pain: positioning, relaxation therapy, and exercise promotion.*

Health care provider-initiated interventions are **dependent nursing interventions** that require an order from a health care provider. The interventions are based on a physician's or nurse practitioner's choices for treating or managing a medical diagnosis. Advanced practice nurses who work under collaborative agreements with physicians or who are licensed independently by state practice acts are able to write dependent interventions. As a nurse you intervene by carrying out the health care provider's written and/or verbal orders. Administering a medication, implementing an invasive procedure (e.g., inserting a Foley catheter, starting an IV infusion), and preparing a patient for diagnostic tests are examples of health care provider-initiated interventions.

Each health care provider-initiated intervention requires specific nursing responsibilities and technical nursing knowledge. You are often the one performing the intervention, and you must know the types of observations and precautions to take for the intervention to be delivered safely and correctly. For example, when administering a medication, you are responsible for not only giving the medicine correctly but also knowing the classification of the drug; its physiological action, normal dosage, and side effects; and the nursing interventions related to its action or side effects (see Chapter 31). You are responsible for knowing when an invasive procedure is necessary, the clinical skills necessary to complete it, and its expected outcome and possible side effects. You are also responsible for adequate preparation of a patient and proper

communication of the results. You perform dependent nursing interventions, like all nursing actions, with appropriate knowledge, clinical reasoning, and good clinical judgment.

Other provider interventions, or interdependent interventions, are therapies that require the combined knowledge, skill, and expertise of multiple health care providers. Typically when you plan care for a patient, you review the necessary interventions and determine whether the collaboration of other health care disciplines (e.g., social work, rehabilitation, pharmacy) is necessary. A patient care conference with an interprofessional health care team results in selection of interdependent interventions.

In the case study involving Mr. Lawson, Tonya plans independent interventions to continue managing Mr. Lawson's pain and to begin teaching him about postoperative care activities. Among the dependent interventions Tonya plans to implement are the administration of an ordered analgesic and wound care. Tonya's other-initiated intervention involves collaborating with the unit discharge coordinator, who will help Mr. and Mrs. Lawson plan for their return home, and the home health department to ensure that the Lawsons have home health visits.

When preparing for health care provider–initiated or other provider–initiated interventions, do not automatically implement the therapies but determine whether they are appropriate for each patient. Every nurse faces an inappropriate or incorrect order at some time. The nurse with a strong knowledge base and clinical experience recognizes an error and seeks to correct it. The ability to recognize incorrect therapies is particularly important when administering medications or procedures. Errors occur in writing orders or transcribing them to a documentation form or computer screen. Clarifying an order is competent nursing practice, and it protects a patient and members of the health care team. When you carry out an incorrect or inappropriate intervention, it is as much your error as the person who wrote or transcribed the original order. You are legally responsible for any complications resulting from an error (see [Chapter 23](#)).

REFLECT NOW

Consider that Tonya has independent, dependent, and other provider-initiated interventions to perform for Mr. Lawson. How does this affect her prioritization of nursing care for the patient?

Selection of Interventions

During planning do not select interventions randomly. For example, patients with the diagnosis of *Anxiety* do not always need care involving the same interventions. You treat *Anxiety related to the uncertainty of surgical recovery* very differently from *Anxiety related to a threat to loss of job*. When choosing interventions, consider six important factors: (1) desired patient outcomes, (2) characteristics of the nursing diagnosis, (3) research base knowledge for the intervention, (4) feasibility for doing the intervention, (5) acceptability to the patient, and (6) your own competency (Butcher et al., 2018) (Box 18.1).

Box 18.1 Choosing Nursing Interventions

Desired Patient Outcomes

- Outcomes serve as the criteria against which to judge efficacy of interventions.
- Nursing Outcomes Classification (NOC) outcomes are linked to NANDA Nursing Diagnoses and ICNP diagnoses with the same label.
- NOC outcomes are also linked to Nursing Interventions Classification (NIC) interventions (Moorhead et al., 2018). Use these resources to develop care plans.

Characteristics of the Nursing Diagnosis

- Choose interventions to alter the etiological (related to) factor or causes of the diagnosis. **Example:** *Acute Pain* related to trauma of surgical incision—choose interventions for Mr. Lawson that relieve swelling and strain on the incision site (positioning and turning measures) and that lower pain reception (analgesic).
- When an etiological factor cannot change, direct the interventions toward treating the signs and symptoms (e.g., assessment findings for a diagnosis). **Example:** *Lack of Knowledge* regarding postoperative care related to inexperience with surgery and impending discharge with self-care needs—choose interventions that provide information that answers Mr. and Mrs. Lawson’s questions about recovery procedures and wound care, and that prepares them to monitor Mr. Lawson’s progress at home.
- For risk diagnoses, direct interventions at altering or eliminating the risk factors for the diagnosis. **Example:** *Risk for Infection* requires interventions for keeping Mr. Lawson’s incisional area clean and free from further trauma, and for maintaining good nutrition.

Research Base

- Be familiar with the research evidence for an intervention, and use it for the appropriate patient group and/or setting (see Chapter 5).
- Research evidence in support of a nursing intervention will indicate the effectiveness of using the intervention with certain types of patients.
- When research is unavailable, use scientific principles (e.g., infection control, learning) or consult a clinical expert about your patient.

Feasibility

- A specific intervention has the potential to interact with other interventions provided by the nurse and other health professionals.
- Know and be involved in a patient’s total plan of care.
- Consider cost of an intervention and the amount of time required for implementation (in consideration of patient’s condition). **Example:** If

you plan to get a patient up into a chair three times a day, will there be staff to assist with the transfer? Is the patient becoming weaker?

Acceptability to the Patient

- When possible, offer a patient a choice of interventions to assist in reaching outcomes.
- Promote informed choice; give patients information about each intervention and how they are expected to participate.
- Consider a patient's values, beliefs, and culture for a patient-centered approach to selecting interventions.

Capability of the Nurse

- Have knowledge of the scientific rationale for the intervention.
- Have the necessary psychosocial and psychomotor skills to complete the intervention.
- Be able to function within the specific setting to effectively use health care resources.

Modified from Butcher GM, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Elsevier.

When developing a plan of care, review resources such as the scientific literature, standard protocols or guidelines, the Nursing Outcomes Classification (NOC) and **Nursing Interventions Classification (NIC)**, policy or procedure manuals, other health professionals, or textbooks. As you select interventions, review your patient's needs, priorities, and previous experiences to select the interventions that have the best potential for achieving the expected outcomes.

Nursing Interventions Classification

Just as with the standardized NOC, the Iowa Intervention Project developed a set of nursing interventions that provides a level of standardization to enhance communication of nursing care across all health care settings and compare outcomes (Butcher et al., 2018). The NIC model includes three levels: domains, classes, and the interventions for

ease of use. The seven domains are the highest level (level 1) of the model, using broad terms (e.g., safety and basic physiological) to organize the more specific classes and interventions (Table 18.3). The second level of the model includes 30 classes or groups of related interventions, which offer useful clinical categories to reference when selecting interventions. An example of a class is *Physical Comfort Promotion*. The third level of the model includes the 565 interventions, defined as any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes (Butcher et al., 2018) (Box 18.2). The interventions can be used with various diagnostic classifications, including NANDA, ICNP, and others (Butcher et al., 2018). Each intervention then includes a variety of nursing activities from which to choose (Box 18.3) and which a nurse commonly uses in a plan of care. For example, if a patient has a nursing diagnosis of *Acute Pain*, the class of interventions that would apply to the patient is *Physical Comfort Promotion*. That class includes 18 interventions, such as aromatherapy, cutaneous stimulation, and pain management: acute. Each class has a variety of activities. The intervention for *Pain Management: Acute* has 20 recommended nursing activities, such as ensuring that the patient receives prompt analgesic care or using combination analgesics. NIC is a valuable resource for selecting appropriate interventions and activities for your patient. It is evolving and practice oriented. The classification is comprehensive, including independent and collaborative interventions. It remains your decision to determine which interventions and activities best suit your patient's individualized needs and situation.

TABLE 18.3

Examples of Nursing Interventions Classification (NIC) Taxonomy—Domains 1-4 and Accompanying Classes of Interventions

Domain 1	Domain 2	Domain 3	Domain 4
Level 1 Domains			
1. Physiological: Basic	2. Physiological: Complex	3. Behavioral	4. Safety
Care that supports physical functioning	Care that supports homeostatic regulation	Care that supports psychosocial functioning and facilitates lifestyle changes	Care that supports protection against harm
Level 2 Classes			
<p>A Activity and Exercise Management: Interventions to organize or assist with physical activity and energy conservation and expenditure</p> <p>B Elimination Management: Interventions to establish and maintain regular bowel and urinary elimination patterns and manage complications caused by altered patterns</p> <p>C Imobility Management: Interventions to manage restricted body movement and the sequelae</p> <p>D Nutrition Support: Interventions to modify or maintain nutritional status</p> <p>E Physical Comfort Promotion: Interventions to promote comfort using physical techniques</p> <p>F Self-Care Facilitation: Interventions to provide or assist with routine activities of daily living</p>	<p>G Electrolyte and Acid-Base Management: Interventions to regulate electrolyte/acid-base balance and prevent complications</p> <p>H Drug Management: Interventions to facilitate desired effects of pharmacological agents</p> <p>I Neurologic Management: Interventions to optimize neurological function</p> <p>J Perioperative Care: Interventions to provide care before, during, and immediately after surgery</p> <p>K Respiratory Management: Interventions to promote airway patency and gas exchange</p> <p>L Skin/Wound Management: Interventions to maintain or restore tissue integrity</p> <p>M Thermoregulation: Interventions to maintain body temperature within a normal range</p> <p>N Tissue Perfusion Management: Interventions to optimize circulation of blood and fluids to the tissue</p>	<p>O Behavior Therapy: Interventions to reinforce or promote desirable behaviors or alter undesirable behaviors</p> <p>P Cognitive Therapy: Interventions to reinforce or promote desirable cognitive functioning or alter undesirable cognitive functioning</p> <p>Q Communication Enhancement: Interventions to facilitate delivering and receiving verbal and nonverbal messages</p> <p>R Coping Assistance: Interventions to assist another to build on own strengths, adapt to a change in function, or achieve a higher level of function</p> <p>S Patient Education: Interventions to facilitate learning</p> <p>T Psychological Comfort Promotion: Interventions to promote comfort using psychological techniques</p>	<p>U Crisis Management: Interventions to provide immediate short-term help in both psychological and physiological crises</p> <p>V Risk Management: Interventions to initiate risk-reduction activities and continue monitoring risks over time</p>

Box 18.3 Example of an Intervention and Associated Nursing Activities

Intervention—Environmental Management: Comfort

Examples of Activities

- Create a calm and supportive environment.
- Provide a single room if it is the patient's preference to offer quiet and rest.
- Adjust room temperature to that most comfortable for the individual.
- Provide a safe and clean environment.
- Determine sources of discomfort: damp dressing, positioning on tubing, wrinkled linen.
- Position patient to facilitate comfort.

- Provide prompt attention to call lights, which should always be within reach.

From Butcher GM, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Mosby.

Systems for Planning Nursing Care

Systems exist for developing and communicating a nurse's plan of care to other nurses and collaborating health care providers. Good planning ensures the safety and quality of care (QSEN, 2018). Each of the systems that exist within health care agencies promotes continuity and use of best practices in patient care.

Health Care Agency Care Plans

In any health care setting nurses are responsible for providing a nursing plan of care for each patient. The plan of care can take several forms (e.g., individual electronic care plan or standardized care plans). With the growth of EHRs within health care institutions, documentation systems typically include software programs for creating individualized and standard nursing care plans. These programs use standardized nursing language, including nursing diagnostic language (e.g., NANDA or ICNP), and NOC and NIC taxonomies, enabling nurses to clearly identify a plan of care using appropriate nursing diagnoses, outcomes, and interventions. This enables nurses and other health care providers to quickly identify a patient's needs and situation. Although EHR plans often follow a standard format, a nurse customizes each plan to the unique needs of each patient. Standardized care plans have typically been developed by a health care agency's clinical experts based on clinical experience and scientific evidence. The standardized plans are usually based on common medical or surgical conditions. They outline the nursing care to be provided for patients with such conditions. A standardized care plan is more difficult to individualize since it is based on agreed standards of care, but such plans are believed to improve the quality of care and are easy to understand (Jansson et al., 2010).

A **nursing care plan** includes nursing diagnoses, goals and/or expected outcomes, individualized nursing interventions, and a section for evaluation findings (see Chapter 20). The plan promotes continuity of care and better communication because it informs all health care providers about a patient's needs and interventions and reduces the risk for incomplete, incorrect, or inappropriate care measures. Nurses revise a plan when a patient's status changes. Preprinted standardized care plans and EHR care plans follow a standardized format, but you can individualize each plan to a patient's unique needs. The plan gives all nurses a central document that outlines a patient's diagnoses/problems, the plan of care for

each diagnosis/problem, and the outcomes for monitoring and evaluating patient progress. The plan of care communicates nursing care priorities to nurses and other health care providers. It also identifies and coordinates resources for delivering nursing care. For example, in a care plan you list specific supplies necessary to use in a dressing change or names of clinical nurse specialists who are caring for a patient.

In hospitals and community-based settings, patients receive care from more than one nurse, health care provider, or allied health professional. Thus more institutions are developing **interprofessional care plans**, which include contributions from all disciplines involved in patient care. The interprofessional plan focuses on patient priorities and improves the coordination of all patient therapies and communication among all disciplines.

The Nursing Care Plan provided below is an example of a care plan for Mr. Lawson, using the standard format found throughout this text.

Nursing Care Plan

Anxiety

Assessment

Mr. Lawson continues to recover, but Tonya observes behaviors that suggest he is worried about recovery. She waits about an hour after administering a pain medication and enters his room. She wants to have a discussion about how the patient is emotionally coping with surgery.

Assessment Activities	Assessment Findings ^a
Ask patient to clarify concerns he has about his recovery from surgery.	Patient reports concern about his wound not healing and keeping him from being able to return to work in 6 weeks. Has difficulty explaining what to expect during recovery.
Assess patient's cognitive function.	Patient does not attend to Tonya's explanation of risk factors for infection and shows poor eye contact when discussing condition.
Observe patient's behaviors during discussion.	Patient is observed to be irritable and displays facial tension when discussing surgical recovery process.

^a **Assessment Findings** are shown in bold type.

Nursing diagnosis

Anxiety related to uncertainty over ability to return to work

Planning

Goals	Expected Outcomes (NOC) ^b
	<i>Anxiety Level</i>
Mr. Lawson will experience reduced anxiety during instruction.	Patient shows less facial tension during discussions about recovery from surgery in 24 hours. Patient maintains attention during instruction about wound care within 24 hours.
	<i>Coping</i>
Mr. Lawson will obtain a clear understanding of what to expect following surgery. Mr. Lawson will accept ability to recover as planned.	Patient will be able to describe expected progression of his wound healing by discharge. Patient will express confidence in being able to recover successfully.

^b Outcomes classification labels from Moorhead S, et al: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Mosby.

Interventions (Nic) ^c	Rationale
Anxiety Reduction	
Use a calm, reassuring approach while explaining expectations for recovery; listen attentively to patient's questions. Encourage patient to express concerns.	For patients to be able to express concerns and ask questions, they must see nurses as being nonthreatening, reliable, and willing to have a human connection (Varcarolis, 2017).
Collaborate with health care provider to provide information about wound care, normal progress of wound healing, and signs of poor wound healing as these factors affect expectations for patient's ability to return to work.	Providing information about the processes of surgical recovery helps patients handle symptoms of anxiety (Johnson, 2017).
Teach patient relaxation exercise using deep breathing and reading relaxing sentences while sitting in chair.	Systematic relaxation technique involving reading relaxing sentences significantly reduced anxiety in older patients undergoing abdominal surgery (Rejeh et al., 2013).

^c Intervention classification labels from Butcher HK, et al: *Nursing interventions classification (NIC)*, ed 7, St Louis, 2018, Mosby.

Evaluation

Evaluation Activity	Patient Response/Finding	Outcome Status
Observe Mr. Lawson’s verbal and nonverbal behavior during instructional session.	Mr. Lawson is able to attend to discussion about his recovery and shows good eye contact. Asks relevant questions and able to perform relaxation during a discussion with nurse.	Patient maintains attention during discussion; shows less facial tension.
Ask Mr. Lawson to describe how his wound is expected to heal during the next 2 weeks. Ask patient how he feels about managing his wound.	Patient able to describe normal inflammation, how wound should look and feel as it heals, and signs of infection. Patient states, “I do feel better about it. I now know what to watch out for, and I know my wife will help.”	Patient able to describe expected progression of wound healing and signs of infection. Patient expresses confidence in managing wound care.

A care plan includes a patient’s short- and long-term goals and outcomes, making it an important part of discharge planning. Thus you need to involve the family in planning care if the patient is agreeable. The family is often a resource to help a patient meet health care goals. In addition, meeting some of the family’s needs can improve a patient’s level of wellness. Discharge planning is especially important for a patient with a disability or injury that was not present before hospitalization. As a result, the patient must undergo long-term rehabilitation in the community and often will require home health care. Same-day surgeries and earlier discharges from hospitals require you to begin planning discharge from the moment the patient enters the health care agency. The complete care plan is the blueprint for nursing action.

Student Care Plans

Student care plans help you learn problem solving, the nursing process, skills of written communication, and organizational skills for nursing care. Most important, a student care plan helps you apply knowledge gained from the scientific literature and the classroom to a practice situation. Students typically write a care plan for each nursing diagnosis, using a table format with columns for assessment findings, goals, expected outcomes, nursing interventions with supporting rationales, and criteria to evaluate outcomes. Similar to health care agency care plans, the student care plan focuses on substantiating interventions with rationales so that students can learn the scientific basis for their practice. Each school uses a different format for student care plans. Often the format used is similar to

the one used by the health care agency that provides clinical experiences for the students. The following questions will help you complete a student care plan:

- *What* is the intervention? Is it evidence based and connected to an outcome?
- *When* should each intervention be implemented?
- *How* should the intervention be performed for the specific patient?
- *Who* should be involved in each aspect of intervention? Is interprofessional collaboration necessary?

Each scientific rationale that you use to support a nursing intervention needs to include a reference, whenever possible, to document the source from the scientific literature. This reinforces the importance of evidence-based nursing practice. It is also important that each intervention be specific and unique to a patient's situation. The planning of nonspecific nursing interventions results in incomplete or inaccurate nursing care, lack of continuity among caregivers, and poor use of resources. Common omissions that nurses make in writing nursing interventions include action, frequency, quantity, method, or person to perform them (see [Chapter 19](#)). These errors occur when nurses are unfamiliar with the planning process. The fifth column of the care plan includes a section for you to evaluate the plan of care: Was each goal/outcome fully or only partially met? Use the evaluation column to document whether the plan requires revision or when outcomes are met, thus indicating when a nursing diagnosis is no longer relevant to a patient's plan of care (see [Chapter 20](#)).

Care Plans for Community-Based Settings

Planning care for patients who are in community-based settings (e.g., clinics or patients' homes) applies the same principles of nursing practice as those for patients who are hospitalized. However, in community-based settings you complete a more comprehensive community, home, and family assessment. Ultimately a patient/family unit must be able to provide the majority of health care independently. You design a plan to (1) educate the patient and designated family caregiver about the necessary care techniques and precautions, (2) teach a patient and family caregiver how to integrate care within family activities, and (3) guide the patient and family caregiver on how to assume a greater percentage of care over time.

Finally, the plan includes nurses' and the patient's/family caregiver's evaluation of expected outcomes.

Hand-Off Reporting

Part of planning is transferring essential information (along with responsibility and authority) from one nurse to the next during transitions in care (e.g., end of shift, during a patient transfer to a new care unit, discharge to another setting). Hand-off reporting is a real-time process that offers a health care provider accepting the care of a patient the opportunity to ask questions to clarify and confirm important details about a patient's plan of care, patient progress, and continuing needs during the transfer of information. Quality hand-off information enables nurses to quickly recognize changes in patient status and to anticipate risks, thereby promoting safe patient care (Birmingham et al., 2015). A correctly formulated nursing care plan facilitates a hand-off report as one nurse communicates to another. You learn to focus your reports on the nursing care, treatments, patient goals, and expected outcomes documented in your care plans. During a hand-off report always provide accurate, up-to-date, and pertinent information to the next nurse assuming patient care. The hand-off is a critical time to ensure continuity of care for a patient and prevent errors or delays in providing nursing interventions. Recent research identifies approaches to use for effective hand-offs and barriers to their effectiveness (Box 18.4).

Box 18.4 Evidence-Based Practice Nursing Hand-Off Reports

PICOT Question: Does the use of bedside hand-off communication compared with standard end-of shift report between nurses in acute care settings improve patient outcomes?

Evidence Summary

A nursing hand-off during change of shift involves a nurse-to-nurse verbal exchange of information about patients. This contrasts with nurses gaining report from taped summaries or written reviews of electronic records. Hand-off reporting became a provision of care standard by The Joint Commission (TJC) in 2010, which states that a health care "organization's process for hand-off communication provides for the

opportunity for discussion between the giver and receiver of patient information” (TJC, 2017). A systematic review of scientific articles discussing nursing hand-offs identified strategies for and barriers to effective hand-offs (Riesenberg et al., 2010). A recent qualitative study found that off-going nurses’ ability to grasp a patient’s story intra-shift was essential to convey the full picture during a hand-off (Birmingham et al., 2015). This emphasizes the importance of knowing patients (see Chapter 16) and being able to understand the full context of a patient’s clinical situation. Hand-offs have multiple purposes, including information transfer, shared decision making, review of treatment options, and shared planning (Riesenberg, 2012; Birmingham et al., 2015). Carefully consider the following strategies and decide whether they are useful and fit your institutional setting and resources.

Application to Nursing Practice

Strategies for Effective Nursing Hand-Offs

- Do prework; manage your time so that you are prepared to give report and be concise.
- Provide information on how to reduce risks to patients so that the receiving nurse is better prepared to coordinate patient care, prevent errors, and detect and intervene if a patient’s status deteriorates. Patient-specific details such as abnormal vital signs or a risk for falls enable the receiving nurse to cue-in more effectively to signs and symptoms of deterioration (Birmingham et al., 2015).
- Keep report patient centered; ask questions and clarify. Use prompts to gather details.
- Standardize the process using tools, forms, and checklists, and be sure that essential information is consistently included. Written notes based on a nurse’s own structured method help him or her remember large amounts of information, stay organized, and prepare for the next end-of-shift handoff (Birmingham et al., 2015).
- During walking rounds include patient and family in discussion of goals.
- Limit interruptions, distraction, and noise.
- Acknowledge information received and transfer of responsibility (Riesenberg, 2012).

Barriers to Effective Nursing Hand-Offs

- Delaying hand-off reports is a barrier caused when nurses arrive late to work and/or off-going nurses are detained in patient care responsibilities (Birmingham et al., 2015). This results in a rushed and incomplete report.
- Communication barriers result when the receiver gets information that is inaccurate, incomplete, untimely, misinterpreted, or otherwise not what is needed (TJC, 2017).
- Social problems, including a culture of blame on the patient care unit that inhibits questioning, may result. Research has shown that off-going nurses may feel the need to defend themselves and that important information may not be communicated when nurses feel flustered, doubted, or unable to think.

Concept Maps

Because nurses care for patients who have multiple health problems and related nursing diagnoses, it is often not realistic to have a written care plan developed for each nursing diagnosis. In addition, care plans usually do not allow you to show the associations among different nursing diagnoses and different nursing interventions. A concept map is a visual representation of all of a patient's nursing diagnoses (including supportive assessment findings) that allows you to diagram interventions for each. A concept map makes a patient's diagnoses more meaningful because it shows the cognitive connections you make between diagnoses and interventions. Using a concept map has been shown to improve self-reflection and critical thinking (Daley et al., 2016). A map shows you the relationships within the nursing process (i.e., how nursing interventions often apply to more than one nursing diagnosis). Concept maps group and categorize nursing concepts to give you a holistic view of your patient's health care needs.

In [Chapter 17](#) you learned how to add nursing diagnostic labels to a concept map. When planning care for each nursing diagnosis, analyze the relationships among the diagnoses. Draw dotted lines between nursing diagnoses to indicate their relationships to one another ([Fig. 18.4](#)). It is important for you to make meaningful associations between one concept and another. The links need to be accurate, meaningful, and complete so that you can explain why nursing diagnoses are related. Mr. Lawson's

concept map has a new, fourth nursing diagnosis, *Anxiety*. Mr. Lawson's *Anxiety* and *Acute Pain* are interrelated; in addition, *Acute Pain* has an influence on his *Lack of Knowledge*.

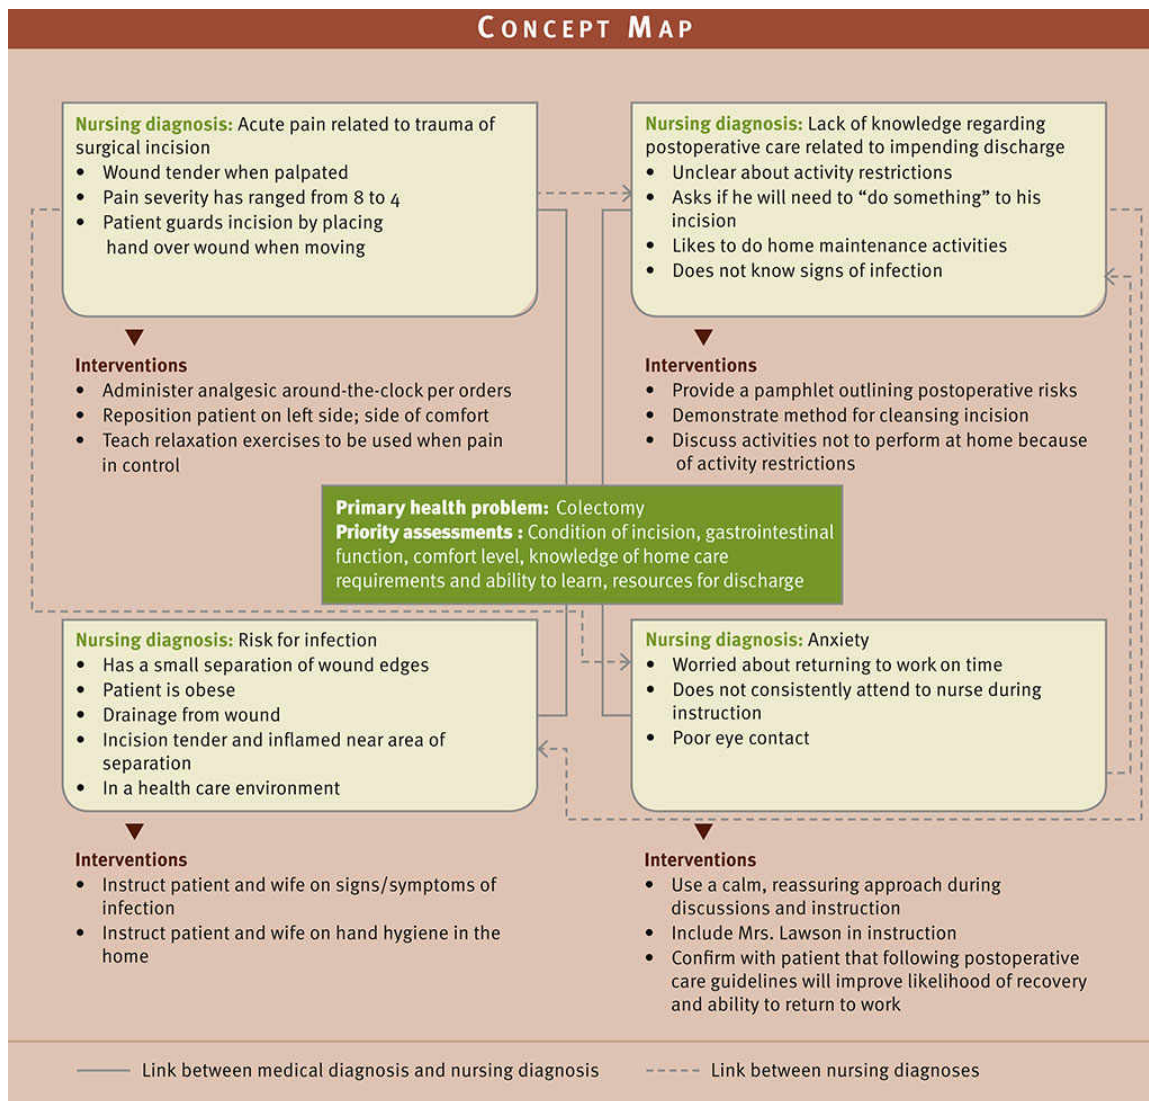

FIG. 18.4 Concept map for Mr. Lawson: Planning.

Finally, on a separate sheet of paper or on the map itself, list nursing interventions to attain the measurable outcomes for each nursing diagnosis. This step corresponds to the planning phase of the nursing process. While caring for a patient, use the map to write his or her responses to each nursing activity. Also write your clinical impressions regarding the patient's progress toward expected outcomes and the effectiveness of interventions. Keep the concept map with you throughout

the clinical day. As you revise the plan, take notes and add or delete nursing interventions. Use the information recorded on the map to document patient care. Critical thinkers learn by organizing and relating cognitive concepts. Concept maps help you learn the interrelationships among nursing diagnoses to create a unique meaning and organization of information collected.

Critical Pathways

Many hospitals are using critical pathways and enhanced recovery after surgery (ERAS) protocols to reduce variations in clinical practice, standardize evidence-based care, reduce patient length of stay, and improve patient outcomes. An ERAS incorporates evidence-based practices and includes a comprehensive projected plan for a patient's journey through the surgical process from preoperative screening through postoperative care (Woolfrey et al., 2018). For example, an ERAS will set time frames for when patients are to progress with mobility, advance diets, receive specific types of medications, and have therapies (such as IV infusion, Foley catheterization) discontinued. A pathway is a clinical management tool that provides a road map for best practices based on clinicians' expertise and clinical guidelines shaped by interprofessional teams (Hipp et al., 2016). Traditionally, critical pathways and ERAS have been developed for medical and surgical conditions that are high volume and shown to be consistent and relatively predictable (e.g., total hip replacement, low back pain, palliative care). Although pathways and recovery protocols offer an approach to a consistent workflow, it is still imperative to individualize patient care. There is a risk that clinical pathways can contribute to fragmentation of care if clinicians focus on the disease rather than on the person as a whole (Beaulieu, 2013).

REFLECT NOW

Consider three ways that the use of a critical pathway might enhance the quality of a hand-off report.

Consulting with Health Care Professionals

You consult with members of the health care team when you face problems in providing nursing or collaborative care or in delivering dependent interventions. A consultation is vital if you need to seek procedural assistance or clinical expertise for a specific problem to ensure a patient receives needed clinical interventions or insights (Stevens et al., 2015).

Consultation can occur at any time, but you usually consult most often during planning and implementation. During these times you are more likely to identify a problem requiring additional knowledge, skills, or resources. One way to initially consult is by using the ISBAR approach, a mechanism for framing conversations, especially critical ones, requiring a clinician's immediate attention and action. ISBAR is an acronym for *Identify, Situation, Background, Assessment, and Recommendation* (IHI, 2018).

Consultation requires you to be aware of your strengths and limitations as a team member. During a **consultation** you seek the expertise of a specialist such as your nursing instructor, a health care provider, or a clinical nurse specialist to identify ways to handle specific problems in patient management or the planning and implementation of therapies. A nurse in practice will consult with dietitians, therapists, or pharmacists, for example. The consultation process offers new insight and specific recommendations for a patient's plan of care. It differs from interprofessional collaboration in that it is often a onetime event. However, consultation can lead to the health care professionals involved collaborating as part of the interprofessional team.

An experienced nurse is a valuable consultant when you face an unfamiliar patient care situation, such as a new procedure or a patient presenting a set of symptoms that you cannot identify. In clinical nursing consultation helps to solve problems in the delivery of nursing care. For example, a nursing student consults a clinical specialist for wound care techniques, a home care nurse on how to help a patient adapt to restrictions in the home, or an educator for useful teaching resources. Nurses are consulted for their clinical expertise, patient education skills, or staff education skills. Be prepared before you make a consultation. Consultation is based on the problem-solving approach, and the consultant is the stimulus for change.

Building Competency in Teamwork and Collaboration

Tonya consults with the unit discharge coordinator, who will help Mr. and Mrs. Lawson plan for their return home. What does Tonya know about Mr. Lawson's situation that should be communicated to the coordinator? Identify three ways in which the coordinator might be most helpful to the Lawson family.

When to Consult

Consultation occurs when you identify a problem that you or the interprofessional team are unable to solve. However, the process requires good interprofessional collaboration. Consultation with other care providers increases your knowledge about a patient's problems and helps you learn skills and use additional resources. A good time to consult with another health care provider is when the exact problem remains unclear. An objective consultant enters a clinical situation and more clearly assesses and identifies the nature of a problem, whether it is patient, personnel, or equipment oriented. Most often you consult with health care providers who are working in your clinical area. However, sometimes you consult over the telephone ([Box 18.5](#)).

Box 18.5 Tips for Making Phone Consultations

- Have the information you need (e.g., medical record notes, medication sheets, recent nurse summary) available BEFORE you make a call.
- Assess the patient yourself before making the call. For example, when you consult with health care providers, they rely heavily on your assessment so that they can give appropriate advice.
- Address both the clinical history and patient's perspective, including social and cultural context.
- Give a diagnosis or interpretation of the patient's problem with an explanation or a summary. Use of the ISBAR approach in reporting is helpful.

- Understand why you are calling for consultation and think through some possible solutions. Your experience in caring for the patient allows you to make useful suggestions.

Data from Maison D: Effective communications are more important than ever: a health care provider's perspective, *J Home Care Hospice Professional* 24(3):178, 2006; Males T: In the dark: risks of telephone consultations, *Sessional GP* 4(2):2012, <http://www.medicalprotection.org/docs/default-source/pdfs/uk-sessional-gp/oct-2012.pdf>. Accessed June 29, 2019.

How to Consult

Begin with your own understanding of a patient's clinical problems. The following list contains important steps to follow in the consultation process.

- Identify the general problem area.
- Choose the appropriate professional, such as another nurse or social worker, to help resolve the problem.
- Provide a consultant with relevant information and resources about the problem area. Provide a summary of the problem, methods used to resolve the problem so far, and outcomes of these methods. Share information from the patient's medical record and conversations with other nurses and the patient's family.
- Do not prejudice or influence consultants. Biasing or showing prejudice blocks problem resolution. Avoid bias by not overloading consultants with subjective and emotional conclusions about the patient and the problem.
- Be available to discuss a consultant's findings and recommendations. Provide a private, comfortable atmosphere for the consultant and patient to meet. However, this does not mean that you leave the environment. A common mistake is turning the whole problem over to the consultant. The consultant is not there to take over the problem but to help you resolve it. Request the consultation for a time when both you and the consultant are able to discuss the patient's situation with minimal interruptions or distractions.
- Incorporate the consultant's recommendations into the care plan. Always give the consultant feedback regarding the outcome of the recommendations.

Successful Planning Equals Patient Participation

The process of planning is comprehensive, evidence-based, and patient outcome oriented. But critical to success is patient participation, involving patients in the decisions that affect their health care. Research has shown factors that influence patient participation include relationships with health care professionals, allocation of sufficient time for participation in planning care, and the recognition of the patient's own knowledge, physical and cognitive ability, and emotional connections, beliefs, values, and experiences in relation to health services (Shaghayegh et al., 2014). Applying the principles of planning discussed in this chapter will address these factors and ensure your patients quality care.

Key Points

- After identifying a patient's nursing diagnoses and collaborative problems, you begin planning, which involves setting priorities based on patient diagnoses and problems, identifying patient-centered goals and expected outcomes, and prescribing nursing interventions for each diagnosis.
- Symptom pattern recognition from patient assessment and certain knowledge triggers (e.g., pathophysiology or knowing patients) help you understand which diagnoses require intervention and the associated time frame during which you need to intervene.
- By ranking a patient's nursing diagnoses in order of importance and always monitoring changing signs and symptoms of patient problems, you attend to each patient's most important needs and better organize ongoing care activities.
- A goal is a broad statement that describes a desired change in a patient's condition, perceptions, or behavior, while an outcome is the measurable change needed to reach a goal.
- Goals and outcomes must be measurable so that you can measure or observe whether a change takes place in a patient's

physiological status or in a patient's knowledge, perceptions, and behavior.

- Mutual goal setting increases a patient's motivation and cooperation to achieve a goal.
- Nurse-initiated interventions are autonomous actions based on scientific rationale.
- Dependent nursing interventions require an order from a health care provider to perform.
- Care plans identify a plan of care based on a patient's appropriate nursing diagnoses, outcomes, and interventions individualized to the patient's unique needs.
- You initiate a consult when your patient is experiencing a problem you cannot solve independently as a professional nurse or when you need the advice of another health care professional to provide quality patient care.
- Interprofessional collaboration is a process that is formed between two or more people from various professional fields to achieve common goals for a patient.

Reflective Learning

Ask to spend some time shadowing an RN who is caring for a group of patients on a hospital unit. If possible, ask the RN to give a brief summary of the patients' needs. After observing the RN performing care, consider these questions:

- What was the priority nursing diagnosis or health care problem for each patient the RN cared for?
- Did any of those priorities change as you observed the RN; if so, why?
- In what way did the RN communicate or collaborate with other care providers for the benefit of his/her patients?

Review Questions

1. Setting priorities for a patient's nursing diagnoses or health problems is an important step in planning patient care. Which of the following statements describe elements to consider in planning care? (Select all that apply.)
 1. Priority setting establishes a preferential order for nursing interventions.
 2. In most cases wellness problems take priority over problem-focused problems.
 3. Recognition of symptom patterns helps in understanding when to plan interventions.
 4. Longer-term chronic needs require priority over short-term problems.
 5. Priority setting involves creating a list of care tasks.
2. Match the elements for correct identification of outcome statements with the SMART acronym terms below.

1. Specific	a. Mutually set an outcome that a patient agrees to meet.
2. Measurable	b. Set an outcome that a patient can meet based upon his or her physiological, emotional, economic, and sociocultural resources.
3. Attainable	c. Be sure an outcome addresses only one patient behavior or response.
4. Realistic	d. Include when an outcome is to be met.
5. Timed	e. Use a term in an outcome statement that allows for observation as to whether a change takes place in a patient's status.

3. A nursing student is providing a hand-off report to the RN assuming her patient's care. She explains, "I ambulated him twice during the shift; he tolerated walking to end of hall each time and back with no shortness of breath. Heart rate was 88 and regular after exercise. The patient said he slept better last night after I closed his door and gave him a chance to have some uninterrupted sleep. I changed the dressing over his intravenous (IV) site and started a new bag of D₅1/2NS. Which intervention is a dependent intervention?
 1. Providing hand-off report at change of shift

2. Enhancing the patient's sleep hygiene
3. Administering IV fluids
4. Taking vital signs

4. A nurse is assigned to care for six patients at the beginning of the night shift. The nurse learns that the floor will be short by one registered nurse (RN) as a result of a call-in. A patient care technician from another area is coming to the nursing unit to assist. Because the unit requires hourly rounds on all patients, the nurse begins to make rounds on a patient who recently asked for a pain medication. The nurse is interrupted by another registered nurse who asks about another patient. Which factors in this nurse's unit environment will affect the ability to set priorities? (Select all that apply.)

1. Policy for conducting hourly rounds
2. Staffing level
3. Interruption by staff nurse colleague
4. Type of hospital unit
5. Competency of patient care technician

5. A nursing student is providing a hand-off report to a registered nurse (RN) who is assuming her patient's care at the end of the clinical day. The student states, "The patient had a good day. His intravenous (IV) fluid is infusing at 124 mL/hr with D₅½NS infusing in left forearm. The IV site is intact, and no complaints of tenderness. I ambulated him twice during the shift; he tolerated walking to the visitors lounge and back with no shortness of breath, respirations 14, heart rate 88 after exercise. He uses his walker without difficulty, gait normal. The patient ate ¾ of his dinner with no gastrointestinal complaints. For the goal of improving the patient's activity tolerance, which expected outcomes were shared in the hand-off? (Select all that apply.)

1. IV site not tender

2. Uses walker to walk
 3. Walked to visitors lounge
 4. No shortness of breath
 5. Tolerated dinner meal
6. Which of the following factors should be considered when choosing an intervention for a patient's plan of care? (Select all that apply.)
1. The specific patient outcome against which to judge effectiveness of interventions
 2. The timing of care activities routinely conducted on the care unit
 3. The scientific evidence available in support of an intervention
 4. The amount of time required for implementation in consideration of patient's condition
 5. The patient's values and beliefs regarding the intervention
7. A nurse on a hospital unit is preparing to hand off care of a patient being discharged to a home health nurse. Match the activities on the left with the hand-off report categories on the right.

Activities	Categories
<ol style="list-style-type: none"> 1. Use a standard checklist for the report. 2. Encourage questions and clarification. 3. Offer specific information on how to reduce patient's risks. 4. Give report at time when shift has ended and other nurses are requesting information. 5. Explain how patient's discharge was delayed by insufficient numbers of staff. 6. Organize time by preparing in advance what to report. 	<ol style="list-style-type: none"> A. Strategy for Effective Hand-off B. Strategy for Ineffective Hand-off

8. A patient diagnosed with colon cancer has been receiving chemotherapy for 6 weeks. The patient visits the outpatient infusion center twice a week for infusions. The nurse assigned to the patient is having difficulty accessing the patient's intravenous (IV) port used to administer the chemotherapy. Despite attempts to flush the port, it is obstructed. This also

occurred 2 weeks earlier. What steps should the nurse follow to make a consultation with a member of the IV infusion team? (Select all that apply.)

1. Ask the IV nurse to come to the infusion center at a time when the nurse starts care for a second patient.
 2. Specifically identify the problem of port obstruction, and attempt to flush the port to resolve the problem.
 3. Explain to the IV nurse the frequency in which this port has obstructed in the past.
 4. Tell the IV nurse the problem is probably related to the physician who inserted the port.
 5. Describe to the IV nurse the type and condition of the port currently in use.
9. A nurse assesses a 78-year-old patient who weighs 108.9 kg (240 lb) and is partially immobilized because of a stroke. The nurse turns the patient and finds that the skin over the sacrum is very red and the patient does not feel sensation in the area. The patient has had fecal incontinence on and off for the past 2 days. The nurse identifies the nursing diagnosis of *Risk for Impaired Skin Integrity*. Which of the following outcomes is appropriate for the patient?
1. Patient will be turned every 2 hours within 24 hours.
 2. Patient will have normal formed stool within 48 hours.
 3. Patient's ability to turn self in bed improves.
 4. Erythema of skin will be mild to none within 48 hours.
10. An 82-year-old patient who resides in a nursing home has the following three nursing diagnoses: *Risk for Fall*, *Impaired Physical Mobility related to pain*, and *Imbalanced Nutrition: Less Than Body Requirements related to reduced ability to feed self*. The nursing staff identified several goals of care. Match the goals on the left with the appropriate outcome statements on the right.

Goals	Outcomes
1. ___ Patient will ambulate independently in 3 days.	a. Patient expresses fewer nonverbal signs of discomfort within 24 hours.
2. ___ Patient will be injury free for 1 month.	b. Patient increases caloric intake to 2500 calories daily.
3. ___ Patient will achieve 5-pound weight gain in 1 month.	c. Patient walks 20 feet using a walker in 24 hours.
4. ___ Patient will achieve pain relief by discharge.	d. Patient identifies barriers to remove in the home within 1 week.

Implementing Nursing Care

OBJECTIVES

- Explain the relationship between nursing interventions and nursing's scope of practice.
- Explain the benefits of standard nursing interventions.
- Describe implications for use of standard care bundles.
- Describe the association between critical thinking and selecting nursing interventions.
- Explain a nurse's role in the implementation process.
- Explain how a nurse balances organizational and patient priorities in time management.
- Describe how nurses anticipate and prevent complications.
- Define the three implementation skills as they relate to direct and indirect nursing interventions.
- Describe common forms of direct and indirect nursing interventions.

KEY TERMS

Activities of daily living (ADLs), p. 265

Adverse reaction, p. 267

Care bundle, p. 259

Clinical practice guideline, p. 258

Counseling, p. 266

Direct care, p. 257

Implementation, p. 257

Indirect care, p. 257

Instrumental activities of daily living (IADLs), p. 265

Interprofessional care plans, p. 267

Lifesaving measures, p. 266

Nursing intervention, p. 257

Patient adherence, p. 268

Scope of nursing practice, p. 257

Standing order, p. 259

*You first met Tonya and Mr. Lawson in [Chapter 15](#). Mr. Lawson is a 68-year-old patient who had abdominal surgery for a colon resection and is preparing to be discharged soon from the hospital. His nurse Tonya developed a plan of care to address four different nursing diagnoses: **Acute Pain**, **Anxiety**, **Lack of Knowledge**, and **Risk for Infection**. Mr. Lawson is interested in learning about his postoperative activity restrictions and in being able to care for his incision, which had a small separation. However, he also shared with Tonya that he is worried about his wound healing and being able to return to work after surgery. Tonya and the other nursing staff have consistently applied the nursing process. Tonya identified the diagnosis of **Anxiety** while planning for Mr. and Mrs. Lawson's education. During implementation Tonya, along with her health care colleagues, will provide planned interventions to achieve the goals and expected outcomes identified in Mr. Lawson's plan of care. Critical thinking, which includes good clinical decision making, is important for the successful implementation of nursing interventions.*

Implementation, the fourth step of the nursing process, begins after you develop a patient's plan of care. It involves the performance of nursing and collaborative interventions necessary to achieve the goals and expected outcomes needed to support or improve a patient's health status. A **nursing intervention** is any treatment based on clinical judgment and knowledge that a nurse performs to enhance patient outcomes ([Butcher et al., 2018](#)). Nursing interventions include direct and indirect care measures, which are either nurse-initiated, physician (health care provider)-initiated, or other provider-initiated (see [Chapter 18](#)). Ideally a nurse chooses nursing interventions that are evidence based (see [Chapter 5](#)), providing the most current, scientifically supported, up-to-date approaches for delivering patient-centered care.

Direct care interventions are treatments nurses provide through interactions with patients or a group of patients (Butcher et al., 2018). For example, a patient receives direct intervention in the form of medication administration, insertion of a urinary catheter, discharge instruction, or counseling during a time of grief. **Indirect care** interventions are treatments performed away from a patient but on behalf of the patient or group of patients (e.g., managing a patient’s environment [e.g., safety and infection control]), documentation, and interprofessional collaboration (Butcher et al., 2018) (Fig. 19.1).

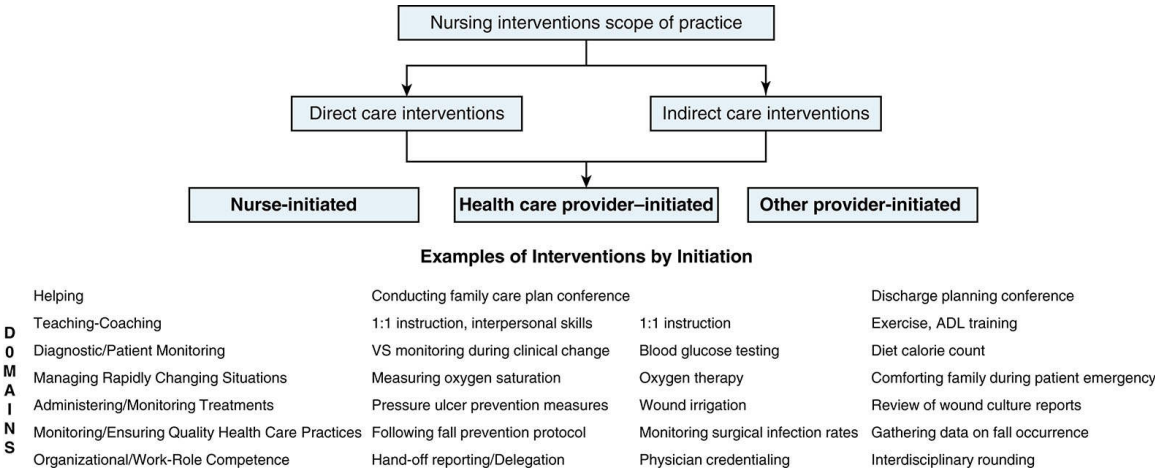

FIG. 19.1 Nursing interventions scope of practice.

Within the **scope of nursing practice**, the [American Nurses Association \(ANA, n.d.\)](#) describes what a nurse is licensed to perform: “Nursing is the protection, promotion, and optimization of health and abilities; prevention of illness and injury; facilitation of healing; alleviation of suffering through the diagnosis and treatment of human response; and advocacy in the care of individuals, families, groups, communities, and populations.” The professional scope of practice identifies the nature and intent of the ways nurses intervene for patients, described by [Benner \(1984\)](#) as the domains of practice ([Box 19.1](#)). How do the scope of practice, nursing domains, and nursing interventions relate? Here is an example: for a nurse to promote a patient’s health status (scope of practice), he or she provides a teaching-coaching function (domain of practice) by delivering 1:1 patient education sessions (direct care).

Box 19.1 Domains of Nursing Practice

- The Helping Role
- The Teaching-Coaching Function
- The Diagnostic and Patient-Monitoring Function
- Effective Management of Rapidly Changing Situations
- Administering and Monitoring Therapeutic Interventions and Regimens
- Monitoring and Ensuring the Quality of Health Care Practices
- Organizational and Work-Role Competencies

From Benner P: From novice to expert, Menlo Park, CA, 1984, Addison Wesley.

The challenges and complexities within health care organizations can make it difficult for nurses to fully fulfill the scope and domains of practice (see [Chapter 2](#)). Nurses are required to have effective organizational skills and to maintain competencies in advanced nursing care. In addition, nurses must manage conflict and effectively advocate for patients in challenging interprofessional relationships. Thus it is important for implementation to be patient-centered. Nursing is an art and a science. It is not simply a task-based profession. You must learn to intervene for a patient within the context of his or her unique situation. Consider these factors during implementation: Who is the patient? How do a patient's attitudes, values, and cultural background affect how you provide care? What does an illness mean to a patient and his or her family? Which clinical situation requires you to intervene? How does a patient perceive the interventions that you will deliver? In what way do you best support or show caring as you intervene? The answers to these questions enable you to deliver care compassionately and effectively with the best outcomes for your patients.

Standard Nursing Interventions

Health care settings offer opportunities for nurses to create and individualize patients' care plans. Although it is critical for each patient to have his or her unique set of interventions, many health care systems have mechanisms for developing standard interventions for more common health care problems. Standard interventions allow nurses to intervene more quickly and appropriately. When clinical expertise and scientific evidence are used to form standard interventions, nurses are able to deliver the most clinically effective care to improve patient outcomes (see [Chapter 5](#)). The creation of standard interventions is supported in health information documentation systems. Using standard interventions helps capture patient care information that can be shared across disciplines and care settings, making it easier to measure the quality of care delivered and supporting ongoing research and analysis ([MBL Technologies, 2017](#)).

As a nurse, you are accountable for individualizing standardized interventions based on your patients' needs and preferences. Nurse- and health care provider-initiated standard interventions include clinical practice guidelines and protocols, care bundles, standing orders, Nursing Interventions Classification (NIC) interventions, and standards of practice. The ANA defines standards of professional nursing practice, while the Quality and Safety Education for Nurses (QSEN) defines skills competencies ([QSEN, 2019](#)). These standards are authoritative statements of the duties that all registered nurses (RNs) are expected to perform competently, regardless of role, patient population they serve, or specialty ([ANA, 2010](#)) (see [Chapter 1](#)).

Clinical Practice Guidelines and Protocols

A **clinical practice guideline** or protocol is a systematically developed set of statements about appropriate health care for specific health care problems or clinical situations (e.g., pressure injury prevention, DVT prevention, fall prevention). Evidence-based research provides the basis for sound clinical practice guidelines and associated recommendations that often improve quality of care. A nurse individualizes nursing interventions for each patient.

Clinicians within a health care agency formally review the scientific literature and their own standard of practice to develop guidelines and protocols to improve the standard of care at their agency. For example, a hospital develops a rapid-assessment medical protocol to improve the

identification and early treatment of patients suspected of having a stroke or sepsis. Some guidelines are already developed by professional health care organizations. In the case of nursing clinical guidelines, the Association of Critical Care Nurses, the Oncology Nursing Society, and the University of Iowa Hartford Center developed evidence-based practice (EBP) guidelines for their specialties.

Ongoing review of the scientific literature and best practices within a health care organization may result in the development of care bundles, a type of clinical guideline. A **care bundle** is a group of interventions related to a disease process or condition. The interventions, when implemented together, result in better patient outcomes than when the interventions are implemented individually (Box 19.2). Care bundles improve quality of care while preventing the most common complications associated with their conditions or diagnoses (Goldstone et al., 2015). You will implement care bundle interventions during your clinical experiences.

Box 19.2 Evidence-Based Practice Use of Care Bundles

PICOT Question: Does the use of care bundles compared with standard practice improve hospitalized patients' recovery outcomes?

Evidence Summary

Care bundles are a set of evidence-based interventions performed collectively and reliably to improve the quality of patient care (Lavallée et al., 2017). Common care bundles include those for deep vein thrombosis, ventilator-associated pneumonia, and surgical site infection (SSI) prevention. A review of studies designed to reduce SSI involved use of core interventions such as antibiotic administration, appropriate hair removal, glycemic (blood glucose) control, and temperature management. The SSI rate in the bundle groups was 7.0% compared with 15.1% in a standard care group. The research showed that surgical care bundles help reduce the risk of SSI compared with standard care (Tanner et al., 2015). In a review of studies designed to better manage chronic obstructive pulmonary disease it was found that the use of discharge bundles reduced hospital readmissions, but there was insufficient evidence that care bundles influenced long-term mortality (Ospina et al., 2017). Care bundles are becoming more common in acute care hospitals and show promising benefits. However, clinical staff do not always perform all interventions within a bundle (Juknevičius et al., 2012). General benefits of care bundles

include simplification of clinical decisions, reduced omissions of interventions, and reduced errors in medical decision making.

Application to Nursing Practice

The following are recommendations when implementing care bundles (Camporota and Brett, 2011).

- Perform the full set of interventions in a care bundle.
- Use clinical judgment when practicing within guidelines of a care bundle.
- If the interventions in a bundle are scientifically sound, perform the interventions, but if the evidence is conflicting, use a critical common-sense approach.
- Consistent use of care bundles for routine and common practices is probably beneficial and unlikely to cause significant harm to patients.
- The optimal balance between care bundle interventions versus individualized care will vary among institutions, depending on staffing and the availability of new research.

Advanced practice registered nurses (APRNs), who provide primary care for patients in a variety of settings, frequently follow diagnostic and treatment protocols for their interventions. A collaborative agreement with a physician identifies protocols for the medical conditions that APRNs are permitted to treat, such as controlled hypertension, and the types of treatment that they are permitted to administer, such as antihypertensive medications. These protocols vary by physician and APRN. APRNs are also able to act independently, developing and applying clinical protocols that outline independent nursing interventions. Databases such as Up-to-Date and the Cochrane library provide valuable treatment guidelines supported by rigorous systematic reviews to provide evidence-based treatment guidelines.

Standing Orders

A **standing order** is a preprinted document containing medical orders for routine therapies, monitoring guidelines, and/or diagnostic procedures for specific patients with identified clinical problems. A standing order directs patient care in a specific clinical setting. Licensed prescribing health care providers in charge of care at the time of implementation approve and sign standing orders. These orders reflect health care provider treatment

preferences and are common in critical care settings and other specialized acute care settings where patients' needs change rapidly and require immediate attention. An example of such a standing order is one specifying certain medications such as diltiazem (Cardizem) and amiodarone (Cordarone) for an irregular heart rhythm. After assessing a patient and identifying the irregular rhythm, the critical care nurse gives the specified medication without first notifying the health care provider because his or her standing order covers the nurse's action. After completing a standing order, the nurse notifies the health care provider. Standing orders are also common in community health settings, where nurses face situations that do not permit immediate contact with a health care provider. Standing orders give nurses legal protection to intervene appropriately in the best interests of patients with rapidly changing needs.

REFLECT NOW

What do you see as a limitation of standard orders when compared with clinical practice guidelines?

Nursing Interventions Classification (NIC) Interventions

The NIC system developed by the University of Iowa differentiates nursing practice from that of other health care disciplines ([Box 19.3](#)) by offering a language that nurses can use to identify treatments nurses perform, organize this information into an understandable structure, and provide a language to communicate with patients, families, communities, and all health care providers ([Butcher et al., 2018](#)). The NIC interventions offer a level of standardization to enhance communication of nursing care across settings and to compare outcomes. Many health care information systems incorporate the NIC system. By using NIC you will learn the common interventions recommended for various nursing diagnoses. [Chapter 18](#) describes the NIC system in more detail.

Box 19.3 Purposes of Nursing Interventions

Classification (NIC)

1. Standardize the language nurses use to describe sets of actions in delivering patient care.
2. Expand nursing knowledge about connections among nursing diagnoses, treatments, and outcomes.
3. Develop a nursing language for software of health care information systems.
4. Provide a standard set of interventions for effectiveness research, productivity measurement, and competency evaluation.
5. Link with the classification systems of other health care providers.

From Butcher HK, et al: Nursing interventions classification (NIC), ed 7, St Louis, 2018, Elsevier.

Standards of Practice

Nurses use the ANA Standards of Professional Nursing Practice ([ANA, 2010](#)) as evidence of the standard of care provided to patients (see [Chapter 1](#)). The standards are formally reviewed on a regular basis. The newest standards include competencies for establishing professional and caring relationships, using evidence-based interventions and technologies, providing ethical holistic care across the life span to diverse groups, and using community resources and systems. The standards emphasize implementing a timely plan following patient safety goals ([ANA, 2010](#)).

Quality and Safety Education for Nurses (QSEN)

The QSEN Institute established standard competencies in knowledge, skills, and attitudes (KSAs) for the preparation of future nurses ([QSEN, 2019](#)). The goal of QSEN is to prepare nurses so that they can continuously improve the quality and safety of the health care systems within which they work. Examples of QSEN skills include providing patient-centered care with sensitivity and respect for the diversity of the human experience, initiating effective treatments to relieve pain and suffering, and participating in building consensus or resolving conflict in the context of patient care (QSEN, 2019).

Critical Thinking in Implementation

Selecting nursing interventions for your patient is part of clinical decision making. Strong clinical reasoning and decision-making skills help you accurately identify appropriate nursing interventions for a patient's specific nursing diagnoses. The critical thinking model discussed in [Chapter 15](#) is a framework for how to make decisions when implementing nursing care. You learn how to implement nursing care by applying appropriate knowledge, experience, attitudes, and standards of care ([Fig. 19.2](#)). Delivering nursing interventions is complex. It is based on the knowledge you have about a patient and the social context of the health care setting where you work. Interprofessional relationships between nurses and health care providers contribute to nursing judgments for understanding a patient's problems and intervening effectively. The context in which you deliver care to each patient and the many interventions required result in decision-making approaches for each clinical situation. Critical thinking allows you to consider the complexity of interventions, changing priorities, alternative approaches, and the amount of time available to act. Always prepare well before providing any intervention.

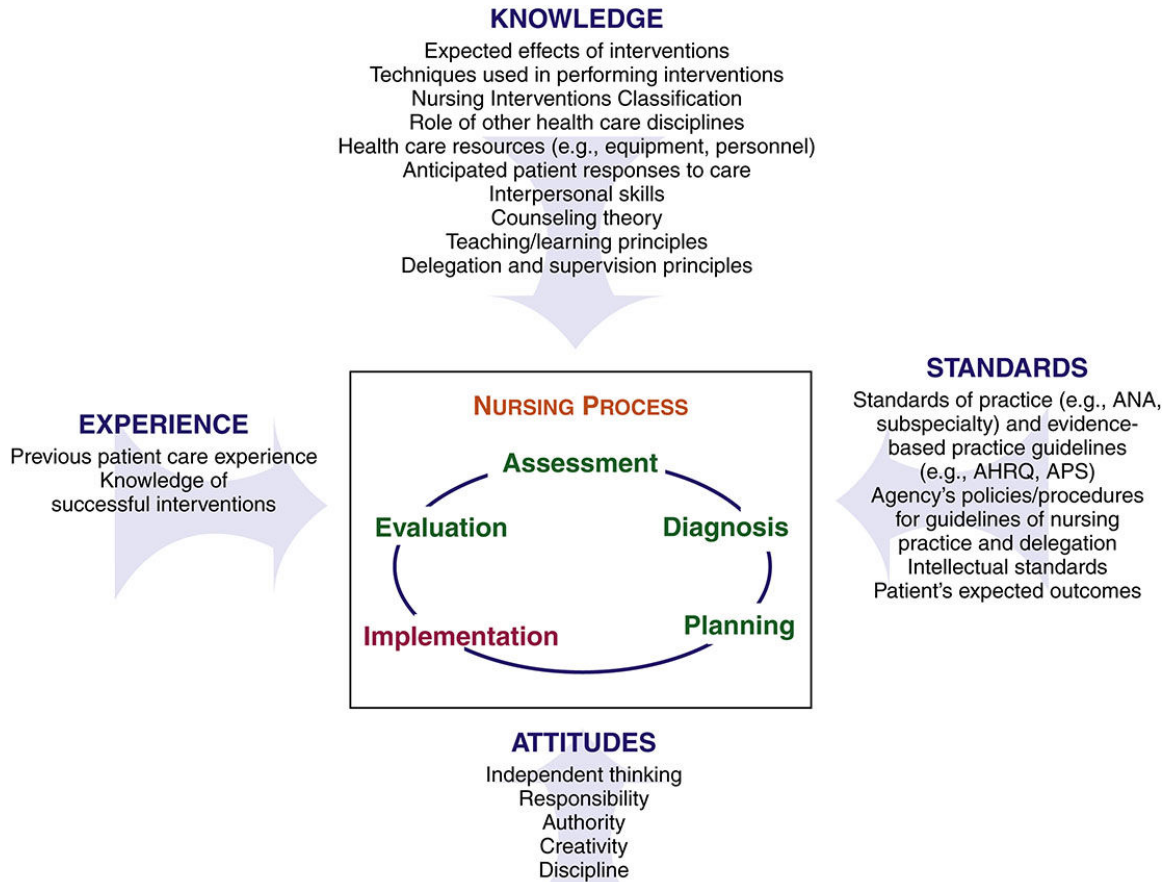

FIG. 19.2 Critical thinking and the process of implementing care. *AHRQ*, Agency for Healthcare Research Quality; *ANA*, American Nurses Association; *APS*, American Pain Society.

*Tonya identified four relevant nursing diagnoses for Mr. Lawson: **Acute Pain** related to trauma of surgical incision, **Lack of Knowledge** regarding postoperative care related to inexperience with surgery, **Risk for Infection**, and **Anxiety** related to uncertainty over ability to return to work. The diagnoses are interrelated, and sometimes a planned intervention (e.g., promoting relaxation exercises) treats or modifies more than one of the patient's health problems (anxiety and acute pain). Tonya applies critical thinking and uses her time with Mr. Lawson wisely by anticipating his priorities, applying the knowledge she has about his problems and the interventions planned, and implementing care strategies skillfully.*

Apply what you have learned during previous clinical experiences in performing specific interventions. Consider which interventions have

worked before and which have not worked in previous clinical situations. With experience you become more proficient in anticipating what to expect in a given clinical situation and how to modify your approach. Be aware of professional and agency standards of practice, which offer guidelines for selection of interventions, their frequency and timing, and whether interventions can be delegated. Also be aware of a patient's changing condition and what you would expect after caring for patients with similar conditions. Then adjust the interventions based on ongoing evaluation (see [Chapter 20](#)). Maintain organization and time management skills to provide safe and effective patient care (see [Chapter 21](#)).

Exercise critical judgment and decision making while delivering each intervention: think before you act. Consider the resources you have and the scheduling of activities in a health care setting, which often influence when and how to complete an intervention. You are responsible for having the necessary knowledge and clinical competency to safely and effectively perform interventions for your patients. Follow these tips for making decisions during implementation:

- Review the set of all possible nursing interventions for a patient's problem (e.g., for Mr. Lawson's pain Tonya considered analgesic administration, positioning and splinting, progressive relaxation, and other nonpharmacological approaches).
- Review all possible consequences associated with each possible nursing action (e.g., Tonya considers that the analgesic will relieve pain; have little or insufficient effect; or cause an adverse reaction, including sedating the patient and increasing the risk of falling).
- Determine the probability of all possible consequences (e.g., if Mr. Lawson's pain continues to decrease with analgesia and positioning and there have been no side effects, it is unlikely that adverse reactions will occur, and the intervention will be successful; however, if the patient continues to remain highly anxious, his pain may not stay relieved, and Tonya needs to consider an alternative).
- Judge the value of the consequence to the patient (e.g., if the administration of an analgesic is effective, Mr. Lawson will probably become less anxious and more responsive to postoperative instruction and counseling about his anxiety).

Building Competency in Evidence-Based Practice

Explore the scientific literature for current evidence on what Tonya might provide to best manage Mr. Lawson's anxiety. What evidence-based strategies can you identify that reduce anxiety with the outcome of improving attention and learning?

As you perform a nursing intervention, apply intellectual standards, which are the guidelines for rational thought and responsible action (see [Chapter 15](#)). *For example, before Tonya begins to teach Mr. Lawson, she considers how to make her instructions relevant, clear, logical, and complete to promote patient learning.* A critical thinker applies critical thinking attitudes when intervening. For example, show confidence in performing an intervention. When you are unsure of how to perform a procedure, be responsible. Seek assistance from others. Confidence in performing interventions builds trust with patients. Creativity and self-discipline are attitudes that guide you in reviewing, modifying, and implementing interventions. As a beginning nursing student, seek out supervision from instructors or experienced nurses or review agency policy and procedures to guide you in the decision-making process for implementation.

Implementation Process

Preparation for implementation ensures more efficient, safe, and effective nursing care. Perform these five preparatory activities: (1) reassess the patient, (2) review and revise the existing nursing care plan, (3) organize resources and care delivery, (4) anticipate and prevent complications, and (5) implement nursing interventions.

Tonya returns to Mr. Lawson's room to begin instruction. His wife is present, and Mr. Lawson reports that his incisional pain is currently a level of 3. Tonya helps the patient sit up in a chair. She sets up the teaching program on the hospital educational TV system and the evidence-based booklets she wants to use to prepare the patient and his wife for infection control, wound care, and activity restrictions in the home. Because Mr. Lawson still has concerns about returning to work, Tonya wants to incorporate discussion about wound care with expected postoperative recovery. Tonya sees the opportunity of using Mr. Lawson's desire to return to work to increase the likelihood of his adherence to postoperative restrictions. If Mrs. Lawson understands how she can help Mr. Lawson in recovery, positive outcomes should be achieved.

Reassessing a Patient

Assessment is a continuous process that occurs each time you interact with a patient. It involves the collection of new data. Reassessment is not the same as evaluating care or determining a patient's response to an intervention (see [Chapter 20](#)). Instead, it is the gathering of additional information to ensure that the plan of care is still complete, current, and appropriate. When you collect new data about a patient, you sometimes identify a new nursing diagnosis or determine that additional interventions might be necessary for not only the new diagnosis but also existing diagnoses. Creating a concept map helps you better understand the relationship between different nursing diagnoses and interventions appropriate to a patient's care ([Fig. 19.3](#)). During the initial phase of implementation reassess the patient to confirm that you have selected appropriate interventions. The reassessment helps you decide if the proposed nursing actions are still appropriate for a patient's level of wellness. *For example, Tonya begins to talk with Mr. and Mrs. Lawson about wound care and the patient's activity restrictions. Mrs. Lawson shares that Mr.*

Lawson’s employer called to ask how he was doing. Tonya notices that Mr. Lawson begins to show more anxiety; as Tonya explains restrictions on lifting, the patient is not able to teach back what he can and cannot do. Tonya decides to redirect the discussion. She says to Mr. Lawson, “Let’s talk about going back to work. Tell me more about when they expect you to return and what your work actually involves.” Tonya realizes that to be effective with instruction she needs an attentive learner. Gaining more detail about the patient’s work will help him express his concerns while at the same time allow Tonya to explain how activity restrictions fit into daily routines.

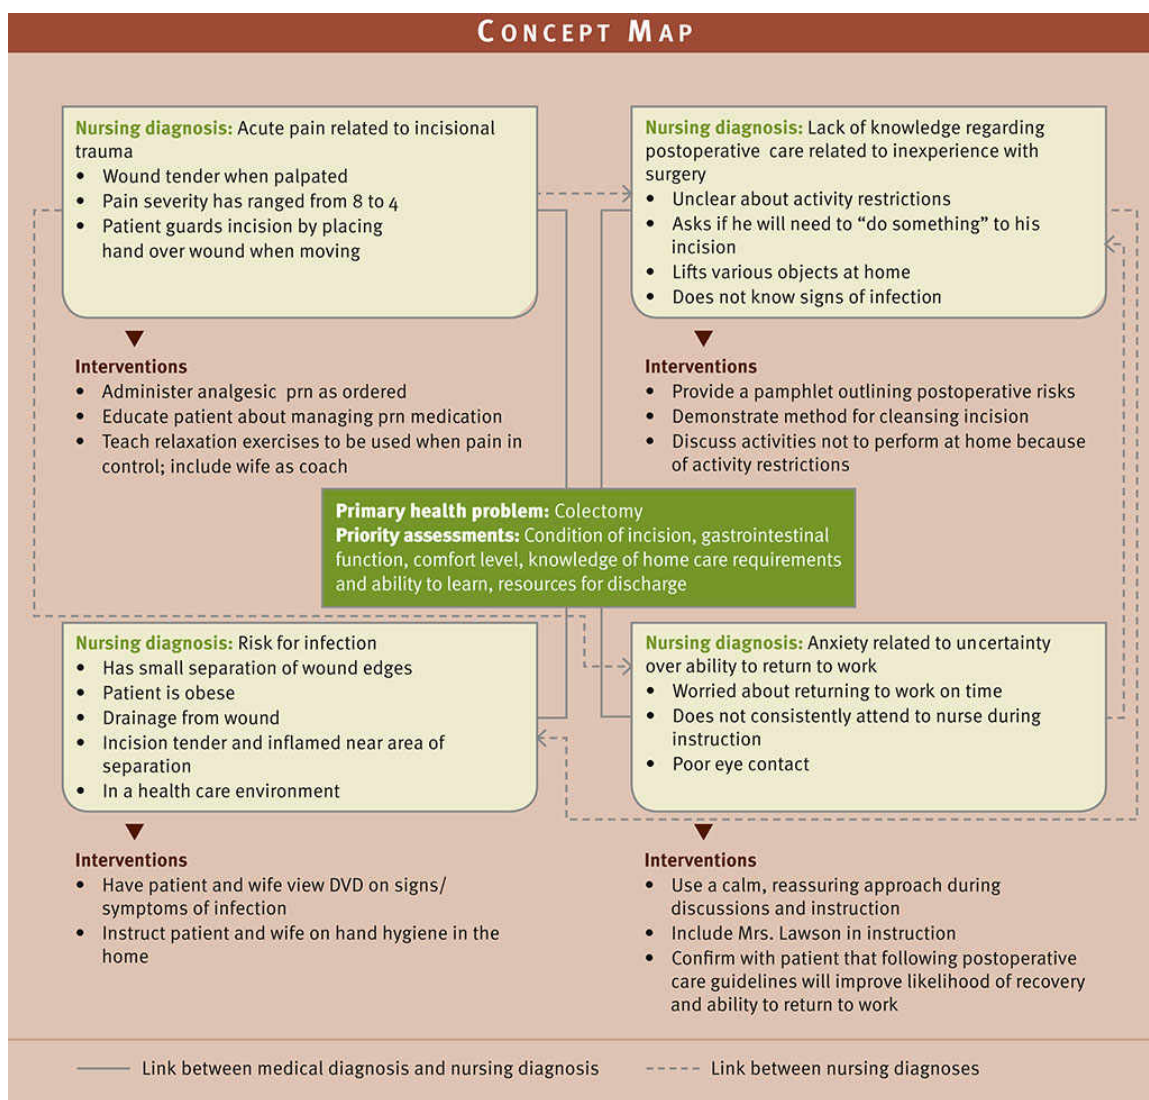

FIG. 19.3 Concept map for Mr. Lawson: Implementation.

Reviewing and Revising the Existing Nursing Care Plan

After you reassess a patient and determine there is a need to add to or modify the plan of care, you revise the care plan. An out-of-date, incomplete, or incorrect care plan compromises the quality of nursing care. When you gather evaluation data (see [Chapter 20](#)) to determine if previously selected interventions were successful and whether outcomes were met, similar types of revisions can be made. Review and revision of a plan enable you to provide more appropriate and timely nursing interventions to best meet a patient's needs. Modification of an existing written care plan includes four steps:

1. Revise data in the assessment column to reflect the patient's current status. Date any new data to inform other members of the health care team of the time that the change occurred.
2. Revise the nursing diagnoses, goals and outcomes. Add any new nursing diagnoses that have been identified and select appropriate goals and outcomes. For existing nursing diagnoses, revise related factors and the patient's goals, outcomes, and priorities as necessary. Date any revisions.
3. Select or revise specific interventions that correspond to the new nursing diagnoses or that are necessary for existing diagnoses. Be sure that revisions reflect the patient's present status.
4. Choose the methods of evaluation that will be used to determine whether the patient achieves his or her outcomes.

As Tonya continues to prepare Mr. Lawson for discharge, she evaluates his pain status. His pain has been controlled well on around-the-clock analgesics and use of relaxation. Tonya reassesses whether Mr. Lawson has ever taken analgesics at home and what works best. In consultation with the physician and in preparation for discharge, the physician decides to discontinue the around-the-clock analgesic and orders an analgesic prn instead. Tonya plans to explain to Mr. and Mrs. Lawson how best to take a prn medication (see [Chapter 25](#)). Tonya also decides to include Mrs. Lawson as a coach to facilitate relaxation exercises for Mr. Lawson.

Preparing for Implementation

The organization of time and resources is an important part of implementation of nursing care. Always be sure that a patient is physically and psychologically ready for any interventions or procedures.

Time Management

Providing patient-centered care is the focus of your nursing practice. You will practice within work environments that are part of the sociocultural context of a health care organization (see [Chapter 21](#)). These are busy environments, and you will assume dual roles: a patient care provider and an organizational employee. In this dual role you need to be aware of the organization's goals of efficiency and cost control. However, you need to competently provide timely, thoughtful, safe, and efficient care. The ability to manage care in a timely way conveys caring and concern to your patients. Poor patient care results when you are hurried, experience interruptions, or are disorganized. Time devoted to nursing care has three components: physical (the physical amount of time consumed in the completion of nursing activities), psychological (what nursing care patients experience and how they experience it), and sociological (the sequential ordering of events within the daily routines of a practice setting) ([Jones, 2010](#)). All components of time occur within the context of an organization and the resources available. As a new nurse, understand that the decisions you make about how your time is allocated, prioritized, and sequenced are always interpreted by the patients you serve ([Jones, 2010](#)). Be aware of factors affecting time with patients and apply time-management principles (see [Chapter 21](#)).

Equipment

Most nursing procedures require some equipment or supplies. Before performing an intervention, decide which supplies you need and determine their availability. Is the equipment in working order to ensure safe use, and do you know how to use it? Place supplies in a convenient location to provide easy access during a procedure. Keep extra supplies available in case of errors or mishaps, but do not open them unless you need them. This controls health care costs, allowing you to be a fiscally responsible member of the health care team. After a procedure return any unopened supplies to storage areas.

REFLECT NOW

Think about a procedure you recently performed in the lab or with an assigned patient. Did you manage your time well in preparing for the skill? What might you have done differently?

Personnel

Nursing care practice models determine how nursing personnel are organized to deliver patient care, including staff RNs, auxiliary staff such as assistive personnel (APs), and RNs in special roles (e.g., nurse specialists). A practice model reflects nursing values that exemplify the culture of a health care organization ([Chamberlain et al., 2013](#)). Common values shared among models include nursing autonomy; empowerment; and cost-effective, quality care. A practice model designates a nurse's role and accountability to patients and other members of the nursing team. Traditional models include team and primary nursing. More recently patient- and family-centered care models and case management have been adopted by nursing departments. [Chapter 21](#) offers details on the various models of care.

Regardless of the practice model, as a nurse you are responsible for deciding whether to perform an intervention, delegate it to an unlicensed member of the nursing team, or have an RN colleague assist you. Your ongoing assessment of each patient, the priorities of care (see [Chapter 18](#)), the activities occurring in the workplace, and not an intervention alone direct your decision about delegation. You have a legal duty to follow delegation guidelines and only delegate interventions within the delegate's training and ability according to the state Nurse Practice Act.

Patient care staff work together as patients' needs demand it. If a patient makes a request such as use of a bedpan or assistance in feeding, help the patient if you have time rather than trying to find an AP who is in a different room. Nursing staff respect colleagues who show initiative, collaborate, and communicate with one another on an ongoing reciprocal basis as patients' needs change. When interventions are complex or physically difficult, you will need assistance from colleagues. For example, a nurse will be more effective in changing a dressing for a large gaping

wound when an AP can assist with patient positioning and handing off supplies.

Environment

A patient's care environment, especially in hospitals, rehabilitation units, and skilled care facilities, needs to be safe and conducive to implementing therapies. Patient safety is your first concern. You can make the environment safer by removing clutter and unnecessary furniture or equipment, creating clear paths for patients to ambulate, and making sure patients' personal items are easily accessible when they lie in bed. If a patient has sensory deficits, physical disabilities, or an alteration in level of consciousness, it is especially important to arrange the environment to prevent injury. For example, provide a patient's assistive devices (e.g., walker or eyeglasses), rearrange furniture and equipment when ambulating a patient, or make sure that the water temperature is not too warm before a bath. Patients benefit most from nursing interventions when surroundings are compatible with care activities. When you need to expose a patient's body parts, do so privately by closing room doors or curtains because the patient will then be more relaxed. Ask visitors to leave as you complete care. Reduce distractions during teaching to enhance a patient's learning opportunities.

The environment influences the ability of a patient to heal and recover. Hospitals and other health care settings are using evidence-based design to create healing environments ([Huisman et al., 2012](#)). This concept is being applied with the building and renovation of hospitals and other care settings. How a nursing unit is designed impacts both patients and care providers. For example, a well-designed hospital unit can contribute to patient outcomes through no errors, safety and security, control, privacy, and comfort ([Huisman et al., 2012](#)) ([Box 19.4](#)).

Box 19.4 Physical Environmental Factors That Promote Patient Healing

- Standardization of patient rooms and equipment for making routine tasks simpler, thus decreasing errors.
- Improving light illumination in areas where medications are dispensed.

- Features of a patient room and bath that reduce falls: no slippery floors, appropriate door openings, correct placement of rails and accessories, correct toilet and furniture height, single-bed rooms, easy-to-clean surfaces, automated sinks, and smooth edges in rooms (for easier cleaning).
- Self-supporting systems, such as control over the position of the bed, control over the temperature, control over the lights (including dimmers), control over the sound (music and television), and control over the natural light.
- Privacy and single-patient rooms

Adapted from Huisman ERCM, et al : Healing environment: a review of the impact of physical environmental factors on users, Building and Environment 58:70, 2012.

Patient

Make sure that your patients are physically and psychologically comfortable before you implement care. Physical symptoms such as nausea, dizziness, fatigue, or pain often interfere with a patient's full concentration and ability to cooperate. Offer comfort measures before initiating interventions to help patients participate more fully. If you need a patient to be alert, administer a dose of pain medication strong enough to relieve discomfort but not to impair mental faculties (e.g., ability to follow instruction and communication). If a patient is fatigued, delay ambulation or transfer to a chair until after he or she has had a chance to rest. Also consider a patient's level of endurance, and plan only the amount of activity that he or she is able to tolerate comfortably.

Awareness of a patient's psychosocial needs helps you create a favorable emotional climate. *Do not rush your care.* Some patients feel reassured by having a significant other present to lend encouragement and moral support. Other strategies include planning sufficient time or multiple opportunities for a patient to work through and ventilate feelings and anxieties. Adequate preparation allows a patient to obtain maximal benefit from each intervention.

Anticipating and Preventing Complications

Risks to patients come from both illness and treatment. Observe for and recognize these risks, adapt your choice of interventions to each situation,

assess the relative benefit of the intervention versus the risk, and take risk-prevention measures. Many conditions place patients at risk for complications. For example, a patient with preexisting left-sided paralysis following a stroke is at risk for developing a pressure injury following orthopedic surgery that requires traction and bed rest. A patient with obesity and diabetes mellitus who has major abdominal surgery is at risk for poor wound healing. Nurses are often the first ones to detect and document changes in patients' conditions. Expert nurses learn to anticipate changes in patient conditions even before confirming that diagnostic signs of complications develop.

Your knowledge of pathophysiology and experience with previous patients help you identify complications that can occur. A thorough assessment reveals the level of a patient's current risk. The evidence or scientific rationale for how interventions (e.g., pressure-relief devices, repositioning, or wound care) prevent or minimize complications help you select the most appropriate preventive measures. For example, if a patient who is obese has uncontrolled postoperative pain, the risk for pressure injury development increases because the patient is unwilling or unable to change position frequently. The nurse anticipates when a patient's pain will increase, administers ordered analgesics, and then positions the patient to remove pressure on the skin and underlying tissues. If a patient continues to have difficulty turning or repositioning, the nurse selects a pressure-relief device to place on the patient's bed.

Some nursing procedures pose risks. Be aware of potential complications and take precautions. For example, the patient with a urinary catheter is at risk for infection. In this case implementing catheter-associated urinary tract infection (CAUTI) care guidelines for UTI prevention reduces infection risk ([Chapter 46](#)).

Identifying Areas of Assistance

Certain patient care situations require you to obtain assistance by seeking additional personnel, knowledge, and/or nursing skills. Before beginning care, review the plan to determine the need for assistance and the type required. Sometimes you need assistance in performing a procedure, providing comfort measures, or preparing a patient for a diagnostic test. Do not take shortcuts if assistance is not immediately available to avoid injury to you and the patient. For example, when you care for a patient who is overweight and immobilized, you require additional personnel and transfer equipment to turn and position the patient safely. Be sure to

determine in advance the number of additional personnel needed. Discuss your need for assistance with other nurses or the APs.

You will require additional knowledge and skills in situations in which you are less familiar or experienced. For example, seek additional knowledge when you give a new medication or perform a new procedure. Because of the continual growth in health care technology, you may lack the motor skills to manipulate new equipment for a procedure. When you are faced with administering an unfamiliar therapy or operating a new piece of equipment, follow these steps.

1. Seek the information you need to be informed about a procedure. Check the scientific literature for evidence-based information, review resource manuals (e.g. hospital formulary or procedure manuals), or consult with experts (e.g., pharmacists, clinical nurse specialists).
2. Collect all equipment necessary for the procedure in order to be organized.
3. Consider the consequences of performing the procedure on each specific patient.
4. Have another nurse (e.g., staff nurse, faculty member, clinical nurse specialist) who has completed the procedure correctly and safely provide assistance and guidance. Requesting assistance occurs frequently in all types of nursing practice. It is a learning process that continues throughout educational experiences and into professional development. One tip is to verbalize with an instructor or staff nurse the steps you will take before performing the procedure to improve your confidence and ensure accuracy.

Implementation Skills

Nursing practice requires cognitive, interpersonal, and psychomotor skills to implement direct and indirect nursing interventions. You are responsible for knowing when one type of implementation skill is preferred over another and for having the necessary knowledge and skill to perform each. For example, interpersonal skills of silence and listening are effective as indirect nurse-initiated interventions within the domains of helping and coaching to better facilitate patient adherence (see [Fig. 19.1](#)).

Cognitive Skills

Cognitive skills include the critical thinking and decision-making skills such as problem solving and clinical decision making described in [Chapter 15](#). Always use good judgment and sound clinical decision making when performing any intervention. This ensures that no nursing action is automatic but instead is thoughtful and patient-centered. Grasp each clinical situation at hand, interpret the information you observe, and anticipate a patient's response so that you individualize patient care appropriately. A cognitive skill involves knowing the rationale for therapeutic interventions and understanding normal and abnormal physiological and psychological responses. Also know the evidence in nursing science to ensure that you deliver current and relevant nursing interventions.

Tonya knows the pathophysiology of colon cancer, the anatomy of the abdomen and surrounding structures, and the normal mechanisms for pain. She considers each of these as she observes Mr. Lawson, noting how the patient's movement and position either aggravate or lessen his incisional pain. Tonya focused initially on relieving Mr. Lawson's acute pain with an analgesic, but now that pain has become well managed, she considers additional nonpharmacological approaches to keep him comfortable and help lessen any anxiety.

Interpersonal Skills

Interpersonal skills are essential for effective nursing intervention. Apply interpersonal communication skills by developing a trusting relationship, expressing caring, and communicating clearly with patients and their families (see [Chapter 24](#)). Good interpersonal communication keeps patients informed and engaged in decision making, provides individualized instruction, and supports patients who have challenging emotional needs.

Proper use of interpersonal skills enables you to be perceptive of your patients' verbal and nonverbal communication, understand their needs and desires, and improve your ability to correctly select relevant interventions. As a member of the health care team, communicate patient problems and needs clearly, intelligently, and in a timely way.

Psychomotor Skills

Psychomotor skills require the integration of cognitive and motor activities. For example, when giving an injection, you need to understand

anatomy and pharmacology (cognitive) and use good coordination and precision to administer the injection correctly (motor). With time and practice you learn to perform skills correctly, smoothly, and confidently. This is critical in establishing patient trust. You are responsible for acquiring necessary psychomotor skills through your experience in the nursing laboratory, the use of interactive instructional technology, or actual hands-on care of patients. When performing a new skill, assess your level of competency, and obtain the necessary resources to ensure that your patients receive safe treatment.

Direct Care

Nurses provide a wide variety of direct care measures, treatments, or procedures performed through interaction with a patient(s) involving the laying-on of hands. How a nurse applies implementation skills affects the success of any direct care activity. Remain sensitive to a patient's clinical condition, previous experiences, expectations, and cultural views as you deliver interventions. All direct care measures require competent safe practice. Show a caring approach each time you provide direct care.

Activities of Daily Living

Activities of daily living (ADLs) are direct care measures usually performed during a normal day; they include ambulation, toileting, eating, dressing, bathing, personal device care, functional mobility (getting into/out of a bed or bathtub), and grooming (Lyon, 2018). A patient's need for assistance with ADLs is temporary, permanent, or rehabilitative. For example, a patient with impaired physical mobility because of bilateral arm casts temporarily needs assistance with eating and bathing. A patient with dementia may initially require coaching to complete tasks, but later require direct assistance (Box 19.5). A patient with an irreversible cervical spinal cord injury is paralyzed and has a permanent need for full assistance. When patients have difficulty performing ADLs or need to learn new ways to perform self-care activities, occupational and physical therapists play key roles in rehabilitation to restore ADL function.

Box 19.5 Assisting Patients With Dementia in Performing Activities of Daily Living

- Patients with early dementia may need reminding to have a bath or complete other grooming.
- Be present in case patients have problems. For example, be sure the person is soaping and rinsing adequately or eating a complete meal; if not, you may prompt them to do so.
- As dementia progresses, a patient may need to be reminded of specific tasks in a bath (such as soap yourself, rinse yourself) in the right sequence. The objects needed for the bath may need to be

prepared for them (basin with water at the right temperature, shaving mug is accessible, towel and clean gown/clothes are on the towel bar).

- Patients may need help for some actions, such as applying soap on the back, washing the toes, or shampooing the hair. Help may be given by guiding the person's wrist or holding the elbow to guide the arm. They often are able to do the task if you help them start the task.
- After dementia continues to progress, patients will need help with trickier tasks, such as tying shoelaces or putting in hearing aids.
- After some days, you may find the person looking at the bath basin in a puzzled way. The amount of assistance needed increases.
- The person may also lose interest in doing anything.

Adapted from Dementia care notes: helping with activities of daily living, 2018, <https://dementiacarenotes.in/caregivers/toolkit/adll>. Accessed July 19, 2018.

When a patient is experiencing fatigue, a limitation in mobility, confusion, and/or pain, assistance with ADLs is probably needed. For example, a patient who experiences shortness of breath avoids eating because of associated fatigue. Help the patient by setting up meals, offering to cut up food, and planning for smaller, more frequent meals to maintain his or her nutrition. Assistance with ADLs ranges from partial assistance to complete care. Remember to always respect a patient's wishes and determine his or her preferences. Patients from some cultures prefer to receive assistance with ADLs from family members. If a patient is stable and alert, it is appropriate to allow family to help with care. Most patients want to remain independent in meeting their basic needs. Allow a patient to participate to the level that he or she is able. Involving patients in planning the timing and types of interventions boosts their self-esteem and willingness to become more independent.

Instrumental Activities of Daily Living

Illness or disability sometimes alters a patient's ability to be independent in society. **Instrumental activities of daily living (IADLs)** refer to activities that support daily life and are oriented toward interacting with the environment, e.g., shopping, caring for pets, home maintenance, preparing meals, housecleaning, writing checks, and taking medications (Lyon, 2018). IADLs are typically more complex than ADLs and generally are managed by occupational therapists. However, nurses within home

care and community health settings frequently help patients adapt ways to perform IADLs (such as providing appropriate assistive devices or creating medication organization systems). Often family and friends are excellent resources for helping patients. In acute care it is important to anticipate how patients' illnesses will affect their ability to perform IADLs so that you can make appropriate referrals to be sure they have the resources they need at home.

Physical Care Techniques

Physical care techniques involve the safe and competent administration of nursing procedures (e.g., turning and positioning, inserting a feeding tube, administering medications, inserting an intravenous catheter, and providing comfort measures). The specific knowledge and skills needed to perform these procedures are in subsequent clinical chapters of this text. All physical care techniques require you to protect yourself and patients from injury, use safe patient-handling techniques during preparation, use proper infection control practices, stay organized, and follow applicable practice guidelines.

You are responsible to be knowledgeable about the procedure itself, the standard frequency, the associated risks, and the necessary assessments/evaluations before, during, and after performing a skill. Always remain thoughtful of a patient's condition and how the patient has responded to the procedure in the past. Know how the procedure is going to affect the patient and which expected outcomes you and the patient desire. For example, if you are going to ambulate a patient, discuss how far you wish the patient to walk and whether there will be opportunity to sit or stop to rest. Ask the patient to tell you if he or she becomes short of breath.

In a hospital you perform many procedures each day, often for the first time. Before performing a new procedure, assess the situation and your personal competencies to determine whether you need assistance, new knowledge, or new skills. Performing any procedure correctly requires critical thinking and thoughtful decision making.

Lifesaving Measures

A **lifesaving measure** is a physical care technique that you use when a patient's physiological or psychological state is threatened (see [Chapter 41](#)). The purpose of lifesaving measures is to restore physiological or

psychological homeostasis. Such measures include administering emergency medications, instituting cardiopulmonary resuscitation, intervening to protect a patient who is confused or violent, and obtaining immediate counseling from a crisis center for a patient who is severely anxious. If a nurse faces a situation requiring emergency measures, the proper nursing actions are to stay with the patient, maintain support, and have another staff member obtain an experienced professional.

Counseling

Counseling is a direct care method that helps patients use problem-solving processes to recognize and manage stress and facilitate interpersonal relationships. As a nurse you counsel patients to accept actual or impending changes resulting from stress (see [Chapter 37](#)). Examples include patients who are facing terminal or chronic illness. Counseling involves emotional, intellectual, spiritual, and psychological support. A patient and family who need nurse counseling have normal adjustment difficulties and are upset or frustrated, but they are not necessarily psychologically disabled. An example is the stress that a young woman faces when caring for her aging mother. Family caregivers need assistance in adjusting to the physical and emotional demands of caregiving. Sometimes they need respite (i.e., a break from providing care). The recipient of care also needs assistance in adjusting to his or her disability. Patients with psychiatric diagnoses require therapy from nurses specializing in psychiatric nursing or social workers, psychiatrists, or psychologists.

Many counseling techniques foster cognitive, behavioral, developmental, experiential, and emotional growth in patients. Counseling encourages individuals to examine available alternatives and decide which choices are useful and appropriate. When patients are able to examine alternatives, they develop a sense of control and are able to better manage stress.

Teaching

Patient education is key to patient-centered care. A teaching plan is essential for every patient, especially when patients need to manage health problems they are facing for the first time. Counseling and teaching closely align. Both involve using good interpersonal skills to create a change in a patient's knowledge and behavior. Counseling results in changes in the

development of new attitudes, behaviors, and feelings, whereas teaching focuses on intellectual growth or the acquisition of psychomotor skills.

When you educate patients, respect their expertise with their own health and symptoms, their daily routines, the diversity of their human experiences, their values and preferences as to how they learn, and the importance of shared decision making. As an educator you present health care principles, procedures, and techniques to inform patients about their health status in such a way that patients can adapt what they learn to their daily routines at home to achieve self-care. Emphasis has been placed on patient education in acute care since 2006, when the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) standardized survey began to be used across the country by hospitals to measure patients' perspectives on hospital care ([HCAHPS, 2018](#)). The survey results currently are a standard for measuring and comparing quality of hospitals. Hospitals stress the importance of nurses addressing the topics covered by the survey, including patient education for discharge preparation.

The HCAHPS initiative stresses the importance of patient education. But remember, teaching is an ongoing process of keeping patients informed. Patients want to know why you do what you do. When performing a procedure, engage your patient and explain the procedure, why it is being done, the expected outcomes, and any problems to look for afterward. Encourage patients to ask questions. Here is an example of incorporating teaching in your daily work. When starting an intravenous (IV) infusion, explain what the IV fluid bag contains, how long the bag should last, sensations the patient will feel if the IV site becomes inflamed, the fact that a small flexible catheter is in the arm, and any potential side effects of medications in the bag.

Teaching takes place in all health care settings ([Fig. 19.4](#)). As a nurse you are accountable for the quality of education you deliver. [Chapter 25](#) provides a thorough overview of patient education principles and practices. Follow these basic patient education tips ([Nurse Journal, 2018](#)):

FIG. 19.4 Nurse providing discharge instructions.

- Delegate more responsibilities to support staff and be more focused on patient education.
- Begin educating patients with every encounter from admission.
- Based on what a patient already knows, correct any misinformation.
- Provide information in layman's terms. Use visual activities as often as possible. People remember what they see far more than what they hear or read.
- Question their understanding of the care, and plan for the next lesson. It is all part of the nursing process.
- Use return demonstration when administering care. Involve the patient from the very first treatment.
- Ask patients to tell you how they would explain (step by step) their disease or treatment to their spouse, partner, or friend.
- Repeat as needed and build upon the teaching with every opportunity throughout a hospitalization or stay.
- Provide patients with information about signs and symptoms to report to their physicians and ensure that they know to do this promptly, without waiting for another crisis to act.

Know your patient; be aware of the cultural and social factors that influence a patient's willingness and ability to learn. It is also important to know your patient's health literacy level (see [Chapter 25](#)). Do not assume that patients understand their illness or disease. If they seem uneasy or refuse a treatment, simply ask what concerns them. This gives you the chance to provide further teaching and correct knowledge deficiencies.

Controlling for Adverse Reactions

An **adverse reaction** is a harmful or unintended effect of a medication, diagnostic test, or therapeutic intervention. Adverse reactions can result from any nursing intervention; thus learn to anticipate and know which adverse reactions to expect. Nursing actions that control for adverse reactions reduce or counteract a reaction. For example, when applying a moist heat compress, you know that burning the patient's skin is a possible adverse reaction unless you protect the skin. First assess the condition of the area where you plan to place the compress. Following application of the compress, inspect the area every 5 minutes for any adverse reaction such as excessive reddening of the skin from the heat or skin maceration from the moisture (see [Chapter 48](#)). Taking the right precautions can prevent adverse reactions.

When completing a health care provider-directed intervention such as medication administration, always know the potential side effects of the drug. After you administer a medication, evaluate the patient for adverse effects. Also be aware of drugs that counteract the side effects. For example, a patient has an unknown hypersensitivity to penicillin and develops hives after three doses. You record the reaction, stop further administration of the drug, and consult with the physician. You then administer an ordered dose of diphenhydramine, an antihistamine and antipruritic medication, to reduce the allergic response and relieve the itching.

When caring for patients who undergo diagnostic tests, you need to understand the test and any potential adverse effects. Although adverse effects are not common, they do occur. It is important that you recognize the signs and symptoms of an adverse reaction and intervene in a timely manner.

Preventive Interventions

Preventive nursing interventions promote health and prevent illness to avoid the need for acute or rehabilitative health care (see [Chapter 2](#)). Changes in the health care system are leading to greater emphasis on health promotion and illness prevention. Primary prevention aimed at health promotion includes health education programs, immunizations, and physical and nutritional fitness activities. Secondary prevention focuses on people who are experiencing health problems or illnesses and who are at risk for developing complications or worsening conditions. It includes screening techniques and treating early stages of disease. Tertiary prevention involves minimizing the effects of long-term illness or disability, including rehabilitation measures.

Indirect Care

Indirect care measures are nursing treatments or procedures performed away from a patient(s) but on behalf of a patient(s) (Butcher et al., 2018). Examples include interventions that manage the patient care environment and interprofessional collaborative actions that support the effectiveness of direct care interventions (Butcher et al., 2018) (Box 19.6). Nurses spend much time in indirect unit management activities. Communicating information about patients (e.g., hand-off report, hourly rounding, and consultation) is critical, ensuring that direct care activities are planned, coordinated, and performed with the proper resources. Delegation of care to APs is another indirect care activity (see Chapter 21). When performed correctly, delegation ensures that the right care provider performs the right tasks so that the nurse and APs work together most efficiently for a patient's benefit.

Box 19.6 Examples of Indirect Care Activities

- Documentation (electronic or written)
- Delegation of care activities to assistive personnel
- Medical order transcription
- Infection control (e.g., proper handling and storage of supplies, use of protective isolation)
- Environmental safety management (e.g., making patient rooms safe)
- Telephone consultations with health care providers
- Hand-off reports to other health care team members
- Collecting, labeling, and transporting specimens
- Transporting patients to procedural areas and other nursing units

From Butcher HK, et al: Nursing interventions classification (NIC), ed 7, St Louis, 2018, Elsevier.

Communicating Nursing Interventions

Any intervention that you provide for a patient is communicated in an electronic, written, or oral format (see Chapter 26). Electronic health

records (EHRs) or written charts have sections for individualized interventions that are part of the nursing care plan (see [Chapter 18](#)) and a patient's permanent medical record. The record entry usually includes a brief description of pertinent assessment findings, the specific intervention(s), and the patient's response. An EHR or written record validates that you performed a procedure and provides valuable information to subsequent caregivers about the approaches needed to provide successful care. Some institutions have **interprofessional care plans** (i.e., plans representing the contributions of all disciplines caring for a patient). You enter nursing interventions into the plan, documenting the treatment and patient's response.

Effective communication and good teamwork reduce medical errors and prevent adverse patient outcomes ([ECRI Institute, 2019](#)). Miscommunication is often the root cause for most reported adverse or sentinel events that occur in health care organizations. Communication with other health care professionals needs to be timely, accurate, and relevant to a patient's clinical situation. Ineffective or incomplete communication often results in caregivers being uninformed, interventions duplicated needlessly, procedures delayed, or tasks left undone. [Chapter 26](#) explains the approach for effective hand-off communication. Always be clear, concise, and to the point when you communicate nursing interventions.

Delegating, Supervising, and Evaluating the Work of Other Staff Members

A nurse who develops a patient's care plan frequently does not personally perform all of the nursing interventions. Some activities you coordinate and delegate to other members of the health care team, including other RNs, LPNs, or assistive personnel. Remember that RNs delegate care tasks but not the nursing process ([ANA and National Council of State Boards of Nursing \[NCBSN\], 2012](#)). You can assign noninvasive and repetitive interventions to certified nurse assistants and other APs. Such activities include skin care, transfer and mobility skills, hygiene, and vital signs for patients who are stable. Evidence shows that the better the communication and collaborative relationship between a nurse and the delegatee, the better the outcome of the delegation process ([National Council State Boards of Nursing, 2016](#)). Delegation requires clinical judgment and accountability for patient care. The frequency and way nursing care

activities are delegated often depends on a nursing unit delivery of care model.

Delegation allows you to use your time more wisely and to have other care providers assist. When you delegate tasks to an AP, you are responsible for ensuring that you assign each task appropriately and that the AP completes each task according to the standard of care. This requires ongoing supervision to be sure the AP has performed the task on time without difficulty. You must be sure that any delegated action was completed correctly, documented, and evaluated. You only delegate direct care interventions to personnel who are competent. [Chapter 21](#) describes the principles to follow in delegation.

Achieving Patient Goals

You implement interventions to achieve patient goals and expected outcomes (see [Chapter 18](#)). In most clinical situations multiple interventions are needed to achieve select outcomes. In addition, patients' conditions often change minute by minute. Therefore it is important to apply principles of care coordination such as good time management, organizational skills, and appropriate use of resources to ensure that you deliver interventions effectively and meet desired outcomes (see [Chapter 21](#)). Priority setting is critical in successful implementation. Priorities help you to anticipate and sequence nursing interventions when a patient has multiple nursing diagnoses and collaborative problems.

Another way to help patients achieve their goals is to help them adhere to their treatment plan. **Patient adherence** means that patients and families invest time in carrying out required health care treatments. [Przemyslaw and colleagues \(2013\)](#) explain that adherence is complicated because, in the case of medication adherence, it includes willingness of a patient to implement a regimen (daily drug-taking) and persistence (continuity of treatment) in taking the medication. Whether a patient chooses to adhere to a treatment relates in part to the values and perceptions placed on the treatment. When a treatment is seen as beneficial and making a difference in a patient's quality of life, adherence is more likely. Similarly, when there is a risk of negative consequences if a treatment is not followed, adherence is more likely. The majority of research on patient adherence has focused on medication management and chronic disease management. Studies on medication management suggest that presence of family and social support, as well as the use of simple treatment regimens, favorably impacts adherence. In contrast, economic factors such as unemployment, poverty, and a lack of or inadequate medical/prescription coverage, as well as a high out-of-pocket cost of drugs, contribute to nonadherence ([Przemyslaw et al., 2013](#)). Interventions that improve adherence have been shown to be technical (e.g., simplification of drug regimen and packaging, pill organizers), behavioral (e.g., memory aids and reminders), educational (e.g., motivational techniques), and multicomponent ([Przemyslaw et al., 2013](#); [van Dulmen et al., 2007](#)).

To ensure that patients have a smooth transition across different health care settings (e.g., hospital to home and clinic, hospital to rehabilitation agency, or hospital to assisted living), it is important to introduce interventions that patients are willing and able to follow. Adequate and timely discharge planning with collaborative patient and family education

are the first steps in promoting a smooth transition from one health care setting to another or to the home. Individualize your care and take into consideration the various factors that influence a patient's health beliefs (see [Chapter 6](#)). *For example, for Tonya to effectively help Mr. Lawson follow the activity limitations required after surgery, she needs to know whether Mr. Lawson understands the risks to wound healing if limitations are not followed. His anxiety about being able to return to work on time will probably improve his motivation to adhere.* You are responsible for delivering interventions in a way that reflects your understanding of a patient's health beliefs, culture, lifestyle pattern, and patterns of wellness. In addition, reinforcing successes with the treatment plan encourages a patient to follow his or her care plan.

Key Points

- A nursing intervention is any treatment based on clinical judgment and knowledge that a nurse is licensed to perform within the professional scope of practice.
- Standard interventions, based on scientific evidence and clinical expertise, are developed for patients with common health problems to assist nurses to intervene more efficiently and appropriately.
- Use of care bundles shows promising benefits but requires implementation of the full set of interventions and use of clinical judgment when practicing within guidelines of a care bundle.
- Nurses use critical thinking in implementation when considering the complexity of interventions, changing priorities, alternative approaches, and the amount of time available to act.
- As a nurse you are responsible for deciding whether to perform an intervention, delegate it to an unlicensed member of the nursing team, or have an RN colleague assist you.
- Time management allows you to competently provide timely, thoughtful, safe, and efficient care.

- The decisions a nurse makes about how time is allocated, prioritized, and sequenced are always interpreted by the patients you serve within the sociocultural context of a health care institution.
- Expert nurses learn to anticipate changes in patients' conditions even before confirming that diagnostic signs of complications develop.
- Knowledge of pathophysiology and experience with previous patients helps nurses identify the risk of complications.
- Nursing practice requires cognitive, interpersonal, and psychomotor skills to implement direct and indirect nursing interventions.
- Direct care interventions include providing ADLs, assisting with IADLs, performing physical care, lifesaving measures, counseling, teaching, preventive interventions, and controlling for adverse reactions.
- Communication of information about patients (e.g., hand-off report, hourly rounding, and consultation) is critical, ensuring that direct care activities are planned, coordinated, and performed with the proper resources.

Reflective Learning

After your next clinical experience review the interventions you provided for your patient(s).

- Which of the interventions were direct nurse-initiated versus indirect nurse-initiated?
- In what way did you communicate the interventions you provided your patient to members of the health care team?
- What nursing skills did you apply in your implementation of patient care?

Review Questions

1. A nurse is assigned to five patients, including one who was recently admitted and one returning from a diagnostic procedure. It is currently mealtime. The other three patients are stable, but one has just requested a pain medication. The nurse is working with an assistive personnel. Which of the following are appropriate delegation actions on the part of the nurse? (Select all that apply.)
 1. The nurse directs the assistive personnel to obtain a set of vital signs on the patient returning from the diagnostic procedure.
 2. The nurse directs the patient care technician to go to the patient in pain and to reposition and offer comfort measures until the nurse can bring an ordered analgesic to the patient.
 3. The nurse directs the patient care technician to set up meal trays for patients.
 4. The nurse directs the patient care technician to gather a history from the newly admitted patient about his medications.
 5. The nurse directs the patient care technician to assist one of the stable patients up in a chair for his meal.
2. A nurse working the evening shift has five patients and is teamed up with an assistive personnel. One of the assigned patients has just returned from surgery, three others are stable and resting, and one has requested a pain medication. The patient in pain has two analgesics ordered prn for pain and has been using cold applications on his surgical site for pain relief. The last time an analgesic was given was 4 hours ago. The patient is scheduled for a physical therapy visit in 2 hours. Which of the following demonstrate good clinical decision making during intervention? (Select all that apply.)

1. The nurse reviews the options for pain relief for the patient.
 2. The nurse assesses whether the prn medication, ordered every 4 to 6 hours and last given 4 hours ago, is effective and whether a new type of medication is needed.
 3. The nurse reviews the policy and procedure for the cold application.
 4. The nurse considers how the patient might react if the pain medication is held until an hour before physical therapy.
 5. The nurse delegates vital sign assessment of the patient returning from surgery to the assistive personnel.
3. A nurse working the evening shift has five patients and is teamed up with an assistive personnel. One of the assigned patients has just returned from surgery, one is newly admitted, and one has requested a pain medication. The patient who has returned from surgery just minutes ago has a large abdominal dressing, is still on oxygen by nasal cannula, and has an intravenous line. One of the other patients has just called out for assistance in setting up a meal tray. Another patient is stable and resting comfortably. Which patient is the nurse's current greatest priority?
1. Patient in pain
 2. Patient newly admitted
 3. Patient who returned from surgery
 4. Patient requesting assistance with meal tray
4. The nurse administers a tube feeding via a patient's nasogastric tube. This is an example of which of the following?
1. Physical care technique
 2. Activity of daily living
 3. Indirect care measure
 4. Lifesaving measure

5. Which principle is most important for a nurse to follow when using a clinical practice guideline for an assigned patient?
 1. Knowing the source of the guideline
 2. Reviewing the evidence used to develop the guideline
 3. Individualizing how to apply the clinical guideline for a patient
 4. Explaining to a patient the purpose of the guideline
6. A nurse is visiting a patient who lives alone at home. The nurse is assessing the patient's adherence to medications. While talking with the family caregiver, the nurse learns that the patient has been missing doses. The nurse wants to perform interventions to improve the patient's adherence. Which of the following will affect how this nurse will make clinical decisions about how to implement care for this patient? (Select all that apply.)
 1. Reviewing the family caregiver's availability during medication administration times
 2. Determining the value the patient places on taking medications
 3. Reviewing the number of medications and time each is to be taken
 4. Determining all consequences associated with the patient missing specific medicines
 5. Reviewing the therapeutic actions of the medications
7. The nurse enters a patient's room and finds that the patient was incontinent of liquid stool. Because the patient has recurrent redness in the perineal area, the nurse worries about the risk of the patient developing a pressure injury. The nurse cleanses the patient, inspects the skin, and applies a skin barrier ointment to the perineal area. The nurse consults the ostomy and wound care nurse specialist for recommended skin care measures.

Which of the following correctly describe the nurse's actions?
(Select all that apply.)

1. The application of the skin barrier is a dependent care measure.
 2. The call to the ostomy and wound care specialist is an indirect care measure.
 3. The cleansing of the skin is a direct care measure.
 4. The application of the skin barrier is an instrumental activity of daily living.
 5. Inspecting the skin is a direct care activity.
8. Match the category of direct care on the left with the specific direct care activity on the right.

1. Counseling __	a. Assisting patient with oral care
2. Lifesaving measure __	b. Discussing a patient's options in choosing palliative care
3. Physical care technique __	c. Protecting a violent patient from injury
4. Activity of daily living __	d. Using safe patient handling during positioning of a patient

9. Which measures does a nurse follow when being asked to perform an unfamiliar procedure? (Select all that apply.)
1. Checks scientific literature or policy and procedure
 2. Determines whether additional assistance is needed
 3. Collects all necessary equipment
 4. Delegates the procedure to a more experienced nurse
 5. Considers all possible consequences of the procedure
10. A nurse is conferring with another nurse about the care of a patient with a stage II pressure injury. The two decide to review the clinical practice guideline of the hospital for pressure injury care. The use of a clinical practice guideline achieves which of the following? (Select all that apply.)
1. Allows nurses to act more quickly and appropriately
 2. Sets a level of clinical excellence for practice

3. Eliminates need to create an individualized care plan for the patient
4. Incorporates evidence-based interventions for stage II pressure injury
5. Provides for access to patient care information within the electronic health record

Answers: 1. 2, 3, 5; 2. 1, 2, 4; 3. 3; 4. 1; 5. 3; 6. 2, 4; 7. 2, 3; 8. 1 b, 2 c, 3 d, 4 a; 9. 1, 2, 3, 5; 10. 1, 2, 4.

Evaluation

OBJECTIVES

- Discuss the relationship between critical thinking and evaluation.
- Explain the difference between evaluative measures and assessment.
- Explain the importance of using the right evaluative measures.
- Explain the relationship among goals of care, expected outcomes, and evaluative measures when evaluating nursing care.
- Explain how evaluation reveals errors or omissions in care.
- Discuss the process of determining the need to revise a plan of care.

KEY TERMS

Evaluation, p. 271

Evaluative measures, p. 272

Nurse-sensitive outcomes, p. 274

Standards of care, p. 277

Evaluation is the crucial fifth step of the nursing process that determines whether a patient's condition or well-being improved after nursing interventions were delivered. It is imperative for nurses to monitor on an ongoing basis a patient's clinical progress. Critical thinking in nursing practice strengthens your clinical performance and reflects your ability to resolve patients' health-related problems ([Shu-Yuan et al., 2013](#)).

Evaluation monitors the progress of each of your patients and gives you valuable information about the efficacy of your interventions. The outcomes of nursing practice are the measurable conditions of patient, family, or community status; behavior; or perception. These outcomes are the criteria for judging the success in delivering nursing care.

Nurses are responsible for evaluating the effect of nursing practice on patient outcomes in the areas of health promotion, injury and illness prevention, and alleviation of suffering (Jones, 2016). Outcome evaluation is a part of every health care organization's quality assessment to determine what clinical practices and nursing care standards are effective. Nurses who provide direct care to patients are the best source of information about nursing practice and patient outcomes on an organizational level (Jones, 2016).

Evaluation is critical to knowing a patient's health status. A patient is diagnosed with pneumonia based on clinical signs such as productive cough, fever, and a chest x-ray showing lung consolidation. After the patient completes a course of antibiotics, the health care provider repeats the chest x-ray and looks for an improvement in cough and lowering of body temperature to determine whether the pneumonia has resolved. When a nurse provides wound care, including application of a warm compress, several steps are involved. He or she assesses the appearance of the wound, determines its severity, applies the appropriate form of compress, and returns later to inspect the wound to determine whether the condition has improved. These scenarios depict what ultimately occurs during the process of evaluation: comparing assessment measures at two different time points to determine a patient's condition and whether the desired outcome of treatment has been achieved. *The nurse performs evaluative measures (e.g., reinspection of wound) to determine whether a patient met expected outcomes (e.g., wound heals within 2 weeks), not whether nursing interventions were completed.* The expected outcomes established during planning (see Chapter 18) are the standards against which a nurse judges whether goals (e.g., wound healing) have been met and care is successful.

In the continuing case study Mr. Lawson is going home in a couple of hours. Tonya organizes her care so that she can take the time needed to evaluate the outcomes of her plan of care. Mr. Lawson took two doses of the prn analgesic ordered for his pain over the past 8 hours. Thirty minutes after the last dose he rated his pain a 3 on a scale of 0 to 10. He states, "I only really notice now when I move too quickly." Mrs. Lawson is in the room, so Tonya takes time to inspect and evaluate Mr. Lawson's wound, describes what she sees, and asks the Lawsons to explain the signs of infection and how to care for the wound at home. Tonya gives the Lawsons the discharge instruction sheet that is part of the standard of care of her nursing unit. She asks Mr. Lawson to explain the types of activity he needs to avoid for the first 2 weeks that he is home.

Standards for Evaluation

Nursing care helps patients resolve actual health problems, prevent the occurrence of potential problems, and maintain a healthy state. Evaluation is an integral step to that end. The American Nurses Association (ANA) defines standards of professional nursing practice (see [Chapter 1](#)), which include standards for the evaluation step of the nursing process. The standards are authoritative statements of the duties that all registered nurses, regardless of role, patient population they serve, or specialty, are expected to perform competently ([ANA, 2010](#)). The competencies for evaluation include being systematic and using criterion-based evaluation, collaborating with patients and health care professionals, using ongoing assessment data to revise a plan, and communicating results to patients and families. Always deliver interventions responsibly and appropriately to minimize unwarranted or unwanted treatment ([ANA, 2010](#)).

Critical Thinking in Evaluation

Critical thinking is key to evaluation (Fig. 20.1). In Chapter 15 you learned that clinical decision making is complex, requiring flexibility and the ability to know and recognize subtle changes or aspects of a patient's condition. A literature review of studies examining critical thinking indicators identified four actions that show a nurse is competent to perform evaluation (Shu-Yuan et al., 2013):

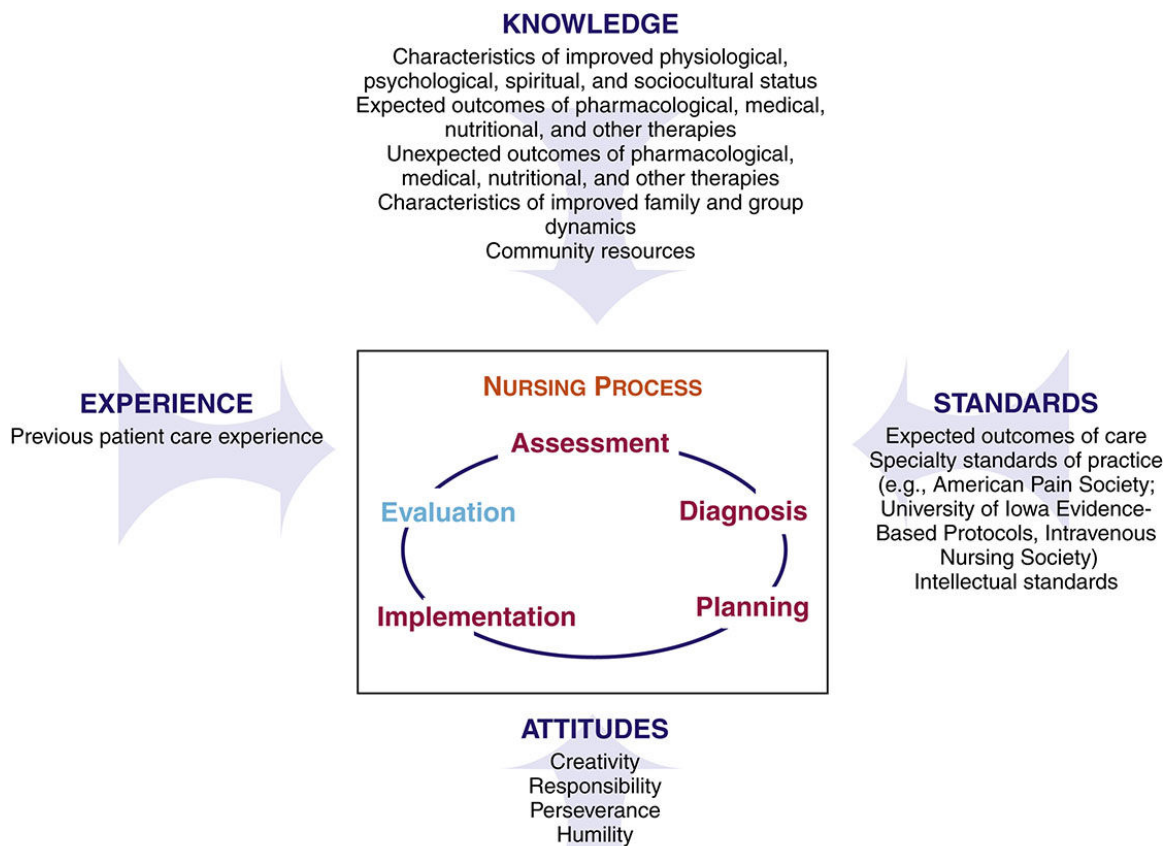

FIG. 20.1 Critical thinking and evaluation.

- Examine the results of care according to clinical data collected.
- Compare achieved effects or outcomes with goals and expected outcomes.
- Recognize errors or omissions.

- Understand a patient situation, reflect on the situation, and correct errors.

The evaluation process is comprehensive and complex. It requires more than making a quick check of a patient to be sure that he or she is stable or without further problems. It is a methodical approach for determining whether nursing implementation effectively influenced a patient's progress or condition favorably.

Examine Results

Nurses are accountable for and obligated to evaluate interventions and outcomes in the areas of health promotion, prevention of illness and injury, and alleviation of suffering (Jones, 2016).

Evaluation occurs whenever you have contact with a patient. It is an ongoing process that includes a before-and-after comparison or an after comparison with an established standard. For example, after assessing a patient's behaviors reflecting anxiety, you offer counseling and instructional support, then compare the behaviors with those shown after interventions are completed. After a patient undergoes tracheal suctioning, comparing the patient's actual oxygen saturation with the presuctioning level and the saturation level you anticipate (standard of >90%) informs you about the efficacy of suctioning and the patient's response.

Once you deliver an intervention, you continuously examine results by gathering subjective and objective data from a patient, family, and health care team members (as appropriate). At the same time you reflect on your knowledge regarding a patient's current condition, the treatment, and the resources available for recovery. By also reflecting on previous experiences caring for similar patients, you are in a better position to know how to evaluate your patient. You can anticipate what to evaluate.

You need to have an open mind, keen observation skills, and a neutral perspective to effectively evaluate patient outcomes (Shu-Yuan et al., 2013). Do not form a judgment about a patient's progress or response without gathering data pertinent to the health care problem. *For example, because Mr. Lawson is being discharged and there have been no delays, Tonya might assume that his pain is under control. However, until Tonya reassesses the patient's pain character and severity, evaluation is not complete.* Be thorough in gathering all clinical information needed to adequately evaluate a patient's condition.

Evaluative Measures

Although you may measure or observe patient data in the same way during assessment and evaluation, an assessment identifies what, if any, problems exist while an evaluation determines whether the problems you identified during assessment have remained the same, improved, or otherwise changed. **Evaluative measures** are similar to and often the same assessment skills and techniques (e.g., observations, physiological measurements, use of measurement scales, patient interview) you perform during a patient assessment (Fig. 20.2). However, evaluative and assessment measures differ based on when you perform them. Evaluative measures are made following nursing interventions, when you make decisions about a patient's status and progress (Table 20.1).

FIG. 20.2 Evaluative measures. Nurse evaluates patient's vital signs.

TABLE 20.1**Evaluative Measures To Determine the Success of Goals and Expected Outcomes**

Goals	Evaluative Measures	Expected Outcomes
Patient's pressure injury will heal within 7 days.	Inspect color, condition, and location of pressure injury. Measure diameter of ulcer daily. Note odor and color of drainage from ulcer.	Erythema is reduced in 2 days. Diameter of ulcer decreases in 5 days. Ulcer has no drainage in 2 days. Skin overlying ulcer is closed in 7 days.
Patient will tolerate ambulation to end of hall with a safe maximal heart rate by 11/20.	Measure patient's radial pulse after patient ambulates and compare with baseline and the safe maximal heart rate (age-predicted HR max equation equals $208 - [0.7 \times \text{Age}]$). Assess respiratory rate during exercise. Observe patient for dyspnea or breathlessness during exercise.	Pulse remains below age-predicted HR during exercise. Pulse rate returns to resting baseline within 10 minutes after exercise. Respiratory rate remains within two breaths of patient's baseline rate. Patient denies feeling of breathlessness.
Patient adheres to medication regimen in 1 week.	Ask patient to fill a pill organizer for 7 days. Have patient identify the schedule for daily medications. Have patient explain purpose and benefits of each ordered medication.	Patient fills a pill organizer correctly for 7 days. Patient identifies daily medication schedule in 2 days. Patient discusses purpose and benefits of ordered medications in 1 day.

In many clinical situations it is important to collect evaluative measures over a period of time. You look for trends to determine whether a pattern of improvement or change exists. A one-time observation of a pressure injury is insufficient to determine that the ulcer is healing. It is important to note a consistency in change. For example, over a period of 3 days is the pressure injury gradually decreasing in size, is the amount of drainage declining, and is the redness of inflammation resolving? Recognizing a pattern of improvement or deterioration allows you to reason and decide whether a patient's problems (expressed as nursing diagnoses or collaborative problems) are resolved. This is very important in the home care or nursing home setting. It may take weeks or even months to determine whether interventions led to a pattern of improvement. For example, when evaluating a patient's risk for falls over time, has the patient, family, or health care team successfully reduced fall risks in the home, such as eliminating barriers in the home, removing factors impairing the person's vision, or providing direction for proper use of assistive devices?

It is important to use the right evaluative measure. For example, pain scales are valid and reliable for assessing pain severity (see [Chapter 44](#)) and change over time. [The European Pressure Ulcer Advisory Panel](#)

(EPUAP) and National Pressure injury Advisory Panel (NPIAP) and Pan Pacific Pressure Injury Alliance (2019a, b) has specific criteria for the accurate staging of pressure injuries (see [Chapter 48](#)) that allow you to identify whether a treated pressure injury has changed. By using the right measure you are more likely to accurately identify a change, if any, in a patient's condition.

Being able to evaluate behavioral change is more difficult. The information about behavior (e.g., taking medications correctly, following a diet, perceiving less grief) often relies on a patient's self-report. An example of a behavioral measure is any survey or interview that evaluates a patient's ability to perform self-care and achieve self-management. Self-report is a measure of a patient's own perceptions or beliefs and may not truly reflect whether change has occurred. Your willingness to use self-report as an outcome measure of behavior or patient perception reflects trust in the patient. When using self-report, it is very important that the patient understands questions posed and why his or her response is important to gauge behavioral change.

Much emphasis in health care today is on patients and their family caregivers to achieve self-management to improve the quality of their lives. The aim of self-management is to minimize the impact of chronic disease or sudden acute illness on physical health status and functioning and to enable people to cope with the psychological effects of an illness. *In Mr. Lawson's case, Tonya planned and implemented educational interventions designed to improve his ability to adopt the behaviors needed for self-care, specifically to follow activity restrictions and perform correct wound care. Tonya evaluates the patient's ability by measuring what he is able to either explain or demonstrate.* There are relevant, objective, and appropriate evaluative indicators of self-management, including knowledge (information relevant to a patient's situation), independence (independence over areas of health and well-being and other areas that patients feel confident to manage, *and* being independent from others), skills (i.e., ability to manage stress and make decisions), bio-psychosocial markers of health (i.e., quality of life), and positive social networks ([Boger et al., 2015](#)) ([Table 20.2](#)).

TABLE 20.2**Self-Management Evaluation**

Evaluation Indicator	Examples of Measures
Self-Efficacy	General self-efficacy (GSE) scale; disease-specific self-efficacy scales (e.g., arthritis, diabetes, cardiac); medication-adherence self-efficacy scale
Health Behavior	Adherence to medication administration (e.g., pill count; number of injections); demonstrated psychomotor skill (e.g., dressing change, self-injection); adherence to medical follow-up visits
Physical Health Status	Clinical indicators (e.g., exercise tolerance, blood pressure control, blood glucose control [HgA1C])
Health Service Utilization	Readmission to hospital in 30 days; admission to emergency department
Quality of Life	Quality-of-life scales (e.g., for chronic illness, cancer, chronic pain)
Psychological Indicators	Perceived-stress scale, self-control, or other validated surveys or scales (e.g., Impulsivity Teen Conflict survey)

During planning a valuable resource for selecting outcomes is the Nursing Outcomes Classification (NOC) (see [Chapter 18](#)). The classification offers a standard nursing language (SNL) for the outcomes used in the evaluation step of the nursing process ([Box 20.1](#)). The benefits of NOC include ([Moorhead et al., 2018](#)):

Box 20.1 Evidence-Based Practice Improved Care Plans Using Standardized Nursing Language

PICOT Question: Does the use of standard nursing language (SNL) compared with no SNL improve the accuracy of nursing care plans for adult patients?

Evidence Summary

One of the essential characteristics of a quality nursing care plan is accuracy. Nursing care plan content must be comprehensive, which is defined as “documentation according to the different phases of the nursing process,” and accurate, which pertains to how precisely the data describe a patient’s situation (Thoroddsen et al., 2013). For example, describing a patient’s pain as moderate is less accurate than noting the patient’s pain severity rating. Also a nursing care plan must contain accurate nursing diagnoses based on the assessment data gathered from a patient.

An international study involving a systematic review of research examined the impact SNL has on nursing documentation and care plans (Johnson et al., 2018). Nurses use SNL in electronic health care records (EHRs) to label the clinical judgments they make during a nursing assessment. The review of articles concluded that critical thinking improved the accurateness of nursing diagnoses when the nurses used SNL (Johnson et al., 2018).

Application to Nursing Practice

- The consistent use of SNL ensures quality data collection that enables care providers and health care organizations to evaluate nursing care practices.
 - Accuracy of nursing care plans depends on accuracy, content, and degree to which plans are based on data (Johnson et al., 2018).
 - In certain EHRs it is increasingly difficult to describe the nursing care that is taking place without SNL (Johnson et al., 2018).
 - Using SNL makes documenting nursing care more efficient and facilitates communication of nursing care across health care disciplines and health care environments (Johnson et al., 2018).
-
- Providing a means for nurses and other health care providers to evaluate the status of patients, family, or community
 - Providing an outcome measurement system using SNL for all health care settings, specialties, and patients across the life span
 - Offering a means to quantify the change in patient status after nursing interventions and to monitor patient progress

The NOC system includes 540 outcomes, with each outcome having a set of evaluation indicators that describe specific states, perceptions, or behaviors related to the outcome, and Likert-type measurement scales (Moorhead et al., 2018) (Table 20.3). The outcomes are very broadly defined, while the indicators are defined in terms like those used to write patient goal statements. For example, the outcome “Comfort Status: Physical” is a broad category, but indicators such as “symptom control,” “physical well-being,” and “fluid intake” could be used as specific patient goal statements. The five-point Likert-type scales are used with all indicators to demonstrate variability in the state, behavior, or perception patients describe when measuring outcomes. For example, the outcome *Gait* is measured on a scale of “severely compromised to not

compromised,” while the outcome *Knowledge: Fall Prevention* is measured on a scale of “no knowledge to extensive knowledge.” The NOC system was designed to be used with the NANDA-I nursing diagnoses (see [Chapter 17](#)) and the Nursing Interventions Classification (NIC) (see [Chapter 19](#)). However, the outcome indicators are totally appropriate for use with the International Classification for Nursing Practice (ICNP) diagnoses.

TABLE 20.3

Examples of Nursing Outcome Classification Outcomes and Indicators

NOC Outcomes	Indicators (Examples)
Anxiety level	Level of restlessness Decreased productivity Level of verbalized anxiety
Knowledge: treatment procedures	Description of treatment procedures Follows restrictions related to procedure Correct use of equipment
Risk control: aspiration	Cleans dentures daily Selects foods based on swallowing ability
Sleep	Hours of sleep Sleep pattern

Adapted from Moorhead S, et al: *Nursing outcomes classification (NOC)*, ed 6, St Louis, 2018, Elsevier.

Building Competency in Informatics

Explain how use of the NOC classification in an electronic health record could improve patient safety. How would such a system help you monitor patient outcomes over time?

Compare Achieved Effect with Goals and Outcomes

A nursing plan of care includes mutually established goals and nurse-sensitive outcomes relevant to a patient’s health status. In [Chapter 18](#) you learned that a **nurse-sensitive** outcome is a state, behavior, or perception that is measured along a continuum in response to a nursing intervention ([Moorhead et al., 2018](#)). During evaluation you perform evaluative measures that allow you to compare clinical assessment data, patient behavioral measures, and patient self-report measures collected before

implementation with measures gathered after administering nursing care. Next you decide whether the results of care match the expected outcomes and goals set for a patient. If outcomes are met, the overall goals for the patient also are met. Critical thinking directs you to analyze the findings from evaluation (Fig. 20.3). Has the patient’s condition improved? Is the patient able to progress, or are there physical factors preventing recovery? Does this patient’s motivation or willingness to pursue healthier behaviors influence responses to therapies?

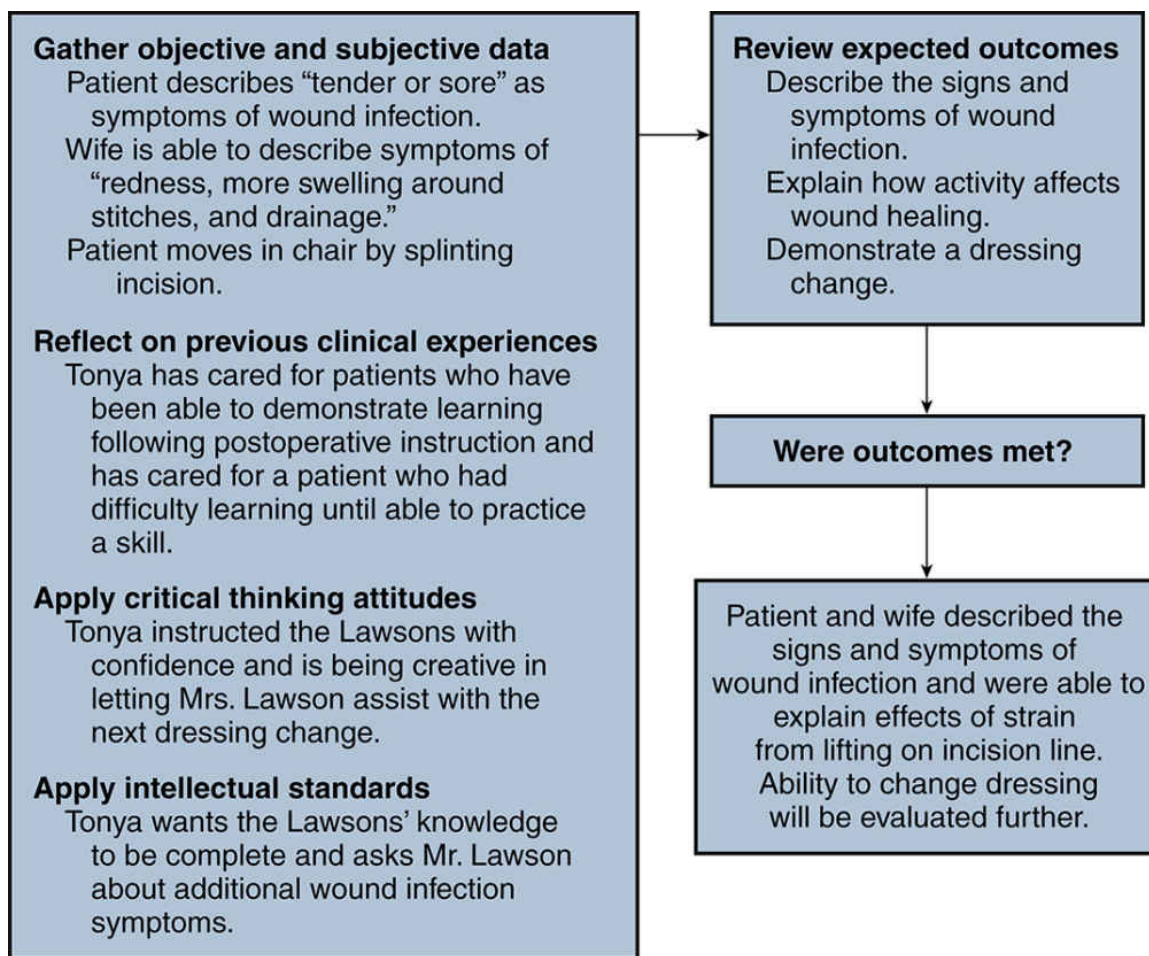

FIG. 20.3 Critical thinking and the evaluation process.

Outcomes are statements of progressive, step-by-step physical, emotional, or behavioral responses that a patient needs to accomplish to achieve the goals of care. When your patients achieve outcomes, the related factors for a problem-focused nursing diagnosis or the risk factors for an at-risk nursing diagnosis usually no longer exist or are better

managed. In Mr. Lawson's case the nursing diagnosis of **Anxiety related to uncertainty over ability to return to work** has the goal of "Mr. Lawson will be able to assume activity restrictions at home." Tonya has planned and implemented nursing care to prepare Mr. Lawson for a smooth postoperative recovery. She intervenes to minimize his anxiety and provides instruction about his activity restrictions so that he will adhere to his treatment plan. The aim is to achieve adherence so that return to work is a reasonable goal. Two of the expected outcomes for Mr. Lawson's goal include that the patient will maintain attention during instructional sessions and that the patient will explain how activity restrictions aid recovery. Tonya uses evaluative measures, including observation of the patient's behavior during instruction and then patient self-report of what he understands about his activity restrictions. If Tonya's plan of care is successful, the related factor of "uncertainty over ability to return to work" was managed. Tonya will know that, because Mr. Lawson was able to attend during instruction and explain how adherence to activity restrictions will hasten his recovery, one source of anxiety has lessened.

REFLECT NOW

What evaluative measures and outcomes might you anticipate for a patient who has the nursing diagnosis *Risk for Fall*?

Interpreting and Summarizing Findings

A patient's clinical condition often changes during an acute illness. In contrast, chronic illness results in slow, subtle changes, although acute exacerbations can occur. When you compare achieved effects of interventions with goals and outcomes, you interpret or learn to recognize relevant evidence about a patient's condition, even evidence that sometimes does not match clinical expectations. By applying your clinical knowledge and experience, you learn to recognize complications or adverse responses to illness and treatment in addition to expected outcomes.

Careful monitoring and early detection of problems are a nurse's first line of defense. Always make clinical judgments based on your observations of what is occurring with a specific patient and not merely on what happens to patients in general. Gather detailed, patient-specific evaluation measures because change in a patient's status frequently is not obvious. Make your evaluation based on your understanding of each patient's behavior, physical status, and reaction to caregivers. Perceptive clinical judgment involves interpreting and summarizing evaluation measures to determine whether a patient's status is improving. Comparing expected and actual findings allows you to interpret and judge a patient's condition and whether predicted changes occurred (Table 20.4). Perform the following steps to objectively evaluate the level of your patient's success in achieving outcomes of care:

TABLE 20.4

Examples of Objective Evaluation of Goal Achievement

Goals	Outcomes	Patient Response	Evaluation Findings
Patient will change surgical dressing correctly by 12/18.	Patient demonstrates correct hand hygiene by 12/16. Patient describes material to use in dressing change by 12/17. Patient demonstrates dressing change by 12/18.	Patient used antiseptic hand rub correctly to wash hands. Patient applied clean gauze correctly and taped securely in place over incision.	Patient shows progression toward outcomes and achieved desired behavior.
Patient's lungs will be free of secretions by 11/30.	Coughing is nonproductive by 11/29. Lungs are clear to auscultation by 11/30. Respirations are 20/min by 11/30.	Patient coughed frequently and productively on 11/29 following nebulization. Lungs were clear to auscultation on 11/30. Respirations were 18/min on 11/29.	Patient will require continued nebulizer therapy. Condition is improving.

1. Examine the outcome criteria to identify the exact desired patient behavior or response.
2. Evaluate a patient's actual behavior or response.
3. Compare the established outcome criteria with the actual behavior or response.
4. Judge the degree of agreement between outcome criteria and the actual behavior or response.
5. If there is no agreement (or only partial agreement) between the outcome criteria and the actual behavior or response, what is the reason? Why did they not agree? What is your next action?

Evaluation is easier to perform after you care for a patient over a long period. You are then able to make subtle comparisons of patient responses and behaviors. When you have not cared for a patient over an extended time, evaluation improves by referring to previous experiences or asking colleagues who are familiar with the patient to confirm evaluation findings. The accuracy of any evaluation improves when you are familiar with a patient's behavior and physiological status or have cared for more than one patient with a similar problem.

Recognize Errors or Unmet Outcomes

During evaluation the recognition of errors or unmet outcomes requires you to have an open mind, to actively pursue truth, to be patient and confident, and to engage in self-reflection ([Shu-Yuan et al., 2013](#)). You cannot assume that your treatment approaches will be successful. You must apply observational skills, critical thinking intellectual standards (see [Chapter 15](#)), knowledge, and reflection to recognize the actual results of your care. Reflection is a conscious effort to think about your interventions and outcomes, consider what was positive or challenging, and consider how the plan of care might be enhanced, improved, or done differently in the future ([Royal College of Nursing, 2015](#)). It usually occurs in the presence of a trigger event, which involves a breakdown or perceived breakdown in practice. For example, a nurse observes how a patient reacts to a treatment (e.g., exercise, positioning, or teaching) and realizes that the approach is ineffective. Or a nurse reviewing a patient's progress identifies that planned interventions were not done or not completed, described in the literature as "missed care" ([Ball and Griffiths, 2018](#)). Reflection involves a nurse's ability to recognize how a patient is responding and then adjust interventions as a result. A nurse will change the frequency of an intervention, change how the intervention is delivered, or select a new intervention based on a patient's response.

Often evaluation reveals patients who have unmet needs. Patients with the same health care problem are not treated the same way. As a result you sometimes make errors in judgment. The systematic use of evaluation provides a way for you to catch these errors. By consistently incorporating evaluation into practice, you minimize errors and ensure that a patient's plan of care is appropriate and relevant and changes according to met and unmet needs.

Correction of Errors

Reflection and subsequent clinical learning are also parts of evaluation. What a nurse gains from caring for patients and carefully evaluating the outcomes of care later contributes to ongoing clinical knowledge development and capacity for making clinical judgments about future patients ([Tanner, 2006](#)). This process helps correct and prevent errors. Reflective reasoning improves the accuracy of clinical decisions and making diagnostic conclusions. This means that, when you gather evaluative measures about a patient, reflection on the findings and exploration about what the findings mean improve your ability to problem solve. Reflection lessens the likelihood that reasoning is based on assumptions or guesswork and increases the likelihood that it is based on objective critical thinking.

REFLECT NOW

Think about an experience in a simulation lab or a recent encounter with a patient. What was your approach and how successful were you? Were there errors made? What might you have done differently to achieve a desired outcome?

Revising the Care Plan

The result of an evaluation helps you decide whether to continue, discontinue, or revise the plan of care. The patient and sometimes family members can tell you how interventions helped or did not help ([Ackley et al., 2017](#)). This information adds to the evaluative measures you collect. If your patient meets a goal successfully, either maintain treatment as planned or discontinue that part of the care plan if intervention is no longer required. For example, in the case of a patient achieving a desired level of exercise, you will still continue an exercise regimen. In the case of a patient who is able to demonstrate knowledge of a topic after instruction, further instruction is not needed. When there are unmet or partially met goals, or if you determine that perhaps a new problem has developed, reassessment is necessary. A complete reassessment of patient factors

relating to an existing nursing diagnosis and etiology is necessary when modifying a plan. If outcomes have not been met, it is helpful to consider the SMART acronym discussed in [Chapter 18 \(Ackley et al., 2017\)](#). For example, were the outcomes Specific? Were the outcomes Measurable? You will often modify or add nursing diagnoses or collaborative problems with appropriate goals and expected outcomes. You then select interventions and redefine priorities of care. Reassessment ensures that the database is accurate and current. It also reveals any missing links (i.e., a critical piece of new information that was overlooked and thus interfered with goal achievement). You sort, validate, and cluster all new data to analyze and interpret differences from the original database (see [Chapter 16](#)). An important step in critical thinking in evaluation is knowing how a patient is progressing and how problems resolve or worsen.

Tonya evaluates through teach-back Mr. Lawson's understanding of how activity restrictions aid recovery. Tonya states, "I want to know how well you understand your activity restrictions. Describe for me the restrictions your doctor explained." The patient states, "My doctor doesn't want me to do any heavy lifting. It could affect how my wound heals." As Tonya listens to Mr. and Mrs. Lawson further discuss going home, Mrs. Lawson comments, "It will be great for my husband to see the grandkids soon. He's really close to them. He loves playing with the 3-year-old." Tonya uses the evaluative measure of patient self-report to determine what Mr. Lawson understands about his activity restrictions. She recognizes that playing with grandkids could involve picking up the children. Tonya decides to modify her plan of care by reassessing the types of activities Mr. Lawson does at home (e.g., type of lifting, exercise, manual work) and adapting her instructions to be more comprehensive.

Discontinuing a Care Plan

After you determine that your patient met expected outcomes and goals, confirm your evaluation with the patient when possible. If you and the patient agree, you discontinue that part of the care plan. Documentation of a discontinued plan ensures that other nurses will not unnecessarily continue interventions for that part of the plan. Continuity of care assumes that care provided to patients is relevant and timely. You waste time and energy when you do not communicate achieved goals with other nurses.

Modifying a Care Plan

When patients do not meet goals and outcomes, you perform a reassessment and identify the factors that interfere with their achievement.

Usually a change in a patient's condition, needs, or abilities makes alteration of the care plan necessary. This will require you to continue interventions either as planned or less/more often, or you will choose to add interventions focused on the factors affecting goal achievement. For example, when teaching self-administration of insulin, a nurse discovers that a patient has developed a new problem, a tremor associated with a side effect of a medication. The patient is unable to draw medication from a syringe or inject the needle safely. As a result, the original outcomes of "Patient correctly prepares insulin in a syringe" and "Patient administers insulin injection independently" are no longer appropriate because they cannot be met. The nurse introduces new interventions (instructing a family member in insulin preparation and administration) and revises outcomes—"Family caregiver correctly prepares insulin in syringe" and "Family caregiver administers insulin injection correctly"—to meet the goal of care.

At times a lack of goal achievement results from an error in nursing judgment or failure to follow each step of the nursing process. Patients often have multiple and complex problems. Always remember the possibility of overlooking or misjudging something. When a goal is not met, no matter what the reason, repeat the nursing process sequence for that nursing diagnosis. Reassess the patient; determine accuracy of the nursing diagnosis; and establish a plan with new goals, expected outcomes, and appropriate priority interventions.

Redefining Diagnoses

After reassessment determine which nursing diagnoses are accurate for the situation. Ask yourself whether you selected the correct diagnosis and if the related factor or risk factor is accurate and current. Then revise the problem list to reflect the patient's changed status. Sometimes you form a new diagnosis or change the prioritization of diagnoses. You base your nursing care on an accurate list of nursing diagnoses. Accuracy is more important than the number of diagnoses selected. As a patient's condition changes, the diagnoses also change.

Revising Goals and Expected Outcomes

When revising a care plan, review the goals and expected outcomes for necessary changes. For example, does the time frame for outcomes need to be revised? Does your reassessment reveal a goal that is unrealistic? Is a more specific measure needed to determine outcome achievement?

Examine the appropriateness of goals for any unchanged nursing diagnoses and remember that a change in one health care problem sometimes affects the goals for others. *In Mr. Lawson's case, if his anxiety were to worsen again, Tonya probably would have to not only revise the plan for managing the anxiety but also consider whether her selection of teaching strategies needs to be changed.* Determining that each goal and expected outcome is realistic for the problem, etiology, and time frame is important. Unrealistic expected outcomes and time frames make goal achievement difficult.

Revising Interventions

The evaluation of interventions examines two factors: the appropriateness of the intervention selected and the correct application of the intervention. Appropriateness is based on the nursing standards of care for a patient's health problem (see [Chapter 19](#)). **Standards of care** (i.e., standard interventions, clinical guidelines, care bundles) are the minimum level of care accepted to ensure high-quality patient care. Standards of care define the types of therapies typically administered to patients with defined problems or needs. For example, if a patient who is receiving chemotherapy for leukemia has the nursing diagnosis *Acute Pain related to oral mucosa inflammation from mucositis*, the standard of care established by the nursing department for this problem includes pain-control measures, mouth care guidelines, and diet therapy. Professional organizations such as the Oncology Nursing Society often have clinical guidelines as standards of care for select health problems. The nurse reviews the standard of care and decides which interventions have been chosen and whether additional ones are required to achieve expected outcomes.

Increasing or decreasing the frequency of an intervention is another approach to ensure appropriateness of the intervention. You adjust interventions based on a patient's actual response to therapy and your previous experience with similar patients. For example, if a patient continues to have congested lung sounds, you increase the frequency of coughing and deep-breathing exercises to remove secretions and add positioning to ensure airway clearance.

During evaluation you find that some planned interventions are designed for an inappropriate level of nursing care. If you need to change the level of care, substitute a different action verb such as *assist* in place of *provide* or *demonstrate* in place of *instruct*. For example, helping a patient walk requires you to assist the patient during ambulation, whereas providing an assistive device (e.g., a cane or walker) suggests that the

patient is more independent. In addition, demonstration requires you to show a patient how a skill is performed rather than simply telling the patient how to perform it. Sometimes the level of care is appropriate, but the interventions are unsuitable because of a change in the expected outcome. In this example discontinue the interventions and plan new ones.

Make any changes in the plan of care based on the nature of a patient's unfavorable response. Consulting with other health care team members often suggests ways to improve the care delivery approach. Experienced nurses are often excellent resources and can provide valuable insight. Simply changing a care plan is not enough. Implement the new plan and reevaluate the patient's response to the nursing actions. *Evaluation is continuous, occurring through each step of the nursing process.*

Collaborate and Evaluate Effectiveness of Interventions

An important aspect of evaluation is collaboration. Patient-centered care is achieved only when a patient and family are actively involved in the evaluation process. This requires you to consider what is important to your patients, including their values, preferences, and expressed needs. When you develop patient care goals and expected outcomes with patients, they are an important resource for being able to tell you whether outcomes are being met. They are able to share their perspective of whether an intervention is successful. For example, a patient knows best if pain has lessened or if breathing is easier. The same holds true for the family, who often can recognize changes in patient behavior sooner than you can because of their familiarity with the patient.

It is essential for nurses to collaborate closely with all members of the health care team during evaluation. Successful collaboration involves interactions in which professionals work together cooperatively with shared responsibility and interdependence toward achieving patient outcomes. Members of the health care team who contribute to the patient's care also gather evaluative findings. Communicating openly and on a regular basis with the health care team improves the likelihood of staying informed about a patient's responses to care.

Proper evaluation determines the effectiveness of nursing interventions. This includes evaluating whether each patient reaches a level of wellness or recovery that the health care team and patient established in the goals of the care plan. In addition, it is important to evaluate whether you have met a patient's expectations of care. Begin by asking patients about their perceptions of care with questions such as "Are you receiving the type of pain relief you expect?" "Do you have enough information to change your dressing when you return home?" "What is your most important need before going home?" Evaluating patient expectations determines a patient's satisfaction with care and strengthens partnering between you and the patient.

Document Outcomes

Documentation and reporting are important parts of evaluation because it is crucial to share information about a patient's progress and current status. Accurate information needs to be present in a patient's medical record and shared during hand-off communication so that nurses and other health care team members know whether a patient is progressing and can make ongoing clinical decisions. For example, clearly documented goals and expected outcomes for new or revised nursing diagnoses are necessary so that all team members are aware of a revised care plan. In settings in which the same nurse will not be providing care throughout a patient's stay, it becomes very important to have consistent, thorough documentation of a patient's progress toward expected outcomes. The use of nursing diagnostic language and the NIC and NOC is becoming more common in electronic medical records, improving the quality, consistency, and accuracy of what is documented. In addition, electronic systems provide linkages to make it easier to interpret cues regarding whether interventions led to expected patient outcomes. When documenting a patient's response to your interventions, describe the interventions, the evaluative measures used, the outcomes achieved, and the continued plan of care. *Here is an example of Tonya's documentation of evaluation of care:*

1430: Instructed patient on importance of handwashing and need to observe surgical wound daily for signs of redness or drainage from incision. Discussed ways to reduce strain on suture line by avoiding lifting any object over 20 lb, including his grandchildren. Asked patient to describe when it is necessary to call doctor about wound. Patient and wife were able to identify signs of infection and occurrence of pain as reasons to notify doctor. Wife was able to demonstrate proper handwashing technique. Patient was able to verbalize several examples of objects not to lift (grandchild, groceries, trash). Provided patient additional instruction in form of pamphlet with outline of wound care steps. Will recommend to home health the need to observe patient and wife perform wound care at home.

Your documentation should present a clear argument from the evaluative data as to whether a patient is progressing. One of the ANA standards for evaluation is to share results of care with patients and their families according to federal and state regulations ([ANA, 2010](#)). Keep patients and families informed about the patients' progress. Be aware of guidelines of your agency for the type of clinical information (e.g., diagnostic findings, results of treatment) that you can communicate.

Evaluation of Health Care

The Centers for Medicaid and Medicare (CMS) do not reimburse health care agencies for the costs associated with treating preventable adverse outcomes such as air embolism, blood incompatibility, or stages III and IV pressure injuries. The occurrence of such outcomes can be potentially fatal to patients. There are 11 preventable adverse outcomes; four of those (severe pressure injuries, falls and trauma, catheter-associated urinary tract infections [CAUTI], and vascular catheter-associated infections) are nursing-sensitive quality outcomes that can potentially be decreased with greater and better nursing care (Burston, et al., 2014; Sung-Heui, 2016). These nursing-sensitive quality outcomes are significant health care problems because they increase patient pain and suffering, prolong hospital stays, and increase health care costs (Burston et al., 2014). As a practicing nurse you will become involved in implementing clinical guidelines, care bundles, and other evidence-based interventions to prevent these outcomes. Health care organizations gather monthly data on the rates of nursing-sensitive preventable outcomes. All patient care units regularly evaluate their progress in reducing these preventable outcomes and implement ongoing quality improvement efforts (see Chapter 5).

A nurse can be most effective in impacting these organization-wide preventable outcomes by delivering patient-centered care and conducting ongoing evaluation of the efficacy of interventions. Learning what is effective for individual patients builds your knowledge of both evidence-based and practical approaches for improving quality of care.

Key Points

- Critical thinking is integral to evaluation as evidenced by the following nursing actions: (1) examining the results of care according to clinical data collected; (2) comparing achieved effects with goals and expected outcomes; (3) recognizing errors or omissions; and (4) understanding a patient situation, participating in self-reflection, and correcting errors.
- Although you may measure or observe assessment and evaluation data in the same way, your assessment identifies what, if any, problems exist while your evaluation determines

whether the problems you identified during assessment have remained the same, improved, worsened, or otherwise changed.

- By using the right evaluative measure you are more likely to accurately identify whether there has been a change in a patient's condition.
- During the evaluation phase of the nursing process you perform evaluative measures to compare clinical assessment data, patient behavior, and patient self-reported data collected before implementation with data gathered after administering nursing care to determine whether the results of care match the expected outcomes and goals set for a patient.
- The evaluation process involves the use of observational skills, critical thinking intellectual standards, knowledge, and reflection to recognize errors or omissions so that adjustments to interventions can be made in care plan revision.
- Conducting evaluation involves reviewing evaluative measures to determine whether goals and outcomes are met successfully so that decisions can be made to either continue, discontinue, or revise a plan of care.
- When patients do not meet goals and outcomes, you perform a reassessment and identify the factors that interfere with their achievement, which usually involves a change in a patient's condition, needs, or abilities.

Reflective Learning

Tonya organizes herself so that she can take the time needed to evaluate the outcomes of her plan of care. Mr. Lawson has the nursing diagnosis of *Acute Pain related to trauma of surgical incision*. The patient has taken two doses of the prn analgesic ordered for his pain over the past 8 hours. Thirty minutes after the last dose Mr. Lawson rated his pain a 3 on a scale of 0 to 10; he states, "I only really notice the pain now when I move too quickly." An outcome for the patient's goal of achieving pain relief is for

pain scores to be at 4 or less. Mrs. Lawson is in the room, so Tonya takes time to give the Lawsons the discharge instruction sheet that is part of the standard of care of her nursing unit. She asks Mr. Lawson to explain the types of activity he must avoid for the first 2 weeks he is at home.

- Describe the type of evaluation measure Tonya uses when asking Mr. Lawson to explain the types of activities he should avoid. What limitations are there in using this type of evaluation measure?
- Explain how Tonya can determine whether the patient's nursing diagnosis of *Acute Pain* has been resolved. Describe how this affects her other priorities.
- Explain how Tonya's evaluation of the patient's ability to learn about activity restrictions can be patient centered.

Review Questions

1. A nurse admits a 32-year-old patient for treatment of acute asthma. The patient has labored breathing, a respiratory rate of 28 per minute, and lung sounds with bilateral wheezing. The nurse makes the patient comfortable and starts an ordered intravenous infusion to administer medication that will relax the patient's airways. The patient tells the nurse after the first medication infusion, "I feel as if I can breathe better." The nurse auscultates the patient's lungs and notes decreased wheezing with a respiratory rate of 22 per minute. Which of the following is an evaluative measure? (Select all that apply.)
 1. Asking patient to breathe deeply during auscultation
 2. Counting respirations per minute
 3. Asking the patient to describe how his breathing feels
 4. Starting the intravenous infusion
 5. Auscultating lung sounds

2. A patient has labored breathing, a respiratory rate of 28 per minute, and lung sounds that reveal wheezing bilaterally. The nurse starts an ordered intravenous infusion to administer medication that will relax the patient's airways. When the nurse asks how the patient feels, he responds by saying, "I feel as if I can breathe better." The nurse auscultates the patient's lungs and notes decreased wheezing with a respiratory rate of 22 per minute. Which of the following evaluative measures may not reflect change in a patient's condition?

1. Counting respirations per minute
2. Asking the patient to describe how his breathing feels
3. Observing breathing pattern
4. Auscultating lung sounds

3. Which of the following statements correctly describes the evaluation process? (Select all that apply.)

1. Evaluation involves reflection on the approach to care.
2. Evaluation involves determination of the completion of a nursing intervention.
3. Evaluation involves making clinical decisions.
4. Evaluation requires the use of assessment skills.
5. Evaluation is performed only when a patient's condition changes.

4. A nurse in a community health clinic has been caring for a young female teenager with diabetes for several months. The nurse's goal of care for this patient is to achieve self-management of insulin medication. Identify appropriate evaluative measures for self-management for this patient. (Select all that apply.)

1. Quality of life
2. Patient satisfaction
3. Clinic follow-up visits

4. Adherence to self-administration of insulin
5. Description of side effects of medications
5. From the following list of indicators, determine which indicators are goals **(G)** and which indicators are outcomes **(O)**.
 1. _____ Will achieve pain relief
 2. _____ Ambulates 10 feet down hallway
 3. _____ Will remain free of infection
 4. _____ Will be afebrile
 5. _____ Reports pain severity reduced from 6 to a 4 on scale of 0 to 10
 6. _____ Will gain improved mobility
6. A nurse has been caring for a patient over 2 consecutive days. During that time the patient had an intravenous (IV) catheter in the right forearm. At the end of shift on the second day the nurse inspects the catheter site, observes for redness, and asks whether the patient feels tenderness when the site is palpated. The nurse reviews the medical record from 24 hours ago and finds the catheter site was without redness or tenderness. Which of the activities below reflect the nurse's ability to perform patient evaluation? (Select all that apply.)
 1. Comparing patient response with previous response
 2. Examining results of clinical data
 3. Recognizing error
 4. Self-reflection
 5. Checking medical record for when IV was inserted.
7. A nurse asks how a patient's condition from a serious infection changed since yesterday while receiving a hand-off report. The nurse leaving the shift reports the patient has two priority nursing diagnoses—fluid imbalance and fever. The receiving nurse begins to provide care by measuring the patient's body

temperature, inspecting the condition of the skin, reviewing the intake and output record, and checking the summary notes describing the patient's progress since the day before. The nurse asks a technician to measure intake and output during the shift. What critical thinking indicators reflect the nurse's ability to perform evaluation? (Select all that apply.)

1. Checking the summary notes
 2. Asking the leaving RN about the patient's condition.
 3. Assigning the technician to measure intake and output
 4. Comparing current outcomes with those set for the patient's goals
 5. Reflecting on patient's progress
8. A nurse in the recovery room is monitoring a patient who had a left knee replacement. The patient arrived in recovery 15 minutes ago. The nurse observes the patient to be restless, turning frequently, and groaning; the patient's heart rate is 92 compared with 76 preoperatively. Blood pressure is stable since admission to the recovery room. The nurse reviews the medical orders for analgesic therapy. The nurse notes that the postop dose of an ordered analgesic has not yet been given. What is most likely to cause the nurse to reflect on the patient's situation?
1. The patient is recovering normally.
 2. The symptoms reflecting restlessness
 3. The patient's blood pressure trend
 4. The delay in administration of the analgesic
9. A nurse enters a patient's room and begins a conversation. During this time the nurse evaluates how a patient is tolerating a new diet plan. The nurse decides to also evaluate the patient's expectations of care. Which of the following is appropriate for evaluating a patient's expectations of care?

1. On a scale of 0 to 10 rate your level of nausea.
 2. The nurse weighs the patient.
 3. The nurse asks, "Did you believe that you received the information you needed to follow your diet?"
 4. The nurse states, "Tell me four different foods included in your diet."
10. Which of the following statements correctly describe the evaluation process? (Select all that apply.)
1. Evaluation is an ongoing process.
 2. Evaluation involves the gathering of data for recognizing errors or omissions in care.
 3. Evaluation involves making clinical decisions.
 4. Evaluation requires the use of assessment skills.
 5. Evaluation is done only when a patient's condition changes.
- Answers:** 1. 2, 3, 5; 2. 2; 3. 1, 3, 4; 4. 1, 3, 4; 5. 1G, 2O, 3G, 4G, 5O, 6G; 6. 1, 2; 7. 1, 2, 4, 5; 8. 4; 9. 3; 10. 1, 2, 3, 4.

Managing Patient Care

OBJECTIVES

- Describe the characteristics and traits of a transformational leader.
- Differentiate among the types of nursing care delivery models.
- Identify the elements of patient- and family-centered care.
- Discuss the ways in which a nurse manager supports staff involvement in a decentralized decision-making model.
- Differentiate among the different elements of the decision-making process
- Create a plan to develop your own leadership.
- Discuss ways to prioritize patient care effectively.
- Discuss evidence-based methods to ensure accurate communication for building teams.
- Discuss principles to follow in the appropriate delegation of patient care activities.

KEY TERMS

Accountability, p. 284

Authority, p. 284

Autonomy, p. 284

Case management, p. 283

Delegation, p. 289

Patient- and family-centered care, p. 283

Responsibility, p. 284

Shared governance, p. 284

Transformational leadership, p. 281

It is important for you to acquire the necessary knowledge and competencies that ultimately allow you to practice as a nurse. The [National Council of State Boards of Nursing \(NCSBN, 2018\)](#) develops licensure examinations for registered nurses (RNs) and licensed practical nurses (LPNs) to ensure entry-level nurses can safely practice nursing. Although nurse practice acts and professional nursing standards vary, you will be expected to possess certain knowledge, skills, and attitudes when you enter the nursing profession ([Box 21.1](#)). Wherever you practice nursing, you use critical thinking to implement professional standards of care, use health care resources appropriately, use time productively, set priorities, collaborate with the health care team, and apply leadership skills. Delivering nursing care within a health care system is a challenge because of the changes that influence health professionals, patients, and health care organizations (see [Chapter 2](#)). However, change offers opportunities. As you develop the knowledge and skills to become a nurse, you learn what it takes to effectively manage the patients for whom you care and to take the initiative in becoming a leader among your professional colleagues.

Box 21.1 Entry-Level Nurse Knowledge, Skills, and Attitudes

- Value placing the patient at the center of care.
- Respect patients' rights, beliefs, culture, spirituality, preferences, values, and needs.
- Understand the health care system and processes to promote safety, reduce harm, and enhance efficiency and effectiveness.
- Manage patient care.
- Think critically and make clinical decisions using the nursing process.
- Use data to monitor outcomes, assess problems, identify and implement solutions, evaluate care, and follow up appropriately.
- Communicate effectively with patients and health care team members, and document events and activities surrounding patient care appropriately in written and/or electronic records.
- Use evidence-based interventions when providing patient care.

- Promote change in patient behavior when needed using appropriate teaching and learning strategies.
- Demonstrate nursing knowledge and display confidence in knowledge base.
- Work effectively in nursing and interprofessional teams, recognizing the contributions of all team members, encouraging open communication, and fostering shared decision making.
- Recognize own limitations and seek help as needed.

Modified from NCSBN: NCLEX-RN® examination test plan for the National Council Licensure Examination for Registered Nurses, 2018, https://www.ncsbn.org/2019_RN_TestPlan-English.pdf; QSEN Institute: QSEN Competencies, 2018, <http://qsen.org/competencies/pre-licensure-ksas/>. Accessed September 2018.

Building a Nursing Team

Nurses who work in health care institutions and on units that have cultures that promote autonomy, quality, and collaboration are more satisfied and experience lower levels of moral distress (Hiler et al., 2018; Shimp, 2017). Professional nurses are self-directed and, with proper leadership and motivation, work together to solve complex problems. Your education and commitment to practice nursing within established standards and guidelines help you become part of a cohesive and strong nursing team that values mentoring, integrity, and teamwork. A strong nursing team works together to achieve the best outcomes for patients. Effective team development requires team building and training, trust, communication, and a workplace that facilitates collaboration (Huber, 2018). Patient care units where teamwork is stronger are associated with improved patient safety and nurse well-being (Welp and Manser, 2016). Stronger levels of teamwork among nurses often contribute to higher levels of job satisfaction among nurses (Kaiser and Westers, 2018).

An empowering work environment brings out the best in nurses. It concentrates on effective patient care systems, supports risk taking and innovation, focuses on results and rewards, and offers professional opportunities for growth and advancement. Building an empowered nursing team begins with the nurse executive, who is often a chief nursing officer. The executive's position within an organization is critical in uniting the strategic direction of an organization with the philosophical values and goals of nursing. The nurse executive is a clinical and business leader who is concerned with maximizing quality of care and cost-effectiveness while maintaining relationships and professional satisfaction of the staff. Perhaps the most important responsibility of the nurse executive is to establish a philosophy for nursing that enables managers and staff to provide quality nursing care.

Effective nurse managers play a critical role in developing successful teams that work together (Huber, 2018; James, 2018; Kivland, 2018) (Box 21.2). The nurse manager who uses **transformational leadership** is focused on change and innovation through team development, serves as a mentor for staff, and develops and supports the moral agency of nurses (Grace, 2018; Huber, 2018). Transformational leaders spend time on the unit with the staff sharing ideas, empowering the staff, supporting opportunities to enhance the team, showing appreciation and recognizing team members for a job well done, and holding team members accountable.

Box 21.2 Characteristics of Effective Leaders

- Develop interpersonal trust and ensure effective communication with individuals and teams.
- Have awareness of personal strengths and weaknesses, allowing vulnerabilities to show.
- Take initiative and sustain motivation, especially during times of uncertainty.
- Seek multiple perspectives and opinions to generate options and solutions when problem solving.
- Rebound from setbacks with positivity.
- Understand what they can and cannot change.
- Schedule time and space to regularly reflect, recharge, and reframe.
- Take responsibility for decisions.
- Display caring, understanding, and empathy for others.
- Motivate and empower others.
- Identify need to change and support change effectively.
- Use different leadership styles (e.g., transformational, authentic, value-based) appropriately.

Modified from James AH: Action learning can support leadership development for undergraduate and postgraduate nurses, *Br J Nurs* 27(15):876, 2018; Kivland C: Successfully managing emotions and behavior: emotional intelligence matters more than ever to your leadership career, *Healthc Exec* 33(1):68, 2018; Huber DL: *Leadership & nursing care management*, ed 6, St Louis, 2018, Elsevier.

Together a manager and the nursing staff share a philosophy of care for their work unit. A philosophy of care includes the professional nursing staff's values and concerns for the way they view and care for patients. For example, a philosophy addresses the purpose of the nursing unit, how staff members work with patients and families, and the standards of care for the work unit. Selection of a nursing care delivery model and a management structure that supports professional nursing practice are essential to the philosophy of care.

A nurse manager's leadership style affects the work environment and patient outcomes. Contemporary nurse leaders have a shared vision that leads the team to a common goal. Because nurses have specialized knowledge, they need leaders who value and foster the attainment of new knowledge (Huber, 2018). Nurse managers who use interactional and relationship-based leadership styles create a positive work environment by fostering interaction and generating stability to create the energy a team needs to adapt to and grow with a constantly changing health care environment (Huber, 2018).

One contemporary relationship-based leadership style is servant leadership. Servant leaders choose to serve others before they decide to become leaders. Their priority is putting the needs of others first and promoting personal growth and autonomy by ensuring their individual employee's highest priority needs are met (Huber, 2018; Savel and Munro, 2017). Servant nurse leaders work closely with their team to understand individual member's strengths and weaknesses. A servant leader creates teams based on this understanding and ensures that the nurses on a unit are working in the positions that best use their strengths (Savel and Munro, 2017). Servant nurse leaders also practice humility. They understand that although they possess a great deal of knowledge, they do not know all the answers. They remain modest and calm, and they give credit to their staff for successes (Savel and Munro, 2017). Effective nurse leaders use a variety of evidence-based strategies to create healthy work environments and lead their teams through change (Box 21.3).

Box 21.3 Evidence-Based Practice Nurses Work

Engagement

PICOT Question: Do nurse leaders who use transformational or relationship-based leadership strategies create healthier work environments and improve patient outcomes?

Evidence Summary

Creating healthy work environments and improving patient outcomes requires effective nursing leadership at all levels in an organization, from the nurse executive to the nurse manager to the staff nurses. Effective nurse leaders often use transformational or relationship-based leadership to create workplaces that promote better outcomes for patients and nurses (Alilyyani et al., 2018; Boamah et al., 2018).

Nurses who attend professional leadership development programs have improved collaboration and communication skills, which ultimately leads to a healthy work environment and better patient outcomes (Lacey et al., 2017). Focusing on transformational or relationship-based leadership is supported by current evidence. For example, authentic leadership, a type of relationship-based leadership, has been shown to improve the work environment (e.g., job satisfaction, employee health and well-being) and patient outcomes (Alilyyani et al., 2018). Authentic leaders choose a leadership style consistent with their personalities. They are dedicated to their own growth and build strong relationships with others. Regardless of the leadership strategy used, strong clinical leaders who encourage collaboration and regular interaction among nurse experts within the same health care organization or across different organizations create environments that have a positive impact on patient outcomes, quality of care, and the culture of the workplace (Brown et al., 2016).

Application to Nursing Practice

- Build positive relationships with colleagues on your nursing unit (Nelson-Bratley, 2018; Alilyyani et al., 2018) as well as with colleagues who work in other health care organizations (Brown et al., 2016).
- Attend professional conferences to stimulate your personal and professional growth and develop your leadership and communication skills (Lacey et al., 2017; Boamah et al., 2018).
- Be engaged with initiatives in your organization that focus on reducing hospital-acquired conditions (e.g., falls, pressure injuries, catheter-associated urinary tract infections) (Lacey et al., 2017).
- Respect the contributions of all members of the health care team and make a conscious commitment to make a positive impact in your workplace every day (Alilyyani et al., 2018; Boamah et al., 2018).

Magnet Recognition Program ®

One way of creating an empowering work environment is through the Magnet Recognition Program (see [Chapter 2](#)). The Magnet Recognition Program is based on five model components—transformational leadership; structural empowerment; exemplary professional practice, new knowledge, innovation, and improvements; and empirical quality results ([American Nurses Credentialing Center \[ANCC\], n.d.](#)). A hospital that is Magnet ® certified has a transformed culture with a practice

environment that is dynamic, autonomous, collaborative, and positive for nurses. The culture focuses on concern for patients. Typically, a Magnet hospital has clinical promotion systems and research- and evidence-based practice programs. The nurses have professional autonomy over their practice and control over the practice environment (Stimpfel et al., 2016). A Magnet hospital empowers a nursing team to make changes and be innovative (Nelson-Brantley et al., 2018). Professional nurse councils at the organizational and unit level help to create an empowerment model. This culture and empowerment combine to produce a strong collaborative relationship among team members and improve patient quality outcomes (ANCC, n.d.; Stimpfel et al., 2016).

Nursing Care Delivery Models

A nursing care delivery model allows you to help your patients achieve desirable outcomes. Nursing care delivery models contain the common components of nurse-patient relationship, clinical decision making, methods for patient assignments and work allocation, interprofessional communication, and management of the environment of care (Huber, 2018).

Two classic nursing models used in some health care institutions are team nursing and primary nursing. In team nursing, care is provided by a group of people led by an RN. The team often includes other RNs, practical nurses, and assistive personnel (APs). To be successful, this model requires effective team leadership, collaboration, and communication (Huber, 2018).

In primary nursing, one RN assumes the responsibility for a caseload of patients from admission to discharge. The same nurse provides care for the same patients throughout their hospitalization. When the nurse is not scheduled to work on the unit, directions are left (in plan of care or other communication mode) for other RNs to follow the plan of care. The model became more popular in the 1970s and early 1980s as hospitals began to employ more RNs. It is typically not practiced today because of the high cost of an all-RN staffing model (Huber, 2018). Total patient care is similar to primary nursing. In this model an RN is responsible for all aspects of care for one or more patients during a shift of care, working directly with patients, families, and health team members.

More common models used today are patient- and family-centered care and case management. **Patient- and family-centered care** promotes mutual partnerships among the patient, family, and health care team to

plan, implement, and evaluate nursing and health. At the center of patient-centered care is the patient or family member as the source of control and full partner in providing care (QSEN Institute, 2018). An RN is the health care leader that assesses patient needs, recognizes clinical changes, and directs care. The Institute for Patient- and Family-Centered Care identified four core concepts for patient-centered care (IPFCC, n.d.):

1. *Dignity and respect*, ensuring that the care provided is given on the basis of a patient's and family's knowledge, values, beliefs, and cultural backgrounds
2. *Information sharing*, meaning that health care providers communicate and share information so that patients and families receive timely, complete, and accurate information to effectively participate in care and decision making
3. *Participation*, whereby patients and families are encouraged and supported in participating in care and decision making
4. *Collaboration*, demonstrated by the health care leaders collaborating with patients and families in policy and program development, implementation, and evaluation and patients who are fully engaged in their health care

Nurses support and promote patient engagement and empowerment when using patient- and family-centered communication, bedside shift report, and patient- and family-centered interprofessional rounds (IPFCC, n.d.; Bigani and Correia, 2018).

Case management coordinates and links health care services across all levels of care for patients and their families while streamlining costs and maintaining quality (see Chapter 2). The case-management system is focused on achieving patient outcomes within effective time frames and with available resources (Huber, 2018). Case managers work with patients to identify issues and overcome barriers to help patients become healthier (CMSA, 2015). Current evidence shows case managers link and coordinate health care services to patients and their families while achieving quality cost-effective outcomes (Brown et al., 2017). Case managers, either individually or as part of a team, oversee the management of patients with complex nursing and medical problems (e.g., patients with diabetes or traumatic brain injury) across all levels of care. Case managers are often advanced practice nurses who, through specific interventions, help to improve patient outcomes, optimize patient safety by facilitating care

transitions, decrease length of stay, and lower health care costs. They are accountable for cost management and quality.

For example, a case manager coordinates a patient's acute care in the hospital and follows up with the patient after discharge, either to home, rehabilitation, or a long-term care setting. Case managers do not provide direct care. Instead, they collaborate with direct-care providers and actively coordinate patient discharge planning. Ongoing communication with team members facilitates a patient's transition to home. Case managers help patients identify health needs, determine the services and resources that are available, and make cost-efficient choices.

Decision Making

Decision making is a critical skill for an effective leader and manager (Huber, 2018). A nurse executive supports nurse managers by advocating a nursing governance structure that incorporates policies and procedures for decision making needed to achieve organizational goals. A nurse manager directs and supports a group of staff in applying an organization's nursing philosophy. Thus, it takes a committed nurse executive, excellent nurse managers, and an empowered nursing staff to create an enriching work environment. Box 21.4 highlights the diverse responsibilities of nursing managers.

Box 21.4 Responsibilities of a Nurse Manager

- Collaborate with staff to establish annual goals for the unit and the systems needed to accomplish goals (e.g., assignment methods, quality improvement activities, patient education methods).
- Monitor professional nursing standards of practice on the unit.
- Develop an ongoing staff development plan, including one for new employees.
- Recruit new employees (interview and hire).
- Conduct routine staff evaluations.
- Role model positive customer service (customers include patients, families, and other health care team members).
- Submit staffing schedules for the unit.

- Advocate for the nursing staff to the administration of the organization.
- Conduct regular patient rounds and problem solve patient or family complaints.
- Establish, monitor, and implement a quality improvement (QI) plan for the unit.
- Review and recommend new equipment for the unit.
- Conduct regular staff meetings.
- Make rounds with health care providers.
- Establish and support staff and interprofessional committees.

Decentralization is a component of the hierarchical level of decision making found in health care institutions. This management approach allows decisions to be made at the staff level. **Shared governance** is the typical decentralized structure used within health care organizations today (Huber, 2018). This structure creates an environment in which managers and staff become more actively involved in making decisions to shape the identity and determine the success of a health care organization. Working in a decentralized structure has the potential for greater collaborative effort, increased competency of staff, increased staff motivation, and ultimately a greater sense of professional accomplishment and satisfaction (Huber, 2018; Sulit Oriza et al., 2016).

Progressive organizations achieve more when employees at all levels are empowered and actively involved in decision making. As a result, the role of a nurse manager is critical in the management of effective nursing units or groups. To make shared governance work, managers move decision making down to the lowest level possible. On a nursing unit it is important for all nursing staff members (RNs, LPNs, and LVNs), nursing assistants, and unit secretaries to become engaged and provide input on practice issues and unit operations. They need to be kept well informed of unit and organizational initiatives. Giving staff the opportunity to participate in problem-solving activities related to direct patient care and unit activities promotes a high level of employee engagement—a key factor in promoting teamwork and collaboration and a healthy work environment (Sulit Oriza et al., 2016). Important elements of the decision-making process are responsibility, autonomy, authority, and accountability.

Responsibility refers to the duties and activities that you are employed to perform. A position description outlines your responsibilities as a

professional nurse and your expected level of participation as a member of a nursing unit.

Responsibility reflects ownership and obligation. An individual who manages employees distributes responsibility, and the employees accept it. Managers need to ensure that staff clearly understand their responsibilities, particularly in the face of change. For example, when hospitals participate in work redesign, patient care delivery models change significantly. A manager is responsible for clearly defining an RN's role within a new care delivery model. If decentralized decision making is in place, the professional nursing staff needs to be engaged to define the new RN role. Each RN on the team is responsible for knowing his or her role and how to perform that role on the busy nursing unit. For example, nurses are responsible for completing a nursing assessment of all assigned patients and developing a plan of care that addresses each of the patient's nursing diagnoses (Huber, 2018) (see Chapters 16 to 20). As the staff implements the plan of care, the nurse evaluates whether the plan is successful. This responsibility becomes a work ethic for the nurse in delivering excellent patient care.

Autonomy is freedom of choice and responsibility for the choices. Autonomy consistent with the scope of professional nursing practice maximizes a nurse's effectiveness (Huber, 2018). With clinical autonomy you make independent decisions about patient care, plan patient care within the scope of professional nursing practice, and implement independent nursing interventions (see Chapter 19). Another type of autonomy for nurses is work autonomy. In work autonomy a nurse makes independent decisions about the work of the unit such as scheduling or unit governance. Autonomy is not an absolute; it occurs in degrees. For example, you have the autonomy to develop and implement a discharge teaching plan based on specific patient needs for your patients and their family caregivers. However, if your unit does not use self-scheduling, you do not have the autonomy to create your own schedule.

Authority refers to the legal ability to perform a task (Huber, 2018). It provides the power for a nurse to make final decisions and give instructions related to the decisions. You use authority to determine whether collaboration was successful. For example, while managing the care of a patient, you discover that one of the members of the health care team, the registered dietitian, did not follow through on a discharge teaching plan. You have the authority to consult with the dietitian to learn why the recommendations on the plan of care were not implemented and

to review the established plan to ensure recommended patient teaching is completed.

Accountability refers to individuals being answerable for their actions. It involves follow-up and a reflective analysis of decisions and an evaluation of their effectiveness. It means that as a nurse you take responsibility to provide excellent patient care by following standards of practice and institutional policies and procedures. You assume responsibility for the outcomes of the actions, judgments, and omissions in providing that care. You are not accountable for the overall outcomes of patient care, but you are accountable for what you do (i.e., performing the nursing process, performing nursing procedures correctly, communicating effectively with health care team colleagues, and staying current on nursing practice issues). You will sometimes delegate responsibility, but you remain accountable for the care you delegated. For example, you delegate taking your patient's vital signs to an AP. You are responsible for knowing what your patient's vital signs are normally and for providing appropriate care if the vital signs are not in the expected range (e.g., verifying the temperature and giving acetaminophen as ordered when your patient's temperature is elevated).

Members of a successful nursing unit support the four elements of decision making: responsibility, autonomy, authority, and accountability. An effective nurse manager sets expectations for the staff in how decisions are made. Staff members need to feel comfortable in expressing differences of opinion and challenging ways in which the team functions. Ultimately shared governance helps the staff on a nursing unit to implement its philosophy and vision of professional nursing care.

Staff Involvement

When transformational or relationship-based leadership and decentralized decision making exist on a nursing unit, all staff members actively participate in unit activities (Fig. 21.1). Because the work environment promotes participation, all staff members benefit from the knowledge and skills of the entire work group. If the staff learns to value the pursuit of knowledge and the contributions of co-workers, better patient care results. Recognizing nurses' exceptional work with patients helps reinforce these behaviors, creates a healthy work environment, and reduces nurse burnout (Kelly and Lefton, 2017). Healthy work environments have nurses who are skilled in communication, promote true collaboration among health care team members, encourage effective decision making, have appropriate levels of staffing to meet patient needs, recognize nurses in a

meaningful way, and have an authentic nurse leader (AACN, n.d.). Authentic leadership results in greater nurse empowerment, improved culture and climate, increased implementation of evidence-based practice, better teamwork between nurses and physicians, greater role clarity, and reduced conflict and ambiguity. The nursing manager supports staff involvement through a variety of approaches:

FIG. 21.1 Staff collaborating on practice issues.
Copyright © iStock/skynesher.

- 1. Establishing nursing practice through problem-solving committees or professional shared governance councils.** Staff committees establish and maintain care standards for nursing practice on their unit. Shared governance is a dynamic process that promotes decision making, accountability, and empowerment in staff nurses and enables them to make meaningful and sustainable changes in patient care (Huber, 2018; Gordon, 2016). The committees review ongoing clinical care issues, identify problems, apply evidence-based practice in establishing standards of care, develop policy and procedures, implement new practice

approaches, resolve patient satisfaction issues, or develop new documentation tools. It is important for the committees to balance their focus between patient outcomes and work issues to ensure quality care on the unit. Quality of care is improved when nurses control their own practice. The committee establishes methods to ensure that all staff have input on practice issues. Managers do not always sit on a committee, but they receive regular reports of committee progress. The nature of work on the nursing unit determines committee membership. At times members of other disciplines (e.g., pharmacy, respiratory therapy, or clinical nutrition) participate in practice committees or shared governance councils.

2. **Interprofessional collaboration among nurses and health care providers.** Interprofessional collaboration among nurses and health care providers (e.g., medical doctors, physical therapists, respiratory therapists) is critical to the delivery of quality, safe patient care and the creation of a positive work culture for practitioners (McBeth et al., 2017; [Interprofessional Education Collaborative Expert Panel \[IECEP\], 2016](#)). Interprofessional collaboration involves bringing various disciplines together to work with patients and families to deliver quality care ([IECEP, 2016](#)). Interprofessional collaboration involves all professions bringing different points of view to the table to identify, clarify, and solve complex patient problems together, providing integrated and cohesive patient care ([Goldsberry, 2018](#)). The nurse plays a unique role within the team and is often viewed as the team leader because it is the nurse who takes on the responsibilities of coordination of communication and patient care ([QSEN Institute, 2018](#)). Open communication, cooperation, trust, mutual respect, and understanding of team member roles and responsibilities are critical for successful interprofessional collaboration ([QSEN Institute, 2018](#); [IECEP, 2016](#)). The [IECEP \(2016\)](#) identified four competencies that health care practitioners need to be effective team members in interprofessional collaboration. The development of these competencies comes through interprofessional education ([Homeyer et al., 2018](#)). Competencies needed for effective interpersonal collaboration include:
 - *Values/ethics for interprofessional practice:* Work with individuals of other professions to maintain a climate of mutual respect and shared values.

- *Roles/responsibilities*: Use the knowledge of one's own role and those of other professions to appropriately assess and address the health care needs of patients and to promote and advance the health of populations.
- *Interprofessional communication*: Communicate with patients, families, communities, and professionals in health and other fields in a responsive and responsible manner that supports a team approach to promote and maintain health and prevent and treat disease.
- *Teams and teamwork*: Apply relationship-building values and the principles of team dynamics to perform effectively in different team roles to plan, deliver, and evaluate patient- or population-centered care and population health programs and policies that are safe, timely, efficient, effective, and equitable.

3. **Interprofessional rounding.** Many institutions that focus on patient- and family-centered care conduct interprofessional rounding to encourage patient and family involvement in planning care, improve patient care coordination, and enhance communication among the health care team (Bigani and Correia, 2018). During rounding members of the team meet and share patient information, answer questions asked by other team members, discuss a patient's clinical progress and plans for discharge, and focus all team members on the same patient goals (Prystajek et al., 2017; McBeth, 2017). Interprofessional rounding improves decision making, nurses' job satisfaction, and quality of care (Perry et al., 2016). For interprofessional rounding to be successful, health care team members need to be flexible and open to ideas, questions, and suggestions offered by others.

4. **Staff communication.** A manager's greatest challenge, especially if a work group is large, is communication with staff. It is difficult to make sure that all staff members receive consistent, clear, accurate, and timely information. Lack of communication about planned changes often leads to mistrust among staff members. However, a manager cannot assume total responsibility for all communication. An effective manager uses a variety of approaches to communicate quickly and accurately to all staff. For example, many managers distribute biweekly or monthly newsletters of ongoing unit or agency activities. Minutes of committee meetings are usually in an accessible location for all staff to read or are sent to individuals via

e-mail. When the team needs to discuss important issues regarding the operations of the unit, the manager conducts staff meetings. When the unit has practice- or quality-improvement committees, each committee member has the responsibility to communicate directly to a select number of staff members. Thus, all staff members are contacted and given the opportunity for input.

5. **Staff education.** A professional nursing staff needs to always grow in knowledge. It is impossible to remain knowledgeable about current medical and nursing practice trends without ongoing education. A nurse manager is responsible for making learning opportunities available, so staff members remain competent in their practice and empowered in their decision making. This involves planning in-service programs, sending staff to continuing education classes and professional conferences, and having staff present case studies or evidence-based practice issues during staff meetings. Staff members are responsible for pursuing educational opportunities for relicensure/recertification and changing information regarding their patient population.

Leadership Skills for Nursing Students

It is important to prepare yourself for leadership roles from the time you decide to become a nurse. Begin by being a dependable, respectful, and competent team member. As a nursing student you are responsible and accountable for the care you give to your patients. Learn to become a leader by consulting with instructors and nursing staff to obtain feedback in making good clinical decisions, learning from mistakes and seeking guidance, working closely with professional nurses, and trying to improve your performance during each patient interaction. These skills require you to think critically and solve problems in the clinical setting (see [Chapter 15](#)). Thinking critically allows you to provide high-quality care, meet the needs of your patients while considering their preferences, consider alternatives to problems, understand the rationale for performing nursing interventions, and evaluate the effectiveness of care. Clinical experiences develop these critical thinking skills ([Benner et al., 2010](#)). Important leadership skills to learn include clinical care coordination, team communication, delegation, and knowledge building.

REFLECT NOW

Think about what you have learned about leadership development so far. Create a personal plan you can use to help you develop your own leadership skills.

Clinical Care Coordination

You acquire necessary knowledge and skills so you can deliver patient care competently and effectively. In the beginning you will probably care for only one patient, but eventually you will be able to care for groups of patients. To coordinate the clinical care of patients, you need to learn how to make clinical decisions, set priorities, delegate safely, gain organizational skills, use resources, manage time, and evaluate your patient's outcomes. Clinical care coordination requires you to use critical

reflection and reasoning and clinical judgment (Benner et al., 2010). These are important first steps in developing a caring relationship with a patient. Use a critical thinking approach, applying previous knowledge and experience to the decision-making process (see Chapter 15).

Clinical Decisions

You will make clinical decisions by applying the nursing process (see Chapters 16 to 20). You begin caring for a patient by conducting a focused but complete assessment so that you know your patient and can make accurate clinical judgments (see Chapter 16). Knowing the patient involves more than gathering formal assessment data. It requires learning a patient's typical patterns of responses and his or her current situation and knowing the patient as an individual. Your initial contact with a patient is an important first step in developing a caring relationship. Encouraging patients to share their stories about their health problems is very useful (e.g., say, "Tell me how you are dealing with ..." or "Can you share what has been your biggest problem since becoming ill?"). After obtaining a thorough assessment and identifying a patient's nursing diagnoses and problems, you develop a plan of care, implement nursing interventions, and evaluate patient outcomes. The process requires clinical decision making using a critical thinking approach (see Chapter 15).

Accurate clinical decision making ensures therapeutic nursing care, especially when a patient's condition changes. An important lesson in organizational skills is to be thorough. Learn to attend and listen to the patient, look for any cues (obvious or subtle) that point to a pattern of findings, and direct your assessment to explore the pattern further. Never hesitate to ask for assistance when a patient's condition changes.

Priority Setting

After forming a picture of a patient's total needs, you set priorities by deciding which patient needs or problems need attention first (see Chapter 18). Priority setting is not the ordering of a list of care tasks but rather a way to organize your care. Symptom pattern recognition from your assessment database and your knowledge help you understand which diagnoses require intervention and the associated time frame to intervene effectively (Ackley and Ladwig, 2017). It is important to set priorities whenever you provide patient care because it allows you to see the most important issues as well as the relationships among patient problems and avoid delays in taking action that can lead to serious complications for a

patient. If a patient is experiencing serious physiological or psychological problems, the priority becomes clear. You need to act immediately to stabilize his or her condition.

Nurses prioritize care in different ways. If you use Maslow's hierarchy of needs, you meet a patient's physiological needs such as oxygen, food, water, sleep, and elimination first. Once physiological needs are met, you help patients meet their higher-level needs, such as safety, security, belonging, esteem, and self-actualization. To prioritize your care, evaluate and weigh each competing task by reflecting on the following three questions:

- Is this a life-threatening situation? Will this patient or another patient be endangered if this task is not done immediately or is left for later?
- Is this task essential to patient or staff safety?
- Is this task essential to the patient's plan of care?

When prioritizing care, you need to understand the "big picture" of your patient's problems and goals. Once you know all your patient's problems, determine the relationships among the problems. Remember that setting priorities is a dynamic process; it changes frequently ([Alfaro-Lefevre, 2017](#)). Always give high priority to patient and caregiver safety (e.g., fall prevention, safe medication administration, and patient education needs). Use the following steps to classify problems into one of three priority levels, and use this information to help you set priorities ([Alfaro-Lefevre, 2017](#)):

1. Assign high priority to first-level problems using *ABC+VL* (**a**irway, **b**reathing, **c**ardiac and circulation problems, **v**ital signs concerns, and **l**ife-threatening laboratory values) and attend to these immediately.
2. Next address second-level problems, which immediately follow the first level and include concerns such as changes in mental status, untreated medical issues, acute pain, acute elimination problems, abnormal laboratory results, and risks.
3. Then tend to third-level problems, which are health problems other than those at the first two levels, such as long-term issues in health management, rest, and family coping.

Many patients have all three levels of problems, requiring you to make careful judgments in choosing a course of action. High-priority needs demand immediate attention. When a patient has diverse priority needs, it helps to focus on his or her basic needs. For example, a patient who just ambulated down the hall is short of breath. The dietary assistant arrives in the room to deliver a meal tray. Instead of immediately helping the patient with the meal, you position him comfortably in bed, offer basic hygiene measures, and then evaluate his breathlessness. The patient is likely to become more interested in eating after he is more comfortable. He also is more receptive to any instruction you need to provide.

Eventually you will be required to meet the priority needs of a group of patients. This means that you need to know the priorities of each patient within the group, assessing each patient's needs as soon as possible while addressing high priorities first. Use information from the change-of-shift or hand-off report, the patient acuity classification system, and information from the medical record to determine which patient to assess first. Over time you learn to spontaneously rank patients' needs by priority or urgency. Priorities do not remain stable but change as a patient's condition changes. It is important to think about the resources available, be flexible in recognizing that priority needs often change, and consider how to use time wisely.

You also set priorities based on your patient's expectations. Sometimes you establish an excellent plan of care; however, if a patient resists certain therapies or disagrees with your approach, your care will not be effective or safe. Be caring and work closely with a patient and family caregiver when setting priorities to establish trust and cooperation.

REFLECT NOW

Think about a patient you cared for recently. How did you prioritize the care you provided your patient? Did you provide care that was effective and efficient? What could you have done differently to improve your prioritization?

Organizational Skills

Implementing a plan of care requires you to be effective and efficient. Effective use of time means doing the right things, whereas efficient use of time means doing things right. Learn to become efficient by combining various nursing activities (i.e., doing more than one thing at a time). For example, during medication administration or while obtaining a specimen, combine therapeutic communication, teaching interventions, and assessment and evaluation. Always establish and strengthen relationships with patients and use any patient contact as an opportunity to convey important information. Patient interaction gives you the chance to show caring and interest. Always attend to a patient's behaviors and responses to therapies to assess whether new problems are developing and to evaluate responses to interventions.

It is easier to provide patient care if you are organized. A well-organized nurse approaches any procedure by having all the necessary equipment available and making sure that the patient is prepared. If the patient is comfortable and well informed, the procedure will probably go smoothly. Sometimes you need help from colleagues to perform or complete a procedure. Keep the work area organized and complete preliminary steps before asking co-workers for assistance.

Although you plan and deliver care based on established priorities, events sometimes occur that interfere with your plans. For example, just as you begin to bathe a patient, an x-ray technician enters to take a chest x-ray film. Once the technician takes the x-ray, a phlebotomist arrives to draw a blood sample. In this case your priorities conflict with the priorities of other health care personnel. It is important to always keep a patient's needs at the center of attention. If the patient experienced symptoms earlier that required a chest x-ray film and laboratory work, it is important to be sure that the diagnostic tests are completed. In another example a patient is waiting to visit family, and a chest x-ray film is a routine order. The patient's condition is stable, and the x-ray technician is willing to return later to shoot the film. In this case attending to the patient's hygiene and comfort so that family members can visit is the higher priority.

Use of Resources

Appropriate use of resources is an important aspect of clinical care coordination. Resources include members of the health care team. In any setting providing patient care occurs more smoothly when staff members work together. Never hesitate to have staff help you, especially when there

is an opportunity to make a procedure or activity more comfortable and safer for patients. For example, assistance in turning, positioning, and ambulating patients is frequently necessary when patients have mobility limitations. Having a staff member such as an AP assist with handling equipment and supplies during complicated procedures such as catheter insertion or dressing changes makes procedures more efficient. In addition, you need to recognize personal limitations and use professional resources for assistance. For example, you assess a patient and find relevant clinical signs and symptoms but are unfamiliar with the physical condition. Consulting with an experienced RN confirms findings and ensures that you take the proper course of action for the patient. Leaders know their limitations and seek professional colleagues for guidance and support.

Time Management

Shorter hospital stays, early discharges, same-day surgeries, and increasing complexity in patient's needs create stress for nurses as they work to meet patient needs in hospital settings (Huber, 2018). One way to manage this stress is to use time-management skills. These skills involve learning how, where, and when to use your time. Because you have a limited amount of time with patients, it is essential to remain goal oriented and use time wisely. Managing yourself better leads to better time management and reduces the risk of developing burnout (Moss and Good, 2016). Effective time management includes being prepared, being organized, and managing priorities.

Make efficient and effective use of your time by remaining focused on your patient's goals. However, also learn how to establish personal goals and realistic time frames. For example, you are caring for two patients on a busy surgical nursing unit. One had surgery the day before, and the other will be discharged the next day. The first patient's goals center on restoring physiological function that is impaired because of surgery. The second patient's goals center on adequate preparation to assume self-care at home. In reviewing the therapies required for both patients, you learn how to organize your time so that you complete your nursing care and your patients achieve their goals. Anticipate when care will be interrupted for medication administration and diagnostic testing, and determine the best time for planned therapies such as dressing changes, patient education, and patient ambulation. Delegating tasks is another way to help improve time management.

One useful time-management skill involves making a to-do list. When you begin to work with patients, it helps to make a list that sequences the nursing activities you need to perform. The hand-off report at the change of shift helps you prioritize activities based on what you learn about a patient's condition and the care provided before you arrived on the unit.

Consider activities that have specific time limits in terms of addressing patient needs such as administering a pain medication before a scheduled procedure or instructing patients before their discharge home. You also analyze the items on the list that are scheduled by agency policies or routines (e.g., medications or intravenous [IV] tubing changes). Note which activities need to be done on time and which activities you can do at your discretion. You need to administer medication within a specific schedule, but you are also able to perform other activities while in the patient's room. Finally, estimate the amount of time needed to complete the various activities. Activities requiring the assistance of other staff members usually take longer because you have to plan around their schedules.

Good time management also involves setting goals to help you complete one task before starting another. You will always deliver care to a group of patients, moving back and forth between patients as needs and priorities change. If possible, complete an activity started with one patient before moving on to the next. Care is less fragmented, and you are better able to focus on what you are doing for each patient. As a result, you will be less likely to make errors. Time management requires you to anticipate the activities of the day and combine activities when possible. When you practice good time management, you focus on organization and setting priorities. Other strategies include keeping your work area clean and clutter free and trying to decrease interruptions as you are completing tasks. [Box 21.5](#) summarizes principles of time management.

Box 21.5 Principles of Time Management

Goal setting: Review a patient's goals of care for the day and any goals you have for activities such as completing documentation, attending a patient care conference, giving a hand-off report, or preparing medications for administration.

Time analysis: Reflect on how you use your time. While working on a clinical area, keep track of how you use your time in different

activities. This helps you become more aware of how well organized you really are and areas you may need to improve upon.

Priority setting: Set the priorities that you have established for patients within set time frames. For example, determine when is the best time to have teaching sessions, plan ambulation, and provide rest periods based on what you know about a patient's condition. For example, if a patient is nauseated or in pain, it is not a good time for a teaching session.

Interruption control: Everyone needs time to socialize or discuss issues with colleagues. However, do not let this interrupt important patient care activities such as medication administration (see Chapter 31), ordered treatments, or teaching sessions. Use time during report, mealtime, or team meetings to your advantage. In addition, plan time to help fellow colleagues so that it complements your patient care schedule.

Evaluation: At the end of each day take time to think and reflect about how effectively you used your time. If you are having difficulties, discuss them with an instructor or a more experienced staff member.

Evaluation

Evaluation is one of the most important aspects of clinical care coordination (see [Chapter 20](#)). You constantly evaluate a patient's condition and progress toward an expected patient outcome. Evaluation is an ongoing process. It does not occur only at the end of an activity. Once you assess a patient's needs and implement interventions for a patient's problem, immediately evaluate whether the interventions were effective and the patient's response. The process of evaluation compares actual patient outcomes with expected outcomes. For example, a clinic nurse assesses a foot ulcer of a patient who has diabetes to determine whether healing has progressed since the last clinic visit. When expected outcomes are not met, evaluation reveals the need to continue current therapies for a longer period, revise approaches to care, or introduce new therapies. As you care for a patient throughout the day, anticipate when to return to the bedside to evaluate care (e.g., 30 minutes after an oral medication was administered, 15 minutes after an IV fluid has begun infusing, or 60 minutes after discussing discharge instructions with the patient and family).

Focusing on evaluation of a patient's progress lessens the chance of becoming distracted by the tasks of care. It is common to assume that

staying focused on planned activities ensures that you will perform care appropriately. However, task orientation does not ensure positive patient outcomes. Learn that at the heart of good organizational skills is the constant inquiry into a patient's condition and progress toward an improved level of health.

Team Communication

Effective communication is critical to all teams ([QSEN Institute, 2018](#)). As a part of a health care team, you are responsible for using open, professional communication. Regardless of the setting, an enriching professional environment is one in which staff members respect one another's ideas, share information, and keep one another informed ([Kaiser and Westers, 2018](#)).

Some health care organizations use evidence-based teamwork principles to improve communication, teamwork, and patient safety. The TeamSTEPPS® system provides training for all health care staff to guide communication, increase team awareness, and eliminate barriers to patient safety ([AHRQ, 2017](#)). Use TeamSTEPPS® principles to promote professional communication and teamwork in your practice setting ([Box 21.6](#)).

Box 21.6 Key TeamSTEPPS® Principles

Team Structure: Identify the complex parts of the health care system that have to work together effectively to promote patient safety.

Communication: Use structured processes to clearly and accurately exchange information among members of the health care team.

Leadership: Ensure that all members of the health care team understand the team's actions, receive information about changes, and have resources needed to perform their jobs.

Situation Monitoring: Actively assess any situation to gather information, improve your understanding, or maintain awareness to support the functioning of the team.

Mutual Support: Understand the responsibilities and workload of all team members so that you can anticipate and support their needs.

Modified from Agency for Healthcare Research and Quality (AHRQ):
Pocket guide: TeamSTEPPS®, 2014,
<https://www.ahrq.gov/teamstepps/instructor/essentials/pocketguide.html#frame>. Accessed September 2018.

Strategies to improve your communication with health care providers include addressing the colleague by name, having the patient and medical record available when discussing patient issues, focusing on the patient problem, and being professional and assertive but not aggressive or confrontational. One way of fostering good team communication is to understand the roles and responsibilities of everyone on the health care team (AHRQ, 2014). A professional nurse treats colleagues with respect, listens to the ideas of other staff members without interruption, explores the way other staff members think, and is honest and direct while communicating. Part of good communication is clarifying what others are saying and building on the merits of co-workers' ideas. An effective team knows that it is able to count on all members when needs arise.

Sharing expectations of what, when, and how to communicate is a step toward establishing a strong work team (AHRQ, 2014). Examples of effective team communication strategies include briefings or short discussions among team members, group rounds on patients, callouts to share critical information such as vital signs with all team members at the same time, and check-backs to restate what a person has said to verify understanding of information. The two-challenge rule allows concerns about safety to be voiced twice. Some patient care settings use different tools to communicate a change in a patient's condition. For example, some use the CUS Tool, which means I am Concerned, I am **U**ncomfortable, and this is a Safety issue (AHRQ, 2014). Another tool often used by health care organizations to share information is Situation-Background-Assessment-Recommendation (SBAR) (Box 21.7; see Chapter 27) (AHRQ, 2014). When using electronic communication, it is important to communicate the appropriate information to the correct person, always maintaining patient privacy and confidentiality.

Box 21.7 SBAR As a Communication Tool

Case Study: A nurse caring for patients on an orthopedic surgery unit administered 1 tablet of oxycodone HCl 5 mg/ibuprofen 400

mg PO to a patient 30 minutes ago for postsurgical pain. The nurse returns to the patient's room to evaluate the effectiveness of the medication. The patient rates his pain as an 8 on a scale of 0–10. The nurse uses SBAR to contact the patient's health care provider.

Situation: The patient is rating his pain as an 8 on a scale of 0–10. He had his pain medication 30 minutes ago.

Background: The patient had a knee replacement and returned from the postanesthesia care unit 6 hours ago. He has 1 tablet of oxycodone HCl 5 mg/ibuprofen 400 mg PO ordered every 6 hours. This is the first pain medication he has taken since being admitted to the unit.

Assessment: His current medication order is not sufficiently managing the patient's pain. He does not want to sit up or move because of the pain he is experiencing.

Recommendation: Request a change of the pain medication order for the patient.

Building Competency in Teamwork and Collaboration

You are caring for Mrs. Saucer, who had a stroke 3 days ago. Upon your initial assessment, she was oriented, smiling, and joking with her visitors. You enter her room 2 hours later and find that Mrs. Saucer remains oriented, but she is tearful, and her emotional status has changed. She states, "I'm not sure what is wrong with me. I feel so much different than I did earlier today." Your intuition tells you that although Mrs. Saucer's physical status and orientation have not changed, there is something that is not quite right. You know that even the slightest neurological change in a patient who has had a stroke could be a sign of worsening neurological status. Using the CUS tool, how would you communicate this change in status to Mrs. Saucer's health care provider?

Delegation

The art of effective delegation is a skill that you need to observe and practice to improve your own management skills. **Delegation** is the process of assigning part of your responsibility to another qualified person in a specific situation (NCSBN and ANA, 2019). Your state's Nurse Practice Act, along with principles of authority, accountability, and

responsibility, provides the basis for effective delegation. Effective delegation results in the achievement of quality, safe patient care; improved efficiency; increased productivity; empowered staff; and skill development (Yoder-Wise, 2015). For example, asking a staff member to obtain an ordered specimen while you administer a patient's pain medication effectively prevents a delay in the patient gaining pain relief. Delegation also provides job enrichment. You show trust in colleagues by delegating tasks to them and showing staff members that they are important players in the delivery of care (Riisgaard et al., 2017). Successful delegation is important to the quality of the relationship you have with all team members, including LPNs and APs (Lyman et al., 2017). Delegating a task that you dislike doing or would not do yourself creates negative feelings and poor working relationships. For example, if a patient asks to be placed on a bedpan and there are no urgent care issues, you assist the patient rather than leave the room to find the LPN or AP. Remember that even though the delegation of a task transfers the responsibility and authority to another person, you are accountable for the delegated task.

As a nurse you are responsible and accountable for providing care to patients and delegating care activities to others (Huber, 2018). Use the five rights of delegation to ensure you stay within an RN's legal scope of practice (Box 21.8). Never delegate clinical reasoning, nursing judgment (e.g., the steps of the nursing process of assessment, diagnosis, planning, intervention, and evaluation or patient teaching), and critical decision making to APs (NCSBN and ANA, 2019). Remember that when you delegate to another member of the health care team, you delegate tasks, not patients. Although LPNs can manage the majority of patient care on their own, do not give APs sole responsibility for the care of patients. One way to accomplish safe delegation is to conduct rounds with LPNs and APs who are assigned to work with you. APs attend to basic patient needs (e.g., hygiene, meal assistance, ambulation) while LPNs can provide basic direct nursing care (e.g., observe and report clinical changes, perform wound care, and ADLs). You delegate care based on assessment findings and priority setting.

Box 21.8 The Five Rights of Delegation

Right Task

The right tasks to delegate are ones that are included in the delegatee's job description or are included in the health care agency's policies and

procedures. Policies and procedures need to describe expectations, limits, and required competency training for the activity.

Right Circumstance

Consider the patient's status. The patient needs to be stable in order to delegate tasks. The delegatee must report changes in patient condition to the licensed nurse. The licensed nurse must reassess and evaluate the situation and appropriateness of delegation when a patient's condition changes.

Right Person

The licensed nurse, employer, and delegatee are all responsible for ensuring the delegatee has the knowledge and skills required to perform the activity.

Right Directions and Communication

Give a clear, concise description of a task, including its objective, limits, and expectations. Communication needs to be ongoing between the licensed nurse and delegatee. The delegatee is responsible to ask questions to clarify information.

Right Supervision and Evaluation

Provide appropriate monitoring, evaluation, intervention as needed, and feedback. The licensed nurse must follow up with the delegatee at the end of the activity to evaluate patient outcomes, be available and ready to intervene when appropriate, and ensure appropriate documentation.

Modified from National Council of States Boards of Nursing and American Nurses Association (NCSBN & ANA): *National guidelines for nursing delegation*, 2019, https://www.ncsbn.org/NGND-PosPaper_06.pdf. Accessed July 28, 2019.

As a leader of the health care team, you give clear instructions, effectively prioritize patient needs and therapies, and give staff timely and meaningful feedback. Do not automatically delegate a task because it is a task. Rather delegate it because it is appropriate for LPNs or APs to perform it. For example, as a nurse, you are always responsible for the assessment of a patient's ongoing status; but if a patient is stable, you delegate administration of medications (exception: IV medications in most states) to the LPN and the taking of vital signs to the AP.

Effective delegation begins with knowing which skills you are able to delegate. Thus you need to be familiar with the Nurse Practice Act of your state, institutional policies and procedures, and institutional job

descriptions for LPNs and APs. These standards define the necessary level of education and competency of all staff and contain specific guidelines regarding which tasks or activities you can delegate. A job description identifies any required education and the types of tasks LPNs and APs can perform, either independently or with direct supervision. Institutional policies define the training required for APs. Procedures detail who is qualified to perform a given nursing procedure, whether supervision is necessary, and the type of reporting required.

As a professional nurse you cannot delegate without considering the implications. Assess the patient and determine a plan of care before identifying which tasks someone else is able to perform. Determine how much supervision is necessary. For example, you are working with an AP who was recently hired. When deciding which tasks to delegate to the AP, determine whether the patient has a complicating factor that makes your assistance necessary. Ask the AP, "Is this the first time you have performed this task?" "Have you cared for patients with similar needs?" "Have you had the chance to do this skill during orientation?" If you decide you can delegate the skill, you need to evaluate whether the AP performed the task properly and whether the desired outcomes were met.

Efficient delegation requires ongoing communication (i.e., sending clear messages and listening so that all participants understand expectations regarding patient care) (Huber, 2018). Provide clear instructions and desired outcomes when delegating tasks. Focus your instructions on the procedure itself, what will be accomplished, when it should be completed, and the unique needs of the patient. You also communicate when and which information to report such as expected observations and specific patient concerns (NCSBN and ANA, 2019). Communication is a two-way process in delegation; thus create a trusting relationship so that the staff you work with (e.g., LPNs, APs) feel comfortable and are able to ask questions and clarify your expectations (NCSBN and ANA, 2019). Effective communication, shared decision making, and sharing of knowledge promote safe patient care (O'Leary, 2016). As you become more familiar with a staff member's competency, trust builds, and the staff member needs fewer instructions. Always clarify patients' specific needs.

When delegating patient care, you evaluate a staff member's performance, achievement of the patient's outcomes, the communication process used, and any problems or concerns that occurred (NCSBN and ANA, 2019). For example, when a newly hired AP performs a task correctly and does a good job, it is essential to provide praise and recognition. If a staff member's performance is not satisfactory, give

constructive and appropriate feedback. Always give specific feedback regarding any mistakes that staff members make, explaining how to avoid the mistake or a better way to handle the situation. Giving feedback in private is professional and preserves the staff member's dignity. When giving feedback, focus on what can be changed, choose only one issue at a time, and give specific details. Frequently when a staff member's performance does not meet expectations, it is the result of inadequate training or assignment of too many tasks. In this case, review the procedure and offer demonstration or even recommend additional training with the education department. If too many tasks are being delegated, this might be a nursing practice issue. All staff need to discuss the appropriateness of delegation on their unit. Sometimes staff need help to learn how to prioritize. In some cases, you discover that you are over delegating. It is your responsibility to complete documentation of the delegated task. Here are a few tips on appropriate delegation to assistive personnel (Yoder-Wise, 2015; NCSBN and ANA, 2019):

- *Assess the knowledge and skills of the person to whom you are delegating:* Assess the person's knowledge and skills by asking open-ended questions that elicit conversation and details about what he or she knows (e.g., "How do you usually apply the cuff when you measure a blood pressure?" or "Tell me how you prepare the tubing before you give an enema.")
- *Match tasks to the person's skills:* Know which tasks and skills the training program includes for APs in your organization. Determine whether APs have learned critical thinking skills such as knowing when a patient is in harm or the difference between normal clinical findings and changes to report.
- *Communicate clearly:* Always provide clear directions by describing a task, the desired outcome, and the time period within which the AP needs to complete the task. Never give instructions through another staff member. Make APs feel as though they are part of the team. Begin requests for help with *please* and end with *thank you*. For example, "I'd like you to please help me by getting Mr. Floyd up to ambulate before lunch. Be sure to check his blood pressure before he stands and record it in his chart. Thank you for your help." Ask the AP to report back to you after completing the task.
- *Listen attentively:* Listen to an AP's response after you provide directions. Does the AP feel comfortable in asking questions or requesting clarification? Does the AP understand your request?

Ask the AP for suggestions in patient care and listen to his or her response. Be especially attentive if the AP is helping another nurse. Help sort out priorities.

- *Provide feedback:* Always give the AP feedback regarding performance, regardless of outcome. Let them know of a job well done. A “thank you” increases the likelihood of the AP helping in the future. If an outcome is undesirable, find a private place to discuss what occurred, any miscommunication, and how to achieve a better outcome in the future.

Knowledge Building

As a professional and accountable nurse, you are responsible for lifelong learning and maintaining your competency (Zittel et al., 2016). Lifelong learning allows you to continuously provide safe, effective, quality care. A leader recognizes that there is always something new to learn.

Opportunities for learning occur with each patient interaction, each encounter with a professional colleague, and each meeting or class session in which health care professionals meet to discuss clinical care issues.

People always have different experiences and knowledge to share. Listen to the contributions of others and value the information they share. In-service programs, workshops, professional conferences, professional reading, and taking classes to further your education offer innovative and current information on the rapidly changing world of health care. To be a safe and competent nurse you need to actively pursue learning opportunities, both formal and informal, and to respectfully interact with the professional colleagues you encounter.

Key Points

- A transformational leader develops effective teams on the nursing unit, empowers staff members, communicates effectively with the nursing team, and guides and supports the nursing team in shared decision making.
- Nursing care delivery models vary according to the responsibility and autonomy of the nurse in coordinating care

delivery and the roles other staff members play in assisting with care.

- Patient- and family-centered care is composed of the core concepts of respect and dignity, information sharing, participation of family members, and collaboration.
- Shared governance, a type of decentralized decision-making model, empowers nursing staff to make decisions about how they practice and deliver patient care.
- Important elements of professional nursing and the decision-making process include responsibility (activities you perform), autonomy (freedom of choice), authority (your legal ability to perform a task), and accountability (being answerable for your actions).
- Nursing students and nurses develop their own leadership skills by being responsible and accountable, thinking critically, reflecting upon and learning from mistakes, and being an engaged member of the health care team.
- Nurses prioritize patient care in different ways. For example, to prioritize patient care, evaluate and weigh each competing task by reflecting on whether the patient is in a life-threatening situation, whether the task is essential to patient or staff safety, and whether the task is essential to the patient's plan of care.
- Nurses use evidence-based communication strategies such as SBAR and CUS to accurately communicate patient problems to other members of the health care team.
- Effective delegation requires effective communication skills and improves productivity and job enrichment. Using the five rights of delegation helps you delegate care appropriately.

Reflective Learning

- Reflect on a recent clinical experience. Which nursing care delivery model was used in this setting? What contributed to the effectiveness of this model? What challenges do you think the team may experience with this model?
- Describe how you prioritized care for a recent patient or group of patients during a recent clinical or simulation experience. Evaluate the effectiveness of your care and the decisions you made. Reflecting on this experience, is there anything you would have done differently? Explain your answer.
- Reflect on a clinical experience. What are some examples of teamwork and collaboration you witnessed? Did you observe any situations in which the health care team did not work well together? If so, what do you think caused this situation and what could be done to improve the work environment to reduce conflict and improve patient care? What effect did the lack of teamwork have on your patient?

Review Questions

1. At 1200 the registered nurse (RN) says to the assistive personnel (AP), "You did a good job walking Mrs. Taylor by 0930. I saw that you recorded her pulse before and after the walk. I saw that Mrs. Taylor walked in the hallway barefoot. For safety, the next time you walk a patient, you need to make sure that the patient wears slippers or shoes. Please walk Mrs. Taylor again by 1500." Which characteristics of positive feedback did the RN use when talking to the AP? (Select all that apply.)
 1. Feedback is given immediately.
 2. Feedback focuses on one issue.
 3. Feedback offers concrete details.
 4. Feedback identifies ways to improve.
 5. Feedback focuses on changeable things.

6. Feedback is specific about what is done incorrectly only.
2. A nurse received change-of-shift report on these four patients and starts rounding. Which patient does the nurse need to focus on as a priority?
 1. The patient who had abdominal surgery 2 days ago who is requesting pain medication
 2. A patient admitted yesterday with atrial fibrillation who now has a decreased level of consciousness
 3. A patient with a wound drain who needs teaching before discharge in the early afternoon
 4. A patient going to surgery for a mastectomy in 3 hours who has a question about the surgery
3. A nurse asks an AP to help the patient in Room 418 walk to the bathroom right now. The nurse tells the AP that the patient needs the assistance of one person and the use of a walker. The nurse also tells the AP that the patient's oxygen can be removed while he goes to the bathroom but to make sure that when it is put back on the flowmeter is still at 2 L. The nurse also instructs the AP to make sure the side rails are up and the bed alarm is reset after the patient gets back in bed. Which of the following components of the "Five Rights of Delegation" were used by the nurse? (Select all that apply.)
 1. Right task
 2. Right circumstance
 3. Right person
 4. Right directions and communication
 5. Right supervision and evaluation
4. While administering medications, a nurse realizes that a prescribed dose of a medication was not given. The nurse acts by completing an incident report and notifying the patient's

health care provider. Which of the following is the nurse exercising?

1. Authority
 2. Responsibility
 3. Accountability
 4. Decision making
5. Which task is appropriate for a registered nurse (RN) to delegate to an AP?
1. Explaining to the patient the preoperative preparation before the surgery in the morning
 2. Administering the ordered antibiotic to the patient before surgery
 3. Obtaining the patient's signature on the surgical informed consent
 4. Helping the patient to the bathroom before leaving for the operating room
6. A nurse performs the following four steps in delegating a task to an AP. Place the steps in the order of appropriate delegation.
1. Do you have any questions about walking Mr. Malone?
 2. Before you take him for his walk to the end of the hallway and back, please take and record his pulse rate.
 3. In the next 30 minutes please assist Mr. Malone in Room 418 with his afternoon walk.
 4. I will make sure that I check with you in about 40 minutes to see how the patient did.
7. Which example demonstrates a nurse performing the skill of evaluation?
1. The nurse explains the side effects of the new blood pressure medication ordered for the patient.

2. The nurse asks a patient to rate pain on a scale of 0 to 10 before administering a pain medication.
 3. After completing a teaching session, the nurse observes a patient drawing up and administering an insulin injection.
 4. The nurse changes a patient's leg ulcer dressing using aseptic technique.
8. The nurse manager from the surgical unit was awarded the nursing leadership award for practice of transformational leadership. Which of the following are characteristics or traits of transformational leadership displayed by the award winner? (Select all that apply.)
1. The nurse manager regularly rounds on staff to gather input on unit decisions.
 2. The nurse manager sends thank-you notes to staff in recognition of a job well done.
 3. The nurse manager sends memos to staff about decisions that the manager has made regarding unit policies.
 4. The nurse manager has an "innovation idea box" to which staff are encouraged to submit ideas for unit improvements.
 5. The nurse manager develops a philosophy of care for the staff.
9. A new nurse graduate is in orientation on a surgical unit and is being mentored by an experienced nurse. Which action completed by the new nurse graduate requires intervention by the experienced nurse? (Select all that apply.)
1. The new nurse stops documenting about a dressing change to take a patient some water.
 2. The new nurse gathered the medications for two different patients at the same time.
 3. The new nurse asked an AP to help transfer a patient from the bed to a wheelchair before discharge.

4. The new nurse educates a patient about pain management when administering a pain medication to a patient.
 5. The new nurse gathers all equipment necessary to start a new IV site before entering a patient's room.
10. A nurse is calling a patient's health care provider about a problem the patient is having following surgery. The health care organization uses the SBAR system in reporting patient problems. Put the statements in order according to the SBAR system.
1. Would it be possible to give the patient an antiemetic to help with the patient's nausea and comfort?
 2. The patient is experiencing nausea right now. The nausea has worsened over the past hour. He states he feels as though he is going to get sick.
 3. The patient had surgery earlier today to remove a tumor in the colon. He was admitted to the surgical unit 4 hours ago. He has a nasogastric (NG) tube in place. There is no postoperative order for an antiemetic.
 4. The patient denies pain and vital signs are stable. B/P 114/68; pulse 76; respiratory rate 20; temperature 98.6° F. The surgical dressing is dry and intact. The NG tube is intact and draining light brown fluid. It flushes well, and placement was confirmed using pH testing of gastric contents. The patient does not want to roll onto his side because of the nausea.

UNIT 4

Professional Standards in Nursing Practice

OUTLINE

22. Ethics and Values

23. Legal Implications in Nursing Practice

24. Communication

25. Patient Education

26. Informatics and Documentation

Ethics and Values

OBJECTIVES

- Discuss the role of ethics in professional nursing.
- Use values clarification when you apply ethics in practice.
- Define the principles and approaches commonly used in health care ethics discussions.
- Describe the difference between an ethical dilemma and moral distress.
- Apply a stepwise approach to ethical problems.
- Discuss contemporary ethical issues that nurses face.

KEY TERMS

Accountability, p. 296

Advocacy, p. 296

Autonomy, p. 295

Beneficence, p. 295

Bioethics, p. 294

Casuistry, p. 297

Code of ethics, p. 296

Confidentiality, p. 296

Deontology, p. 297

Ethics, p. 294

Ethics of care, p. 298

Feminist ethics, p. 298

Fidelity, p. 295

Justice, p. 295

Morals, p. 294

Nonmaleficence, p. 295

Utilitarianism, p. 297

Value, p. 294

Ethics is the study of what is right and wrong in our conduct. It concerns our obligations to individuals, groups and society. Acts that are ethical reflect a commitment to standards that individuals, professions, and societies strive to meet. When decisions must be made about health care, understandable disagreement can occur among health care professionals, families, patients, friends, and people in the community. The right thing to do can be hard to determine, particularly when individual values, beliefs, and perceptions conflict. This chapter describes concepts that will help you embrace the role of ethics in your professional life and promote resolution when ethical problems develop.

Basic Terms in Health Ethics

Ethical issues differ from legal issues. Legal issues are resolved by reference to laws that are usually concrete and publicly determined. Breaking a law results in a public consequence such as a ticket for speeding or jail time for stealing. However, ethics has a broader base of interest than the law, referring more to issues of behavior and character. The terms *ethics* and *morals* sometimes are used interchangeably. **Morals** usually refer to judgment about behavior, based on specific beliefs, and *ethics* refers to the study of the ideals of right and wrong behavior.

Values play an important role in understanding ethics. A **value** is a deeply held personal belief about the worth a person holds for an idea, a custom, or an object. The values that a person holds reflect cultural and social influences. For example, a person who makes a living in a rural place may value the environment differently than someone who visits rural areas for recreation. Ethical codes grow from shared values, negotiated and discussed over time through religious groups, ethnic groups, or work groups. As you enter the nursing profession, you undergo a similar process of learning shared values. Clarity about your values and your own point of view will guide you in making effective ethical decisions.

The study of **bioethics** represents a branch of ethics within the field of health care. The study of bioethics has grown over the last 50 years, beginning with the emergence of technologies related to organ transplant. When researchers perfected kidney transplant procedures in the early 1970s, only a limited number of kidneys were available for transplant compared with the number of patients in need. This lack of resources became an immediate ethical concern. The health care community in the United States began to address this issue by means of ethical discussion in local and national groups.

Changing medical technologies continue to require societies to face difficult ethical questions. Why should we do genetic testing for diseases we cannot cure? How shall we define quality of life? Who should decide? In the study of bioethics, health care professionals agree to negotiate these difficult and important questions by referring to a common set of ethical principles.

An understanding of the concepts common in ethical discourse will help you participate thoughtfully in discussions with others and may help you shape your own thoughts about ethical issues. The application of the concepts is fundamental to developing skills in ethical decision making.

During the ethical decision-making process, you will apply the concepts of autonomy, beneficence, nonmaleficence, justice, and fidelity.

Autonomy

Autonomy refers to freedom from external control. In health care the concept applies to respect for the autonomy of patients. It can also apply to institutional respect for the autonomy of health care professionals. A commitment to respect the autonomy of others is a fundamental principle of ethical practice.

Respect for patient autonomy refers to the commitment to include patients in decisions about all aspects of care (Klugman, 2017). It is a key feature of patient-centered care. In respecting patient autonomy, you acknowledge and protect a patient's independence. Respect for autonomy reflects a movement away from paternalistic patient care in which health care providers made all decisions. Involving patients in decisions about their care is now standard practice. We often demonstrate respect for patient autonomy through the informed consent process. Rather than the health care team making choices about the patient's care, the team's role is to inform patients about risks and benefits of treatment options and then, with the patient, determine a plan of care that matches their goals and values. In many cases (e.g., surgery and diagnostic procedures), the consent of a patient is documented by the patient's signature.

Another way nurses show respect for patient autonomy is by explaining nursing procedures such as obtaining a blood pressure or administering medications. Nurses also demonstrate respect for patient autonomy by supporting patients who raise questions about procedures and by ensuring that they get the information they request. In addition, your conversations with patients and families can help them to articulate their preferences, values, and goals. Clarifying what is important to them is a key step in making autonomous health care decisions.

Respect for professional autonomy refers to the relationship between members of the health care team and the institutions in which they work. What happens when a health care professional is asked to perform duties that conflict with a religious or personal belief? Institutions have developed policies that accommodate respect for health care professionals by finding a way to reassign duties when this conflict occurs. However, the reassignment is conducted so that the patient is protected from abandonment and patient care is not compromised. What happens when an individual employee takes issue with policies or practices of an

institution and is concerned that a practice is unsafe? Employees may be concerned about reporting information because of potential retaliation. Some organizations have an anonymous reporting system for this reason. Institutional whistle blower protections prohibit retaliation against an employee who makes a legitimate report about clinical safety issues. These protections represent expressions of respect for professional autonomy.

REFLECT NOW

Consider decisions that you make about the activities you engage in or the people you are friends with. Do these decisions reflect autonomous choices or do factors outside your own preference influence them?

Beneficence

Beneficence refers to taking positive actions to help others (Klugman, 2017). The concept of beneficence is fundamental to the practice of nursing and medicine. The agreement to act with beneficence implies that the best interests of the patient remain more important than self-interest. It implies that nurses practice primarily as a service to others, even in the details of daily work.

Nonmaleficence

Maleficence refers to harm or hurt. **Nonmaleficence** refers to the avoidance of harm or hurt. In health care, ethical practice involves not only the will to do good but the equal commitment to do no harm (Klugman, 2017). A health care professional tries to balance the risks and benefits of care while striving at the same time to do the least harm possible. A bone marrow transplant procedure may offer a chance at cure; but the process involves periods of suffering, and it may not be possible to guarantee a positive outcome. Decisions about the best course of action can be difficult

and uncertain precisely because nurses agree to avoid harm at the same time as they commit to promoting benefit.

Justice

Justice refers to fairness and the distribution of resources (Klugman, 2017). The term is most often used in discussions about access to health care, including the just distribution of scarce services and resources. Discussions about health insurance, hospital locations and services, and organ transplants generally are among the issues that cite the concept of justice. The term itself is open to interpretation, as people interpret fairness differently. Does the concept of justice mean that health care resources should be available to those who have earned them? Or is it fairer to distribute them equally? Should those with a greater need for resources receive more than others? Especially as health care costs continue to rise, the issue of justice remains a critical part of the discussion about health care reform and access to care.

The term *just culture* refers to the promotion of open discussion without fear of recrimination whenever mistakes, especially those involving adverse events, occur or nearly occur. Blame is withheld at least at first so that system issues and other elements can be investigated for their contributions to the error. By fostering open discussion about errors, members of the health care team become more richly informed participants, able to design new systems that prevent harm.

Fidelity

Fidelity refers to faithfulness or the agreement to keep promises (Doherty and Purtilo, 2016). As a nurse you have a duty to be faithful to the patients you care for, to the institution you work for, and to yourself. If you assess a patient for pain and offer a plan to manage the pain, the standard of fidelity encourages you to initiate the interventions in the plan as soon as possible and to monitor the patient's response to the plan. Fidelity is honored when we strive to provide excellent care to all patients, including those whose values are different from our own. We recognize a professional duty to apply the same skills and knowledge to the care of patients and families, regardless of their background, lifestyle, or past or present choices. When our need to exercise our own autonomy leads us to remove ourselves for a particular treatment or situation, fidelity demands

that we not abandon the patient but instead find an equally qualified professional to provide the care we are unable to give.

Our duty to be faithful to the institution employing us means that we follow the policies and procedures set forth, or in the event that the policy or procedure is not appropriate, we seek to correct it and improve the standard of care provided by the institution. Finally, fidelity to oneself is honored when we attend to our own needs for emotional support, mentoring, or continuing education. Honoring our commitment to ourselves is essential to the delivery of safe and effective care to patients.

Professional Nursing Code of Ethics

A **code of ethics** is a set of guiding principles that all members of a profession accept. It is a collective statement about the group's expectations and standards of behavior. The American Nurses Association (ANA) established its first Code of Ethics for Nursing in 1950, and the organization has continued to review and revise it periodically. The provisions of the Code of Ethics describe the nurse's obligation to the patient, the role of the nurse as a member of the health care team, and the duties of the nurse to the profession and to society ([ANA, 2015](#)). A few of the key principles in the code include advocacy, responsibility, accountability, and confidentiality.

Advocacy

Advocacy refers to the application of one's skills and knowledge for the benefit of another person. Lawyers are sometimes called "advocates" because they use their expertise to advance their clients' best interests. As a nurse you advocate for the health, safety, and rights of patients, including their right to privacy and their right to refuse treatment ([Giuliante, 2017](#)). Your special relationship with patients provides you with knowledge that is specific to your role as a registered nurse and as such with the opportunity to make a unique contribution to understanding a patient's point of view.

Responsibility

The word *responsibility* refers to a willingness to respect one's professional obligations and to follow through. As a nurse you are responsible for your actions, the care you provide, and the tasks that you delegate to others. This responsibility also means maintaining your competence to provide care and seeking guidance when you are uncertain of your skills and knowledge. You also demonstrate responsibility by applying your workplace's policies and procedures to the care you provide.

Accountability

Accountability refers to answering for your own actions. You ensure that your professional actions are explainable to your patients and your employer. Health care institutions also exercise accountability by

monitoring individual and institutional compliance with national standards established by agencies such as The Joint Commission (TJC). TJC establishes national patient safety guidelines to ensure patient and workplace safety through consistent, effective nursing practices (TJC, 2019). The ANA Code of Ethics promotes ethical decision making by setting standards for collaborative interprofessional communication (ANA, 2015).

Confidentiality

Patients have the right to keep their personal health information private. **Confidentiality** refers to the health care team's obligation to respect patient privacy. Confidentiality is a fundamental part of the trusting relationship between a nurse and a patient (Doherty and Purtilo, 2016). Federal legislation known as the Health Insurance Portability and Accountability Act of 1996 (HIPAA) mandates confidentiality and protection of patients' personal health information. The legislation defines the rights and privileges of patients for protection of privacy. It establishes fines for violations (USDHHS, 2017). In practice, you cannot share information about a patient's medical condition or personal information with anyone who is not involved in the care of the patient. HIPAA calls this the "right to know." HIPAA also regulates communication of patient information contained in medical records (see Chapter 26).

Values

Nursing is a work of intimacy. Nursing practice requires you to be in contact with patients physically, emotionally, psychologically, and spiritually. In most other intimate relationships, you choose to enter the relationship anticipating that at least some of your values will align with those of the other person. But as a nurse you agree to provide care to your patients solely on the basis of their need for your services. The ethical concepts of beneficence and fidelity shape the practice of health care and distinguish it from other common human relationships such as friendship, marriage, and employer-employee. By its very nature, relationships in health care sometimes occur in the presence of conflicting values.

A value is a deeply held belief about the worth of an idea, attitude, custom, or object that affects choices and behaviors. While values reflect cultural and social influences, they can change over time as individuals become part of different groups. For example, you have personal values from your family, education, and other experiences, and then, as a nurse, you develop professional values as a member of the nursing profession and the health care team. Recognizing your own values is like seeing the bubble you live in; most of the time, we look at the world through the lens of our values without acknowledging them. Values are intrinsic to our view of the world. Learning to appreciate your values as your own individual perspective is the first step to working effectively with other health care professionals, patients, and families whose values are different.

Values Clarification

Ethical dilemmas almost always occur in the presence of conflicting values. To resolve ethical conflicts, one needs to distinguish among value, fact, and opinion. Facts are supported by objective data, and opinions are views or ideas that are not necessarily based on facts. Sometimes people have such strong values that they consider them to be facts. However, when people express a strong emotional reaction, this is often a sign that their values are threatened. Sometimes people are so passionate about their values that they become judgmental in a way that intensifies conflict. Clarifying values—your own, your patients', your co-workers'—is an important and effective part of ethical discourse.

Examine the cultural values exercise in [Box 22.1](#). The values in the exercise are in neutral terms so that you can appreciate how differing values need not indicate “right” or “wrong.” For example, for some people

it is important to remain silent and stoic in the presence of great pain, and for others it is important to talk about it to understand and control it. Identifying values as something separate from facts can help you understand others even when there are differences that set you apart.

Box 22.1 Cultural Values Exercise

The column on the right contains statements describing an opinion; the column on the left contains statements describing the opposite opinion. Neither statement is right, nor is it wrong. These statements reflect opinion, not necessarily fact. If people from a variety of cultures were given this questionnaire, some would strongly agree with the beliefs on the right and others with the opinions on the left. Read each statement and reflect on your own values and opinions. Circle 1 if you strongly agree with the statement on the left and 2 if you moderately agree. Circle 4 if you strongly agree with the statement on the right and 3 if you moderately agree.

Statement	Rank	Statement
Preparing for the future is an important activity and reflects maturity.	1 2 3 4	Life has a predestined course. The individual should follow that course.
Vague answers are dishonest and confusing.	1 2 3 4	Vague answers are sometimes preferred because they avoid embarrassment and confrontation.
Punctuality and efficiency are characteristics of a person who is both intelligent and concerned.	1 2 3 4	Punctuality is not as important as maintaining a relaxed atmosphere, enjoying the moment, and being with family and friends.
When in severe pain, it is important to remain strong and not to complain too much.	1 2 3 4	When in severe pain, it is better to talk about the discomfort and express frustration.
It is self-centered and unwise to accept a gift from someone you do not know well.	1 2 3 4	It is an insult to refuse a gift when it is offered.
Addressing someone by his or her first name shows friendliness.	1 2 3 4	Addressing someone by his or her first name is disrespectful.
Direct questions are usually the best way to gain information.	1 2 3 4	Direct questioning is rude and could cause embarrassment.
Direct eye contact shows interest.	1 2 3 4	Direct eye contact is intrusive.
Ultimately the independence of the individual must come before the needs of the family.	1 2 3 4	The needs of the individual are always less important than the needs of the family.

Modified from Renwick GW, Rhinesmith SH: *An exercise in cultural analysis for managers*, Chicago, 1995, Intercultural Press.

Approaches to Ethics

Historically, health care ethics constituted a search for fixed standards that would determine correct actions. Over time ethics has grown into a field of study that is more flexible and is filled with differences of opinion and deeply meaningful efforts to understand human interaction. The following review introduces you to some of the philosophical approaches to ethics that you may encounter during ethical discussions in health care settings. These approaches can be intentionally adopted to help you interpret and address ethical problems in practice. *To illustrate how these approaches work, consider a situation in which a nurse is caring for an older adult, Stella, who has dementia and whose son, David, does not adhere to the unit's visitation policy, namely, that he leave her bedside for half an hour during change of shift.*

Deontology

Deontology proposes a system of ethics that is perhaps most familiar to health care practitioners. **Deontology** defines actions as right or wrong based on their adherence to rules and principles such as fidelity to promises, truthfulness, and justice (Klugman, 2017). Instead of looking at consequences of actions to determine whether they are right or wrong, deontology examines a situation for the existence of essential right or wrong. *In the situation of Stella and David, the nurse applying a deontology approach may see the right action as seeking help in enforcing the visitation policy. Her fidelity to the institution supports a duty to enforce its regulations. Making an exception for David when other family members are following the rules is an injustice.*

Deontology requires a mutual understanding of justice, autonomy, and goodness. But it still leaves room for confusion to surface. The principle of respect for autonomy can be complicated when dealing with children and patients, like Stella, who may be unable to voice their preferences. *If Stella stated clearly that she desired David's presence at all times, a respect for her autonomy could be the guiding principle. In this case, the nurse should advocate for an exception to the visitation policy.* A commitment to respect the "rightness" of autonomy is a guiding principle in deontology, but adherence to the principle alone does not always provide clear answers for complicated situations.

Utilitarianism

A utilitarian system of ethics proposes that the value of something is determined by its usefulness. This philosophy is sometimes called consequentialism because its main emphasis is on the outcome or consequence of action. The greatest good for the greatest number of people is the guiding principle for determining right action in a utilitarian system (Klugman, 2017). As with deontology, **utilitarianism** relies on the application of a certain principle (i.e., measures of “good” and “greatest”). The difference between utilitarianism and deontology is the focus on outcomes. Utilitarianism measures the effect that an act will have; deontology looks at the act itself and judges its “rightness” by the rules or principles it upholds.

In the case of Stella and David, a nurse applying a utilitarian approach may determine that resolving the issue about David’s visit should be done in a manner that creates the least risk of disturbing the rest of the patients and the other staff members on the unit. The nurse interprets the greatest good for the greatest number as the absence of conflict and thus negotiates an exception to the visitation policy. While violating the policy is unacceptable in a deontological approach because that action itself is not good, in utilitarianism, if the outcome, a peaceful interaction with the son, is good, then the action itself is correct.

As with deontology, the utilitarian approach has some flaws, mainly that it can be taken too far. Do the ends always justify the means? A classic example in health care is the idea of removing organs from a perfectly healthy person to save the lives of seven other people who are awaiting transplantation. Seven people are more than one, so the outcome is good, but does that make the action, killing that one person, right? In addition, people have conflicting definitions of “greatest good.” As with deontology, utilitarianism provides guidance, but it does not guarantee agreement.

Casuietry

Casuietry, or case-based reasoning, turns away from conventional principles of ethics as a way to determine best actions and focuses instead on the details of a situation. People who take this approach to ethics find similar precedent cases and determine a course of action on the basis of what was done to manage that prior situation (Strong, 2013). *A nurse applying this approach to the case of Stella and David would consider past*

instances in which families were permitted to stay at the bedside, even during change of shift, or other instances in which families made a similar request but were asked to follow the policy as it stands. A key step in applying this approach is comparing the details of Stella and David's situation, such as her prognosis and his ability to contribute to her care, to determine which prior situation is the closest match. A weakness of the casuistry approach is that finding a similar precedent case may be challenging, particularly in complex situations with unique features.

Feminist Ethics

Noting the limitations of deontology and utilitarianism, scholars who focused on differences between genders, especially women's points of view, developed a critique of conventional ethical philosophies. Called **feminist ethics**, it looks to the nature of relationships to guide participants in making difficult decisions, especially relationships in which power is unequal or in which a point of view has become ignored or invisible (Green, 2012). Writers with a feminist perspective tend to concentrate more on practical solutions than on theory and to ask questions about the people involved and their relationships rather than looking to underlying principles.

For Stella and David, a nurse taking the feminist approach might look for a power imbalance and seek to take action that addresses it. Is David's presence at the bedside intimidating for Stella? Are staff members seeking to enforce the policy assuming a position of unjustified power over David? These questions, which may not surface in a traditional approach, will help determine the action that is right from a feminist ethics perspective.

Critics of feminist ethics worry about the lack of appeal to traditional ethical principles. Without guidance from concepts such as autonomy and beneficence, they argue, solutions to ethical questions will depend too much on subjective judgment.

Ethics of Care

The **ethics of care** offers an alternative view to utilitarianism and deontology. Similar to feminist ethics, care-based ethics focuses on understanding relationships, personal narratives and the context in which ethical problems arise. Unlike feminism, ethics of care emphasizes the role of the decision maker in the situation. With deontology and utilitarianism, the decision maker is detached and objective, gathering facts, identifying

principles, or predicting outcomes. In the ethics of care, the decision maker lies in the context of the situation, relating to the people involved (Lachman, 2012). This philosophy often resonates with nurses who, in their intimate experiences with patients, are often making ethical decisions while engaged in caring relationships.

A nurse taking the ethics of care approach with Stella and David first learns more about the relationships involved in the current situation and then identifies the course of action that best supports them. Stella and David have a relationship to each other, and the nurses caring for Stella also have a relationship with each of them. What action, allowing David to stay or asking that he leave, will have the best impact on those relationships? Are there additional actions, such as listening to David's reasons for wanting to stay, that might have a positive impact on these relationships?

Nursing Point of View

All patients in health care systems interact with nurses at some point, and they interact in ways that are unique to nursing. Nurses generally engage with patients over longer periods of time than other disciplines. They are involved in intimate physical acts such as bathing, feeding, and special procedures. As a result, patients and families may feel more comfortable in revealing information or asking questions they have not shared with other health care providers. Details about family life, information about coping styles, personal preferences, and details about fears and insecurities are likely to come out during the course of nursing interventions. Your ability to shape your care based on this special knowledge provides an indispensable contribution to the overall care of your patient.

The care of any patient involves the collaboration of many disciplines. Therapists, physicians, surgeons, social workers, and pharmacists are some of the interprofessional team members who will provide care to patients with you and bring their own points of view. In addition, managers and administrators from many different professional backgrounds contribute to ethical discourse with their knowledge of systems, distribution of resources, financial possibilities, and limitations (Fig. 22.1).

FIG. 22.1 Nurses collaborate with other professionals in making ethical decisions.

REFLECT NOW

Consider a time in which you disagreed with a family member or a friend about the correct action to take in a situation. What factors helped you or prevented you from honestly expressing your own point of view? What did it feel like to listen to the other person's perspective?

Types of Ethical Problems

Two common ethical problems that nurses encounter are ethical dilemmas and moral distress (Robichaux, 2017). As an example, take a situation in which a nursing student working with an older adult finds that the patient refuses to take her morning pills. "I won't take a single one until you give me my hormone medicine." The patient has several medical problems, but none of her morning pills fit the description of "hormone medicine." In relating the issue to another member of the health care team, she is advised, "Why don't you go in there with one of the pills she needs and tell her it is her hormone pill? Then she'll cooperate with you."

Ethical Dilemma

The nursing student immediately feels conflicted by this advice. If the student follows the suggestion, the student can accomplish the task of delivering the medications, a task that is in the patient's best interest and so could be justified by the principle of beneficence. At the same time, the student feels uncomfortable lying to the patient. Lying to her is a violation of the patient's autonomy, a betrayal of her trust. This interpretation of the situation is a classic example of an ethical dilemma. The student cannot do both options—take the advice to lie so that the patient gets the benefit of the medications *and* be truthful in identifying the pills to the patient. An ethical problem is called a dilemma when two opposing courses of action can both be justified by ethical principles (Robichaux, 2017).

Moral Distress

Now imagine the same situation with a change in details. The person the nursing student consults for help is the patient's attending physician, and the advice to lie about the pills feels to the student like a specific direction —not so much a suggestion but more of an order. At the same time, envision that at this moment during the clinical day, there is no one else the student can turn to for help. The student was told by her clinical instructor about the need to be more efficient in completing tasks and the medications were due to be given 30 minutes ago. Given the pressure of time and the source of the advice, the student might feel compelled to lie to the patient. But what if, based on her values, the student feels that action is morally wrong? Now the student is at risk for moral distress, a different ethical problem. In moral distress, instead of competing options for action, the nurse feels the need to take a specific action while believing that action to be wrong (Robichaux, 2017).

Distinguishing between ethical dilemmas and moral distress is important to achieving resolution. When the problem is a dilemma, with two opposing but justifiable options, often the application of the nursing process will include identifying more options. For example, the student might be able to succeed in giving the patient her medications without lying if the student builds trust with the patient by spending time with her. With moral distress, as this example shows, the environment often contributes to the problem. Discuss situations that generate moral distress with another person when they are identified. Additional resources, such as nursing colleagues, managers, and other health care professionals, can work together to address the factors that contribute to moral distress (Box 22.2).

Box 22.2 Evidence-Based Practice Moral Distress

PICOT Question: Do strategies that build moral resilience reduce moral distress among acute care nurses?

Evidence Summary

Moral distress describes the anguish experienced when a person feels unable to act according to closely held core values. Evidence indicates that causes of moral distress among acute care nurses include inadequate staffing, poor communication between members of the health care team, and situations that involve end-of-life care (Rodney, 2017). Nurses need to be aware of moral distress and recognize the need for moral reasoning (Rushton, 2017). While multiple studies document the existence of moral

distress and its association with aspects of the work environment, interventions to address moral distress are an area of evolving research (Rushton, 2017). Strategies to address moral distress consider not only the individual experiencing the problem but also the work environment. Institutions often offer services such as an ethics resource or a moral distress service to specifically address the needs of nurses. Hamric and Epstein (2017) described a Moral Distress Consult Service that is accessible to all units in the hospital and helps address pervasive or persistent issues that are causing moral distress. On the unit level, proactive interventions may be applied to prevent moral distress. For instance, an assessment tool to identify patient care situations with a high likelihood of generating ethical problems allows early allocation of resources, such as multidisciplinary discussion, to reduce the risk (Pavlish et al., 2015). An additional unit-level strategy is to find and correct problems in the work environment (Sofer, 2017). The American Association of Critical-Care Nurses (AACN) created the Standards for Establishing and Sustaining Healthy Work Environments and an Assessment Tool that health care teams can use to identify and address gaps (AACN, 2016). Moral resilience is the ability to grow and even gain confidence from adverse and complex ethical problems (Rushton, 2017). While further study is needed, deliberate attention to building moral resilience among nurses may reduce their susceptibility to moral distress.

Application to Nursing Practice

- Develop and practice skilled communication. Learning to talk with colleagues, patients, and families in a professional manner that conveys a desire to share your own views and an openness to theirs can help prevent conflicts and reduce moral distress.
- Be aware of the resources available to help you reduce moral distress. Find out whether your hospital has an ethics committee or other resource for support and how that resource is consulted (Hamric and Epstein, 2017).
- Find a mentor or leader on your unit with a particular skill in examining ethical problems to help you process ethical situations.
- After you've had some experience on a unit, you may notice a pattern in which certain clinical situations repeatedly lead to moral distress. When caring for a patient in that kind of situation, seek support before conflict arises. Early action may help reduce your distress (Pavlish et al., 2015).

Processing an Ethical Problem

Resolving an ethical problem is similar to the nursing process in its methodical approach to a clinical issue. However, it differs from the nursing process in that it requires negotiation of differences of opinion and clarity about situations where there may not be a single right answer. Finding clarity and consensus can occur when the following elements remain essential to the process: the presumption of goodwill on the part of all participants, strict adherence to confidentiality, patient-centered decision making, and the welcome participation of families and primary caregivers.

Because they involve values and obligations, ethical problems can raise troubling emotions. Processing an ethical problem begins with recognizing that an ethical problem exists (Doherty and Purtilo, 2016). Sometimes communication problems look like ethical problems, and taking the time to speak openly and listen to others achieves resolution. You then gather pertinent information about the case, including recent clinical evaluations, the views of colleagues, and the values and perspectives of the patient and family involved. Examining your personal values at this point can help to differentiate between fact and opinion, an important part of the process. Once information is gathered and ethical elements identified, developing a statement of the problem will facilitate discussion. The next step, listing all possible courses of action, requires some creativity and is best done in a conversation with others. Deciding on an action and implementing it sometimes requires courage. The final step is an evaluation of the outcome (Doherty and Purtilo, 2016) (Box 22.3).

Box 22.3 Key Steps in the Resolution of an Ethical Dilemma

Step 1: Ask: Is this an ethical problem?

Step 2: Gather information relevant to the case. Patient, family, institutional, and social perspectives are important sources of relevant information.

Step 3: Identify the ethical elements in the situation by clarifying values and recognizing the principles involved. Distinguish among fact, opinion, and values.

Step 4: Name the problem. A clear, simple statement of the problem is not always easy, but it helps to ensure effectiveness in the final plan and facilitates discussion.

Step 5: Identify possible courses of action. Access others for their input and be creative in identifying different options.

Step 6: Create and implement an action plan. Gather support from others and identify an alternative action if the chosen one does not achieve resolution.

Step 7: Evaluate the action plan to determine whether further action is needed or if lessons learned in this experience can be applied forward.

If the process involves a family conference or changes in the treatment plan, you document all relevant information in the medical record. Some institutions use a special ethics consultation form to structure documentation. However, if the ethical concern does not directly affect patient care, you may document the discussion in meeting minutes or in an e-mail to those involved in the discussion.

To review the process of ethical decision making, consider the following situation:

You are caring for Miguel, an 18-year-old with diabetes. Another nurse tells you that his parents are supportive, involved, and knowledgeable about his condition, but Miguel is mostly angry and uninterested in diabetes education. You walk into the room and find that a friend from Miguel's high school is visiting and has brought in candy and other snacks that contradict Miguel's prescribed diet. What is the best action to take?

Step 1. Ask: Is this an ethical problem?

While feeling uncertain about how to respond can be an indication of an ethical problem, not all uncertainty involves values and obligations. Some uncertainty can resolve with asking for advice or gathering more information. When strong emotions are triggered and when you are in a situation in which the action you take will demonstrate your personal or professional values, then you may have an ethical problem. If the problem is an ethical dilemma, you will likely feel conflicted between opposing courses of action, which each seem right in some ways and wrong in others. Moral distress often manifests as anger or frustration ([Rushton et al., 2017](#)).

In this case, more clinical information alone will not resolve the problem; you know that Miguel's health could be harmed if he ate all the candy and snacks his friends brought him. You may feel angry that Miguel is threatening his own health, which, as a member of the health care team, you feel obligated to protect. At the same time, you may also value Miguel's autonomy; he is technically an adult and has a right to select his diet, as long as he is informed of the risks and benefits. If you feel compelled to allow him to enjoy the snacks his friend brought while also feeling that it is wrong to do so, the situation may become morally distressing. There could be an ethical dilemma because two opposing actions—to try to stop Miguel from eating the snacks or to leave him alone—can both be justified. The situation is an ethical problem.

Step 2. Gather information that is relevant to the case.

Resolution of ethical problems can come from unlikely sources. Helpful information may include clinical information about the patient's current state of health, literature about his disease process, and information about his religious, cultural, and family background. A key strategy in gathering information is asking open-ended questions and taking time to listen. Because our interpretation of a situation is based on our own values, we need focused interaction to hear the perspectives of others.

A review of Miguel's chart shows that his diabetes is poorly controlled. There is a note from the hospital's diabetes education program indicating that Miguel and his parents were given information about a diabetic diet and appeared to understand the information. There is also a note by the social worker concerned that Miguel is having trouble accepting this diagnosis.

Step 3. Identify the ethical elements in the problem and examine your values.

Part of the goal is to accurately identify your own perspective, and an equally critical goal is to form respect for the perspectives of others. Consider whether the principles discussed earlier support a particular course of action. Take a moment to examine whether there are relationships involved that need to be supported or that could be adversely affected by actions to resolve the problem.

Reflect on your values. You want to ensure that Miguel manages his diabetes because you value his health. At the same time, you recognize that as a

teenager, he wants the freedom to make his own choices, unrestrained by his disease process. You value him as a person and recognize that in addition to his physical health problems, he has developmental needs. Beneficence, the obligation to do good, supports you in seeking the action that is best for Miguel. The concept of autonomy supports actions that respect his right to make his own choices, while fidelity to the health care team supports actions that adhere to the current treatment plan.

Step 4. Name the problem.

This step is harder than it sounds and often goes better if you involve others—either a friend, another nurse, or the health care team. While it is possible to develop a statement that specifically describes the problem on your own, speaking aloud encourages you to use the right language and allows you to get feedback from others. As you will find in Step 5, you may need to collaborate in later steps too, and so identifying someone to talk to at this step may facilitate a faster resolution.

After reviewing Miguel’s medical record, you find a colleague who has a few minutes to hear your story. As you talk to her, you say, “On the one hand, I want to go in there and take away that food because he really shouldn’t have it, and I know he knows that. On the other hand, I can see where he may be trying to show his independence from his parents and do things that other teenagers do.” You arrive at the conclusion that you have an ethical dilemma between acting with beneficence to protect Miguel’s health and respecting his autonomy.

Step 5. Consider possible courses of action.

In a dilemma, there are two courses of action that can be justified, but they are opposing, so it is often helpful to think of other options. At this stage, it is important to know your resources. Ask yourself what the options are and also ask who is available to help. Like most aspects of health care, ethics is best managed as a team and not in isolation. Knowing the resources available to help you with ethical problems is similar to knowing the resources for clinical issues. [Box 22.4](#) lists some of the resources to consider.

Box 22.4 Resources to Address Ethical Problems

Nursing colleagues—to listen to the problem, offer alternative actions, and help you articulate the issue. Giving and receiving support from other nurses promotes a positive work environment.

Nurse leaders—may include a preceptor, charge nurse, manager, educator, or advanced practice registered nurse. They may have faced and managed similar situations and so have guidance to offer. They can also access other resources within the hospital.

Members of the interprofessional team—includes physicians, social workers, therapists, pharmacists, and chaplains. All may be interacting with the patient or aware of the situation that you are facing. Hearing their perspectives can help you to identify the problem and consider solutions.

Consultation services—may include ethics committees and palliative care specialists. Ethics committees often gather members of the team with divergent views and facilitate productive conversation. Palliative care consult services are a resource in some institutions for the management of seriously ill patients.

Professional organizations—often set standards for nursing practice and have web-based resources to help you develop knowledge and skills in ethical analysis.

Boards of Nursing—can help address questions about scope of practice and competency.

As you talk to your colleague, you identify the option of taking a tough stance with Miguel and removing the food and the option of avoiding his room and pretending to be unaware of his behavior. Your colleague points out that another option is to ask him about his behavior but in a kind way, not punitive or threatening. You also consider calling in Miguel's doctor to talk to him, calling his parents and asking that they intervene, or pulling Miguel's friend out of the room and explaining to him that he needs to leave and take the food with him because he is disrupting Miguel's care.

Step 6. Create an action plan and carry it out.

Often through the process of articulating the problem and listing the options, the course of action that is the best fit becomes clear. Rather than determining a single action to take, it may be helpful to select what to do first and then what to do later if that first step is ineffective in achieving resolution. For instance, if in identifying options for action you decide to call on a particular resource, such as a manager, for help, you may also decide that if the manager validates the issue, you will go on to consult the hospital ethics committee.

This step requires courage. Because ethics deals with values and obligations, unpleasant emotions such as fear and anger can occur. As much as possible, focus on your desired outcome, which is resolution of the ethical issue, to help you enact the plan.

You decide to take your colleague's advice and go to the room to speak to Miguel. If that is ineffective, then you will call on other members of the health care team. Your colleague helps you to plan the words you will use. Despite your nervousness, you enter the room and tell Miguel, "I don't want to stop you from enjoying your friend's visit, but I'm concerned about the snacks he brought. I know you've had education about your diet. Can we talk about that?"

Miguel shrugs and says, "I don't really care." You then ask, "Well, what do you care about?" Miguel looks surprised. His friend smiles and says the name of a computer game Miguel likes. "That's what Miguel cares about," the friend says. A conversation ensues among you, Miguel, and his friend, and for the first time Miguel seems content rather than sullen and angry. After the conversation, you ask Miguel if his friend can take the snacks with him when he leaves, telling him, "It sounds as if you have things to do that are better than being in the hospital, and these snacks won't help you get out of here." Miguel nods and helps you pack the food back into the friend's grocery bag.

Step 7. Evaluate the action plan.

This is the step where you decide whether further action is needed or resolution has been achieved. If the evaluation shows that the issue has resolved, be sure to consider what aspects of your actions and the actions of others made that happen. These are lessons to apply in the future. If the situation is not resolved, then further action is required.

In evaluating the outcome with Miguel, you realize that spending a few minutes to learn more about him made it easier to negotiate the removal of the snacks. He came to trust you because of the interest you showed in him as a person; this is often more effective than education that tells the patient what he or she can and cannot do. This is a strategy you can apply in the future.

Ethics Committees

Most hospitals have an ethics committee devoted to the teaching and processing of ethical issues and dilemmas. An ethics committee involves individuals from different disciplines and backgrounds who support health care institutions with three major functions: providing clinical ethics consultation, developing and/or revising policies pertaining to clinical ethics and hospital policy (e.g., advance directives, withholding and withdrawing life-sustaining treatments, informed consent, organ procurement), and facilitating education about topical issues in clinical ethics ([University of Washington, 2018](#)). In most institutions, any person seeking ethical advice, including nurses, physicians, health care providers, patients, and family members, can request access to an ethics committee.

Ethics committees often conduct their work by calling a meeting with the members of the team and the patient and family involved in the situation. When you attend an ethics meeting, be sure to articulate a personal point of view and at the same time to show respect for the points of view of others. A successful meeting is one in which every perspective is heard. Sometimes these meetings result in consensus around a specific course of action; other times the meeting ends without a clear plan but with an improved understanding of one another's perspectives.

You may also process ethical issues in settings other than a committee. Nurses provide insight about ethical problems at family conferences, staff meetings, or even in one-on-one meetings. As a member of a health care community, regardless of your work setting, you can reduce the risk for moral distress by promoting discourse even when disagreements or confusion are profound. You will find it helpful when engaged in these conversations to assume that all the participants want to do good, even if they may have different ideas about what that means.

Building Competency in Patient-Centered Care

You are assigned to care for a 75-year-old patient who is readmitted to the hospital after having knee surgery a week ago. He was brought to the hospital by ambulance because his family could not wake him up. In the emergency department, he responds well to treatment for opioid overdose, becoming more awake and alert. When you enter the room to do an initial assessment, the daughter expresses anger at her father's situation, namely that he was discharged after surgery with "too much medication." She states her belief that the care on the last hospital stay

was “really inappropriate, especially since the news tells us we are in an opioid crisis.” How will a focus on patient-centered care help you address this patient’s needs and the daughter’s concern?

Issues in Health Care Ethics

Ethical issues change as society and technologies change, but common denominators remain: the basic process used to address the issues and your responsibility to deal with them. The following section describes a few of the many current sources of ethical concerns.

Social Media

The access to Internet-based social networks, such as Facebook, Twitter, Snapchat, and Instagram, may present ethical challenges for nurses. On one hand, social media can be a supportive source of information about patient care or professional nursing activities and can provide you with emotional support when you encounter hardships at work. Social media can also be a source of support to your patients, to connect with friends and loved ones who cannot be physically present. On the other hand, the risk to patient privacy with social media is great (NCSBN, 2018). Posting information or pictures about patients, even without specific identifiers, is a violation of confidentiality.

Interactions between health care professionals and patients on social media is also problematic. Online “friendship” with a patient risks clouding your ability to remain objective in your clinical perceptions. This crosses the professional boundary between the patient and professional, and the relationship becomes more personal. The public nature of online interactions poses the additional risk that other users will recognize the nature of your relationship with the patient and learn more than they should about that person’s health (NCSBN, 2018). Workplace policies may help to answer questions you have about when and where it is appropriate to engage in social media. In addition, the ANA (n.d.) has created a webpage with principles to guide nurses’ use of social media (see <https://www.nursingworld.org/social/>).

Quality of Life

Quality of life is deeply personal. Health care researchers use quality-of-life measures to scientifically define the value and benefits of medical interventions. Any intervention creates a burden for the patient and family, and this must be offset by the benefit that they will receive from that care. Injections of flu vaccine, for instance, cause pain, but the short-term nature of this burden is offset by the large benefit of potentially

avoiding infection with the flu or spreading of the flu, which are low-quality experiences. A more complex intervention, such as a 6-month course of chemotherapy, creates a greater burden and so impacts the quality of the patient's life to a greater degree. That impact is acceptable if the treatment outcome is a return to quality of life, based on the patient's definition. In the event that the treatment is unlikely to result in a quality of life that the patient finds acceptable, a different plan of care is considered.

Objective measures of quality of life can include the age of a patient, the patient's ability to live independently, or the ability to contribute to society in a gainful way. Subjective measures involve asking patients to identify their priorities, what they enjoy, and what matters most to them. Increasingly, scientists incorporate not just observed measurement but also patient self-reports about quality of life and other outcomes, referred to as Patient-Reported Outcomes (Basch et al., 2017). As a nurse, you can facilitate conversations about treatment choices by encouraging patients to articulate their definition of quality of life.

REFLECT NOW

What matters most to you and so should be included in your own personal definition of quality of life?

What roles, relationships, or activities are you engaged in that are most meaningful to you?

Care At the End of Life

Providing care to patients at the end of life and to those with serious illness who may be nearing end of life is a frequent source of ethical problems. While everyone can agree that a "good death" is desirable, there are a variety of opinions about what a "good death" looks like. In addition,

patients and families may have goals for end of life, such as adequate pain control or being with family, but expect that this will happen much later and not now. Predictions about health outcomes are not always accurate, and thus health care providers may have difficulty conveying to patients with serious illness that end of life is at hand. Because views about death and dying are part of deeply held spiritual and cultural beliefs, conflicts about end-of-life care are common in health care. These conflicts can occur between members of the health care team and between patients, families, and team members (Giuliano, 2017).

The term *futile* refers to something that is hopeless or serves no useful purpose. In health care discussions, the term *futile* refers to interventions unlikely to produce benefit for a patient (Giuliano, 2017). The concept is slippery when applied to clinical situations. If a patient is dying of a condition with little or no hope of recovery, almost any intervention beyond symptom management and comfort measures is seen as futile. In this situation an agreement to label an intervention as futile can help the health care team members, families, and patients turn to palliative care measures as a more constructive approach to the situation (see Chapter 36).

Access to Health Care

Access to health care is an ethical issue of justice (Kub, 2017). The questions of “Is health care a right that everyone can claim?” and “How can we best divide the health care resources we have?” involve fairness and justice. In the United States, the cost of care is such that few can afford services unless they are enrolled in an insurance plan. In some cases, health insurance is provided as a benefit of employment. Those who do not have employer-based health insurance may qualify for state-based Medicaid programs on the basis of need or for Medicare, a federal insurance program available to all individuals over the age of 65. Because of conflicting views about what is fair and because of its effect on everyone, access to health care is a controversial issue.

While the nature of insurance coverage varies, most plans allow an individual to access some basic preventive care and more expensive urgent services when unexpected changes in health occur. In the latter part of the 20th century, as health care costs increased at a dramatic rate, the number of people with insurance declined. In 2010, the Affordable Care Act (ACA) was passed to create regulations that control costs and improve the availability of insurance. This legislation has facilitated access to care for

millions of formerly uninsured individuals in the United States. According to a 2017 report by the National Health Center for Health Statistics, part of the US Department of Health and Human Services, the number of uninsured people in the United States declined by 20 million between 2010 and 2016 (Cohen et al., 2017). The ACA also offered changes in payment for services to reward practices that reduce harm and promote quality outcomes. The aim of this part of the legislation was to expand access to less expensive preventive health services and so reduce the incidence of expensive, burdensome chronic illness. How people access health care in the United States will continue to evolve. Staying knowledgeable about affordable care in your community as a way to ensure healthy outcomes is an important part of your role as advocate for your patients and will reflect your ethical commitment to justice (Box 22.5).

Box 22.5 Cultural Aspects of Care Access to Affordable Health Care

Since the implementation of the Affordable Care Act, more residents in the United States have access to care than ever before. But according to the National Healthcare Disparities Report (NHDR), people of color, ethnic minorities, and low-income residents are “disproportionately represented among those with access problems.” Reports from the National Healthcare Quality Report and NHDR reveal that lack of health insurance is the most significant contributing factor to poor quality of care (AHRQ, 2016).

Implications for Patient-Centered Care

- Issues of justice and the just distribution of resources help to inform the discussion about access to care and its effect on health care outcomes.
- Health outcomes often correlate directly to health care access.
- Know and respect patients’ cultural practices regarding health promotion and health care needs (see Chapter 9).
- Identify culturally appropriate resources for patients and families in their communities.

The courage and intelligence to act as both an advocate for patients and a professional member of the health care community come from a committed effort to learn and understand ethical principles. As a professional nurse, you provide a unique point of view regarding patients, the systems that support patients, and the institutions that make up the health care system. You have an obligation and a privilege to articulate that point of view. Learning how to identify and discuss ethical issues are some of the skills necessary to exercise this privilege. Review and consideration of various ethical principles help you form personal points of view, a necessary skill in the negotiation of difficult ethical situations.

Key Points

- Learning and applying the language of ethics is an essential element of nursing practice.
- Understanding our own values and encouraging patients, families, and colleagues to clarify their values promote productive discussion of ethical problems.
- You apply fundamental concepts such as autonomy, justice, fidelity, and beneficence to ethical decision making.
- Approaches to ethics include deontology, utilitarianism, and a relationship-based perspective.
- In an ethical dilemma, a nurse faces two equally justifiable courses of action, whereas in moral distress the nurse feels unable to take the action that is correct.
- Using a systematic approach similar to the nursing process promotes resolution of ethical issues. While the specific ethical issues nurses face evolve and change over time, the values and obligations remain constant.

Reflective Learning

- Do you think there are situations in which maintaining confidentiality and withholding private information are not the right actions? Discuss why.
- Think about your first impression of a patient early in the day, when you first met. How did this impression change over the course of spending a shift involved in their care? How do you think this change in your perspective relates to your ethical obligations as a nurse?
- What questions might you ask a patient if you wanted to better understand the patient's view of quality of life?

Review Questions

1. The nurse is caring for a patient who needs a liver transplant to survive. This patient has been out of work for several months, does not have health insurance, and cannot afford the procedure. Which of the following statements speaks to the ethical elements of this case?
 1. The health care team should select a plan that considers the principle of justice as it pertains to the distribution of health care resources.
 2. The patient should enroll in a clinical trial of a new technology that can do the work of the liver, similar to the way dialysis treats kidney disease.
 3. The social worker should look into enrolling the patient in Medicaid, since many states offer expanded coverage.
 4. A family meeting should take place in which the details of the patient's poor prognosis are made clear to his family so that they can adopt a palliative approach.
2. When designing a plan for pain management for a patient following surgery, the nurse assesses that the patient's priority is to be as free of pain as possible. The nurse and patient work

together to identify a plan to manage the pain. The nurse continually reviews the plan with the patient to ensure that the patient's priority is met. If the nurse's actions are driven by respect for autonomy, what aspect of this scenario best demonstrates that?

1. Assessing the patient's pain on a numeric scale every 2 hours
 2. Asking the patient to establish the goal for pain control
 3. Using alternative measures such as distraction or repositioning to relieve the pain
 4. Monitoring the patient for oversedation as a side effect of his pain medication
3. The application of deontology does not always resolve an ethical problem. Which of the following statements best explains one of the limitations of deontology?
1. The emphasis on relationships feels uncomfortable to decision makers who want more structure in deciding the best action.
 2. The single focus on power imbalances does not apply to all situations in which ethical problems occur.
 3. In a diverse community it can be difficult to find agreement on which principles or rules are most important.
 4. The focus on consequences rather than on the "goodness" of an action makes decision makers uncomfortable.
4. The *ethics of care* suggests that ethical dilemmas can best be solved by attention to relationships. How does this differ from other approaches to ethical problems? (Select all that apply.)
1. Ethics of care pays attention to the context in which caring occurs.
 2. Ethics of care is used only by nurses because it is part of the Nursing Code of Ethics.
 3. Ethics of care requires understanding the relationships between involved parties.

4. Ethics of care considers the decision maker's relationships with other involved parties.
 5. Ethics of care is an approach that suggests a greater commitment to patient care.
 6. Ethic of care considers the decision maker to be in a detached position outside the ethical problem.
5. The following are steps in the process to help resolve an ethical problem. What is the best order of these steps to achieve resolution?
1. List all the possible actions that could be taken to resolve the problem.
 2. Articulate a statement of the problem or dilemma that you are trying to resolve.
 3. Develop and implement a plan to address the problem.
 4. Gather all relevant information regarding the clinical, social, and spiritual aspects of the problem.
 5. Take time to clarify values and identify the ethical elements, such as principles and key relationships involved.
 6. Recognize that the problem requires ethics.
6. What is the best response for the nurse to give if a patient asks the nurse to send a photo of an x-ray to him via a messaging tool in a social media site?
1. Yes, if you remove all patient identifiers before sending
 2. No, because the patient's x-ray results should be discussed with a provider
 3. Yes, because respect for autonomy means honoring this patient's request
 4. No, because health information of any kind should not be shared on social media

7. Resolution of an ethical problem involves discussion with the patient, the patient's family, and participants from appropriate health care disciplines. Which statement best describes the role of the nurse in the resolution of ethical problems?
 1. To articulate the nurse's unique point of view, including knowledge based on clinical and psychosocial observations
 2. To study the literature on current research about the possible clinical interventions available for the patient in question
 3. To hold a point of view but realize that respect for the authority of administrators and physicians takes precedence over personal views
 4. To allow the patient and the physician private time to resolve the dilemma on the basis of ethical principles
8. Which statements reflect the difficulty that can occur for agreement on a common definition of the word *quality* when it comes to quality of life? (Select all that apply.)
 1. Community values influence definitions of quality, and they are subject to change over time.
 2. Individual experiences influence perceptions of quality in different ways, making consensus difficult.
 3. The value of elements such as cognitive skills, ability to perform meaningful work, and relationship to family is difficult to quantify using objective measures.
 4. Statistical analysis is difficult to apply when the outcome cannot be quantified.
 5. Whether a person has a job is an objective measure, but it does not play a role in understanding quality of life.
9. Which statements properly apply an ethical principle to justify access to health care? (Select all that apply.)
 1. Access to health care reflects the commitment of society to principles of beneficence and justice.

2. If low income compromises access to care, respect for autonomy is compromised.
 3. Access to health care is a privilege in the United States, not a right.
 4. Poor access to affordable health care causes harm that is ethically troubling because nonmaleficence is a basic principle of health care ethics.
 5. If a new drug is discovered that cures a disease but at great cost per patient, the principle of justice suggests that the drug should be made available to those who can afford it.
10. Match the following actions (1 through 4) with the terms (a through d) listed below:

a. Advocacy	1. You see an open medical record on the computer and close it so that no one else can read the record without proper access.
b. Responsibility	2. You administer a once-a-day cardiac medication at the wrong time, but nobody sees it. However, you contact the provider and your head nurse and follow agency procedure.
c. Accountability	3. A patient at the end of life wants to go home to die, but the family wants every care possible. The nurse contacts the primary care provider about the patient's request.
d. Confidentiality	4. You tell your patient that you will return in 30 minutes to give him his next pain medication.

Answers: 1. 1; 2. 2; 3. 3; 4. 1, 3, 4; 5. 6, 4, 5, 2, 1, 3; 6. 4; 7. 1; 8. 1, 2, 4; 9. 1, 2, 4; 10. 1d, 2c, 3a, 4b.

Legal Implications in Nursing Practice

OBJECTIVES

- Compare constitutional, civil, and criminal law.
- Describe statutory law as it affects nursing practice.
- Define the scope of nursing practice and the standards of nursing care.
- Define the standard of proof required to establish a nurse's negligence.
- Discuss examples of federal statutes that affect nursing practice.
- Analyze under what circumstances a patient can be chemically or physically restrained.
- Explain what a nurse's witnessing of a patient's informed consent indicates.
- List the elements needed to establish negligence and malpractice.
- Determine nursing actions most often associated in a breach of nursing practice.
- Identify proactive measures nurses can take to help reduce their legal risks.

KEY TERMS

Administrative law, p. 307

Battery, p. 314

Case law, p. 307

Civil law, p. 306

Professional licensure defense, p. 312
Risk management, p. 317
Scope of nursing practice, p. 307
Slander, p. 314
Standard of proof, p. 307
Standards of nursing care, p. 307
Statutory law, p. 306
Torts, p. 314
Unintentional torts, p. 315

Safe evidence-based and competent nursing practice requires nurses to know laws, policies, and other valid, reliable, and applicable sources that define their practice. Laws, standards, and policies help to frame the health care system in which nurses practice. They include state Nurse Practice Acts, the scope and standards of nursing care, and the code of ethics for nursing practice. Understanding where you fit in the health care system demands clinical judgment skills. Society expects safe health care delivery, especially from nurses, who typically are perceived as being part of the most ethical and trusted profession. As patient care becomes more complex and practice innovations and new health care technologies emerge, the principles of negligence and malpractice liability are being applied to challenging new situations. Thus, you need to know laws governing nursing practice to provide evidence-based care that keeps the patient at the center of decision making.

Legal Limits of Nursing

Sources of Law

Many types of law govern nursing practice, including constitutional law, statutory law, common law, administrative law, and case law. Knowing these sources of law informs your practice and identifies why it is important to provide current evidence-based care when working with your clients.

Constitutional law is derived from federal and state constitutions. For example, in the United States, a constitutional right afforded to every citizen is the right to refuse treatment (Furrow et al., 2018). As a nurse, you must know the parameters of the right of your patients to refuse treatment even when you may not agree with their decisions.

Statutory law is derived from statutes passed by the US Congress and state legislatures. These laws are either civil or criminal. **Civil laws** protect the rights of individuals and provide for fair and equitable treatment when civil wrongs or violations occur (Furrow et al., 2018; Pozgar, 2016). **Nurse Practice Acts** are civil state laws that define nursing and the standards you must meet within individual states. As a nursing student, you will find your scope of practice, the educational requirements you must have, and information you may need in the future when you want to take the NCLEX exam in your state's Nurse Practice Act (Oyeleye, 2019; Pozgar, 2016). Nurse Practice Acts also distinguish nursing from other health professions (e.g., medicine, therapists, and alternative medicine providers).

Criminal laws protect society and provide punishment for crimes, which are defined by municipal, state, and federal legislation (Furrow et al., 2018). Typically, actions that violate criminal laws are defined as either misdemeanors or felonies. Criminal mistreatment of vulnerable adults is an example of criminal statutory law. Criminal mistreatment is classified as either a misdemeanor or felony offense depending on the severity of harm done to a vulnerable patient.

Administrative law, or regulatory law, more clearly defines expectations of civil and criminal laws. For example, a Nurse Practice Act, as a civil statutory law, states that you have a duty to care for your patients. Regulations typically state that duty means you will observe, assess, diagnose, plan, intervene, and evaluate patient care. Providing current, evidence-based care is essential to meeting nursing statutory duty and regulations. Regulatory law also describes the process to report

incompetent or unethical nursing conduct to the State Board of Nursing or Nursing Commission. A nurse who does not report unethical or incompetent conduct violates regulatory law. Nurses can appeal violations to the State Board of Nursing or the Nursing Commission. In comparison, criminal mistreatment statutes have regulations to determine the intent of the person who commits the crime. The degree of offense often distinguishes whether the person intentionally committed the mistreatment, knew or should have known harm would result, or didn't consider that harm would result. Nurses who are accused of violating a regulatory law typically knew or should have known their actions could result in patient harm.

Common law originates from decisions that were made in the absence of law. For example, the right to privacy is implied in the US Constitution. Thus, patient confidentiality originated as common law. Prior to the passage of multiple related laws, a patient's right to confidentiality, which prevents nurses and health care providers from sharing patient information with others who are not caring for the patient, was implied through common law (Furrow et al., 2018; Busch, 2019; McGuire et al., 2019).

Case law describes decisions made in legal cases that were resolved in courts. After a case is presented to a judge or jury, there is a report of the issue, facts, findings, and subsequent decision that was made to resolve the issue. For example, In *Re: Estate of Turner v. M. Medical Center* (2018), the guardian of the estate of Ms. Turner alleged that her health care providers did not meet the standard of practice when caring for a tracheostomy required to assist her to breathe. Subsequently, she died. At trial, the jury concurred and awarded the estate \$22 million. After an appeal and a lengthy analysis, the court awarded in favor of the estate for \$7 million in light of past damages, but it denied the request for future damages in the amount of \$15 million.

Scope and Standards of Nursing

The **scope of nursing practice** defines nursing and reflects the values of the nursing profession. **Standards of nursing care** reflect the knowledge and skill ordinarily possessed and used by nurses (Furrow et al., 2018; Black, 2020) (see [Chapter 1](#)). Standards of nursing care are derived from health care laws, best practice guidelines, professional organization white papers, evidence-based nursing knowledge, and citizen advocacy groups.

The American Nurses Association (ANA) (2015a) and specialty nursing organizations develop standards for nursing practice, the code of ethics for nurses, and policy statements. For example, the scope of nursing and 17 standards of practice that describe what nurses do are published by the ANA (2015a). Nursing is defined, and the responsibilities and expectations of a registered nurse (RN) are clearly explained. They define the scope, function, and role of the nurse in practice and guide your practice. Sometimes they are used when legal actions are taken against nurses.

Nursing policies and procedures within health care agencies are based on the scope and standards of nursing practice. They must reflect current best practice and the evidence that supports the processes that they describe. The Joint Commission (TJC) (2019) requires written nursing policies and procedures that are accessible on all nursing units. Agency policies and procedures must conform to state and federal laws and community standards (TJC, 2019; Furrow et al., 2018).

For example, bedside report is a best practice for health care settings because it places patients at the center of decision making and emphasizes the importance of clear communication with patients and their families. When a hospital establishes a policy and procedure to implement bedside hand-off reporting, the nurse who is transferring care of a patient to another nurse, the nurse accepting the care of the patient, and the patient should be involved in the reporting process. If the nurses decide not to follow the policy and procedure and conduct the report without including the patient, the nurses are not following the policy and procedure. Thus, the nurses may be at risk for litigation, especially if harm occurs to the patient because of not following the hospital's policy. Thus, it is important to know the scope and standards of nursing practice as well as the health care agency's policies and procedures intended to implement them.

Standard of Proof

The **standard of proof** is typically what a reasonably prudent nurse would do under similar circumstances in the geographic area in which the alleged breach occurred. Malpractice is the result of nursing care falling below a standard of care. In a malpractice lawsuit, it is typically required that the nurse had a duty of care (i.e., Nurse Practice Act), that the duty was breached (i.e., nursing regulations), that physical harm occurred (i.e., testimony and records), and that in that state damages or monetary compensation are allowed. The standard of proof in this case is the degree

to which the evidence must show that a duty of care was violated, resulting in harm to the patient.

During a malpractice suit, a nurse's actual conduct is compared with nursing standards of care (i.e., Scope and Standards of Nursing Care [[ANA, 2015a, b](#)]) to determine whether the nurse acted as any reasonably prudent nurse would act under the same or similar circumstances ([Furrow et al., 2018](#); [Philo et al., 2015](#)). For example, if a patient is burned from a warm compress application, negligence is determined by reviewing whether the nurse followed the correct procedure for applying the compress. If a procedure is not followed, the policy is reviewed. If there is no policy, this could reflect a systemic problem because the nurses are not provided information regarding current evidence-based knowledge to guide them on how to appropriately apply warm compresses. There is a greater possibility that other patients are at risk for, or have already had, burns due to erroneous application of warm compresses. The scope and standards of nursing practice are also being violated; subsequently, litigation would encompass more than failure to simply follow a procedure. The policies and procedures that guide your practice need to be updated regularly and reflect current best practice evidence. When you follow your agency's policies and procedures, you ensure that your care is similar to what other reasonable, prudent nursing colleagues would provide under the same or similar circumstances.

Federal Statutes Impacting Nursing Practice

Federal statutes and regulations affect nursing practice in many ways. Typically, they are linked to certification contracts for Medicare and Medicaid reimbursement. They are often expanded when states pass laws that increase application of the federal statute to others in that state. For example, the Omnibus Reconciliation Act of 1987 mandated that skilled nursing facility residents are given rights, including but not limited to being able to vote, receiving visitors privately, receiving a 30-day notice of discharge before moving from the facility, and being able to participate in meetings to develop their plan of care. Many states subsequently passed laws where these same rights were given to patients in retirement homes, assisted-living facilities, and adult family homes. Thus, it is important to consider federal statutes in context with how they are implemented in each state.

Patient Protection and Affordable Care Act

The Patient Protection and Affordable Care Act (PPACA) was passed in 2010. Its name was later changed to the Affordable Care Act (ACA). The ACA is characterized by four themes embedded in nursing practice: (1) consumer rights and protections, (2) affordable health care coverage, (3) increased access to care, and (4) quality of care that meets the needs of patients. The ACA has been challenged in court many times since its enactment. Examples of issues discussed in court around the ACA include mandatory enrollment in health care insurance and eligibility for insurance for patients with a pre-existing condition.

A new Patient's Bill of Rights, created by the ACA, prohibits patients from being denied health care coverage because of prior existing conditions, limits on the amount of care for those conditions, and/or an accidental mistake in paperwork when a patient got sick (PPACA, 2010). More than 17.6 million children with preexisting conditions became eligible for health care and more than 105 million Americans no longer have lifetime limits to receive care when they are ill because of the ACA.

The ACA intended to reduce overall medical costs by (1) providing tax credits, (2) increasing insurance company accountability for premiums and rate increases, and (3) increasing the number of choices available to patients to select insurers that best meet their needs. In addition, the ACA

increased access to health care. Patients now receive recommended preventive services such as screenings for cancer, blood pressure, and diabetes without having to pay copays or deductibles. The ACA improved Medicare coverage for vulnerable populations by improving access to care and prescriptions, decreasing costs of medications, extending the life of the Medicare Trust Fund until 2024, and addressing fraud and abuse in billing practices ([USDHHS, 2015](#)).

The ACA reduced the number of uninsured Americans from over 44 million people in 2013, right before the act's health care coverage provisions began, to just below 27 million people in 2016. In 2017, however, the number of uninsured people went up by almost 700,000 people ([KFF, 2018](#)). The high cost of medical insurance and not having access to medical coverage through an employer are the main reasons people remain uninsured. Other adults are ineligible for financial assistance for health care coverage, especially those who live in states that did not expand Medicaid coverage. Those who remain uninsured typically are in families who have at least one family member who works, who are in families that have a low income, and who are adults under 65 years of age. The largest increases in the number of people who are uninsured occurred in non-Hispanic blacks and people living above poverty ([KFF, 2018](#)).

Like all statutes, the ACA has and will continue to change. For example, the Centers for Medicare & Medicaid Services ([CMS, 2019](#)) proposed changes in the act to increase the affordability of coverage, to allow people the choice to join Qualified Health Plans (QHPs) that do not cover termination of pregnancy services, and to provide greater flexibility in how people shop for QHPs. It is especially important that nurses have current factual knowledge about these changes and provide accurate information to patients when they seek guidance about their health care. Nurses are often at the center of those decisions with their patients. It is critical that when helping patients make decisions about their care, the decisions are clinically sound and based on the patient's preferences, values, and beliefs.

Emergency Medical Treatment and Active Labor Act

The [Emergency Medical Treatment and Active Labor Act \(EMTALA\) \(1986\)](#) prohibits the transfer of patients from private to public hospitals without appropriate screening and stabilization. It is intended to prevent

what is referred to as patient dumping. This act ensures that when patients come to the emergency department or the hospital, an appropriate medical screening occurs. Staff must assess all patients who enter the hospital and cannot discharge or transfer them until their conditions stabilize.

Exceptions to this provision include if a patient requests transfer or discharge in writing after receiving information about the benefits and risks of the transfer or if a physician or nurse practitioner certifies that the benefits of transfer outweigh the risks.

Health Insurance Portability and Accountability Act

The Health Insurance Portability and Accountability Act ([HIPAA, 1996](#)) provides rights to patients and protects employees. It includes standards regarding accountability in the health care setting. Notably, it establishes patient rights regarding privacy of their health care information and records.

HIPAA established a patient's right to consent to the use and disclosure of protected health information, to inspect and copy one's medical record, and to amend mistaken or incomplete information ([Privacy Rights Clearinghouse, 2014](#)). It limits who can access a patient's record. It establishes the basis for privacy and confidentiality concerns, viewed as two basic rights within the US health care system. Privacy is the right of patients to keep personal information from being disclosed.

Confidentiality protects private patient information once it is disclosed in health care settings. Nurses help health care agencies protect patients' rights to privacy and confidentiality. Although HIPAA does not require extreme measures such as soundproof rooms in hospitals, it does mean that nurses and health care providers need to avoid discussing patients in public hallways and provide reasonable levels of privacy when communicating with and about patients in any manner. For example, message boards used in hospital rooms to post daily patient care information can no longer contain information revealing a patient's medical condition. Thus, nurses must be especially vigilant to assure that patients are afforded the privacy they are entitled to and that is mandated in law.

Health care information privacy is also protected by standards set by the Centers for Medicare and Medicaid Services (CMS) for hospitals and health care providers who participate in Medicare and Medicaid ([CMS, 2018](#); [Furrow et al., 2018](#)). These standards require that hospitals and

health care providers give notice to patients of their rights to decisions about their care, grievances regarding their care management, personal freedom and safety, confidentiality, access to their own medical records, and freedom from physical or chemical restraints that are not clinically necessary (see [Chapter 14](#)). In addition, many state laws allow patients to access their medical records. Exceptions apply to psychotherapy notes or when a health care provider has determined that access would result in harm to the patient or another party (Privacy Rights Clearinghouse, 2018).

Health Information Technology Act

The Health Information Technology for Economic and Clinical Health Act ([HITECH Act, 2009](#)) was passed with HIPAA in response to new technology and social media. HITECH expands the principles extended under HIPAA, especially when a security breach of personal health information (PHI) occurs. Under the HITECH Act, nurses must ensure that patient PHI is not inadvertently conveyed on social media and that protected data are not disclosed other than as permitted by patients ([Box 23.1](#)). Best practice, regardless of patient consent, is to never enter patient information on social media. Electronic data are accessible, regardless of assurances to the contrary. Civil and criminal sanctions may be brought against both a nurse and an organization if either or both violate HIPAA or the HITECH Act. Report violations of patient confidentiality to your supervisor.

Box 23.1 Evidence-Based Practice **Social Media and Legal Liability**

PICOT Question: Do nurses who use social media as a part of their professional practice put themselves at greater risk for legal liability compared with nurses who do not use social media?

Evidence Summary

Social media is used today to reach millions of patients, colleagues, and peers. It is a useful tool for promoting collaboration, disseminating and sharing information, and providing education. Nurses are ultimately responsible and accountable for understanding the use, implications, and guidelines associated with the use of social media (NCSBN, 2018; Scruth et al., 2015). The NCSBN (2018) and the International Nurse Regulators

Collaborative (INRC) identified nurses' behaviors for appropriate use of social media. Nurses who follow current professional guidelines and laws can use social media to enhance their practice and do not place themselves at greater risk for liability (NCSBN, 2018; Scruth et al., 2015).

Application to Nursing Practice

- Understand the risks and benefits of using social media (NCSBN, 2018).
- Maintain professional boundaries (NCSBN, 2018).
- Present a professional image in all social media interactions (Scruth et al., 2015).
- Maintain privacy and confidentiality (NCSBN, 2018).
- Understand the implications of identifying yourself as a nurse (NCSBN, 2018).
- Know state laws governing use of social media (NCSBN, 2018).

Americans With Disabilities Act

The Americans With Disabilities Act (ADA) of 1990 and amended in 2008 is a civil rights statute that protects the rights of people with physical or mental disabilities (ADANN, 2018; Dupler et al., 2012). The ADA prohibits discrimination and ensures equal opportunities for people with disabilities in employment, state and local government services, public accommodations, commercial facilities, and transportation. As defined by the statute and the US Supreme Court, a disability is a mental or physical condition that substantially limits a major life activity, including seeing, hearing, speaking, walking, breathing, performing manual tasks, learning, caring for oneself, and/or working. Employers must provide reasonable accommodations to employees or applicants who are qualified to hold a job. Reasonable accommodations enable a person to perform the essential functions of a job (ADA, 2019). For example, as expanded under the ADA, an employer must consider the needs of a person with diabetes mellitus as a potential disability and reasonably accommodate that person's needs. A person with a disability makes the choice whether to tell others of his or her disability. By exception, several cases have held that a health care provider must disclose if he or she has human immunodeficiency virus (HIV). Despite these rulings and as enforced by the Office of Equal Employment Opportunity, the ADA protects health care workers in the workplace with disabilities such as HIV infection. Likewise, health care

workers cannot discriminate against patients who are HIV-positive (Furrow et al., 2018).

Mental Health Parity and Addiction Equity Act

The Mental Health Parity and Addiction Equity Act of 2008 (MHPAEA) (as amended by the Health Care and Education Reconciliation Act of 2010 and collectively part of the ACA) requires health insurance companies to provide coverage for mental health and substance use disorder (SUD) treatment, just as they do for medical coverage. The ACA extended these requirements to small group and individual health insurance plans (US Department of Treasury, 2013). The ACA requires parity (the state or condition of being equal) in the provision of 10 specific services, including mental health, behavioral health, and SUD services. Insurers may not discriminate or deny coverage to patients with mental illness or SUD because of preexisting conditions. However, the ACA does not clearly define mental illness or SUD. Thus, many believe that insurers will provide services; however, the cost of the insurance may be so high that the services will not be affordable to those who need them.

The Mental Health and Substance Use Disorder Parity Task Force first met in March 2016. It facilitates coordination of services among federal agencies and assures that consumers receive the care and treatment they require. The task force improved awareness of the benefits that parity for mental health and substance use disorders provides. For example, to increase transparency, the task force has helped stakeholders (e.g., insurers, regulators, and consumers) understand what equality means in relation to treatment of mental health illnesses and substance use disorders. The task force also provides resources to ensure that coverage is consistent with the intent of the MHPAEA

(<https://www.hhs.gov/programs/topic-sites/mental-health-parity/index.html>).

Admission of a patient to a mental health or SUD unit occurs involuntarily or on a voluntary basis. Involuntary admission to a mental health center usually occurs when patients are a danger to themselves (e.g., patients who are suicidal) or others. Typically, this determination is made by a mental health professional (MHP) in the emergency room. In some states, patients with a SUD can also be placed in a treatment center by a SUD professional if they are a danger to themselves or others. In either case, the professional who assessed the patient, a court-appointed guardian ad litem, a family member, or another interested party can ask

the court to determine whether a longer stay is required to protect the patient from continuing to harm self or others. A judge may order the patient to be hospitalized for 21 more days for treatment. From a legal perspective this is viewed as taking away a patient's constitutional rights. Nurses must clearly and accurately document the patient's behaviors. The court will review this evidence when making its decisions (Furrow et al., 2018; Barr et al., 2019). Under constitutional law, having the right to move from place to place is at the very basis of being a US citizen. When removing that constitutionally protected right, the case must be made that not doing so would result in significant or deadly harm.

When patients attempt suicide within health care settings, it is typically alleged that nurses failed to provide appropriate individualized care, supervise the patient adequately, and adhere to existing policies and procedures to keep the patient safe. When providing care to patients with mental illnesses and SUDs, consider the scope and standards of nursing care as well as the specific statutes and regulations associated with their care. You also need to know your employer's policies and procedures when caring for patients at risk of harm. Integrate this knowledge to provide evidence-based nursing and to ensure that your documentation reflects the care you provided.

Patient Self-Determination Act

The Patient Self-Determination Act (PSDA) enacted in 1991 requires health care institutions to provide written information to patients concerning their rights to make decisions about their care, including the right to refuse treatment and to formulate an advance directive. A patient's record must indicate whether a patient has signed an advance directive and include a copy of the directive if it is available. Patients must also be offered information about advance directives.

An advance directive is a document developed by the patient that instructs others to do tasks before, during, and after his or her death. At a minimum, an advance directive includes a statement of the patient's wishes if a respiratory or cardiac arrest occurs and a copy of the patient's **durable power of attorney for health care (DPAHC)**. Instructions regarding care before or during cardiac or respiratory arrest should be signed by either a physician or nurse practitioner. Unless otherwise specified by state law, the document should be treated as an order; it may direct whether to provide lifesaving measures such as cardiopulmonary resuscitation (CPR) or to provide comfort care only.

Most DPAHCs begin with a statement that says the designated person can make decisions when the patient becomes incapacitated. This means that patients cannot be bypassed—they retain the ability and the right to make their own decisions whenever they can. This is true whether they are at home, in the emergency room, or in an inpatient setting. Decisional capacity is the patient's ability to make choices about his or her care. The health care provider, working in conjunction with information from nurses and family members, can make the determination of decisional capacity. The power of attorney for health care may not be asked and cannot make health care decisions until a provider makes an assessment that the patient no longer has the capacity to make decisions. The assessment that triggers the beginning of the DPAHC should be reflected in the record.
